To those responsible for the discovery and evolution of anesthesia.

Preface

This story describes events in three succeeding eras: first, events during the time preceding and immediately after the demonstration of anesthesia; then those in the subsequent 90 years of slow evolution of the specialty, ending in the 1950s; and finally those from the 1950s to the present, a period of explosive growth. Our lives span the last of these, the era in which modern anesthesia evolved from empiricism—“doing what worked”—to a practice relying on science and evidenced-based medicine. We sought to tell this story before too many grand participants died or were unable to tell their story. Many died in the past decade: Safar (2003); Marx (2004); Greene (2005)—including since we began this project in 2007—Haglund, Ibsen and Keats (2007); Gray (2008); Parsloe (2009); Smith and Terrell (2010); Gordh, Morris and Pierce (2011). We would have lost too many opportunities had we failed to act.

We enlisted 100 authors to construct 53 chapters (The Individual Stories) describing specific aspects of the evolution of anesthesia: people, countries, drugs, science, organizations, education, and more, each a thread in the tapestry of a larger story, each chapter written by anesthesiologists and others who lived this history. These 53 chapters make up the second part of our book. The first part wove stories from these chapters into chronologies described in 14 additional chapters (The Woven Stories) which provide a coherent picture of the development of anesthesia, a framework that facilitates an understanding of how events and people described in the second part of the book jointly shaped the development of the specialty.

Our contributors represent the Americas, Europe, the Middle and Far East, and Australia and New Zealand. They were chosen because of demonstrated expertise and/or actual participation in the development of a specific subject or of the specialty in a specific geographic area. Several chapter titles may seem idiosyncratic for a history book and were chosen because the subjects seemed to represent existing trends that were likely to influence the future.

A book of this breadth could not have been produced without the help supplied by our 100 contributors. Each endured multiple suggestions, changes, requests for no fewer than four revisions and a gentle nagging for more and more and more that in retrospect probably bordered on abuse. A few did not tolerate our intrusiveness and withdrew before completing their assignments. Fortunately, replacements were found and despite a shortened timeline for completion they met our deadlines. To all of these dear friends we offer our gratitude—we are in your debt!

The book is a story, not a recitation of pharmacology or physiology. It is not intended to educate the student in techniques or mechanisms. It describes the issues that shaped anesthesia, the incidents and humor, the anecdotes that put a human face to this wonderful specialty. We hope it shows the interactions between diverse forces that made this great specialty grow, and provides a sense of where those forces may take us in the future.

We three editors (Fig. 1) and many of our contributors hail from English speaking countries. While our respective forms of English are nearly identical they do differ slightly in spellings, e.g., an(a)esthesia, vapo(u)r, (o)esophagus, antagoni(s)ze, and many more. Rather than dictating the use of American English throughout, we elected to use the spelling common to the country of the chapter’s author(s).

Redundancy in the descriptions of subjects, persons, and events is a frequent complaint lodged against multi-authored books, especially those like ours wherein the stories span centuries. Rather than purging the text of such repetitions, we allowed them to remain where and

Fig. 1 The three editors, from left to right: Edmond (Ted) Eger, Lawrence J. Saidman, and Rod N. Westhorpe

whenever they obviously belonged. The largest example, the discussion of Danish anesthesiologist Bjørn Ibsen's impact upon intensive care medicine, intensive care units, and associated issues appears in five chapters, each with its own focus.

Finally, a tribute to **The Power of Three** (Fig. 1). As might have been expected, in the 6 years over which we wrote and re-wrote this book, we disagreed regarding the how, who, when, where, why, and whether of many things. We settled each of these disputes (mostly) without rancor by taking a vote. For anyone anticipating a similar future exercise, we advise avoiding an even number of participants.

It has been a wonderful journey that has allowed us to re-live lives we loved.

Part I

The Woven Story of Anesthesia: Eras, Exemplars, and Looking Forward

Edmond I Eger II, Lawrence J. Saidman and Rod N. Westhorpe

Summary

Surgeons in ancient times undertook diverse operations, usually at great speed to diminish the duration of suffering. Skulls from 5,000 BCE show trephination, the removal of a piece of bone from the head. Egyptians in 3,600 BCE performed circumcisions and tracheotomies. In 1700 BCE, Babylonians excised tumors. Egyptians cauterized breast tumors and excised peripheral aneurysms. The Roman surgeon, Galen, in the second Century CE, treated cataracts to restore sight, and he cut out the uvula to cure chronic coughing. Surgeons in Europe might be physicians, monks or barbers who in the thirteenth and fourteenth centuries wrote books on surgery. They gained recognition by their study of the anatomy of cadavers. Thus, in 1543 Vesalius published “*On the Fabric of the Human Body*”, demolishing centuries of errors, and opening the door to the performance of accurate surgery.

The horrors of pain, shock, and infection hindered surgeons. Operations brought infection, an added threat to life. Surgeons had surprising remedies, some desperately wrong (e.g., venesection), and some perhaps surprisingly wise (e.g., irrigating wounds with alcohol).

Before the advent of anesthesia, humans used diverse means to diminish pain, including pressure or ice to numb extremities. They administered herbal potions including mandragora, hemp-marijuana, opium, and alcohol. The Incas may have known of the topical effect of coca/cocaine, but they had no way to inject it other than spit coca-laced saliva into the wound. That might have some effect, but the amount of active cocaine was small and the effect probably too little to produce anesthesia.

Some potions contained hallucinogens, particularly scopolamine. Some prescriptions with wonderful names had unknown components: In 500 BCE, Hua Tuo gave “mafeisan” or “cannabis boil powder”. In the Middle Ages, patients might suck liquid or breathe vapors from soporific sponges. And since the 1700s, we knew that we could produce immobility with a curare tipped dart, but we now know that would not eliminate pain.

Practitioners applied positive thinking and forms of suggestion, including modern magical rings, necklaces, and charms for the parturient. Greeks applied oils and warm compresses during labor, anticipating the warm compresses, massage and herbal teas used today. Were they placebos (which can have positive effects)? Mesmer’s late eighteenth century creation of animal magnetism may have also relied on suggestion, perhaps a form of hypnosis that inconsistently assuaged surgical pain.

World Events Before 1798

The Jews credited 3761 BCE as the date of creation, but scientists suggest it was billions of years earlier. By 4000–3000 BCE, civilizations had arisen in China, Korea, Japan, Mesopotamia, and Egypt, aided by the development of ag-

riculture, domestication of animals, invention of the wheel (including the potter’s wheel), and writing. The Bronze Age appeared in 3000–2000 BCE, and the Egyptians constructed the pyramids. Parallel great kingdoms ruled Egypt and China, and an egalitarian civilization arose in the Indus Valley. In 2000–1000 BCE, Central Asian Indo-European invaders on horse-powered chariots overran Egypt and Babylonia. The Iron Age appeared in 1000–0 BCE, and Judaism, Zoroastrianism, Hinduism, Jainism and Buddhism developed. Greece conquered Persia, and the Romans conquered Greece and established the Roman Republic. In the first century CE, Rome dominated Europe, North Africa and the Near East, and the Han Dynasty ruled China. In the second century, Cai Lun invented paper, and Roman civilization peaked. The Prophet Muhammad began the Muslim conquests in 622 CE. In this century, India gave smallpox to Europe, and the world’s population shrank to 200 million. In the eighth century, Arabian expansion continued,

and Charlemagne came to power. Vikings repeatedly invaded Britain in the ninth century. The eleventh century saw the worst of Europe's Dark Ages (500–1500 CE), but great advances in science took place in China. Gutenberg invented mechanical movable type printing about 1439. The Spanish Inquisition began in 1492 the same year that Columbus landed in America. Copernicus proposed the sun as center of the universe in the 1540s. In the seventeenth century, Newton invented the calculus and his Laws of Motion. The eighteenth century saw French, American, and industrial revolutions, including invention of the steam engine.

Ancient Approaches to Pain Relief

We cringe, thinking of Galen, a prominent physician and surgeon in ancient Rome,¹ performing uvulectomy, cataract extractions, caesarean sections, and amputations in unanesthetized patients. We cringe, thinking of children forcibly restrained to allow surgery to proceed. Despite the absence of any clear path to pain-free surgery, surgeons in ancient times undertook diverse operations, usually at great speed to diminish the duration of suffering. How did these ancient surgeons deal with the issue of pain?

Ancient civilizations may have used pressure or ice to numb extremities. Magical herbs, including marijuana, might have been given. Perhaps the first known use of anesthesia came from China, where in 500 BCE, Hua Tuo combined herbs and wine into a concoction known as “mafeisan” or “cannabis boil powder”.

In 40–90 CE, the Greek, Pedanius Dioscorides, used opium or mandragora to minimize pain during surgery. However, such therapies might be lethal or ineffective, or both. Opium could cause patients to stop breathing. Belladonna drugs in mandragora might lead to a fatal increase in temperature. Other surgeons experimented with opioids, alcohol, or a blow to the head—imperfect techniques that did not offer the control and reversibility required for anesthesia. Alcohol, for example, needed to be consumed in precisely the right quantity to cause unconsciousness, but not death. Persuading the underdosed inebriate to drink more might be impossible, and in the meantime, their irrational behavior and propensity to vomit made such a remedy ineffective.

Some remedies may have anticipated modern approaches. South American Indians may have chewed coca leaves and spat into the surgical field, thereby applying the first local anesthetic. However, the lack of cocaine alkaloids available in raw coca leaves may have limited its effectiveness [1].

¹ In the second century CE, Galen treated cataracts to restore sight and cut out the uvula to cure the chronic cough.

Surgery Without Anesthesia: A Painful Proposition

The Earliest Surgeries

A history of anesthesia is not complete without a discussion of the history of surgery. Anesthesia is a recent invention relative to surgery. Brutality attended the earliest surgeries. One early procedure appeared in all parts of the world except the Far East. Called “trephination,” it involved making a hole through the patient's skull to expose the brain. Archeologists have unearthed skulls dating to 10,000 BCE, that show evidence of the practice. Some such skulls had healed, indicating that the holes resulted from a deliberate surgical act. The purpose of trephination remains a matter of speculation. Did it have religious implications? Did it release evil spirits?

Even in ancient times, humans performed complex surgical procedures. By 3,600 BCE, Egyptians performed tracheotomies, cutting a hole in a patient's windpipe to ease airflow. In 1,700–1,600 BCE, Egyptian surgeons operated on tumors and aneurysms. They used cautery to remove breast cancers and treat other ailments, literally burning away the offending body part.

So common were surgical procedures, that the 1,700 BCE Code of Hammurabi (Babylon) dictated the cost of surgeries, including incisions of tumors, giving discounts for operations on slaves. The Code dealt harshly with surgical failure: “if a physician make a large incision with the operating knife, and kill him, or open a tumor with the operating knife, and cut out the eye, his hands shall be cut off.” We may assume that malpractice was rare.

Egyptian and Greek surgical practices may have anticipated modern therapies. *The Edwin Smith Papyrus*, an Ancient Egyptian medical text and the oldest known surgical treatise on trauma, described the healing of injuries in 3,000 BCE, and suggested the application of meat to wounds to decrease bleeding, possibly using tissue clotting factors to achieve hemostasis. The ancient Greeks treated wounds with wine, perhaps acting to sterilize the incisions.

Records indicate the types of care given to wounds during this period, and the diversity of surgical procedures, but few records indicated attempts to dull the pain of surgery. How did ancient humans endure having a quarter-sized hole bored into their skull, the extraction of tumors, and the destruction of maladies by burning? The agony is difficult to imagine.

As the new millennium approached, surgeries became more complex, and the center of progress shifted from Greece to Rome. The Romans contributed to the knowledge essential for conducting surgery. The ancient Roman physician, Celsus (25 BCE–CE 50), accurately described the body's response to trauma or infection, using terms characteristic of inflammation—redness, swelling, heat and pain. The great Roman surgeon, Galen (CE 129–199), performed

cataract extractions, perhaps by displacing the opaque lens into the vitreous humor with a needle. A surgeon to gladiators, he made major contributions to the knowledge of anatomy through his observations of normal and abnormal structure. He dissected pigs and apes because human dissection was forbidden. However, by relying on dissection of animals, some of his extrapolations to human anatomy initiated errors that continued for centuries, errors sustained because of Galen's fame.

Ancient Jews in the Middle East also conducted surgeries. The Talmud described the suturing of wounds, the reduction of dislocations, the amputation of limbs, and the performance of Caesarian sections. The Jews had quaint remedies including the application of onions to wounds, a therapy for preventing infection that has modern support [2].

Dealing with the Pain of Surgery in the Ninth Through Twelfth Centuries

Church edicts during the Middle Ages, particularly the Dark Ages, diminished the use of surgery, and in 1163, the church forbade monks from shedding blood—and thus from performing surgery. Enter the barbers, men taught surgery by the monks before the Church's prohibition. These barber-craftsmen continued performing surgeries. They repaired hernias, removed bladder stones and cataracts, among other procedures, thereby preserving a modicum of surgical craft.

Pain always accompanied surgery; what to do about the pain? In the Middle Ages, patients might suck liquid or breathe vapors from sponges which offered mandrake, henbane or other hallucinogens such as hyoscyamine and scopolamine [3]. It sounds wonderful, a sponge to cause sleep, to shield its beneficiaries from the cruelty of the knife.

“The most popular method of inducing narcosis was the so-called soporific sponge, *spongia somnifera*. Historians have found descriptions of it in manuscripts dating to the ninth century. Nicholas of Salerno described its ingredients in the twelfth century as opium, hyoscyamine, mulberry juice, lettuce seed, hemlock, mandrake and ivy. A fresh sea-sponge was to be soaked in the mixture and allowed to dry ‘in the sun during the dog-days until all the liquid is consumed.’ When required for use, the concoction was re-constituted by dipping the sponge in water. Because the medieval manuscripts recommended applying the sponge to the subject's nostrils, it has been thought that this was meant to be a form of inhalation anesthesia, but there is good evidence that the potion was usually administered as a drink [4].”

Medieval physicians even thought of an antidote: “Reversal of the narcotizing effect was to be attained with the juice of fennel-root or with vinegar [4].” But the soporific sponge probably could not produce anesthesia. Patients given scopolamine may not remember the agony of surgery, but they would move in response to the inflicted pain, and they might move vigorously [5].

Thirteenth–Fourteenth Centuries: Ether is Synthesized and Surgery Grows

In 1275, Spaniard Raymond Lully (Fig. 1.1) created a compound that, centuries later, would become the world's most important anesthetic. He combined sulfuric acid with wine to produce ethyl ether, which he called sweet oil of vitriol. But Lully did nothing further with his discovery, and patients everywhere would have to wait nearly 600 years for ether to be used to produce anesthesia.

Italian and French surgery resumed, growing as the Middle Ages ended. Published in Salerno, the earliest book on operations, the Bamberg Surgery, elevated the prestige of Italian surgery. Italian and French barber-surgeon guilds competed with each other and with so-called “masters of surgery”, for royal recognition and support. Italian master surgeon, Lanfranc of Milan, irrigated wounds with wine (as had Greek physicians 1,500 years earlier) before closure of the wounds. In 1,290, Lanfranc left for France, thereby transferring considerable surgical authority from Italy to France. His 1296 book, *Practice and Art of All of Surgery*, further inspired French surgery.

French master surgeon Guy de Chauliac's 1368 book, *Inventory of the Complete Works of Surgery*, supplemented Lanfranc's work. Both Lanfranc's and de Chauliac's books appeared in Latin, and thus were inaccessible to most barber-surgeons until translated into French and other European languages. This contributed to the stiff competition between the master surgeons (who were likely to speak Latin) and the barber-surgeon guilds. The books guided surgery in France, and to some extent in England, for two centuries. They advised treatment of tumors, sores, and fractures, and prescribed antidotes and drugs. England however, remained a backwater controlled primarily by barber-surgeons, who competed with the less numerous military surgeons.

Fifteenth and Sixteenth Centuries

The 1425 translation of Guy de Chauliac's book from Latin into French and English, aided the barber-surgeons (known as the “surgeons of the short gowns”) in their mounting competition with Latin-educated university surgeons (the “long gown” academic surgeons). Barber-surgeons grew more numerous than their long-gown counterparts, in part because the barber surgeon was more accessible. Although the barber-surgeons lacked social status or academic rank, the public found them to be more approachable, and eventually recognized that they also possessed superior skills that decreased complications and mortality.

Two self-educated Frenchmen, Pierre Franco and Ambroise Paré, advanced surgery in France and the reputation of such surgery in the world. They learned to perform surgery

Fig. 1.1 In 1275, Raymond Lully (pictured with words coming from his mouth) synthesized diethyl ether (“ether”) by mixing wine and sulphuric acid, calling it sweet oil of vitriol, but he made nothing of it

from itinerant lithotomists and herniotomists (Franco), and barber-surgeons (Paré). Franco is thought to have fought charlatans, and Paré helped bridge the divide between the barber-surgeons and academic surgeons.

The Renaissance generated a new era of discovery in surgery. The Renaissance diminished the power of the Church and thereby limited its power to prevent human dissection. As a consequence, surgeons gained important new insights into anatomy that materially advanced surgery. In 1543, 29 year-old Andreas Vesalius published his classic book *On the Fabric of the Human Body*, demolishing centuries of errors based on Galen’s dissections of animals, or ignorant imaginings [6, 7].

A half-century later, in 1597, Gaspare Tagliacozzi published *The Surgery of Defects by Implantations*, a treatise on the management of mutilating injuries—plastic surgery in 1597. Tagliacozzi precisely instructed surgeons on the reconstruction of noses and ears. The uncomplaining immobilized

patient waited for two or three weeks for the skin graft from the arm to gain circulation from the nose [6, 7]. Plastic surgery without a drop of anesthesia.

It was not for lack of an anesthetic. It was not for lack of an observation that the anesthetic might block pain. As Lully had done three centuries earlier, in 1540, 25 year-old Valerius Cordus (Fig. 1.2a) once again produced ether (sweet oil of vitriol) by adding sulfuric acid to wine [8, 9]. About the same time, Theophrastus Bombastus von Hohenheim (Fig. 1.2b), better known as Paracelsus [10] noted that ether “has associated with it such a sweetness that it is taken even by chickens, and they fall asleep from it for a while but awaken later without harm.” Paracelsus continued, “On this sulphur no other judgment should be passed than that in diseases which need to be treated with anodynes (pain killers) it quiets all suffering without any harm, and relieves all pain, and quenches all fevers, and prevents complications in all illnesses [8].”

Why did no one notice? A potent painkiller, ether would eventually be widely used as an anesthetic, but Paracelsus died in 1541 without demonstrating this possibility. Had anyone tumbled to the possibilities inherent in Paracelsus’ observation that ether put chickens to a reversible sleep, one which relieves all pain, anesthesia might have been discovered three centuries sooner.

Perhaps Italian scholar, polymath and playwright, John Baptista Porta, had discovered the anesthetic potential of ether. In his 1597 work on “*Natural Magic*,” Porta noted:

At last shall be related a wonderful method by which any sleeping person may inhale a soporific medicine. From what we have said, any one will easily know that he is liable to suffer severely after sleep caused by medicine, and to have his suspicions aroused [11].”

“But the quintessence is extracted from a number of the above named medicines by somniferous (sleep-inducing) menstrual. This is put into leaden vessels perfectly closed, lest the least aura should escape, for the medicine would vanish away. When it is used, the cover being removed, it is applied to the nostrils of the sleeping person, he draws in the most subtle (sic) power of the vapour by smellings, and so blocks up the fortress of the senses that he is plunged into the most profound, sleep, and cannot be roused without the greatest effort. After the sleep, no heaviness of the head remains nor any suspicion of trick or fraud. These things are plain to the skilful physician, but unintelligible to the wicked [11].”

Although he does not describe what chemicals he uses, Porta (who sometimes was called a “professor of secrets”) could have been describing ether. Much later, John Snow (author of *On Chloroform and other Anaesthetics: Their Action and Administration*) reflects on Porta’s 1597 book and makes his own astute observations concerning Porta’s description. Snow states,

“The author [Porta] does not make known what the ‘somniferous menstrual’ were, with which the ‘quinta essentia’ were

Fig. 1.2a Using the approach used by Lully nearly three centuries earlier, Valerius Cordus (I.2) synthesized ether in 1540.

1.2b However, this time someone—Paracelsus (I.3)—made observations on pharmacological qualities of the new compound: “...it quiets all suffering without any harm, and relieves all pain...”

extracted. As sulphuric ether had been described more than fifty years before he published his work, it is not improbable that this was the evanescent substance which required the vessel be carefully closed up, and that the profound sleep was simply caused by this, as the narcotic principles dissolved in it would remain in the bottle in the form of extracts...Porta does not say that operations were performed under the influence of the inhalation, or in fact, that it was applied to any useful purpose whatever [11]”.

Why didn't Porta apply his observations to relieve the pain of surgery? Why didn't Paracelsus do the same? As Winston Churchill observed: “Men stumble over the truth from time to time, but most pick themselves up and hurry off as if nothing happened.”

And what of possibilities other than ether might there been to diminish pain? Shakespeare reminds us of remedies such as the Mandrake root:

“Not poppy, nor mandragora,
Nor all the drowsy syrups of the world,
Shall ever medicine thee to that sweet sleep
Which thou ow'dst yesterday.”
Shakespeare: Othello III.iii

Just like the soporific sponge, the Mandrake root contains deliriant hallucinogenic tropane alkaloids, such as hyoscyamine and scopolamine [12]. Those who take sufficient hyoscyamine (an alkaloid precursor of scopolamine) may lapse into a coma, one that adds a risk of lethal increases in temperature because scopolamine can prevent sweating [13]. Enormous doses of scopolamine or its sister, atropine, have been used in the treatment of depression, so they are relatively safe as long as the ambient temperature does not require

sweating to keep cool [14, 15]. As already noted, although such doses may eliminate the remembrance of surgery, they do not produce anesthesia. They do not produce a patient who is immobile in the face of noxious stimulation [5].

The Seventeenth Century

By the turn of the seventeenth century, surgical procedures became more complex (and thus more painful), and the practice of medicine more professional. The scientific revolution was in full swing, and experimentation began to replace speculation. William Harvey's 1628 book, *An Anatomical Exercise on the Motion of the Heart and Blood in Living Beings*, described his momentous discoveries concerning the anatomy and physiology of the circulation of blood, how blood moved from heart to artery to vein and back again [7]. And Hieronymus Fabricius ab Aquopendente, a teacher to Harvey, not only demonstrated venous valves but also used a technique for tracheotomies—puncturing the windpipe to allow passage of air—that is similar to the approach used today. Adding to Harvey's contribution, in 1661, Marcello Malpighi described the capillaries and their function.

In the 1500s–1600s, Colleges of Physicians arose in England, Scotland and Ireland, acquiring the Royal prefix by the 1600s. This brought prestige to physicians (internists), but little to the surgeons. Surgeons continued to struggle for recognition in their field. French barber-surgeons eventually received the legal right to treat all wounds. As is the case today, the “private practice” barber-surgeons received higher fees

than their academic competition, the master surgeons. Even so, to make ends meet, in addition to doing surgery, barber-surgeons performed bloodletting and mundane wound care. They became more technically proficient than the academicians but did not contribute to advances in knowledge.

The seventeenth century saw the first demonstration of the possibility of intravenous anesthesia. In 1656, Christopher Wren (the architect for St. Paul's cathedral and a founder of the Royal Society) infused wine and ale from a syringe made of dog's bladder, through a goose quill needle into the vein of a dog [16, 17]. Wren wrote "I have injected wine and ale in a living dog into the mass of blood by a veine (sic), in good quantities, till I have made him extremely drunk, but soon after he pisseth it out." The dog survived the experiment. The dog, incidentally, was provided by Robert Boyle, author of Boyle's law. Wren later gave opium intravenously via a quill to dogs, causing unconsciousness in some animals but killing others [17]. Wren's experiment was the first known injection to produce anesthesia.

The Eighteenth Century: The Verge of Discovery

The eighteenth century brought the professionalization of medicine to Europe and eventually, to the US. By the 1700s, academic surgeons gradually became recognized as professionals equal to physicians, largely because they demonstrated the importance and interdependence of pathological (diseased) anatomy and pathophysiology (diseased function). French surgical training increasingly included teaching an accepted body of knowledge in courses and schools. Two events moved French surgery closer to a profession. One was the 1731 establishment of the Royal Academy or College of Surgery. Second was a 1743 Royal Declaration, forbidding master surgeons to work as barbers. Laws promulgated after the initiation of the French Revolution in 1789, added to the rise of surgery in France. The Faculty of Medicine and the College of Surgery were abolished in 1792, replaced in 1794 by the School of Health that imposed identical educational requirements for those practicing medicine and surgery [6, 7].

In the last half of the eighteenth century, surgery in Great Britain also progressed rapidly. In 1745, the British Parliament separated surgeons from the barber guilds by enacting a bill that formed a Corporation of Surgeons. Led by Percival Pott and John Hunter, [6, 7] Britain displaced France as the most important European center for surgical education and training. Pott and Hunter's knowledge of anatomy advanced surgery as a scientific discipline. Hunter made important observations, describing, for example, the pathophysiology of surgical diseases, and supplying observations on malignant tumors and the growth of collateral circulation after arterial occlusion. This information was particularly important to

treatment of aneurysms.² Pott connected the occupation of chimneysweeps with their development of scrotal cancer.

Medicine and surgery were stagnant in North America from 1600 to 1750, and self-educated "physicians" served most medical needs. As 1800 approached, Americans increasingly admired physicians, prompting progressive numbers of Americans to obtain training from the more advanced European system of medical education.

Eighteenth century internal medicine sped forward in diagnosis and treatment. The parallel development of eighteenth century pathological anatomy and experimental physiology strengthened the connection of internal medicine and surgery. Surgeons increasingly correlated disease with anatomical (pathological) changes. This reflected the view long held by physicians, that disease processes had physiologic consequences. Regardless of these developments, without anesthesia and antisepsis, surgery advanced slowly.

Several important discoveries were made during this period. One was by Englishman Joseph Priestly, who had committed himself to the ministry, but believed that understanding nature would further the aims of religion. Priestly's experiments resulted in the discovery of new gases or "airs", among them oxygen and nitrous oxide. He produced nitrous oxide by heating iron filings with nitric acid in 1772, publishing his studies three years later. However, like Paracelsus' oversight about the possibilities of ether two and a half centuries earlier, Priestly missed the significance of his discovery and little was then made of the new air.

Perhaps the most important discovery of the time originated from a 1735 expedition, led by French explorer Charles de la Condamine into South America's Amazon River region, where he observed the natives using blowpipes to propel poisonous arrows with lethal effects while hunting [18]. In 1769, while in South America, English physician Edwin Bancroft wrote of his observations of the natives concentrating the poisonous mix of bark and roots, noting that they avoided exposing wounds in their skin to the confection [19]. Bancroft brought samples of the poison, known as curare, back to England.

In 1811, English surgeon Benjamin Brodie, reported that although the poison caused breathing to cease in a donkey, the heart continued to beat, [20] and beating could be sustained if ventilation was supported [21]. In an 1814 demonstration, Brodie and Sewell, a veterinary surgeon, dramatically demonstrated the innocuousness of curare if ventilation

² Ironically, Hunter had angina pectoris, presciently noting that "my life is in the hands of any rascal who chooses to annoy and tease me." A fatal heart attack at age 65 followed an argument at St. Georges Hospital on 14 October 1793. Pott described the anatomy of congenital inguinal hernias in his "Treatise on Ruptures." He advocated emergent operations for incarcerated hernias. Most famous was his 1775 *Chirurgical Observations*, a 5-page essay correctly connecting scrotal cancer in chimney sweeps to their exposure to tars.

was supported. Sykes, a well-known surgeon described the experiment as follows [22]:

A she-ass received the wourali poison in the shoulder, and died apparently in 10 min. An incision was made in its windpipe, and through it the lungs were regularly inflated for two hours with a pair of bellows. Suspended animation returned. The ass held up her head and looked around; but the inflating being discontinued, she sunk once more in apparent death. The artificial breathing was immediately recommenced, and continued without intermission for two hours more. This saved the ass from final dissolution; she rose up, and walked about; she seemed neither in agitation nor in pain. The wound, through which the poison entered, was healed without difficulty...and by Midsummer (the ass) became fat and frisky...The kind hearted reader will rejoice on learning that Earl Percy, pitying her misfortunes, sent her down from London to Walton Hall, near Wakefield. There she goes by the name Wouralia. Wouralia shall be sheltered from the wintry storm; and when the summer comes she shall feed in the finest pasture. No burden shall be place on her and she shall end her days in peace.”

To survive the paralytic effects of curare, Wouralia the donkey had a tracheotomy and ventilation with a bellows. Wouralia did just as Sykes described, and lived another 25 years in peace. The local paper supplied an obituary.

Prior to Brodie and Sewell’s experiments, interest had already developed in approaches to secure the airway. As a result, their efforts built on the practice of earlier surgeons like Hooke, Kite, Herholdt and Rafn. In 1667, Robert Hooke performed an extraordinary and cruel sequel to Vesalius’ 1550s experiment. Hooke showed that blowing air down the windpipe and out through multiple punctures in the lungs of an awake dog sustained life, even though the lungs were still. In 1788, Kite ventilated a drowning victim’s lungs through a tube he placed blindly through the oropharynx and into the windpipe. Nearly a decade later, Herholdt and Rafn described blind digitally assisted tracheal intubation, to resuscitate drowning victims.

Some aspects of modern surgery and management of the airway arose early. Concentrating cohorts of war casualties or victims of epidemics in one place enhances their monitoring and care—in ancient or modern times—anticipating the development of hospitals. The Bible implies the use of mouth-to-mouth respiration (2 Kings, iv, 34), and midwives used it to revive the new-born. Slowly, science and medicine would bring together the airway and ventilatory necessities, the concentrating of patients to supply the intensive care that became part of modern anesthesia.

And What About Positive Thinking?

Other than Priestly’s discovery of nitrous oxide, little else anticipated the approaching demonstration of anesthesia in 1846 besides the mind control that physicians and others long had practiced. Practitioners have seemingly forever

applied positive thinking and various forms of suggestion, including modern magical rings, necklaces and charms for the parturient. Greeks applied oils and warm compresses during labor, anticipating the warm compresses, massage and herbal teas used today. Were these placebos (which can have positive effects)? In the latter part of the eighteenth century, Franz Mesmer created “theories of animal magnetism,” perhaps a form of hypnosis. Mesmerism provided an inconsistently effective management of the pain of surgery. The scientific establishment noted the absence of any rationale for Mesmerism’s effectiveness.

Reprise

By the nineteenth century, the surgeon had become a full member of the medical community, contributing to the knowledge of human anatomy and pathology, and to an elaboration of surgical procedures. The operations performed included amputations, cataract removal, cesarean sections, cosmetic surgery, removal of bladder stones, ligation of major arteries, excision of superficial tumors, excision of anal fistulas, and repair of hernias. The range staggers the imagination, more so, given the absence of anesthesia. Surgeons focused on acute processes, conditions requiring immediate care: simple fractures, dislocations, and abscesses. Infection compromised treatment and was a constant threat to life. But most of all, pain limited the number of surgeries that might be performed, and thus limited progress in surgery.

Summary

The gases and vapors later known as anesthetics had been synthesized or isolated before (ether, nitrous oxide and carbon dioxide) or would be synthesized in (chloroform) the period from 1798 through 1846. They served various purposes. In 1798–1800, Humphry Davy used nitrous oxide for recreation and research, noting its capacity to diminish or even abolish pain. He suggested its use for surgery, but no one noticed. In 1823, Hickman used carbon dioxide to cause what he called “suspended animation”, a state that permitted apparently painless surgery in animals. But no one noticed. In the 1840s, Clarke, Long, and Smilie each administered ether in amounts sufficient to permit surgery to be undertaken without pain. But they thought too little of what they had done, or didn’t know what they had done, to request public credit for their accomplishment. And no one noticed.

As indicated in the preceding chapter, despite the absence of anesthesia, despite the agony of surgery, despite the great risk of infection and death from infection, surgery intruded into any immediately accessible structure thought to need attention. The exemptions might be abdominal, thoracic, and intracranial operations, but surgeons might go even there. The agony of remembrance of surgery was expressed vividly, revealing what we know today as post-traumatic stress disorder (PTSD).

World Events in the Half Century Before Ether Day

In 1799 Napoleon staged a coup d’état, becoming First Consul of France, five years later crowning himself Emperor. With the 1803 Louisiana Purchase, the US more than doubled its size, buying The West. The steam engine appeared in 1804. Nelson defeated Napoleon’s fleet at Trafalgar in 1805, and winter defeated Napoleon’s army in Russia in 1812. After his defeat he was exiled to Elba (1814), but he escaped the next year, and began the Hundred Days leading to his final defeat at Waterloo. In 1820, a Russian expedition discovered Antarctica. Three years later, James Monroe declared his eponymous Doctrine (any effort by European nations to interfere with governance in North or South America or colonize land would be viewed by the US as an act of aggression). The first electric motor appeared in 1829 and in 1836, Samuel Colt

manufactured his six shooter. Several inventors made “telegraphs”, the one by Samuel Morse in the late 1830s being the most successful. Rowland Hill introduced the postage stamp in 1840. The first publicly funded telegraph line in 1844 sent Morris’ message: ‘What hath God Wrought?’ Two Opium Wars waged from 1839 to 1860 forced China to make many concessions to France, the UK, the US, and Russia, greatly weakening China’s power.

A Chronology of Major Themes up to Ether Day

1798–1800: Humphry Davy Misses the Gold Ring

In Bristol, England, Thomas Beddoes established the Pneumatic Institution to treat pulmonary tuberculosis with “new airs”, various gases including nitrous oxide. Traveling in 1798, he met the precocious 20-year-old Humphry Davy (1778–1829) and recruited him to superintend his laboratory. Davy (Fig. 2.1) vigorously pursued his charge, particularly in studies of nitrous oxide, studies involving self-experimentation to the point of addiction. Well, we might say, of course, but Keys points out that this took a bit of courage: “...an American chemist and physician, Samuel Latham Mitchill, administered nitrous oxide to animals with such dire results that he came to the conclusion that this gas was very poisonous [1].” We know now, that lack of oxygen rather than the nitrous oxide itself caused death, but who knew that then? “He (Mitchill) also believed that nitrous oxide

Fig. 2.1 Humphry Davy, the precocious superintendent of the Pneumatic Institution in Bristol, described the capacity of nitrous oxide to prevent pain, suggesting its use in surgical procedures, but no one took up his suggestion

might possibly be the contagium for the spread of epidemics [1].” In addition, 5 years before Davy’s discoveries, Mitchill described the “anesthesia” produced by inhalation of nitrous oxide [2]. Thus, a mixture of courage, bravado, foolishness and addictive behavior probably underlay Davy’s inhalation of nitrous oxide. Keys wrote that “instead of dying, he (Davy) experienced many pleasurable sensations; he felt an agreeable sense of giddiness, a relaxation of the muscles, noticed his hearing to be more acute, and in general felt so cheerful that he was compelled to laugh.” By 1800, Davy had written a 580 page book describing his adventures [3], displaying more than a passing fondness for its properties: “... a desire to breathe (nitrous oxide) is always awakened in me by the sight of a person breathing, or even by that of an air-bag or an air-holder.” His is an early example of the potential of anesthetics to produce addiction.

On page 465 of Davy’s book, he described his self-treatment for the pain associated with eruption of a wisdom tooth:

“In cutting one of the unlucky teeth called *dentes sapientiae*, I experienced an extensive inflammation of the gum, accompanied with great pain, which equally destroyed the power of

repose and consistent action. On the day when the inflammation was most troublesome, I breathed three large doses of nitrous oxide. The pain always diminished after the first four or five respirations; the thrilling came on as usual, and uneasiness was for a few minutes swallowed up in pleasure. As the former state of mind returned, the state of organ returned with it; and I once imagined that the pain was more severe after the experiment than before.”

Part of this fits with what we now believe about the effects of nitrous oxide. It may decrease the perception of pain (i.e., cause analgesia), in part, by activating the receptors turned on by opioids such as morphine [4]. Tolerance (a decreased effectiveness) develops with nitrous oxide, especially with repeated administration, possibly explaining enhanced pain on recovery [5].

On page 556 of his book, we find Davy’s famous quotation suggesting the possibility of surgical anesthesia: “As nitrous oxide in its extensive operation appears capable of destroying physical pain, it may probably be used with advantage during surgical operations in which no great effusion of blood takes place [3].” His suggestion went unnoticed. This meteor of a man went on to discover several elements including sodium, and construct the miners’ safety lamp, but his inaction regarding nitrous oxide cost him anesthesia’s gold ring, the greatest discovery in all of medicine. He was immortalized by Edmund Clerihew Bentley’s poem (a *clerihew* is a poetic 4-line verse that takes the form AA, AA, BB, BB). The first-ever clerihew was perhaps written during a particularly boring chemistry lecture:

Sir Humphry Davy
Was not fond of gravity
He lived in the odium
Of having discovered sodium.

1800–1810

As the nineteenth century began, the US had but 4 medical schools. Benjamin Rush (1745–1813), professor at the foremost school, the University of Pennsylvania, had attempted to minimize labor pain by applying leeches to remove blood. Since the pain of childbirth caused stimulation, he reasoned that bloodletting would offer relief by producing an opposing depression. In defense of higher learning in the US, note that Rush obtained his medical education at the University of Edinburgh and St Thomas’ Hospital in London. Others shared his belief in the curative power of the removal of blood by venesection (Stanley, p 54) [6]: “In 1809, The Times reported on an American, Captain James Niblett, who over two months had been bled of 600 ounces of blood, more than fifty instances in addition to leeches.”

In 1803, Serturmer isolated morphine from opium.

Fig. 2.2 The agony of surgery without anesthesia and the violence of the response to surgery are readily imagined

1810–1820

Numerous reports describe the agony of surgery and the lingering after effects, what we might now call post traumatic stress disorder (PTSD). Columnist David Brooks wrote [7]: “In 1811, the popular novelist Fanny Burney learned that she had breast cancer and underwent a mastectomy without anesthesia:

“I felt the instrument—describing a curve—cutting against the grain, if I may so say, while the flesh resisted in a manner so forcible as to oppose & tire the hand of the operator who was forced to change from the right to the left,..I began a scream that lasted intermittingly during the whole time of the incision—& I almost marvel that it rings not in my ears still.’ The surgeon removed most of the breast but then had to go in a few more times to complete the work: ‘I then felt the Knife racking against the breast bone—scraping it! This performed while I yet remained in utterly speechless torture.’”

Brooks noted that Burney wrote about more than the immediate experience. She described the recurring impact on her emotions. “Not for days, not for weeks, but for months I could not speak of this terrible business without nearly again going through it!... I dare not revise, nor read, the recollection is still so painful.” PTSD, indeed!

A patient of Scottish surgeon James Simpson provided another vivid description of the agony of remembrances of surgery [8]:

“Suffering so great as I underwent cannot be expressed in words...but the blank whirlwind of emotion, the horror of great darkness, and the sense of desertion by God and man, which swept through my mind, and overwhelmed my heart, I can never forget...Those are not pleasant remembrances. For a long time they haunted me, and even now they are easily resuscitated; and though they cannot bring back the suffering attending the events which gave them a place in my memory, they can occasion a suffering of their own, and be the cause of a disquiet which favors neither mental nor bodily health.”

It might have been nearly impossible for four strong men to restrain a terrified woman or man subjected to the knife (Fig. 2.2). And the struggles of the consenting patient could be sufficient to cause the operating table to disintegrate [9].

Yet surgery continued despite the woe it induced, despite the agony, despite the haunting memories. For some, pain was something to be borne, a misery that nonetheless did not preclude surgery or surgical advancement.

In 1818, Michael Faraday noted parallels between the effects of ether and nitrous oxide [10, 11]:

“When the vapour of ether mixed with common air is inhaled, it produces effects very similar to those occasioned by nitrous oxide...In trying the effects of the ethereal vapour on persons who are peculiarly affected by nitrous oxide, the similarity of sensation produced was very unexpectedly found to have taken place. One person who always feels a depression of spirits on inhaling the gas, had sensation of a similar kind produced by inhaling the vapour.”

Faraday raised a caution regarding ether [10]: “By the imprudent inspiration of ether, a gentleman was thrown into a very lethargic state, which continued with occasional periods of intermission for more than 30 hours, and a great depression of spirits; for many days the pulse was so much lowered that considerable fears were entertained for his life.”

Surgeons used counter-irritants “to inflict pain in the hope of healing [6].” They would apply blistering agents. They would remove blood with lances and leeches. In 1819, Sir Walter Scott, plagued with stomach cramps was subjected to

“profuse bleeding and liberal blistering” causing him to scream “without interval through the night, terrifying his family and servants...Looking back on the ordeal Scott reflected wryly that his doctors had told him that ‘mere pain cannot kill’...The suffering inseparable from treatment before or besides surgery, however, explains how the acute pain of surgery was perhaps merely an intensification of a regime in which prolonged pain was seen as an inevitable part of healing [6].” (p 56)

1820–1830

In the first half of the nineteenth century, surgeons devised operations of increasingly greater complexity, invasiveness and duration. Stanley [6] reported (pp 64–5) that in 1822,

“Working in a cottage in poor light Liston excised a tumour beneath McNair’s shoulder blade...I began by making an incision of a foot long...I felt my finger and knife dip into the body of the tumour...I immediately thrust my sponge into the cavity, so as to command the haemorrhagy. The patient, who had borne the operation well...now dropped his head off the pillow, pale, cold, and almost lifeless. I then...saw that nothing but a bold stroke of the knife could save the boy from immediate death. Pulling out the sponge, therefore, with one rapid incision I completely separated the upper edge of the tumour...After removing the tumour, I found it necessary to saw off the ragged and spongy part of the scapula, so as to leave only a fourth part of that bone....’ Liston’s patient survived the operation but died four months later....”

The Lancet was first published in 1823. Five years later, the *Boston Medical and Surgical Journal* (later the *New England Journal of Medicine*) began publication. Such journals plus newspapers described medical discoveries, including ether’s anesthetic properties just two decades later.

In 1823 and 1824, a young English surgeon, Henry Hickman (1800–1830), gave animals carbon dioxide to breathe, causing a “suspended animation” that allowed apparently painless amputation. Hickman reported his observations to the Royal Society and to Charles X in France, but neither responded. Well, he tried and then died of tuberculosis. Credit him with advancing the idea that surgery might be undertaken painlessly by the inhalation of an agent whose elimination could rapidly reverse the pain-relieving effect. This idea may have been crucial to the discovery of anesthesia. Otherwise the widespread belief of the inevitability of pain would prevent a search for a remedy.

In 1829, Babbington viewed the glottis, the opening to the larynx, using indirect laryngoscopy, i.e., viewing the larynx using mirrors. Increasingly we shall see attempts to control the freedom of the passage of air to the lungs. Viewing the larynx was important to such attempts.

1830–1840

The great surgeon, James Syme, operated on 95 patients in Minto House in 1830 [6]: 10 major amputations of the legs; 9 minor amputations of fingers or toes; 7 novel excisions of elbows or knees (i.e., removal of a diseased portion of the knee or elbow, thus avoiding amputation); 4 breast resections for cancer; excision of an upper jaw; removal of 11 tumors; 4 lithotomies (for bladder stone); ligation of 2 aneurysms; and repair of a strangulated hernia. He performed several minor operations: 6 for hemorrhoids; 4 for anal fistulas; 3 nasal

polyps; and 1 for cataract. All this in 1 year when Syme was aged 30.

In 1831, von Liebig, Soubeiran and Guthrie independently discovered chloroform.

1840: The State of Medicine and Surgery

By 1840, the US had 30 medical schools. The curriculum typically occupied two four-month blocks, and covered seven courses. Ability to pay entrance fees determined admission to most schools. Physicians supplemented their training with apprenticeships, the “house pupil” experience, or they traveled to Europe for advanced training. No medical students were women.

Latin American surgeons undertook operations in homes, hospitals, or local inns. In Europe, surgery and delivery might be accomplished in hospitals. Despite the absence of anesthesia, there seemed little that surgeons would not do. Nordic surgeons performed major operations; they removed the mandible, performed gastrectomies, and repaired inguinal hernias and cleft lips. In Chap. 3, Stanley [6] noted the many major procedures done in Great Britain that were improved upon in the first half of the nineteenth century, including trephination, amputation, herniotomy and lithotomy, each with multiple surgical approaches. The rectum offered 23 operable conditions.

“By the 1840s over twenty arteries could be ligated (for aneurism consequent to the considerable incidence of syphilis), most frequently the aorta, the popliteal (in the thigh), the inguinal (in the groin), the subclavian (near the collarbone), and the carotid (in the neck)...In 1832 in the distant colony of New South Wales, Australia, William Bland, one of Sydney’s most prominent surgeons attempted to ligate a subclavian aneurism of William Mullen, a convict. Mullen, whose wife had paid Bland twenty pounds, died after eighteen days. Bland attempted a second operation in 1837, keeping the patient on the table for five-and-a-half hours.” (Stanley pp 76–7)

Fergusson performed more than 200 cleft palate repairs in unanesthetized children – with a mortality rate of only 1% [12]. Most procedures were accomplished with dispatch. In London, Liston famously said before he began surgery: “Time me, gentlemen, time me!” Infection and mortality were ever present.

What could be done to diminish the agony of surgery? Latin American clergy and shamans used opium, herbal extracts, and alcohol to decrease surgical pain. Patients required restraint. In Australia and New Zealand, neither the aborigines nor the Maori used “anesthesia”, although aborigines chewed “pituri” or “pedgery”, herbs producing intoxication or hallucination. Pituri could cause respiratory arrest and death in animals.

Stanley (p 203) [6] argued that courage supported the surgeon as well as the patient. The surgeon dreaded the pain

he (no female surgeons) inflicted. He knew the immediate, sometimes bloody, disasters that awaited his actions. Loss of blood might kill the patient sooner, and infection later. “The desire to finish an operation quickly (whether from concern for the patient or for reputation) imposed a peculiar strain on operators. Some expressed this tension by shouting at the patient, colleagues or dressers. The tension showed in the haste with which, as Samuel Cooper said, surgeons sawed through bone with ‘short, very rapid, and almost convulsive strokes.’” Operations were done speedily to diminish the anguish of the patient. Amputations of the upper or lower extremities might be accomplished in 15 to 30 seconds with closure to follow (Stanley, pp 226–7) [6]. Although the operation might be accomplished with dispatch, cleaning up and closure could impose an hour of great misery: “As dressers wiped a sponge over the raw surface ‘perhaps studded by the truncated ends of large nerves,’ patients would twitch and gasp. At each ‘catch of the forceps and noosing of the ligature’ the patient might shriek” (Stanley, p 229) [6].

“The surgeon might lament what he had to do, ending surgery with tears in his eyes or retiring to vomit in solitude. Surgeons were known to faint mid-operation and their assistants had to supervene. Appetite lessened and sleep came hard.” (Stanley, p 205) [6] A tension existed between the necessity of surgical pain and the desire to heal. The focus of the surgeon might be intense: “After performing an amputation by transfixion in the Adelaide Hospital, (George Mayo) remarked ‘How quiet the patient has been!’ A colleague, startled at his absorption, retorted ‘Why, man, he was screaming all the time’” [6].

But there was a certain resignation. As the French surgeon Alfred Velpeau said in 1839, “The abolishment of pain in surgery is a chimera. It is absurd to go on seeking it...knife and pain are two words in surgery that must forever be associated in the consciousness of the patient.” Again, note this impediment to the discovery of anesthesia, the remedy that Velpeau said could not exist.

One also sees the foolishness of physicians in this time. In the early 1840s, surgeons treated stuttering by operation: “Yearsley...excised the patients’ uvula and tonsils...(giving) the patients ‘instantaneous’ relief.’ Patients previously ‘scarcely able to articulate half a dozen words’ became able to speak ‘with a wonderful degree of fluency.’” (Stanley, p 248) [6]—shades of Galen.

1840–1846: The Non-discovery of Ether Anesthesia

In the 1840s, several physicians/dentists discovered the anesthetic effects of ether before Ether Day, but either didn’t publicize their findings at the time, or didn’t appreciate what they had found. They knew of the inebriating effects of ether and employed it in one or a few patients. These early timid

Fig. 2.3 In 1842, Crawford Long used ether to deliberately provide anesthesia. He did not report this, despite his repeated successful application of ether for anesthesia. Like many others, he missed the gold ring. (Courtesy of the University of Pennsylvania Art Collection, Philadelphia, PA)

successes illustrate the caution and apprehension of those who didn’t realize that they had succeeded. Perhaps success required audacity, a daredevil ego, and greed. In 1842, William Clarke, who “was in the habit of entertaining his companions with inhalations of ether,” anesthetized a Miss Hobbie with ether poured on a towel [13]. Dr. Elijah Pope then extracted a tooth from Miss Hobbie “without pain” [13]. “This would appear to be the first use of ether anesthesia on record; it antedated the work of Crawford Long (1815–1878) by at least two months. Apparently Clarke considered his contribution of no importance, for it is not mentioned in an account of his life in Stone, RF: *Biography of Eminent American Physicians and Surgeons*, Indianapolis, Carlton and Hollenbeck, 1894, p. 89” [13]. Clarke’s failure to publicize his discovery cost him his place in history.

Like Clarke, Long (Fig. 2.3) had engaged in ether frolics; he knew the inebriation it produced and that ether might be safe to breathe, at least to levels that produced inebriation.

“The first patient to whom I administered ether in a surgical operation, was Mr. James M. Venable, who...consulted me on several occasions in regard to the propriety of removing two small tumours situated on the back part of his neck, but would

postpone from time to time having the operations performed, from dread of pain. At length I mentioned to him the fact of my receiving bruises while under the influence of the vapour of ether, without suffering, and as I knew him to be fond of, and accustomed to inhale ether, I suggested to him the probability that the operations might be performed without pain and proposed operating on him while under its influence. ...The ether was given to Mr. Venable on a towel; and when fully under its influence I extirpated the tumour....The patient continued to inhale ether during the time of the operation; and when informed it was over, seemed incredulous, until the tumour was shown him. He gave no evidence of suffering during the operation, and assured me, after it was over, that he did not experience the slightest degree of pain from its performance. This operation was performed on the 30th March, 1842" [14].

Long anesthetized and operated on several additional patients, including a child for an amputation. So he was both an adult and pediatric anesthetist. But he did not report his findings until 1849 [14]. As with Clarke, Long's delay cost him his provenance as the discoverer of anesthesia.

In 1846, Elton Romeo Smilie (1819–1889) also gave ether and produced anesthesia, not realizing that ether had caused the anesthesia [15, 16]. He sought to diminish the coughing of a tubercular clergyman by administering opium. Thinking to vaporize the opium with ether, he did not realize that the ether and not the opium would vaporize – leaving the opium behind. This worked well for the good clergyman. Smilie published his findings, including the use of the mixture for the lancing of an abscess [16]. But because he reported that the opium caused the effect, he gained no credit for the discovery.

Smilie's efforts also indicated the concern that he had regarding the potential for untoward effects of his treatment with ether or opium. Wolfe wrote (pp 187–8) [17]:

"After the patient had inhaled the mixture (of opium and ether), Smilie sent him home, but when calling upon him a few hours later, he found that the patient had fainted and had bumped his head on a table while falling; thus he gave him no more...Smilie's enthusiasm for continuing his use of this panacea was soon deflated by his medical friends, who dissuaded him, telling him that opium had been used extensively in surgery and had been found to be dangerous in large doses that were effective."

Reprise

So close were all these—Clarke, Long, and Smilie, or, Humphry Davy, or Hickman. But not close enough. We might think that they should have been driven by the need to relieve the agony of surgery. But they were not. Surgery and pain were inseparable partners, and always had been. Anesthesia was a chimera. The stories of those who made the discovery are told in Chap. 3.

1844–1846: The Discovery and Demonstration of Anesthesia

3

Edmond I Eger II, Lawrence J. Saidman and Rod N. Westhorpe

Summary

Gardner Colton, a Columbia University medical student, began the discovery of anesthesia by offering (for pay) a public entertainment, a demonstration of the intoxicating effect of nitrous oxide. The dentist Horace Wells attended a demonstration in Hartford, observing that while inebriated, Samuel Cooley injured himself, apparently not feeling the injury as it occurred. Seeking a means to practice painless dentistry, Wells asked Colton to attend his office the next day, and to administer nitrous oxide to Wells while an associate, John Riggs, pulled one of Wells' teeth. Wells felt no pain, and then gave nitrous oxide to several of his patients, practicing painless dentistry on most of them. His success prompted him to approach the great surgeon Warren at the Massachusetts General Hospital (MGH), requesting that he allow Wells to attempt a public demonstration at the Harvard Medical School. The demonstration failed, the audience denouncing Wells for his "humbug".

Two men claimed to have thought of ether anesthesia. Charles Jackson alleged that he supplied the dentist William Morton, an associate and pupil of Wells, with the idea. Morton had observed Wells' early success with nitrous oxide and recalled that ether given in ether frolics had effects similar to those of nitrous oxide and thus might substitute for nitrous oxide. Morton anesthetized his father's dog and other small farm animals with ether. Subsequently he breathed ether, himself, noting the numbness and sedation it produced. On the evening of 20 Sept 1846, Morton put ether on a handkerchief and applied the handkerchief to a patient, Eban Frost, from whom he then painlessly extracted a bicuspid. On subsequent days, he gave ether to several more patients. Success with these patients, and the notion that money might be made from the discovery emboldened Morton who attempted a public demonstration in what became known as the Ether Dome. The demonstration succeeded. Warren announced: "Gentlemen, this is no humbug"; and the news quickly went around the world.

World Events, 1844–1846

In 1844, Morse patented the telegraph in the US, and George Williams founded the YMCA in London. Parliament passed the Factory Act, imposing a maximum 12 h working day for women, and a 6 h day for children aged 6 to 13. In 1845, British inventor Stephen Perry patented the rubber band. But the big year was 1846. In that year, the US acquired the Oregon Territory and began the Mexican-American War.

Mexico lost, ceding Texas, California, Arizona, New Mexico, Utah, and Nevada to the US. Richard March Hoe invented the rotary printing press, and Elias Howe invented the sewing machine. The potato famine caused 1.6 million Irish to immigrate to the US. The illegitimate son of the Duke of Northumberland, James Smithson, established the Smithsonian Institution with a grant of \$ 500,000. Orson Squire Fowler published his bestseller, *Matrimony: Or, Phrenology and Physiology Applied to the Selection of Congenial Companions for Life*. British Prime Minister, Robert Peel, repealed the Corn Laws, replacing the Colonial mercantile trade system with Free Trade. Finally, the first recorded baseball game was played in Hoboken, New Jersey on 9 June under the Cartwright Rules. The New York Nine beat the Knickerbockers 29 to 1, even though the Knickerbockers' owner, Alexander Cartwright, served as umpire.

And 16 October 1846, William Morton demonstrated ether anesthesia in what came to be called the Ether Dome.

Major Themes Leading to and Following Ether Day

Where previous chapters covered decades, centuries or millennia, the present chronology spans two years. Where previous chapters described incremental steps, the present story is of men in 10-league boots who discovered anesthesia. These disparate men argued, each with some justification, that they deserved credit for the discovery of anesthesia: the honorable dreamer-dentist Horace Wells; the snobbish, brilliant, knowledgeable, self-aggrandizing chemist Charles Jackson; and the unscrupulous, rapacious scoundrel, dentist William Morton—whom most credit for the discovery. All three died unhappily; Wells a suicide, Jackson a cripple, and Morton impoverished.

A larger group facilitated but never claimed the discovery. For the most part, these men came to happy ends. They included the showman-medical student Gardner Quincy Colton, whose public exhibition prompted Wells' test of nitrous oxide, and the elderly distinguished surgeon John Collins Warren who facilitated two attempts at a demonstration of anesthesia although he likely had little faith that either would work. The surgeons Henry Bigelow and George Hayward arranged Morton's appearance at the Massachusetts General Hospital operating theatre on 16 Oct 1846, Ether Day. Glassmakers Joseph Wightman and Nathan Chamberlain made the globe that Morton used to deliver ether to the patient. Augustus Gould advised Morton on how to avoid asphyxiating the patient during ether administration (Morton

boarded with Gould who was a physician). And Gilbert Abbott "volunteered" to be the first patient publically anesthetized with ether (etherized).

Several books detail the circumstances of the discovery: Fenster's lyrical "Ether Day" [1], Wolfe's scholarly "Tarnished Idol" [2], and Wolfe and Patterson's defense in "The Head Behind the Hands" [3] of Jackson's role come immediately to mind. There are more: Keys' classic "The History of Surgical Anesthesia" [4], and Thorwald's riveting (but sometimes inaccurate) fictionalized description in "The Century of the Surgeon" [5]. We cheerfully acknowledge that much of the present chapter draws on these books.

The Dentist Deserves Credit

The story of the discovery, and the first public demonstration that inhaled gases could make painless surgery possible, began with Horace Wells, the Vermont son of affluent parents. Having completed a dental apprenticeship in 1836, the 21 year-old Wells moved to Hartford Connecticut. His practice flourished, and he worried that wealth might compromise his morality. Fenster (p. 54) quotes him [1]: "It is my sincere desire to do as much good as possible, and I hope and pray that no selfish motive may ever influence me to go contrary to this principle." This good and trusting, but naïve man, became a chicken amongst the foxes.

Many had used the long-known inebriating effects of nitrous oxide and ether for recreational purposes (Fig. 3.1) and

Fig. 3.2 Replication of a poster advertising an exhibition of the inebriation produced by nitrous oxide. (From a larger picture broadcast on the internet by general-anaesthesia.com.)

public entertainments (Fig. 3.2). Gardner Colton (Fig. 3.3) was an enterprising medical student seeking funds to put himself through what today would be Columbia University. He advertised in the *Hartford Courant* [6]:

“A grand exhibition of the effects produced by inhaling nitrous oxide, exhilarating or laughing gas! will be given at Union Hall this (Tuesday) evening, Dec 10th, 1844. Forty Gallons of Gas will be prepared and administered to all in the audience who desire to inhale it.

“Twelve Young Men have volunteered to inhale the Gas, to commence the entertainment.

“Eight Strong Men are engaged to occupy the front seats to protect those under the influence of the Gas from injuring themselves or others. This course is adopted that no apprehension of danger may be entertained. Probably no one will attempt to fight.

“The Effect of the Gas is to make those who inhale it either Laugh, Sing, Dance, Speak or Fight, etc., etc., according to the leading trait of their character. They seem to retain consciousness enough to not say or do that which they would have occasion to regret...Those who inhale the Gas once, are always anxious to inhale it the second time. There is not an exception to this rule.

“Entertainment to commence at 7 o’clock. Tickets 25 cents.”

Samuel Cooley gave his remembrances of the evening’s events to a Congressional Committee charged with determining who had priority in the discovery of anesthesia. The resulting Walker Report found that Cooley,

“while under the influence of the gas did run against and throw down several of the settees (benches) in the...hall and thereby throwing himself down, and causing several severe bruises upon his knees and other parts of his person; and that after the peculiar influence of said gas had subsided, his friends then present asked if he had not injured himself, and then directed his attention to the acts which he had committed unconsciously while under the operation of said gas. He then found by examination that his knees were severely injured, and he then exposed his knees to those present, and found that the skin was severely abraded (sic) and broken...(Cooley) ‘believed that if a person could be restrained, that he could undergo a severe surgical operation without feeling any pain at the time.’ Dr. Wells then remarked, ‘that he believed that a person could have a tooth extracted while under its influence and not feel any pain.’”

That attracted Horace Wells’ attention. He was looking for a way to practice painless dentistry.

Fig. 3.3 Gardner Colton. (Courtesy of Wikipedia.)

The Walker Report continued, noting that Wells (Fig. 3.4) seized on this idea and convinced Colton to come to his office the succeeding day, to administer nitrous oxide. With Wells under its influence, an associate, John Riggs, pulled one of Wells’ teeth. Wells claimed he felt no pain. In the ensuing weeks, Wells learned to produce nitrous oxide and applied it successfully in more than a dozen patients for the extraction of teeth. He then sought to demonstrate this discovery. George Hayward acted as an intermediary between Wells and the Hershey Professor of Anatomy and Surgery at Harvard, John Collins Warren.

In a later defense of his claim to be the discoverer of anesthesia, Wells wrote a letter to the editor (published 9 Dec 1846) of the *Hartford Courant*:

“I was so much elated with this discovery, that I started immediately for Boston, resolving to give it into the hands of proper persons, without expecting to derive any pecuniary benefit therefrom. I called on Drs. Warren and Haywood (in fact Dr. George Hayward) and made known to them the result of the experiments I had made. They appeared to be interested in the matter, and treated me with much kindness and attention. I was invited by Dr. Warren to address the Medical Class upon the subject, at the close of his lecture. I accordingly embraced the opportunity, and took occasion to remark that the same result would be produced, let the nervous system be excited sufficiently by any means whatever; that I had made use of nitrous oxide gas or protoxide of nitrogen as being the most harmless. I was then invited to administer it to one of their patients who was expecting to have a limb amputated. I remained some two or three days in Boston for this purpose, but the patient decided not to have the operation performed at that time. It was then

proposed that I should administer it to an individual for the purpose of extracting a tooth. Accordingly a large number of students, with several physicians, met to see the operation performed—one of their number to be the patient. Unfortunately for the experiment, the gas bag was by mistake withdrawn much too soon, and he was but partially under its influence when the tooth was extracted. He testified that he experienced some pain, but not as much as usually attends the operation. As there was no other patient present, that the experiment might be repeated, and as several expressed their opinion that it was a humbug affair, (which in fact was all the thanks I got for this gratuitous service), I accordingly left the next morning for home. While in Boston, I conversed with Drs. Charles T. Jackson and W.T.G. Morton, upon the subject, both of whom admitted it to be entirely new to them. Dr. Jackson expressed much surprise that severe operations could be performed without pain....”

Wells had the reasoning wrong. Anesthesia doesn’t result from excitation (although excitation may appear in the transition from the awake to anesthetized states). It results from a depression of the nervous system. But his reasoning would have been irrelevant had he succeeded in his demonstration. He nearly did.

Fenster (p. 64) [1] summarized observations made later by CA Taft who was present at the attempted demonstration:

“The students in the audience...jeered at their laughing-gas man. He heard the word ‘humbug,’ called out over and over again. No one took much notice when the patient awoke fully and protested that he had experienced almost no pain.”

The medical profession’s skepticism had been confirmed.

With Considerable Help, a Scoundrel Succeeds

Now to William Morton (Fig. 3.5). Wolfe noted (Chap. 2) [2], that Morton was born in August 1819 in Charlton Massachusetts, son to a Quaker, James Morton a well-off farmer, then merchant, who fell on hard times in the mid-1830s. Early in life, Morton demonstrated what might be thought of as psychopathic behavior, including the story that he had “nearly killed his young sister Elizabeth by forcing ‘some unearthly compound down her throat, as she lay asleep in her cradle’.” He attended several educational academies within a few years and his “separation from these schools may not have been entirely voluntary.”

With the collapse of his father’s finances, Morton headed west to seek his fortune, but not entirely from honest work. In large part, Morton’s activities were uncovered by his competitor for the discovery of anesthesia, Jackson, who sought to discredit Morton. From 1836 to 1839, Morton lived in Rochester, New York, where initially he worked as a clerk in the dry-goods trade. Morton used his knowledge to swindle several thousand dollars from Loren Ames, with whom he had formed a partnership. He next swindled Phineas Cook,

again in Rochester. He was expelled for profanity and dishonesty from the Brick Church. Finally, he swindled Sarah Seward who ran a private seminary, indicating he would support his sister's schooling but failing to do so.

Morton's unsavory reputation made Rochester inhospitable, so early in 1839 Morton decamped for Cincinnati, where he spent 9 months. He now swindled Charles Pomroy (yet another dry goods merchant) and several customers of Pomroy and Company, becoming increasingly proficient at various forms of lying, forgery and false accounting. He stole from his own company. George Bates (swindled by Morton) noted (Wolfe, p. 27): "The cunning unscrupulousness & boldness with which he carried on his operation, in my belief, mark his career as being without parallel among the swindlers who from time to time have infested our city."

On to St. Louis where through lies and forgeries, Morton attempted to swindle James Sickles, but was discovered and foiled. Deposed years after the demonstration of ether anesthesia, Mordicai DeLange gave an additional view of Morton, one repeated in various guises (Wolfe, p. 30): "...in Morton I had discerned a degree of general ignorance which would make a scientific discovery by him, appear to me to be no less than miraculous." A newspaper in 1839 (Wolfe, p. 32) described Morton as

"...about five feet, ten or eleven inches high, well made, a slouching gait. His features are well formed, his complexion is fair and ruddy, his hair light and rather coarse, and pushed up from his head. His eyes are blue, his teeth white and perfect... He dresses in good clothes, but rather foppishly... His voice is coarse and loud; he is remarkably ignorant of matters of general knowledge, and is very apt to betray his ignorance, by the silliness of his remarks."

This public rebuke pushed Morton back to Cincinnati. While in Cincinnati, Morton became engaged to the daughter of a wealthy Jewish merchant and apparently in furtherance of this relationship underwent circumcision—without anesthesia (Fenster, p. 87) [1]. Morton traveled from Cincinnati to Baltimore in 1840 where he narrowly failed to swindle a Mr. NS Jacobs. An attempt at arrest was made too late; Morton escaped, leaving behind materials he used to commit forgery.

By the early 1840s, Morton realized that his actions might soon lead to imprisonment. He transiently disappeared, perhaps to Charlton, while the heat cooled. His next activities suggested a more cautious approach to amassing a fortune. He turned to dentistry, in 1843 attaching himself to Wells as an apprentice and then as a business partner. Consistent with his previous behavior, he did not live up to his bargain with Wells. He enrolled at Harvard Medical School (admissions were slightly more lax than at present) with Charles Jackson (Fig. 3.6) as his preceptor in medicine.

According to Keys (p. 25) [7], Morton developed a process for making artificial teeth that required removal of the patients teeth, including the roots. The pain associated with

Fig. 3.6 Charles Jackson. (Courtesy of Wikipedia.)

removal of the teeth limited the number of interested patients. Jackson recommended that Morton sprinkle ether in the area surrounding the operative site, apparently envisioning a local effect. In July 1844, a Miss Parrott asked to have a tooth filled. Morton applied the ether as recommended by Jackson and found it effective in minimizing the pain from his procedure.

Considerably after the demonstration of ether anesthesia, Jackson argued that he had known about ether's effects since 1842 when he experienced irritation of his airway from the accidental breathing of chlorine gas (Fenster, pp. 124–7) [1] and self-medicated with inhalation of ether. He obtained relief and repeated the experiment on himself finding that his body became numb. He thought (in 1842, he said) that this might serve as an anesthetic. Why didn't he then advertise his thought to the world or try its demonstration? We recall from Chapter 2 that Crawford Long privately demonstrated anesthesia, albeit failing to publicize his results. Jackson neither experimented nor publicized "his" idea. He had opportunities: he was an apprentice physician, and he had connections to the greatest surgeons in Boston (he was a personal friend of Warren). But nothing. He left such trivial matters to Morton.

Jump forward to Sept 1846. Morton knew of Well's successes and failures with nitrous oxide. He approached

Fig. 3.7 Inside the Ether Dome. The statue of Apollo (left) and the mummy in the case were there in the room on Ether Day. Warren and Lucia Prosperi created the painting seen in the background depicting the surgery on Ether Day [8]. (Courtesy of Dr. Rajesh Haridas, Australia.)

Jackson for advice. Morton indicated that he approached Jackson for help with details, and Jackson obliged, in particular suggesting the use of pure ether (ether adulterated with alcohol, for example, might be ineffective because the presence of the alcohol would diminish the vapor pressure—the concentration—of ether). Jackson also suggested a delivery system consisting of a rubber bag containing ether connected to a glass tube from which a patient might breathe. Jackson contended that he told Morton that ether might be used to impart insensibility sufficient to allow the performance of surgery without pain. Each man may have lied. Morton reported that he experimented with ether using himself and his dog as subjects, finding that numbness and unconsciousness ensued. On 30 Sept 1846, he gave ether to Eben Frost. With Frost under the influence of the ether, Morton painlessly removed an abscessed tooth from Frost, a success reported the next day in the *Boston Transcript* (Fenster, p. 74) [1]. Jackson attended neither this demonstration nor any other that he claimed to have prompted.

Morton continued to experiment with ether in his patients. The surgeon, Henry Bigelow (who ultimately facilitated the demonstration of anesthesia with ether), encouraged Morton. Morton's motives were clear. He wanted to patent (and he did patent) the discovery of anesthesia in order to gain a fortune. Through Bigelow, he applied to Warren to demonstrate the insensibility produced by his new discovery, and on 16 Oct 1846, he was scheduled to do just that in what would become known as the Ether Dome (Fig. 3.7). Morton arrived late, being delayed by the glassmaker who had modified his inhaler for ether. Warren greeted him testily: "Well, sir, your patient is ready!" Morton prepared his inhaler and had the patient, Gilbert Abbott, breathe the ether until unconscious-

ness supervened. Morton then turned to Warren, repeating the earlier taunt: "Your patient is ready, sir!"

Warren's matter of fact report described the next few moments that changed the world.

"The patient being prepared for the operation, the apparatus was applied to his mouth by Dr. Morton for about three minutes, at the end of which time he (Abbott) sank into a state of insensibility. I immediately made an incision about 3 inches long through the skin of the neck, and began a dissection among important nerves and blood vessels without any expression of pain on the part of the patient. Soon after he began to speak incoherently, and appeared to be in an agitated state during the remainder of the operation. Being asked immediately afterwards whether he has suffered much, he said that he had felt as if his neck had been scratched; but subsequently, when inquired of by me, his statement was, that he did not experience pain at the time, although aware that the operation was proceeding."

The demonstration was later posed and photographed (Fig. 3.8). In 2001, Warren and Lucia Prosperi created a painting of the event (seen in the background of Fig. 3.7) [8].

Warren's report understates this arguably greatest of all medical discoveries. It also doesn't repeat what is anesthesia's most famous quotation. Recalling the audience's jeering of Wells nearly two years earlier, immediately after the conclusion of the procedure, Warren is alleged to have said: "Gentlemen—This is no humbug."

One other postscript: It seems that the first successful demonstration of anesthesia was, in fact, a demonstration of ether analgesia (freedom from pain in a conscious patient), something Artusio applied to patients a century later [9, 10].

The Name

What should this new state, this release from the agony of surgery be called? Morton favored *Letheon*, a name he devised for his patented ether. *Anesthesia* came from Oliver Wendell Holmes in a 21 November letter to Morton (Keys, p. 30) [4]:

"My Dear Sir: Everybody wants to have a hand in a great discovery. All I will do is give you a hint or two as to names—or the name—to be applied to the state produced and the agent.

"The state should, I think, be called 'Anaesthesia.' This signifies insensibility—more particularly (as used by Linnaeus and Cullen) to objects of touch...."

The word was not new, but its meaning in the context used by Holmes was new. Hippocrates used anesthesia to indicate a "loss of the power of feeling" as a consequence of a severe disease process, one usually anticipating death [11]. Holmes' use of "anesthesia" was for a drug-induced reversible state.

Fig. 3.8 A posed photograph after the fact with Morton appearing to give ether while Warren and his colleagues stand by. (From Harvard University and pub.acs.org.)

Squabbles and Sadness

None of the claimants to the discovery fared well after 16 October. The ever-ambitious Morton patented (with Jackson) ether, naming it Letheon, but found the patent to be unenforceable. Even the US government violated the patent. The use of ether quickly spread, with little money flowing to Morton whose expenses exceeded his income. Morton returned to dentistry and land speculation, borrowing money to support his activities, money rarely repaid. For a decade-and-a-half after 1849, Morton turned to another cash source, Congress. Morton claimed that he was the sole discoverer of anesthesia, and because of the failure of the government to protect his patent rights, he deserved a compensation of \$ 100,000–\$ 200,000. A select committee took up the issue, agreeing with Morton and recommending to the full Congress, an award of \$ 100,000. Through publicity and lobbying, Morton tried but failed to convince Congress to approve the recommendation. True to form, Morton’s lobbying was underwritten by funds embezzled by William Tuckerman from the Eastern Railroad (Wolfe, Chapter 21) [2]. Tuckerman was later caught for stealing from the US mails and imprisoned.

Despite the illegal base which supported Morton, he might have succeeded in his appeal to Congress had Charles Jackson and the Connecticut legislature (below) not intervened. Learning of the possibility of an award to Morton, Jackson wrote to senator Charles Sumner, asserting that he, Jackson, deserved the award. Jackson noted that the patent for ether named him as a co-discoverer of ether’s anesthetic effects. He also detailed Morton’s crooked dealings as proof of Morton’s undeserving character, but this went nowhere as relevant to who might have discovered anesthesia.

As noted above, Jackson claimed to have thought of the application of ether as an anesthetic in 1842—but then did nothing to demonstrate its properties. What strength had such a claim? It was clearly less than that of Crawford Long who had the idea and put it into practice but also failed to broadcast his discovery to the world.

Wells might have tried again to persuade the surgeon Warren to allow a second demonstration. Had he succeeded, the prize would have been his. Even so, the Connecticut legislature designated him posthumously as the discoverer, an act that compromised Morton’s efforts for recognition and reward. As Fenster notes (p. 174) [1], “...the emergence of Horace Wells and his eloquent defenders was a godsend for all those in the U.S. Congress who just didn’t want to give one hundred thousand dollars to anybody for anything, least of all to Morton for Letheon.” Wells drifted from dentistry (which would have nicely supported him), to dealing with minimal success in the sale of reproductions of art. He dabbled with chloroform, inhaling the vapors, himself. He descended into madness and addiction to chloroform, ending with his arrest in New York City in January 1848 for throwing sulfuric acid at several ladies of ill repute. In his cell he inhaled chloroform, slashed his femoral artery, and died. He did not deserve such an end.

Morton and Jackson continued squabbling, to the financial detriment of both in their efforts before Congress. In 1861, the Civil War began and Morton provided anesthesia to Union soldiers to bolster his case, but to no avail. He tried lecturing, but his lectures were disasters.

On 15 June 1868, New York City was exceptionally warm. Morton had come to the city, seeking help to rebut an article in the prestigious *Atlantic Monthly* that had accorded

Jackson the honor of anesthesia's discovery. Morton fell ill, became increasingly irrational, and died soon thereafter.

In contrast to Morton, for most of his life Jackson enjoyed financial stability, a consequence of an inheritance and his work as a geologist/surveyor. In 1868, he discovered that a cousin had seized his inheritance (Fenster, p. 233) [1]. In May 1873, he suffered a stroke which left him incapacitated for the remaining seven years of his life.

Who Deserves Credit?

Who deserves credit for the discovery/demonstration of anesthesia? Wells and Jackson contributed—and so did many other people. In the late 1840s, France's Académie des Sciences (one of the leading arbiters of science) adjudicated the claims of Jackson, Morton and Wells for the discovery of anesthesia, first giving the honor to Jackson. Then in 1850, the Academy changed its mind, awarding the prize equally to Jackson and Morton, while the Medical Society of Paris gave it to Wells (the news arriving in Hartford a few days after his suicide). The details of the protagonists' lobbying of French academia may be found in Chapter 28.

But it was Morton, Morton the rogue, the greedy scoundrel, the crook looking for the fast buck, the man who lived on the edge of being jailed for his crimes and misdemeanors who showed the world. Of the discovery, Julie Fenster said wonderfully (pp. 126–7) [1]:

“(Morton) had to travel fast and he knew it; he was standing in the operating theater of the Massachusetts General Hospital demonstrating etherization within seventeen days of the emergence of the discovery of September 30 (Morton's first use of ether in Eben Frost)...Morton threw it like a paper airplane into the future. It happened to land on October 16.”

Most, including the editors of this book, credit him with the discovery.

Why Wasn't Anesthesia Discovered Earlier? ...and Why Boston?

The means to produce anesthesia had been at hand long before the discovery. That ether and/or nitrous oxide could diminish or abolish pain, could produce unconsciousness, was known. Lully synthesized ether in 1275. Cordus repeated the synthesis in 1540, and Paracelsus noted its soporific and analgesic properties in 1541. Priestly synthesized nitrous oxide in the early 1770s, and Davy wrote of its anesthetic properties in 1800. In his Chapter 16, Norman Bergman (1926–1999) detailed the considerable numbers of observations on narcotic and other effects of ether before 16 Oct 1846 [12]. These included soporific, analgesic and inebriating effects that paralleled the effects of nitrous oxide. In the US, Guthrie

had discovered chloroform in 1831. He described it as “a grateful diffusive stimulant, and that...it may be probably introduced into medicine”, although there is doubt that he had any inkling as to its soporific effect [13]. He was actually seeking a pesticide.

So why the delay in the discovery of anesthesia? Several possibilities jointly provide an explanation:

- Pain is God's will, His punishment for sin
- Pain is natural and beneficial, essential to healing
- Individual suffering is unimportant; only the group is important
- The production of insensibility is too dangerous
- Anesthesia isn't needed to perform surgery
- Anesthesia can't possibly exist.

Pain is God's Will, His Punishment for Sin

Campagna echoed this explanation, the view that pain should not be avoided lest the guilty party incur God's wrath [14]. Campagna further argued that the religious injunction against the abolition of pain, a conservative view supporting the status quo, explained why anesthesia was first demonstrated in Boston. At the time of the demonstration of the anesthetic effects of ether, Boston was a medical backwater, ceding first place to cities such as Philadelphia. Supporting this view, Campagna [14] quoted a wonderfully snooty letter written at that time on behalf of the University of South Carolina in petitioning their state legislature for a medical school: “...I say nothing respecting those [hospitals and medical schools] of New England, because they have furnished no manifest occasion for peculiar notice, nor have they risen beyond the level of mediocrity.” Many in the New World considered that pain and sickness were manifestations of sin to be enjoyed as a means of expurgation. They were visitations of God's will and thus to be welcomed. But Boston's clerics/physicians, particularly Cotton Mather, were not so sure that ills were God's punishment. When smallpox struck the Boston area in 1721, Mather urged a Dr. Boylston to practice variolation—the inoculation of uninfected persons with effluent from sores on infected patients. The practice was clearly effective, making God's will suspect, yet not convincing the townsmen who often violently opposed variolation for religious reasons (God's will, again).

The Revolutionary War diminished Boston's population by 75%, particularly physicians because they actively supported the revolution. A new medical community arose, one intimately acquainted with the injuries and diseases of war. In the 1780s, Harvard College opened a medical school with John Collins Warren as the first Hersey Professor of Anatomy and Surgery. Warren helped in the formation of the Boston Medical Society and the Journal which became the New England Journal of Medicine.

Smallpox struck again in 1799–1801, but this time an acceptance of variolation began in Boston and spread to other parts of the country. Campanga argued that by 1820–1846,

“To variable degrees, the millennium-old belief that sickness was a punishment that had origin in God’s anger had dissipated. The seemingly innate ‘urge’ to relieve pain, an urge that was sanctioned neither by social nor theological premises, became a tenable thought amenable to critical analysis and scientific experimentation. Slowly but assuredly, medical traditions of dubious value came under the scrutiny of the medical practitioners of Boston and elsewhere. With each success, physicians and their patients solidified their belief that the thoughtful application of scientific reasoning could improve man’s lot in the world and that men were not powerless against diseases long considered evidence of God’s will.”

Pain is Natural and Beneficial, Essential to Healing

Stanley noted (p. 288) [15] that even after the demonstration of the anesthetic effects of ether and chloroform some surgeons abjured their use. This may have derived from the

“belief that pain, far from being undesirable, was natural and beneficial...Its very absence, a surgeon asserted, was itself ‘a symptom of disease...Patients could read devotional works offering, for example, *Motives and Encouragements to Bear Afflictions Patiently* which suggested ‘the more Pains...the greater glory’”.

An Individual’s Suffering is Unimportant; Only the Group is Important

Papper proposed that a focus on the importance of the group as opposed to the individual delayed the discovery of anesthesia. If the individual was unimportant, then the individual’s suffering also was unimportant [16], but the romantic movement, the belief that mankind has the right to pursue happiness, succeeded in convincing society that the individual was important.

The Production of Insensibility is too Dangerous

We previously noted the finding that nitrous oxide could kill and ether could produce prolonged somnolence that gave fear for the health of the sleeper. Such observations perhaps tempered enthusiasm for their use to abolish the pain of surgery. Adding to the sometimes untoward findings with nitrous oxide and ether was the unwarranted connection to the known dangers of alcohol and opium (the competing anesthetics). Alcohol and opium might blunt the perception of pain, and patients had used both in anticipation of surgery. However, the production of anesthesia with alcohol or opium presented extraordinary dangers and did not permit

control of the anesthetic state. Alcohol and opium had to be swallowed. Ingest too little and anesthesia didn’t result—but the inebriated—yet insufficiently anesthetized—patient might be too sedated to ingest more alcohol or opium. What about the other extreme? Ingesting an excess of alcohol or opium presented enormous risks and, in the case of opium, an inadequate return on investment. An overdose of opium alone, even an enormous dose, does not produce anesthesia (the recipient still may move in response to surgery), and doses of opium too small to adequately blunt pain could cause patients to stop breathing—and die. Stanley (p. 285) [15] quotes Moore: “The strongest dose we dare venture has little or no effect in mitigating the sufferings of the patient during the operation.” And opioids caused vomiting, which some surgeons felt was a harbinger of death.

Alcohol wasn’t much better, although a sufficient dose of alcohol produced anesthesia. One problem was that “zero order kinetics” underlay the metabolism (elimination) of alcohol—the rate of metabolism is constant per minute regardless of whether there is a large or small amount of alcohol in the body. Ingest too much alcohol and it takes a long time to recover, and it may kill by excessively depressing breathing before recovery can occur (note the examples of alcohol poisoning among college students at fraternity initiations). And all that fluid that goes with the alcohol may come rushing back up the gullet and flood the lungs, quickly strangling the patient. Bergman (p. 350) called it “anesthesia by deadly intoxication” [12].

So the physician, the surgeon, and the patient might view these alternatives to the agony of surgery as unpredictable in effect and likely lethal. The common view probably held that nitrous oxide and ether were no better than opium and alcohol. Fenster (p. 39) [1] added that nitrous oxide (and ether) may have fared poorly because they were fads ridiculed by satirists. As noted above, when Mitchill gave 100% nitrous oxide he quickly killed animals, and the “imprudent inspiration” of ether produced prolonged narcosis that caused Faraday to fear for the patient’s life. Better to suffer and live.

What wasn’t appreciated was how greatly ether and nitrous oxide differed from alcohol and opium. Both ether and nitrous oxide could be added to effect without assistance from the patient. The patient didn’t have to swallow to take in more anesthetic, just keep breathing. And unlike alcohol and opium, neither ether nor nitrous oxide depressed breathing at anesthetic concentrations [17, 18]. And first order, not zero order kinetics governed the elimination of both ether and nitrous oxide; that is, the more anesthetic present, the greater the rate of elimination (i.e., an overdose could be eliminated quickly). Elimination always occurred as long as breathing continued. Thus ether and nitrous oxide were inherently safer anesthetics, far safer than alcohol or opium. But who knew that in 1600 or 1700, or 1800?

Anesthesia is not Needed to Perform Surgery

The observation that surgery advanced despite the absence of anesthesia tells us something contrary to conventional wisdom. Dreadful and dangerous as surgical pain might be, it did not preclude progress. Stanley [15] (p. 73): “The popular modern view, that surgeons were able to perform only ‘a small number’ of procedures before the introduction of anaesthesia, is simply wrong.” This speaks to the fifth reason why anesthesia was not discovered earlier; it wasn’t necessary!

Anesthesia Cannot Possibly Exist

We suggest that the most likely explanation for the delay in the discovery of anesthesia was the belief that it did not, could not, exist. If it did not exist, then a search for this dragon would be fruitless. French surgeon Velpeau said in 1839, “The abolishment of pain in surgery is a chimera. It is absurd to go on seeking it...knife and pain are two words in surgery that must forever be associated in the consciousness of the patient” [19]. One bit of circumstantial evidence further supports the credibility of this explanation—that no one believed that anesthesia could exist—as the most plausible reason for the delay in the discovery of anesthesia. The immediate, worldwide acceptance of anesthesia suggests that the first five explanations carried little weight. As Snow noted (p. 19) [20], “No great improvement in the practice of medicine was probably ever established so readily as the inhalation of ether for the prevention of pain.” Why would anesthesia be immediately accepted, if pain is God’s will or pain is beneficial, or individual suffering is unimportant (undermining explanations 1 through 3)? One or two successes should convince surgeon or patient that anesthesia is safe (eliminating explanation 4). And if anesthesia isn’t needed to perform surgery then why did so many take it up (demolishing explanation 5)? The simplest plausible explanation for the failure to search for anesthesia is that no one thought it could exist (Occam’s razor).

Reprise

Three people vied for the honor of having discovered anesthesia: Wells, Jackson, and Morton. Wells produced anesthesia privately but failed in his attempt at a public demonstration. Jackson never attempted a public demonstration, and his claim is as valid as his bogus claim to have invented the telegraph. The fearless, greedy, ignorant, embezzling, fraud and thief Morton demonstrated the idea (no matter that he may or may not independently have thought of it), and rightly claimed the prize. None of these men died well. Several who

facilitated the discovery, particularly Warren and Colton, led admirable lives fully and well. And why wasn’t anesthesia discovered sooner? We supply several possibilities, but favor the notion that too few interested parties thought it could exist.

1846–1860: Following the Discovery of Anesthesia

4

Edmond I Eger II, Rod N. Westhorpe and Lawrence J. Saidman

Summary

Four things soon followed the discovery of ether anesthesia. First, within weeks to months, ether was used in distant and disparate parts of the world—Europe, Australia, Mexico and Latin America. Second, for the moment, nitrous oxide was abandoned. Third, in 1847 Simpson discovered the anesthetic properties of chloroform that, for a time, replaced the pungent, flammable ether, especially in the UK. Fourth, the discovery of anesthesia was one thing, but how to deliver it safely was another. We needed a guidebook, a description of the clinical characteristics of anesthesia that might allow control of the anesthetic state. In 1847, Snow supplied just that for ether. In 1858, he similarly described the degrees of chloroform anesthesia, in the process analyzing the dangers of this more dangerous anesthetic and teaching how to avoid disaster. He, more than anyone, laid the groundwork for the specialty we call anesthesiology.

World Events, 1846–1860

The 1848 Revolution in France established the Second French Republic and led to political instability in Europe. In that year, Brigham Young led the Mormons to Utah, Marx and Engels published the Communist Manifesto, and gold was discovered at Sutter's Mill in California. In 1851, a miner luckless in California returned to Australia and found gold, initiating a gold rush that swelled the population six-fold by 1856. The 1850 Taiping Rebellion in China led to civil war and 20 million deaths over the ensuing 15 years. In 1855, the world's first transcontinental railroad was completed—across the Isthmus of Panama. The Crimean War began, ending a year later but not before Florence Nightingale built the foundation for professional nursing. In 1859, Darwin published *On the Origin of Species*, and construction of the Suez Canal began.

A Chronology of Events Soon After the Discovery of Anesthesia

1846

The news of Morton's 16 October 1846 demonstration (Ether Day) traveled fast. A successful trial of ether took place in Paris on 16 December 1846, followed by anesthesia in both Scotland and London on 19 December, the one in London "...by a dentist named James Robinson (1813–1862). Within a few days, John Snow had heard of the subject and was sufficiently interested to make arrangements to see the process first hand." [1] More on Snow in a moment. Liston used ether on 21 December 1846 in London, for an amputation, supposedly remarking "*This Yankee dodge beats mesmerism hollow.*"

How famous, how important was this discovery? Pretty famous, pretty important. As we shall note, it revolutionized surgery. The citations that the report of its discovery received in the *New England Journal of Medicine* suggest its fame and worth. The most cited of all *New England Journal of Medicine* reports is Bigelow's 1846 description of the discovery [2]. And the second most cited is Warren's report, also in 1846 [3]. Two more reports on ether anesthesia make the top ten: Cox's essay, also in 1846 [4], and Hayward's 1847 essay [5].

1847: Ether Is Given Around the World

On 23 January 1847, Heyfelder gave ether anesthesia in Germany. It was also given in Argentina, Brazil, Cuba,

Guatemala, Mexico, Peru, Uruguay, and Venezuela in 1847. In that year, Peter Parker introduced ether anesthesia into China, using an apparatus supplied by Charles Jackson. Relying on news arriving in Hobart and Sydney via London, Australians William Pugh and John Belisario both gave ether on 7 June. A New Zealand instrument maker (no medical man, he), James Marriott, gave the first surgical anesthetic to a Wellington Gaol inmate on 27 September. Prompted by Edward Barton, US and Mexican forces used ether anesthesia in 1847 in the Mexican-American war. The world did not hesitate to employ this amazing discovery.

Simpson Looks for Something Better

Scottish obstetrician, James Simpson, used ether to produce anesthesia, but soon searched for something better than the pungent ether for his delicate ladies. As described by his colleague, a Professor Miller, Simpson found chloroform on 4 November 1847 [6]:

“(O)n returning home after a weary day’s labour, Dr. Simpson with his two friends and assistants, Drs. Keith and Duncan, sat down to their somewhat hazardous work in Dr. Simpson’s dining-room. Having inhaled several substances, but without much effect, it occurred to Dr. Simpson to try a ponderous material . . . that happened to be a small bottle of chloroform. It was searched for and recovered from beneath a heap of waste paper. And with each tumbler newly charged, the inhalers resumed their vocation. Immediately an unwonted hilarity seized the party—they became brighteyed, very happy, and very loquacious—expatiating on the delicious aroma of the new fluid. The conversation was of unusual intelligence, and quite charmed the listeners—some ladies of the family and a naval officer, brother-in-law of Dr. Simpson. But suddenly there was a talk of sounds being heard like those of a cotton mill louder and louder; a moment more and then all was quiet—and then crash! On awakening Dr. Simpson’s first perception was mental—‘This is far stronger and better than ether,’ said he to himself. His second was to note that he was prostrate on the floor, and that among the friends about him there was both confusion and alarm. Hearing a noise he turned round and saw Dr. Duncan beneath a chair—his jaw dropped, his eyes staring, his head bent half under him; quite unconscious, and snoring in a most determined and alarming manner. More noise still and much motion. And then his eyes overtook Dr. Keith’s feet and legs making valorous attempts to overturn the supper table, or more probably to annihilate everything that was on it. By and by Dr. Simpson having regained his seat, Dr. Duncan having finished his uncomfortable and unrefreshing slumber, and Dr. Keith having come to an arrangement with the table and its contents, the *sederunt* was resumed. Each expressed himself delighted with this new agent, and its inhalation was repeated many times that night...until the supply of chloroform was fairly exhausted.”

Miller probably embellished the circumstances of discovery. And several contributors to the discovery of the anesthetic effects of chloroform in addition to Simpson have been suggested [7]. With minor resistance from clergy and others, Simpson introduced chloroform into practice. It became the “British” anesthetic while ether remained the “Yankee dodge”.

As with ether, chloroform, a more easily given but more dangerous anesthetic, was quickly accepted in countries most influenced by the UK. By the end of 1847, chloroform replaced ether in France as the anesthetic of choice despite sudden and inexplicable fatalities with its use. More countries joined up in succeeding years. Chloroform displaced ether in Argentina, Brazil, Chile, Peru, Uruguay, and Venezuela. Soon ether and chloroform were used everywhere—slowly or quickly overcoming religious objections and medical skepticism. In 1847, Fanny Longfellow, wife of the poet, received ether to aid in delivery. Simpson gave ether to relieve the pain of childbirth for a woman with a deformed pelvis. And in 1853, Queen Victoria received chloroform to relieve the pain of childbirth. The anesthetist was John Snow.

The First Theory of Narcosis

In 1847, Harless and von Bibra noted that ether and chloroform could dissolve lipids. They proposed that anesthetics acted by removing lipids from the brain. Anesthetics dried the neurons. That perhaps explained how anesthesia was produced. But it didn’t explain how recovery from anesthesia occurred, and occurred so rapidly. What returned the lipids to the brain and put them in the proper place?

Anesthetic Choice Affects Anesthetic Practice

Nicholas Greene argues that the US discovery of ether anesthesia led to pride of ownership. This proprietary position hindered the advancement of the specialty of anesthesia in North America [8]. The relative safety of ether did not demand that someone make a career from its delivery. In contrast, chloroform was the UK discovery. They owned that anesthetic. The dangerous chloroform made anesthesia more interesting. Quoting Valpeau: “*On the subject of ether, that it is a wonderful and terrible agent, I will say of chloroform, that it is still more wonderful and more terrible*”[9]

Near the time when Eger thought to become an anesthetist in the US, Lundy advised that only incompetent physicians became anesthetists [10]. Henry Beecher made a similar, if more politic, observation: “...anesthesia technique can be mastered by ordinary men who are ordinarily deft, with only a modest requirement of intelligence and of knowledge and judgment.”[11] Ether delivery required little skill. What a difference from the British world beset with chloroform! And lucky Britain immediately found the greatest anesthetist that ever lived. The US had William Morton who didn’t understand what he was doing, and England had John Snow (Fig. 4.1) who knew exactly what he was doing—and told the world. Snow’s work anticipated many elements of modern anesthesia.

Fig. 4.1 John Snow

Snow Tells How to Give Anesthesia

In 1847, the medical community needed to know how to deliver anesthesia smoothly and safely and how to control the depth of anesthesia with as much precision as the available anesthetics and extant equipment permitted. Expressions such as a greater depth or level of anesthesia indicated achievement of a greater anesthetic effect. Enter Snow's classic book on the delivery of ether [12]. A decade later, he supplied his second classic book—on the delivery of chloroform [13]. To digress a moment: Snow's genius extended beyond anesthesia. He was the father of epidemiology, famously diagnosing the cause of an 1854 cholera epidemic in London that killed 500 people in 10 days (in the preface of the referenced book) [13]. To deal with the epidemic, Snow told the vestrymen of St. James district to remove the handle from the Broad Street pump (p xxi). His studies revealed that the dead had drawn from the Broad Street well. The vestrymen of St. James's (the district containing the well) were "incredulous, but had the good sense to carry out the advice. The pump-handle was removed, and the plague was stayed."

Snow, born in York, on 15 June 1813, was the eldest son of a farmer. In 1827 he was apprenticed to a surgeon. Other apprenticeships followed. For a few years Snow became a vegetarian (he determined later that it was not healthful) and temperance advocate. He came to London to study at the Hunterian School of Medicine, becoming a physician in 1838. His friend Richardson described Snow as "Not particularly quick of apprehension, or ready in invention, he yet always kept in the foreground by his indomitable perseverance and determination in following up whatever line of investigation was open to him (p v)." [13]

John Snow's observations on anesthesia were as brilliant (although not as flamboyant) as his prescription for stopping the cholera epidemic. Regarding ether [12], Snow described 5 degrees (i.e., stages) of anesthesia, anticipating by more than half a century, Guedel's classic four Stages (and many Signs) of anesthesia [14]. Snow observed (p 1): "In the first degree of etherization I shall include the various changes of feeling that a person may experience, whilst he still retains a correct consciousness...and a capacity to direct his voluntary movements." Aha! So in the first degree, the patient is awake, aware, and remembers.

Snow continued (p 2): "In...the second degree, mental functions may be exercised, and voluntary actions performed, but in a disordered manner." The patient is still awake and aware—but there may be no memory of that awareness.

Snow (p 10) noted that anesthesia produces amnesia and described much of MACawake (the anesthetic concentration preventing awareness in half of subjects who, however, respond appropriately to commands such as "open your eyes") [15] a century before the concept was developed: "...and if...the patient is allowed to recover still further during the operation, it will probably happen that in the second degree he will either lie perfectly calm, or talk in his dreams about subjects totally unconnected with pain, or the operation which is still going on."

Snow repeatedly returned to the notion of dreams occurring in the second degree of anesthesia but "there can be no dreams or ideas of any kind in the third and fourth degrees..." (p 11). This accords with the modern determination that dreams occur during recovery from anesthesia and not during anesthesia [16]. "In the third degree, there is no evidence of any mental function being exercised, and consequently no voluntary motions occur; but muscular contractions, in addition to those concerned in respiration, may sometimes take place" (pp 1–2) [12]. Thus, in the third degree, the patient may respond to surgery with movement.

Snow, like Morton, noted another component of the third or even the second degree, one that anticipated Joseph Artusio's 1950s publications [17, 18] on ether analgesia (p 10). Unlike Morton, the far more perceptive Snow knew what he had. "I believe that pain is seldom felt in the stage of which we are treating—the third degree succeeding the fourth (i.e., during recovery from the fourth degree)—and of course

never remembered afterwards, as there is no knowledge or mental perception of it.”

The analgesia noted above for the second or third degree, seemed to be most obvious during recovery from anesthesia and not during induction of anesthesia. Snow speculated that this might be the result of ether acting on peripheral nerves rather than on the central nervous system, an intriguing idea that might fit with the known lesser blood flow to nerves and the greater affinity of anesthetics for nerves as compared to brain. The smaller flow and the greater affinity would delay the establishment of a sufficient ether concentration in the nerves, and hence delay the appearance of analgesia. Snow’s idea remains to be tested.

“In the fourth degree, no movements are seen except those of respiration, and they are incapable of being influenced by external impressions.”

Snow’s description of movement with incision in the third degree, and its absence in the fourth degree, anticipated by a century, the discovery of MAC (the minimum alveolar concentration preventing movement in response to incision in 50% of patients) [19]. Indeed, Snow wrote: “Ether contributes other benefits besides preventing pain. It keeps patients still, who otherwise would not be” (p 53) [12]. And (p 6): “If this degree of etherization is not well established when the operation begins, the first cut may cause a sudden contraction of the whole muscular system.” And thus Snow appreciated the need for equilibration of the site of action with the ether delivered to that site. And (p 7): “In (the fourth) degree of etherization the patient always remains perfectly passive under every kind of operation; and...the muscles are completely relaxed...” He even described the use of a supramaximal stimulus as important to a test of the efficacy of anesthesia (p 36) [12]: “...there may be insensitivity to a slight lesion—as a suture in the skin, for instance—at a time when a greater wound would cause signs of pain.” Thus Snow observed that one level of anesthesia may permit a muscular response to a supramaximal stimulus, but one degree deeper prevented that response once equilibrium had been obtained. Snow only needed the ability to measure the concentration of ether in the lungs (the alveoli) to have described MAC, the modern standard by which the unit depth of anesthesia is defined [20].

“In the fifth degree...respiratory movements are more or less paralysed and become difficult, feeble, or irregular.” Snow advised against entering the fifth degree, concerned that undue depression of breathing and the heart might follow.

Snow described eye signs, changes that allow the assessment of anesthetic depth (p 5) [12]: “The patient may have moved his eyes about in the second degree, and even directed them to objects, but in this degree (deeper anesthesia) they are stationary, or if they do move, their motions have nothing of a voluntary character...The eyelids may be either open, or partly or tightly closed, but in either case, if lifted or moved by the finger, the orbicularis palpebrarum (the eyelid) contracts.” These degrees (or Guedel’s variation on them) were used to define depth of anesthesia for the next century.

Fig. 4.2 Snow found that as temperature of an anesthetic increased, so did the concentration in the air overlying the anesthetic. (From Snow J: On the Inhalation of the Vapour of Ether in Surgical Operations: Containing a Description of the Various Stages of Etherization, and a Statement of the Result of Nearly Eighty Operations in Which Ether Has Been Employed In St. George’s and University College Hospitals. London: John Churchill; 1847. pp 1–88.)

Snow was amazingly perceptive. He anticipated that ether might be metabolized (p 84) [12]: “It is not improbable that some of the ether inhaled is decomposed in the body; but this does not alter the question of de-etherization...for assuredly by far the greater portion of the ether escape by the breath exhaled.” Actually, he may have erred there because by far the lesser portion of some inhaled anesthetics escape by exhalation [21, 22]. We don’t know about ether.

He recognized that age and breathing affected ether kinetics (the movement of ether into and out of the body; p 43) [12]: “Elderly people are slower in recovering than young ones as their respiration is less active, and the ether takes a longer time to evaporate in the breath. For the same reason, if sickness has been caused by the ether, the patient is longer in recovering, as it depresses the respiratory movements.”

Snow recognized the importance of control over the concentration of ether and the connection between concentration and the degree of anesthetization (p 15) [12]: “I have spoken of a knowledge of the strength of the vapour as being essential to a correct determination of the state of the patient at all times: and this brings us to the apparatus for the administration of the vapour, as, without a suitable one, the proportions of air and of vapour cannot be determined.” He recognized the importance of controlling the temperature of the vaporizer (with a water jacket) to avoid changes in the concentration of anesthetic (Figs. 4.2 and 4.3). He recognized the need to supply sufficient surface area to assure the saturation of the gas passing through the vaporizer with anesthetic. His vaporizer allowed for the introduction of air to dilute the ether stream (anticipating the modern “variable bypass vaporizer” by more than a century.)

Snow made the inspiratory tube leading from his vaporizer large enough to minimize resistance to breathing. And

Fig. 4.3 A genteel lady breathes ether or chloroform from a vaporizer constructed to ensure the fullest concentration of anesthetic. A jacket filled with water buffers the vaporizer against temperature changes and thus against changes in the anesthetic concentration issuing from the vaporizer. A valve on the mask may be slipped more or less to one side to allow room air to dilute the anesthetic drawn from the vaporizer. When in place over the hole exiting from the mask, the valve allows no room air in but allows easy exit of the gases inspired by the patient (p 82) [12]. (From Snow J: *On the Inhalation of the Vapour of Ether in Surgical Operations: Containing a Description of the Various Stages of Etherization, and a Statement of the Result of Nearly Eighty Operations in Which Ether Has Been Employed In St. George's and University College Hospitals*. London: John Churchill; 1847. pp 1–88.)

he provided a mask covering mouth and nose and a valve that produced a non-rebreathing system (Fig. 4.3).

He noted (p 21) that “...many of the apparatuses at first invented did not allow of easy respiration, but offered obstructions to it, by sponges, by the ether itself, by valves of insufficient size, but more particularly by tubes of too narrow caliber; and there is reason to believe that, in many instances, this was the cause of failure, and that in others the insensibility, when produced, was partly due to asphyxia...” His valves were “...made of vulcanised India rubber; they (were) light, (were) attached so as to rise with the least appreciable force and they closed again, of themselves, in any posture in which the patient can be required to be placed.”

Snow was a plodding sedulous genius.

Simpson Disagrees with Snow

Simpson disagreed with Snow’s complex approach to anesthetic delivery. Simpson preferred delivery by a few drops of chloroform on a handkerchief. And, in various forms, much of the world agreed with him well into the twentieth century. The handkerchief approach precluded a calibrated delivery, a precision of control over anesthesia depth. Thus it demanded the evaluation of anesthetic effect found in Snow’s degrees to guide anesthetic delivery, but those degrees had a subjective element that made them imperfect guides.

More Observations by Snow

Snow recognized that impurities might compromise the delivery of the ether and described how to secure a purer ether (pp 23–4) [12], particularly by using water to remove the alcohol that was frequently a contaminant. He observed that the water that therefore also entered the ether was salutary (pp 22–3) [12]. “I...allow this small quantity of water to remain in the ether, in order that the air which is inhaled with the vapour of ether may be always saturated also with vapour of water, when it will be more bland, and less irritating, than if it contained but little moisture...”, a finding duplicated a century later with another kind of ether [23]. What a clever fellow.

Snow developed an understanding and delivery of anesthesia with powers of observation and carefully thought out rudimentary apparatus. He had the endearing arrogance of the great anesthetist (p 33) [12]: “...there is no person who cannot be rendered insensible by ether...” No one can resist; no one.

Snow Turns to Chloroform

Like Ross Terrell a century later [24], Simpson and Snow sought the better anesthetic. In 1847, Snow turned his attention to Simpson’s “British” anesthetic. His resulting classic book compared ether and chloroform [13]. The five degrees of anesthesia were essentially unchanged. Snow experimented with animals, making discoveries confirmed a century later. Like later investigators [25], Snow (pp 72–3) [13] found that a greater body temperature increased anesthetic requirement.

Snow Explains Why Chloroform Kills

More than 50 reports of deaths associated with chloroform use appeared in the 10 years following its discovery. Hannah Greener, aged 15, was first, dying at Winlaton, near Newcastle on 28 Jan 1848. Reports came from North America (first, Cincinnati), France (Boulogne), India (Hyderabad), Ger-

Fig. 4.4 In those cases of death in association with the use of chloroform where the age of the patient was known, death appeared most frequently in young adults. (From Snow J: *On the Inhalation of the Vapour of Ether in Surgical Operations: Containing a Description of the Various Stages of Etherization, and a Statement of the Result of Nearly Eighty Operations in Which Ether Has Been Employed In St. George's and University College Hospitals*. London: John Churchill; 1847. pp 1–88.)

many (Berlin), Jamaica (Kingston), Sweden (Stockholm), Austria (Vienna), and on the high seas near Mauritius. But mostly from Great Britain. Snow recognized that chloroform was more dangerous than ether, believing "...that ether is altogether incapable of causing the sudden death by paralysis of the heart, which has caused the accidents which have happened during the administration of chloroform" (p 362) [13]. He thought that the chloroform deaths were preventable, often a consequence of the excessive use of chloroform, producing what he called cardiac syncope. "...accidents from this agent would arise by its suddenly paralyzing the heart, if it were not sufficiently diluted with air; and a careful review of all the recorded cases of fatal accident shows that nearly every one of them has happened in this way..." (p 251) [13].

Snow recognized that death associated with chloroform correlated with age in an unexpected manner. He believed that the incidence of surgery increased with increasing age, but he found that deaths occurred in younger patients (Fig. 4.4). We now know that younger patients should be more resistant to cardiac arrest from depression of the heart but may be more susceptible to lethal rhythms such as ventricular fibrillation, a condition in which the heart contracts in an uncoordinated manner because of a flaw in the electrical impulses prompting the heart to beat. Snow also found that sudden death occurred early in the administration of anesthesia (Fig. 4.5), presumably during a time of heightened sympathetic activity, something that would predispose to ventricular fibrillation.

Fig. 4.5 Snow found that deaths associated with chloroform usually occurred soon after initiation of anesthesia, a timing we now know [25] to be consistent with ventricular fibrillation secondary to sensitization of the heart to the increased sympathetic activity associated with excitation.

Chloroform is an alkane, and alkanes predispose to ventricular fibrillation, while ethers do not [26].

Snow may also have failed to adequately recognize one other crucial limitation of chloroform. Chloroform depresses breathing whereas ether does not [27], at least in the range of concentrations needed for surgical anesthesia. Snow knew quite a bit about breathing but didn't appreciate the consequence of the small reserve of oxygen available to his patients. Today's patients may breathe 100% oxygen, making depression of respiration a minor matter, but Snow's patients breathed room air—21% oxygen—and were at risk of inadequate oxygenation. Snow recognized that breathing could become partially obstructed ("stertorous") but didn't advise what to do until complete obstruction of the airway occurred—in which case he would pull the tongue forward. He resuscitated two patients in that manner (pp 254–5) [13].

Snow beat back the attacks on chloroform, taking heart from his statistics showing that the introduction of chloroform did not increase mortality. If he had not defended it as cogently as he had, one wonders whether chloroform would have survived the adverse publicity. Part of his defense lay in his observation that "...chloroform possesses advantages over ether, in being more convenient and less disagreeable..." (p 23) [13], but his greatest defense was his summary recitation of his anesthetization of nearly 5,000 patients without a death from "cardiac syncope." You just had to do it right! As Greene observed [9], giving chloroform anesthesia safely required skill, while less skill was required to give ether safely.

Snow's contributions are today commemorated in many ways, one being the John Snow Society. Membership is open to anyone who has visited the John Snow pub in Broadwick Street, Soho, adjacent to the site of the original water pump. It is the only ale house in the world, named after an anesthetist.

In 1847, one more inhaled anesthetic was discovered [28]. Flourens described the anesthetic properties of ethyl chloride, and a year later, Heyfelder gave it to three patients. Although administered occasionally, it languished for the next half century because of the inconvenience associated with its containment and use: it boiled at room temperature (boiling point 12.5°C). It also didn't help that it cost more than chloroform and ether to make.

1849

In 1849, Elizabeth Blackwell received her medical degree from Geneva Medical College in NY. Blackwell was the first woman physician in modern times to receive a medical degree, and she led the entry of women into medicine throughout the world. And also in that year, facilitated by the discovery of anesthesia, the great US surgeon James Sims repaired a vesicovaginal fistula, a passage for leakage from the bladder to the vagina, and the first major surgical advance after the discovery of anesthesia.

1850

In 1850, John Warren addressed the American Medical Association, describing what constituted adequate anesthesia care: Have a dedicated person continuously deliver anesthesia to a fasting supine patient. Administer anesthesia sufficient to produce relaxation. Beware of obstructing breathing, and don't set fire to the operating room. Yes, that should do it.

1853

In 1853, Perry's battleships opened Japan to western influences, including anesthesia. And Queen Victoria chose chloroform to relieve labor pain during the birth of Prince Leopold. She thereby ended any lingering moral opposition to the relief of pain during childbirth, and her request for chloroform at the births of two of her children, accelerated the acceptance of anesthesia.

The hollow needle devised by Francis Rynd in 1844, and the hypodermic syringe introduced by Charles Pravaz in 1853 enabled additions to anesthesia such as premedication. They

were essential to the later development of regional (local) anesthesia and the intravenous approach to anesthesia.

1854

Veterinarians hesitantly adopted anesthesia, some considering that excitation during induction indicated suffering or pain. Others were concerned by reports of accidents and deaths. Veterinarians initially used anesthesia as much to prevent struggling during surgery as to prevent pain. US physician and veterinarian George Dadd described his use of ether and chloroform in animals to prevent pain from surgery in animals, incidentally recognizing the greater safety of ether. Dadd's book, *Modern Horse Doctor* [29], recommended that (p 252): "...in all operations of this kind, the subject be etherized, not only in view of preventing pain, but that we may, in the absence of all struggling on the part of our patient, perform the operation satisfactorily, and in much less time after etherization has taken place than otherwise."

1855

In Japan, Sugita gave the first ether anesthetic, for a patient having a mastectomy, and ether anesthesia reached Iceland.

1858

Acting on the need for purer ether, physician Squibb formed Squibb Pharmaceutical.

Snow died 16 June 1858 at age 45 while composing the last portion of his book on chloroform. Autopsy revealed that he died from the untoward effects of failure of his kidneys (p xlv) [13]. The immediate cause of death appears to have been a stroke. Snow's friend, BW Richardson, completed Snow's book *On Chloroform and other Anaesthetics*. Snow's summaries of his cases (pp 271–318) [13], most from the 1850s, tell us about the surgical needs for anesthesia (Table 4.1). The surgeries that Snow listed, were the surgeries that had been done before anesthesia's discovery, including repairs of cleft lips, ligation of arteries, and lots of teeth pulled without pain. It took decades for surgeons to fully use Morton's gift.

The brevity of most procedures in the 1850s informed the delivery of anesthesia. So did Snow's description of the degrees of anesthesia. Anesthesia was like a ball bounced on the pavement, a descent into oblivion and then a partial recovery following by second and third descents and recoveries. This may have been the safest method for delivery of anesthesia, especially with chloroform because of the profound

Table 4.1 Some operations for which Snow gave chloroform, 1848–58

Operation	Number
Bladder stone removal	246
Urethral operations	137
Amputation of the thigh, leg, arm, ankle, or miscellaneous	109
Operations for necrosis	197
Excisions: head of the femur, elbow, knee, or wrist	43
Removal of tumors of the jaw	24
Tumors of the female breast	222
Tumors behind the angle of the jaw	41
Cysts	71
Fatty tumors	66
Miscellaneous tumors	87
Nevi	116
Ligature of arteries	14
Hare-lip	147
Division of nerves	28
Operations on the eye	158
Removal of foreign bodies and polyps from the ear or nose	22
Operations in the mouth	24
Plastic operations	50
Raising depressed sections of skull	4
Operations for ununited fractures	7
Reduction of dislocations	27
Forcible movement of stiff joints	22
Tenotomy	78
Operation for strangulated hernia	19
Operations for hemorrhoids or fissure of the anus	215
Fistula involving the anus	218
Ovarian tumors	9
Operations for cancer of the vagina	18
Operations for rupture of the perineum (prolapse)	14
Removal of testicle or penis	27
Operations for phymosis	76
Removal of enlarged bursa	6
Evulsion of the nails	28
Laryngectomy for croup (!)	2
Extraction of teeth	867
Total	3439

Snow gave more anesthetics, including those for childbirth, but with a few exceptions (e.g., for two of Queen Victoria's deliveries) those for childbirth were not recorded

depression of breathing, and because without supplemental oxygen there was a great risk of asphyxia. But it was also employed with ether—down and up and down again—far different from the later approach that produced a sustained level of anesthesia, one appropriate to longer surgical procedures.

Reprise

Morton's discovery, perhaps the greatest discovery in all of medicine, began an enormous change in patient care, one that continues to this day. Snow transformed Morton's

clumsy beginnings into an art, and a science. Snow's science dominated anesthetic delivery for the better part of a century. His work anticipated modern vaporizers and concepts such as MAC, pharmacokinetics (what the body does to drugs), and pharmacodynamics (what drugs do to the body).

1860–1910: The Specialty of Anesthesia Develops Slowly

5

Edmond I Eger II, Lawrence J. Saidman and Rod N. Westhorpe

Summary

The discovery of anesthesia ultimately enabled remarkable advances in surgical care, but did not immediately change operations. At first, surgeons still pulled teeth, managed injuries, amputated limbs, and performed brief operations requiring momentary but deep levels of anesthesia. So the anesthetist drove the level of anesthesia down and then allowed it to “bounce” up, the surgeon operating at deeper levels of anesthesia. Further advances required improvements.

First, appreciating anesthesia’s potential, surgeons devised longer operations that required steadier levels of anesthesia. Less bouncing up and down. This mandated the development of delivery systems allowing increasingly precise control of the anesthetic; it prompted the invention of the anesthetic machine, bringing together compressed gases in iron cylinders, a means to blend the gases, control their flow, and add vapors in some ordered, better known manner.

Second, immediately after anesthesia’s discovery no anesthetists existed. A surgeon became surgeon *and* anesthetist, something undesirable for lengthy, procedures. So the surgeon engaged an assistant to supply anesthesia, in the UK another physician, but in much of the world nurses or technicians (a euphemism for secretaries, orderlies, medical students)—part-time anesthetists with little skill. The resulting morbidity and mortality were initially ignored, perhaps because operations were few in number (few patients died), or perhaps because infections killed more than did anesthesia. Surgeons developed antisepsis and asepsis, and then anesthetic deaths did matter.

Third, with Koller’s 1884 demonstration of cocaine’s local anesthetic effects, some surgeons again became both anesthetist and surgeon. German speaking surgeons seized the opportunity to develop regional anesthesia and remain in charge. But still, things could go awry. Someone best keep an eye on the patient.

Fourth, increasing surgical complexity and increasing demands for better anesthetic delivery mandated the rise of professional anesthetists, sooner in the US and the UK than in other countries. Nurses led the way in the US (with physicians not far behind), and physicians/surgeons supplied anesthesia in the UK, some of the Commonwealth, and Europe. Much of the world relied on technicians and nurses directed by surgeons.

Anesthesia increased surgical possibilities, resulting in formal residencies to educate surgeons, but formal programs lagged for nurse and physician anesthetists. Between the 1850s and early 1900s, women in the US founded 17 medical schools. All but Drexel closed shortly after the turn of the century.

World Events, 1860–1910

More than 500,000 combatants died in the 1861–1865 American Civil War. In 1865, Lewis Carroll published *Alice’s Adventures in Wonderland*. A year later, Gregor Men-

del reported his laws of inheritance, beginning the modern study of genetics. In 1876, Alexander Graham Bell patented the telephone, and Mark Twain published *The Adventures of Tom Sawyer*. Thomas Edison patented the light bulb in 1879. In 1884–1885, Chicagoan William Le Baron Jenney oversaw the construction of the first skyscraper. Karl Benz patented and produced the first gasoline-powered automobile, a 1-cylinder beauty, in 1885. Two years later, Heinrich Hertz discovered the photoelectric effect. In 1888, Louis Le Prince produced the first movie (*Roundhay Garden Scene*), and the first edition of the *Oxford English Dictionary* was published. New Zealand gave women the right to vote in 1893—a first. In 1894, Emile Zola wrote *J’accuse*, attacking anti-Semitism in the Dreyfus Affair. Wilhelm Roentgen discovered X-rays in 1895, and for this received the first Nobel Prize in physics. Svante Arrhenius and Thomas Chamberlin connected CO₂ emissions to global warming in 1896, but no one noticed

for a half-century. In 1897, Karl Braun invented the modern cathode ray tube. HG Wells created science fiction with his 1898 *War of the Worlds*. In 1903, the Wright Brothers flew a heavier than air craft at Kitty Hawk, North Carolina, and Marie Curie shared the Nobel Prize in Physics with her husband Pierre Curie and Henri Becquerel. France failed in their attempted 1890–1903 construction of the Panama Canal. The US took up the challenge in 1904, completing the Canal in 1914. In 1905, Albert Einstein proposed his theory of special relativity. In 1907, Pablo Picasso painted *Les Femmes d'Alger*, beginning cubism. In 1908, Ford initiated mass production with his Model T Ford.

Introduction

Several parallel, yet connected, stories unfolded in the half-century that followed 1860. The present chapter provides these stories, noting how each might have influenced the other. They are stories of growth, of wars, of visionaries and visions, sometimes advancing by reason, often by trial and error, but always advancing.

The Development of Surgery

The Surgeon Before the Discovery of Anesthesia

The discovery of anesthesia facilitated enormous changes in surgery and the surgeon. The surgeon Frederick Treves described the surgeon in the days before anesthesia [1]:

We find him an ignorant, illiterate, sordid creature, not above the allurements of money-grubbing, and not without suspicion of dishonest practices and of a leaning towards the bottle. He was to a large extent a mere retailer of physic, and in the public eye he ranked with the quacks and nostrum-sellers with whom he competed...The training of the surgeon was paltry, casual, and inefficient.

Lest we smile, let us remember that the early anesthetist, particularly in the US, had much the same defects. Then Treves described the impact of the discovery of anesthesia on surgery and surgeons [1].

The changes that the discovery has wrought in the personality of the surgeon, in his bearing, in his methods, and in his capabilities are as wondrous as the discovery itself. The operator is undisturbed by the harass of alarms and the misery of giving pain. He can afford to be leisurely without fear of being regarded as timorous. To the older surgeon every tick of the clock upon the wall was a mandate for haste, every groan of the patient a call for hurried action, and he alone did best who had the quickest fingers and the hardest heart. Time now counts for little, and success is no longer to be measured by the beatings of a watch. The mask of the anaesthetist has blotted out the anguished face of the patient, and the horror of a vivisection on a fellow-man has passed away. Thus it happens that the surgeon

has gained dignity, calmness, confidence, and, not least of all, the gentle hand.

Anaesthetics have, moreover, greatly extended the domain of surgery by rendering possible operations which before could only have been dreamt about, and by allowing elaborate measures to be carried out step by step.

The introduction of anaesthetics has not only developed surgery, but it has engendered surgeons. It has opened up the craft to many, for in the pre-anaesthetic days the qualities required for success in operating were qualities to be expected only in the few.

So surgery grew because ether and chloroform anesthesia had been discovered. The discovery sufficed for all surgical requirements—and so, apart from Snow telling us how to do it safely (along the way devising an anesthetic delivery system including a stable-delivery vaporizer, making astute observations on the cardiorespiratory effects of anesthetics, and telling us how chloroform killed patients), nothing more seemed necessary. The greater need was to improve the surgeon and what he might do (there were no she surgeons) [1]:

The surgeon at the commencement of the (nineteenth) century appears to have lacked most of what we now consider to be the essentials of the art, and we can only view with amazement the scantiness of his learning and the poverty of his equipment. He knew little more of inflammation than that it was represented by swelling, heat, redness, and pain. His knowledge of the causes of inflammation and of those dangers which follow upon open wounds was scarcely in advance of that professed in the days of Hippocrates. He had no glimmer of the possibilities of asepsis. He had no anaesthetic, no hypodermic syringe, no clinical thermometer and no practical means of investigation in clinical chemistry. The very name bacteriology did not exist, and the treatment of disease by prepared serums would have appeared to him as wild as the wildest therapeutic dream of ancient days. Although vaccination had been introduced in the last year of the eighteenth century, the magnitude and nature of the principle it involved had not been appreciated.

The microscope as an aid to diagnosis played no part in the equipment of the surgeon. He had neither laryngoscope nor ophthalmoscope, and his acquaintance with otology, skin affections, and the diseases of women was at the best rudimentary and indistinct. He had only rude mediaeval orthopedic appliances, and he knew nothing of the lithotrite (an instrument for crushing a kidney stone) nor of the array of instruments which are now in daily use in connection with ophthalmic, laryngeal, cranial, and abdominal surgery. It would seem indeed that there was little for him to do but to open abscesses and sow the seeds of chronic septicemia, to excise tumours of the structure of which he talked much and knew little, to amputate limbs for diseases he could not mend, and to draw blood whenever doubt existed as to what was best to be done.

In sum, Treves tells us that in the nineteenth century, the surgeon had mountains to climb, the biggest of which had been the absence of anesthesia. Once anesthesia was discovered, once every patient could be anesthetized, once that colossal step was taken, nothing more was immediately required of the anesthetist or of anesthesia.

Brutal procedures could be accomplished at a leisurely pace without agony. Patients who had rejected surgery because of the anticipation of unbearable pain now allowed surgery, increasing the numbers of surgical procedures undertaken. Surgeons could improve everyday operations (e.g., pulling/restoring teeth, amputations, removing bladder stones.) A thousand and one minor modifications might be tried to advance the quality of surgical outcomes. And the surgeon could quickly learn which approaches gave the best results because many more patients would accept surgery—all because of anesthesia. No Committees on Human Research slowed what the good and bad surgeon might try. Surgery grew, limited only by the numbers, ingenuity, energy and skill of surgeons. The economic attractiveness of surgery expanded the numbers of increasingly more qualified physicians into the practice, compounding the rate at which surgical knowledge grew. All because ether and chloroform anesthesia had been discovered.

Antisepsis and Asepsis are Invented

The picture wasn't quite as rosy as the last paragraph implies. Anesthesia enabled an expansion of surgery, but the most elegant operation was useless if the patient died from infection. Elegance was the mark of a successful surgeon, striding to the operating table, pausing to remove his top hat and leather gloves. His frock coat might bear dried blood from previous operations, and the lapel served as a convenient place to hold surgical needles ready-threaded with silk. His hands might carry infection from one patient to the next. Anesthesia only solved one problem; infection carried enormous risk, even for the simplest operation.

In 1867, Joseph Lister published a series of articles in *The Lancet* (March–September 1867) under the title *Antiseptic Principle of the Practice of Surgery*, urging surgeons to wash their hands before operations with 5% carbolic acid (phenol) solutions, to wash instruments in the same solution, and to spray the solution in the operating theatre. The resulting reduction in infection decreased morbidity and mortality and thereby encouraged the use of hospitals for surgery. Hospitals had rightly been thought of as a source of a dangerous contagion.

In 1886, Ernst von Bergmann (1836–1907) added to Lister's remedy. von Bergmann developed steam sterilization, thereby ensuring the sterility of instruments, an essential ingredient of asepsis. Other rituals such as the use of masks, operating gowns, hats, and sterile gloves evolved rapidly thereafter. The addition of asepsis to antisepsis further decreased infections, and accordingly increased surgical care in hospitals. But a few surgeons aided by anesthetists (e.g., Nicoll [2] in Scotland and Waters [3] in the US) bucked this trend in the first 70 years of the twentieth century, harbingers

of outpatient surgery that would become 80% of US practice by the end of the twentieth century.

The Great, Heroic Surgeons Appear

Surgeons arose to seize the opportunity offered by anesthesia, with or without infection. First (Table 5.1), in 1849 the US gynecologist, J. Marion Sims, successfully repaired a vesico-vaginal fistula, that disastrous connection between bladder and vagina plaguing and ostracizing many young African post partum women that Abraham Verghese described in his beautiful story, *Cutting for Stone*. Two decades later, German surgeon Theodor Billroth began a series of innovative operative procedures, beginning with perineal prostatectomy in 1867. In 1873 he added laryngectomy, and in 1881 gastrectomy, ultimately in two flavors (Billroth I and Billroth II).

In 1881, US surgeon William Halsted performed the first emergency blood transfusion—on his sister. In 1889, he introduced rubber surgical gloves, less to avoid sepsis than to protect the hands of his fiancée who just happened to be his scrub nurse. In the mid 1890s, he established the US model for training surgeons (including the pyramid system that kept budding surgeons in servitude for what must have seemed like a lifetime) and developed the radical mastectomy. This unnecessarily mutilating operation would eventually be abolished, but not for nearly a century. Indeed, in 1899 the American Surgical Association established Halsted's mastectomy and inguinal hernia repair as gold standards. He was not a quick surgeon. Will Mayo is said to have remarked after two hours of observing Halsted work: "My God, this is the first time I have seen the wound healing at the upper end while it is still being operated upon at the lower end [4]."

From the 1880s to the 1900s, Swiss surgeon Theodor Kocher removed thyroid glands for goiter and hyperthyroidism, receiving the Nobel Prize for Medicine in 1909, for showing the importance of thyroid secretion. He also won fame for abdominal, orthopedic, and intracranial operations, and for contributions to antisepsis.

Surgeons started to go places where they had never gone, in the process increasing demands on anesthesia, forcing anesthesia to grow. In 1896, Rehn in Frankfurt sutured a wound of the heart, one of the first operations on the heart, up to then an off-limits organ for the surgeon. In 1902, Hill in Montgomery, Alabama repeated the feat. In 1901, Norwegian surgeon Christian Igelsrud performed the first successful open cardiopulmonary resuscitation. The world took little note. In 1910, Harvey Cushing drove to the base of the brain to remove pituitary tumors.

The last half of the nineteenth century saw the surgeon become the equal of other physicians, become an admired

Table 5.1 Great Surgical and Surgical Adjunct Developments in the Nineteenth and Twentieth Centuries

Date	Contribution	Surgeon/Scientist
1849	Repair, vesico-vaginal fistula	J. Marion Sims
1867	Perineal prostatectomy for cancer	Theodor Billroth
1867	Antisepsis	Joseph Lister
1871	Esophagectomy	Theodor Billroth
1873	Total removal of the larynx for cancer	Theodor Billroth
1875	Suprapubic bladder tumor removal	Theodor Billroth
1881–1885	Gastrectomy for stomach cancer (Billroth I and II)	Theodor Billroth
1882	Radical mastectomy for breast cancer	William Halsted
1882	Successful open cholecystectomy	Carl Langenbush
1882	Drainage of a pancreatic cyst	Carl Gussenbauer
1886	Steam sterilization (asepsis)	Ernst von Bergmann
1888	Repair of aneurysm	Rudolph Matas
1889	Improved inguinal hernia repair—the gold standard	William Halsted
1891	Hemipelvectomy	Theodor Billroth
1895	X-rays discovered	William Roentgen
1901	Discovery of human blood groups	Karl Landsteiner
1901	Visualization of the abdominal contents through a tube	George Kelling
1906	Direct blood transfusion	George Crile
1909	Development of surgery for thyroid disease	Theodor Kocher
1909	Tracheal insufflation for aeration	Rudolf Matas
1910	Pituitary tumor removal through the nose	Harvey Cushing
1912	Suturing of blood vessels	Alexis Carrel
1913	Resection of cancer of the esophagus	Franz Torek
1923	Treatment of aortic obstruction	Rene Leriche
1924	X-ray visualization of the gall bladder	Evarts Graham
1928	Observation of effect of penicillin	Alexander Fleming
1932	First sulfonamide	Gerhard Domagk
1933	Pneumonectomy for cancer	Evarts Graham
1935	Resection for pancreatic cancer	Allan Whipple
1938	Closure of a patent ductus arteriosus	Robert Gross
1941	Hormonal influence on prostate cancer	Charles Huggins
1945	Resection of an aortic coarctation	Robert Gross
1946	Endarterectomy for arterial occlusions	J. Cid Dos Santos
1948	Repair of a mitral valve	Harken & Bailey
1951	Resection and graft replacement of aortic aneurysm	Charles Dubost
1953	Successful cardiopulmonary bypass	John Gibbon
1954	Successful transplant of a kidney between two humans	Harrison & Murray
1983	Cause and treatment of peptic ulcer discovered	Marshall & Warren
1991	Laparoscopic cholecystectomy	Erich Muhe

Table 5.2 Surgeon Nobel Laureates in Medicine and Physiology, 1901–2005

Year	Laureate	Reason for Prize Award
1909	Theodor Kocher	Contributions to thyroid physiology and surgery
1911	Allvar Gullstrand	Dioptrics of the eye
1912	Alexis Carrel	Blood vessel suturing
1914	Robert Barany	Pathophysiology of the vestibular apparatus
1922	Frederick Banting	The discovery of insulin
1949	Walter Hess	The importance of the diencephalon to the circulation
1956	Werner Forssmann	Heart catheterization and circulatory pathology
1966	Charles Huggins	Hormonal treatment of prostatic cancer
1990	Joseph Murray	Organ transplantation

physician-scientist. Fredrick Treves was Sir Frederick Treves. And in the twentieth century, surgeons repeatedly won the Nobel Prize for their work (Table 5.2) [5]. Surgeons and surgery had arrived, primarily because anesthesia had been discovered.

Anesthesia Practice Evolved in Disparate Ways Across the World

The Evolving Practice of Anesthesia in the US

The staggering numbers of wounded produced by the Civil War (1861–1865) engendered the development of surgeons, but did nothing to develop anesthetists or further anesthetic delivery:

...ether or chloroform poured or dropped on a towel, a rag, or other vaporizer was the accepted method for anesthetizing the many wounded soldiers of the Union and Confederate armies during the Civil War, and for most patients during the rest of the nineteenth and the early twentieth centuries in America. Surgeons directed all aspects of treatment of their patients. They recruited anesthetists from the operating room personnel, such as nurses, hospital porters (orderlies), janitors, and even the surgeons' secretaries...the anesthetist was regarded as the 'low man on the totem pole' during the late 1800s and the early 1900s [6].

The surgeon supervised anesthetic delivery, a demanding responsibility that distracted from his primary task. Anesthesia continued to be dangerous as suggested by an 1885 survey by the Scandinavian Society of Surgeons giving an anesthetic mortality of 1 in 2,000–3,000, perhaps more with chloroform than ether [7]. Concerns regarding the safety and the availability of anesthetic service may have prompted US surgeons in the Midwest to employ Catholic Sisters (nurses) to provide anesthesia on a full-time basis. Thus Mary Bernard at St. Vincent's Hospital in Erie Pennsylvania, was recruited

in 1877. At first directed by the surgeon, these anesthetists increasingly gained experience by trial and error. Unlike the part-time anesthetist, they had the advantage of frequently repeated opportunities to learn their craft.

By the 1880s, more than 90 Midwest Catholic hospitals used sisters for anesthesia, thereby providing a more consistent and likely safer service than did the part-time anesthetist, physician or not. Most famously, in the late 1880s, sisters Edith and Dinah Graham became the first nurse anesthetists at the Mayo Clinic. In 1893, the Mayo brothers recruited Alice Magaw, the most celebrated nurse anesthetist of the nineteenth century. Magaw replaced the Graham sisters. The Mayo brothers soon added Florence Henderson.

The Mayos had given the job to Miss (Edith) Graham and then to Miss (Alice) Magaw in the first place through necessity; they had no interns. And when the interns came, the brothers decided that a nurse was better suited to the task because she was more likely to keep her mind on it, whereas the intern was naturally more interested in what the surgeon was doing [8].

Although the brothers provided initial training, Magaw and Henderson then independently perfected the smooth and safe delivery of anesthesia with ether.

The situation differed in other parts of the US. Anesthesia in the US had no distinction in the medical community. Training of physicians in anesthesia and the reputation of the physician anesthetist (in contrast to the nurse anesthetist) was abysmal. The 1894 experience of Harvey Cushing, later the father of neurosurgery, as a student at Harvard illustrates anesthesia's low standing and the disasters that ignorance brought [9]:

My first giving of an anaesthetic was when, a third-year student, I was called down from the seats and sent in a little side room with a patient and an orderly and told to put the patient to sleep. I knew nothing about the patient whatsoever, merely that a nurse came in and gave the patient a hypodermic injection. I proceeded as best I could under the orderly's directions, and in view of the repeated urgent calls for the patient from the amphitheatre it seemed to be an interminable time for the old man, who kept gagging, to go to sleep. We finally wheeled him in. I can vividly recall just how he looked and the feel of his bedraggled whiskers. The operation was started and at this juncture there was a sudden great gush of fluid from the patient's mouth, most of which was inhaled, and he died. I stood aside, burning with chagrin and remorse. No one paid the slightest attention to me, although I supposed I had killed the patient. To my perfect amazement, I was told it was nothing at all, that I had nothing to do with the man's death, that he had a strangulated hernia and had been vomiting all night anyway, and that sort of thing happened frequently and I had better forget about it and go on with the medical school. I went on with the medical school, but I have never forgotten about it.

This terrible event embodied the state of anesthesia in some parts of the US: an orderly directed a third year medical student in the administration of an anesthetic to a seriously ill and ill-prepared patient. As he promised, Cushing never forgot about it. Moreover, to the benefit of anesthesia, he

did something about it. With Codman, in 1895 he developed the anesthetic record with intraoperative recording of heart rate and blood pressure (itself, a new measurement in medicine) in that record at five-minute intervals. That record persists to the present, albeit now in an electronic form [10, 11]. The record was adopted in the US, but its use in other countries might vary. In the UK, use of anesthetic records, indeed, measurement of heart rate and blood pressure in the operating room, only began in the last half of the twentieth century.

Thus, by the beginning of the twentieth century in the US, the quality of anesthesia had a tri-modal distribution. First, nurse anesthetists, particularly in the Midwest, pursued anesthesia as a full-time occupation and honed their skills by regular practice. They took pride in what they did and did it well. They might know little about the science of anesthesia, but they were likely to give anesthesia safely and smoothly, and they taught other nurses how to do the same. Second, the part-time anesthetist, physician, medical student, nurse, orderly, or secretary, was also likely to know little about the science of anesthesia, but in contrast to the full-time nurse anesthetist was unpracticed in the art, and relied on the equally limited surgeon to provide direction. Anesthesia given by such persons was neither smooth nor safe (note Cushing's experience, above). Third, a small, but growing, number of physicians elected to pursue a full time practice of anesthesia, and like the Midwest nurses, might acquire skill in anesthetic delivery. Unlike nurses, these physicians might be driven to a career in anesthesia by their ineptness as physicians. In the 1900s, we find that "... the dean of Harvard Medical School wrote to the president of Harvard that the practice of anesthesia '...is so narrow a subject that a good man would not want to tie himself down to that and would hardly be willing to do so.' [12, 13]" But some of them, particularly women, would be leaders. For example, in the latter part of the 1890s, Isabella Herb practiced anesthesia at Augustana Hospital in Chicago, in 1922 becoming president of the first nationwide US anesthesia society, the American Association of Anesthetists (AAA). In 1898, Mary Botsford practiced anesthesia at the Children's Hospital of San Francisco. In 1922, she led the effort to found the Anesthesia Section of the California Medical Association, and was its first president.

The Evolving Practice of Anesthesia in the UK

Soon after the 1846 demonstration of ether anesthesia and the 1847 demonstration of chloroform anesthesia, Great Britain embraced anesthesia as part of the practice of medicine. Physicians, not nurses or orderlies, gave anesthesia. Perhaps this resulted from a preference for the use of the more dangerous anesthetic, chloroform, possibly a provincial response

to chloroform's discovery as an anesthetic in Scotland. Perhaps this resulted from the power of John Snow's studies and writings and those of other giants (Simpson, Clover and more) who accompanied him.

Regardless of the reason, a cadre of physicians gave anesthesia in the UK from the beginning of the history of anesthesia. Buxton advocated the compulsory study of anesthetics in medical curricula. Hospital residents or family doctors gave most anesthetics in Australia where deaths associated with chloroform repeatedly brought calls for full-time chloroformists, calls that were ignored. Commonly the surgeon invited the referring general practitioner to be the "chloroformist". The low professional and economic status of anesthetists impeded the attraction of young doctors into the specialty as full-time practitioners, a condition that continued worldwide to the mid-twentieth century.

The World's First Anesthetic Society Forms in the UK

In the UK, the number of physicians principally practicing anesthesia became sufficient to merit the formation of a society. Frederick Silk noted that "for some years...the subject of anaesthetics had occupied a very prominent position in the professional controversies of the period and its importance as a branch of medical education and special practice was becoming more generally recognised. It seemed to me therefore that...an attempt should be made to form a special Society of Anaesthetists [14]." And so in 1893, 40 founding members established the Society of Anaesthetists in London, electing Woodhouse Braine as President, Silk as secretary and Dudley Buxton as treasurer. George Oliver made the first presentation to the Society: "The size of the radial pulse under anaesthesia". This first true anesthetic society soon gathered members from Europe, North America, South Africa and Australia, and by 1900, grew to more than 100 members, many of them women. Indeed, it was the first medical society admitting women as full members. That it arose in the UK, and that so many members were to be found, indicated the pre-eminence of British anesthesia.

Surgeons Outside the US and UK Might Give and Direct Anesthesia

Surgeons were not fools. They realized the risks imposed by the inept or ignorant anesthetist. In the early 1900s, they popularized regional anesthesia with enthusiastic reports and textbooks describing virtually all modern block techniques in some form. By using regional anesthesia, they could continue to control anesthetic delivery and give safer anesthesia into the bargain. In 1901, Cleveland Clinic founder, surgeon George Crile, showed that regional techniques blocked "surgical shock", presaging "pre-emptive analgesia".

Unlike the situation in GB, where physician-anesthetists controlled anesthetic delivery, in Germany, surgeons directed anesthesia and devised methods for anesthetic delivery. In 1894, Schleich unsuccessfully advocated specialization in anaesthesia. In 1895, Witzel continuously dripped liquid ether or chloroform from bottles onto masks invented by Esmarch and Schimmelbusch, progressively increasing the anesthetic concentration, a technique used for the next half century or more. The direction by the German surgeon of part-time anesthetists, was the model for much of the anesthetic world outside of the US and the UK. In summary, by the 1900s, the anesthetic world consisted of three kinds: the nurse anesthetist/physician anesthetist/surgeon-directed model used in the US; the part-time/full-time physician-anesthetist model adopted in the UK and Commonwealth; and the surgeon-directed model used in most other places.

The First Anesthetic Society in the US

A few but growing number of physicians in the US took a small step, an advance that would grow in importance. The step indicated how far anesthesia had come. On 6 October 1905, nine physician-anesthetists met at Long Island College Hospital in Brooklyn at the invitation of Adolf Erdmann "because, as he put it, 'there are a few physicians practising (sic) anesthesia in the area, and these men ought to get together and form a society' [15]." Thus was formed The Long Island Society of Anesthetists (LISA). This new society would "promote the art and science of anesthetics" [15]. An excellent goal since the practice often possessed little art and less science. Bringing practitioners together allowed the sharing of experiences and enabled the cultivation of outside wisdom (e.g., bring in a speaker; appropriate for a society but hard to justify for just one person.)

These worthy goals alone, could explain the formation of what became the American Society of Anesthesiologists. However, one wonders whether other incentives prompted this convening. Given that anyone could administer anesthesia, the title of anesthetist provided little status. Surgeons (who now had a considerable cachet) often regarded anesthetists with disdain, even contempt. An anesthetic (or any) society, bestowed an authority onto its members, an armor against disdain and contempt. It allowed its members to argue that they possess something of value.

LISA morphed into the New York Society of Anesthetists in 1911, then into the American Society of Anesthetists in 1936, and finally to the American Society of Anesthesiologists in 1945. As with the formation of the Society of Anaesthetists in the UK in 1893, the establishment of LISA twelve years later indicated that a critical mass had been reached in the US. Both organizations would supply the specialty with educational, political, and economic powers that would grow

progressively. These would provide a positive feedback that would increase the attractiveness and influence of the specialty. But it would take several decades to produce major changes. This was the first trickle in what was destined to become a world-wide torrent.

The First Anesthesia Journal

In 1891, dentist Samuel Hayes began a vanity press quarterly publication, ‘Dental and Surgical Microcosm’. This might be considered the first anesthesia journal, for it discussed anesthetic matters and preached against ‘asphyxial (nitrous oxide) anesthesia’ without the provision of oxygen. Hayes died in 1897 and so did *Microcosm*. And why a dentist? Perhaps because dentists used anesthesia, especially nitrous oxide, more than did surgeons. They were interested in the safe and convenient delivery of anesthesia, and as we shall see, they disproportionately contributed to the early evolution of the anesthetic machine.

Anesthesiologists and other Scientists Consider How Drugs Act

How Does Curare Produce Paralysis?

In the 1860s, Claude Bernard showed that curare neither depressed conduction along nerves, nor prevented muscles from contracting when they were directly stimulated. Curare, he determined, caused paralysis by preventing the nerve impulse from traveling to the muscle through the junction between nerve and muscle, the myoneural junction [16].

How Do General Anesthetics Work?

Bernard proposed that a reversible coagulation of nerves underlay the production of anesthesia by some means that applied to all forms of life—a unitary mechanism of anesthesia. In contrast, two years later, LR Hermann suggested that the solution of anesthetics in brain lipids might be the basis for how they acted.

At the turn of the century, Meyer and Overton recognized that the theory proposed by von Bibra and Harless in 1847 (ether and chloroform acted by dissolving neural lipids) could not explain the rapid reversibility of narcosis, adding the further problem that dilute aqueous solutions of ether would not dissolve lipids although they could cause anesthesia. Like Hermann, Meyer and Overton proposed instead that anesthetics produced their effect by dissolving in the lipids. In support of this idea, they showed that anesthetic potency correlated with partitioning of the anesthetic between water

and lipid. Partitioning that favored the lodgment of the anesthetic in lipid also favored greater potency.

Another Revolution; the Application of Local Anesthetics

Koller Discovers Local Anesthesia

The discovery of the anesthetic effects of ether and chloroform revolutionized the practice of surgery. A second, quieter revolution was to come with the discovery of local anesthesia.

In 1862, von Schroff reported that cocaine numbed the tongue but did not apply his observation to surgery. What a chance missed! It was not the last. In 1873, Alexander Bennett demonstrated the anesthetic properties of cocaine (Keys, p. 108) [17], but little was made of this. In 1880, von Anrep recommended testing cocaine as a local anesthetic but like von Schroff, von Anrep did not apply his suggestion. He, too, missed his chance.

Subsequently, Sigmund Freud and Carl Koller experimented with cocaine while both were in residence at the Vienna General Hospital, where Koller was intent on becoming an ophthalmologist. On one occasion, when Freud was away, Koller’s colleague, Engel, licked some cocaine off the blade of his penknife and remarked that his tongue was numb. Koller wrote:

I realized that I had in my possession the local anaesthetic which I had previously been searching for. I went at once to Striker’s laboratory, made a solution of cocaine and instilled a drop in the eye of a frog, and afterward of a guinea pig, I found the cornea and conjunctiva anesthetic—that is, insensitive to mechanical, chemical, thermic and faradic stimulation. Afterwards I repeated these experiments on myself, some colleagues and many patients [18].

Koller prepared a report for the Heidelberg Ophthalmological Society meeting to be held in September, 1884, but could not afford to attend. Instead, his friend Joseph Brettauer presented his paper. Koller’s report that cocaine produced corneal insensibility for ophthalmological procedures was a sensation, a second anesthetic revolution that marked the birth of local anesthesia. The news spread as quickly as had the news of ether some 38 years previously. Recognition of cocaine’s ability to induce insensibility led to application for topical and then other forms of anesthesia. In 1887 Corning produced regional anesthesia by injecting cocaine into a specific nerve (Keys, p. 109) [17]. Ordinary and great (e.g., William Halsted) surgeons used cocaine to produce peripheral nerve blocks.

Surgeons seized on Koller’s discovery, partly because it enabled them to control both anesthesia and surgery. It encouraged operations in the surgeon’s office. However, in the late 1880s and the 1890s, reports of central nervous system

and cardiac toxicity attended cocaine's expanded use. Concerns regarding these factors and an increased knowledge of chemistry prompted a search for new local anesthetics. As cocaine was a benzoic acid ester, synthetic efforts focused on this class of compounds, and in 1890, Ritsert identified benzocaine. But benzocaine's poor water solubility made it suitable only for topical anesthesia, a sunburn remedy. In 1904 a better benzoic acid ester was made: procaine.

Bier Produces Spinal Anesthesia with Cocaine

Although Corning developed spinal anesthesia using cocaine in 1885, it remained for Bier in the late 1890s to make spinal anesthesia popular. In 1897, Bier gave the first spinal "block" in Germany. Obstetricians and gynecologists implemented this form of anesthesia. German surgeons first rejected the method because of reported side effects. Bier's work led most of the world to adopt spinal anesthesia. From 1898 into the 1900s, spinal blocks were produced with cocaine, while after 1903, Amylocaine (stovaine) briefly became the agent of choice. However, stovaine was identified as a nerve irritant and was displaced in 1904 by procaine, synthesized by the German Alfred Einhorn. Procaine suffered from two limitations. Its duration of action was brief (perhaps 45 minutes), and allergic sensitivity to its metabolite, para-aminobenzoic acid, appeared. These limitations notwithstanding, spinal anesthesia was performed in Argentina, Brazil, Chile, Colombia, Ecuador, Peru, Uruguay, and Venezuela. Spinal anesthetics were given in Mexico, Cuba, Guatamala, El Salvador and Nicaragua, and probably Panama. They were given in Europe and North America. Spinal anesthesia was increasingly adopted because it cost little, made minimal equipment demands, and allowed surgeons to give the anesthetic and then attend to the surgery.

In 1907, AE Barker solved a problem that Bier had noted, the tendency for spinal anesthesia to be uncontrolled in the extent to which the level of anesthesia spread [19]. Barker showed that the spread could be controlled by controlling the baricity—the weight—of the anesthetic-containing liquid injected into spinal fluid. Inject liquid heavier than spinal fluid and the liquid would sink to the part of the spinal canal that was most dependent.

Intravenous Regional Anesthesia

In 1908, Bier described "intravenous regional anesthesia", a technique in which a tourniquet was used to isolate a limb from its circulation while local anesthetic was injected into the venous portion of the isolated limb. The technique continues to be used today.

Addiction

Many who gave cocaine found it addicting. Indeed, addiction had been a problem for anesthetists from the beginning of

its history (e.g., remember Wells' addiction to chloroform). From 1883 to 1900, 35% of male morphine addicts in an Ontario treatment center were physicians (not just anesthetists).

Commercialism in the 1890s increased the potential for addiction to cocaine. Both Coca Cola and "vin Mariani", a "tonic wine" to "fortify and refresh body and brain, restoring health and vitality" contained cocaine. In 1892, William Osler noted that physicians injecting morphine to control pain had a greater incidence of morphine addiction. In 1894, Jansen Mattison reported that physicians comprised 70% of the morphine-addicted patients in his Home for Habitues. Some medical literature characterized opioid addiction as a loss of "moral will" or a problem affecting susceptible, weak individuals. Mattison disagreed: "... talk about weak will as a reason why strong men succumb to morphia ... is twaddle." Whether addiction to drugs was a disease or a sign of weak will remained a question for many societies and individuals.

More on Inhaled Anesthetics

Ethyl chloride anesthetized skin, the nearby anesthetist, and the patient

Carlson used ethyl chloride in 1894 for local anesthesia [20]. Spray it on the skin and its evaporation made the skin cold to the point of anesthesia. The evaporation might also anesthetize the nearby anesthetist. It produced a rapid pleasant induction of general anesthesia and allowed a rapid recovery, but it was hard to control since it boiled at 12.5°C and it was costly. It was used mainly for brief procedures or for induction prior to ether anesthesia [21]. In 1922, Oldenbourg listed its contraindications: "It is not suitable for prolonged administration on account of its dangers, expense, and great strain on the anesthetist." He added: "It should not be used in alcoholists and neurotics, and is decidedly contra-indicated in mechanical and inflammatory respiratory obstruction; in cardio-vascular degenerations and all conditions giving rise to marked dyspnoea [22]."

Whatever Happened to Chloroform?

From the year of its discovery forwards, deaths attended the use of chloroform. They continued to plague the practice of anesthesia, and increasingly provoked mention in the medical, and even the daily press. There were two schools of thought as to causation: the Edinburgh school, based on Professor of Surgery, James Syme's (1799–1870) belief that death was due to paralysis of respiration, and the English school, convinced that the heart stopped first.

Syme was a great friend and supporter of James Simpson, and advocated the use of chloroform, with the dictum (not based on any evidence) that one should "attend to the respiration, never mind the pulse." Flourens in France, and Snow

in England, studied animals to determine why the heart stopped. Flourens proposed that chloroform was so dangerous that it should not be used at all. Snow, with limited means, found that death resulted from excessive percentages of chloroform, and that although respiration usually ceased first, sometimes it was the heart that stopped.

In 1855, a Chloroform Commission was held in Paris, concluding that in animals, the respiration ceased first. Snow went further. He divided the vagus nerves and found that at low percentages of chloroform given for long periods, the respiration failed first, while at high percentages, the circulation often failed first. Still the dispute raged.

In 1864, the Royal Medical and Chirurgical Society appointed a committee that confirmed Snow's findings. In addition they found that the blood pressure always fell before the respiratory arrest. They advised the use of an alcohol, chloroform, ether mixture, the A.C.E. mixture as a safer alternative. Other experiments tended to support Snow's findings, and most suggested that chloroform was primarily a heart poison. Views remained divided. The English school advised close observation of the circulation and the respiration, while the Scottish school, following Syme's dictum, believed that watching the respiration was all that was necessary, and that watching the circulation may distract from the more important observation.

Enter Surgeon Lieutenant Colonel Lawrie, Syme's former pupil, with apparently a great admiration for his former teacher. Lawrie convinced the Nizam of Hyderabad to fund research that might answer the question once and for all. The commission of 1888 was dismissed as being inadequately conducted. A second commission was sought by Lawrie, again funded by the Nizam. A large number of experiments, all carefully documented with chart recordings etc. showed that:

- Chloroform has no direct injurious effect on the heart
- Chloroform anaesthesia is absolutely free from risk if attention be paid to the respiration.
- The danger in chloroform anaesthesia rests entirely with respiratory interference.
- Respiration always fails before the heart.
- Slowing or arrest of the heart by nervous interference under chloroform is beneficial.
- Fall of blood pressure from the administration of chloroform is beneficial.

This convinced many, but some skeptics questioned the science. Starting with cross circulation studies in animals by Gaskell and Shore, demonstrating that chloroform caused cardiac arrest in an animal which had not inhaled the agent. Many researchers around the world entered the fray. Lawrie attacked them all with vitriol, asserting faulty technique.

Leonard Hill in London repeated the Hyderabad commission's experiments in 1897 and could not support their conclusions. Many others, in different countries, found that death was primarily due to cardiac arrest. In 1901, a British

Medical Association report also suggested that the cause was cardiac. Lawrie commenced a concerted and sometimes bitter campaign in the journals of the day to sway others to his view.

In the meantime, Edward Embley, anesthetist, and part time researcher in the pathology department at Melbourne University, conducted experiments in dogs [23]. He showed that cardiac syncope, due to vagal stimulation, caused death on induction, and that general depression, and a fall in blood pressure, followed by respiratory failure caused later death. His research was published in the *British Medical Journal* in 1902, over 33 pages and three sequential issues. Embley cleverly chose dogs, whose vagal and cardiac responses to chloroform are similar to those in humans, while several of the previous studies used cats. In cats, chloroform causes excitability. Embley also monitored the dogs throughout the experiment. Lawrie's dogs were anesthetized outside the laboratory, and deaths during induction were ignored. In 1912–1914, A Goodman Levy showed that the cardiac syncope was due to ventricular fibrillation...but he had the advantage of the use of an electrocardiogram [24, 25].

Controlling Anesthetic and Oxygen Delivery to the Patient

Evolution of the Use of Nitrous Oxide

Colton, the showman whose exhibition prompted Wells' 1844 failed demonstration of nitrous oxide anesthesia, traveled to California in search of gold. Not finding any, he returned to New England where, in 1863, he took up dental anesthesia with nitrous oxide (Keys, p. 108) [17]. He kept a casebook indicating the administration of 100,000 anesthetics without a fatality—a world record for the next century. His successful use revived the fortunes of nitrous oxide, at least for dental practice or for brief procedures. It could only be given continuously for one or two minutes because the use of pure nitrous oxide excluded oxygen—not a safe thing to do.

In 1868, the surgeon Edmund Andrews suggested the solution to the problem of hypoxia when giving nitrous oxide: add oxygen [26]. This is obvious now, but was less so then. John Snow cavalierly said in 1847: "If the skin becomes inclined to purple, the face-piece may be removed for half a minute...but there need be no alarm [27]." Andrews was ahead of his time, but his solution presented logistic difficulties resulting from the inability to store compressed gases. Imagine going to the patient with an enormous balloon filled with nitrous oxide and oxygen. Adding oxygen demanded the production and storage of compressed gases, a means of mixing those gases, and a method of presenting them to the patient. Thus Andrews' suggestion did not produce an immediate change, for no anesthetic machine existed to deliver

nitrous oxide combined with oxygen. The delivery of 100% nitrous oxide with occasional breaths of fresh air continued for several years.

In early 1870, Coxeter and Son supplied refillable cylinders with liquefied nitrous oxide, at a cost of 3 pence per gallon. Soon after, Johnston Brothers of New York supplied the American market with liquefied nitrous oxide [17]. This was an essential step in the practical deployment of nitrous oxide.

In 1879, Paul Bert showed that Andrews was correct. Nitrous oxide safely produced anesthesia if given in a hyperbaric pressure chamber with sufficient oxygen [28]. A century later, Hornbein showed that such anesthesia was less than ideal [29]. Using a hyperbaric chamber, Hornbein found in volunteers, that anesthetic partial pressures of nitrous oxide caused muscle rigidity and considerable post anesthetic nausea and vomiting.

In 1885, nearly two decades after Andrews' suggestion, industry added high-pressure oxygen cylinders to the cylinders already built to hold liquid nitrous oxide. The SS White Company then patented what might be recognized as an anesthetic machine. In 1886, Viennese dentist Hillischer produced a machine dispensing the combination of nitrous oxide (he called it Schlafgas or sleeping gas) and oxygen. The SS White Co. machine and Hillischer's machine provided a rough control of oxygen concentrations.

In 1887, Frederick Hewitt invented a machine to concurrently administer nitrous oxide and oxygen—but not ether [30]. Other machines for the delivery of nitrous oxide and oxygen followed, and ultimately ether delivery was added in various ways, some safer than others. Hewitt explained why the combination of nitrous oxide with ether was so useful: “It is obvious that if the etherisation be preceded by the administration of nitrous oxide, the taste and odour of ether, and the other objections here referred to, will be completely relieved. It may indeed be said that nitrous oxide supplies the deficiencies of ether just as ether supplies the deficiencies of nitrous oxide” [31]. This form of anesthetic delivery continued for more than a half-century.

As a resident (1956–1958), the primary anesthetic I (EIE) gave was nitrous oxide plus ether in a background of oxygen, the so-called ‘gas-oxygen-ether’ (GOE) mixture. I also gave ‘open-drop’ ether, ether dripped onto a gauze-covered mask without nitrous oxide. The difference from GOE anesthesia was considerable.

Premedication Becomes Part of Anesthetic Delivery

In the late 1800s, clinicians increasingly injected morphine and scopolamine or atropine before ether anesthesia. The combination shortened induction and decreased anesthetic requirement. Scopolamine blocked the production of secretions resulting from the irritant effects of ether, and had

the added benefits of decreasing preoperative apprehension and providing amnesia for the unpleasantness attending induction of anesthesia. Morphine accelerated induction (by providing some of the anesthesia before the first drop of ether was poured) and minimized perception of ether's irritant effects. The capacity of morphine to depress breathing was of limited concern because ether itself did not depress breathing.

Beyond their use for premedication, morphine plus scopolamine were given in increased amounts to produce “twilight sleep” providing analgesia and amnesia for surgical procedures and obstetric deliveries. This technique was largely, but not completely, abandoned in the US in 1914 because of associated morbidity and mortality. LJS remembers in 1961 being bitten by a patient in which the combination had been used. The patient did not remember the event, but LJS did.

Control Over the Delivered Concentration of Volatile Anesthetic

Snow had invented a vaporizer that delivered a known and constant partial pressure of ether or chloroform, the saturated vapor pressure. Such a high partial pressure/concentration greatly exceeded that needed clinically. Joseph Clover solved the problem of delivering a precisely known, *clinical* concentration of chloroform to a patient. He devised a large, air-tight bag into which he added a known quantity of liquid chloroform and a known amount of air. Beyond the cumbersome nature of such a solution was the problem of adjustment of the delivered concentration. Only the originally concocted concentration was known with precision.

Another approach provided little to no control over the delivered concentration but might induce anesthesia rapidly. In 1880, Danish Surgeon Oskar Wancher introduced his airtight bag. He added 50 mL of liquid ether plus the exhaled air of the patient to the bag. The patient then breathed and rebreathed this mixture, producing increasing hypercapnia and hypoxia. The danger from breathing too little oxygen and too much carbon dioxide was partially countered by the hyperventilation that they produced. The approach accelerated the induction of anesthesia because of the hyperventilation, complimented by the anesthetic effect of hypoxia.

Improved Anesthetic Machines and the Addition of Ventilators

In 1902, dentist Teter developed a gas machine that delivered a variable mixture of oxygen and nitrous oxide, each controlled by separate but inaccurate valves, and without an

indication of percentage or flow. Still we were making progress, and dentists like Teter often led the way. A year later, Dragerwerk developed a device to absorb carbon dioxide from rebreathed gases using soda lime (mostly calcium hydroxide spiked with a bit of sodium and potassium hydroxide). Another step forward.

The increasing demands of surgery for a safe sustained delivery of anesthesia, led to the invention of new devices. In 1906, US dentist (yes, another dentist!) Jay Heidbrink, modified Teter's machine to produce an oxygen-nitrous oxide anesthesia machine. In that year, Green and Janeway began building machines to deliver intermittent positive pressure ventilation (IPPV) and demonstrated the advantages of controlled (as opposed to assisted) ventilation. However, they prematurely discontinued their groundbreaking work. A year later, Dräger produced the Pulmotor, a compressed-gas powered IPPV ventilator designed to breathe for rescued miners, later applied to the anesthetized patient.

In 1908, Koppers introduced the rotameter to deliver a precisely measured gas flow. Gas (oxygen or nitrous oxide, perhaps) lifted a rotating cylinder within a tube that broadened with increasing height (i.e., was tapered); a greater height of the cylinder indicated a greater flow, and this could be determined and the rotameter thereby calibrated. Neu subsequently used it in an anesthesia apparatus. The rotameter became the primary gauge of flow in the last half of the twentieth century. Also in 1908, Ombrédanne devised his inhaler for ether. It became the favored method for anesthetic delivery in France and Latin America for a half century, the French reluctantly parting from it in the 1950s.

Development of Standards

As might be imagined, because of the flammable nature of ether, the major anesthetic of the time, the National Fire Protection Association, formed in 1896, became the first of several organizations to set standards for anesthesia and anesthesia equipment. Other organizations included the US Food and Drug Administration (1906); the US Compressed Gas Association (1913); and the American Standards Institute (1918). These dry developments would materially increase the safety of anesthetic delivery.

Studies of Oxyhemoglobin

Uptake of Oxygen by Blood Changes the Absorption of Light

In 1862, Hoppe-Seyler crystallized the pigment that supplies blood's color, naming it hemoglobin. Oxygen and hemoglo-

bin, he found, form a dissociable compound he called oxyhemoglobin. He proved that hemoglobin caused the absorption of green and blue light, the "Soret band," and that this absorption changed when he shook the solution with air (the air delivering oxygen to the blood). He thereby gave us the beginnings of oxyhemoglobin percent saturation measurement in the blood, the beginnings of oximetry.

In 1876, von Vierordt found that stopping circulation in the finger, caused the two bands of reflected light representing oxyhemoglobin to disappear and that of deoxygenated hemoglobin to appear. He measured the finger's oxygen consumption by timing this change. His observations brought us another step closer to oximetry.

In the 1890s, Danneel, in Nernst's laboratory, found that dissolved oxygen reacts with a negatively charged metal (cathode) in proportion to the oxygen pressure. Although he identified the principle of the polarographic electrode, organic substances "poisoned" the cathode surface, making it useless for the determination of oxygen partial pressures in protein-containing solutions like blood.

Assuring an Unobstructed airway

Pulling or Pushing the Tongue Forward

The obstructed airway was increasingly recognized as a source of danger during anesthesia. One might pull the tongue forward with a forceps to relieve obstruction, but that often caused tongue injury. In 1873, Norwegian Heiberg invented the "jaw thrust" (pulling the jaw, and thus the tongue, forward) to remove airway obstruction. Esmarch advocated the technique 5 years later and was credited with the invention, but Heiberg should get the credit. Jaw thrust continues to the present as an effective way to maintain an open airway.

However, maintenance of a patent airway by jaw thrust required two hands to lift the jaw. In 1880, Howard suggested an alternative, head tilt and extension, something that might be done with one hand, a technique still used to relieve obstruction by the tongue. But head tilt and extension concurrently moved the tongue, jaw and head en bloc; so why should such a maneuver relieve obstruction? The contemporary answer is that the extension lifts the hyoid cartilage, the bony structure just above the Adam's Apple portion of the larynx. Extending the head tightens the muscles attached from jaw tip to hyoid cartilage and from cartilage to sternum, thereby pulling the hyoid cartilage forward. Since the tongue attaches to the hyoid, this maneuver lifts the tongue from the back of the pharynx and relieves obstruction. As already noted, part of the magic is that head tilt and extension can also be accomplished with just one hand, a great advantage to the anesthetist who already has too few hands.

Put a Tube in the Trachea

Pulling or pushing the tongue didn't always solve the problem. Enter the Scot, William Macewen, who intubated the trachea with a metal tube in awake patients, blindly guiding the tube with his fingers. He then might deliver anesthesia through the tracheal tube. Although Macewen pioneered blind orotracheal intubation for anesthetic delivery, he abandoned this approach in 1880 when a patient died during the use of intubation associated with induction of anesthesia. However and under different circumstances, in 1882, New York surgeon O'Dwyer blindly put a metal tube into the glottic opening to bypass the suffocating pseudo membranes of diphtheria in children. In 1887, Fell used intermittent positive pressure ventilation (IPPV) from a bellows delivered via a face mask to inflate the lungs. Combining the O'Dwyer tube with the Fell bellows produced the Fell-O'Dwyer apparatus. In 1894, Alfred Kirstein reported looking at the larynx with his "autoscope", and a year later, Killian used Kirstein's autoscope to visualize and extract a foreign body from a patient's bronchus. In 1899, van Stockum constructed a metal tracheal tube fitted with an inflatable cuff.

Or Use an Oral Airway

In 1908 Hewitt devised a simple but vital advance—an oropharyngeal artificial airway to relieve airway obstruction in patients in whom the trachea is not intubated. Such an artificial airway relieved obstruction by providing a clear passage to the rear of the pharynx. The artificial airway continued to evolve and save patients' lives for the rest of the century, passing through the Waters and Guedel versions of the oropharyngeal airway in the 1930s to the remarkable laryngeal mask airway in the 1980s.

Respiratory physiology

Control of Ventilation

In 1876, Woillez described a manual ventilator that applied intermittent negative pressure to the chest, a forerunner to the iron lung. However, this approach was cumbersome and would present a barrier to operations on the chest or lung. In 1899, Matas reported the successful use of intermittent positive pressure ventilation applied to the airway during an operation to remove a chest wall tumor.

In 1902, Tuffier and Hallion reported on "Intrathoracic operations with artificial respiration by insufflation"—blowing oxygen containing anesthetic into the airway (e.g., the oropharynx)—in animals using a rhythmic inflation method. This solved the "Pneumothorax problem" the problem of

lung collapse when the chest is opened, a problem that leads to insufficient oxygen in the blood [32], and like Matas' method, allowed access to the chest.

In 1909, Meltzer and Auer repeated Tuffier and Hallion's insufflation. This technique continued in use for a half century. Eger remembers its frequent application in the late 1950s during tonsillectomies, blowing oxygen laden with ether into children's mouths. The happy surgeons and slightly less happy anesthetists would go home partially anesthetized from the fumes they inhaled. Incorrectly, surgeons also thought that insufflation supplied "ventilation."

German surgeon, Sauerbruch, had another solution to the pneumothorax problem. He wanted to perform thoracic surgery, but opening the chest caused lung collapse, hypoxia and death. To prevent lung collapse, in 1903 he built a giant chamber having a negative pressure of about 5 cm of water. It enclosed the patient's body with the head protruding from the chamber. The surgeons joined the patient in the chamber, but they kept their heads inside. This maintained inflation of the patient's lungs, but it did not supply ventilation. Sauerbruch demonstrated its use in 1904, and could not be convinced that ventilation also needed to be supplied. That would have been unphysiologic, he said.

Reprise

Morton's demonstration of ether anesthesia on 16 October 1846 (ether day) accelerated progress in surgery, enabling both increased numbers of surgeries and new operations. Such increases affected the demand for superior education and training of surgeons. Germany, Austria, the UK and the US soon led as centers of surgical knowledge. Formal organizations were established to further surgical learning and to improve standards of care in Britain (The Royal College of Surgeons 1815), Germany (Deutsche Gesellschaft für Chirurgie 1872), France (College of Surgery 1880) and the US (American Surgical Association 1880) [33]. The last half of the nineteenth century produced an age of giants: James Sims (1813–1883) and William Halsted (1852–1922) in the US; Theodor Billroth (1829–1894) in Austria; and Theodor Kocher (1841–1917) in Switzerland. A need arose for the communication of the dramatic increase in the number and type of procedures, giving rise to new journals such as *Archiv für Klinische Chirurgie* (1860) and *Annals of Surgery* (1885). These supplemented or displaced the textbooks and treatises that had been the foundation of medical writing.

Snow extended Morton's and Simpson's discoveries as much into science as could be done in that age, and his work was little improved upon for decades. Ether and chloroform, supplemented by nitrous oxide and oxygen, remained the mainstays of anesthetic practice for the next century. Anesthesia failed to advance or it advanced slowly, primarily in

improved methods of delivery and ways to keep the airway open. Ether and chloroform are gone now, and nitrous oxide may disappear, too [34]. But anesthesia with ether and then chloroform constituted a colossal advance that enabled the development of surgery without further advances in anesthesia. It took surgeons a half, perhaps a whole century, to catch up to and then demand more of anesthesia [35].

1910–1950: Anesthesia Before, During, and After Two World Wars

6

Edmond I Eger II, Rod N. Westhorpe and Lawrence J. Saidman

Summary

Who gave anesthesia from 1910 to 1950? Physicians in GB and the British Commonwealth, a mix of nurse anesthetists and physicians in the US, and surgeons directing part-time anesthetists in Europe and the rest of the world. Anesthetic societies arose, in GB (1893), the US (1905), France and Australia (1934), Canada and South Africa (1943), and Argentina (1945). And societies published *Anesthesia & Analgesia* (1922), the *British Journal of Anaesthesia* (1923), *Anesthésie et Analgésie* (1935), *Revista Argentina de Anestesia y Analgesia* (1939), *Anesthesiology* (1940), and *Anaesthesia* (1946). In the US and France, nurse anesthetists vied with physician anesthetists, conflicts not yet ended. Societies also governed formal training and certification, a tangible recognition of the quality care that a diplomate could provide.

The first nurse anesthesia school opened in Portland in 1909, with four others added before World War I. Supported by surgeon Crile, Hodgins opened her nurse school at the Cleveland Clinic in 1915, spawning 54 similar schools in the next two decades. In 1927 at the University of Wisconsin, Waters initiated the world's first academic department of anesthesia. In 1936, Beecher, not trained in anesthesia, became Anaesthetist-In-Chief at the Massachusetts General Hospital. In 1937, Macintosh became the Nuffield Professor of Anaesthetics in Oxford. In World War II, the US armed services ordered many drafted physicians to give anesthesia, greatly increasing the pool of US physician anesthetists.

With the rise in formal training, came the first subspecialties: Robson developed pediatrics in 1919; Lundy set up the first US blood bank in 1935; Labat and Rovenstine established elements of pain medicine and regional anesthesia in the 1930s, further pursued in the 1940s by Moore and Bonica; and in the 1940s and 1950s, Hershenson, Apgar and Marx promoted obstetrical anesthesia.

Rudimentary anesthetic machines from the 1860s to 1910s evolved in the 1910s to 1950s to provide greater control and safety. Morris' 1948 Copper Kettle allowed precisely delivered volatile anesthetics. New drugs accompanied advances in equipment: cyclopropane (1929), divinyl ether and meperidine (1932), thiopental (1934), curare (1942), lidocaine (1948), and succinylcholine (1949).

In 1918–1920, Magill and Rowbotham insufflated ether through rubber tracheal tubes to anesthetize patients with facial injuries. In 1926, Starling invented a piston pump ventilator. In the 1930s, Waters and Guedel introduced oral airways that are still used to maintain an airway. With Nosworthy in Great Britain, Waters and Guedel applied intubation and controlled ventilation during anesthesia. In 1931, Waters and Gale used one lung ventilation to supply a quieter operative field for pulmonary surgery. Luft invented the infrared analyzer in 1937. In the 1940s, Courmand and Forssmann advanced special catheters into the pulmonary artery and got the Nobel prize. In the 1940s, Miller and Macintosh described their blades for laryngoscopy. In 1949, Carlens invented the double-lumen tube.

World Events Before, During, and After Two World Wars

In 1912, the Royal Mail Steamer (RMS) Titanic struck an iceberg in the North Atlantic and sank. World War I (1914–18) devastated Europe and nearby countries, including Russia. In 1915, TS Eliot published *The Love Song of J. Alfred Prufrock*. Between 1918 and 1920, the Spanish flu killed 20 to 100 million people. In the 1920s, women gained the right to vote in multiple countries (US, 1920). In 1922, James Joyce published *Ulysses*, and the Soviet Union

was created. The Great Depression followed the 1929 stock market crash. Mohandas Gandhi led the 1930 non-violent Satyagraha movement in India. Movies and radio became dominant means of communication and entertainment in the 1930s. Franklin Roosevelt was elected in 1932, beginning the New Deal. In 1933, Hitler and the National Socialist German Worker's Party (the Nazi Party) seized power. Between 1935 and 1938, Germany annexed Austria, Czechoslovakia, and the Saar, leading to the Munich appeasement ("Peace in our time"). Between 1936 and 1939, Franco's army fought and won the Spanish Civil War, Pablo Picasso painted "Guernica", and Japan invaded China, starting the Second Sino-Japanese War. In 1938, Robert Watt invented radar. In 1939, Germany invaded Poland, initiating World War II (1940–1945), the most destructive armed conflict in human history. The US destroyed Hiroshima and Nagasaki in 1945 with atomic bombs, leading to the Japanese surrender. In 1947, the Cold War and the Marshall plan (which enabled the economic recovery of Europe) began. Arthur Miller's play, *Death of a Salesman*, premiered in 1949. In 1950, Joseph McCarthy began his witch-hunt for communist sympathizers.

Introduction

The US, GB, and Europe provided major anesthetic developments from 1910 to 1950. Several small events laid a base for the gigantic leaps forward that anesthesia took after 1950. These included growth in the numbers of full-time physician and nurse anesthetists, and the development of societies and associated journals (science), subspecialties, formal training, and certification. The presence of greater numbers of anesthesiologists gave rise to the earlier development of societies. Part of the base for the leap into modern anesthesia included advances in drugs and airway management, and an increasing sophistication in control over anesthetic delivery. Chapter 6 provides its stories as a group of parallel evolving, chronological streams that often touched each other.

Surgical and Surgical Adjuvant Advances and Demands on Anesthesia

Surgeons Develop New Surgical Procedures

The great surgeons of the previous half century had already devised procedures familiar to us today (see Table 5.1). In 1910, US surgeon Harvey Cushing developed hypophysectomy (removal of pituitary tumors), safely accessing the pi-

tuinary which lies at the base of the brain through an ingenious route, the nose.

Increasingly, surgeons ventured into hitherto forbidden sites, particularly the lung and heart, aided and abetted by increasingly skilled anesthetists, both physicians and nurses. In 1933, US surgeon, Evarts Graham excised a cancerous lung from a fellow physician [1]. The patient was cured, the first such patient. Graham, a smoker, however, died from lung cancer, but not before reporting that cigarette smoking had carcinogenic effects [2].

Children also benefited. In 1936, surgeon William Ladd began development of pediatric surgery at Boston Children's Hospital, happily dependent on Betty Lank, the chief nurse anesthetist. Lank gave ether or cyclopropane via mask, even to prone patients breathing spontaneously. She was an exceptional anesthetist, talented and fearless. Lank gave anesthesia for several surgical firsts. In 1938, unsupervised, resident surgeon Robert Gross closed a congenital defect, a blood vessel between the aorta and the pulmonary artery (a patent ductus arteriosus), a connection of major blood vessels. In that year, Ladd repaired an abnormal congenital connection between the esophagus and trachea (a tracheoesophageal fistula). Mortality usually exceeded 70% for such procedures. In Sweden, Clarence Crafoord repaired a coarctation (narrowing) of the aorta in 1944. A year later, Robert Gross, now a "real" surgeon, resected an aortic aneurysm (a dilation of the aorta), again with the aid of Lank. At this time, Merel Harmel (a mere resident) and Austin Lamont gave open drop ether to Alfred Blalock's patient for the first Blalock-Taussig shunt treatment of the combination of congenital abnormalities constituting the tetralogy of Fallot. They described what they did in the first cardiac anesthesiology paper [3]. Truly a giant step into an unknown world described in Chapter 61. Lank later taught Harmel and Lamont to use cyclopropane and tracheal intubation.

In 1948, Smithy devised and accomplished the first commissurotomy for mitral stenosis, blindly opening the deformed valve with a finger inserted through a small hole in the left atrium. Ironically, he suffered from mitral stenosis and pleaded that his operation be applied to him. To no avail; Smithy died at age 34 from his disease.

The Price of Advances in Surgery?

In an "Anaesthetic Number" of the 1938 Medical Journal of Australia, Geoffrey Kaye published results from a survey of nearly 400,000 anesthetics at 14 hospitals, finding a mortality from anesthesia of around 1:1,000. Over subsequent years, the College of Anesthetists continued the tradition of reviewing and publishing mortality data for Australian

anesthesia, becoming a major worldwide advocate of measures to decrease mortality and morbidity from anesthesia.

The Surgeon as Anesthetist

Local anesthesia was thought to be safer than general, particularly chloroform anesthesia. The use of local anesthesia minimized respiratory problems associated with general anesthesia, and allowed a control over anesthesia by the surgeon. Accordingly, surgeons, particularly European surgeons, physicians with a love of anatomy, quickly seized on the possibilities offered by Koller's 1884 discovery of the local anesthetic properties of cocaine, devising many regional anesthetic techniques still used (see Chapter 5). This approach to anesthesia continued in the 1910s. In 1911, Hirschel invented the axillary approach to the brachial plexus while Kulenkampff described the supraclavicular approach.

Tools that Furthered the Cause of Surgery

In the 1920s, physicist William Bowie developed the electrocautery [4], a device that stopped bleeding by burning blood vessels. Harvey Cushing first used the "Bovie" in 1927 [4]. Surgeons used it because it hastened the conduct of surgery. But surgeons and anesthetists alike used it with apprehension (justified, it turns out, by the occasional report of explosion killing all in the vicinity) or not at all in the presence of flammable and explosive anesthetics such as ether, ethylene and cyclopropane.

Further Attacks on the Problem of Infection

For millennia, two colossal problems had limited the advance of surgery: pain and infection. General anesthesia with ether or chloroform from the 1840s, and regional anesthesia from the 1880s, had overcome the first, and antisepsis and asepsis from the 1860s had done much to counter the second. However antisepsis and asepsis sometimes failed both surgeon and patient. Something was needed to manage infection that eluded antisepsis and asepsis.

In 1928, Alexander Fleming discovered the antibiotic penicillin. He couldn't make sufficient pure quantities, and so for a time penicillin remained a laboratory curiosity. In 1938, Howard Florey and Ernst Chain began the work that eventually supplied the world with penicillin, and with Fleming, in 1945 they won the Nobel prize in Medicine. Add the 1932 discovery by Gerhard Domagk, a German biochemist, that the sulfanilamide Prontosil had antibiotic properties. The age of antibiotics had arrived, making surgery—and thus anesthesia—yet safer.

Socioeconomic Factors from 1910 to 1950 Affect Progress in Anesthesia

The Flexner Report

Abraham Flexner's report, *Medical Education in the United States and Canada*, described the shortcomings of North American medical education compared to European education. Over the next 10 years, the Flexner report contributed to closure of approximately one-third of US medical schools. Sixteen of the 17 schools devoted to the education of women closed for lack of support for the scientific underpinnings that the Flexner report revealed and demanded.

World War I

The Great War (World War I) that ravaged Europe began in 1914. In that year, surgeon George Crile and his personal and chief nurse anesthetist, Agatha Hodgins, provided service in Europe in an American "ambulance" (hospital), delivering and perfecting anesthesia with nitrous-oxide/oxygen after belladonna plus morphine premedication (Crile termed the result anoci-association, a state in which patients did not perceive pain. It foreshadowed balanced anesthesia.) In Europe, nurses provided anesthesia in American Hospitals before and during World War I, using the Crile-Hodgins approach. This was thought to be particularly useful in soldiers who had lost considerable blood. Three years earlier, Crile had reported before the American Surgical Association on 10,787 operations anesthetized under Hodgins' supervision with no anesthetic death [5].

World War I involved many nations, and killed 5 to 10 million participants. Few physicians in the American Expeditionary Force (active from 1917 through 1919) had trained in anesthesia (no formal training programs for physicians existed), and anesthetic equipment was primitive, often delivered with open drop ether or chloroform. How did the anesthetist safely provide anesthesia for vast numbers of American surgical casualties when orderlies and secretaries and stretcher-bearers provided part-time anesthetic care?

Enter Arthur Guedel, the motorcycle anesthetist. Guedel rode his motorcycle from hospital to hospital to train diverse "anesthetists" and direct the administration of ether anesthetics. His system was so effective that it became a standard, one that EIE used 40 years later. It was so profoundly ingrained that it was applied to new anesthetics that appeared five decades later, although it really only applied to ether [6].

Guedel understood the need to train and supervise a cadre of orderlies, secretaries and stretcher-bearers. His genius recognized the need for simplification, for the construction of a scheme whereby anyone, even those with little training,

might assess the degree of anesthetization and use the degree to guide anesthetic delivery (see Fig. 39.2, [7]). Guedel's scheme had the elements described by John Snow 70 years earlier [8], but Guedel made it more accessible to someone with limited training by supplying a chart to guide the anesthetist. Breathing and the eyes told the anesthetist everything needed to gauge how much anesthetic to give or withhold. There were 4 "stages" of anesthesia, akin to Snow's 5 degrees:

In the first stage, the patient might respond to command and although not anesthetized might have considerable analgesia. Breathing would be regular. The patient controlled movement of the eyes. The pupils were normal in size and constricted in response to light.

Hallmarks of stage 2, or "excitation" included irregular breathing and roving of the eyes. The pupils might vary in size but would constrict if exposed to light. Movement, sometimes violent movement requiring restraint of the patient might occur in this stage during induction of anesthesia. Such movement was less likely during recovery from anesthesia.

Stage 3, the stage of surgical anesthesia, had 4 "planes". In plane 1, breathing was deep and regular. Movement of the eyes might occur, particularly at the upper end of this plane. Pupils were normal in size and constricted to light. Plane 2 scarcely altered breathing, but eye movement ceased and the pupils dilated slightly—but still constricted in response to light. In plane 3, breathing decreased and became "jerky". The pupils now dilated and incompletely responded to light. In plane 4, breathing progressively decreased, and the pupils dilated widely and did not respond to light.

In stage 4, breathing ceased. The heart might stop beating in stage 4 or even in plane 4 of stage 3. As with Snow's fifth degree, the anesthetist was encouraged to avoid stage 4 or even plane 4 of stage 3.

Perhaps the quality of anesthetic care provided by the British exceeded that provided by the American Expeditionary Force because a physician (rather than the better trained nurse) was designated as the anesthetist—although he (there were no females—see below) might not have engaged in anesthesia since medical school [9]. But the tasks overwhelmed even the full-time physician anesthetists. The wounded poured into casualty clearing stations (CCS) at a sometimes ferocious rate: "At the Battle of the Somme, for example, some 14,000 casualties moved through the CCSs on the first day, and CCS number 29 at Gezaincourt alone received 11,186 wounded soldiers in the first 3 days of conflict." [9]

The British also tried various approaches to anesthesia, discovering that spinal anesthesia resulted in excessive hypotension in patients already suffering from shock. They discovered that nitrous oxide combined with ether improved

survival and applied the combination increasingly as the war progressed. This, of course, necessitated the production of anesthetic machines. Geoffrey Marshall and Henry Boyle, both working in France, independently devised a portable anesthesia apparatus, using bubble flowmeters as developed by James Gwathmey of New York. Coxeter and Son produced commercial versions of both. Thus, the use of anesthetic machines began in earnest (e.g., in GB, Boyle introduced his anesthetic machine with the Boyle's bottle for vaporization of anesthetic in 1917). Delivery of anesthetic from machines increasingly displaced the gauze mask-open drop ether approach to anesthetic delivery. The Americans joined in this move.

Both British and American anesthetists/surgeons in World War I studied the management of shock [9]. Giving salt-water solutions (normal saline) provided short-lived benefit. German surgeon Hercher used hypertonic solutions for fluid resuscitation in wounded soldiers. Gum-acacia solutions had a longer effect than saline. The best result came from applying the new knowledge of blood types and preservation of blood, with the consequence that the war accelerated the development of transfusion medicine.

The beleaguered Germans in World War I probably had the worst time of all. "In the German Army, it was proposed by Professor Schleich that (ether) be carried mixed with some ethyl chloride, so as to be self-administered after injury in order to allow the regimental medical officer to concentrate solely on treatment." [9]

World War II Advances Anesthesia in the US but Detracts Elsewhere

World War II severed European contact with advances in anesthesia in the US and GB. This and the demands of the war hindered progress in Europe and much of the world. The approach of the War increased the pressure in GB to educate anesthetists. The Association of Anaesthetists of Great Britain and Ireland (AAGBI) trained full-time anesthetists.

World War II dramatically accelerated the growth of physician anesthesia, nurse anesthesia, and women in medicine in the US. The number of schools of nurse anesthesia approved by the American Association of Nurse Anesthetists (AANA) increased. On the debit side, the war delayed implementation of the first nurse anesthesia qualifying examination until 1945. The urgent need to enlarge the pool of anesthetists, particularly anesthesiologists (physician anesthetists) to manage great numbers of casualties resulted in "crash" training programs for drafted physicians, who were ordered to become anesthesiologists. By the war's end, many such drafted anesthesiologists discovered that they liked the associated technical demands and opportunities.

Women in Medicine

In 1914, 8 women were members of the American Association of Anesthetists (AAA), 9% of membership. By 1916, 15 women (9%) were members. In 1915, 3.6% of physicians were women. Among women, only gynecology exceeded anesthesia in popularity. World War I opened a 19-month window of increased opportunities for American women to enter medical schools and internships. It also offered opportunities that comedian-commentator Jon Stewart would have seized. In 1917, the US Army's Judge Advocate General ruled that since women cannot vote, they were not "citizens," and could not be commissioned medical officers.

By 1920, 5.0% of US physicians were women, an increase consequent on the vacancies in medical schools left by men who were fighting in World War I. By 1930, this had decreased to 4.4%. When World War II began, the US had 7,708 women physicians, less than in 1910. In 1920, three women headed anesthesia "departments" in the US: Herb at Rush, Botsford at UCSF, and her trainee Palmer at Stanford. Passage of the nineteenth amendment in 1920 gave US women the right to vote. In 1922, at the University of Iowa, Mary Ross became the first woman anesthesia resident. In that year, Isabella Herb became president of the first nationwide US anesthesia society, the American Association of Anesthetists (AAA). Also in 1922, Mary Botsford, who practiced anesthesia at the Children's Hospital of San Francisco, led the effort to found the Anesthesia Section of the California Medical Association, and was its first president. In 1930, Botsford became president of the Associated Anesthetists of the United States and Canada, an organization that evolved from the AAA.

In 1938, working in Peking Union Medical College in Beijing, Ma Yueqing became the first Chinese anesthesiologist. In that year, the fourth female trained by Ralph Waters, Virginia Apgar, became Director of the Division of Anesthesia and Attending Anesthetist at Columbia. There is a "delicious irony" in that Waters had earlier commented to Guedel: "...M.D. ladies...are useless in the profession. I am through with them. Ladies are nice socially but not (as) professionals" (from Selma Calmes in Chapter 16).

During World War II, 10 million men were inducted into the armed services. The resulting shortage of civilian male candidates opened medical school, internship and residency opportunities for women. And anesthesia was attractive to these new female physicians. In 1940, 87 (12%) of ASA members were women. In 1949, 251 (9.9%) were women, becoming 11% in 1963, nearly twice the percent of females in the physician population (6%). Ironically, the armed services excluded female anesthesiologists. In 1942, Surgeon General James Magee proclaimed that "Women should not belong" and only six served as anesthesiologists in World War II. Nine had served in World War I.

Evolution of US Anesthetic Organizations

American Society of Anesthesiologists (ASA)

The London Society of Anaesthetists, the first anesthetic society, was founded in 1893. A dozen years later, 9 professional brothers founded the second society, the Long Island Society of Anesthetists (LISA). Membership grew to 23 in 1911, and the enlarged society changed its name to the grander New York Society of Anesthetists (NYSA), reflecting the broader geographical distribution of its membership [10]. At the last meeting of the old society, Yandell Henderson of Yale spoke of the importance of physiological chemistry to the anesthetist, and Max Verworn from the University of Bonn lectured on Narcosis, suggesting that anesthesia resulted from an inadequate supply or use of oxygen. The establishment of LISA and the NYSA reflected the growing numbers of anesthetists and the interest in their craft. A new constitution reaffirmed the notion that the purpose of the society was "the advancement of the science and art of anesthesia." The yearly dues tripled, from \$ 1 to \$ 3. The NYSA sought but was denied recognition by the American Medical Association (AMA). The NYSA Fellowship Committee certified candidates in oral, written and practical examinations.

In the ensuing two decades, other anesthetic societies arose in the US: the American Association of Anesthetists (1912), the Interstate Association of Anesthetists (1915), the American Society of Regional Anesthesia (1923), and the International Anesthesia Research Society (IARS, 1925). These and local and regional societies focused on the education and competitive practices of this developing medical specialty. They sought to create a certifying system for practitioners. In the early 1930s, Ralph Waters, Paul Wood, and John Lundy unsuccessfully lobbied for creation of a Section of Anesthesiology within the American Medical Association. In support of the evolution of the NYSA to a national organization, in 1936 the NYSA changed its name to the American Society of Anesthetists. In 1945, the American Society of Anesthetists changed its name to the American Society of Anesthesiologists (ASA). This and the appearance of other new societies reflected the increasing numbers of physicians engaged in anesthesia.

These activities reflected the growing numbers of physician anesthetists in the US, but it should be noted that the number of nurse anesthetists was increasing concurrently. The increases in both accelerated in the 1940s.

We do not know the motivations that led physicians to enter anesthesia, but the need to strengthen their status seems clear, and this likely added to the desire to form societies. A lowly status may have been deserved: In 1947, John Lundy wrote that "there was a tendency for only those physicians who were incompetent in general practice or in other branches to limit themselves to the practice of anesthesia." [11] Why

the incompetent? Did the study of anesthesia lack depth, lack challenge? Perhaps. Consider the letter that the Dean of Harvard Medical School wrote to the President of Harvard in 1906: “The practice of anesthesia is so narrow a subject that a good man would not want to tie himself down to that and would hardly be willing to do so.” [12] Keith Sykes and John Bunker described many anesthetists of the time as perhaps “...simply attempting to escape from the responsibilities of an unsuccessful or bothersome practice.” [13] What a dismal state! And finally Beecher (yes that one) stated that “anesthesia technique can be mastered by ordinary men who are ordinarily deft, with only a modest requirement of intelligence and of knowledge and judgment.” [14]

Membership in societies supplied one route to status. Societies also provided forums for developing a body of knowledge that might certify the value of anesthesia and the anesthetist. Both the IARS and the ASA held yearly national meetings to advance the causes of education and research in anesthesia, meetings that gradually grew in size and quality. The IARS had offered such meetings for decades; the first Annual Session of the ASA was held in 1945.

As indicated above, Societies first formed in GB (1893) and the US (1905). No national societies were added for 3 decades thereafter. Societies developed in Australia and France in the 1930s. World War II transiently slowed additions, and then began a flood of societies that subsequently continued for 6 decades.

Waters had established the first anesthesia residency training program with his arrival at the University of Wisconsin in 1927. By 1943, 45 US anesthesia residency training programs were approved, increasing to 213 by 1950—with only 107 residents. This grew to 5,556 residents in 132 programs in 2010.

With the ending of World War II in 1945, the ASA created a “Committee on Postgraduate Education” to define how to educate returning physicians who had served as anesthetists during the war, and new physicians seeking training in anesthesia. Approximately a half decade later, the Committee issued “Recommendations for a Curriculum in Anesthesiology”, prescribing a minimum of 2 years of training for candidates with no prior instruction, but crediting the experience of those who had received “on the job” training.

In 1949, Paul Wood’s collection of historical materials became the Wood Library-Museum (WLM). The WLM found a permanent home at the Park Ridge ASA offices in 1963.

The International Anesthesia Research Society (IARS)

One charismatic anesthesiologist, Francis McMechan, shaped much of the history of anesthesia, particularly the story of the IARS, from 1910 to 1939. In 1911, rapidly pro-

gressing rheumatoid arthritis prevented McMechan from continuing his medical/anesthetic practice. McMechan joined the American Association of Anesthetists, formally organized in 1912, and quickly became its leader and the “union organizer” for anesthesia, encouraging the development of several regional societies. The Interstate Association of Anesthetists (Ohio and Kentucky) formed in 1915, in 1925 morphing into the Mid-Western Association of Anesthetists. McMechan encouraged development of the Canadian Society of Anesthetists in 1921, the Pacific Coast Society of Anesthetists in 1922; the Southern Association of Anesthetists in 1922; and the Eastern Society of Anesthetists in 1923. McMechan organized a parallel National Anesthesia Research Society (NARS) in 1919 that became the International Anesthesia Research Society (IARS) in 1925. The IARS became the umbrella society for McMechan’s other organizations in 1941.

In 1925, The IARS limited membership to physicians, dentists and researchers with advanced degrees, and offered certification to anesthesiologists. Through written communications and travel promoting anesthesiology, McMechan attracted authors, society members and subscribers to *Current Researches*, a vehicle for scientific communication and IARS announcements. Commercial advertising was introduced. McMechan’s wife, Laurette McMechan, acted as Assistant Editor, an indispensable assistance to the wheelchair-bound McMechan.

In the early 1930s, rheumatoid arthritis increasingly crippled McMechan, and Laurette McMechan assumed a growing role in the management of the IARS and *Current Researches in Anesthesia and Analgesia*. McMechan intentionally had placed himself in a seated position so that as his joints fused he retained visual contact with others during his travels [15]. McMechan died on 29 June 1939.

The American Association of Nurse Anesthetists (AANA) and Training of Nurse Anesthetists

Before 1910, informal training programs for nurse anesthesia had developed in the Midwest US, particularly at the Mayo Clinic and Cleveland’s Lakeside Hospital, strongly supported by their respective surgical leaders, the Mayo brothers and George Crile. The threat of The Great War (World War I) prompted St. Vincent’s Hospital, Portland, OR (1909); St. John’s Hospital, Springfield, IL (1912); The New York Post-Graduate Hospital, New York City, NY (1912); and Long Island College Hospital, Brooklyn, NY (1914) to train nurses in anesthesia in 6 month on-the-job programs. A diploma was issued upon completion, but there was no mention of an assessment or a graduation examination.

In 1915, with Crile’s support, Hodgins opened her influential school for nurse anesthetists at Lakeside

Hospital (later part of the Cleveland Clinic). By 1940, Hodgins' school had spawned 54 schools of nurse anesthesia. Training of nurse anesthetists thus began decades before the major development of physician anesthesia training in the US.

In 1916, McMechan unsuccessfully made legislative efforts to prohibit nurse anesthesia, arguing that it allowed nurses to practice medicine. Subsequent statutes in numerous states legalized nurse anesthesia practice, but specified physician supervision of nurse anesthetists. The recent Bush administration modified the supervisory limitation, allowing states to “opt out” of the requirement for physician supervision. By 2012, 17 of 31 eligible states had opted out.

Efforts to suppress nurse anesthesia turned to the courts. In 1917, surgeon Louis Frank with nurse anesthetist Margaret Hatfield sued the Kentucky State Board of Health to test the contention that Hatfield was practicing medicine. Frank and Hatfield won.

In 1923, Agatha Hodgins fostered the formation of the Lakeside Alumni of nurse anesthetists. The Lakeside Alumni would grow, and in 1931 became the National Association of Nurse Anesthetists (NANA) through the efforts of pioneers Hodgins, Helen Lamb, and Gertrude Fife. The NANA was the first specialty nursing organization in the US. Formal education at this time required 4 months training. State nurse anesthetist societies arose concurrently in the US (e.g., Ohio first in 1931). In 1933, the National Association of Nurse Anesthetists published a report (now the ‘AANA Journal’) of their first annual meeting. And NANA president Fife proposed establishing a national board examination for nurse anesthetists.

Before World War II, the American Board of Surgery pressured the NANA to meet with the ABS and the American Board of Anesthesiology, to consider having the ABA approve a training curriculum and certification for nurse anesthetists. Distrust however, caused the discussions to founder, losing an opportunity to strengthen the physician-nurse relationship.

In 1939, the NANA concluded that training required a minimum of 6 months, and that a NANA curriculum needed development, but insistence on specific curriculum content and durations were set aside for the duration of the war. In that year, the NANA changed its name to the American Association of Nurse Anesthetists (AANA).

In 1941, AANA President Shupp suggested that passage of a qualifying examination should define eligibility for AANA membership, and by the mid 1940s, new members were qualified by examination, except for those grandfathered in. In 1945, the first AANA qualifying examination was administered, leading in 1956 to the appellation Certified Registered Nurse Anesthetist (CRNA).

Certification of Physician-Anesthetist Competency: Evolution of the American Board of Anesthesiology (ABA)

In 1931, the NYSA established a Committee on Fellowships, initiating development of a certification process. The Committee incorporated in New York as the “American Board of Anesthesiology” (ABA). The ABA initially only certified local practitioners, precluding recognition by the nationally-based American Medical Association (AMA). In 1935, the ABA accepted anesthetists from 17 states for examination.

Anesthesiology in the US sought recognition by the medical establishment, including recognition of its capacity to certify competency. In 1936, the New York Society became the American Society of Anesthetists. Despite this change, the American Medical Association, the official grantor of certification, would not recognize it as a “regional” society. The next maneuver bypassed the AMA. In 1938, the AMA's Advisory Board for Medical Specialties (ABMS) approved the affiliation of an American Board of Anesthesiology (ABA) with the American Board of Surgery (ABS), a move proposed by Erwin Schmidt, Chief surgeon at the University of Wisconsin, and a friend to Ralph Waters. That is, the ABA became an affiliate board of the already approved ABS. The ABA proposed to examine and certify the fitness of those who met certain standards, and to establish standards for training in anesthesia. Ralph Tovell, Henry Ruth, Emery Rovenstine, John Lundy, Paul Wood, Ralph Waters and others guided this birth of the ABA. In 1939, the AMA Council on Scientific Assembly recommended establishment of a Section on Anesthesia, a recommendation approved by the AMA House of Delegates in 1940. Anesthesia had arrived in the US!

More broadly to the issue of medical education in the US, in 1937 the ABMS created the Commission on Graduate Medical Education, with a mandate to “formulate the educational problems and principles involved in the continuation of medical training for a period of years after graduation and the adequate training of specialists, and to make recommendations for methods whereby those in practice, general and limited, may keep abreast of new developments in diagnosis, treatment and prevention.”

While McMechan was alive, he had promoted certification of specialists in anesthesia by the IARS. This and the condemnation of non-physician anesthetists had separated his and ASA organizations, and precluded collaboration in forming the ABA. Once the ABA was formed, IARS certification gradually became irrelevant. The IARS Board rejected a proposed amalgamation with the ASA, continuing two societies, two annual meetings and, ultimately, two journals.

In 1939, the American Board of Anesthesiology became an independent board and certified 9 diplomats by examination. This number would increase to 105 by 1940 and 706 by 1950.

The ABMS now required at least three years of post-graduate training, a few years in practice, and the successful completion of written, oral, and practical examinations to achieve diplomate status. Thus, while medical schools and teaching hospitals controlled US undergraduate educational experience, the professions themselves governed graduate medical education.

In 1944, the ABA made two years of approved anesthesia training mandatory for credentialing—except that credit was given for military anesthesia practice. Saklad questioned the reliability of ABA essay examinations. The horde of military anesthesiologists returning to civilian practice after World War II made the issue moot; grading essay examinations became impractical.

In 1945, Meyer Saklad also questioned the validity of ABA oral examinations because the examiners chose the questions asked. This issue recurred over the years, causing a transition to a Guided Question (all candidates are questioned about the same clinical scenario) format in the 1960s. One of the editors of this book (LJS) recalls fondly his oral exam taken before the development of the Guided Question. Fully one half of his exam dealt with inhaled anesthetic pharmacokinetics, this occurring after he had spent a year as research fellow with Ted Eger. In the 2000s, computers applied algorithms that compensated for the bias imposed by harsher versus more lenient examiner grading and by more difficult questions.

Veterinary Anesthesia

Initially, some veterinarians hesitated applying anesthesia, viewing the struggles during induction of anesthesia as reflecting pain. In addition, large struggling animals might endanger both animal and veterinarian. Once past the induction, however, animals became quiescent, and veterinarians increasingly used anesthesia, doing so initially as much to immobilize as to relieve pain. Although they initially questioned whether anesthesia prevented or caused pain, veterinarians came to accept that anesthesia prevented the perception of pain. The 1876 Cruelty to Animals Act restricted the use of animals in experiments to licensed persons who had obtained Home Office permission for particular procedures.

In 1915, Louis Merillat noted the increased use of anesthesia to relieve pain rather than produce restraint. In the same year, Frederick Hobday published the first English textbook devoted exclusively to veterinary anesthesia, *Anaesthesia and Narcosis of Animals and Birds*. In 1919, the British Parliament enacted an Anaesthetics Bill for Animals, specifying that anesthesia must "...prevent the animal feeling pain". A much later (1964) Anaesthetics Bill allowed flexibility in anesthetic choice as long as it produced "adequate anaesthesia".

In 1924, Bemis and colleagues published a summary of contemporary regional nerve blocks in horses [16]. Smith-cors noted that, "It remained for veterinarians Retzgen of Berlin [and also Pape and Pitzch] in 1925, and Franz Benesch of Austria in 1926, to demonstrate in horses and cattle respectively, that epidural anesthesia with the needle introduced distal to the spinal cord proper, was a safe technique." [17] Other reports of regional anesthesia appeared later, surprisingly, for surgery in large animals.

In 1937, one of the giants of veterinary medicine, Wright, first used thiopental intravenously in animals. In 1941, Wright's first edition of *Veterinary Anaesthesia* laid the foundations of *modern* veterinary anesthesia. It was a well-received book. In 1961, Wright and LW Hall (of Cambridge University) co-authored the 5th edition.

Anesthesia Subspecialties

Obstetric Anesthesia

Twilight sleep, the state resulting from the intramuscular injection of scopolamine and morphine, had been introduced in Europe in the first decade of the twentieth century, for use in labor and delivery. In 1914, US women organized the National Twilight Sleep Association in the US, successfully bringing this popular European technique to North America. However, the amounts of morphine were often insufficient to minimize pain. Laboring women might thrash and scream yet reported a pain free birth experience because the scopolamine suppressed memory. In 1915, a prominent advocate of the approach died during childbirth, having received twilight sleep. This brought the National Twilight Sleep Association to an end. Nonetheless, twilight sleep remained in use in a few US hospitals until the 1960s.

In the 1920s, one in two hundred (0.5%) British women died during childbirth. This unacceptable mortality led a group of British women in 1928 to form the National Birthday Trust Fund, that aimed to reduce the mortality and make modern pain relief during childbirth available for all women.

In 1940, Bert Hershenson was the only full-time obstetrical anesthesiologist in the US. He established the first US Division of Obstetric Anesthesia at the Boston Lying-In Hospital in 1942, and wrote the first textbook devoted solely to obstetric anesthesia. Weiss, a successor to Hershenson in Boston, advocated the use of epidural analgesia. Also in 1940, continuous spinal anesthesia developed in the US with William Lemmon's malleable needle that could be left in place after insertion. And Virginia Apgar became treasurer of the ASA, the last woman to serve as an ASA Officer for the next 27 years.

In 1942, Robert Hingson and Waldo Edwards adapted Lemmon's malleable needle for injections into the caudal

canal and for extended analgesia for labor and delivery. Hingson later taught the technique to Gertie Marx, the grand dame of obstetrical anesthesia.

Pediatric Anesthesia

Returning from service in World War I, Charles Robson, became Anaesthetist-in-Chief at Toronto's Hospital for Sick Children in 1919, continuing in that role for 3 decades. Recognized as the father of pediatric anesthesia, he defined the major problems extant in pediatric anesthesia—and their solutions.

In 1945, Bob Smith became head of pediatric anesthesia at Boston Children's Hospital, noting that chief nurse anesthetist Elizabeth Lank “made me a pediatric anesthesiologist.” Smith's program changed the world of pediatric anesthesia.

Regional Anesthesia and Pain Management

In 1921, Spanish surgeon Fidel Pagés-Miravé described the lumbar epidural injection of local anesthetic. A decade later, Italian Achille Dogliotti popularized the technique. It may have been more than that. A colleague of Cedric Prys-Roberts claimed that he saw Dogliotti operating on the thyroid gland under cervical epidural anesthesia (personal communication, 15 Nov 2012).

In 1924, William Mayo invited John Lundy to develop the anesthesia department at the Mayo Clinic. The changes that he introduced included the increased application of regional anesthesia. In 1935, Emery Rovenstine succeeded Gaston Labat at Bellevue and applied regional techniques to treat pain, initiating a movement that gained momentum in the second half of the century.

Thus, in the 1920s and 1930s, regional anesthesia had begun with Lundy, Labat and Rovenstine in the Eastern and Midwest portions of the US. Earlier it had been advanced by European surgeons. Perhaps the biggest boost came in the US Northwest after World War II. In 1947, John Bonica was appointed chief of the Department of Anesthesiology at Tacoma General Hospital where he established a multidisciplinary team to manage chronic pain. He subsequently pioneered regional anesthesia techniques for labor pain relief, later writing arguably the most comprehensive textbook on regional anesthesia [18]. He devoted the last part of his career to the relief of chronic pain, a deeply personal endeavor. More about that later. At approximately the same time, senior surgeons at the Virginia Mason Clinic in Seattle hired Daniel Moore to supply anesthesia for increasingly complex surgical procedures. Moore established a residency in anesthesia in 1948, and by 1953, 50% of patients undergoing surgery at the Clinic received regional anesthesia.

Fig. 6.1 The cumulative increase in the number of books (first editions) on anesthesia accelerated after World War II. (Data from Keys' History of Surgical Anesthesia.)

Books and Journals

Books

Books can be the repositories of accrued knowledge, and as such reflect the growth in knowledge. They may also indirectly reflect the numbers of parties interested in a field of knowledge. Keys' History of Surgical Anesthesia indicates first editions of published books focused on anesthesia. A cumulative graph of their numbers (Fig. 6.1) suggests a rough parallel to the growth in the number of anesthetists.

The following gives a chronology of some of the books published between 1910 and 1950: In 1915, Frederick Hobday published the first English textbook devoted exclusively to veterinary anesthesia, *Anaesthesia and Narcosis of Animals and Birds*. A year later, Norwegian Nils Groendahl published the first Nordic anesthesia textbook—for nurses—and by 1920, nurse anesthetists gave most anesthetics in Nordic countries. In 1920, Charles Mayo recruited Frenchman Gaston Labat, to the Mayo's clinic where Labat wrote his famous textbook on regional anesthesia. At the clinic and later at Bellevue Hospital, Labat introduced the regular use of regional anesthesia. In 1923, The first pediatric anesthesia textbook “Anesthesia in Children” was published in GB. Bert Hershenson at the Boston Lying-In Hospital published the first textbook devoted solely to obstetric anesthesia in 1942. “Anaesthetic Methods” was published in 1946. Written by Geoffrey Kaye, Robert Orton, and Douglas Renton, it was the second and most important anesthesia textbook in Australia and New Zealand.

Fig. 6.2 The cumulative number of anesthetic journals launched between 1910 and 1950 rectilinearly increase. (Data from Chapter 34)

Journals

Individuals and anesthetic societies contributed to advancement of knowledge by the publication of such knowledge in journals as well as books. Seven or more journals were launched in the period between 1910 and 1950 (Fig. 6.2).

In the 1910s, Joseph McDonald, managing editor of the ‘American Journal of Surgery’, had mentored Francis McMechan who edited a ‘Quarterly Supplement’ ‘Anesthesia and Analgesia’. When McDonald died in 1922, McMechan created the National Anaesthesia Research Society (later the International Anesthesia Research Society) which in August 1922 first published ‘*Current Researches in Anesthesia and Analgesia*’, the predecessor of *Anesthesia & Analgesia*, the world’s first major anesthetic journal. In 1925, the International Anesthesia Research Society (IARS) succeeded the National Anesthesia Research Society, becoming the owner and publisher of *Current Researches in Anesthesia and Analgesia*.

Hyman Cohen, a soldier in the US Army, married a Manchester girl in 1904, entered medical school at St Bartholomew’s Hospital in London, graduated in 1916 and became a full-time anesthetist. In 1923 he initiated the *British Journal of Anaesthesia* “devoted entirely to the interests of anaesthesia and its practitioners”, continuing as editor from 1923 to 1928.

The journals, *Der Schmerz*, and *Narkose und Anaesthesie*, formed in 1928, merging to *Schmerz, Narkose und Anaesthesie* in 1929, and lasting until 1943. These added to pressures in Germany to specialize in anesthesia, but influential surgeons rejected the idea, and World War II stopped discussion and publication. In 1935, The French Society of Anaesthesia and Analgesia launched ‘*Anesthésie et Analgésie*’. In 1939, ‘*Revista Argentina de Anestesia y Analgesia*’, perhaps the

first multinational anesthesia journal, began publication in Buenos Aires.

Out of respect for McMechan, the ASA had refrained from publishing a journal that would compete with *Anesthesia & Analgesia*, but with his death in 1939, publication of *Anesthesiology* soon followed. The first edition appeared in June 1940 with Henry Ruth as editor.

The Jan–Feb 1940 issue of *Current Researches in Anesthesia and Analgesia* announced Howard Dittrick’s appointment as Directing Editor. He was a physician (a gynecologist) with a background in medical editing, but was not an anesthesiologist. With Dittrick’s appointment, the IARS Board of Governors became the Editorial Board and confirmed Laurette’s continuing roles as Assistant Executive-Secretary-Editor. *Anesthesiology* provided stiff competition to *Current Researches in Anesthesia and Analgesia*, dominating it as a repository for important clinical and basic research for the next 50 years. World War II added to *Current Researches in Anesthesia and Analgesia*’s difficulties. The Journal continued bimonthly publication throughout the 1940s, but the numbers of society members and subscribers declined. Having a non-anesthesiologist serve as Editor-in-Chief may have contributed to the diminished position of the Journal.

Anaesthesia, the Journal of the Association of Anaesthetists of Great Britain and Ireland was founded in 1946.

The Rise of Academic Departments

At the Turn of the Century

In the latter part of the 1890s, a few US anesthesiologists assumed teaching and leadership roles. Two women established the beginnings of what might be thought of as departments in the early 1900s. Isabella Herb practiced anesthesia at Augustana Hospital in Chicago, in 1922 becoming president of the first nationwide anesthesia society, the American Association of Anesthetists (AAA). In 1898, Mary Botsford practiced anesthesia at the Children’s Hospital of San Francisco. In 1922, she led the effort to found the Anesthesia Section of the California Medical Association, and was its first president. In 1930, Botsford became president of the Associated Anesthetists of the United States and Canada, an organization that evolved from the AAA.

Three World Leaders in Anesthesia

Although many giants contributed to the development of the specialty in the 1930s, three stand out, leaders who dramatically expanded the depth of training, clinical care, and research in anesthesia. These were Ralph Waters, Henry Beecher, and Robert Macintosh.

A chance visit by Ralph Waters to the University of Wisconsin, and the desire of the then chair of surgery, Erwin Schmidt, to improve the quality of anesthetic delivery at Wisconsin, led to Waters' appointment as an Assistant Professor of Anesthesia in January 1927. Surgery was beginning to repay its debt to anesthesia! Waters thus chaired the first department of anesthesia (as opposed to a division of a department of surgery) in the US [13]. (¹However, an alternative "first" may exist.) [19]

Waters developed an academic department dedicated to optimum patient care, education of medical students and interns, post-graduate education, and research into the scientific foundations of anesthesia. Roughly following the example set by departments of surgery, he created a 3-year post-graduate residency program. He expected graduating residents to serve as leaders, thereby imposing his vision for academic anesthesia across the country. His graduates, and, in turn, graduates of their programs established most US academic programs. For example, Saidman, an editor of this book, held the chair at the University of California, San Diego. He traced his academic heritage back through Stuart Cullen (UCSF), through Emory Rovenstine (Bellevue), and then to Waters (U Wisconsin). The University of Wisconsin residency program also served as a model for early programs in GB and Canada.

In contrast to Waters' emphasis on clinical care, the second great department in the US emphasized research. In 1936, Harvard appointed a partially trained surgeon, Henry Beecher, as an instructor in anesthesia and, incidentally, the Anesthetist-in-Chief in the Division of Surgery. That is, Harvard designated someone with no training in anesthesia to oversee anesthetic delivery.

"Beecher responded to the challenge by teaching himself how to give anesthetics, by writing a textbook on *The Physiology of Anaesthesia*, and by introducing the basic principles of laboratory research to the clinical practice of anesthesia. His efforts were rewarded when he was appointed Henry Isaiah Dorr Professor of Research and Teaching in Anaesthetics and Anaesthesia, a Chair that had been funded originally in 1917. In 1938, he thus became the first incumbent of the first Chair to be endowed in anesthesia." [13]

"Dr. Beecher's 'hands on' clinical performance was not the cause of many accolades."² Conversely, Beecher was a su-

¹Dr. Jane Fitch and her associate, Dr. Vaidy Rao, noted to EIE that the University of Oklahoma should be given recognition as one of the earliest—if not the first—departments of anesthesia. "This department was not organized until 1930, at which time John Alfred Morrett, M.D., became its head, from 1930 to 1938...Floyd Jackson Bolend, M.D... (was)...head of the hospital Department of Anesthesia until 1930, at which time the School of Medicine's Department of Anesthesiology was formed."

²George E. Battit: Henry K Beecher and the Early Years of the Anesthesia Service. Chapter 5 in the privately published book "This is No Humbug!" edited by Richard J. Kitz.

perb investigator whose work reflected well on anesthesia. He advanced our understanding of the power of the placebo [20]. He observed that the brain controlled the perception of pain [21]. He gave us one of the first outcome studies (more about that later), a study that stands today as one of the best of its kind, one showing that anesthesia could kill patients [22]. And finally, he established ethics as an important arm of anesthesia and medicine (more about that, too, later) [23]. He truly was a giant.

Academic anesthesia in GB owes much to bicycles built by William Morris (Lord Nuffield) [13]. His successful business morphed into the profitable production of automobiles, first the Morris Bullnose that went 50 mph, got 50 miles to the gallon, and defeated Ford in Great Britain. Fortunately for anesthesia, Morris enjoyed golf and purchased the Huntercombe Golf Club, a club frequented by physicians, including New Zealand born anesthetist, Robert Macintosh. Morris wished to found a school of medicine at Oxford and told his physician friends that he intended to underwrite the establishment of chairs in medicine, surgery, and obstetrics, the then dominant triumvirate. Macintosh smiled and asked why anesthesia had been omitted? Morris had been pleasantly anesthetized by his friend Macintosh, and after a bit of reflection, Morris added a fourth—an anaesthetic—chair to his potential bequest. Oxford first refused (anesthesia was unworthy) but relented when Morris threatened to withdraw his offer for all of the endowment. He also sweetened the bequest from 1.2 million pounds to 2.0 million pounds. So was born the Nuffield Chair of Anaesthetics in 1937, the first occupant being Macintosh, later Sir Robert. World War II dictated a clinical direction for the first years of the department, and only after that war did Oxford contribute information vital to the basis for anesthesia, continued under the guidance of Sir Keith Sykes, one of the contributors to the present history.

Why Waters, Beecher, and Macintosh? Is it the Willie Sutton Principle? Recall that Sutton, a bank robber, was asked why he robbed banks? Answer: "Because that's where the money is!" Waters, Beecher, and Macintosh because that's where the physician-anesthetists of the world were—half in the US and much of the rest in GB.

1910–1950: Diverse Anesthetic Developments in Various Parts of the World

Australia-New Zealand

In 1929, in Australia only Rupert Hornabrook and Fred Green in Melbourne, and Gilbert Brown in Adelaide were full time anesthetists. Geoffrey Kaye, a young and enthusiastic doctor had shown a keenness for anesthesia, despite it being considered "suitable only for the physically unfit or

the unambitious”. He attended the Australasian³ Medical Congress, which had newly established a section of anaesthetics, and met Francis McMechan. He was to become McMechan’s protégé leading to lifelong communication with Waters, McKesson, Lundy and others. In 1932, *Practical Anaesthesia*, the collated work of several anaesthetists, edited by Kaye, appeared in Australia.

In 1934, the Australian Society of Anaesthetists was founded. A diploma course began at Sydney University in 1944, and at Melbourne University in 1946. In 1946, Kaye established the teaching centre at Melbourne University, together with a library and museum, and in 1948, Kaye assisted in forming The New Zealand Society.

In 1949, Harry Daly, President of the Australian Society of Anaesthetists, negotiated with the College of Surgeons (representing both Australia and New Zealand) to establish the Australian Faculty of Anaesthetists.

Great Britain and Ireland

In 1932, Henry Featherstone and Ivan Magill guided the founding of the Association of Anaesthetists of Great Britain and Ireland (AAGBI).

In 1935, Magill assisted in the inauguration of the Diploma in Anaesthesia (DA), awarded by the Anaesthetic Section of the Royal Society of Medicine. The Diploma was not quite awarded by anaesthetists [13]. Magill and the Association of Anaesthetists of Great Britain and Ireland struggled to provide the diploma, but it could not be awarded by the Association because the Association was not “an Examining Body”. To bypass this impediment, a Conjoint Board of the Royal Colleges of Physicians and Surgeons (surgeons again to the rescue) conducted the examination. Anaesthetists gained control of the process after World War II, in 1948.

Soon after the conclusion of World War II, universities at Bristol (1946), Newcastle-upon-Tyne (1949), Cardiff (Welsh National School of Medicine; 1952) and Liverpool (1959) created Departments of Anaesthesia. Cecil Gray and his colleagues popularized the use of curare (d-tubocurarine), creating the ‘Liverpool technique’ a forerunner of balanced anaesthesia. Research blossomed in support of new surgeries that required controlled ventilation and circulation.

In 1948, AAGBI Diplomates were in place when anaesthesia was recognized as a medical specialty in GB. The Faculty of Anaesthetists formed within the Royal College of Surgeons, and the Fellowship Diploma was instituted (FFARCS). AAGBI representations to the Spens Committee led to equal status and pay of the all-too-few anaesthetists with other hospital-based specialists.

³ Australasia refers to Australia and New Zealand, as in the Royal Australasian College of Surgeons.

France

In 1934, the French Society of Anesthesia and Intensive Care (originally the Société Française d’Etude de l’Anesthésie et de l’Analgésie—name changed to the current one after 1957) was founded, but became inactive during World War II. It was reborn in 1946, the Société Française d’anesthésie et d’analgésie (SFAA) with 117 members, mostly French surgeons but including 17 anaesthetists.

Until 1947, surgeons directed anaesthesia and received all fees, with about 10% given to “assistants”. Anaesthetists provided all drugs and equipment, prompting the use of the least expensive approaches to anaesthesia. In 1947, the newly created Chair of Surgical Techniques in Paris assembled a 6-week course supplemented by a 6-month hospital assignment supervised by surgeons or physicians. Students (doctors and nurses) completing this course received a “Certificate of Anaesthesia”. Article 45 of the code of practice gave the French “surgeon... the right to choose his operating assistants as well as the anaesthetist.” Anaesthesia was only a “competence”. From 1947, “Special anaesthesia” given by a qualified anaesthetist was paid separately from the surgeon’s fee. Progress!

In 1948, examinations were added to the 6-month course for doctors, leading to award of the Diplôme d’Anesthésie-Réanimation (Diploma in Anaesthesia and post-operative care). French nurse anaesthetists continued to receive the Certificate of Anaesthesia, which now required successful completion of a written examination. From 1948 to 1973, nurse anaesthetist training schools opened in France and trained 1500 students. From 1960, almost all cities with universities had a nurse-anaesthetists school. Passage of an examination led to the *Certificat d’Aptitude aux Fonctions d’Aide Anesthésiste*. Like physicians, nurse anaesthetists organised training programs and trade unions, and worked in accordance with statutes that they had devised. They competed with doctors, producing antagonisms yet to be resolved. However, in contrast to the case in the US, they could not work independently.

Nordic Countries

Having trained with Beecher in 1938, in 1940, Torsten Gordh introduced anaesthesia training in Sweden, occupying the first position established for an anesthesiologist in Scandinavia and mainland Europe, at the Karolinska Hospital in Stockholm. Then and in subsequent years, nurses (learning from on-the-job experiences) gave anaesthesia in Nordic countries and surgeons carried the responsibility. Many surgeons argued that anaesthesia should be established as a medical specialty, and positions for physician anaesthetists were increasingly funded in major hospitals. Pioneer Nordic

anesthesiologists usually trained abroad. They included Trier Mørch and Ole Secher (Denmark); Eero Turpeinen (Finland); Elias Eyvindsson (Iceland); Otto Mollestad and Ivar Lund (Norway); and Gordh (Sweden).

Nordic societies were established soon after World War II: the Swedish Society of Anesthesiologists was founded in 1946; the Norwegian Association and the Danish Anesthesia Association in 1949; the Finnish Society of Anesthesiologists in 1952; and the Icelandic Society of Anesthesia and Intensive Care in 1960. In 1949, Nordic pioneers founded the Scandinavian Association of Anesthesiologists.

And in Other Parts of Europe

With the return to peace after World War II, 1-to-3 year anesthesia training programs arose in Europe. The average mandated period was 2 years, matching that in the US and focusing on anesthetic delivery. In 1947, the Dutch organized a national training curriculum, and the Unitarian Service Committee sent American anesthesiologists to Austria, to lecture on and demonstrate modern anesthetic techniques.

In 1948, the Netherlands Society of Anesthesiologists was founded and anesthesia was recognized as a specialty. The Belgians and Italians began training courses.

In 1949, the World Health Organization (WHO) and Denmark (Copenhagen) jointly established a one-year course for anesthesiologists in theoretical and practical techniques of delivering anesthesia. This successful course was repeated 23 times, continuing to 1972.

While working in Germany, in 1949, American anesthetist Jean Henley completed the first modern German anesthesia textbook, *Einführung in die Praxis der modernen Inhalationsnarkose (Introduction to the Practice of Modern Inhalation Anaesthesia)*. German authors soon followed suit. In 1981, the German Society of Anesthesiology and Intensive Care Medicine awarded Henley an honorary membership.

Latin America

The Mexican Society of Anesthetists was founded in 1934. In Brazil, aspects of training in anesthesia were established and expanded to the first Brazilian specialty school in 1941. By 1946, Mexico was sufficiently large to organize its own congresses, while other Latin American countries joined regional organizations. In 1947, Marín founded the first “*School of Anesthesia*” for Columbian physicians, and teaching of clinical anesthesia began in Uruguay. In 1948, Vicente García Olivera created the first center for pain treatment in Mexico.

Far East

In 1934, the Nippon Dental Junior College initiated the first anesthesia department in Japan.

World War II and the following civil war had devastated China. Anesthesiology had to rebuild from the basic delivery of open-drop ether or chloroform or regional/spinal anesthesia. It spread outward from Shanghai and Beijing. Physicians, students, nurses, nuns, and technicians, and only a few professional anesthesiologists (e.g., Yueqing Ma from Peking Union Medical College) delivered anesthesia. The founders of Chinese anesthesiology (Jone Wu and Xingfang Li from Shanghai; Deyan Shang, Rong Xie and Huiying Tan from Beijing) returned from the US and Europe with modern ideas concerning anesthetic delivery. Shang established the first Department of Anesthesiology in China in the National Lanzhou Hospital.

New Delivery Systems and Drugs

Devices for Delivery of Nitrous Oxide (with or without Ether) Anesthesia

The first anesthetic by Horace Wells delivered 100% nitrous oxide from a bag, thereby imposing hypoxia—interrupted by periods of inadequate anesthesia while the patient breathed room air. The former of these troublesome limitations could be dealt with as Edmund Andrews suggested in the 1860s, by adding oxygen to the nitrous oxide. Over the succeeding 30–40 years various advancements led to gas machines, such as that invented by Teter (a dentist) in 1902, that delivered a variable mixture of oxygen and nitrous oxide, each controlled by separate but inaccurate valves and without an indication of percentage or flow. Kupperts’ 1908 invention of the rotameter allowed delivery of a precisely measured gas flow and known oxygen/nitrous oxide concentrations. The German, Neu, used rotameters to precisely deliver readable flows of anesthetic gases from the Rotameter Company’s new anesthesia machine. Other machines in the 1900s allowed the addition of ether or chloroform to compensate for the limited potency of nitrous oxide.

In 1915–16, Dennis Jackson described a carbon dioxide absorption system for delivery of rebreathed anesthetic gases [24, 25]. This was not immediately widely applied but laid the groundwork for modern anesthetic delivery. Jackson had suggested the use of the circle absorption system but used a solution of base to accomplish carbon dioxide absorption—an impractical solution.

By 1920, Dräger machines could deliver nitrous-oxide-oxygen-ether (the so-called gas-oxygen ether or GOE anesthetic). Gauss gave acetylene as an anesthetic, but explosions limited its acceptance. The high import costs of nitrous-oxide

Fig. 6.3 A photograph of a later version of the McKesson Nargraf machine. (Courtesy of the Wood Library-Museum of Anesthesiology, Park Ridge, IL)

led to the use of rebreathing to minimize its consumption. In 1923, Waters introduced the to-and-fro carbon dioxide absorption system allowing low gas flows and rebreathing.

In 1925, Drägerwerk of Germany developed the first circle breathing system for use in their Model A anesthesia machine. There were separate hoses for inhalation and exhalation; large, low resistance, thin mica unidirectional valves that forced the gases to move in a circle; a cartridge for the soda lime; a reservoir bag, and a pressure-limiting valve—all the ingredients found in modern circle systems.

However, in 1930, McKesson departed from the direction of anesthetic equipment development described above by introducing the McKesson-Nargraf machine (Fig. 6.3). It could (deliberately) deliver lethal concentrations of oxygen, as suggested by an experience reported by Gerald Zeitlin [26]:

“Let’s return to the Whittington Hospital on the high and leafy hills of North London. The Senior Consultant in Anaesthesia was named Otto by his parents, the Belams. I called him ‘Sir’. One quiet afternoon Dr. Belam asked me if I would kindly replace him at a dental surgeon’s office in a shopfront in nearby Holloway Road.

“All she needs for her extractions is some gas from a McKesson machine. She keeps open on Wednesday evenings for the working men. She is very quick. Get there just before six.”

“The dentist was a middle-aged lady with frosty hair. She met me in her empty waiting room.

“Otto phoned me you’d be coming. Go in there and fiddle with his machine. The first one’ll be here in ten minutes. No fillings. Just exodontia on Wednesday evenings.”

“I had never seen such an anesthesia machine before. I ‘fiddled’ with it. I peered at the dial at the top. This indicated that by turning the dial one could deliver a mixture of two gases, in precise percentages from zero to one hundred; or from one hundred to zero. Very ingenious. And it made sense, to be able to vary

precisely the percentage of oxygen the patient breathes. I read an engraved label indicating that the McKesson Company in Toledo, Ohio, had made it. I had never encountered an American machine before. I stood back to gain perspective.

“Then I saw the ugliness of my situation. The only two gas cylinders attached were one each of nitrous oxide and oxygen. Nitrous oxide is a very weak anesthetic agent: so feeble at rendering people unconscious that it has become known as ‘laughing gas’, that is, it makes you drunk and giggly. Never before had I given it without adding something more potent, ether and more recently, halothane.

“Dr. Frosty the dentist introduced me to the first patient, a muscular builder still in his paint-covered overalls. He was sweating, not from exertion but fear. Anesthesia for dental surgery requires the patient to breathe a gas mixture from a mask that fits over the nose but leaves the mouth accessible. I cursed myself for not even thinking of asking Dr. Belam about taking some Pentothal for intravenous use. I must have been mesmerized by that phrase so rarely used by anesthesiologists about surgeons, ‘She’s quick.’

“I applied the nasal mask and dialed a 90% nitrous, 10% oxygen mixture.

“‘Please take some deep breaths through your nose,’ I said. And he did. He closed his eyes but continued to sweat. My free hand counted his pulse rate: about 110 beats per minute. He was not frightened. He was terrified.

“‘Shall I begin?’ she asked.

“‘Yes,’ I said because I did not know enough to choose between ‘yes’ or ‘no’ and ‘yes’ seemed more optimistic. I am known as an optimist.

“‘I can’t even open his mouth. Anyway he’s too pink. Otto gets them very black and then they relax and I can get the bite-block in—to keep his mouth open,’ she said kindly.

“‘I cut the oxygen to 5%. To put it another way, I increased the nitrous oxide to 95%. I felt nervous. My hand holding the nose mask felt shaky.

“‘What are you going to do? He’s still pink and his teeth are clenched,’ she said less kindly.

“‘I dare not give him any less oxygen. I’m afraid to.’

“‘Well Otto is not, so why are you? You are no use to me. Go back to the hospital and tell Otto not to send me people without experience. I’ll use local, but all these big men hate needles,’ she said without any kindness at all.”

Zeitlin continued, describing McKesson’s technique of “secondary saturation”, a euphemism for producing profound hypoxia by administration of 100% nitrous oxide for a few minutes and then supplying sufficient oxygen to sustain life. The combination of nitrous oxide and hypoxia was akin to a blow to the head and rendered the patient unconscious, relaxed, and, sometimes brain injured as Zeitlin found in his reading of Courville’s book [27]. EIE remembers the urban legend suggesting that the IQ of the citizens of Toledo where McKesson built his machines, was less than that in other parts of the US.

A Simple Anesthetic System with Wide Application

In 1937, Ayre in GB described his use of a simple “T”-piece for endotracheal anesthesia in children. Patients breathed

spontaneously from this device although a “sigh” could be provided by occluding the expiratory limb. (Care was needed, however, to avoid overexpansion of the lungs). Ayre had a cleft lip and palate, speaking with a “honking” sound that mesmerized children when he induced anesthesia. Later, this simple device was modified by Jackson Rees by adding tubing and a bag—a modification commonly used today to provide anesthesia for children or to provide supplemental oxygen to patients in transit from the OR to the PACU or ICU.

The Heyday of the In-circuit Vaporizer

In a circle system, the vaporizer can be located inside the breathing system (“in-circuit”) or outside the system. Produced and sold from the late 1930s to the 1960s, the Ohio #8 bottle was the most popular in-circuit vaporizer in North America. Its sister, the Goldman, was used throughout the rest of the world. Both were potentially dangerous because increased ventilation increased the passage of circulating gases through the vaporizer. That was fine if ventilation were spontaneous and if the anesthetic depressed breathing because the depressed ventilation would prevent the delivery of more anesthetic. But if the anesthetist controlled ventilation manually, then all bets were off and the anesthetist could rapidly deliver sufficient anesthetic to produce cardiac arrest. This potential risk increased when using anesthetics having relatively low blood solubility, high potency, and high vapor pressure (halothane for example) were employed in the in-circle device in a patient whose ventilation was being controlled. With controlled ventilation a delivered concentration approaching the saturated vapor concentration (33% in the case of halothane) could theoretically be delivered within seconds or minutes, potentially leading to cardiac arrest [28].

A New Vaporizer, the Copper Kettle

In 1943, Lucien Morris graduated from Western Reserve Medical School. Chance and personal interest lead him to chemistry and medicine, to Ralph Waters and an anesthesia residency that he pursued after World War II, and to the invention of the Copper Kettle.

In 1947, during his second year of residency, Lucien Morris participated in the ongoing departmental study of chloroform as though it were a new anesthetic agent. The poor control over chloroform vapor concentration frustrated him, and he foolishly lamented that “anyone ought to be able to make a better vaporizer than this”. Waters took him up on his complaint and persuaded him to deal with the issue. Morris applied the principles that John Snow used a century earlier: adequate anesthetic vaporization and control over vapor pressure. He added the goals of delivery of a known con-

centration of anesthetic at a measured fresh gas inflow rate. As did Snow, Morris controlled the anesthetic temperature, and thus its vapor pressure, by housing it in a copper sump. He delivered two precisely known flows—one to the sump and the other bypassing the sump. Flow through the sump passed through a sintered bubbler, ensuring complete vapor equilibration with the flow. Knowing the liquid anesthetic temperature and the two flows allowed a precise calculation of the anesthetic concentration delivered to the circle system. In 1948, the Foregger Company of New York delivered the first prototype Copper Kettle to Morris.

New Inhaled Anesthetics Are Developed and Old Ones Studied

Ethylene

The development of the anesthetic machine enabled the use of anesthetics not heretofore applied. Having noted that ethylene in illuminating gas “put carnations to sleep”, Arno Luckhardt demonstrated that it also put animals to sleep. In 1923, Luckhardt and Carter introduced ethylene as an inhaled anesthetic at Presbyterian Hospital in Chicago [29]. “I (EIE) gave this smelly (like garlic) gas in that hospital only three decades later, perhaps in the same room. I wonder.” Ethylene was sufficiently more potent than nitrous oxide, such that at an effective concentration, e.g. MAC [30], normoxia (normal hemoglobin oxygen saturation) could be maintained. It may therefore have satisfied Dr Frosty without scaring Dr Zeitlin. However, it was explosive, and that combined with its disagreeable odor resulted in a relatively short life as a clinical anesthetic.

Divinyl Ether, the Designer Anesthetic

Most anesthetics were discovered by happenstance, but a few were discovered by design. In 1930, pharmacologist Chauncy Leake (with M-Y Chen) noted that ether (diethyl ether) consisted of two ethanes joined by an oxygen. Further, he noted that ethylene (an ethane from which two hydrogens had been removed) was more potent than ethane. How about, he thought, substituting ethylenes for the ethanes in diethyl ether? [31] The resulting compound, divinyl ether, was more pleasant and far more rapid-acting than diethyl ether [32]. It was typically used to induce anesthesia, followed by diethyl ether to maintain anesthesia. EIE used divinyl ether for more than a decade. No matter that it also caused mutations [33], and was probably a carcinogen (who knew?) And there are stories about convulsions with divinyl ether. Leake was a character, beloved by some and sneered at by a few.

Cyclopropane

In 1933, Waters gave cyclopropane in clinical practice [29, 34], using his to-and-fro rebreathing technique for carbon

dioxide absorption [35] so that he could deliver just a small volume of this expensive and explosive gas. Cyclopropane became the “champagne” of anesthetics: It had no pungency, it was potent (could cause anesthesia all by itself), and it produced anesthesia rapidly, in part because it had a limited solubility in blood. The low solubility meant that the body didn’t soak up a lot of molecules before becoming sufficiently full. Unlike most inhaled anesthetics, cyclopropane did not depress blood pressure—desirable in patients at risk of hypotension from hemorrhage or decreased cardiac function. However, hypotension (also called cyclopropane shock) might appear at the end of surgery as the cyclopropane was withdrawn, perhaps because the removal of cyclopropane decreased the stimulation of sympathetic tone.

The low solubility and absence of pungency made cyclopropane a marvelous induction anesthetic. When faced four decades later with a need to anesthetize volunteers with ether for studies of that anesthetic’s effects on breathing and the circulation [36, 37], EIE used cyclopropane to induce anesthesia, telling the volunteers that if they just took 10 breaths, they would be asleep (and then he’d turn on the smelly, pungent ether with no problem). He lied. It only took 3 breaths. Wham! What a neat anesthetic—except that if a spark happened nearby it blew up, killing patient and anesthetist, too. Even so, cyclopropane continued as one of the significant anesthetics in the US through the 1950s.

The Atomic Bomb Advanced Fluorine Chemistry and Made Modern Inhaled Anesthetics Feasible

From 1943 to 1945, fluorine chemistry advanced consequent to the need for separation and purification of uranium isotopes to make an atomic bomb in the Manhattan project. The process attached 6 fluorines to each uranium atom and thereby converted the uranium into gases. The gaseous isotopes then were separated by centrifugation. The knowledge gained in fluorine chemistry ultimately enabled development of what we call the modern inhaled anesthetics, compounds halogenated with fluorine to eliminate flammability. Methoxyflurane was synthesized incidentally as part of the Manhattan project but was not thought of as an anesthetic. However, we did get halothane, enflurane, isoflurane, desflurane, and sevoflurane—and Teflon®.

New Local Anesthetics and Their Uses

Dibucaine

In 1925, the local anesthetic dibucaine, was synthesized to overcome difficulties with procaine, allergy and short duration. It was clinically useful but displayed a narrow therapeutic ratio. Dibucaine later found a use in the diagno-

sis of the cause of prolonged neuromuscular blockade from succinylcholine (the dibucaine number).

Lidocaine

Swedes Nils Löfgren and Bengt Lundqvist synthesized lidocaine in 1943, and Torsten Gordh studied it in volunteers and patients in 1945, leading to its clinical release. Lidocaine acted faster with longer anesthetic effects than procaine, and did not produce allergic reactions. As we shall see, Swedish scientists developed new local anesthetics into the last half of the twentieth century and were key to increasing the use of regional techniques.

Local Anesthetics as General Anesthetics

In Buenos Aires, Gregorio Aranés and Ivar Castellanos reported “*Brief observations on anesthesia with Pentothal Sodium and Procaine*” in 1949. The effectiveness, low cost and compactness of this Latin American technique led to its widespread application. In later years, lidocaine replaced procaine.

New Barbiturates

Pentobarbital

In 1928, pentobarbital was synthesized. Pentobarbital might be substituted as premedication for or added to morphine. It offered two advantages over morphine: greater sedation and much less postoperative nausea and vomiting [38]. It was also used before regional anesthesia to increase the threshold to local anesthetic-induced seizures. Of course this might also obscure the fact that an intravenous injection of local anesthetic had occurred.

Hexobarbital

In 1932, the great German chemist Helmut Weese and Walter Scharpff synthesized the first water-soluble, short-acting barbiturate, hexobarbital, briefly used worldwide—until displaced in many countries by the release of thiopental two years later. In 1943, Weese invented 4% polyvinyl pyrrolidone, which was used successfully as a plasma substitute during the German North African campaign and later to manage hemodynamic instability during surgery.

Thiopental

In 1934, Waters gave thiopental (Pentothal®) to a patient [39]. So did Lundy a few months later [40]. The introduction of this induction anesthetic into clinical practice was widely accepted as a major advance, although its advantages vis-à-vis hexobarbital were not great. Hexobarbital was the “German” drug while thiopental had been discovered by chemists working at Abbott Laboratories in the US. Hexobarbital administration was sometimes associated with

muscle movement. Both barbiturates altered the induction process for the better. Induction of anesthesia with ether had been an unpleasant process for anesthetist and patient. EIE remembers (as a patient) such an induction with horror. A choking swirling down into a vortex of descending blackness, much as one might imagine dying to be. Induction with a barbiturate produced a quick and pleasant transformation from wakefulness to sleep. “Count backwards, please, from one hundred....” Sleep came before 90, arriving effortlessly and without claustrophobia and terror.

The First Synthetic Opioid

The approach of World War II and a possible interruption to the supply of anticholinergic (belladonna) drugs led the German government to underwrite the synthesis of meperidine (Demerol) in 1932. Meperidine had weak anticholinergic properties, but better yet, it was soon found to be a good synthetic opioid, and the supply of opium was also tenuous. One of the initial claims touting the advantages of meperidine was that it spared respiration (but then the same was said about other opioids). In 1947, after induction with thio-pental, Neff used meperidine and nitrous oxide to produce “balanced anesthesia”.

Neuromuscular Blockade Comes to Anesthesia

Although surgeon Arthur Lawen gave curare in 1912 to facilitate tracheal intubation and assisted ventilation for surgical procedures, the idea did not catch on—perhaps because the curare was impure and its effects difficult to predict. But what an opportunity missed. In the 1930s, Richard Gill brought curare from South America to the US in large amounts, offering a supply to pharmacologist AR McIntyre who with Squibb chemists partially purified the crude extract. Horace Holaday devised the rabbit head drop test to assay the potency and thereby standardize the concentration, allowing its consistent use for studies as Intocostrin (partially purified curare).

In 1939, US psychiatrist Abram Bennet reported that Intocostrin prevented compression fractures from convulsive therapy. Bennet neither supported ventilation nor reversed residual neuromuscular blockade. Like Goldilocks, he gave just enough.

In the early 1940s, Stuart Cullen gave Intocostrin to dogs, and because it appeared to cause bronchospasm said it has “*no place in anesthesia*”. He should have read Lawen’s work. In 1942, with no IRB approval, no oversight, and no previous experience, Harold Griffith and Enid Johnson at the Homeopathic Hospital of Montreal successfully administered Intocostrin to 25 patients anesthetized with

cyclopropane [41]. They described “complete muscle relaxation” lasting 10–15 min without serious effects on respiration pulse or blood pressure and no artificial respiration was used! Goldilocks, again. This description notwithstanding, curare’s introduction ultimately mandated the control of ventilation and stimulated the development of ventilators in the 1940s. These developments increased the reach of surgeons into the chest and heart.

In 1949, Daniel Bovet observed the paralytic effect of succinylcholine which quickly became a popular means to rapidly produce transient paralysis. This relaxant soon became the standard for inducing complete muscle relaxation, relaxation sufficient to allow tracheal intubation. Because of unwanted side effects however, the search for a rapid acting relaxant of short duration has proceeded for more than 40 years. Although several held promise, none acted with the rapidity of succinylcholine.

Pharmacokinetic/Pharmacodynamic (PK/PD), Mechanisms, and Genetics

In 1924, Howard Haggard began the study of anesthetic pharmacokinetics (what does the body do to drugs?) with his examination of ether pharmacokinetics in dogs. However, unlike the 1950s when the specialty was ready for PK/PD (pharmacodynamics: what do drugs do to the body?) information, Haggard’s research did not result in clinically useful practice changes at that time.

In 1935, Meyer’s son, Kurt, reformulated the Meyer-Overton theory: “Narcosis commences when any chemically indifferent substance has attained a certain molar concentration in the lipoids of the (brain)” [42]. The most parsimonious theory that followed from this observation was that changes to membrane lipids caused anesthesia. A few souls (but only a few) still believe there may be something to this.

In 1941, building on Archibald Garrod’s identification of inborn errors of metabolism as a recessive trait, Beadle and Tatum proposed their ‘one gene, one enzyme’ theory [43].

Why These New Drugs and New Theories?

What prompted this burst of new anesthetics after a near century of limited inactivity? World War I and the development of anesthetic machines made some of it possible. And the recruitment of some giants into the practice of anesthesia didn’t hurt. Another factor might have been simply an increase, albeit still small, in the numbers of anesthetists who thought of anesthesia as more than just a job. Such physicians and nurses might look for new agents, for better ways, to provide anesthesia to an increasing patient base and to meet broadening surgical demands.

In this endeavor they were sometimes helped, sometimes hindered, by their surgical colleagues. As Ralph Waters' surgical colleague, Erwin Schmidt wrote in the *Annals of Surgery* in 1937:

“Anesthesia was gladly welcomed, but received little aid or stimulation either as an art or a science, by the surgical profession...attempts to improve the status of anesthesia by medical men were frowned on by the surgical profession, and often deliberately hindered. This attitude placed anesthesia in the hands of young assistants who looked upon it as a necessary evil, a step, or stage on their way to become a surgeon, or into the hands of a technician.” [44]

Looking Down the Airway; Providing an Airway; Ventilating the Lungs

Looking

In 1910, Chevalier Jackson had invented a direct laryngoscope, and two years later, Charles Elsberg used it to enable tracheal intubation. In 1939, Noel Gillespie developed a pediatric laryngoscope. In 1941, Robert Miller described his straight blade for laryngoscopy by direct elevation of the epiglottis. Two years later Robert Macintosh added his blade for indirect elevation. These simple inventions remained the mainstays of anesthetic laryngoscopy from then to the present.

Tubes in the Trachea

In 1919, Ivan Magill and Stanley Rowbotham inserted a narrow-bore rubber tube into the trachea for insufflation, later complimenting that with an exit tube. Merging these produced the rubber tracheal tube. In 1940, Sydney Leader founded Portland Plastics (eventually Portex). As World War II progressed, he promoted the change from harder rubber tubes to softer polyvinyl chloride tubes, tubes used to the present.

Artificial Oral and Tracheal Airways

In 1908, Frederic Hewitt described his oropharyngeal airway, little more than a slightly curved tube that provided a conduit to the posterior oropharynx. Karl Connell introduced a curved metal airway in 1913, that in 1933, Guedel copied in hard black rubber. Waters added an insufflation port. Oral airways contoured to fit the oropharynx, remain the present gold standard. They were a marvelous advance in airway management, as much for their time as the laryngeal mask airway introduced a half century later. Contributing further to airway management, these two pioneers in the US, and Michael Nosworthy in GB popularized Macewen and Matas' principles of tracheal intubation and positive pressure ventilation during anesthesia. In 1935, in GB, Francis Shipway attacked the problem of aspiration with a cuffed oropharyngeal airway, thereby anticipating the development of the laryngeal mask airway by a half-century.

Although essential to the advancement of thoracic surgery, positive pressure ventilation required thoracic surgeons to operate on moving lungs. Waters and Joseph Gale solved this problem in 1931 by ventilating only the non-operated lung. Better yet, in 1949, Swede Eric Carlens invented the double-lumen tube for use in bronchspirometry and a year later for use in anesthetized patients. Now the surgeon had the luxury of operating on immobile lungs and other intrathoracic structures (esophagus, aorta, diaphragm).

Ventilate the Lungs

In 1916, K Giertz described the advantages of intermittent positive pressure ventilation (IPPV) over Ferdinand Sauerbruch's method of simply inflating the lungs, but Giertz' publication was in Swedish, and the world did not read it. In 1929, Philip Drinker and Charles McKann produced the iron lung, a mechanical external ventilator that applied intermittent negative pressure to the chest wall (and the rest of the body, excluding the head) and cost \$ 3,000. In 1931, John (Jack) Emerson manufactured a machine similar to Drinker and McKann's from standard parts, and costing \$ 1,000. Drinker sued pleading infringement but Emerson prevailed. Over the next 30 years these “iron lungs” saved many lives, but cumbersomeness and cost, even at \$ 1,000, limited their availability and usefulness. In 1933, the Swedish company AGA with surgeon Paul Frenckner (A Swedish ENT physician) constructed the respirator (Spiropulsator), described by Giertz in 1916, and improved by Crafoord in 1938 who used it for ventilatory support during pneumonectomy. In 1947, a motor engineer, JH Blease, in England produced a prototype mechanical ventilator with a commercial model realized in 1950.

In 1938, polio broke out in GB. Seeing a need for machines to support breathing, Lord Nuffield turned to Macintosh for advice, Nuffield offering to provide a tank ventilator for every Commonwealth hospital requesting one. Australian Ted Both, had designed a simple wooden version of the Drinker “iron lung” and allowed Nuffield to use his design. By 1947, the Morris car factory had built 1,750 of Both's ventilators.

In 1948, Albert Bower and Ray Bennett provided ventilatory support as needed to nearly 300 cases of patients in California suffering from polio. For unclear reasons they supported ventilation with a combination of a tank (Drinker) ventilator and intermittent positive pressure ventilation (via mask or tracheostomy) [45, 46]. They analyzed blood to assess the adequacy of their management [47]. Their work antedated Bjørn Ibsen's similar 1952 management of the great polio epidemic in Copenhagen, which led to the worldwide development of intensive care units. Ibsen gave credit to them in his description of his work.

In Germany, in 1935, W Capelle gave continuous post-operative subcutaneous injection of local anaesthetics into

abdominal areas to facilitate deep breathing and decrease the incidence of postoperative pneumonia [48]. This technique has gained favor intermittently over the years, the most recent version being the On-Q PainBuster® Post-op Pain Relief System providing continuous infusions of dilute local anesthetic through subcutaneously implanted perforated cannulae.

Monitoring Respiratory Gases

In 1932, Corning Glass marketed the first precise pH glass capillary electrode.

In 1935, Matthes constructed the first device to continuously measure the hemoglobin oxygen saturation of human blood in vivo by transillumination of an ear. In 1941, Millikan developed a lightweight ear oxygen meter he called an oximeter. Wood made calibration possible by adding a capsule to Millikan's oximeter to squeeze the blood out of the tissue to set zero, then letting the blood back in. Closer yet were we to the pulse oximeter.

In 1937, in Germany, Luft invented the principle underlying the infrared anesthetic and carbon dioxide analyzers so ubiquitous today. The Germans later used it for tracking V-bombs, the ram-jets and rockets that rained down on GB towards the end of World War II.

Using the EEG to Monitor Anesthesia

In 1937, in humans, Gibbs in the US documented the effects of various drugs on the electroencephalogram (EEG). From 1949 to 1952, anesthesiologist Albert Faulconer and neurologist Reginald Bickford at the Mayo Clinic used the electroencephalogram to define depth of anesthesia and brain well-being. Faulconer showed that inhaled anesthetics and thiopental produced an EEG pattern that changed in a roughly predictable manner with increasing anesthetic concentrations [49–52]. Twenty years later while at UCSD, Bickford continued his involvement with anesthesiologists, when he developed the Compressed Spectral Array—a processed form of the EEG, simplifying identification of decreased blood flow to the brain during cardiopulmonary bypass [53].

Physicians and the Problem of Drug Abuse

In the 1930s, Federal treatment of addiction began with the establishment of drug addiction treatment hospitals by the US Public Health Service, facilities with features of both hospitals and prisons, consistent with a view of addiction as a disease and a vice. In 1947, the UK Home Office found that 21% of addicts were physicians; 23% in 1956. It was not long before it was recognized that anesthesiologists were represented in drug abuse facilities at a far greater rate than expected, based on their percentage among all physicians.

Reprise

A renaissance in anesthesia, particularly in the US and GB, occurred between 1910 and 1950. World War I drew physicians into anesthesia and forced some technical improvements such as the Boyles anesthetic machine and use of blood transfusions. Guedel developed his technique for defining depth of anesthesia. As the numbers of anesthetists grew in the US, two societies arose: the American Society of Anesthesiologists and the International Anesthesia Research Society, and in Great Britain the Association of Anaesthetists of Great Britain and Ireland. Academic departments developed at the University of Wisconsin (Waters chair); Harvard (Beecher) and Oxford (Macintosh). In combination, the societies and academic departments increased recognition of the role of the anesthetist and improved quality through education and examination for certification/credentialing. Similar developments occurred in the rest of the world in subsequent years.

New anesthetics, especially thiopental, ethylene, divinyl ether, and cyclopropane, came into being. And the invention of the Bovie and the discovery of antibiotics helped the surgeon, the patient, and, thereby, anesthesia. The development of the atomic bomb required increased knowledge of fluorine chemistry, leading to Teflon® and modern inhaled anesthetics. Chance and interest led Lucien Morris to the invention of a device that allowed the precise delivery of those anesthetics, the Copper Kettle.

World War II dramatically increased the numbers of anesthesiologists in the US. Many of those drafted into anesthesia discovered an attraction to the specialty. Their service eased their requirements for credentialing, and the advent of health insurance ensured a reasonable compensation. Similar changes occurred in other countries but because of the devastation of World War II and civil wars, did not occur immediately, but at times delayed by decades.

History Reflected in the Evolving Approaches to Anesthesia for a Patient Undergoing Cholecystectomy

7

Lawrence J. Saidman, Rod N. Westhorpe and Edmond I Eger II

Cholecystectomy in the 1880s

The evolving management of today's second most common procedure [1], cholecystectomy, the simple removal of the gall bladder, illustrates the history of anesthesia and surgery, ancient and modern. Cholecystectomy is not part of the numerous operations conducted before the discovery of anesthesia in 1846 because the gall bladder could not be accessed in the living unanesthetized human. Nor did cholecystectomy occur immediately after Morton's demonstration, because the operation wasn't invented. Credit Berlin surgeon Carl Langenbuch at the Lazarus Hospital for his 1882 report of a cholecystectomy [2]. Given the date, we might surmise that he might or might not have premedicated his spontaneously breathing patient with morphine and scopolamine. He directed the anesthesia, given by a nurse or student who dropped ether (or chloroform) onto a Schimmelbusch gauze mask. The anesthetist sought deeper levels of ether to produce the muscle relaxation needed to access the gall bladder. This was heading into dangerous territory, and the awakening would have been slow, especially following a "deep" ether anesthetic. Lister's carbolic acid spray would have provided antisepsis during the procedure. The chances of survival would have been around 80%, a 20% mortality

from the combined risk of the anesthesia and postoperative infection.

Approaching the 1950s

The three editors of this book have been clinical anesthesiologists during most of the 60+ years described in this essay characterizing the changing nature of anesthesia care since 1950. Just imagine the experience (and challenge) of beginning a career as an "etherist" and ending it using a videolaryngoscope. Yet one aspect of our careers that made leaving clinical medicine so difficult has not changed—the wonder of the "miracle" of anesthesia—and the amazing sensation that occurs after telling your patient to "just take a few breaths" while you inject a drug allowing you to assume responsibility for that patient's very existence. Few physicians appreciate how addictive that can be.

As the 1950s approached, the care provided by anesthesiologists expanded, and ether (or cyclopropane) was increasingly supplemented by the use of IV agents, tracheal intubation, and sometimes, muscle relaxation. The next 60 years saw a revolution in anesthesia care, resulting from many incremental changes, including the development of new anesthetics (Fig. 7.1). These played out in different ways in different regions of the world, largely influenced by the aftermath of World War II and local economics. The greatest diversity in development was in the 30 years from 1950 to 1980, after which advances continued in parallel, particularly in the developed world.

In the early 1950s, Europe was recovering from the physical and economic devastation of World War II, and Great Britain was essentially broke. The British Commonwealth, including Australia, New Zealand, Canada, and South Africa, all endured delayed economic recovery. Asia and Japan were similarly affected, and other countries depended on Britain, Europe or the US for experience and training in anesthesia. In the immediate post war period, only the US had the financial resources to make major investments in health

Inhaled Anesthetics Used in Clinical Practice (Cumulative Listing)

Fig. 7.1. Ether, chloroform and nitrous oxide served most of the world's needs for general anesthesia for a century. The increasing importance of anesthesia was associated with the development of inhaled anesthetics (e.g., cyclopropane) that competed with these original anesthetics in the 1920s and 1930s. Advances in fluorine chemistry resulting from the need to purify uranium in the 1940s for the atomic bomb led to the development of modern anesthetics (anesthetics containing fluorine; agents noted to the left of the cumulative graph.)

care. There was another confounding factor. Clinical anesthesia in the US greatly depended on nurse anesthetists, and they followed protocols, unlike physicians, who were more inclined to do it "their way".

Thus, developments in anesthesia tended to occur first in the US, where they could be afforded, and subsequently were adopted elsewhere. The following descriptions of practice, discuss US practice, noting differences from practice in other parts of the world.

As we approached the 1950s, the anesthesia for a cholecystectomy might have been similar in many parts of the world. Events flowing from World War II were about to shape anesthesia in different ways, in different countries, but they hadn't done so yet. Ether, even after 100 years, was still the mainstay of anesthesia care (Fig. 7.1). The male patient, who at this time was almost certainly a smoker with a chronic cough, would have his preoperative care managed entirely by the surgeon, and might not see the anesthetist until he reached the operating room. Anesthesia would be induced, thankfully, by an intravenous (IV) injection of thiopental, after premedication with morphine and scopolamine. It is unlikely that IV fluids would have been administered, and in the unlikely event that the new muscle relaxant, Intocostrin, had been available, it probably would not have been used. Ether was still the usual anesthetic, perhaps assisted by some additional morphine. It likely would be given by mask, but

in a few patients the trachea would have been intubated with a red rubber tracheal tube. In some cases cyclopropane might be used, with a circle absorption circuit to limit its escape and minimize the risk of explosion.

Postoperatively, the patient returned to their hospital room, and would likely spend two weeks recuperating. Pain would be managed by intramuscular or subcutaneous injections of morphine, administered sparingly by nurses according to a routine prescribed by the surgeon. Vomiting would be managed by the provision of a bowl. The diet would consist of weak tea, graduating to thin soup, and eventually something more substantial. The risk of dying was about 1:1000, a risk that would decrease by two orders of magnitude by the 2000s.

The 1950s Anesthetic

The patient requiring a cholecystectomy was still a smoker, and, reflecting the diet of the time, was lean. The anesthesiologist visited the patient in hospital the evening before surgery, reviewed the laboratory and chest X-ray results, took a rudimentary history, examined the chest, and described the likely anesthetic course to the patient. Pentobarbital was given to encourage sleep the night before surgery. As before, morphine and scopolamine were injected intramuscularly, an hour before surgery. A nasogastric tube was inserted before the patient left for the operating room (OR).

In the OR, 5% dextrose in water was infused IV via a steel needle inserted into a vein on the back of the hand, which was carefully padded to avoid infiltration. In the UK, no IV infusion was initiated preoperatively, only as necessary once the surgery had begun. Induction began with an injection made directly through a standard hypodermic needle taped in place. In the US, blood pressures were obtained manually using Riva Rocci's method and palpation of the superficial temporal artery allowed monitoring of heart rate. The US anesthetist manually recorded these vital signs every 5 minutes on a chart devised a half century earlier by Codman and Cushing [3]. Elsewhere, the anesthetist might neither measure nor record such details. Oxford's Macintosh famously argued that "The pulse is of little value as a guide to nitrous oxide anaesthesia [4]." The anesthetist injected thiopental from a glass syringe to induce anesthesia which was then sustained with nitrous oxide plus diethyl ether vaporized from an in-circuit Ohio 8 bottle in the US or a Goldman bottle elsewhere. In Great Britain and the Commonwealth, a Boyle's machine might be used, with ether vaporized into a Mapleson "A" circuit from a Boyle bottle. As always, the anesthetist judged the amount of ether to give by the patient's responses to the ether given [5]. Small doses of d-tubocurarine (Intocostrin) facilitated relaxation yet permit-

ted continuing spontaneous, manually-assisted, ventilation via a hard conductive-rubber mask. Others might have given open drop ether via a Schimmelbusch mask just as in 1882 or provided anesthesia with cyclopropane.

The surgeon made a right subcostal incision. No antibiotics were given, nor was temperature monitored. The surgeon's satisfaction and the anesthesiologist's observation of the abdomen defined relaxation. OR personnel wore cotton clothing and shoes having conductive soles, and anesthetic circuits were conductive to reduce the likelihood of static electricity igniting the ether, or more importantly, the cyclopropane. The flammability of ether and cyclopropane usually precluded the use of electrocautery. As the fascia was closed, the anesthetist augmented relaxation by controlling ventilation (still by mask) and increasing the ether concentration, and then with fascial closure complete ceased ether delivery and control of ventilation. The UK anesthetist antagonized residual effects of curare, but the US anesthetist might not give neostigmine for fear of stopping the heart.

No supplemental oxygen was given during transport to the hospital room unless cyanosis was evident. Blood pressure and pulse rate might be monitored. The surgeon prescribed intramuscular injections of morphine to manage postoperative pain. Postanesthetic visits were rarely performed and notes documenting complications were written into the chart. A junior surgical house officer visited the patient twice daily to provide postoperative care. Recovery in hospital might exceed a week with no prophylaxis for deep vein thrombosis.

The 1960s Anesthetic

In the 1960s, the work of surgeon Thomas Shires prompted the use of salt-containing IV fluids [6]. Succinylcholine followed induction of anesthesia with thiopental, and the trachea was intubated with a cuffed red rubber tracheal tube cleansed with soap and water after its use in a prior patient.

Anesthesia was established and maintained with halothane in 70% nitrous oxide, and might but usually did not include intermittent IV doses of morphine or meperidine. Small doses of d-tubocurarine sustained relaxation. Later in the 1960s, (the 1970s in many countries) these changed to disposable polyvinylchloride tracheal tubes, enflurane, fentanyl, and pancuronium. Given the conversion to halothane or enflurane, the surgeon now used the electrocautery. OR personnel still wore shoes having conductive soles to reduce the likelihood of static electricity igniting cyclopropane or ether if they were used—an increasingly rare occasion. Ventilation was controlled either manually or with the aid of a mechanical ventilator. The effects of curare were empirically antagonized using neostigmine and atropine (toward the end of the decade, twitch height might be monitored).

Once spontaneous ventilation and patient movement began, the tracheal tube was removed. The patient was transported to the Post Anesthesia Care Unit (PACU) rather than immediately to their room. Recovery took several days with no prophylaxis for deep vein thrombosis. Pain was controlled by intramuscular injection of opioid at prescribed intervals with allowance for additional doses at the patient's request. Persistent vomiting, now much less common with the demise of ether, might invite an intramuscular injection of prochlorperazine.

The 1970s Anesthetic

The patient's IV fluids flowed through a disposable plastic catheter. Enflurane displaced halothane in the US because of concern regarding halothane hepatotoxicity, and flammable agents disappeared. Fear of bowel distension from nitrous oxide administration diminished or eliminated the use of that anesthetic [7]. Monitoring of blood pressure might use an oscillotonometer in GB and other countries, where a pulse meter might be attached to a patient finger, giving a needle deflection with each heartbeat, but no sound. An electrocardiogram CRT waveform might be displayed, with leads attached to all four limbs by small gel covered metal plates, each secured by a rubber strap.

Postoperative pain management might include an opioid infusion. Intermittent leg compression supplied deep vein thrombosis prophylaxis. Nausea and vomiting was still a problem.

The 1980s Anesthetic

Major changes have occurred. The patient arrived at the hospital in the morning for afternoon surgery, clutching a folder of X-rays, including his/her chest film. Apart from a slice of toast and a cup of tea early this morning, he/she had fasted since dinner the previous night. An electrocardiogram and blood tests for hemoglobin and electrolytes were performed as an outpatient. The anesthesiologist saw the patient at noon, obtained a short medical and anesthesia history, examined the heart and lungs, and briefly discussed the anesthetic process. Midazolam and fentanyl were given for anxiolysis and preparation for induction of anesthesia.

In the operating room, if one of the new pulse oximeters was available, the sensor was applied before induction of anesthesia. Electrocardiogram electrodes were placed on the patient using disposable adhesive discs with conductive gel. A blood pressure cuff was applied and connected to an automated device measuring blood pressure and heart rate every five minutes. A lower thoracic epidural catheter was placed under local anesthesia and might be used for intraoperative

anesthesia. It would be used to supply postoperative analgesia. Some centers would have used this approach in previous decades. The patient breathed oxygen from a soft clear disposable facemask while awaiting induction of anesthesia. Thiopental, succinylcholine, atracurium (the newly available muscle relaxant), and fentanyl were drawn into unlabeled disposable plastic (no more reused glass) syringes. Following the relaxation produced by thiopental and succinylcholine, the anesthetist inserted a new disposable PVC tracheal tube. Isoflurane in oxygen-enriched air was administered from an absorption circuit. A mechanical ventilator supplied intermittent positive pressure ventilation (IPPV). The anesthesiologist didn't need to squeeze the sphygmomanometer bulb, but still had to write heart rate, blood pressure, and hemoglobin oxygen saturation (SpO₂) values by hand.

The monitored ECG had a heart rate alarm. An expensive new analyzer might measure end-tidal CO₂. A disconnect and high-pressure alarm were attached to the ventilator circuit. Temperature was not controlled nor was a prophylactic antibiotic given.

Following emergence from anesthesia, the patient was placed on their side and covered with a warm blanket before transport to the PACU while breathing supplemental oxygen. Blood pressure and pulse rate were monitored, and oxygen supplied until return to the ward.

Postoperatively, an epidural infusion or Patient Controlled Analgesia device might be used. Metoclopramide would be prescribed in case of nausea or vomiting. It was unlikely that the anesthesiologist visited the patient again. Regular mechanical, intermittent lower extremity compression supplied deep vein thrombosis prophylaxis.

The 1990s Anesthetic

Little change occurred in the preoperative preparation for what now would be a laparoscopic cholecystectomy in a patient who verged on morbid obesity. In the operating room, the patient reclined on a wedge that raised the chest and head. The anesthetist gave cefazolin IV as per hospital guidelines [8]. Preoxygenation via a soft, clear, disposable plastic mask increased SpO₂ to 100%. Induction of anesthesia with fentanyl, propofol (which has replaced thiopental), and rocuronium, decreased SpO₂ which returned to normal with tracheal intubation and positive pressure ventilation. Tracheal intubation was confirmed by the CO₂ waveform measured with a stand-alone infrared analyzer that also measured end-tidal anesthetic concentrations. Isoflurane or desflurane in O₂ was administered and IPPV provided to produce slight hypoxemia. A neuromuscular monitor indicated the extent of muscle paralysis. Delivered anesthetic in 60% O₂ (balance N₂) was increased to produce an end-tidal concentration of 1 MAC. A remifentanyl infusion was initiated. Blood

pressure decreased to 105/65 mmHg (heart rate 69), and the end-tidal anesthetic concentration was decreased to 0.5 to 0.7 MAC. Both arms were padded and strapped to boards set at 90° to the body. Esophageal temperature was 36°C and was maintained above this level by forced air warming to minimize the risk of postoperative infection [9]. The wedge was removed.

The head of the table was angled upward, and blood pressure decreased to 85/55 mmHg but increased to 110/65 mmHg with infusion of phenylephrine. The surgeon used videoscope guided instruments to enter the abdomen and attend to gall bladder removal laparoscopically [10]. The abdominal cavity was inflated with carbon dioxide, to enable the surgeon to operate. Anesthesia continued with inhaled anesthetic at half MAC or slightly more, supplemented with an infusion of remifentanyl. Ventilation was increased to compensate for the increased end-tidal CO₂ produced by absorption of CO₂ from the peritoneal cavity. As the end of surgery approached, the remifentanyl infusion was decreased and ventilation was slowed to permit end-tidal CO₂ to rise. Neostigmine and atropine were given despite no measurable neuromuscular blockade. With placement of the last cutaneous sutures, the anesthetist halted anesthetic delivery, increased O₂ inflow, deflated the tracheal tube cuff, and stopped the remifentanyl infusion. If desflurane was used, as expected from its low solubility and rapid elimination, in 3 minutes, the patient's eyes would open, breathing began, and the tracheal tube was removed.

On awakening, the patient was transported to the PACU breathing supplemental oxygen from a bag and mask. He or she was able to respond verbally to questions regarding comfort, pain and nausea. The patient spent the night in the PACU, monitored for episodes of apnea. A PCA device dispensing small doses of morphine easily controlled pain. Prophylaxis for deep vein thrombosis included subcutaneous heparin and compression stockings. The patient was discharged the following day.

The 2000s Anesthetic

As in the 1990s, our patient was seen for a preoperative assessment at the Anesthesia Perioperative Medicine Center the day before surgery. Examination revealed a normal patient except for a Mallampati 3 value with limited forward displacement of the mandible but normal flexion-extension of their neck. Additional laboratory testing was not performed. Surgery in an Outpatient Surgery facility adjacent to a full service hospital was planned. Preanesthetic preparation was identical to that provided in the 1990s except that our anesthesia machine now incorporated an electronic anesthesia record, and while the patient breathed oxygen, the circulating nurse conducted a "time out" to confirm the name

of the patient, the proposed surgery and its intended site, and queried the anesthesiologist regarding known drug allergies. The time-out might also have covered concerns about airway management, availability of blood, and when the prophylactic antibiotic was administered. Following induction of anesthesia with fentanyl and propofol (both given, as were all drugs, from labeled syringes), the ability to ventilate the lungs was confirmed and rocuronium, and sevoflurane in O₂ were administered. Once an elicited twitch was eliminated, laryngoscopy using a video-laryngoscope allowed easy tracheal intubation and anesthesia was maintained using remifentanyl, sevoflurane, oxygen, and air to produce an FiO₂ of 80%, the greater FIO₂ nominally sought to minimize postoperative infection [11]. With closure of the fascia, the neuromuscular block was antagonized using neostigmine and atropine, and ketorolac was injected for postoperative analgesia. Triple antiemetic therapy was administered to diminish postoperative nausea and vomiting in this patient who was at high risk for PONV [12]. Postoperative notes were recorded electronically.

The anesthesia for our 2000s patient might differ in other developed countries, particularly in some parts of Europe where total intravenous anesthesia (TIVA) had become popular, especially TIVA using target controlled infusions based on Schwilden's algorithm [13]. In the US and some other parts of the world, because of concern regarding awareness, and despite some disagreement regarding the efficacy of computer-processed electroencephalograms, the sedative element of TIVA might be guided by on-line computer analysis of the electroencephalogram. And some anesthesiologists used a hybrid combination of techniques applying a modest concentration, perhaps 0.5 MAC, of a poorly soluble inhaled anesthetic with infusions of propofol and an opioid and one of the programs supplying the result of a computer-processed electroencephalogram [14].

Reprise

Our patient illustrates the evolving nature of modern anesthesia, showing the progression of drugs used (inhaled anesthetics, induction agents, anxiolytics, opioids, neuromuscular blocking drugs), the means of their delivery (for both injected and inhaled agents), approaches to anesthetic and surgical practice (in patient vs. out patient; long stay vs. short stay), control over the anesthetic state and postoperative pain, and means to manage the airway and postoperative nausea and vomiting. They hint at the evolution of patient, surgeon, and anesthesiologist and the interactions among the three. But beyond surface appearances, they do not show the profound changes wrought in the quality and education of the anesthesiologist and surgeon, the improvement in outcomes, the amazing decreases in mortality and morbidity. They do

not consider the implications of those changes to the future of the specialty.

Summary

World War II and subsequent local conflicts (e.g., the Chinese Civil War) left Europe and much of the Far East in tatters while the US applied its great military, economic and scientific strengths to diverse purposes, including support for the development of anesthesia. Anesthesia in some regions (South-Central America and Mexico) and countries (Switzerland, Sweden) progressed because they had not participated in the War. Despite limited resources, discoveries changing the face of anesthesia arose in Europe. Suckling, at Imperial Chemical Industries in England, synthesized 12 compounds in his search for a better anesthetic, striking gold on the ninth try, halothane, the first successful modern (fluorinated) inhaled anesthetic. In Copenhagen, with meager equipment and a willingly dragooned rag-tag corps of students, physicians and dentists, Bjørn Ibsen successfully fought a virulent epidemic of polio, in the process inventing intensive care medicine and intensive care units, and hastening the development of ventilators and blood gas analysis. 1955 marked the founding of the World Federation of Societies of Anaesthesiologists in London.

The 1950s saw a doubling of US nurses and physicians dedicated to a career in anesthesia. Bonica continued his contribution to the management of pain. With American Medical Association (AMA) support, the American Society of Anesthesiologists (ASA) demanded that anesthesiologists practice on a fee-for-service basis, leading to unforeseen increases in the attractiveness and economic power of anesthesia as a specialty and in the support of anesthetic research. The quick-on-quick-off neuromuscular blocking drug succinylcholine was released for use in 1951. In 1953, Apgar published her simple score, remarkably advancing our immediate estimate of a newborn's well-being. In 1954, Beecher and Todd described their monumental outcomes study, reporting that the use of curare increased mortality 6-fold, but (amazingly) not realizing that the probable cause was lack of reversal of residual relaxant effect. The release of the Copper Kettle (1953) and Fluotec® variable bypass (1956) vaporizers allowed a precise control over the delivered concentrations of inhaled anesthetics. They enabled the safer delivery of the new anesthetic, halothane. Beecher promoted the use of the placebo and controlled trials. In the next decade, these led to the development of informed consent and Institutional Review Boards to protect subject rights, laying the basis for modern ethical human experimentation. Finally, in 1959, Webb and Graves described their results for patients cared for on an outpatient basis, presaging the development of modern ambulatory surgery.

World Events in the 1950s

Global wars disappeared when World War II ended in 1945, only to be replaced by undeclared wars like the Cold War, the 1950–1953 Korean War, and civil conflicts in Cuba and elsewhere. Joseph McCarthy began a witch-hunt revealing

the presence of communists in the highest levels of the US government but also destroying the lives of many innocents despite their contributions to society. McCarthy forced the US to the right and towards isolationism. So did Russia's launch of Sputnik 1 which pushed the US to put humans on the moon in the next decade. It was a decade of stunning scientific-medical advances: Crick, Watson, and Franklin discovered the helical structure of DNA; the first organ transplants were done in Boston and Paris; and Jonas Salk's polio vaccine ended the terror of that dread disease. There were memorable (some might say trivial) cultural shifts in this decade. Elvis Presley began his superstar career, Hemingway wrote *The Old Man and the Sea*, Nabokov wrote *Lolita*, and Pasternak wrote *Doctor Zhivago*. Hugh Hefner launched *Playboy* magazine. Hula Hoops and the Frisbee appeared. Toward the end of the decade, six countries signed the Treaty of Rome, leading to the European Union and great hope for a better economic and social future.

Fig. 8.1 Countries with more anesthetists than the median in 2006, of 160 members, formed societies roughly one-and-a-half to three decades sooner than those having less than the median. (Data from the World Federation of Societies of Anaesthesiologists.)

Fig. 8.2 The rapid growth in societies that began in the 1940s continued in the 1950s with the addition of 22 new societies, 12 in Europe, 5 in Central-South America-Caribbean, and 5 in the Far East-Asia. (Data from the World Federation of Societies of Anaesthesiologists.)

Generalizations

As with all history, each new era builds on the preceding ones. By the 1950s, a sufficiency in the numbers of interested anesthesiologists enabled the formation of societies and journals in various countries. For reasons partly related to an abiding interest in anesthesia, US and European countries had larger numbers of anesthesiologists, and such numbers likely facilitated the earlier development of anesthetic societies and associated instruments (Fig. 8.1). The rapid growth in anesthetic societies in specific countries began in the 1940s and continued in the 1950s with the addition of 23 new societies (Fig. 8.2), 12 in Europe, 5 in Central-South America-Caribbean, and 5 in the Far East/Asia.

As may be apparent from the preceding figures and discussion, anesthesia societies arose at different rates in different parts of the world (Fig. 8.3). Despite the devastation wreaked on Europe by World War II, anesthesia societies in Western Europe appeared in the late 1940s and early 1950s, a decade before they appeared in less affluent, more slowly reconstructed, Russian-controlled Eastern Europe. Western European countries benefited from the Marshall plan. Societies in South America appeared at times between these extremes. Having fewer resources and fewer anesthesiologists, Central American and Caribbean Island societies arose a decade after those in South America.

World War II Unevenly Affected the Geographic Growth of Anesthesia

At the beginning of the War, few trained anesthetists existed in any part of the world, and most of those few were from English-speaking countries. Countries who were slow to recover from the war could not support a major development of a trained cadre of anesthetists; their goal was survival and rebuilding of their infrastructure and industry. Furthermore, in much of the world, anesthesia had been, and continued to be, viewed as something anyone could undertake. Anyone could give anesthesia. No anesthesiologists? What's the problem?

Thus, despite the enormous increase in the numbers of operations imposed by war, anesthesia made few advances in numbers or status in Eastern Europe, the USSR, and Asia. In the UK, physicians had long been the providers of anesthesia and a subset of UK physicians practiced only anesthesia. The US had responded to the increase in surgeries in World War II by forcing physicians into the delivery of anesthesia. Why physicians? Well, they were men, and men could be drafted. More trained anesthetists were nurses, but most of these were women [1]. Compounding the problem, if a nurse anesthetist volunteered for service, she was not guaranteed to practice anesthesia! [That wasn't unique to nurses. Following residency in 1958 I (EIE) was drafted into

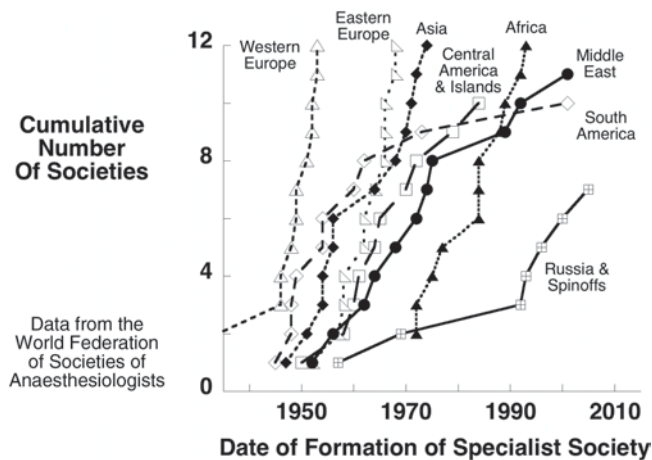

Fig. 8.3 The relationship seen in Fig. 8.1 partly explains the differences seen in Fig. 8.3. Larger numbers of anesthesiologists in Western Europe led to an earlier development of societies than in South America, Eastern Europe, Asia, Central America, the Caribbean islands and the Middle East. Economic advancement may add to the explanation of differences in the appearance and growth of anesthesia in different regions. (Data from the World Federation of Societies of Anaesthesiologists.)

the army more than a decade after the end of World War II. Although I was the Chief of the Anesthesia and Operative Section (in charge of 1 operating room and a closet), I was also a general duty medical officer who did a lot of physical examinations. I remember finding a thyroid nodule during a routine examination one day and giving anesthesia to the patient the next day for removal of his cancer.] The spectacular increases in the numbers of US physicians forced to practice anesthesia imply something else. These were young anesthetists with the energy and ambition that comes with youth. They made their way against established but older specialists.

Drafted US Physicians Become Anesthesiologists

In the early phases of World War II, waves of US physicians trained to become anesthetists in programs lasting up to 3 months, the products of these courses calling themselves 90-day wonders. In 1942, (Col.) Ralph Tovell surveyed American military hospitals in England and found that insufficiently trained physicians provided anesthesia services. In the following year, this led 99 officers to receive 1 month or more training in the better-prepared British hospitals. Parallel courses for the 90-day wonders were given in the US.

“Until the war, there had been only one military course in anesthesia. Stevens J. Martin, M.D., who trained in Wisconsin under Ralph M. Waters, M.D., organized the first Army course in anesthesia in July 1941 at Tilton General Hospital, Fort Dix, New Jersey. This course became the model used for the anesthesia courses developed by The Subcommittee on Anesthesia of the National Research Council....Courses began in the summer of 1942.” [1]

Because of the great need for anesthetists, many physicians pressed into service as anesthetists did not even have the limited training described above. They were self-taught. In 1944, the Army recognized a need for upgrading their skills and knowledge and

“gave four intensive courses in anesthesia taught by ‘the outstanding physician-anesthetist in the theater.’ (the military theater of operations)...A fourth cohort was an amalgam of on-the-job training and informal and formal apprenticeships by medical officers in the theater. In American units with adequately experienced medical officers, training and apprenticeship programs for local and rotating officers were established. The newly trained physician-anesthetists then returned to their own hospitals to train more medical officers...in anesthesia...As the war continued, required apprenticeships were implemented to address the increasingly inadequate number of physician-anesthetists. In fact, because of the shortage, in November 1944, it was determined that a trained replacement was required before an anesthetist could move out.” [1]

The unintended effect of the War was an enormous increase in the number of anesthesiologists dedicated to the specialty. In 1940, there were 568 ASA members, of which 105 were ABA diplomats. By 1950, these numbers had increased to 3,393 and 706. They were to double again in the 1950s. This forced growth in the number of US physician-anesthetists presented unexpected opportunities, while other factors imposed by the war augmented the effects of those opportunities.

First, physicians pressed into administering anesthesia often discovered that they liked what they did, finding that anesthesia presented surprising pleasures and challenges such as the use of regional anesthesia—more than half of the operations were performed under regional anesthesia [1]. General anesthesia was increasingly administered through a tracheal tube, demanding the acquisition of a technical skill [1]. And the anesthesiologist assumed the role of perioperative physician, responsible for the patient before and after as well as during anesthesia.

Second, surgeons supported by physician-anesthetists, found that they liked what they got.

“...surgeons have made or will make their first contacts with competent anesthesiologists in the armed forces and work under such improved conditions provided by them. After such an experience, it is to be seriously doubted whether many of them will be content on their return to civilian practice to retrogress to the inferior type of unsupervised technician anesthesia, where, as the law requires...the surgeons...must assume full responsibility for the anesthesia, even though fully occupied with the technical requirements of the surgery....” [2]

In Great Britain and its Commonwealth countries however, surgeons had been used to anesthesia being provided by physicians, but that didn’t stop them from maintaining their place at the top of the tree.

A third factor encouraged physicians forced into anesthesia to continue as anesthesiologists. The American Board of Anesthesiology credited such physicians with a year of residency—i.e., half the time mandated to complete a residency. Take just one year of residency and become (if you passed your exams) a board-certified anesthesiologist.

Waisel noted a fourth factor supporting the growth of anesthesia as a specialty during and after World War II: wage and price controls [1]. These controls were imposed to limit inflation. To compensate for this limitation to recruitment of workers, corporations increased benefits, including health insurance, something that prompted the increased use of medical/surgical services and, ultimately, the demand for anesthesia and anesthesiologists. As an aside, one might note that this means of paying for health care partly underlies our present health care crisis. Outside the US, anesthesiologists continued to be remunerated at a fraction of the rate pertaining to surgeons. Many were actually paid a moiety out of the surgeons' fee. In GB, the National Health Service ensured that all doctors were paid the same—within the service.

To summarize, several factors contributed to what became the basis for a remarkable growth in physician-anesthetists and nurse-anesthetists. Physicians drafted into anesthesia discovered that it was more challenging and rewarding than they had anticipated. Many surgeons became supporters of such physician-anesthetists. The financial base for anesthesia increased in the US. And board certification was made easier to acquire for those with on-the-job training. One might add the reasons given by residents today: the attractions of acute care, of seeing an immediate effect of anesthetic ministrations, the everyday application of principles of physiology and pharmacology.

But I (EIE) believe there is a sixth reason, one more powerful than the above five incentives to a career in anesthesia. My conversion to anesthesia provides an illustration.

“My career in anesthesia began on a pleasant spring day in 1952 as a newly minted first year medical student who wished to make money as an anesthesia extern. After a two-month summer apprenticeship in anesthesia, I would take call for my mentor, who could rest secure at home knowing that the care of emergency patients was in my capable hands! On that first day, he showed me how to start an intravenous infusion of 0.2% thio-pental, dial a 70% concentration of nitrous oxide, properly hold a rubber mask to the patient's face, and watch the rebreathing bag. Then he left the room. And I was in trouble. The rebreathing bag moved less and less and finally stopped. I knew little of anesthesia, just information supplied in a couple of lectures in pharmacology. But I knew that breathing was good and not breathing was bad. In a squeaky voice I told the surgeon that the patient had stopped breathing. With great presence of mind, and instead of berating me for obvious incompetence, he asked if I wanted him to give artificial respiration. “Yes, please.” I responded, voice still high-pitched. The surgeon squeezed the chest, the rebreathing bag now moved, and the circulating nurse fetched my mentor—who noted that the rebreathing bag could be used to ventilate the patient's lungs. I finished the

Fig. 8.4 The increasing numbers of residency programs in the US after World War II in part reflected the demand for training in anesthesia. This demand stabilized, as did the number of approved residencies, in the 1950s. The increase may also have reflected the desire by hospitals to access anesthetic services at low cost. (Data from Betcher et al. *Anesthesiology* 17:226–64, 1956.)

day exhausted and smelling of terror. The epiphany came as I sat thinking of the day's events. To that moment I'd dreamed of becoming a second Robert Koch, a country physician who would make great medical discoveries as a general practitioner. A wonderfully naïve dream that suddenly vanished as I thought 'You nearly killed a patient, today, and if you chose anesthesia as a career, you could do that every day. Every day you could take a patient's life in your hands. Every day.' To a control freak (me) that image was as seductive as seduction comes." [3]

I'm probably not alone. Anesthesia confers enormous power. With each anesthetic, the anesthetist takes a patient's life in their hands, exerts complete control over another human being, over the brain, breathing, the circulation, the muscles. Enormous power, and with it, enormous responsibility, an addictive and intoxicating mix.

Worldwide Training in Anesthesia

These diverse forces dramatically increased the numbers of physicians and nurses who chose anesthesia as a career in the US. Training programs increased, particularly after World War II, to accommodate this career choice (Fig. 8.4). Parallel growth occurred worldwide, but as noted above, the timing and rate of growth differed as a function of social and economic factors. South America had been spared the horrors of World War II, and in the 1950s–1960s, residencies arose in Bolivia, Brazil, Colombia, Peru, Uruguay and Venezuela, some of 2 years duration. Between 1948 and 1973 in France, nurse anesthesia training schools opened in most cities, training 1500 students who on passing an examination, received a *Certificat d'Aptitude aux Fonctions d'Aide*

Anesthésiste. As in the US, the graduating nurse anesthetists established their own institutions and competed with anesthesiologists, resulting in continuing antagonisms.

The length of formal training varied enormously worldwide, particularly soon after World War II. By the 1950s, with internship, it would be 3 years in the US. It was already 3 years in GB, including internship, and it started as 3 years in Australia and New Zealand in 1952. Given that World War II had placed the US as leader in many ways, much of the world initially might use 3 years as a standard. The 1950s were a time of great diversity and change in the perception of the appropriate duration of training. Limited economic resources and an immediate need for trained anesthetists might favor shorter periods of training. In the 1950s in Europe, the minimum prescribed periods differed by an order of magnitude. But by the 1980s this had narrowed to between 4 and 7 years, with most European countries agreeing that 5 years were needed.

It is a cruel irony that training in anesthesia, and anesthesia societies, developed slowly in the USSR and China, countries suffering most from World War II, countries that had contributed the most human lives, whose infrastructure had been devastated, and who had access to fewer resources that might assist rebuilding. Isolated by the cold war, devoting limited resources to strengthening military power, continuing to bleed from civil war (China) and government tyranny (in the USSR; and note China's Cultural Revolution), these countries educated few anesthesiologists and had but limited and diverse durations of training. Contrast this with growth in Japan which had also lost substantial human life and infrastructure, but was occupied by what turned out to be a benevolent force, imposing a stability that allowed rebuilding to occur. The Japanese Society of Anesthesiologists was established in 1954, whereas the Russian Federation of Anaesthesiologists and Reanimatologists was not established until 1972, and the Chinese Society of Anesthesiologists began in 1988.

Fee-for-Service and the Association of University Anesthesiologists (AUA)

The Association of University Anesthetists, later the Association of University Anesthesiologists, perhaps the leading organization for anesthetic academicians in the US, developed in the early 1950s. Emanuel Papper played a crucial role in its birth, a role he described in a witty, self-deprecating history [4]. A stated purpose of the AUA was "...to promote and discuss research and teaching in Anesthesia." [5] The larger truth was a bit seamier [4]. In 1950, organized anesthesia (namely the American Society of Anesthesiologists—the ASA) pressured practitioners to not accept a salary for their anesthetic services. The ASA argued that anesthesia was the practice of medicine and a hospital (the management paying the salary)

could not practice medicine. The ASA appeared to adopt the Hess Report of the American Medical Association: "A physician should not dispose of his professional attainments or services to any hospital, lay body, organization, group or individual, by whatever name called, or however organized, under terms or conditions which permit exploitation of the services of the physician for the financial profit of the agency concerned." Papper believed that the ASA and the Directors of the American Board of Anesthesiology (ABA) interpreted this section of the Hess Report to mean that salaried forms of the practice of anesthesiology were unethical. He contended that "Attentive reading of the approved Hess Report does not support this interpretation so clearly." What a diplomat was our Papper. The concern regarding fee-for-service was peculiar to the US. In other countries in the world, salaried medical practice, in hospitals, was and continues to be an accepted practice.

The pressure applied by the ASA included the threat of loss of ASA/AMA membership and Board certification. It never was clear that the ASA would broadly impose sanctions on salaried academics, many of which were—and are—quite happy with a salaried arrangement, unconcerned with any ethical implications. But we know of one case where pressure was supposedly brought to bear on an anesthesiologist for accepting a salaried arrangement. In the Ellensburg Daily Record, June 10, 1954 the report reads:

"Physician Sues Medical Society In King County. SEATTLE (UP)—Claiming he has been socially ostracized and denied membership in the King County Medical Society because he works for a salary rather than for fees, Dr. Lloyd H. Mousel has filed suit against the society and seven other medical groups. The doctor, formerly of Washington, D.C., and the Mayo Clinic, has worked at Seattle's Swedish Hospital since 1949 as director of anesthesiology on a salary basis. This, he said, has resulted in rejection of his application to transfer his membership from the District of Columbia to the King County Medical Society."

Papper argued that "Little recognition was given then, or for that matter now, on the dangerous irrelevancy of linking ethical behavior of a physician in practice to the manner in which he or she earned a living as a matter of principle. It is *how* these practices are used that determines whether the method leads to inequities and to abuse of patient care rather than the process itself."

The potential intrusions of the ASA distressed four academics. Perhaps most distressed was the ethicist Henry Beecher—joined by Papper, Austin Lamont, and Robert Dripps, anesthetic giants of the period. Over several months, these four constructed an organization that might voice the views of academia. The organization, of course, would have research and education as its stated primary purpose, but in fact, the underlying purpose would be to keep the ASA from dictating the economics of anesthetic academia.

The AUA has served academic anesthesia and the specialty well. It initially had elitist pretensions. The original

Table 8.1 A comparison of median annual salaries of some specialties in the USA in 2011

Speciality	Median Salary
Orthopedic Surgeon	\$ 500,672
Gastroenterologist	\$ 405,000
Invasive Cardiologist	\$ 402,000
Anesthesiologist	\$ 370,500
General Surgeon	\$ 357,091
Obstetrician-Gynecologist	\$ 275,152
Emergency Medicine	\$ 267,293
Ophthalmologist	\$ 238,200
Neurologist	\$ 236,500
Urologist	\$ 222,920
Pediatrician	\$ 209,873
Family Medicine	\$ 208,861

Data from SK&A, A Cegedim Company. 2601 Main St, Suite 650, Irvine, CA 92614; 800-752-5478. U.S. Physician Compensation Trends. Revised August 2011

by-laws mandated a membership that was not to exceed 100. Tom Hornbein and John Bonica challenged this with the argument that the membership needed to be broadly based if it were to truly represent academia. Their egalitarian view prevailed, and in 1971 the 100 member limit was removed.

Further to elitist pretensions, at the AUA meeting in 1973, the membership discussed the possibility of awarding some honor for the best research done during that year. I (EIE) was all for it. However, Papper demolished the proposal by suggesting that it was “OK, but it really was like little boys who gave each other medals and epaulets.” Immediately after the day’s meeting ended, Hornbein and I found an army-navy supply store and bought the biggest, gaudiest pair of epaulets available and attached double-sided tape to each. Before that evening’s formal black-tie (more elitist stuff) AUA banquet, we convinced the AUA President, Nick Greene, that this was the time to put Papper’s suggestion to work. At the banquet, after reading the usual announcements, Greene, intoned that this evening he would reveal the First Manny Papper Awardee for Excellence in Research. “Would Dr. Papper please stand for the Award?” Papper hesitantly rose. Hornbein and I strode up from behind and clapped the epaulets onto his shoulder. Ruefully, Papper commented that he “should have kept his mouth shut.” This was the first and last Manny Papper Award.

The AUA has grown, with 613 active and 176 senior members as of 2012 (Email from Annie DeVries, AUA Administrative Assistant, 15 Nov 12). Beyond a research mission, it has a larger focus on educational and political matters. Despite its initial hostility to the ASA, it has a present cordial and cooperative relationship with the ASA.

In 1978, the Federal Trade Commission required that the ASA sign a Consent Decree agreeing, “...that an anesthesiologist is free to choose whatever arrangement he prefers for compensation of his professional services.” A demand for

a fee-for-service arrangement could no longer be imposed by the ASA or the ABA. Nonetheless, the nearly three decades over which fee-for-service had been the main method of compensation had, with other factors (see above), made anesthesiology an economically attractive specialty in the US, an attraction that continues to this day (Table 8.1). This attraction had several consequences. It added to the ease of recruitment into the specialty, including physicians from outside the US. It enabled academic departments to support research with time and seed money. This luxury helped make US anesthesiology a world leader in anesthesia research for much of the 1950s to the 1980s.

New Inhaled Anesthetics and New Vaporizers for Their Delivery

The Development of Modern Inhaled Anesthetics

The anesthesia provided by ether and chloroform in 1846 and 1847 was an enormous step forward. It enabled unheard-of, unthought-of surgeries. For a century, it sufficed for most purposes that surgeons could imagine. Advances were not required until surgeons began to push boundaries for which ether and chloroform, and the technology and skills needed for anesthetic delivery, were insufficient. Surgery demanded more. The benefits of the electrocautery (the Bovie, first used by Cushing in 1926) and other electrical equipment, encouraged development of new nonflammable anesthetics. Chloroform was nonflammable but too toxic. The coincidence of this need, plus the new fluorine chemistry required for development of the atomic bomb, gave rise to modern inhaled anesthetics, compounds halogenated with fluorine.

Why fluorine? Because this smallest of halogens clings with greater strength to other atoms, particularly carbon atoms. The chlorine in chloroform can be torn from its carbon mate and this underlies the toxicity of chloroform; prevent the separation of the two atoms and you prevent hepatic injury [6]. Fluorine-carbon combinations are usually less vulnerable than chlorine-carbon combinations to degradation by carbon dioxide absorbents or to metabolism, and thus are usually less subject to the sometimes-toxic consequences of degradation or metabolism. Fluorination had another virtue. It made compounds less soluble and thus more readily eliminated; patients awoke sooner after anesthesia.

The first of these modern inhaled anesthetics was fluoroxene, synthesized by Julius Shukys in the late 1940s and released in 1953. I (EIE) had come into anesthesia at this time in Chicago, having suddenly decided on a career direction change from general practitioner to anesthesiologist (see above). This caused me to try to learn all that I could

about anesthesia. It wasn't hard to do because there wasn't much to learn. I sought out the teaching venues in Chicago. The head of the University of Illinois program, Max Sadove, led one of these. Each week he presided over the morbidity and mortality sessions (now portentously called Grand Rounds), cigar in hand, calling for cases to present. It was not a formal enterprise. I remember a discussion of fluroxene, ending with Sadove's paraphrased comment that "We've tried it now in humans; perhaps we should test it in dogs." Lucky they went in that direction because it is toxic to many animals (including dogs), [6] but not to humans [7]. Fluroxene enjoyed a minor vogue and commercial success, but it caused cardiovascular stimulation, [8] was irritating to breathe, and produced substantial postoperative nausea and vomiting. Its trade name was Fluromar, but it sometimes disparagingly was called Vomomar or Flurobarf.

The first truly successful modern inhaled anesthetic was halothane, synthesized in 1951 by Charles Suckling of Imperial Chemical Industries in England. He was acting on an inspired guess by his boss, John Ferguson, who had studied fluorine-containing agrochemical agents for fumigation of grain silos, noting that some of the agents knocked out weevils and beetles who recovered quite nicely [9]. After testing by James Raventos in animals, Michael Johnstone used halothane clinically in 1956 [10]. Halothane was less soluble in blood and thus allowed a more rapid awakening from anesthesia than did chloroform. However, the bigger concern was injury to the liver (hepatotoxicity). Chloroform was a classic hepatotoxin. If you gave it to an animal, it injured the liver. The more you gave, the greater the injury [11]. At least in the beginning, halothane didn't do that in humans. Chance favored halothane. The first patient scheduled to be anesthetized with halothane had her surgery cancelled because of a slight illness that subsequently became manifest as jaundice due to hepatitis. Had she received halothane, the subsequent hepatic illness would surely have been considered to be due to the anesthetic. But the gods smiled on halothane, and the next patient survived uneventfully.

Michael Johnstone was not the only one to test the new anesthetic. Cedric Prys-Roberts (personal communication to EIE, 15 Nov 12) remembered that

"it was also sent to Roger Bryce-Smith in Oxford, and to George Ellis at St Bartholomews Hospital. As a medical student early in 1957 I did an anaesthetic attachment for one month, mostly with George Ellis. He used halothane in a Marrett head (vaporizer within a circle system with CO₂ absorption) with spontaneous breathing after a thiopentone induction. He taught me to anaesthetize patients for retropubic prostatectomy (open abdomen, slight head down tilt) with this technique—his admonitions: 1) never squeeze the bag! (for obvious reasons)¹—if the patient

stops breathing—leave them alone so long as they are pink—they will start breathing again when they are ready; 2) don't take the blood pressure—you will only be worried because it will be low, and; 3) don't turn down the halothane vaporizer setting unless you can feel an irregular pulse"

The University of Iowa was one of the clinical test centers for this new anesthetic. I (EIE) remember its arrival in large brown-glass bottles in 1956. We would smell it, impressed with the absence of pungency that the familiar ether imposed. Unwittingly, we found that it also dulled the sense of smell. Having sniffed from one of the new bottles, I found that there was scarcely any odor on sniffing a second time. My fellow residents ran this test on the new bottle with the same result. We concluded that it came from a weakened batch and poured the contents down the drain! How easy it was to induce anesthesia with this potent, non-flammable, non-pungent anesthetic that appeared to spare the liver from harm. And so it succeeded, in the process making hundreds of millions of dollars for ICI. By 1960, halothane had mostly swept the decks clear, largely displacing chloroform, ether, and cyclopropane from clinical practice.

The introduction of halothane did more than decrease the use of other inhaled anesthetics; it changed the practice of anesthesia. Because it had no pungency, was potent, and had a low solubility, anesthesia with halothane could be induced rapidly and without untoward airway responses such as excessive secretions, coughing and laryngospasm. Gone was the advantage of premedication with morphine (to hasten induction, decrease the need for inhaled anesthetic, and depress the response to airway irritation) and scopolamine (to minimize the appearance of secretions and decrease the remembrance of the terror of induction of anesthesia). Add to this that morphine imposed disadvantageous effects: unlike ether, halothane decreased breathing, an effect that administration of morphine enhanced. In addition, morphine increased postoperative nausea and vomiting. Thus the elimination of morphine-scopolamine premedication occurred, but surprisingly it did not occur immediately. Inertia is a powerful force, even in the face of fact and reason.

New Vaporizers

Although the earliest great anesthetists understood the need to control the concentration of anesthetic delivered to the patient, such control was usually unknown or ignored in favor of looking for and being guided by the patient's responses to the anesthetic being delivered—the signs of anesthetic depth so beautifully described by Snow, [12] and later, Guedel [13]. These signs could however lead the anesthetist astray. The art of deciphering these signs was less than perfect, even in the best of hands. Compounding the problem was a lack of knowledge of the anesthetic

¹The ventilation would potentially increase the inspired and alveolar halothane concentrations to lethal levels because of the use of the in-circuit vaporizer.

concentration that the patient breathed. The patient breathing from a gauze mask wetted with ether or chloroform breathed a concentration that might be anything! A few “non-rebreathing” vaporizers might deliver a known concentration, but these were part of wasteful systems, systems in which all the flow of gases went through the vaporizer and the patient did not breathe the gas again. Some vaporizers delivered a graded concentration (e.g., the Boyles vaporizer), but with these the anesthetist knew only that he/she delivered more or less anesthetic when the vaporizer dial was adjusted up or down. Where a vaporizer was used in a rebreathing system (a system in which the patient rebreathed the anesthetic after carbon dioxide had been extracted from the rebreathed gases), again the control was up or down but the specific concentration remained unknown. The importance of rebreathing with such a system was doubly risky. Not only was the amount added by the vaporizer unknown, the extent of rebreathing was also unknown.

The anesthetic gases (nitrous oxide, ethylene, and cyclopropane), gases as opposed to the vapor anesthetics like halothane, could be delivered in known concentrations. The concentration of cyclopropane delivered to a rebreathing system could be accurately calculated from the readings on the flowmeters delivering oxygen and cyclopropane: if the cyclopropane flowmeter indicated a flow of 200 ml/min and the oxygen flowmeter indicated 800 ml/min, then the delivered concentration of cyclopropane was 20%. But these gases were either on their way out (ethylene and cyclopropane), or had insufficient potency to be used by themselves (nitrous oxide).

The Copper Kettle

The ease of calculation of concentrations of gaseous anesthetics like cyclopropane did not apply to volatile liquids and their vapors, such as ether or chloroform. In the late 1940s, Lucien Morris saw that it could. If a known flow of oxygen could be delivered through a liquid anesthetic such as ether, that anesthetic would be added to the stream in a known concentration, a concentration determined by the vapor pressure of the anesthetic relative to barometric pressure.

In the late 1940s, Morris began work on his invention of the Copper Kettle, with delivery of the first commercial version in 1951 [14]. Why copper? For the same reason that Snow had made his vaporizer of copper—great heat conductivity and thus stability of temperature in the face of cooling by vaporization of anesthetic. The Copper Kettle enabled the precise prediction of the anesthetic concentration delivered to the anesthetic circuit (the rebreathing system). Many anesthetists disliked the Copper Kettle because it required a calculation to apply properly, but, my, it did work.

It arrived at a propitious time. Although it was invented to allow a precise delivery of chloroform, it could be used for

the precise delivery of any volatile anesthetic. The discovery and release of halothane followed soon after the introduction of the Copper Kettle—and the Copper Kettle could be (and was) used to deliver halothane. The safe use of halothane demanded more control over the delivery of anesthesia than did ether. Halothane was far more dangerous because it was more potent, [15] and less soluble in blood [16, 17]. Add to this the absence of pungency and a high vapor pressure, and it is easy to understand that halothane could produce anesthesia with dangerous rapidity. Dangerous because it depressed breathing [18] and the circulation [7, 19] whereas ether might not, or even do the opposite [7, 20, 21]. There were imitations (equally good) of the Copper Kettle (e.g., the Vernitrol®—perhaps from “vernier control”). They, too, were used for the safer delivery of halothane and other modern inhaled anesthetics.

The Variable Bypass Vaporizer

The Cyprane Company circumvented the anesthetist’s fear of algebra—of having to calculate the concentration produced by the Copper Kettle. In the last half of the 1950s, Cyprane introduced (at great expense and profit) the variable bypass vaporizer, the Fluotec®, to accompany the introduction of halothane (with the commercial name Fluothane®). The algebra-challenged anesthesia community in the US welcomed the Fluotec®. The variable bypass vaporizer dial gave an immediate reading of the delivered anesthetic concentration (no calculations needed), largely unaffected by inflow rate or room temperature. That, alone, would probably have ensured the success of the Fluotec® (and its imitations). In the US, Ayerst Laboratories, the purveyor of halothane, added to the incentive by offering the Fluotec® free with a minimum purchase of halothane. The same approach was not used in the worldwide promotion of halothane where less safe vaporizers (e.g., Boyles) continued in use. The decision by Ayerst to donate Fluotecs to institutions purchasing halothane accelerated the acceptance of halothane. It also hastened the demise of the competing Copper Kettle and Vernitrol®.

Polio Prompts the Development of Intensive Care Medicine (ICM) and Intensive Care Units (ICUs)

A Plague Strikes Copenhagen Poliomyelitis (polio) has afflicted humans since the dawn of history. It comes and goes, is sometimes mild and is sometimes crushing, with a substantial fraction of the population severely affected. In the last 5 months of 1952, Copenhagen, a city of 1.2 million, was struck by such a severe attack [22]. The Blegdam Hospital of 500 beds received approximately 3000 patients

suffering from polio, roughly a third of whom evidenced paralysis, including a “high incidence of respiratory insufficiency with or without impairment of swallowing”. Over 300 patients had this “bulbar polio.” [22] At the peak of the epidemic in early September, 50 cases were admitted daily with 10% of them breathing inadequately. Death was erroneously considered to result from viral infection of the base of the brain [23, 24].

Compare these circumstances with those from previous times. From 1934 through 1944, Blegdam had admitted 76 cases of polio with respiratory failure requiring use of cuirass ventilators. Of these patients, 80% died [22]. Blegdam was unprepared to deal with the 1952 onslaught, having one tank respirator (an Emerson) and 6 largely ineffective cuirass ventilators. HC Lassen, the Chief Physician, gave his estimate of the grave situation in which he found his patients:

“I do not want to dramatize the state of affairs existing in the middle of August 1952, but it certainly was desperate! Nearly all our patients with bulbar poliomyelitis had died! On August 25 we decided to call into consultation our anaesthetist colleague, Dr. Bjørn Ibsen....” [22]

The Ibsen Plan and Its Consequences Ibsen had trained in anesthesia for a year at the Massachusetts General Hospital, learning and applying the principles of positive pressure ventilation. He saw this as the best approach to dealing with the critical situation. Lassen agreed, and together they implemented a program designed by Ibsen. A tracheotomy was performed on each patient evidencing bulbar polio, a cuffed tube was inserted through the tracheotomy, and manual positive pressure ventilation was maintained via a bag connected to a humidified source of 50% oxygen/50% nitrogen through a to-and-fro canister. But who would supply the ventilation? “At the height of the epidemic the staff of doctors permanently on the job was 35–40; we had about 600 trained nurses and 250 medical students coming in daily, working in relays.” [22] At times, dental students were added to the work force. Working 6-hour shifts, each had to supply continuous positive pressure ventilation, monitor the patient, manage tracheal secretions that might accumulate, and alert attending physicians to problems. The mortality rate in this cohort with bulbar polio decreased from 90% to 25%—still high but a rate that was less than it probably would have been without Ibsen’s intervention.

The principles learned in the 1952 Copenhagen polio epidemic revolutionized the management of sick patients requiring intensive care. An appreciation of the therapeutic power of intensive care, of gathering similarly sick patients in one area for treatment such as ongoing support of ventilation, in short order led to intensive care medicine (ICM) and intensive care units (ICUs). Ibsen opened the first ICU a year later.

Part of the management of Ibsen’s patients included the evaluation of the effectiveness of ventilation through analysis of respiratory gases (e.g., CO₂) in arterial blood, with an

approach specifically devised during the epidemic by Poul Astrup [25]. Blood-gas analysis could be done, with cumbersome, time-consuming methods that could never have met the needs of Ibsen’s far too numerous patients. Astrup’s work shortened and simplified the process. It was a major step in the evolution of blood gas analysis, culminating in Severinghaus’ 1958 construction of the first 3-function (O₂, CO₂, pH) blood gas apparatus that is used in some form in every modern hospital [25].

And, of course, the epidemic and the need for controlled ventilation prompted the development of automatic ventilators devised specifically to provide continuous intermittent positive pressure ventilation without fail, 24 hours a day, 7 days a week. It seemed as though an infinite number of anesthetists and engineers came to see what happened in Copenhagen and went home and made a newer, better IPPV ventilator. Many were primitive yet enjoyed widespread and long use (e.g., the Radcliffe ventilator introduced in 1953). Engström in Sweden invented one of the world’s most successful mechanical ventilators, tested in the 1952 Copenhagen epidemic and the 1953 Swedish polio epidemic. The British parallel to the Engstrom was the Smith-Clarke ventilator. Diverse and often less expensive ventilators followed (e.g., the Howells, the Manley, and the Barnet ventilators). US Engineers Bird and Bennett developed ventilators powered by compressed gas. And all the above led to a need for and the development of personnel to manage the ventilator. This took two general forms. In the US, the respiratory therapist with specific training and credentials managed respiratory care. Elsewhere, ICU nurses with special additional training managed the ventilator. All of the above developed because of the confluence of a polio epidemic and a few visionaries.

A postscript. In 1954, Lassen [26] and Honey [27] reported survival of patients with severe tetanus who received curare and mechanical ventilation. They applied the lessons learned in the 1952 polio epidemic.

The First Massive Anesthesia Outcome Study

Curare Has a Dark Side

Like today’s consortiums studying cancer and other medical problems, consortiums have studied anesthetic-related outcomes, sometimes with surprising results. Beecher and Todd led the first major consortium in anesthesia to study a serious outcome, an investigation of the factors predicting death after anesthesia in 599,500 patients in 10 university institutions. They concluded that curare had a dark side, an unexpected association with a 6-fold increase in mortality [28, 29]. 1:2100 deaths occurred in the absence of curare and 1:370 in cases in which curare was given (see Beecher and Todd,

Table 8.2 Severity of surgery and increased death rates associated with curare

Curare	Surgery	Total Number of Patients	Number of Anesthetic Deaths	Anesthetic Death Rate	Increased Death Rate With Curare
No	Minor	349,939	69	1:5071	
Yes	Minor	205,519	162	1:1270	4.0-fold
No	Major	27,777	12	1:2314	
Yes	Major	16,313	85	1:192	12-fold

Table 13) [28, 29]. Many of the cases not given curare were minor cases and critics might have suggested that this skewed the results. But dividing the cases into minor and major gave qualitatively similar findings (Table 8.2). Similarly, physical status did not affect the ratio: Those with PS 1, 2, and 5 had death rates of 1:660 if given curare and 1:3100 if not, whereas those with PS 3, 4, 6, and 7 had respective death rates of 1:96 versus 1:560. Beecher and Todd's Table 16 demonstrates that over the five years of the study, deaths associated with the use of thiopental progressively decreased when not accompanied by curare (from 1:720 to 1:3400) whereas they remained constant when curare was given (1:380 to 1:420).

An additional subanalysis examined the effect of ether vs cyclopropane, with and without curare, on mortality. In the absence of curare, mortality was similar with ether (1:2500) and cyclopropane (1:3300). But when curare was added, mortality was greater with ether (1:250) than with cyclopropane (1:1200). We know that awakening occurs far slower after anesthesia with the more soluble ether, and perhaps this exaggerated any residual effect of curare in the partially paralyzed patient lying unattended in the recovery room or ward. They thereby might have had a greater likelihood of airway obstruction, hypoxia or other untoward respiratory event.

Initial Rejection of the Beecher-Todd Results

The anesthesia community did not immediately embrace Beecher and Todd's conclusions, perhaps because the results were published in a surgical journal [28], and surgeons then sometimes suggested to anesthetists that they were doing something dangerous. Some surgeons insisted that anesthetists refrain from using the "deadly" curare.

Abajian and colleagues faulted Beecher and Todd's study [30]. A primary concern was Beecher and Todd's failure to gather data concerning "...site of operation, depth of relaxation required, duration of anesthesia and operation, and severity of surgical trauma." Indeed, such confounding variables might have explained the results without resort to a consideration of the effect of muscle relaxants. Abajian et al. also noted statistical lapses and anomalies. For example, over the course of this 5-year study "...the use of 'curare' was increas-

**Fig. 8.5** Beecher and Todd [28, 29] found a lower mortality associated with the administration of anesthesia by nurse anesthetists. (Data from their Table XIX B)

ing by 64 per cent (from 1:18 to 1:11) (Table XII), (while) the total anesthesia death rate was falling by 23 per cent (from 1:1440 to 1:1880) (Table XXVIII)." [30] They emphasized the likelihood of an associative rather than a causal relationship of curare and death. Nowhere did they raise a question concerning reversal of neuromuscular blockade.

In a further rebuttal, Dripps et al. performed a retrospective study for a 10-year period (1947–1957) from which they culled 33,224 patients who had either spinal anesthesia or general anesthesia with muscle relaxants [31]. No deaths

"attributable to anesthesia (arose) in the 16,000 physically fit patients anesthetized by either technique. As the patients' physical condition worsened, deaths related to anesthesia increased in incidence...No evidence of an inherent toxicity of muscle relaxants could be found. When deaths were related to the use of muscle relaxants, errors of omission or commission were always apparent."

Relaxant was thought to contribute to death in 12 patients; in 8 of these, death occurred because of "failure to provide adequate pulmonary exchange." The death rate in those receiving relaxants was 1:536. Nowhere did they raise a question concerning reversal of neuromuscular blockade.

Some of Beecher and Todd's findings seemed to fly in the face of reason. Training as a physician anesthetist did not appear to decrease mortality (Fig. 8.5). Beecher and Todd explained:

"Common observation indicates that the physician specialist on the average cares for the patient faced with the more trying and difficult operation than does the nurse, even though both groups work with a comparable number of patients in poor physical status. This is supported by the data of Table XIX, where it can be seen that although the physician specialist anesthetizes only half as many patients as the nurse, he is charged with an equal number of anesthesia deaths. In the light of this, to deny the greater difficulty of the physician specialist's cases is to reduce the matter to an absurdity where one would be obliged to argue that the physician's learning was a dangerous thing."

But Beecher and Todd's data did not show that the nurse anesthetists were assigned less major surgery (this wasn't stated) or less vulnerable patients. Regarding the latter point,

of the patients anesthetized by nurse anesthetists, 14% were listed as Physical Status 3, 4, 6, or 7 (PS 6 corresponds to the current Physical Status 3E and 4E and 7 corresponds to 5) whereas only 12% of those anesthetized by anesthesiologists were given such a PS. Thus, if anything, the nurses anesthetized sicker patients. For a moment consider another possibility that might explain the lower mortality associated with anesthesia given by nurse anesthetists. By the late 1940s, over 50 schools for the formal training of nurse anesthetists had come into existence [32]. Anesthesiologists and nurse anesthetists may have been trained differently, but training was given to many nurse anesthetists. Perhaps because of their lesser medical background, nurse anesthetists were trained to follow “cookbook” guidelines, faithfully giving anesthesia by prescribed methods, an approach that we now appreciate may have certain safety advantages, particularly when less options are available [33, 34]. They may have been less flexible in their approach to anesthesia, but perhaps as Mies van der Rohe said, sometimes “Less is more.”

Residual Blockade Probably Underlay the Greater Mortality

The increased mortality associated with curare in Beecher and Todd’s study was probably due to the inadequate reversal of residual paralysis. We knew how to reverse the paralysis with drugs such as neostigmine, but often we didn’t. Perhaps we thought, “Well, the patient can breathe and move; isn’t that enough?” The patient could move, could breathe, but had less than normal strength. Perhaps full strength was needed to deal with vomit that might appear in the back of the throat or to cough sufficiently to expel mucous deep within the lungs. Have we learned from this? Maybe less than completely. A 2005 outcomes study of a cohort derived from 870,000 patients, again suggested the potential lethality of the residual effects of muscle relaxants whose effects have not been antagonized [35].

Research in Anesthesia

The preceding discussions suggest the clinical focus of research in anesthesia in the 1950s. Attention was paid to the development of new anesthetics (e.g., halothane) and anesthetic adjuvants (succinylcholine) and to increasing the control over their delivery and safety (Copper Kettle and variable-bypass vaporizer). Attention was paid to the new clinical management of disasters such as the Copenhagen polio epidemic, the associated clinical research leading to intensive care medicine, new ventilators, and modern blood gas analysis. Attention was paid to outcomes as in Beecher and Todd’s controversial massive study.

In largest part, research support came from industry or the personal contributions of individuals who gave their time and thought. Support also came from government agencies, not necessarily those we think of today. For example, the Medical Research and Development Board, Office of the Surgeon General, Department of the Army underwrote Beecher and Todd’s study. Private sources also supplied support. The Wellcome Trust gave \$140,000 to support anesthesia research at McGill University. “The Trust award is seen by McGill as a great breakthrough for the specialty, which is unsupported by British Research Councils and other grant-giving agencies at this time.” (At <http://www.wellcome.ac.uk/timeline/>, type in Anaesthesia in the search box.) The Trust also gave \$69,000 to fund a Chair of Anesthesiology in New York. The considerable increase in support for anesthesia research by the National Institutes of Health began in the next decade.

Other Important Events in the 1950s

1950

Pain Management At mid-century, interest in regional anesthesia waned, partly because new drugs producing general anesthesia made general anesthesia more attractive, and partly because of issues of duration and safety of regional anesthesia (e.g., the development of paralysis after spinal anesthesia) [36]. Notwithstanding this view, the 1950s saw the rise to prominence of giants in regional anesthesia, leaders such as John Bonica and Daniel Moore. They followed in the footsteps of previous giants in the US (e.g., John Lundy and Emery Rovenstine) and the largely German approaches to methods of peripheral and neuraxial (think August Bier) nerve block developed within 2-3 decades of the discovery of the local anesthetic properties of cocaine in 1884. Bonica enlarged the importance of regional anesthesia and particularly the management of pain control, including the development of pain clinics. At mid-century, both Moore and Bonica published now classic books on regional anesthesia and pain management.

Dogs and Cats Benefit, Too Humans were not the only beneficiaries of the growth in the specialty. UK veterinarians Barbara Weaver and Leslie Hall became the first veterinarians to exclusively practice anesthesia. Weaver wrote: “In the 1950s when Leslie and I became interested in anaesthesia, realizing we were some 50 years behind the ‘medics’ we adapted human techniques for our patients.” (Personal communication to Eugene Steffey, 2010).

Management of Postoperative Nausea and Vomiting (PONV) The earliest anesthetics, nitrous oxide and ether,

produced PONV, perhaps in part as a consequence of their capacity to stimulate the sympathetic nervous system. For the first century of anesthesia, PONV was accepted as an inevitable byproduct of anesthesia, but then some questioned whether patients really needed to suffer this side effect. By 1950, the antihistamine dramamine had been discovered and was used to treat motion sickness. A natural extension was to apply this remedy to the management of PONV [37]. Thus began the discovery and application of a series of antiemetics including the antihistamine cyclizine (1955); phenothiazines (1960); the dopamine receptor antagonist droperidol (1961); and the serotonin antagonist ondansetron (1980s).

1951

A New Rapid and Short-acting Muscle Relaxant Daniel Bovet had noted the paralytic effect of succinylcholine in 1949, and this neuromuscular blocking drug was released for clinical use in 1951. It had qualities that anesthetists sought in a drug to produce relaxation, particularly a rapid onset (more rapid than any other neuromuscular blocking drug) and a faster offset than the long lasting curare. It seemed just right for the anesthetist wanting a brief period of relaxation such as that needed for the insertion of a tracheal tube. Indeed, at first it seemed perfect: “*Its use is not accompanied by unwanted side-effects and the incidence of post-operative complications after its use is low.*” [38] Its rapid offset was due to its degradation by plasma cholinesterase. But it wasn’t perfect. It could cause prolonged neuromuscular blockade after being used for prolonged periods of time, or in patients who (it was subsequently discovered) lacked the ability to break the drug down. The lack of the enzyme, plasma cholinesterase, was genetically determined and unraveling this mystery led to a new appreciation of the potential pharmacological consequences of genetic abnormalities, and to the development of a new science called pharmacogenetics, a term Freidrich Vogel invented in 1959 [39].

1952

Chloroprocaine, a New Local Anesthetic Released for clinical use in 1951, the local anesthetic chloroprocaine did not receive immediate acclaim. It was an ester-linked local anesthetic and seemed therefore to be a reversion to anesthetics like tetracaine and procaine, each of which had drawbacks, including toxic reactions or allergic responses to p-amino benzoic acid. Many considered that these had been minimized with the release for clinical use of the amide-linked local anesthetic, lidocaine. But chloroprocaine had an underappreciated advantage, a vulnerability to rapid degradation

by plasma cholinesterases. It remained intact as long as it wasn’t in blood, but once in blood it was degraded and its local anesthetic toxicity removed. This benefit led to its resurrection decades later.

Beecher and Human Experimentation In the 1950s, Henry Beecher made several influential suggestions regarding human experimentation. In 1952, noting the powerful effect that placebos have, he argued for their use in human trials as an essential control [40]. In 1959, his thoughts about controlled experiments led him to argue for informed consent for all participants in studies on humans. To oversee the imposition of informed consent required the development of Institutional Review Boards in the succeeding decade. All of these developments govern the conduct of human research today.

1953

Virginia Apgar Scores Virginia Apgar, then the leader of obstetrical anesthesia at Columbia University, was at breakfast with a medical student who asked her how she would evaluate the physical status of a newborn child. “Easy” she is reported to have said, immediately writing the five elements of her 10-point Score on a cafeteria napkin. After a bit more work, she published her eponymous score, “the Apgar”, which defines the condition of all babies born in the world today, correlating closely with the immediate well-being of the newborn [41]. Later in her career, “Ginny” worked to prevent crippling birth defects, becoming president of the March of Dimes Foundation. She received the ASA Distinguished Service Award in 1961.

Also in 1953, Bonica published the first edition of his classic book, “The Management of Pain”, and Gibbons successfully applied a heart-lung machine, allowing greater time for surgeons to work in a bloodless field without injury to the brain.

1954

An Invention of War Becomes One of Peace Luft invented the infrared analyzer in Germany in 1937 [42]. It had been put to various war-time purposes (e.g., tracking the V-bombs). Liston-Becker used the invention to manufacture and sell an infrared analyzer in the early 1950s [43]. Ultimately, this device became a ubiquitous bit of operating room furniture, and a savior to many patients. It allowed a breath-by-breath estimate of the adequacy of breathing (by the measurement of CO₂) [44] and the adequacy of anesthesia (by measurement of the vapors causing the anesthesia). Perhaps most importantly, it certified the presence of respired gases by the detection of CO₂, and thereby guaran-

teed the placement of a tracheal tube into the trachea rather than the esophagus.

Were Neuroaxial Blocks Safe? For various reasons, by mid-century, concern had been raised regarding the safety of local anesthetics, particularly when delivered to the spinal canal. Cases of paralysis had been reported [36]. In 1954, Dripps and Vandam reported the results of a prospective study of 10,098 patients given spinal anesthesia with tetracaine, finding no severe neurologic problem [45]. Coupled with the introduction of aminoamide local anesthetics such as lidocaine, their findings supported a resurgence of interest in regional techniques in the US.

And Incidentally in 1954 ... Hall and Weaver introduced balanced anesthesia including curare to the clinical management of dogs and cats, not finding the bronchospasm in dogs that had troubled Stuart Cullen. US surgeons Harrison and Murray successfully transplanted a human kidney.

James Elam showed that medically untrained individuals taught to maintain a clear airway without a tracheal tube could provide normal levels of oxygen and carbon dioxide for prolonged periods with Expired Air Resuscitation (mouth to mouth breathing). Elam persuaded Peter Safar to join a crusade to promote Expired Air Resuscitation. By 1958, Safar had demonstrated that laypersons could relieve obstruction of the airway by the tongue, by thrusting the jaw forwards and tilting the head backwards. Also in 1958, Safar developed the first ICU in the US.

In one of anesthesia's most quoted articles, Mapleson described how systems not using carbon dioxide absorption (open systems) worked to assure normal carbon dioxide levels in the patient breathing from such systems [46]. Such systems rely on a sufficient inflow rate to eliminate carbon dioxide. Mapleson told us what those flows were.

1955

The Birth of the World Federation of Societies of Anaesthesiologists (WFSA) Although still in disarray consequent to the ravages of World War II, remnant members of the Société d'études sur l'anesthésie et l'analgésie (SEAA) organized an international congress in Paris in 1951. Societies from 32 countries considered founding an international society. Marcel Thalheimer, Secretary of the Société des Etudes, persisted in pursuing the organization of such a society, advancing the idea at the September 1951 Congress of Anaesthesia in London. Representatives of 32 societies elected an interim committee tasked with constructing the structure of a new international organization of anesthesiologists. From this came the WFSA, with its first meeting in Scheveningen, The Netherlands, in 1955. Societies from 28 countries contrib-

uted to the founding, including the International Anesthesia Research Society (IARS) from the US, one of Francis McMechan's creations. The IARS represented the US on the planning committee since the ASA preferred to remain an "Official Observer". Harold Griffith (then Chair of the Board of Trustees of the IARS) was elected as the first WFSA President. Establishment of the WFSA achieved McMechan's dream of an international organization of anesthesiologists.

1956

Nitrous Oxide Can Be Lethal In 1956, Lassen et al. attempted to minimize pain in patients suffering from tetanus by having them breathe nitrous oxide [47]. The therapy decreased pain, but over the course of days, the continued inhalation of nitrous oxide produced severe bone marrow depression and death. Was it something to do with prolonged administration of anesthetics or was there something peculiar to nitrous oxide (or both)? Decades later, the capacity of nitrous oxide to uniquely destroy a vital enzyme, methionine synthase, was shown [48]. The inactivation of methionine synthase led to a decreased availability of the essential amino acid methionine and decreased production of folate, essential for the production of DNA.

Also in 1956 The initials CRNA (Certified Registered Nurse Anesthetist) came into use in the US. At this time, a year was required to complete training in nurse anesthesia. This would more than double in subsequent years.

Methohexital (Brevital), a shorter-acting barbiturate was introduced. Because it stimulated the central nervous system, it competed poorly with thiopental—except for the anesthetic management of patients undergoing electroconvulsive therapy. It remains popular today for the management of such patients because it has less capacity to suppress the induction of convulsions.

1957: An Important Political Change that Ultimately Influenced Anesthesia

Six countries signed the Treaty of Rome, creating the European Economic Community (EEC) that grew to today's European Union (EU) of 27 member states with lots of opportunities and problems. Increasing mutual recognition of medical qualifications and harmonization of medical education accompanied this political process.

1959

Modern Outpatient Anesthesia Begins Canadian anesthesiologists Eric Webb and Horace Graves reported their 6-month

experience with 494 surgical patients cared for as outpatients [49]. Others had earlier provided anesthesia to outpatients. In 1909, a Scot, James Nicoll, reported his experiences with this approach in approximately 9000 children [50]. Indeed, he may be the father of outpatient anesthesia. Ralph Waters had provided outpatient anesthesia in the 1910s [51], but it is Webb and Graves who started the modern move to this approach to anesthetic delivery, a move that expanded in the next decade.

Late 1950s

Resusci-Anne Norwegian toy-manufacturer, Åsmund Laerdal developed the mannequin “Resusci-Anne”, used to teach cardiopulmonary resuscitation (CPR). Resusci-Anne was released in 1960. Laerdal’s work complemented the thrust of the research by Peter Safar and James Elam on cardiopulmonary resuscitation. Resusci-Anne began the modern movement towards teaching with simulators.

Manufacturers Make Anesthesia Safer The late 1950s saw a mundane addition to the safety of anesthetic delivery, the invention of the Pin Index Safety System and Diameter Index Safety System by Wayne Hay and Harold May, employees of the Ohio Medical and Surgical Equipment Co. Prior to the invention and application of this system, a tank of nitrous oxide might be attached to the place normally occupied by an oxygen cylinder—with disastrous results from the delivery of gases lacking oxygen. Hay and May donated the resulting 1963 patents to the Compressed Gas Association facilitating the use of the system by all manufacturers, internationally. All patients having general anesthesia potentially benefited from their generous act.

Reprise

The effects of World War II accelerated—and retarded—the rise of modern anesthesia. It arrested development in Europe, the USSR, and Asia, but hastened development in the US. The recruitment (drafting) of physicians into the US Armed Services for a brief period of training in anesthesia, followed by a mandated practice of anesthesia, caused this acceleration. Physicians forced to learn and practice anesthesia often discovered that the calling pleased them. Succinylcholine became available in 1951. Perhaps the most important advance of the 1950s arose from Bjørn Ibsen’s management of the 1952 polio epidemic in Copenhagen. His work led to the establishment of Intensive Care Medicine and Intensive Care Units, and to the development of ventilators and blood-gas analysis. The World Federation of Societies of Anaesthesiologists was founded in 1955. The advances in fluorine chemistry, needed to develop the atomic bomb paved the way for

Suckling’s synthesis of the inhaled anesthetic halothane. Released for clinical use in 1956, halothane soon displaced essentially all its predecessors. Important to the safe delivery of halothane, our ability to control the delivery of inhaled anesthetics increased enormously with the invention of the Copper Kettle and variable bypass vaporizers. Muscle relaxants were first used in humans in 1942. In 1954 Beecher and Todd’s outcomes research indicated that muscle relaxants could be a mixed blessing if not managed properly, if their residual effects were not reversed. In the 1950s we had two new drugs in addition to halothane—succinylcholine and chloroprocaine. Beecher successfully argued for the use of placebo-controlled experimentation, for the use of informed consent, and ultimately for the establishment of Institutional Review Boards (IRBs). Finally, in 1959, Webb and Graves reported their results with the first modern outpatient anesthesia.

Summary

Several developments dominated progress in anesthesia in the 1960s. Consistent with the maturing of a clinical specialty, anesthesia related research began to emerge in selected departments—mostly within the US and Europe. Emanuel Papper's actions as special consultant to the Institute of General Medical Sciences facilitated greater NIH funding earmarked for anesthesiology, particularly for studies examining inhaled anesthetic pharmacokinetics, pharmacodynamics, and toxicity. Investigations of toxicity culminated in the National Halothane Study largely exonerating halothane as a hepatotoxin. Pharmaceutical companies introduced several new anesthetic drugs (pancuronium ketamine, fentanyl, droperidol, bupivacaine, and enflurane), advancing patient care and facilitating faculty development via interactions between academia and industry, largely in the US and Europe. Surgical subspecialty development spurred parallel developments in anesthesiology, promoting targeted research efforts in obstetrical, neurosurgical, and cardiac anesthesia.

Expanding clinical research increased concerns regarding the ethical treatment of human subjects. Beecher's landmark article in 1966 exposed questionably ethical clinical research performed without informed consent, and led to the requirement for prior review and approval by Institutional Review Boards (IRBs), revolutionizing clinical research practices. Manpower concerns about the specialty in the US, as a result of a relatively small number of American medical graduates (AMGs) selecting training in anesthesiology, resulted in an ASA program underwriting medical student anesthesia preceptorships. This program was ultimately associated with a tripling in the number of graduates electing anesthesiology as a career choice. It also helped that several factors increased economic opportunities in anesthesia, including support from Medicare.

International development of the specialty was reflected by formation of the Latin American Confederation of Societies of Anesthesiologists in Lima Peru in 1962 and the first International Training Center of Anesthesiologists of the World Federation of Societies of Anaesthesiologists (WFSA) in Caracas in 1967. In 1963, the European Union of medical Specialists stipulated training requirements for anesthesiologists and in the 1960s formal training programs were established in many European countries for nurse anesthetists.

World Events in the 1960s

Theodore Maiman's demonstration of a working laser and release of the oral contraceptive opened the decade. Regarding the increasing use of LSD, Jefferson Airplane's Paul Kantner famously said "If you can remember anything about the sixties, you weren't really there." Soviet cosmonaut Yuri Gagarin orbited the Earth, and Kennedy established the Peace Corps. Then, a series of near-cataclysmic events descended. In 1961, the US invasion of Cuba (The Bay of Pigs) failed.

In 1962, the USSR deployed ballistic missiles in Cuba aimed toward the US, provoking a crisis that came within days of initiating a nuclear war. LJS remembers becoming temporarily deranged and stocking up on Dinty Moore Stew the night before the missiles were to fly. In the course of 15 years (mainly the 1960s), the US progressively increased its commitment to South Vietnam in its War with North Vietnam, at its peak sending more than 500,000 troops. In the US, assassinations of President John F Kennedy (1963), Senator Robert Kennedy (1968), and civil rights leader Dr. Martin Luther King (1968) caused extreme political and social unrest. Combined with protests against the Vietnam war, these events destroyed the presidency of Lyndon Johnson and caused the election of Richard Nixon. The 1967 Six Day War between Israel and Egypt, Syria, and Jordan changed the military balance of power in the Middle East and increased the West's dependency upon OPEC. But it didn't matter because this was The Summer of Love in San Francisco. In 1965, Richard Feynman was awarded the Nobel prize in physics. He paved the way to a greater understanding of the quantum

nature of the atom, and pioneered far-reaching advances in chemistry. Finally, Neil Armstrong and Buzz Aldrin walked on the moon, ending the 1960s on a positive note by opening the age of Space exploration.

Anesthetic-Induced Organ Toxicity and Metabolism of Inhaled Anesthetics

The decade opened with concerns regarding halothane-induced morbidity following sporadic reports of post anesthetic hepatic toxicity [1]. These reports prompted the Committee on Anesthesia of the National Academy of Science-National Research Council (NAS-NRC) to conduct a retrospective, 34-institution 850,000-patient study (the National Halothane Study) [2] to assess the risk of hepatic injury and death from anesthesia with halothane [3]. The study showed that halothane did not increase the overall risk of hepatic injury or death, decreasing the immediate level of concern.

Nonetheless, reports of rare, otherwise unexplained cases of injury sustained concerns regarding halothane hepatotoxicity. These led some anesthetists to avoid using halothane in patients undergoing liver surgery or in patients with prior signs of hepatic injury following halothane...or using halothane at all. Supporting a causal relationship between halothane administration and hepatic injury, shortly after publication of the National Halothane Study, Rehder et al demonstrated significant hepatic metabolism of halothane [4]. Once the patent on halothane expired, its low cost and many advantageous properties dictated its continued use through the next several decades, especially in less developed countries. In developed countries, its use in adults decreased with the introduction of the less hepatotoxic enflurane in the late 1960s. The decrease in the use of halothane occurred more rapidly in the litigious US than in other developed countries. In Europe, enflurane, and later isoflurane, were slow to be adopted. Because of issues of pungency and because hepatotoxicity in children was thought to be less evident, halothane continued to be used in children until sevoflurane was introduced in the 1990s.

Similar concerns regarding methoxyflurane resulted in a rethinking of criteria used to assess the potential risks of newer volatile anesthetics. Methoxyflurane metabolism resulted in high blood and urine concentrations of free fluoride ion, potentially causing renal injury [5–7]. The discovery of the renal lesion associated with the administration and metabolism of methoxyflurane, significantly curtailed its continued use. Anesthesiologists had also become increasingly sophisticated, recognizing that the high blood and lipid solubility slowed the rate of induction, slowed emergence, and prolonged postoperative somnolence. The development of enflurane, a safer (less metabolized to noxious metabolites)

Fig. 9.1 The percent of anesthesiology residents who were IMGs increased to 58% in 1972, falling to a nadir of 9% two decades later. A second peak followed Clinton's focus on the development of primary care physicians in the 1990s

and kinetically advantageous (much less soluble) alternative, added to the incentive to abandon methoxyflurane.

Anesthesia Manpower in the US and the ASA Preceptor Program

In 1960, International Medical Graduates (IMGs) filled 38% of anesthesiology residency positions in the US (Fig. 9.1), a percentage that exceeded that for other specialties and subsequently increased to nearly 60% by 1972. While not necessarily reflecting resident quality, this characterization of the specialty diminished its prestige among American Medical Graduates (AMGs), such that, in 1964, ASA President Al Betcher, convinced the ASA to survey the status of the specialty in education, research, and teaching. Completed in 1967, the survey prompted the formation of a Council of Education that included a Committee on Medical Student Preceptorships. This committee developed a Preceptorship Program that provided an 8 week paid experience to medical students who had completed two years of medical school. During the 8 weeks, they were assigned to an anesthesiologist in private practice or academia, observing, and where feasible participating, in day-to-day care of patients. Between the initiation of this program in 1966, and 1969, more than 1100 students participated. The number of American Medical Graduates (AMGs) electing anesthesiology as a career tripled following the implementation of the program. While the percentage of IMGs in anesthesia training programs continued to increase, it peaked in 1972, and was followed by a progressive decline, reaching a nadir of 9% by 1988 (Fig. 9.1) [8].

My (LJS) experience as a medical student predicted success of the Preceptorship Program. If you exposed students to the specialty, “they will come”. As a 1960 junior medical student at the University of Michigan, I chose anesthesia to satisfy the requirement for a 6 week surgical subspecialty rotation. My choice was determined when I drew an ace of diamonds from a worn deck of cards used to decide medical student surgical rotation assignments. Anesthesia was a “plum assignment” because the assigned student actively participated in patient care...and because there were no student night call obligations. Although the anesthesia department at the University of Michigan conducted little if any laboratory research, the staff anesthesiologists were attentive to students, perhaps giving a bit more responsibility than was warranted. I remember accompanying a young staff anesthesiologist to Jackson prison—at the time the largest penal institution in the US—and while caring for three patients requiring tracheal intubation, deftly inserted the tracheal tube...into the esophagus. My mentor calmly suggested the tube be removed and assured me that all would be well and that this was not an uncommon event for the budding anesthesiologist. I found the experience of caring for patients whose lives depended upon me exhilarating, and my life was serendipitously changed forever. In retrospect, I wonder if providing care for some really rough desperados might also have inspired my career choice....

Returning to the issue of IMGs versus AMGs, in the 1990s, the number of AMGs selecting anesthesia again decreased when following Bill Clinton’s election to the US Presidency in 1992, he appointed his wife, Hilary Clinton in 1993, to Chair a task force charged with developing a program that would provide universal health care. Passage of this program was doomed however when Conservatives, Libertarians, organized medicine, and the health insurance industry suggested that such a new bureaucratic structure that incorporated universal coverage, mandating purchase of insurance, would limit patient choice and adversely affect medical care. In addition, medical school deans/administrators may have advised medical students that practice opportunities might not be available in anesthesia while there would be a large increase in positions for primary care physicians. The number of AMGs electing anesthesia upon graduation decreased to zero in many programs with a reciprocal increase in the percentage of IMG anesthesia residents to 58% by 1999 before declining once again to less than 20% (Fig. 9.1)

Anesthesiology Grew Worldwide

In the 1960s, societies continued to grow worldwide. Eastern Europe, Asia, Central America and the Middle East experienced an increase in the numbers of trained anesthesiologists who hungered for collegial interactions and education. This

Fig. 9.2 Worldwide, large numbers of anesthetic societies continued to be added in the 1960s, two dozen in all

growth was superimposed on that achieved in the previous decades in Western Europe, Latin America, and the English-speaking countries. Altogether in the 1960s, two dozen anesthesia societies were founded worldwide (Fig. 9.2).

Emergence of Research in Academic Anesthesia Departments

As the 1960s began, anesthesiology worldwide was a specialty short of trained physicians. In the US, fewer than 2500 board-certified anesthesiologists served a country of 180 million or approximately 1.4/100,000 population. Many US medical schools had anesthesia divisions rather than departments, divisions housed within departments of surgery. Most were consumed by large clinical responsibilities. Only a handful of academic departments (e.g., Harvard, Columbia, Pennsylvania, Iowa, Wisconsin, UCSF, University of Washington) supported research activities with mature trained investigators. Fewer yet had NIH-supported research grants. There were hardly any trained subspecialists. This began to change in the 1960s, starting a transformation of the specialty in the US from one dominated by empiricism to one employing the tools of modern science, spreading its clinical involvement from the operating room, to the delivery suite, intensive care unit, post anesthetic care unit, ambulatory surgery suite and acute and chronic pain management departments.

Between 1960 and 1971, 15 new university departments headed by chairs, were established in GB. While clinical

anesthesia was their primary responsibility, several of these became the spearheads of research, encouraging higher academic qualifications. In 1968, the Anaesthetic Research Society was formally established out of a less formal group that had begun in 1958.

In the 1960s, research in anesthesiology was largely “phenomenological” (a term now considered pejorative), observational studies lacking a mechanism explaining the cause of the observation. The titles of typical research papers began with “The effect of” rather than “Here is the reason for the effect of”. But “we needed to walk before we could run”. We first needed to provide observations. These would lead to questions such as why and how.

A confluence of factors was needed to enable the first steps. These included devices capable of accurately and rapidly measuring small amounts of anesthetic drugs, research funds sufficient to support talented but unproved academics who were freed from clinical responsibilities, and prescient department leaders in and out of the specialty who recognized the need to develop a scientific base leading to important questions. IS Ravdin, a surgeon at the University of Pennsylvania, had addressed this issue nearly 20 years earlier, stating that “While the importance of the technical advances in a young field is not to be minimized, it is the fundamental contributions which lead to a better understanding of anesthesia that will mark the real maturity of anesthesiologists [9].” Robert Dripps, Chairman of Anesthesia also at the University of Pennsylvania, stated in 1949 that “Talented young men in the specialty of anesthesiology must be encouraged and supported if their inclinations are toward investigation” and “once trained, these young scientists will require budgets, laboratories, and time free from clinical responsibilities [10]”. Finally, in an editorial in 1950, Salter (a non-anesthesiologist) stated:

“There must be trained a group of so-called academic anesthesiologists. They must have the special training and sufficient leisure to advance the basic concepts of applied science. They must not be run ragged with routine assignments but must be protected from the irate surgeon who demands “service now” in the name of all humanity and the trustees”. [11]

Although several factors accounted for the delayed development of anesthesiology as a specialty in Asia and much of Europe, the factor that was undeniably of greatest importance was World War II, with its horrific devastation, millions killed, destruction of physical and governmental infrastructure, and the resulting revisions of social order and scientific institutions—a complete reordering of society. With democracy replacing authoritarianism in Japan and German speaking countries, virtually every institution required restructuring. Combined with the fact that the specialty had been slow to develop before the war, these factors delayed its development until nearly the 1960s. For example and as nicely described by Goerig in Chapter 29, up to the 1950s, tracheal intubation

was still performed digitally and under topical anesthesia and it was not until the clinical use of muscle relaxants well into the 1950s that laryngoscopes were used. Goerig observed that in 1959, German nursing authorities officially refused to perform “intravenous anaesthesia methods, intubation procedures, controlled ventilation or use of curare”.

In Japan, the specialty was slow to develop, partly because of the impact of World War II and partly because anesthesia even by the middle 1950s was not considered a recognized specialty. Of importance was the number of leaders trained in the US in the 1950s, returning to Japan as professors in key universities. Suwa notes (Chapter 31) that this system initially allowed permanent qualification as a specialist following two years of training and/or experience administering general anesthesia to 300 patients. This has changed to a far more demanding system today.

1960s Research Themes: Pharmacokinetics, Pharmacodynamics and MAC

In the 1920s, Haggard investigated the absorption, distribution, and elimination of diethyl ether in dogs [12, 13], and 30 years later Severinghaus measured nitrous oxide uptake in humans [14]. Those were the sum of the pharmacokinetic work up to the 1960s, work that dominated much of research in anesthesia in that decade. Some might add that the great Seymour Kety supplied the first paper explaining the pharmacokinetics of inhaled anesthetics [15], but he missed the importance of the differential distribution of tissue blood flow. In 1960, Henry Price published the first pharmacokinetic paper providing insight into why drugs distribute as they do, using a physiological-anatomical model. Price described the distribution of thiopental in humans (Fig. 9.3) [16], in the process correcting Kety’s error.

Now go back two decades. The attack upon Pearl Harbor in 1941 killed thousands of Americans. It was asserted (apocryphally) that more deaths resulted from intravenous thiopental than from bombs or other projectiles. The simulation provided by Price explained this statement. Traumatic injury and blood loss decreased the volume of the central blood compartment. Thiopental injected into this smaller volume would produce a greater concentration which, when delivered to highly perfused tissues (viscera such as the heart and brain) would result in greater anesthetic depth, cardiac depression, hypotension...and death. This simple explanation would apply to any intravenous medication and was a cornerstone of non-inhaled PK principals over the remainder of the decade. Obviously, this effect could be mitigated by decreasing the dose, and or restoring blood volume with blood transfusion and or intravenous fluid.

However, while the theory may have been convincing and the explanation logical, it appears that the facts conflicted

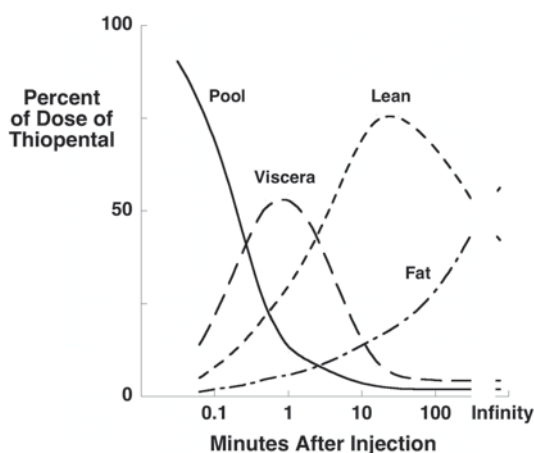

Fig. 9.3 Using an analogue model, Price convincingly argued that thiopental nearly immediately redistributed from the central pool of blood into which it was injected into the viscera where it acted, and that its evanescent effect depended on further redistribution, first and most importantly to muscle and later to fat. Until publication of his work, fat had been considered the cause of the evanescence. (From Price HL: A dynamic concept of the distribution of thiopental in the human body. *Anesthesiology* 1960; 21: 40–5, with permission.)

with both. In Chapter 47, Paul White comments that: “... an analysis by FE Bennetts suggested that...despite shortages of oxygen and transfusion supplies, thiopental caused few deaths [17].”

Early in the 1960s, interest in pharmacokinetics flourished. The 1962 symposium on this topic sponsored by the New York Academy of Medicine and the National Research Council-National Academy of Sciences, illustrates the intense focus. Thirty five scientists from around the world (four from the UK, one from Canada, and the remainder from the US) presented the results of largely unpublished research, using measurements and simulations to define what was then known about the pharmacokinetics of inhaled and intravenous agents [18]. The simulations might apply electrical analogs or complicated mathematical models. The contributors speculated on and provided indirect evidence for the inter-tissue diffusion of inhaled anesthetics. They set the stage for further measurements and simulations that continued for the next four decades. For the inhaled anesthetics, research was initially dominated by researchers at UCSF led by Edmond Eger and his many colleagues and trainees in the US, Europe, and Asia. The results from these studies informed our understanding of clinical pharmacokinetics for the subsequent 40 years. Many of the ideas were gathered in Eger’s 1974 book, *Anesthetic Uptake and Action* [19].

Before the 60s, empiricism ruled both practice and research in the specialty. Little could be measured accurately, and clinical experience rather than evidence based medicine drove clinical care. A typical anesthetic, reflecting the changing nature of the specialty between 1950 and 2013, for an adult in the US, undergoing major abdominal or thoracic

surgery is described in Chapter 7. The amount of inhaled agent delivered was driven by the vital signs and surgical requirements such as control of blood loss or the relaxation required to perform surgery. But what was the needed dose/concentration, and how did one define “needed”? How did altered physical status, associated co-morbidities, and physiological changes (e.g., body temperature or blood gases) influence this dose? Up to the late 1950s, the volatile anesthetic dose could not easily be measured, and an agreed upon response was not available. Should it be a change in blood pressure or pulse rate or respiratory rate? Of course, patient condition and surgical circumstances would affect these responses. On the other hand, how about an end point that everyone could agree upon, one that made clinical sense? And thus was born MAC—the minimum alveolar concentration preventing movement in response to a noxious (surgical incision) stimulus—perhaps the most utilized metric of anesthetic dose ever! A bit of irony—the study first describing MAC used both halothane and halopropane—the latter an anesthetic *never released* for clinical use [20].

Edmond (Ted) Eger trained in anesthesia at the University of Iowa, and following two years in the US Army stationed at Ft Leavenworth Kansas, joined Stuart Cullen and John Severinghaus in the anesthesia department at the University of California San Francisco (UCSF). Eger’s interest in pharmacokinetics, and ultimately MAC, began in 1957 while he was a first year resident. Severinghaus (then a second-year resident at Iowa) lectured on the uptake of inhaled anesthetics, using Kety’s ideas and Severinghaus’ results from his study of nitrous oxide uptake. He said that uptake of greater amounts of anesthetic (as with the highly soluble anesthetic ether) would slow the induction of anesthesia. To Eger (and most anesthesia residents yet today hearing this for the first time) it seemed obviously incorrect. A greater uptake would deliver more anesthetic to the blood and brain, so how could Severinghaus be right? Eger argued with Severinghaus for an hour after the lecture, but Severinghaus wouldn’t budge. Higher solubility, greater uptake, slower onset of action. It just didn’t seem correct...but it was. Severinghaus was always correct.

And now Eger was hooked. The more he thought about the reason that ether acted slowly, the more he was drawn to the beauty of the relationships that led to that idea. He spent days, weeks, and years dreaming about the relationships. Finally, it was time to put pen to paper. During his two years in the US Army (1958-1960), Eger used algebra and iterations to develop his descriptions of inhaled anesthetic pharmacokinetics. Along with parallel ideas from others in the field, Eger’s thoughts opened a new era of understanding as to why we do what we do, and how to logically conduct inhaled anesthesia taking into account hemodynamic and respiratory perturbations. The ideas and thoughts opened new ways to assess the worth of new inhaled anesthetics prior to FDA approval. The principles elucidated over this decade revised

Fig. 9.4 The three investigators who developed the notion of MAC, John Severinghaus, Giles Merkel, and Edmond Eger. (From UCSF departmental photographs from the early 1960's)

the way in which anesthetics were administered, and more importantly, enhanced understanding of pharmacokinetics by those responsible for delivery of anesthesia.

Equally important and influential was the development of the above-noted MAC by Eger and his colleagues (Fig. 9.4). The two crucial components in the definition of MAC were “alveolar” concentration and “muscular response” to a noxious stimulus such as a skin incision. Alveolar concentration (or its surrogate, partial pressure) was crucial because it approximated the anesthetic partial pressure in arterial blood, that in turn is presumed to approximate the partial pressure at the anesthetic site of action preventing movement in response to surgery. While this site of action was initially opined to be the brain, subsequent findings by Antognini and Schwartz at UC Davis [21] and Rampil et al at UCSF [22] established the spinal cord as the major site of action.

Movement was the second crucial component of MAC because preventing movement is the principal responsibility of the anesthetist to both the patient and to the surgeon. And it was an easily recognized and unambiguous response occurring in every experimental subject and species (avoidance to noxious stimulation), and was thus as applicable in the laboratory as it was in the operating room.

MAC-related research quantified clinically important physiological and physical effects of inhaled anesthetics. In particular, it allowed a comparison of these effects by different agents at multiples of equipotent concentrations, with the reasonable assurance that the results of a study performed at one site anywhere in the world could reasonably be compared with results performed elsewhere, as long as the MAC multiples were the same. Similarly, employing MAC as a measure of anesthetic depth simplified the study of new anesthetics. This meant that when enflurane (late 1960s), isoflurane (1980s), sevoflurane and desflurane (1990s) were released for clinical use, similar studies at similar anesthetic

depths had been performed at different institutions with reasonable assurance that nearly identical conditions had been present for each agent.

Serendipity: MAC and Malignant Hyperthermia

The first study measuring MAC in humans was conducted at UCSF in 1962-63 using surgical patients anesthetized with halothane with or without nitrous oxide or opiate premedication [23]. In each patient a predetermined alveolar concentration was achieved and held steady for at least 15 minutes prior to the skin incision to allow equilibration of the end-tidal anesthetic concentration to its site of action in the central nervous system. Following incision, the patient was observed for purposeful movement. MAC was based on the combined responses from a group of patients. The investigators decided to validate the accuracy of this measurement by studying the response of four patients, each serving as their own control. In these patients, following induction of anesthesia with halothane and oxygen, needles were inserted subcutaneously in the forearm and attached to a stimulator that could provide a supra-maximal stimulus. Similar to the method described above, once a predetermined alveolar halothane concentration had been achieved, the stimulus was applied and the response—movement or not—was noted. If movement occurred, the alveolar concentration was increased in steps until movement was abolished, and the process repeated in the opposite direction. Thus several “cross-overs” were achieved and the midpoint of the concentrations allowing and preventing movement was designated as MAC.

The first patient studied was an obese (BMI 33) 47 year-old man scheduled for repair of a ventral hernia by a surgeon noted for his insistence on profound muscle relaxation. After

completing the MAC study, Saidman and Eger relinquished care of the patient to the resident and staff anesthetist and departed for the lab. However, shortly after, they were recalled to the OR because the patient's temperature had increased. Temperature was not routinely monitored in 1963, but fortuitously and fortunately it was monitored in this case because of the MAC determination. Although a succinylcholine infusion had been and was being used, the surgeon complained that abdominal rigidity interfered with his work. The patient was sweating and breathing deeply, the color of the carbon dioxide absorbent indicated exhaustion, and the succinylcholine infusion was running rapidly. The temperature of the patient now exceeded 107 F, ultimately increasing to 108.5 F. One of the original blood-gas machines assembled by John Severinghaus and Freeman Bradley [24] was available and an arterial sample revealed a pH of 6.82, a $p\text{CO}_2$ of 179 mmHg, a $p\text{O}_2$ of 143 mmHg and a severe metabolic acidosis (base deficit—14.3 meq/L). Blood pressure decreased from 110/70 mmHg to 40/0 mmHg and was treated with metaraminol. The surgeon was asked to quickly complete the procedure, the patient was packed in ice, 3000 ml of lactated Ringer's solution were rapidly infused, and bicarbonate was given to correct the metabolic acidosis. Within 30 minutes, the temperature decreased to 103 F and in another 30 minutes to 97.2 F. The blood pressure increased to 110/70 without further therapy, and the patient survived without any apparent neurological deficit. Dantrolene, a muscle relaxant presently used in the management of malignant hyperthermia, was not available in 1963.

This case was presented before the anesthesia section of the 1964 AMA meeting held in San Francisco and when the moderator queried the audience if any had experienced a similar case, several replied that they had in patients who, similarly, had also been anesthetized with halothane and paralyzed with succinylcholine. This patient had likely suffered from malignant hyperthermia and provided the first ever determination of the metabolic aberration associated with this syndrome [25]. An earlier paper by Denborough highlighted the fact that a similar syndrome had been noted in many relatives (some of whom had died) within a family. Because the title of the paper did not mention temperature, it escaped notice when the UCSF patient was being reviewed [26].

Variations of these MAC studies also allowed other clinically relevant metrics to be defined including the concentration at which awareness is likely (MAC Awake) [27], the concentration at which coughing in response to endotracheal intubation is likely (MAC EI) [28], the concentration which blocks an adrenergic response to surgical stimulation (MAC-BAR) [29], and MAC as a function of age [30]. In addition, because MACs were later shown to be additive, the substitution of a fractional MAC concentration of an anesthetic with less cardiovascular depression, for a portion of a second anesthetic, permitted the anesthetist to provide an equal

Fig. 9.5 Photograph of a young Rod N. Westhorpe conferring an Honorary FANZCA on Emmanuel Papper in 1996. (Courtesy of Rod N. Westhorpe.)

anesthetic depth while causing less total cardiovascular depression.

Emanuel Papper Goes to Washington

As mentioned earlier, anesthesia research in the first half of the 1960s in the US was largely phenomenological, and research funding for the specialty was limited, few departments receiving support. Emanuel (Manny) Papper (Fig. 9.5) the Chairman of the anesthesia department at Columbia University took a leave of absence to serve as Principal Consultant to Fred Stone, the Director of the Institute of General Medical Sciences of the NIH. Papper acted to assist Stone in developing programs especially targeting young academic anesthesiologists. Commenting on Papper's performance, Stone opined that "In his six months as Principal Consultant

for the Institute, Doctor Papper accomplished what it would have taken staff three years to accomplish [31].”

Subspecialties and the Evolution of Specialty Research and Training

Except for pediatric anesthesiologists and perhaps a few obstetrical anesthesiologists, as the 1960s approached, most anesthesiologists were “generalists”, caring for all patients regardless of age, surgical procedure, or gender. However, during this decade several factors increasingly led to subspecialization in anesthesia and surgery. Increasing numbers of certified anesthesiologists allowed time for a few to train in subspecialty academic programs pursuing a body of knowledge unique to that subspecialty (e.g. obstetric related physiology and pharmacology), and those who performed research on problems related to a specific cohort of patients (parturients or perhaps pregnant ewes) similarly increased. Although there is little evidence describing a cause-effect for this change, one might speculate that a key factor included surgical advances demanding more of anesthesia and anesthesiologists. Moreover, increased interest, knowledge and training evolved into discrete clinical specialty rotations, and subsequently to specialty (fellowship) training programs for trainees. Small cohorts of practitioners then provided care to patients having a limited spectrum of diseases (Neurosurgical, Obstetrical, Cardiac, Thoracic).

Initially, generalists resisted subspecialty development. It would narrow options for generalists, perhaps affecting income. It might lessen their worth, and it would alter call-schedules, relegating the generalists to what may be thought of as less interesting work than those working in more “exotic” specialties. However, the tide toward sub-specialization moved inexorably forward, leading to discrete work groups within departments concentrating on cardiac, obstetric, pediatric, neurosurgical, regional anesthesia, critical care, anesthesia for ambulatory surgery, and, more recently, management.

These groups increasingly grew in the 1960s, forming formal societies in the 1970s that in turn sponsored scientific and educational meetings, published scientific journals, defined educational goals and requirements for certification, and finally became exclusionary, constricting practice opportunities of generalists especially in teaching hospitals. Remarkably, specialty societies in both the US and the UK grew at a nearly simultaneous rate during the 1970s and beyond (see Fig. 10.2).

Initial research among the specialties largely remained phenomenological, describing effects, rather than explaining why they occurred. Thus, neurosurgical anesthesiologists measured the effect of volatile anesthetics on cerebral blood flow and metabolism to define the “best” combination of drugs to use in patients with increased intracranial pressure.

Obstetric anesthesiologists noted the effect of different vasoactive drugs on fetal lamb well being, or in humans comparing Apgar scores, or in-utero heart rate patterns. Great excitement accompanied the NEJM article from the MGH group of cardiac anesthesiologists in 1969, showing “high dose morphine” to be associated with greater cardiovascular stability, especially in patients with valvular disorders, but it, too, was phenomenological [32]. Of course as with many, *innovative* (including phenomenological) discoveries, this had been suggested earlier [33]. Unfortunately, the use of high-dose morphine anesthesia was sometimes associated with patient awareness.

Differential Solubility and Gas Transfer into and from Gas Filled Spaces in the Body

In 1936, Aird suggested that if a space in the body were filled with a gas of blood solubility greater than nitrogen, the space would decrease in size because the gas would be removed from the space faster than nitrogen could be brought into the space (and even faster if oxygen rather than air was breathed). This also assumed that the same gas was not being simultaneously breathed [34]. An appreciation of the more rapid elimination of more soluble gases from body spaces was applied to accelerate the removal of the gas used for pneumoencephalography and thereby shorten the duration of the headache associated with this procedure [35]. In 1953, it was recognized that the converse would occur if a closed space within the body was filled with a gas of blood solubility less than that of nitrogen. Such a space would increase in size if the walls were compliant [36, 37].

These effects of differential solubility were applied during the 1960s to prevent increases in the size of, or pressure within, gas filled spaces in the bodies of patients. Thus anesthesiologists might avoid using nitrous oxide during surgery for which the risk of air embolism was increased, such as intracranial surgery in a patient in the sitting position [38], a patient with a large emphysematous bullous, or a patient with intestinal obstruction (Fig. 9.6) [39]. Conversely nitrous oxide might be used to **deliberately** provoke an increase in the size of the space to provide an “early warning” that air has been entrained in this same patient in the sitting position. Also in 1965, Saidman and Eger demonstrated that the administration of the more soluble gas, nitrous oxide, would increase the pressure in a non-compliant space (e.g., the intracranial space) containing the less soluble gas, nitrogen [40]. Such a potentially dangerous change arose in patients undergoing pneumoencephalography or any procedure in which air was allowed within the skull. More recently, ophthalmologists used the principle to maintain pressure within gas filled spaces (injecting a bubble of very low solubility sulfur-hexafluoride into the posterior chamber of the eye to “stent the retina”

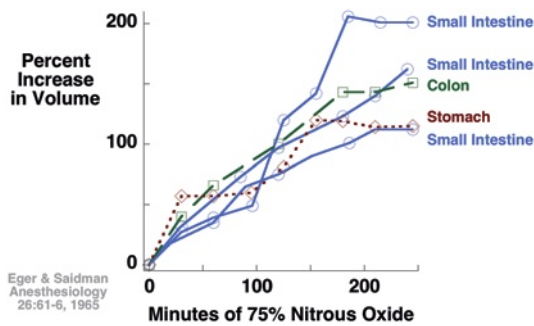

Fig. 9.6 The administration of 75% nitrous oxide to dogs increases the volume of gas contained in various portions of the intestinal tract by approximately equal amounts. Data from Eger and Saidman who in their report did not indicate why they studied 3 loops of small bowel but only one stomach and one colon. (From Eger EI, II, Saidman LJ: Hazards of nitrous oxide anesthesia in bowel obstruction and pneumothorax. *Anesthesiology* 1965; 26: 61–6, with permission.)

following surgery for retinal detachment). This incurred a risk of a great increase in intraocular pressure if such a patient then breathed nitrous oxide. The resulting increase in pressure could lead to retinal ischemia and blindness [41].

Other Important Changes in the 1960s

Physiology An understanding of cardiorespiratory physiology and pharmacology underlay advances in pharmacokinetics and patient care. One of the great pioneers in this field from the late 1950s to the 1980s was the British anesthesiologist, John Nunn. He began work at the Royal College of Surgeons, then became Professor in Leeds, and subsequently assumed the directorship of the Medical Research Council unit at Northwick Park Hospital. Initially his studies centered on lung ventilation/perfusion relationships during anesthesia and surgery [42], and their effects on oxygenation during, and especially after, anesthesia [43, 44]. Such studies led to his world-renowned book on Applied Respiratory Physiology [45]. He had a special affection for diverse aspects of inhaled anesthetic pharmacology, ranging from the effects of volatile anesthetics on depolymerisation in cellular microtubules [46], to the toxic effects of nitrous oxide [47]. His prodigious output led to receipt of the ASA Excellence in Research Award in 1991. He retired in the 1990s to pursue his lifelong love and study of Egyptian hieroglyphics.

Pharmacogenetics It was the rare anesthesiologist who had not at some time been confronted by a patient experiencing prolonged paralysis following an intravenous injection of succinylcholine. The 1950s discovery of genetic polymorphism of the esterase responsible for the metabolism of succinylcholine, led to Kalow's work on dibucaine numbers [48], and his classic 1962 monograph [49].

New Drugs Pancuronium. In 1960, d-tubocurarine (curare) was the most frequently used muscle relaxant. Unless the initial dose far exceeded that required for relaxation during surgery, its onset was relatively slow and thus unsuitable for rapid sequence induction. In addition, use of a large dose risked substantial hypotension due to histamine release, and delayed the ability to pharmacologically reverse its effect. Thus, when concerned about a patient considered at risk of vomiting and aspiration during induction of anesthesia, and if for some reason succinylcholine was contraindicated, awake tracheal intubation, unpleasant for both patient and anesthetist, was often employed.

Curare was essentially replaced in 1967 when pancuronium, an amino steroid, was released for clinical use [50]. Its principal advantages compared with curare were that 1) side effects related to histamine were rare; and 2) the onset of action was faster making it more suitable for use during a rapid-sequence induction. However, pancuronium increased heart rate. Indeed, the use of pancuronium might be preferred to prevent the bradycardia associated with a large dose of fentanyl.

Fentanyl also came to the market in the 1960s. Initially it was combined with droperidol as "Innovar", in a fixed 50:1 dose ratio (2.5 mg droperidol:0.050 mg fentanyl), producing what had been popularized as neurolept-analgesia, a term according to Paul White, that Oliver Wendell Holmes considered prior to coining "anaesthesia". Initially used as premedication, Innovar could produce a panic like effect that might cause an occasional cancellation of surgery [51]. Because of this side effect and a dislike for fixed dose combinations of drugs, Innovar was soon abandoned. Fentanyl on the other hand was increasingly adopted for use, first in small doses and then in larger ones. It continues (when not in short supply) as a nearly universally used rapid-onset, relatively short acting opioid during most types of surgery, sedation, and as an adjunct for spinal and epidural anesthesia.

Ketamine, introduced during the 1960s, was developed for clinical use by Gunter Corssen and Ed Domino [52]. It had two distinguishing differences. First, its sympathomimetic actions recommended it as a suitable substitute for thiopental for the induction of anesthesia in patients displaying hemodynamic instability, particularly those scheduled for a rapid induction of anesthesia. This benefit was shared by etomidate which has more recently largely replaced ketamine for this purpose. Second, given at doses that cause anesthesia, ketamine caused undesirable psychomimetic after-effects, at times lasting for days and distressing patients and their caregivers. Lesser doses, however, appeared to not produce such effects, yet had the capacity to produce analgesia. Because of these analgesic effects, ketamine has more recently been used as an anesthesia adjunct especially in patients with long standing chronic pain problems for which they take "industrial" sized maintenance doses of opioids [53].

Bupivacaine, a longer-acting, lipid-soluble anesthetic was released into clinical practice in Scandinavia in 1963. As Drasner points out in chapter 51, in laboratory studies, bupivacaine's systemic toxicity appeared to be equivalent to that of tetracaine and four times greater than that of mepivacaine, paralleling their relative potency [54]. However, in the 1970s, several clinical reports suggested the potential for cardiac toxicity. Prentiss suggested that toxicity resulted from a direct effect of this lipid-soluble, highly-bound anesthetic [55]. By 1982, concerns regarding toxicity led to elimination of the 0.75% formulation, the widespread use of a test dose, and incremental injections as standard anesthetic practice. These modifications provided effective, but not foolproof, protection of the patient.

Beecher: Science and Ethics—A Giant Astride Medicine

As described in Chapter 8, during the 1950s, Henry Beecher published two landmark contributions. In conjunction with Donald Todd, in 1954 Beecher reported the first large prospective anesthesia outcome study, providing the incidence of anesthesia related mortality including the finding that administration of curare increased mortality [56]. In the same year, Beecher described the importance of the placebo response [57]. It is difficult to imagine two more important papers shaping anesthesia research and clinical care for generations.

Beecher was not yet done however. During the 1960s, he continued to make momentous contributions to medicine in general and the specialty in particular. Subsequent to the original Nuremberg trials in 1947, the Doctors Trial resulted in convictions of German physicians accused of medical experimentation on human beings. Ultimately ten principles evolving from the trial became known as the Nuremberg Code, and defined the principles governing future human experimentation. These principles included:

1. The voluntary consent of the human subject is absolutely essential. This means that the person involved should have legal capacity to give consent;
2. The experiment should potentially yield fruitful results for the good of society, be unprocurable by other methods or means of study, and not be random and unnecessary in nature.
3. The experiment should be based on the results of animal experimentation and knowledge of the natural history of the disease.
4. The experiment should be so conducted as to avoid all unnecessary physical and mental suffering and injury.
5. No experiment should be conducted where there is a prior reason to believe that death or disabling injury will occur.
6. The degree of risk to be taken should never exceed that determined by the humanitarian importance of the problem to be solved by the experiment.
7. Proper preparations should be made and adequate facilities provided to protect the experimental subject against even remote possibilities of injury, disability, or death.
8. Only scientifically qualified persons should conduct the experiment.
9. During the course of the experiment the human subject should be at liberty to bring the experiment to an end.
10. During the course of the experiment the scientist in charge must be prepared to terminate the experiment at any stage, if he has probable cause to believe...that a continuation of the experiment is likely to result in injury, disability, or death to the experimental subject.

Although these principles were a foundation for the Helsinki Principles initially published in 1964, it seems that they had not been sufficiently codified to prevent abuses described in the now historic paper by Beecher. The paper was probably instrumental in the NIH requirement that local institutional review boards (IRBs) approve all human experimentation supported by NIH funds [58]. Beecher stated in his paper (rejected for publication in JAMA) that "Evidence is at hand that many of the patients in the examples to follow never had the risk satisfactorily explained to them. And it seems obvious that further hundreds have not known that they were the subjects of an experiment although grave consequences have been suffered as a direct result of experiments described here". Beecher examined "100 consecutive human studies published in 1964, in an excellent journal; 12 of these seemed to be unethical". Examples of these 100 studies were classified as either: Withholding Effective Treatment, Study of Therapy, Physiologic Studies, Studies to Improve the Understanding of Disease, Technical Study of Disease, or Bizarre Study. Selected examples from among these studies included: injection of melanoma from a daughter into an informed and volunteering mother, who died from metastatic melanoma nearly 15 months later; performing a placebo vs penicillin controlled study in patients with streptococcal respiratory infections in spite of the known efficacy of penicillin—2 of the controls developed acute rheumatic fever and in one, acute nephritis occurred; and in order to define the toxicology of chloramphenicol, 2 G vs 6 G were given to randomly selected patients with aplastic anemia subsequently developing in 10% and 86% respectively.

In his second 1960s initiative, Beecher attempted to define brain death [59]. The burden posed by brain-injured patients on the family (both social as well as economic), the need for hospital beds, and "the obsolete criteria for the definition of death that can lead to controversy in obtaining organs for transplantation" prompted the initiative. In the absence of anesthesia, hypothermia, or drug intoxication, four criteria defined brain death: Unawareness and unresponsiveness; lack of movement or breath-

ing; absent reflexes; and absent EEG activity. This assessment must be made by a physician. When completed and discussed by the attending physicians and all other care givers (all of whom must concur with the conclusions), the respirator may be turned off. Commenting on the issues surrounding creation and promulgation of these criteria, Ed Lowenstein observed that “it seems likely that the whole brain criteria for brain death promulgated by Henry K Beecher and the Harvard Ad Hoc Committee 40 years ago will remain the standard for the foreseeable future [60].”

Thus this body of work in the two decades following World War II shaped the conduct of human research in ways not previously imagined. Although only the Beecher-Todd report is solely applicable to the specialty, we take enormous pride in acknowledging Beecher as “one of ours”.

Reprise

The decade of the 1960s might be described as the “Golden Age of Anesthesia” because of the changes throughout the world profoundly influencing all aspects of the specialty and some that reached beyond the specialty. Research into the pharmacokinetics and pharmacodynamics of anesthesia grew to maturity in this and the next decade. In a search for “why and what”, phenomenological research increasingly turned into basic “how and where” research. New drugs appeared (bupivacaine, enflurane, fentanyl, ketamine, etomidate, pancuronium) or disappeared (Innovar, methoxyflurane), and their effects were investigated. Sub-specialization was soon accompanied by worldwide specialty societies, and specialty oriented journals facilitated training of experts and spurred targeted research contributing to improved anesthetic care. In the US, recruitment into the specialty grew out of an ASA initiative aimed at exposing medical students to the specialty while still early in their careers. Also in the US, passage of the Medicare Act in 1965 included anesthesiologists in Part B, stipulating reimbursement on a fee for service basis (similar to that for most physicians), improving salaries for anesthesiologists, and coinciding with a nearly exponential growth in anesthesiologist numbers in every subsequent decade.

Summary

Specialist anesthesiologists increased in numbers and influence, in the process creating subspecialty societies and journals. In some countries (e.g., Cuba and Panama), numbers of nurse anesthetists decreased dramatically, but in others (e.g., the US) they increased. Continuing a trend initiated in the 1960s, investment in anesthesia research expanded.

In the 1960s, halothane displaced ether as the volatile anesthetic agent of choice. However, postoperative liver dysfunction attributed to halothane led many anesthesiologists of the time to prematurely abandon its use in favor of probably inferior alternatives. Methoxyflurane and trichloroethylene had their champions, but neither matched the advantageous features of halothane. The search was on for a replacement. By the mid 1970s, enflurane supplanted halothane in many developed countries (especially the US) except in children because of halothane's absence of pungency.

Understanding of neuromuscular blocking drug pharmacokinetics and pharmacodynamics led to more rational use and monitoring of muscle relaxants. Dantrolene was used to treat malignant hyperthermia.

Anesthesia expanded from the operating room to support the use of new imaging technology. Outpatient surgery greatly increased in the US—fifty years after Ralph Waters' "Downtown Anesthesia Clinic" began this trend. New understanding of pain pathways, and the introduction of new methods of pain relief moved anesthesiologists into post-operative pain management. Opioid receptors were discovered, and opioids were given intrathecally to provide analgesia. Regional anesthesia became established as an integral part of everyday anesthesia practice. Led by their respective champions, Alon Winnie and John Bonica, the subspecialties of regional anesthesia and pain medicine established an international presence.

In 1978, Cooper and colleagues published the results of their study of critical incidents during anesthesia. Having obtained taped interviews from anesthesiologists, and making use of new developments in computer technology, they looked objectively at the roles of human factors and equipment failure in the causation of incidents during anesthesia. This study began the worldwide "safety movement" in anesthesia.

"You, you may say I'm a dreamer" said John Lennon, and for anesthesia, some of those dreams came true.

World Events in the 1970s

"Imagine," John Lennon's immortal song, released in 1971, epitomised the aspirations of younger people for a safer and better world. It was not all to be. The 1970s heralded myriad changes in the world. Science, technology and the social fabric of society were to be altered forever. In 1970, people wrote letters by hand, using a ballpoint pen, a Bic©. The

first microprocessor appeared in 1971, and IBM released a mini-computer, the 5100, in 1975. It was a complete programmable system designed for professional and scientific problem-solvers. It was also expensive—up to \$ 20,000. Apple computer Inc. was founded in 1976. Writing letters changed after 1979, when a word processing system was introduced (Wordstar), turning illegible hand-written letters to clearly written documents. And we placed these in stamped envelopes and waited, and waited, for a reply. The next step, transmission via the internet, arose in the 1980s. The counterculture movement that began in the late 1960s, epitomized social change in the 1970s. The long running Vietnam War ended in 1973 with the US and its allies withdrawing their troops after loud and sometimes bloody public protests. In the aftermath of the 1972 burglary of the Watergate offices of the Democratic National Committee, Richard Nixon resigned his presidency in 1974. Urban terrorism raised its profile with the murder of Israeli athletes at the 1972 Munich

Fig. 10.1 The cumulative number of anesthetic societies in the world continued to grow—by 18—in the 1970s. Most arose in developing countries

Olympics, and in 1973, the Arab-Israeli conflict (the Yom Kippur War) once again led to a crisis in the price and availability of oil. China remained in the paralyzing grip of Mao's cultural revolution until 1976. In 1979 under Ayatollah Khomeini, the Iranian revolution transformed Iran from the Shah-led autocracy into a theocracy. And Russia occupied Afghanistan, much to its later regret.

Anesthesia, a Child of the 1970s

The previous two decades set the scene for the massive changes in the specialty that would occur in the remainder of the twentieth century. Most developed countries and many others had established training programs in anesthesia. Countries with lesser numbers of anesthesiologists per head of population lagged behind in the development of anesthesia societies (see Fig. 8.1), particularly those in Africa, Central America, the Middle East, China and the USSR. Many of these countries added anesthetic societies in the 1970s (Fig. 10.1). Most developed countries established societies to enable this new breed of medical specialists to share knowledge and advance their status (see Fig. 8.3). It was still a “junior” specialty, but was starting to flex its muscles. A specialty that was perceived to immediately connect physiology and pharmacology to patient care attracted increasing numbers of doctors.

Anesthesia also attracted women into the specialty. The proportion of women as medical students in the US greatly increased in the 1960s and 1970s. Title IX of the 1972

Higher Education Act banned discrimination in admissions and salaries in any institution receiving federal government funding. Although the number of women accepted into medical school almost tripled from 1971 to 1975, it would be some time before women fully achieved senior roles in specialist medical organisations. There were exceptions. In Australia, women assumed leading roles in the specialty as early as the 1950s. Mary Burnell became the first woman President of the Australian Society of Anaesthetists in 1955, and in 1966, she became Dean of the Faculty of Anaesthetists, just as Patricia Mackay (nee Wilson) was elected President of the Society. In the US, before the 1980s, few women had assumed major roles in anesthesia since Virginia Apgar and Gertie Marx, had done so some 20 or more years earlier.¹

Professionalism and Consolidation

At the beginning of the 1970s, many surgeons recognised the value of an anesthesiologist to their own practice but were reluctant to acknowledge the place of another senior physician in the operating room. The operating room is referred to as the operating “theatre” and surgeons had long relished their place in (or at least under) the spotlights as “the captain of the ship.”

In his February 1976 editorial in *Anesthesiology*, Nick Greene noted that the traditional approach to anesthesia—“the best anesthetic is the one the anesthetist is most familiar with”—was no longer acceptable. He argued that the goal should be to administer an anesthetic optimizing the patient's care. The growth of professionalism accompanied the maturation of anesthesia departments and societies, with a gradual rejection of subservience of the anesthesiologist to the surgeon. There was a significant economic imperative in this process, since in countries where private practice predominated, there were substantial fee differentials between anesthesiologists and surgeons. Although some societies divested the responsibility for training to sister organisations in the form of Faculties (notably of Colleges of Surgeons or Physicians), most societies maintained a primary educational role while developing an increased profile in political negotiation for better conditions and remuneration.

By 1980, the place of the specialty was firmly established. Younger surgeons recognised the value of a productive working relationship with the emergent specialty, and placed increasing trust in the anesthesiologist, including their involvement in preoperative assessment and postopera-

tive care. Still, some of the “old guard’s” influence remained, and sometimes their prejudices rubbed off on their trainees.

Non-specialist Anesthesia

In many countries, the 1970s saw the gradual disappearance of non-specialists in anesthesia practice. As training programs generated more specialists, full-time anesthesia practice replaced the part-time anesthetist in general practice. In some European (especially Nordic) countries and many developing countries, as well as in the US, nurses continued to play an important role in the provision of anesthesia services. In the US, the traditional place of the nurse anesthetist came under threat when in 1974, the US Office of Education required that a body independent of the American Association of Nurse Anesthetists (AANA) would be needed to accredit training centers. The AANA had been the training and certifying organization since 1931, and proposed an independent body comprised of Certified Registered Nurse Anesthetists (CRNAs), anesthesiologists and members of the public. The American Society of Anesthesiologists (ASA) sought to establish a competing Faculty of Nurse Anesthesia to accredit CRNAs. The ASA did not succeed in gaining control over CRNA accreditation which was ultimately entrusted to the Council on Accreditation of Nurse Anesthesia Programs (CANAP), as proposed by the AANA.

Sub-specialization

Although most anesthesiologists in 1970 were “generalists”, as the specialty matured and the scope and complexity of anesthesia grew, some developed skills and enthusiasm for particular branches of the specialty. These involved obstetric, pediatric, neurosurgical, cardiac, and regional anesthesia, and intensive care. The desire to share information, and advance the quality of care through focussed research and education, led to the formation of sub-specialty organizations, or special interest groups. The establishment of these groups required sufficient numbers of practitioners to sustain them, and this was initially only possible in places like the US and Great Britain, where formal specialty training and certification had been in place for sufficient time. (Fig. 10.2). The Society of Obstetric Anesthesia and Perinatology (SOAP) was established in 1968, and in the following year, the Obstetric Anaesthetist Association was established in Great Britain. By 1970, Great Britain had also established a society for anesthetic research. Then, in the 1970s, several new subspecialist societies or associations formed in both the US and Great Britain, paving the way for the establishment of similar groups in the 1980s and 1990s in other regions of the world. Although there might have been sufficient numbers

Fig. 10.2 The cumulative increase in the number of subspecialty anesthesia societies occurred linearly and in parallel in the US and UK

of European anesthesiologists to sustain the creation of subspecialty anesthesia organizations, they did not arise until the 1980s. This probably reflected the later establishment of formal training programs. The subspecialty societies or associations formed in Great Britain during the 1970s encompassed critical care, pediatric, cardiovascular, dental and regional anesthesia with several parallel organizations arising in the US (Fig. 10.2).

Training and Examinations

Between 1970 and 1980, most countries in Europe established formal training programs in anesthesia with durations commonly of 3 to 5 years. Not all imposed a formal examination process.

Since the 1950s, training in the US had been overseen by the Anesthesiology Residency Review Committee (RRC) comprising representatives of the AMA Council on Medical Education and Hospitals, and the American Board of Anesthesiology. Attempts to rationalise all postgraduate medical training in the late 1960s had failed and in 1972, five bodies, the AMA, the Association of American Medical Colleges, the American Board of Medical Specialties, American Hospital Association, and the Council on Medical Specialty Societies convened to resolve matters. This resulted in two accrediting bodies, only one of which was to survive, the Liaison Committee on Graduate Medical Education.

A further complication arose because there were two examining bodies, the American Society of Anesthesiologists' American College of Anesthesiology (ACA), and the

American Board of Anesthesiology (ABA). The ACA certified some practitioners whom the ABA considered unsuitable, or who had failed the ABA examination. This created uncertainty for hospitals and credentialing committees. Arthur Keats led the resolution of the impasse. In 1971, he became chairman of the ABA examinations committee while he was also editor in chief of *Anesthesiology*. Through his efforts, the ACA ultimately ceased awarding certificates. At the same time, Keats led a revision of the examination system, creating the Guided Question (intended to provide a more standardized exam), and a comprehensive analysis of the then scope of anesthesiology practice. Both written and in-service training examinations were revised, and a computerized analysis of the results of the exam was introduced. Further, the ABA (using the Rasch model), oversaw the introduction of analysis of the written examination, to ensure that it was a valid test of required knowledge, and would enable feedback to both examiners and residents.

In Great Britain, the Association of Anaesthetists of Great Britain and Ireland established a formal training program in 1932, some time after Waters established his program in 1923. The first formal examination took place in 1935, the Diploma in Anaesthetics, awarded by the Anaesthetic Section of the Royal Society of Medicine. By the 1970s, the Faculty of Anaesthetists within the Royal College of Surgeons, was well established. Training was of four years duration with one year of “higher professional training” to be undertaken after successful completion of the primary and final examinations. Both examinations had written and oral components.

In Europe, the six signatories to the Treaty of Rome in 1957, established the Union Européenne des Médecins Spécialistes (UEMS) in 1958. Intended as a source of discussion and consultation for European Economic Community (EEC) legislation, it eventually became the umbrella organization for national medical specialist organizations in all EEC countries, as well Norway and Switzerland. Specialist sections were created and the Section of Anesthesiology first met in 1962. In 1963, the Section stipulated a minimum training of 3 years, at a time when training in the six member countries varied from 2 to 7 years. The Section reviewed the directive in 1969, agreeing on a minimum training period of 4 years. In 1973, the periods of training still varied between 3 and 7 years in EEC countries, and between 2 and 6 years in non-EEC countries.

In Canada, the Royal College of Physicians and Surgeons of Canada (RCPSC) was established in 1929, and began by recognizing the need to give recognition to doctors engaged in “special work”. The qualification was initially gained by invitation, with an examination introduced in 1931, leading to the title “Fellow”. It was primarily aimed at physicians and surgeons in an academic role, while anesthesiologists were not considered in the “same league”. In 1937, a less

rigorous program of “certification” was introduced, however anesthesia was still not considered as a specialty, although it was eventually included in 1942. Until 1971, the dual system of certification and fellowship persisted, with both fellows and certificants being recognized as specialist anesthesiologists. In 1971, a single training, examination and accreditation system was instituted. This and the four-year training program meant that Canadian specialists were at last treated as equal to other specialists within the RCPSC.

In Australia and New Zealand, the training and examination process for certification as a Fellow of the Faculty of Anaesthetists of the Royal Australasian College of Surgeons, was similar to that in Great Britain, without the requirement for a year of higher professional training.

In Japan in the 1960s, two years training and/or experience in administering anesthesia to 300 patients resulted in a permanent qualification that once obtained, remained in force indefinitely. The duration of training has increased to at least 4 years at the first step of certification (see Chapter 31).

Medical practice in China recovered slowly from the 1966–1976 Cultural Revolution, which had forced many doctors to perform non-medical manual work. Despite these hindrances, in 1979, the Chinese Society of Anaesthesiology was formed with 44 members.

In Mexico, and Central and South America, development of anesthesia lagged behind that in the US, Canada, and Europe. Nevertheless, by 1970, most countries in this region had established specialist societies (see Figs. 6.2, 8.2, and 9.2), and some had instituted training programs. Through the 1970s, with growth in the number of academic departments of anesthesia, more training programs were established. The 1970s also saw the disappearance of nurse anesthetists from many countries in the region.

Academic Development

In Great Britain, during the 1960s, 15 new academic departments of anesthesia were created, consolidating the advancement of academic anesthesia. Several university research departments were created, and several anesthesiologists acquired MDs or PhDs. This enhanced the status of anesthesia in the region and had the effect of attracting many anesthesiologists from current and former British Commonwealth countries (Australia, Canada, India, New Zealand, Pakistan, and South Africa) to Great Britain. Many of these anesthesiologists returned to their countries of origin to assist in establishing academic departments, although in most cases it took some years before university research departments were created.

In the US, funded academic departments were well established, and the 1970s saw an expansion of anesthesia research, championed by enthusiastic and dedicated people.

Theirs was the model that many other countries wished to emulate, but few could afford.

This was also a period when collaboration between academic anesthesiologists and industry reached a new peak. Several companies enthusiastically pursued the development of anesthesia equipment and drugs—Ohio (enflurane), Cypriane (variable bypass, tec-type vaporizers), ICI (propofol), Glaxo (althesin), Burroughs Wellcome (atracurium), Organon (pancuronium), to name a few, and all had close ties with research anesthesiologists.

Journals

By 1970, many of the major anesthesia journals of the world were well established (e.g., see Fig. 6.1), and the only further one to appear during the decade was *Anaesthesia and Intensive Care*, first published by the Australian Society of Anaesthetists in 1972. The 1970s did however see the appearance of subspecialty journals. As might be expected, the earliest subspecialty journals to appear were consistent with the first subspecialties to create organisations, except for obstetric anesthesia. *Critical Care Medicine* was first published in 1973, and following the formation of the International Association for the Study of Pain (IASP) in 1974, *Pain* was published in 1975, with Patrick Wall as its first editor-in-chief. *Pain* eventually achieved the highest impact factor of all anesthesia-related journals in 2011. In 1976, *Regional Anesthesia* was first published, later to be renamed *Regional Anesthesia and Pain Medicine*. In 1978, another journal dedicated to regional anesthesia appeared as a supplement to *Der Anaesthetist*, named *Regionale Anaesthesie*.

The Beginning of the End for Halothane

At the beginning of the 1970s, anesthesia commonly relied on the use of thiopental, nitrous oxide, and halothane, with the probable addition of a muscle relaxant and opioid. The notation on many anesthetic records of the time “GOH”, signified the mainstay of practice; “Gas (nitrous oxide), Oxygen and Halothane”.

The documentation of cases of liver dysfunction following halothane had led to widespread investigation in the 1960s. The detailed results, published in 1969, pointed to a rare but real mortality rate from hepatotoxicity of some 1:120,000 [1]. This was enough to reassure some, especially pediatric anesthesiologists, but the coming demise of halothane was established. In many cases it was not anesthesiologists who condemned it, but physicians (internists), who quickly blamed any episode of postoperative jaundice on halothane, often without justification. Outside the US, some anesthesiologists chose to use alternatives, either methoxyflurane or

Fig. 10.3 Few cases of hepatic injury were reported in the first 5 years following the release of halothane, but after 5 years, a dramatic increase in published reports of injury followed. This biphasic response would be expected if an allergic response underlay injury. The steep increase would require an initial “sensitization” to halothane. In contrast to halothane, no dramatic increase in published reports of injury occurred in the first 10 years after the release of enflurane for clinical use

trichloroethylene, and some even clung to ether. All had their problems, and were to disappear from general use by the mid 1970s. The possibility of renal failure as result of free fluoride ion from degradation of methoxyflurane had been described previously, but was characterised by Mazze and Cousins in 1973 [2]. The search was on for a replacement.

Ross Terrell had identified enflurane in the mid-1960s, a fluorinated methyl ethyl ether with characteristics likely to make it safer than halothane, an alkane. He noted that the ethers had less propensity to cause arrhythmias and that only 2–3% of enflurane was metabolised, resulting in fewer potentially toxic metabolites. Introduced in the early 1970s, enflurane was the answer to many prayers, only to be tarnished by the appearance of tonic and clonic muscle movement, associated with EEG epileptiform activity. This was not a major impediment, and in the US and some other developed countries around the world, enflurane displaced halothane from the operating room. With increasing use of enflurane, it was clear that hepatotoxicity was much less than with halothane [3]. In particular, the number of cases reported in the years after release appeared at a far slower rate than after the release of halothane (Fig. 10.3).

The Trouble with Isoflurane

Ross Terrell synthesized the isomer of enflurane, isoflurane, in 1965. It was more difficult to produce and purify, delaying its development. Once a suitable method was found, and animal tests had been done, clinical trials began in 1971. Initial results were encouraging. Isoflurane met many of the criteria of the ideal inhalational agent; it was stable, had low blood solubility, low level of biodegradation (0.2%), and was non-flammable. It was also devoid of epileptogenic activity and allowed a rapid recovery. Just as it was about to be released

in 1975, a study by Tom Corbett at the University of Michigan suggested that isoflurane was a carcinogen in mice [4].

Corbett phoned Eger with the news. Eger, Terrell and Jim Vitcha from Ohio Medical (the manufacturer of isoflurane) went to the University of Michigan to discuss the experiment with Corbett, finding several key flaws in the study. In particular, there were too few negative control animals, no dose-response relationship had been determined, and Corbett had not blinded his examination of animals for tumor [4]. Even more frighteningly, there were no control animals given alternative anesthetics. Corbett had assumed the problem was limited to isoflurane, but other anesthetics were far more vulnerable to metabolism and the production of potentially toxic metabolites that might have produced genetic changes. Still, that magic word “cancer” made such objections moot. Clearly the test would have to be repeated with the flaws eliminated. Everyone involved knew this.

But Eger also knew that Ohio would dither while it decided whether to fight the findings or support (at great cost) the required study. Not willing to wait for what they knew would be a long-delayed decision, the impatient Eger and his colleague, Wendel Stevens, elected to initiate the study using discretionary funds Eger had gathered from previous work, believing that Ohio would be forced to pursue and support the study. They would sponge off the university for a few months.

For a time, it went as planned. Ohio capitulated nearly a year later and asked Eger and Stevens to proceed with the study, now clandestinely underway, a study of thousands of animals. But for a phone call requesting a small change in the protocol, the conspirators would have pulled it off, covering up their early start. Vitcha called Eger asking if the study animals might be kept alive three months longer than originally planned after their in utero exposure to the anesthetics, 18 rather than 15 months. Too late; the animals were already in formaldehyde! Eger and Stevens flew to Chicago to meet with their friends from Ohio Medical and confess their sins.

The conspirators then completed the study, convincing Corbett to join them, this time as a blinded examiner of the tissues of the study animals for cancer. The result was that none of the study anesthetics, none of the modern anesthetics, caused cancer except that the most metabolized anesthetic, methoxyflurane tended to show a trend towards an increased incidence [5].

Published in 1978, this negative result allowed the clinical release of isoflurane to proceed. Isoflurane was marketed in another year or two, becoming the dominant inhaled anesthetic of the 1980s.

In the 1970s, pediatric anesthesiologists continued using halothane because it was less pungent than enflurane, and did not have the stigma of epileptogenicity. Anesthesia was commonly induced in children by inhalation, and their in-

duction and recovery was as fast with halothane despite the modestly lower solubility of enflurane. In addition, halothane had not been incriminated in the causation of liver injury in children.

Calibrated Vaporizers

Both the Copper Kettle and the Fluotec Mark 2 (the Mark 1 was recalled shortly after release because of a problem with the control knob) had been available since the 1950s. The Copper Kettle could be accurately used with any volatile inhalation agent, and would be used for halothane, methoxyflurane, and enflurane until it was superseded by variable bypass vaporisers. The Fluotec Mark 2 was a modification of the Tritec, the first temperature compensated vaporiser produced by Cyprane in England, for use with trichloroethylene. The “tec” vaporiser was later modified to accommodate methoxyflurane (Pentec), and enflurane (Enfluratec). There was also an Ethertec designed for use in developing countries.

Despite the availability of calibrated, temperature compensated vaporisers, at the beginning of the 1970s, many anesthetics were still given using the old Boyle bottles, particularly outside North America. Because the Copper Kettle and the Vernitrol had an established place in the US as universal vaporisers that could be used with either ether or halothane (albeit requiring some mathematical calculations on the part of the anesthesiologist), the initial marketing of halothane in the US was accompanied by an aggressive joint campaign by Ayerst Laboratories marketing halothane, and Fraser Sweatman, the agents for the Cyprane “Fluotec” vaporiser. This ensured that hospitals procuring a supply of halothane would receive free vaporisers. Boyle bottles and the Ohio #8 vaporizer quickly became obsolete, and the Copper Kettles and Vernitrols gradually disappeared.

In Germany, Drager had introduced the “Vapor” temperature compensated vaporiser, but elsewhere outside North America, where there was no competition for the Fluotec, Boyle bottles were still in use, as there was no incentive for hospitals to equip their operating rooms with new and expensive devices. These had originally been used for ether, were uncalibrated, and could deliver high concentrations of halothane. Producing new glass bottles labelled “Fluothane” or “Trilene” served to identify them as “new” vaporisers, but they were little better than dripping the agent onto a towel—the anesthesiologist had no idea how much was being administered. The recent establishment of the principle of MAC by Eger and colleagues had little meaning to those forced to use such equipment by the lack of investment by hospitals in the emerging specialty. Boyle bottles were of course convenient for many anesthesiologists in private practice who had to supply their own halothane, allowing them to empty the remaining contents back into their personal container at the

end of a case. This advantage was also somewhat dangerous if the anesthesiologist did not label and/or empty the “bottle” and a second person filled it with a different agent.

Cyprane introduced the “Tec” 3 vaporiser in 1969. It had several advantages over the “Tec 2” models. The output was linear at all flow rates, and it eliminated the “pumping” effect of positive pressure ventilation that could silently increase output. By the end of the 1970s, all inhalation agents were delivered through calibrated, temperature compensated vaporisers, usually the Tec 3 or similar devices manufactured by Ohio or Drager. The concept of MAC had informed the 1970s anesthesiologist as to the concentration of anesthetic agent required for elimination of a response to the surgeon’s knife, but until the end-tidal concentration was routinely monitored, could only be interpreted in terms of the inhaled concentration. At least by the end of the decade, the anesthesiologist had a calibrated vaporiser to help.

Induction with Steroids

Thiopental retained its place as the primary induction agent at the beginning of the 1970s, but was to be challenged by alternatives. Thiopental found an additional role after Michenfelder and Theye showed in 1973 that it reduced cerebral metabolism and might protect the brain against hypoxic injury [6]. The use of the drug for cerebral protection by “induced coma” continued for many years. Such virtues notwithstanding, the search was on for a replacement for thiopental, for a drug that avoided the cardio-respiratory depression so characteristic of induction, especially in the patient with vascular disease.

Etomidate, a carboxylated imidazole derivative rather than a barbiturate, was released in the mid 1970s. Because it was hydrophobic, it was formulated in propylene glycol, however the pain and irritation on injection, and myoclonic movements after injection, limited its popularity. It did nevertheless provide greater cardiovascular stability than its rival, thiopental.

Glaxo released a new anesthetic induction agent in Europe in 1973, comprising a mixture of two steroid molecules. Althesin included alphaxalone as the anesthetic, accompanied by alphadolone to increase the solubility in a Cremophor EL solution. Althesin provided a smooth painless induction accompanied by little cardiovascular effect and rapid recovery. It gained a firm place in outpatient anesthesia until reports of allergic reactions began to appear, reactions largely related to the presence of Cremophor EL. Althesin was never released in the US.

Ketamine, a phencyclidine derivative was developed in 1962. It was first used clinically on American soldiers in the Vietnam War in 1970, and although it was devoid of cardiovascular depressant effects, its hallucinogenic tendency,

a consequence of its chemical heritage, resulted in what was to be called “dissociative anesthesia”. Such a label was of little comfort to those who experienced the less desirable manifestations including perceived loss of their arms or legs. Ketamine found a place in field use in civil disasters and in low dose infusions for pain management, but that was after the 1970s.

Thus, by the end of the 1970s, thiopental had defended its place as the induction agent of choice. It was now only available as a 2.5% formulation (requiring mixing of powder and sterile water before use) because the previously available 5% solution had been shown to cause skin necrosis after extravasation, and ischemia after arterial injection. Use of the 2.5% solution largely eliminated these complications. The drug was available in multi-dose bottles, commonly 100 or 250 ml. The fear of disease transmission was unheard of, and anesthesiologists of the time recall prepared solutions being used for several days on subsequent patients. Perhaps that wasn’t quite as foolish as it might sound. Alkalinity of thiopental solutions (pH 10–11) made them sterile. By 1970, in most countries, metal intravenous cannulae (needles) had been replaced by plastic disposable cannulae (catheters), often still with a metal hub.

Relaxed about Relaxants

In 1970, the available muscle relaxants included succinylcholine for rapid action and short procedures, and d-tubocurarine (curare) or pancuronium for prolonged effect. The 1970s will not be remembered for new relaxants, but for the increased understanding of their pharmacology and pharmacokinetics, and the introduction of routine methods of monitoring the depth of neuromuscular blockade.

As the decade began, the ways in which injected drugs acted on the body (pharmacodynamics) and how they were affected by the body (pharmacokinetics), were little understood. In 1973, Leslie Benet and colleagues created the concept of “clearance” in landmark research that led to greater understanding of individual dosage and toxicity of drugs [7]. At the same time, Lewis Sheiner introduced the concept of “concentration—effect” relationships, leading Sheiner and Stuart Beal to develop NONMEM, a computer program for modelling of pharmacokinetics [8]. Using these tools, Ronald Miller and colleagues, also at UCSF, studied the action of curare. Measuring the concentration of a drug at its effect site (the neuromuscular junction in the case of curare) is not feasible. But Miller and Sheiner recognised that the effect (and the concentration) at the effect site always lagged behind what the anesthesiologist had given (i.e., the blood concentration) to induce paralysis, and that the opposite was true during recovery [9]. This enabled an estimation of drug concentration at the effect site, and from this they could infer

the effects of such things such as hepatic or renal failure on drug concentration and clearance. Their work enabled a new understanding of the pharmacodynamics and pharmacokinetics of curare, and indeed, of many other drugs used in anesthesia.

In 1970, Hassan Ali and colleagues applied a series of four identical stimuli to the ulnar nerve via surface electrodes at half second intervals. The response of the pollicis longus muscle to the fourth stimulus was compared to the first. Ali determined that a ratio of less than 0.7 indicated residual paralysis from a muscle relaxant. The “Train of Four” did not require a baseline measurement, and therefore could be applied after injection of the neuromuscular blocking drug, and could even be used in awake patients with minimal discomfort. Crude estimation of the ratio could be performed by the anesthesiologist manually sensing the twitch response. The use of surface electrodes also eliminated the need for needles. The ability to monitor the depth of neuromuscular block, and the adequacy of reversal was a great advance in the prevention of postoperative hypoventilation due to residual paralysis [10].

Alon Winnie Promoted Regional Anesthesia

Although no new local anesthetic agents appeared in the 1970s, the polio-stricken Alon Winnie championed the use of regional plexus blocks, in particular of the brachial, cervical and lumbar plexuses. Anesthesiologists embraced these new techniques for intraoperative use as part of the expanding armamentarium of anesthesia practice. Fine, high quality disposable spinal needles were developed, and epidural anesthesia benefited from the development of precise loss of resistance syringes, encouraging a greater use of these techniques as part of anesthesia care.

Beyond his clinical contributions, Winnie’s great legacy from the 1970s was his re-establishment, with colleagues, of the American Society of Regional Anesthesia (ASRA). The Society was dedicated to the promotion, investigation and teaching of regional anesthesia. The first congress of the Society was held in 1976, soon followed by the publication of the first issue of the journal *Regional Anesthesia*. The formation of ASRA, and Winnie’s international profile, encouraged the establishment of similar organisations elsewhere in the world, with the European Society beginning in 1979.

In 1976, Danish gastrointestinal surgeon Henrik Kehlet’s observations of stress responses to surgery convinced him that epidural regional anesthesia imposed before surgery and continued postoperatively could attenuate the catabolic (i.e., protein-wasting) effects of surgery. The notion was to prevent “central sensitization”, to block afferent nociceptive traffic completely. To avoid central sensitization required a

sufficient density of neural afferent blockade for a sufficient time, over a sufficient number of spinal segments [11].

A cautionary note on regional anesthesia appeared in 1979, with the first report of the cardiotoxic effects of bupivacaine, ultimately leading to revised guidelines on dosage [12].

The Painful Truth

The 1970s brought a change in the way anesthesiologists approached pain management, intraoperatively at first, and later postoperatively. Just before the start of the decade, high dose morphine anesthesia became popular in patients having valvular heart surgery because it blocked the hemodynamic and metabolic responses to surgical stress. Outcome studies suggested however, that such patients had incomplete amnesia and suffered from greater histamine release, consequent venodilation, and prolonged postoperative respiratory depression. Venodilation also resulted in greater transfusion requirements. High dose fentanyl, introduced in the late 1960s, offered a suitable alternative, with less histamine release and less hypotension. Fentanyl began to displace morphine (and meperidine) from routine anesthesia practice, although its propensity to lead to respiratory depression was recognised as a limitation. Anesthesiologists had to “learn” how to use a new analgesic with quite different pharmacokinetics. Most importantly, fentanyl (and its later sisters alfentanil, sufentanil, and remifentanil) easily passed through the blood-brain barrier whereas morphine did not. The result was that fentanyl acted quickly—within minutes from the time of its injection—and its effect disappeared as it left the blood consequent to hepatic metabolism. In contrast, morphine’s effect came on slowly, reaching a peak in perhaps 45 minutes. And although the blood level might decrease, morphine remained in the brain and its blood levels might not reflect its continuing effect.

Anesthesiologists took an increasing interest in acute pain management, and in particular, in postoperative pain. John Bonica led this movement, no doubt stimulated by his personal problems with pain imposed by the result of injuries suffered in his earlier career as a professional wrestler. In 1972, he initiated a global organization to establish pain as a differentiated field of study. He oversaw the organisation of an international meeting in 1973 that attracted 102 international speakers. As noted earlier, attendants at that meeting established the International Association for the Study of Pain (IASP), and planned a new journal, *Pain*.

The 1970s saw the introduction of acute pain services, usually led by anesthesiologists. Surgeons and other clinicians saw the benefits of such services and compounded the enthusiasm. Sechzer reported the first patient controlled analgesia (PCA) system for postoperative pain in 1968 [13]. In

this manually controlled system, a nurse administered small increments of morphine or meperidine according to patient demand. Forrest and colleagues described the first automated device in 1970 [14]. Increasingly sophisticated devices appeared through the 1970s, culminating in Hull's On Demand Analgesia Computer (ODAC) in 1979 [15].

The idea that opioids might act on specific receptors emanated from Wall's and Melzack's 1965 gate control theory. In 1973, Pert and Snyder discovered specific opioid receptors in neural tissue [16]. In 1976, neuroscientists Arthur Duggan and Tony Yaksh provided unequivocal evidence of a spinal site of action of morphine [17, 18]. Wall, while visiting Israel, convinced Florella Magora and her colleagues to administer morphine epidurally for various types of pain. Their results were published in a letter to *The Lancet* on 10 March 1979 [19]. The ensuing publication by Behar et al. encouraged Michael Cousins and colleagues to issue a preliminary report of their study of intrathecal morphine and meperidine, and epidural meperidine. They had been prompted to embark on the study after Wang published the results of a small 1978 study of intrathecal morphine [20]. Matas had described his use of intrathecal morphine in 1900 [21], but at that time the dangers of cephalic spread of the drug were not recognized. The blood and CSF pharmacodynamic and pharmacokinetic data, and neurological assessment, strongly suggested a spinal site, with sparing of normal non-noxious sensation, motor power and sympathetic function. Cousin's Letter, titled "Selective Spinal Analgesia", was accepted 24 hours after receipt and published in May 1979 [22].

Anesthesia Machines: Still the Same, But Not for Long

In any 1970s operating room, the anesthesiologist's main tool-in-trade, the anesthesia machine, had remained largely unchanged for two decades. In many instances, the machine was likely to be 20 years old. The only major improvement was the attachment of a calibrated vaporiser, when administrative and funding support were available. It was still possible however, to administer two different inhalation agents in series, and guidelines were in place suggesting the order in which the vaporisers should be positioned to minimize the danger of this arrangement.

The conduct of anesthesia was however changing. By the 1970s, anesthetists usually routinely measured blood pressure, and pulse meters had appeared in GB (Fig. 10.4). ECG devices with their "beep" provided the alternative in the US. Pulse meters were small devices attached to the patient's fingertip, using a pressure sensor to create a deflection of an ammeter needle and later a flashing light or audible beep. They alleviated the need for the anesthesiologist to constantly palpate the patient's radial or superficial temporal artery. The

Fig. 10.4 The pulse meter, a simple device supplying a continuous visual (but not auditory) measure of pulse rate. (Courtesy of Rod N. Westhorpe.)

anesthesiologist's task was increasingly demanding! Often holding a face mask on a patient, watching an electrocardiograph, taking the occasional blood pressure (one handed if one could afford an oscillotonometer), and manually recording events. The pulse meter was a great innovation.

Another great innovation was the 1976 introduction of an automated non-invasive blood pressure device, the "Dinamap" by Maynard Ramsey III. Ramsey, who graduated first in chemistry, then in medicine, and then obtained a doctorate in biomedical engineering, described his career as "satisfying, challenging, rewarding and much of the time, lots of fun" [23]. He developed his first disposable intra-arterial pressure device while still a medical student. Using newly available miniature electronic components, he developed the model 825 Dinamap (Device for Indirect Non-invasive Mean Arterial Pressure). It measured only mean arterial pressure, Ramsey considering that the measurement was more informative as an indication of tissue perfusion than systolic and diastolic pressures. He may have been correct, but anesthesiologists were not ready to accept his reasoning, and he responded with the model 845 in 1978, which measured systolic, diastolic and mean pressures as well as heart rate [24].

Another change that occurred in the 1970s was the disappearance of the flammable anesthetics ether, ethylene, and cyclopropane, thus eliminating the need for conductive rubber, and other antistatic measures in the operating room. Nevertheless, there was a long lag time before all protective measures were eliminated...just in case.

How Safe?

In 1971, Scurr described the trend of deaths associated with anesthesia in Great Britain, in relation to the increased number of anesthesia services being performed. He found improvement, and that this had started in the mid 1930s. He suggested the improvement related to “proper education and training in anesthesia” [25].

The 1970s revealed a watershed in the recognition and study of the factors involved in the generation of anesthesia-induced morbidity and mortality. In his paper “There, but for the grace of God...” Wylie commented on the analysis of 66 cases of cardiac arrest during anesthesia reported to the Medical Defence Union in Britain from 1964 to 1973, noting that the number of deaths associated with anesthesia had been falling dramatically since the 1950s, coinciding “with the early days of modern anaesthesia and of specialization...” Wylie determined that about 50% of the cardiac arrests were preventable and 18% resulted from negligence. He suggested that the latter might have been prevented had a proper preoperative assessment been made by an anesthetist or had the anesthetist maintained direct responsibility in the immediate postoperative period [26].

But, it was reasoned that counting the dead was not necessarily a good way to assess the safety of anesthesia, especially when the number of deaths was falling.

Jeffrey Cooper promoted a new approach to this problem. Cooper graduated with a Masters in biomedical engineering and a PhD in chemical engineering in 1972, and joined the bioengineering unit of the Department of Anesthesia at the Massachusetts General Hospital. His close contact with anesthesiologists at work led to his talk at a NATO conference on Human Factors in Healthcare in 1974, entitled “The Anesthesia Machine; An Accident Waiting to Happen”. An audience member suggested that he use the Critical Incident Technique described in the 1950s by Flanagan, to study operating room accidents [27, 28]. So began Cooper’s landmark studies leading to minimum monitoring standards and the analysis of human factors in the safety of anesthetic delivery. The patient safety movement was born and would ultimately be embraced by all of healthcare.

In their first paper, in 1978 Cooper and his colleagues analysed 359 critical incidents identified at interview with staff anesthesiologists and residents. Human error was involved in 82% of incidents, and equipment failure could only be blamed in 14%. The most frequent incidents were breathing circuit disconnections, inadvertent changes in gas flow, and “syringe swap” [29].

These results led the team to look at preventive strategies in both anesthesia practice, and in the design of equipment. They developed a prototype anesthetic machine, “The Boston Anesthesia Machine”, that was displayed at the 1976 annual meeting of the ASA. It was the first application of

microprocessor technology, replacing rotameters with solenoid valves and representing gas flows by bar graph displays. An injector system (from a Volkswagen) introduced volatile agents into the breathing system, each agent having a separate non-interchangeable canister. A microprocessor controlled oxygen concentrations in breathing gas, and the actual percentage and circuit pressure were measured automatically. Alarms were applied to various machine parameters, and could be set by the user. The display included messages regarding system faults and corrective strategies. Although never used in patients, the machine gave a foretaste of what was to come [30].

In 1978, Canada became the first country to have a comprehensive standard for anesthetic gas machines. Because both Left (British) and Right handed (American) machines were in common use, sometimes in the same hospital, instances had occurred where the oxygen knob was inadvertently turned off instead of nitrous oxide.

The most important outcome of Cooper’s studies was the adoption in 1979 of the anesthesia machine standard, the American National Standards Institute standard Z79.8–1979. The standard aimed to eliminate or warn of serious problems. The requirements included flowmeters in series instead of in parallel, fluted oxygen flow control knobs for tactile feedback, and a means to prevent administration of a hypoxic mixture. Machines manufactured after publication of this standard needed to meet all its requirements.

Soon, some colleagues also began to examine the anesthesiologist’s workplace. Ergonomics entered anesthesia in the late 1970s with studies of the anesthesiologist at work. The spatial activity of the anesthesiologist had extended to 360 degrees, and the traditional arrangement of the anesthetic machine behind the anesthesiologist was no longer an efficient one. These studies would direct changes in the operating room over the following two decades.

Safely Anesthetizing the Patient with Cardiovascular Disease

In the 1980s and 1990s, several study results argued that controlling heart rate with beta sympathetic blocking drugs decreased morbidity and mortality, and these will be discussed in succeeding chapters. In 1972, one view held that therapy with beta-receptor blocking drugs for treatment of severe angina should be halted because patients receiving such drugs tolerated anesthesia poorly and had impaired cardiovascular responses to stresses such as hemorrhage [31]. In 1973, Prys-Roberts’ group presented an alternative view, suggesting that “hypertensive patients are protected (by pretreatment with a beta-receptor antagonist) from the undesirable sequelae of laryngoscopy and intubation, and from myocardial ischemia associated with arterial hypotension...” [32] Validation and

an expansion of such work by Mangano, Wallace and others was yet to come.

Poison in the Air

Perhaps more than patients were at risk from anesthesia. A 1967 study by Vaisman, published in Russian, alerted anesthesiologists and operating room personnel to the potential hazard of breathing trace concentrations of volatile agents for long periods [33]. Vaisman surveyed Russian anesthesiologists and found an increased incidence of poor health, miscarriages and neurological problems, problems associated with exposure to volatile agents, long working hours, emotional stress, and excessive attention to their work.

Many supporting reports followed. In 1971, Ellis Cohen et al surveyed operating room nurses and found an increased incidence of miscarriage, followed by Knill-Jones et al in 1972, who showed that female anesthesiologists had an increased incidence of miscarriage and of congenital anomalies in their offspring. In 1973, Corbett et al showed an increased incidence of cancer in anesthetic nurses, and later, an increase in congenital anomalies in offspring. Although a study by Ericson and Kallen in 1979 failed to confirm the results of the earlier studies, the die was cast [34]. The National Institute for Occupational Safety and Health (NIOSH) had initiated the ASA National Health Survey of Operating Room Personnel, but before completing the study, it released its recommendations in 1977, believing that sufficient circumstantial proof had been gathered. Standards on safe practice and scavenging were produced, along with recommendations on maximum safe levels of all inhaled agents—all arbitrarily determined.

These studies and reports led to the worldwide introduction of stringent measures to minimize or even eliminate trace levels of anesthetic gases from the operating room. Many persist to this day. This despite Spence and colleagues' publication in 1987 [35]. Spence surveyed all female UK medical school graduates under the age of 40 working in hospitals from 1977 to 1984. They surveyed 11,500 women and found that there was no difference in the incidence of infertility, miscarriage, cancer, neuropathy or congenital anomalies in offspring, in anesthesiologists compared with unexposed female hospital doctors.

Ventilators

In the early 1970s, there was still some support for the use of Negative End Expiratory Pressure (NEEP) during the expiratory phase, in the belief that a reduced intrathoracic pressure would improve venous return. Many ventilators of the era included the option of NEEP, but PEEP soon superseded NEEP

when it was realised that NEEP could impair alveolar gas exchange while PEEP might do the opposite. The notion that PEEP might help followed the paper by Ashbaugh et al in the *Lancet* in 1967 [36]. Ventilation improved in patients with what would be called Acute Respiratory Distress Syndrome, when they were treated with 5 to 10 cm H₂O of PEEP. PEEP was applied in anesthesia by the end of the 1970s, initially to critically ill patients. Anesthesia ventilators came to be fitted with a PEEP option as standard.

Most anesthesia ventilators of the time were simple devices. In Great Britain, the Manley ventilator, designed by Roger Manley in 1959 while he was a House Officer, was virtually ubiquitous. It was powered by the fresh gas flow of the anesthetic machine, and was used to provide ventilation from a non-rebreathing circuit. The Manley ventilator had no alarms, and had a maximum inspiratory pressure of 30 cm H₂O.

In the US, the Bird and Air Shields Ventilators were commonly used, usually with a "bag-in-bottle" arrangement driving a rebreathing circuit with CO₂ absorption. When not enough ventilators were available, the anesthesiologist squeezed the rebreathing bag. Anesthesiologists in Australia and New Zealand largely relied on the latter method, although some used the "auto hand", a simple electrically driven device comprising two boards hinged at one side, with the rebreathing bag placed between them.

Europeans were more sophisticated. They used the Engström ventilator and a variety of others developed as a consequence of the 1952 Copenhagen polio epidemic. Although originally designed for use in intensive care, or in thoracic surgery, they found their way into the operating room. In 1971, the Elema-Schönander company introduced the first Servo ventilator, a microprocessor controlled device designed for intensive care, but ultimately used by anesthesiologists. The new ventilator was so quiet that during one early trial, the company representative found the ventilator pushed into a corner each morning. The staff were convinced that the lack of noise indicated the ventilator wasn't working. Another hospital asked the company to insert a window in the ventilator so that they could see the bellows move [37].

Early ventilators had to be equipped with autoclavable patient circuits. However in the mid 1970s, sterilisable low volume bacterial filters became available. Although these could be placed in the patient circuit and decreased the threat of infection, they did not eliminate the need for sterilization.

Rubbered Out

Although polyvinyl chloride tubes had been on the market since World War II, in 1970, many countries still used red rubber tracheal tubes. The reason was simple. The sterile and

individually pre-packed PVC tubes were expensive when compared with the reusable rubber tubes. The cuffs on reusable tubes did not last as long as they used to, because now they were subject to disinfection by autoclaving or high temperature washing [38–40].

Disposable PVC tubes with an inflatable cuff were introduced in 1964, with thick cuff material mirroring the design of rubber cuffs. In 1969, Geffin and Pontopiddan stretched the standard PVC cuff in boiling water to make it thinner, and the result was considered less likely to cause compression injury to the tracheal wall [41]. Through the 1970s, the manufactured cuff became even thinner, with a larger diameter, enabling lower cuff inflation pressures. The use of disposable PVC tubes also decreased or eliminated the standard test of cuff competency before each use when it was realised that the practice was largely a waste of time.

In 1975, a revolutionary new tracheal tube was designed to replace the “Oxford” pattern red rubber tube, often used for oral or nasal surgery. The Oxford tube had a 90-degree bend, and could then be attached to a right angle connector to produce a 180 degree turn, allowing the patient circuit to be placed parallel to the patient’s chest and chin. This ensured that the anesthetic circuit was away from the surgical field. Ring, Adair and Elwin performed 10,000 intubations with their prototype before publishing their results, and introduced the RAE pre-formed tube in 1975 [42].

Disposable anesthetic circuits were sold in the US in the 1970s. Much of the remainder of the world did not adopt their use, at least immediately, because of the additional cost. EIE remembers Henrik Bendixen (then Chair at the University of California, San Deigo) rejecting their use, saying that it would increase the landfill problem.

Plastic disposable facemasks also appeared in the 1970s in the US. Again, the cost was prohibitive for most countries to introduce them to routine practice, and the traditional black antistatic rubber masks continued in use.

Ikedda reported on a new flexible fiberoptic bronchoscope in 1971. Stiles et al published the first 100 cases using the device for tracheal intubation, demonstrating that intubation could be performed in less than 60 seconds [43].

Outpatient Anesthesia

Nicoll initiated outpatient anesthesia with 7000 Scottish children undergoing surgery for various conditions between 1899 and 1909 [44]. The first free-standing surgical outpatient clinic was Ralph Waters’ “Downtown Anesthesia Clinic”, described in 1919 [45]. Charles Hill followed Waters in establishing a free-standing outpatient facility in Providence, Rhode Island in 1968. The facility included a fully-equipped operating suite and a recovery room. However it failed due to lack of financial support from government

and insurers. In 1970, free-standing units within hospital settings were established at the Hammersmith Hospital in London, and the Gulson Hospital in Coventry, England [46]. In Phoenix, Arizona, Ford and Reed, learning from Hill’s experience, obtained clearance from local authorities, and sought funding approval from insurers before opening their Surgicenter® in 1970. In 1976, Ford and Reed described how they had treated more than 33,000 patients without a death or malpractice suit [47]. Others, both in the United States and internationally followed their lead. By the 1980s, outpatient anesthesia caught the eye of the accountants and blossomed.

Anesthesiology Outside the Operating Room

Anesthesiologists also began moving away from the operating room. The first computerized tomography (CT) scanner (called the EMI Scanner) was installed at a hospital in London. It is said that EMI funded the development and early commercial production of the scanner through their association with The Beatles. So began an increasing demand for anesthesia in CT facilities, usually in circumstances that were not anesthesiologist-friendly. Although many applauded the passing of pneumoencephalograms, early CT devices took up to 30 minutes to complete a set of images. With improved technology, the scan time diminished to the point where anesthesia would rarely be needed, except in children. The first magnetic resonance imaging scan of a human being was performed in 1977. That’s another story.

And also in the 1970s

A Test and a Treatment for Malignant Hyperthermia

Werner Kalow, who had been instrumental in defining the dibucaine test for pseudocholinesterase variants, and had effectively established the science of pharmacogenetics, tested some muscle samples for contractile force in vitro. In 1970, he and Britt noted that muscle from malignant hyperthermia (MH) patients contracted with abnormal strength in the presence of caffeine [48]. They thereby created the first test for susceptibility to MH. In 1971, Ellis and colleagues further demonstrated that halothane augmented muscle contraction in such patients [49].

Dantrolene was first proposed as a new type of muscle relaxant in 1967, and it was used to treat spasticity in the 1970s. In 1975, Gainsford Harrison reported that dantrolene treatment minimized the MH response induced by halothane in susceptible pigs. This provided the only effective pharmacological treatment so far identified [50].

Anesthetics and How They Act

Before the 1960s, the Meyer Overton theory of anesthetic action provided a major basis for our notion of how anesthetics acted. The theory suggested that the solution of anesthetic agents in the lipids of neural cell membranes caused anesthesia. The 1970s saw the rejuvenation of lipid theories. The best known one was the “Critical Volume Hypothesis” originally proposed by Mullins and refined by Miller and Smith. It had the advantage of providing an explanation for the experimental “pressure reversal” of anesthesia (i.e., pop an anesthetized mouse into a hyperbaric chamber and raise the pressure to 100 atmospheres and the mouse would wake up). A popular theory held that anesthetics induced a thickening in the lipid bi-layer of neural cell membranes, thus altering permeability. Nick Franks and William Lieb had opposing views about the thickening or thinning of the layer. In 1975 they used X-ray and neutron diffraction to show that neither was correct—there was no change (see Chapter 45). There were other problems with the lipid theories, for example, how to explain the absence of anesthesia with some lipid soluble drugs, and the variation in anesthetic effect with enantiomer drugs. Despite all the theories, we were little the wiser.

Aoyagi and the Oximeter

Japanese Takuo Aoyagi was working as a research engineer with Nihon Khoden in Japan in 1971, seeking to non-invasively measure cardiac output by a dye dilution technique using an ear densitometer. The pulsatile variations in the transmitted light signal produced an artefact that prevented accurate measurement. In attempting to eliminate the artefact, Aoyagi realised that the variation in transmitted light with red and infrared light was analogous to the principle underlying hemoglobin oxygen saturation measurement by previously described oximeters. He selected two wavelengths, 630 nm and 900 nm, the latter being insensitive to the dye he was using, and the former known to be sensitive to oxygen saturation. He found that the 900 nm wavelength was also sensitive to oxygen but in the opposite direction. This serendipitous result led him to further investigate the phenomenon, and by late 1973, he had developed a prototype ear oximeter. In 1974, he presented the “improved earpiece oximeter” to the Japanese Society of Medical Electronics and Biological Engineering. A first commercial version was produced, but the company decided not to pursue further development and did not patent the device. Aoyagi was transferred to another division within the company and the pulse oximeter was to become the story of the next decade.

Reprise

Increasing anesthesiologist numbers and diversity in the 1970s led to subspecialty societies and journals. Women constituted a rising fraction of anesthesiologists. The practice of anesthesia became more diverse with an expanding application of outpatient surgery, establishment of regional anesthesia in everyday practice, and a rising use of anesthesia outside the operating room.

Our understanding of anesthetic drugs and how to best use them changed. In the US, and to a lesser extent elsewhere, the minimally hepatotoxic enflurane replaced halothane. We explored neuromuscular pharmacokinetics and clinically defined recovery from neuromuscular blockade. Dantrolene treatment of malignant hyperthermia was initiated. We incorrectly thought we might understand how inhaled anesthetics acted. We found opioid receptors in the spinal cord, leading to intrathecal opioid administration to provide analgesia. Patients received opioid analgesia on demand.

The worldwide “safety movement” in anesthesia started in the 1970s, growing rapidly in succeeding decades. Part of this resulted from an examination of the underlying causes of injury. Part probably resulted from the increasing application of automated monitoring of simple things such as pulse rate, ECG, blood pressure, and blood oxygen saturation, and increasing precision in inhaled anesthetic delivery and ventilation. Safety also likely followed from greater numbers of highly trained anesthetists. These trends continued in succeeding decades.

Summary

The 1980s were anesthesia's "adolescence". The specialty became increasingly independent and self-assured, ceasing subservience to surgeons or any specialist. Part-time anesthetic practitioners diminished in numbers or vanished.

The anesthetist's acknowledged love of "gadgets" enlarged, the specialty embracing technology, applying it to the delivery and control of anesthesia. More importantly it underlay a revolution in patient monitoring.

Anesthesia benefited from two new drugs, isoflurane and propofol, as well as from new analgesics, local anesthetics, muscle relaxants and antiemetics. The benzodiazepine, midazolam, nearly foundered after causing deaths from respiratory depression, particularly in the elderly, because of inadequate supervision. Archie Brain invented the Laryngeal Mask Airway, the most important new airway device since Hewitt's invention of the oral airway in 1908.

Arguably, the greatest change came in the examination of safety and outcomes in routine practice. Partly stimulated by medico-legal attention given to adverse outcomes, the specialty instituted processes to examine and prevent potential failures in patient care. The "patient safety" movement was established, and pervaded all of health care by the century's end.

Michael Jackson said it in his 1988 song, "The Man in the Mirror": We needed to change ourselves to make the world a better place.

World Events in the 1980s

The 1980s expanded the benefits and drawbacks of technological advances. Ted Turner founded CNN in 1980, and by mid-decade, the PC, the MAC, and Windows were released, altering how we work, play, and communicate. The 1988 opening of the internet added to the revolution. Events and international politics proceeded in unexpected directions, all under the watchful gaze of television and international media. We learned of John Lennon's 1980 assassination. We learned that a toxic gas leak killed 16,000 people in Bhopal, that an earthquake devastated Mexico City, that an oil spill from the Exxon Valdez contaminated hundreds of miles of pristine Alaskan coastline, and that a meltdown occurred in the Chernobyl nuclear energy plant. Thousands of spectators and millions on television saw the

space shuttle Challenger explode shortly after launch. The world watched the brutal suppression of protest in Tiananmen Square in 1989.

In 1979, the Iron Lady, Margaret Thatcher, became Britain's first woman Prime Minister. With Helmut Kohl and Ronald Reagan, in the 1980s she revived right-wing politics in the West. The Soviet Union disintegrated, several eastern European countries found new democratic freedoms, and the Berlin Wall fell in 1989. The 1980–1988 Iran–Iraq war ended in an uneasy peace, but not before chemical weapons made their ugly entrance. Russia departed Afghanistan, opening the way for a resurgent fundamentalist Taliban. The AIDS epidemic began in earnest, and Michael Jackson rose to international fame.

Anesthesia Flexes Its Muscles

By 1980, the number of non-specialists providing anesthesia in developed countries had diminished and would largely disappear by 1990, as specialist training and certification solidified around similar worldwide standards. Departments of anesthesia became independent of surgical departments, following the lead established in the US and GB. Regional societies flourished with increasing membership bases, allowing some to exert political influence.

Fig. 11.1 Anesthetic societies continued to accumulate, a dozen in the 1980s

More and Larger Societies

Many smaller and developing nations established societies in the 1980s, as did some Middle Eastern countries such as Saudi Arabia and Egypt (Fig. 11.1). The two French societies that had supported opposing views about anesthesia practice reconciled in 1982. In 1960, a disagreement regarding the election of a non-anesthetist to the presidency of the Société Française d'Anesthésie, d'Analgesie et Réanimation (SFAAR) followed an ongoing controversy over the method of anesthesia. There were two camps. Pierre Huguenard led the "Laboritiens" who followed the teachings of Henri Laborit (1914–1995) favouring neurolept anesthesia. They were at odds with those embracing inhalation anesthesia, led by Jean Lassner. Lassner had also established an alternative journal to the official Society journal (edited by Huguenard). Huguenard left the Society and with Jean Bimar, founded l'Association des Anesthésistes Français, with a new journal. Following the reconciliation, the new society, la Société Française d'Anesthésie et Réanimation (SFAR) established the still published journal *Annales Françaises d'Anesthésie Réanimation*.

In South America, in 1987, the societies in Argentina, Brazil, Paraguay and Uruguay formed the Federation of South American Societies of Anesthesiology (FASA), later to be joined by Bolivia, Chile, and Colombia. In the same year, the larger Latin American Confederation of Societies of

Anesthesiologists (CLASA) that had been established in 1962, became the South American Regional Section of the World Federation of Societies of Anaesthesiologists (WFSA). The Pan Arab Section and the African Section remained to be created in 1990 and 1997 respectively.

The American Society of Anesthesiologists (ASA) continued to grow in numbers and influence. Membership increased from just under 17,000 in 1980, to 27,000 in 1990. It came into conflict with government and non-government agencies in the 1980s. In the late 1970s, the Federal Trade Commission questioned the billing practices of anesthetists, citing curtailment of competition through the use of a common guide to fee setting, the Relative Value Guide. The ASA was large enough to take on the FTC, and in 1979 successfully defended use of the RVG. Predictably, the FTC did not go away, and targeted groups and individuals for uncompetitive practices and in particular, relationships with nurse anesthetists. These matters and others kept the ASA busy for the whole decade, prompting the Society to establish a permanent Office of Government Affairs (OGA) in Washington DC, in 1984. The decision was vindicated in 1985. Congress passed a bill giving nurse anesthetists the right to practice independently in the care of government employees, but through the efforts of the OGA, the ASA secured a Presidential veto of the legislation.

The ASA perceived that the public did not appreciate the contributions and importance of anesthesia delivered by anesthesiologists. Accordingly, the ASA began a public education program in 1981, utilizing the media, videos and brochures, with media tours targeting major cities. A 1985 review of the program for its effectiveness found that "the man in the street in this country is not the least bit concerned about anesthesiology, let alone anesthesiologists". As a result, by 1987, the program had been substantially curtailed, targeting only hospital administrators and legislators [1]. Several other countries failed to learn from this experience, and spent large sums of money on media-based public education programs (National Anaesthesia Days) in the early 2000s, only to abandon them within a few years of their commencement.

Through the 1980s, women increasingly influenced the specialty. They accepted leadership roles in the US including 3 academic chairs in 1986 (but this out of more than 100 programs). In 1988, Gertie Marx received the ASA Distinguished Service Award. Nevertheless, their rate of board certification was less, and academic advancement appeared to be slower. This prompted a request by a group of women activists to the ASA for the formation of an ad hoc committee on women's issues and a panel to discuss such issues at the Annual Meeting. The request was denied. In 1986, ASA delegate Betty Stephenson proposed a resolution that the ASA bylaws be degendered. The resolution also failed approval

by the ASA House of Delegates, but ASA President, Peter McDermott later administratively degendered the ASA's bylaws and documents. As noted in Chapter 2: "In October 1992, I (McDermott) became ASA president and issued an order degendering the language of ASA bylaws and other documents. It would have been embarrassing to have the issue debated (in the House of Delegates) by old white men."

Subspecialty Societies

The burgeoning specialty spawned subspecialty organizations in Europe for regional anesthesia (1980), intensive care (1982), cardiothoracic anesthesia (1985), and pediatric anesthesia (1986). International societies established in the previous decade accommodated subspecialty interest in obstetrics, neuroanesthesia, and pain. The European Society of Intensive Care Medicine created the European Diploma in Intensive Care (EDIC) in 1988, and this became widely accepted.

In Canada, Australia, and New Zealand, subspecialty societies or "special interest groups" began to appear under the auspices of the major organisations, the Faculty of Anaesthetists (Australia and New Zealand), and the Canadian Anaesthesiologists Society. International subspecialty organisations for pain, obstetric anesthesia, neuroanesthesia, and regional anesthesia supported membership from all countries.

In the US, the Society for Ambulatory Anesthesia (SAMBA) was established in 1984, reflecting the increasing focus on outpatient surgery and anesthesia, and the Society for Pediatric Anesthesia (SPA) was established in 1986.

The Growth of Education

The 1980s saw further expansion and consolidation of basic and advanced education in anesthesia.

In the US, in 1980, after years of disagreement between the organizations involved in undergraduate and postgraduate medical education, the Coordinating Council on Medical Education (CCME) was disbanded. The Liaison Committee on Graduate Medical Education had been accrediting postgraduate programs since 1975, and in 1981 was renamed the Accreditation Council for Graduate Medical Education (ACGME) under the auspices of the American Medical Association (AMA), the American Hospital Association (AHA) and the Advisory Board for Medical Specialties (ABMS). The ACGME continues to be the accrediting body for all medical internship and residency training programs.

The American Board of Anesthesiology refined the examination process, in particular determining means to diminish variability in both questions and assessment of oral

examinations. During the 1980s, the Board initiated internal discussions regarding the introduction of recertification and the number of Board certified diplomats increased from 9800 to 19000.

The Society for Education in Anesthesia (SEA) was formed in the early 1980s with an aim of engaging consultant anesthetists in the education of medical students and residents. A founder, Philip Liu, wrote in the first newsletter in 1984 of his hope that that "members of this Society will develop a genuine sense of fellowship, so that individuals with an interest and vocation in the teaching of anesthesiology will find a network of support and a resource for communication." The Society has continued its educational role, and has never sought a political one.

In 1977, Jean Lassner established the European Academy of Anesthesiology (EAA) in Paris, to promote meetings and exchange of ideas between European anesthetists, with a particular emphasis on teaching methods. The Academy established the *European Journal of Anaesthesiology* in 1984, edited by British anesthetist, John Zorab. In the same year, the European Diploma in Anaesthesia and Intensive Care (EDA) was introduced.

The Diploma comprised a two part multi-lingual examination, with the second part to be taken after completing 6 years of post graduate medical practice,¹ including 4 years in anesthesia. This was at a time when the Anaesthesiology Section of the Union Européenne des Médecins Spécialistes (UEMS), established in 1962, was the official body under the European Union for recommending minimum training times, but without any formal power. The Diploma, although not officially recognized, provided evidence that the diplomate had met uniform educational standards. Nevertheless, it did not replace individual national accreditation, and did not provide for cross-border portability. In 1989, the EAA also created a voluntary Hospital Recognition Program, primarily for those countries that did not have their own hospital accreditation system. Although not accepted by the UEMS, the program was supported by the Anaesthesiology Section.

During the 1980s, several European countries adopted all or part of the EDA as a mandatory part of their accreditation process for specialist recognition. In 1980, the Section recommended a minimum training time of 5 years. However during the decade, the minimum duration in most western and eastern European countries was 4 years (see Fig. 38.1). In contrast, training in Russia varied from less than one, to two years. In Paris, in 1989, a new Diploma, the *Diplôme d'études supérieures en anesthési-réanimation* (DESA) was created, requiring 5 years of postgraduate anesthesia training.

In 1986, anesthetists in The Netherlands, France and Belgium established the *Fondation Européenne d'Enseignement*

¹ Practice, as in medical practice after graduation as a doctor.

en Anesthésiologie (FEEA) to provide continuing medical education (CME) in anesthesia, through the conduct of refresher courses. FEEA extended its activity to more countries as the size of the European Union grew.

Matters were further confused by the establishment of the European Society of Anaesthesiologists (ESA) in 1992, the European Board of Anaesthesiology (EBA) in 1993, and the Confederation of European National Societies of Anaesthesiology (CENSA) that had evolved from the WFSA regional section. These anesthesia-related educational bodies functioned independently, but co-operatively, and in the 2000s were brought under the joint umbrella of the ESA and EBA.

In Great Britain, while functioning within the Royal College of Surgeons, the Faculty of Anaesthetists had long provided training, accreditation and examination for Fellowship. Reflecting the earned status of the specialty, in 1988, the Faculty became an independent College of Anaesthetists. By this time the period of training was 7 years including basic, intermediate and specialised training. Because these requirements exceeded those for European qualification, few European anesthetists could practice as specialist consultants in Great Britain. Reciprocal arrangements were to be resolved during the next decade.

In other areas of the globe, anesthesia training was either being established or extended. By the end of the 1980s, all major Latin American countries had formal training programs in place with a minimum period of 3 years.

Despite the short time since the 1976 end of the Cultural Revolution, Chinese anesthetists had established the Chinese Society of Anesthesiology in 1979 and several Colleges in the succeeding decade. The first College was in Xuzhou Medical School in 1987, with three more founded in 1988, at Harbin, Hunan, and Tongji medical universities. These were undergraduate medical courses, offering major studies in anesthesia, critical care and pain management. In the 1980s, three new journals were launched, the *Chinese Journal of Anesthesiology*, the *Foreign Medical Sciences (Anesthesiology and Resuscitation)*, and *The Journal of Clinical Anesthesiology*. Despite this, in many hospitals, anesthesia was often considered a technical rather than a clinical (i.e., professional) practice. This changed in 1989, when the Ministry of Public Health formally defined the criteria for a department of anesthesiology: “The department of anesthesiology should be a clinical department rather than a technical department. More emphasis should be showed on personnel training, instrument and equipment. The working level should be improved to meet the demands of medical development.”

Intensive (Critical) Care Training

Beginning with Bjørn Ibsen’s management of the 1952 polio epidemic in Copenhagen, anesthesiologists have been at the

forefront of the development of intensive care medicine, utilizing their skills in respiratory and emergency care. Accordingly, anesthesia training programs increasingly stipulated training in intensive care. In 1982, the European Society of Intensive Care Medicine (ESICM) was founded, and 6 years later the Society created the European Diploma in Intensive Care (EDIC). At the time, the specialty was not recognized as a separate section under the UEMS, partly due to its multidisciplinary nature. This was to occur in 1999. It remains separate from the ESA.

In the US, critical care medicine had been one of several subspecialties, in which experience was required as part of the formal accreditation process by the American Board of Anesthesiology (ABA). Critical care experience was distinguished by being the only subspecialty for which a minimum time was stipulated (2 months). In 1985, the ABA introduced the first subspecialty certificate—in critical care medicine.

Nurse Anesthetists

In few countries is the presence of nurse anesthesia of greater importance to anesthetic delivery than in the US. In the US, during the late 1970s, the intertwined relationship between the certification process for nurse anesthetists, and the political role of the American Association of Nurse Anesthetists (AANA) was finally separated. After 1982, the independent Council on Certification issued a certificate (Certified Registered Nurse Anesthetist—CRNA) that no longer required membership in the association. Through the remainder of the 1980s, the Council embarked on a process to standardize and validate the large number of training programs, and introduce an objective standardized examination process.

In 1989, a meeting of nurse anesthetists in Switzerland, representing 11 countries, founded the International Federation of Nurse Anesthetists.

Academic Anesthesia

In Great Britain, Margaret Thatcher’s conservative government curtailed funding for academic support, and anesthesia research suffered. Universities relied largely on public funding for their operation, applying it to both teaching and research within their own jurisdiction. After reviewing the method of funding, in 1986, funding for research was redistributed to research councils. Universities, or their research staff, now had to compete for grants. Universities became business enterprises, competing in a marketplace for research funds. Suddenly, anesthesia researchers contended against everyone else for a portion of a diminished pool. Fields of investigation that had greater perceived or real benefit to the population were at a distinct advantage. Anesthesia became

a victim of its own success; too few patients died or were injured by anesthesia. For anesthetists who were partly academic and partly clinical and teaching practitioners, the situation was worse as they did not have the same time or level of support in writing grant applications as did their full time academic colleagues.

The Japanese Society of Anaesthesiology began publication of the *Journal of Anaesthesia* in 1987, an English language journal that would compete with Masui.

Isoflurane Finally Makes It

After being cleared of the reported carcinogenic risk that had thwarted its planned release in the mid 1970s, isoflurane was introduced to clinical anesthesia in 1981. It soon replaced its structural isomer, enflurane, having the benefits of faster induction and recovery, absent epileptogenicity, and only 0.2% biodegradation. Seemingly, the only drawback was a mild pungency, making it less suitable as an inhaled induction agent. The pungency ensured the persistence of halothane in pediatric practice.

Was it too good to be true? Soon a potential issue appeared. Isoflurane caused a dose-related decrease in blood pressure, due to vascular dilation, rather than myocardial depression, as with halothane. The dilation also affected coronary vessels, and a debate began about “coronary artery steal”, diverting blood flow away from collateral vessels that were unable to dilate. Subsequent studies showed the fears to be unfounded.

Japan Tries a Reject

Ross Terrell had synthesized sevoflurane and desflurane in the 1960s. Both had been set aside as unsuitable for further study, sevoflurane because it was unstable in soda lime, and desflurane because it was difficult to make, had a low potency and high saturated vapour pressure. Increasingly, the extent of metabolism and the absence of degradation by CO₂ absorbants were considered crucial properties of desirable modern inhaled anesthetics. Less was better, dictating subsequent development of enflurane, isoflurane, and desflurane, all agents with progressively less metabolic degradation than halothane or methoxyflurane.

Despite these concerns, sevoflurane was transiently resurrected in the 1970s. Animal studies suggested that it might show promise as an “ideal” inhalation agent. Minimal cardiorespiratory stimulation accompanied a low pungency and rapid induction. However, in addition to the instability in soda lime, the potential for fluoride-induced renal failure (as with methoxyflurane) was raised on the basis of experiments in rats. Baxter and ICI shelved sevoflurane in the late

1970s, although human trials in the early 1980s, confirmed sevoflurane’s suitability from a clinical, if not a laboratory perspective.

Anaquest resurrected desflurane in the 1980s, as part of a search for a better anesthetic for outpatient surgery. The first human subject, Jeremy Cashman, received desflurane at Guy’s hospital in 1988. He survived and went on to an academic career in anesthesia. Meanwhile, Baxter offered the rights to Anaquest, for development of sevoflurane for the North American market. Anaquest took an option for one year while they considered the matter.

Anaquest thus had the rights to desflurane, the option from Baxter on sevoflurane, and a difficult choice: which one to develop for the anesthesia market? Despite the difficult and expensive manufacturing process, the need for a radically new vaporiser, and its airway irritability, desflurane had a long patent life, was more stable and less soluble than sevoflurane and underwent negligible metabolism. It was a close decision, but sevoflurane lost.

Enter Maruishi, a Japanese pharmaceutical company operating in a less regulated environment. They bought the rights to sevoflurane from Baxter and succeeded with its commercialization in Japan in the late 1980s. Maruishi licensed the international rights to sevoflurane to Abbott Laboratories, in 1992.

Two Out of Five

The 1980s saw the release of five new muscle relaxants, only two of which survived. Vecuronium was released in 1980 as the first “designer” relaxant. Once the exact structure of curare was known, and the cause of the vagolytic and neuromuscular blocking effects of pancuronium could be defined at a molecular level, the new monoquaternary drug, vecuronium was conceived. It had the same potency as pancuronium, one twentieth of the vagolytic action, and an effect that lasted half as long. The latter property resulted from its dual elimination via both the liver and kidney, unlike pancuronium’s dependence on renal elimination.

Not long afterwards, another new relaxant, atracurium appeared. Its advantage over other relaxants was that its elimination was partly by Hofmann spontaneous degradation in plasma and tissue, as well as by ester hydrolysis and organ metabolism. Atracurium became popular worldwide. There was however, widespread caution because the drug was known to cause histamine release with resulting hypotension and tachycardia. Except in rare circumstances, these effects were mild and transient, and were often overstated [2].

An additional atracurium related concern was raised due to laudanosine, a by-product of the metabolism of atracurium, that if present in sufficient concentrations may cause seizures due to a decreased seizure threshold. However, because

Hofmann degradation reduces the atracurium concentration, it was unlikely that laudanidine would reach concentrations capable of causing seizures—also the case for the isomer of atracurium, cisatracurium.

John Savarese introduced mivacurium in 1984, as a relaxant with a short duration of action, resulting from its hydrolysis by plasma cholinesterase, just like succinylcholine. But it lasted twice as long as succinylcholine, and more importantly, it also took twice as long to act. It never achieved great popularity but continues to be available in some countries. Doxycurium and pipecuronium were also released in the 1980s, but offered no advantages over vecuronium and atracurium, and failed to find a market.

The advent of neuromuscular blocking drugs having fewer side effects and kinetics allowing easier reversal, encouraged their use in critical care units for the control of patients requiring mechanical ventilation. This reflected the increased use of long-term ventilation, and a mistaken view among some critical care physicians that muscle relaxants possessed analgesic and/or anxiolytic properties. (As far as the authors know, this view was not expressed in print and may just be an urban legend. But it has a curious support in the 2003 finding that muscle relaxant administration can decrease the BIS value, albeit with no decrease in consciousness [3].) An unforeseen result of long term paralysis was prolonged muscle weakness after tracheal extubation, identified in 1985 [4]. Use of smaller and intermittent doses solved the problem.

A Problem with Bupivacaine

A 1979 editorial in *Anesthesiology*, by Albright, brought attention to six cases of cardiac arrest associated with the use of the local anesthetics, bupivacaine and etidocaine [5]. Several additional cases were soon reported. Many were fatal, and were associated with the use of 0.75% bupivacaine in obstetrics. In 1983, the US FDA banned the use of 0.75% solution in obstetrics. These cases also resulted in the recommendation of a test dose in epidural anesthesia as well as incremental dosing. Studies suggested that bupivacaine affects voltage-gated sodium channels in cardiomyocytes, but the exact mechanism is yet to be defined.

Intravenous MAC

During the 1980s, three groups chased the automatic control of total intravenous anaesthesia, Prys-Roberts' group in Bristol, the Schwilden/Schuttler group in Germany, and the Stanford group in the US. In 1980, Cedric Prys-Roberts conceived of a "MAC" for intravenous anesthetics. His group determined EC_{50} and EC_{95} values for quasi-steady state in-

fusions of methohexital and althesin [6], and for the new emulsion formulation of propofol [7]. While others used the Dixon up-and-down method (which is parsimonious in terms of numbers of patients required) to provide the EC_{50} , Prys-Roberts and colleagues used a probit analysis, arguing that such analysis allowed determination of both the EC_{50} and EC_{95} . Prys-Roberts' group opted to develop closed-loop control systems knowing that they probably would not be able to control anesthesia precisely (because no single variable or parameter can accurately differentiate between consciousness and unconsciousness, let alone the more complex so-called "depth of anaesthesia" paradigm.) The Germans followed a similar approach, and the Stanford group went the pharmacokinetic route. All reached similar conclusions. Prys-Roberts' group determined the pharmacokinetic and pharmacodynamic model in small children using probit analysis [8], and joined forces with an engineering group in Oxford to develop a neural network approach using parametric modelling and on-line statistical pattern recognition of the EEG during anesthesia. Prys-Roberts wrote to LJS (personal note 16 Nov 2012): "I am as convinced now as I was then that it is no more difficult to control total intravenous anaesthesia (e.g., propofol/alfentanil/relaxant) using a manually controlled set of pumps [9] than it is to control inhalational anaesthesia by adjusting the setting of a vaporiser."

Regarding the parallel development in Germany, pharmacologist, Ekkehard Krüger-Thiemer devised mathematical models for drug uptake in the 1960s. Using these, Bonn anesthesiologist and mathematician, Helmut Schwilden, in 1981, developed a theoretical pharmacokinetic model to achieve a target plasma concentration. With colleagues, he then developed a programmable infusion pump called CATIA, or Computer Assisted Titration of Intravenous Anesthesia. This was the first "Target Controlled Infusion" or "TCI" device [10, 11].

During the early to mid 1980s, Stanski and colleagues at Stanford used power spectral analysis of the EEG to study the pharmacokinetics of hypnotics and opioids. Their studies with thiopental supported the feasibility of TCI. The release of propofol in 1986, with its faster biodegradation, lent itself to TCI. Audrey Shafer and Paul White performed much of the early work in determining the pharmacokinetic and pharmacodynamic profile for propofol at Stanford University. Using this and additional information, Gavin Kenny and Colleagues in Glasgow developed a TCI device in 1990, which was released commercially in 1993 [12, 13].

Brain's Brilliant Idea

After many years of development, British anesthetist, Archie Brain introduced the first completely new airway device since Hewitt introduced his airway in 1908. Using and modifying rubber nasal masks to fit snugly around the laryngeal

inlet, and connecting the mask to a tube, he developed the Laryngeal Mask Airway. He tried around 100 prototypes in over 6000 patients, before approaching a major commercial endotracheal tube manufacturer. Brain's confidence in the device led him to establish the Laryngeal Mask Company, and the commercial version was made of autoclavable silicone and introduced to the market in 1988 (1992 in the US, due to delays in FDA approval). It has since been made in disposable PVC, and has proven to revolutionize airway management, largely eliminating "mask anesthesia" while adding to the armamentarium for dealing with difficult airway issues.

The acceptance of the "LMA" was not immediate, and might have taken much longer had it not been for the concurrent introduction of propofol which replaced the use of thiopental. Propofol was introduced in 1986, first in New Zealand, after considerable effort to find a suitable vehicle for intravenous use. Propofol displaced thiopental because of its rapid degradation, its lower incidence of postoperative nausea and vomiting, and its depression of upper airway reflexes. The depression of these reflexes facilitated the insertion of the LMA that would often have induced gagging after thiopental. Thus two new products synergised each other's adoption into clinical practice. Propofol did not gain approval from the FDA in the US until 1989.

Airway Management Advanced in Other Ways

In the early 1980s, Roger Bullard introduced a rigid fiberoptic intubation laryngoscope. In 1982, Hiroshi Inoue invented the "Univent" tube, a disposable reinvention of the bronchus blocker and endotracheal tube described by Macintosh in 1935. In 1987, Frass and colleagues in Austria invented the "Combitube" and Mizus invented a tube exchanger, the Mizus Endotracheal Tube Replacement Obturator (METTRO), superseded by the Cook exchanger in 1990. Ikeda and the Asahi Corporation developed a flexible video endoscope.

Outpatient Anesthesia

Outpatient anesthesia had become popular by 1980, receiving several boosts during the decade. In 1984, the Society for Ambulatory Anesthesia (SAMBA) was established, just when surgeons embraced endoscopic or minimally invasive surgery. The introduction in the late 1980s of propofol and the LMA added to the rise in outpatient anesthesia. Rapid recovery to full wakefulness, less nausea and vomiting, and new methods of airway management without the need for tracheal intubation facilitated the management of patients on a day only basis.

In the US, the number of "Office-based" procedures also increased, from 2 to 5% of all procedures, over the period from 1984 to 1990.

Anesthesia Embraces Technology

Several technological advances introduced in the 1990s improved the practice of anesthesia, although the improvement was not validated statistically. Intuitive application correlating with dramatically reduced mortality inspired the confidence of the specialty in those advocating the changes. Monitoring of respired gases (carbon dioxide, oxygen, and inhalation agent concentrations), and of oxyhemoglobin saturation (oximetry) added to the existing armoury of modalities that informed the anesthetist as to the status of the patient and the anesthesia delivery system. The delivery system also began to change from the traditional "gas machine" to an integrated workstation.

Capnometry

John Severinghaus and colleagues installed a mass spectrometer in a 10 room operating suite in the mid 1970s. Using multiplexed sampling through 30 metre nylon catheters, they monitored respiratory gases at 1-minute intervals. It was expensive to install and maintain, but gave the anesthetist and researcher a taste of what could be done. Indeed, those who used the device became addicted to the minute-by-minute arrival of the latest end-tidal anesthetic and carbon dioxide values, and when the mass spectrometer "went down" (which it sometimes did) they felt uneasy. This led to the increasing adoption of stand-alone infrared analysis. The development of the infrared CO₂ analyzer began with the "Luft" cell, described in Chapter 55. The first clinically usable infrared capnometer was the 1950s Beckman LB1. The sampling head of this large and cumbersome device needed to be pressurized by a bicycle pump to prevent ingress of potentially flammable anesthetic gases. EIE commented that "It may have 'needed' to be pressurized but rarely was, and no explosion ever resulted that I knew of. It would be difficult to imagine how an explosive concentration could have been achieved within the device."

Both Hewlett-Packard and Siemens-Elema developed mainstream infrared capnometers in the late 1970s. The HP47210A, a spin-off from a contract to develop an exhaust gas analyser for General Motors, was designed for use in the operating room, while the Siemens-Elema 930 was designed specifically for use with the series 900 ventilators. The 930 was released around 1976, and the HP47210A in 1980. The HP47210A was the first practical infrared analyser for use in anesthesia, displaying end-tidal and instantaneous CO₂ measurements and respiratory rate, with alarms. It also could measure transcutaneous CO₂ using a heated electrode.

Although there was no waveform display, over 50,000 units were sold.

Datex Instrumentarium, a Finish company, developed a sidestream capnometer, the CD-101, at about the same time. It had an analogue needle display showing the instantaneous CO₂ on a percentage scale. As with the HP device, interference from nitrous oxide was countered by a switch, introducing an electrical adjustment. Similarly, all early devices required regular calibration, both at zero and with a known sample gas. The Netherlands was probably the first country to recommend capnometry as a monitor for all patients undergoing controlled ventilation, in 1978. By the end of the 1980s, capnometers with waveform displays, of both sidestream and mainstream variety were readily available, but were not yet routinely used.

Oxygen Gas Monitoring

Oxygen Analysers. By 1980, polarographic oxygen monitors were readily available. They were easily calibrated and accompanied by alarm functions, and ideal for verifying that the gas emanating from the anesthetic machine when oxygen was turned on, was indeed oxygen. Surprisingly, they did not find their way into routine use until later in the decade, when they became part of the first minimum monitoring standards. (See below)

Pulse Oximetry. Takuo Aoyagi's discovery of pulse oximetry in 1971, led his employer, the Nihon Kohden company, to develop a commercial model in 1974, primarily for use in respiratory physiology laboratories. They patented the technology in Japan but not elsewhere, and did not pursue further development. Minolta produced another commercial version in 1977, but it was not a commercial success and was sensitive to movement. Biox Technology refined and marketed the device in the US in 1980, again for respiratory laboratories. Another Minolta was tested at Stanford University by Bill New and colleagues. Soon, two pulse oximeters were marketed primarily for use in anesthesia, the Biox 3700 (now owned by the Ohmeda Corporation) and the Nellcor N100 (developed by a new company named after its founders, Bill New, Jack Lloyd, and Jim Corenham). A feature of the Nellcor N100 was the modulated sound signifying a changing oxygen saturation, and was patented by Nellcor. However, recognizing the potential value to patient safety, Nellcor elected to not enforce its patent rights [14].

Pulse oximeters assumed an increasing place in routine anesthesia monitoring, and some anesthetists considered it to be the major advance in the specialty during the 1980s. Nevertheless, it took some time for oximeters to be adopted universally. Many anesthetists doubted their value relative to their initial high cost. The industry was not entirely confident either. The Nellcor company looked to become a public com-

pany listed on the stock exchange, but were told that they needed more than oximetry. Accordingly, they developed the Nellcor N1000 that combined capnometry with pulse oximetry, and success was assured [15].

Transesophageal Echocardiography. In the mid 1980s, two-dimensional transesophageal echocardiography was introduced to the cardiac operating room. Cardiologists were first to employ the technology, but anesthetists were quick to embrace it.

Cooper, Harvard and Standards

In 1978, Jeff Cooper and his colleagues from the Massachusetts General Hospital, published the preliminary studies of critical incidents in anesthesia, suggesting that human error played a significant role in their causation. In the years following, they collected further data, resulting in the landmark publication in 1984 of "*An analysis of major errors and equipment failures in anesthesia management: Considerations for prevention and detection*". Collection of the new data was crucial; as the last sentence in the paper states, "Awareness of the problems is a necessary first step". Equipment failure explained only 4% of incidents leading to substantive negative outcomes; human error was the dominant factor in causation of incidents. To address human factors in prevention, the authors suggested strategies that tackled training, supervision, organization, ergonomics, and monitoring [16].

At the same time, the medical malpractice insurer for the Harvard group of 9 hospitals had noticed an increase in the number and cost of anesthesia-related claims, out of proportion to any increase in the number of anesthesia providers. The Harvard Risk Management Committee was established, with Cooper as a member, to review all cases reported over the years 1976 to 1984. The committee determined that the majority of incidents involved failures of ventilation or oxygenation that might be preventable by the institution of appropriate monitoring and practices. The anesthesia chairs of the 9 hospitals endorsed the recommendations and these were published in the Journal of the American Medical Association in August 1986, to become universally known as the "Harvard Monitoring Standards" [17]. The standards advised the continued presence of an anesthetist, measuring and recording the heart rate and blood pressure at least at five-minute intervals. They recommended continuous monitoring of ventilation and circulation (by any means), the continuous use of an electrocardiogram, continuous monitoring (with alarm capability) of oxygen concentration in gas delivery, and use of a breathing circuit disconnect alarm during mechanical ventilation. Temperature monitoring was to be available.

Fig. 11.2 Karen Domino's report in the 2009 ASA Newsletter provided data suggesting that 1980s and later efforts to increase the safety of anesthesia bore fruit. Implementation of various reforms was associated with a decrease in malpractice costs by approximately 40%

No previous attempt, anywhere, had set mandatory guidelines for medical practice, and opposition from anesthesiologists in practice was therefore anticipated. To this end, staff in the 9 hospitals were consulted in the development of realistic standards that were technically achievable and affordable, recognising that some practices would need to change and some equipment would need to be upgraded. Widespread acceptance followed, and within a short time, excellent compliance with the standards occurred within the Harvard group. Eichhorn and colleagues noted at the end of their paper that "Insurance carriers may provide the impetus, but physician leadership is required" [17].

In October 1986, the American Society of Anesthesiologists adopted a set of standards, based on the Harvard standards, but augmented by the non-mandatory addition of pulse oximetry, capnography, and a monitor of airway gas flow or volume. Many anesthesiologists reacted negatively, claiming that they had practiced safely for years without new and expensive technology. But they were gradually outnumbered. The rest is history, as they say, as the standards were repeatedly updated, and both anesthesia-related mortality, and malpractice premiums declined (Fig. 11.2).

Anesthesia Patient Safety Foundation (APSF)

In parallel with the adoption of standard guidelines, the President of the American Society of Anesthesiologists, Ellison ("Jeep") Pierce, together with Cooper and Richard Kitz, organised a 1984 International Symposium on Preventable Anesthesia Mortality and Morbidity. From that initiative came

the APSF, founded in 1986. The APSF became the model for the National Patient Safety Foundation (NPSF) founded in 1997 with its headquarters in Boston.

Safety Sought in Australia, New Zealand, and Other Countries

In Australia and New Zealand, the potential consequences of the "Harvard Standards" were soon appreciated. Malpractice insurance was becoming a growth industry, and limitations on hospital funding restricted expenditure on new technology, especially in anesthesia. The standards prompted a legal misinterpretation that if a patient had been injured or had died as a result of anesthesia, and an electrocardiogram had not been used, then the anesthesiologist would be considered culpable. It was widely believed that although electrocardiographic monitoring was vitally important in many patients, it was not a good monitor of circulatory integrity, was not the most appropriate monitor in young and healthy patients [18]. Indeed, in many instances it was not used correctly as an indicator of myocardial ischemia. It was also clear that pulse oximetry was a useful monitor of circulatory integrity, but was expensive. These thoughts prompted Bill Runciman to convene a meeting of some 60 anesthesiologists in Adelaide in 1987, to discuss monitoring and safety. From that meeting came the Anaesthesia Incident Monitoring Study (AIMS) in 1988, the promulgation of Australian and New Zealand anesthesia monitoring standards in 1988, and the Australian Patient Safety Foundation (APSF) in 1989.

The 1988 anesthesia monitoring standard in Australia and New Zealand, endorsed by the Faculty of Anaesthetists of the Royal Australasian College of Surgeons, was similar to the Harvard standards, differing in the mandatory continuous presence of a physician anesthesiologist, the availability (not mandatory use) of an electrocardiogram, and the recommendation that a pulse oximeter should be available for every patient. They were revised in 1990, to institute mandatory use of pulse oximetry in every anesthetised patient by the beginning of 1992.

Other countries introduced similar standards, some making the electrocardiogram mandatory, others not. In all cases, the standards have been repeatedly updated in the context of the country in which they are used, and in 2008, the World Federation of Societies of Anaesthesiology published "International Standards for the Safe Practice of Anaesthesia".

Did these efforts influence the malpractice crisis that prompted their initiation? We cannot tell for certain, but in succeeding years, the cost of malpractice insurance in the US decreased by roughly 40% (Fig. 11.2). In Australia, the cost never reached the dizzying heights seen in the US, but has nevertheless also decreased substantially. This surrogate measure of morbidity and mortality suggests the value of the efforts.

Counting the Dead

The 1980s also saw an increasingly concerted effort to collect data on mortality related to anesthesia. The first report of the Confidential Enquiry into Perioperative Deaths (CEPOD), in 1987, was a joint initiative of anaesthetists and surgeons in Great Britain. The recommendation that practitioners audit their practices in a quest to improve patient care was an important stimulus to the introduction of quality assurance into anesthesia. Collection of morbidity and mortality data has continued to be an important contribution to education and safe practice.

Critical Incidents and Simulation

The AIMS study in Australia and New Zealand applied the critical incident analysis, pioneered in anesthesia by Cooper, to the collection of data. The resulting enormous body of data could be used to validate the usefulness of various monitors and processes, and to confirm the appropriateness of published minimum monitoring standards. The data were also used to develop crisis management algorithms that could be applied in every day anesthesia practice. This was an application of the system used in the aviation industry to eliminate subjective and intuitive solutions to a rapidly emerging crisis. Some physicians found it difficult to adopt this concept, having spent all their formative education based on deductive reasoning. The failure of such a process in the midst of a crisis prompted Runciman and colleagues to develop the algorithms [19, 20].

Building on the information provided by critical incident analysis, and also following the lead of the aviation industry, David Gaba established a mannequin-based anesthesia simulator at Stanford in 1988. Nik Gravenstein established a similar simulator in Gainesville, Florida, shortly afterwards.

First applied in health care to the specialty of anesthesia, critical incident analysis is now the mainstay for the review of patient safety in all fields.

Machine Design

Critical review of the anesthetist's workplace began in the 1970s. Studies of the operational environment and Cooper's investigations from the early 1970s led to the publication of the American National Standards Institute's ANSI Z79.8-1979 standard for anesthetic machines. It focused on the design and placement of controls and displays, taking into account human factors engineering. One of the principals, Leslie Rendall-Baker, had co-designed the Fraser-Harlake "line of sight" machine in 1976 by adapting a standard machine and aligning the breathing bag, flowmeters, monitors, ventilator and vaporisers, adjacent to the patient's head. In 1980, Boquet et al published their study of the anesthetist's activity during normal practice, using these data to develop

a mock-up design. Rendall-Baker published "Problems with Anesthetic Machines and Their Solutions" in 1982. This was the era of change from the standard design of the previous 40 or more years to today's anesthesia workstation [21, 22].

In the early 1980s, two commercial designs heralded what was to come. The Engstrom series 2000 was a modular vertical component machine, mirroring Boquet's proposal, and the Ohio Modulus Wing reflected the Fraser Harlake design. Neither was commercially successful, partly because of entrenched user resistance. Part of the issue was also the serial adoption of new monitors (pulse oximetry, capnography and others) as separate units with distinctive displays, alarms and connections, additions stacked onto a traditional machine in a haphazard, often unstable manner, reminiscent of a "Christmas tree". Not until the end of the 1980s were controls, monitors, displays and alarms ergonomically integrated [23].

Two novel anesthesia machines appeared in the 1980s. In 1986, the Swedish Engström company introduced the "Elsa" machine with digital flowmeter displays, and an integrated capnometer, oxygen analyser, anesthetic agent monitor, and ventilator. The machine had three ports for the connection of standard factory bottles of halothane, isoflurane, or enflurane. Liquid agent was withdrawn and injected into the gas stream under electronic control. It had a quirky bistable valve to change from spontaneous to controlled ventilation, that many anesthetists found difficult to use at first.

The "Physioflex" machine, developed by the Dutch company, Physio BV, was a radical design based on a closed circuit where gases were circulated by a blower. Based on a constant combined circuit and lung volume, ventilation was achieved by changing the machine circuit volume. Like the "Elsa", standard bottles of volatile anaesthetic agent were attached to indexed ports. Anaesthetic agent was added to the gas stream by liquid injection, and the selected end-tidal concentration of the agent was then servo controlled, during both spontaneous and controlled ventilation, using a charcoal filter to extract the agent from the circuit if necessary. The "Physioflex" was eventually bought by Drager, and an agent port for sevoflurane added [23]. Both machines were confined to the European market, and did not find widespread acceptance. They were at least a decade ahead of their time.

Recognizing an Old Problem

Substance abuse and drug addiction are ancient problems. The experiences of people participating in "nitrous oxide parties and ether frolics" engendered the discoveries of the anesthetic properties of nitrous oxide and ether. The bad news was that those who might know better, knowledgeable physicians and nurses, abused drugs. Horace Wells' suicide directly resulted from his addiction to chloroform, and self-exper-

imentation with morphine and cocaine. Self-administration, usually by intravenous injection, of opioids, CNS stimulants and depressants led many early and late anesthetists unwittingly into a life of addiction. Misuse of almost every opioid, sedative-hypnotic, and anesthetic drug has continued, and some of the brightest anesthesiologists and other physicians have died from overdoses or from taking other drugs to ease their withdrawal symptoms. The problem increased, in parallel with the rise in illicit drug use in the community.

In 1975, the Georgia Medical Association instituted the Impaired Physician Program. In 1983, it was reported that of the first 507 patients admitted to the program, 9.6% were anesthesiologists, yet anesthesiologists comprised only 4% of physicians. In parallel surveys, 13% of physicians in impaired physician programs were anesthesiologists. Success of treatment varied, and a high relapse and death rate accompanied the use of parenteral opioids. In the 1980s, Gravenstein anonymously surveyed 31 academic departments of anesthesia, reporting in 1983 that for the years 1974 to 1979, between 1 and 2% of anesthetists had misused drugs, with 47 associated deaths [24].

Lecky and colleagues, at the University of Pennsylvania provided advice on the recognition and management of potentially impaired colleagues, through a staff educational program [25]. This anticipated the many prospective programs to assist in the early recognition of colleagues at risk from substance abuse or other issues including stress, depression, and physical health. Today, the most common cause of physician impairment is the abuse of alcohol and other mood altering drugs. Recovery programs are offered throughout the US, and the addicted physician is mandated to enter them as a condition for retaining his or her medical license.

Pain Management Made Disparate Advances

In 1980, “Project Pain” was established at MGH and Shriners Burn Institute, to study pain in burned children. The results led to greater recognition of pain in burned children, and the use of subcutaneous lidocaine and adrenaline during grafting procedures. In 1983, Clifford Woolf confirmed that spinal anesthesia given before injury can prevent central sensitization. In 1984, Cousins and Mather published a review of intrathecal and epidural opioids that became the most cited anesthesia paper in the literature [26]. In 1988, Brian Ready reported on the first formally established Acute Pain Service.

And in the 1980s

Slogoff and Keats published their study “Does perioperative myocardial ischemia lead to postoperative myocardial infarction?” [27], linking intraoperative tachycardia to post-

operative myocardial infarction and leading to widespread use of β -blockers. Around the same time, Franks and Lieb developed an experimental model using luciferase (a protein) from firefly tails to demonstrate competitive binding by anesthetics to protein binding sites, thereby undercutting support for lipid theories of anesthetic action [28]. Bernie Wetchler published “*Anesthesia for Ambulatory Surgery*”, and in 1990, Paul White published “*Outpatient Anesthesia*”, such books reflecting the importance that “same day” anesthesia and surgery had achieved.

Reprise

The 1980s could arguably be described as the modern decade of greatest change in anesthesia practice. Change was largely driven by anesthesiologists, anesthesiologists aided and abetted by other specialists and by industry invention and investment. Anesthetists were offered new anesthetics (isoflurane, sevoflurane, desflurane and propofol) and a new sedative drug (midazolam) that remain today’s standards. Anesthetists could use newer, safer muscle relaxants, vecuronium and atracurium. Safety continued its wondrous advance through the development of organizations focused on decreasing mortality and morbidity from anesthesia, and through the rise of subspecialties. Safety was furthered by the increasing use of infrared analysis of respiratory and anesthetic gases and by the development and application of the pulse oximeter. Airway management improved marvelously, adding to safety, most notably through the release of the Laryngeal Mask Airway. Gadgets were introduced to clinical practice that promised great control over the anesthetic delivery, including Target Controlled Infusions. Anesthetists and surgeons could be guided by transesophageal echocardiography. Outpatient anesthesia reached maturity. Altogether, the 1980s could be called the decade in which modern anesthesia came of age.

Summary

Advances and retreats in the 1990s often appeared in pairs. Two rapid acting neuromuscular blocking drugs, rocuronium, and the isomer of atracurium, cisatracurium, came onto the market. Unlike rocuronium, elimination of cisatracurium did not require hepatic degradation. The inhaled anesthetics, desflurane and sevoflurane, were released for clinical use. Although possessing greater stability and lower solubility, desflurane stimulated cardiorespiratory systems while sevoflurane did not, ultimately causing the popularity of sevoflurane to eclipse that of desflurane.

Several studies focused on the safety of regional anesthesia. Injection of 5% lidocaine through intrathecal micro-bore catheters could produce spinal cord injury, probably by confining the injected lidocaine to a small area. Lidocaine injected intrathecally could also produce transient neurological injury. Ropivacaine, an enantiomer of bupivacaine, was developed to decrease systemic local anesthetic toxicity. If toxicity arose anyway, intravenous infusion of lipid could decrease the availability and thus toxicity of a local anesthetic. The 1990s saw the use of ultrasound to guide local anesthetic placement, adding to safety by decreasing the amount of anesthetic needed, and adding to patient comfort by avoiding the earlier use of paresthesias to guide needle placement.

Various initiatives such as application of evidence-based algorithms and checklists decreased anesthesia-related morbidity and mortality in the decades leading to the 1990s. The WFSA adopted the multi-language online journal ‘*Update in Anaesthesia*’, spreading knowledge of the science and safe practice of anesthesia in developing countries. Adding to anesthetic safety, 1990s studies found that the slow heart rate produced by beta blocking drugs could protect the heart from ischemia. Later research demonstrated that potent inhaled anesthetics protected the ischemic heart by a mechanism akin to that with ischemic preconditioning. Other studies showed that a normal temperature, and maybe more oxygen, prevented wound infection.

In the 1990s, new anesthesia machines combined all needed components into a lovely, albeit costly, “anesthesia workstation”. The Engstrom-General Electric version included the computer-controlled Anesthesia Delivery Unit (ADU) that precisely delivered any anesthetic, including desflurane. Except for the US, the world approved machines to provide a Target Controlled Infusion of propofol.

Experiments in the 1990s advanced our appreciation of how inhaled anesthetics acted. To the surprise of many, investigators reported that the spinal cord (not the brain) mediates the immobility produced by inhaled anesthetics. Further decreasing the notion that inhaled anesthetics acted by altering the lipid bilayer, many highly halogenated compounds were found to disobey the Meyer-Overton correlation. The argument that proteins were the site of anesthetic action thereby gained traction. The finding of stereospecific effects of isoflurane isomers on MAC and ion channels added support to that notion.

World Events in the 1990s

The decade began hopefully with Germany’s reunification, but the first Gulf War cast a pall. CNN covered the war with an immediate presence, establishing that network as the major television source for world news. Instability and advances marked 1991 with the Soviet Union disintegrating and the Cold War and the Warsaw Pact ending. A series of positive world events followed: The internet arrived. In 1992, Bill Clinton signed the North American Free Trade Agreement (NAFTA), beloved by capitalists and despised by US unions. The 1993 Treaty of Maastricht established

Fig. 12.1 Sixteen new anesthesia societies appeared in the 1990s, several from the new countries that arose from the ashes of the Soviet Union

the European Union, a mixed blessing. The Global Positioning System (GPS) became fully operational. To the world's astonishment and applause, in 1994, South Africa peacefully elected Nelson Mandela as its first black President. In the next year, protease inhibitors were released, markedly decreasing AIDS mortality. The search engine Google appeared in 1997. About then, things took a turn for the worse. The Taliban seized control of Afghanistan in 1996, the year that the First Chechen War began, lasting until 1998, the year that India and Pakistan acquired nuclear weapons. In 1999, the Euro became the official currency for 12 countries. It seemed like such a good idea at the time.

Still More Anesthesia Societies

The 1991 disintegration of the Soviet Union into individual countries resulted in the appearance of several new anesthesia societies. These joined with societies that arose in other countries in the 1990s, in which the numbers of anesthesiologists had reached a critical mass (Fig. 12.1). Altogether, 16 new societies appeared.

Better Neuromuscular Blocking Drugs? Yes and No

The search for better neuromuscular blocking drugs continued, particularly the search for a drug with a faster onset and an assured termination of effect. Succinylcholine fitted that description but it caused muscle pain, untoward increased potassium release, and prolonged effects in patients with pseudocholinesterase deficiency. So the search went on. Organon synthesized rocuronium, and in 1989, the first report of its use in animals appeared [1]. Within a year, results in humans were published, [2] leading to its release for clinical use in 1994. It appeared to have a faster onset than the then competitor, vecuronium and many anesthesiologists used it. A competing company, Burroughs Wellcome (now Glaxo-SmithKline) had manufactured the rapid-acting drug atracurium. However, atracurium caused histamine release/allergic reactions, making it less than perfect. A stereoisomer of atracurium, cisatracurium avoided these side effects. In 1995, cisatracurium dosing and recovery characteristics were reported for humans, [3] and it became clinically available soon thereafter. Like atracurium, cisatracurium elimination did not require renal or hepatic function, instead depending on Hofmann elimination (hydrolysis). Recovery was therefore assured and many anesthesiologists felt more secure with its use.

But neither rocuronium nor cisatracurium were perfect; neither produced paralysis as rapidly as did succinylcholine. In 1999, Organon reported synthesis of a drug with these properties, rapacurium [4]. Initial uses in hundreds of patients gave promising results. Unfortunately, when hundreds of thousands of patients were given rapacurium, a few (especially children) developed severe bronchospasm, [5] and in 2001 rapacurium was removed from the market.

The Continuing Advance of Inhaled Anesthesia

In much of the world, halothane was the inhaled anesthetic of the 1960s; enflurane, the 1970s; and isoflurane, the 1980s. By the 1980s, the practice of surgery increasingly turned from a hospital-based to an ambulatory-based practice, taking with it or being led by anesthesia. The "come-and-go" nature of ambulatory surgery increased the need for anesthetics with more transient effects, anesthetics that allowed a more rapid recovery, and safe release of patients to go home. Thus the shift to propofol in the 1980s. In the 1990s, desflurane and sevoflurane, poorly soluble inhaled anesthetics that complimented the rapid recovery from propofol, were released for clinical use.

In 1990, Ron Jones described some of desflurane's effects in volunteers [6]. Other studies in humans concurrently detailed desflurane's cardiorespiratory, neuromuscular,

metabolic and cerebral effects. Anaquest pursued the commercialization of desflurane, with presentations to the FDA in 1991 that gained desflurane's approval and allowed marketing in 1992—at the same time that isoflurane's patent expired and its profitability to Anaquest declined (as told in Chapter 10, isoflurane had been synthesized by Anaquest employee, Ross Terrell, in the 1960s and commercialized by Anaquest in the 1980s).

Sevoflurane was resurrected at about the same time as was desflurane. Terrell had also synthesized sevoflurane in the 1960s but had not pursued its development because it was unstable in the presence of a base, as found in CO₂ absorbents. Bernard Regan at Travenol Laboratories had independently synthesized sevoflurane. Studies by Richard Wallin detailed some of sevoflurane's pharmacology [7, 8]. Wallin appreciated but was less deterred by the vulnerability of sevoflurane to degradation. In 1981, Duncan Holiday reported that sevoflurane induced anesthesia rapidly and smoothly in volunteers [9]. For a time, that was as far as it got; Some laboratory studies had found toxic effects of sevoflurane in rats [10, 11], and so it was put aside.

Baxter (successor to Travenol) approached Anaquest in 1987 to discuss licensing of sevoflurane by Anaquest. After a year of considering that possibility, Anaquest rejected Baxter's offer, reasoning that their then-being-developed desflurane's lesser solubility and greater stability made it superior. Furthermore, by a fortunate oversight, desflurane had patent protection. In the 1960s, Terrell had made desflurane using a process that required elemental fluorine. It was dangerous and expensive to make, and its lesser potency (a third that of isoflurane) meant that much more would have to be produced—adding to the expense. Terrell thought so little of desflurane's prospects that no patent had been obtained and no publication had detailed its properties. The absence of public declarations meant that desflurane could be patented as though it had been discovered yesterday. In contrast, sevoflurane had been in the public domain for decades and had, at most, a 5-year exclusivity protection. Rebuffed by Anaquest, Baxter sold sevoflurane to Maruishi, a small Japanese pharmaceutical, who after further study brought sevoflurane to market in Japan in 1990 where it was a success... without reports of injury. Maruishi then turned to Abbott Laboratories which in 1992 accepted an offer to license sevoflurane for worldwide sales excluding Japan and China [12]. In 1993, Abbott made sevoflurane available.

The proponents of sevoflurane and desflurane had grand struggles in the 1990s. Statistically significant differences were found that didn't always translate to meaningful clinical differences. In 1991, Nobu Yasuda showed that the kinetics of desflurane were superior to those of sevoflurane [13, 14]. Studied by Richard Weiskopf in volunteers in 1992, desflurane did not produce evidence of renal injury [15], but

five years later, Eger showed that prolonged anesthesia with sevoflurane at 2 L/min inflow rate could produce nephrotic levels of albumin in the urine of volunteers [16], a finding confirmed in studies of patients by Higuchi et al. in 1998 [17]. Such transient injury correlated with the amount of a degradation product of sevoflurane, compound A, that the subject breathed [16–19]. These findings appeared to confirm Anaquest's decision to pursue desflurane rather than sevoflurane. However, although injury might be produced (and even that was not accepted by many sevoflurane proponents), the injury required prolonged (8-hour) exposure at relatively high sevoflurane concentrations (1.25 MAC) with fresh Baralyme® absorbent (which produced greater amounts of compound A from sevoflurane degradation than did other absorbents or partially used absorbents). And the injury was transient. Thus the proponents of sevoflurane might reasonably dismiss any injury as clinically unimportant.

There is a delicious irony to this story. In response to Eger's (yes the same Eger as the editor of this book) compelling testimony to the FDA regarding the potential for renal injury, sevoflurane administration in humans in the US was limited by the FDA to 2 MAC hours at 1 L/min for two hours after which the fresh gas flow had to be increased to 2 L/min. Because of this proscription, however, most anesthetists used the higher flow (2 L/min—or even 3 L/min) thus generating greater profits for Abbott (the licensee from Maruishi), the rival company to that producing desflurane, the anesthetic favored by Eger. Who would have guessed?

More relevant was the finding that desflurane, but not sevoflurane, might stimulate the cardiovascular system [20, 21], and irritate the airway (Fig. 12.2) [22]. Such clinically important unwanted effects of desflurane ultimately caused the popularity of sevoflurane to eclipse that of desflurane. Too late, it was appreciated that such unwanted effects of desflurane only became apparent at concentrations exceeding 1 MAC [6, 23], and that the concurrent use of opioids like fentanyl diminished or abolished such effects [24].

Dexmedetomidine and Mivazerol

The alpha₂-adrenoceptor agonist dexmedetomidine had been developed in the late 1980s, and this continued to its approval for human use in the 1990s. In 1988, Vickery et al showed that it decreases anesthetic requirement (MAC) in dogs, and if given in sufficient dosage could suffice, alone, for anesthesia [25]. It does more than just affect anesthetic requirement. It decreases heart rate, and as shown in the late 1990s, it and a sister drug, mivazerol could protect the heart with coronary artery disease from ischemic injury [26, 27].

Fig. 12.2 Ter Riet et al. induced anesthesia in patients with 2 MAC of desflurane, isoflurane, or sevoflurane, finding postoperatively that few if any complained of irritation of the airway when anesthetized with sevoflurane [22]

Advances in Local Anesthetics and Their Delivery

Placement of catheters in the cerebrospinal fluid of the spinal canal requires making a hole in the arachnoid membrane of a size that predisposed to leakage of cerebrospinal fluid and thereby increased the potential for “spinal headache”. It seemed obvious that the smaller the catheter, the better. Animated by this notion, in 1991, Rigler and Drasner used such catheters to produce spinal anesthesia with lidocaine. To their surprise, they found an associated spinal cord injury [28]. Studies suggested that this resulted because the slow injection, forced by the narrowness of the microbore catheter, concentrated the injected lidocaine, and because lidocaine had a greater inherent toxicity than previously appreciated. Further study led to the 1993 observation that even when a microbore catheter was not used, the subtle neurotoxicity of lidocaine produced a “transient neurological syndrome” (TNS) [29]. This effect was not seen with bupivacaine [30]. The TNS peculiarly associated with lidocaine, plus the rare serious injury, markedly decreased the use of lidocaine as a spinal anesthetic.

Local anesthetics also have a dose-dependent capacity to cause untoward effects from their systemic presence. In particular, bupivacaine can cause profound cardiac depression [31]. Investigators attacked such toxicity in several ways. One effective strategy proposed in the 1980s decreased bupivacaine dosage, using a smaller concentration as well as

smaller incremental volumes [31]. A less effective one took advantage of potential differences in bupivacaine’s two enantiomers, leading to the 1996 marketing of ropivacaine [levobupivacaine, the S (–) enantiomer] which has less affinity for cardiac sodium channels than the R (+) mirror image [32]. But the differences in toxicity between bupivacaine’s enantiomers were small and probably of little clinical significance. Weinberg described another strategy for dealing with toxicity, in 1998 finding that lipid infused intravenously could absorb and thereby decrease the availability and toxicity of bupivacaine [33].

Finally, accurate placement of local anesthetic to achieve anesthesia enhances the safety of local anesthetics/regional anesthesia by minimizing the amount of local anesthetic required and by avoiding injection of anesthetic in blood vessels. In 1994, University of Vienna investigators described ultrasound identification of peripheral nerves (specifically the brachial plexus) [34]. This advance revolutionized regional anesthesia, not only decreasing the amount of anesthetic required and potentially reducing complications, but also decreasing patient discomfort since it avoided the use of paresthesias to guide needle placement. To that time, paresthesias or anatomical landmarks had been the standard approaches to identifying the correct position of the tip of the needle used to inject the local anesthetic.

Outcomes Studies and Mundane Checklists Add to Safety

Various 1990s outcomes studies increased the safety of anesthesia. Several studies built on the 1985 observation by Slogoff and Keats that a slower heart rate protected against postoperative myocardial infarction in patients having coronary artery bypass operations [35]. In the late 1990s–2000s, Mangano [36] and Wallace [37] found that administration of atenolol or clonidine to decrease beta adrenergic activity, decreased mortality in patients having operations for cardiac disease.

Inhaled anesthetics could also play a protective role. In 1997, Cason’s group showed that isoflurane administration produced cardioprotection akin to protection produced by “ischemic preconditioning” [38]. Other potent inhaled anesthetics had this effect, a cardioprotection that long (days) outlasted the presence of the anesthetic [39]. Thus in 2003, De Hert showed that the use of anesthetics such as desflurane or sevoflurane could greatly decrease myocardial injury from the myocardial ischemia inherent to coronary artery surgery [40]. On the other hand, injected anesthetics could sometimes play an untoward role. In 1992, Parke et al. found that prolonged (days) infusion of propofol produced a profound acidosis, lipidemia, and myocardial failure that could be lethal to children [41]. Whether this resulted from

the vehicle used to deliver propofol, to propofol itself, or to some other factor was unclear.

The ability of the anesthetist to control physiological variables could increase patient welfare. In 1996, Kurz, Sessler and Lenhardt showed that maintaining normal body temperature protected against wound infection after colon resection [42]. This study profoundly influenced practice in the US and worldwide. Use of forced air warmers to maintain normothermia in all but brief procedures became standard. In 1997, Hopf and Hunt demonstrated that breathing greater concentrations of oxygen decreased wound infection and hastened healing [43]. It is not clear that this prompted the use of greater inspired concentrations of oxygen.

The US Institute of Medicine report “To Err Is Human” published in 1999, suggested that anesthesia-related mortality decreased from 2 deaths per 10,000 anesthetics in the 1980s to about 1 death per 200,000 a decade later [44]. This admirable increase in safety resulted from numerous worldwide initiatives. For example, in 1991, Gaba convened a conference focused on human error in anesthesia, leading to the introduction of algorithms and checklists similar to those used to ensure safety in commercial aviation. In 1999, Pronovost et al. reported on the use of such an approach to decrease morbidity and mortality from venous catheter induced infection [45]. Not everyone agreed that the decreased overall rate of mortality was as dramatic as suggested [46].

Safety advanced worldwide. To do this, less developed countries relied on proven simple approaches to safety, approaches disseminated by means that such a world could access and afford. In 1992, the World Anaesthesia Society, a Specialist Society of the Association of Anaesthetists of Great Britain and Ireland, funded ‘*Update in Anaesthesia*’ the international journal of the World Federation of the Societies of Anaesthesiologists (WFSA), with supplemental funding by the UK Overseas Development Administration.¹ The WFSA adopted ‘*Update in Anaesthesia*’ to spread knowledge of the science and safe practice of anesthesia in developing countries. Free copies were sent to 3,000 English-speaking anesthetists. Free download from the internet was available in English, French, Mandarin, and Spanish.

Electroconvulsive therapy (ECT) remains as the primary therapy for major depression. It comes at a price. Patients correctly apprehend that such therapy can decrease mental function and can be associated with prolonged memory loss. With his anesthesia colleagues in Vienna, psychiatrist Langer hypothesized that the electrical silence that followed convulsions, rather than the convulsions, themselves, produced the desired effect, resetting the brain. For those with limited to no computer expertise, this notion is similar to the underlying cure of computer woes sometimes magically achieved by turning the computer off and then on again. Langer continues

with his proposal: Perhaps using inhaled anesthetics to achieve electrical silence might produce the same effect as convulsions without causing memory loss. Consistent with that hypothesis, in 1985, they demonstrated that deep anesthesia with isoflurane, inducing a period of ‘electrocerebral silence,’ reduced depression in 9 of 11 subjects [47]. They confirmed these results in 1995 [48].

In 1993, a separate group from Wurzburg confirmed that burst-suppression-level isoflurane was as effective as ECT [49], with the caveat that anesthesia required more time and monitoring than ECT. Perhaps this explains why the use of isoflurane for management of major depression has not become routine. Or perhaps anesthetic management of depression is not used because psychiatrists make treatment decisions and because the evidence supporting treatment with isoflurane came from small studies, only some of which were randomized and controlled. But it seems a pity this isn’t resolved. We’d rather have a brief anesthesia than ECT for our depression.

Advances in Equipment

Before the 1990s, hospitals and anesthetists purchased anesthesia machines and monitors separately, this offering the advantage of modular selection of the “best” device. However, displays, controls and alarms varied, predisposing to confusion. In the 1990s, purveyors of anesthetic equipment integrated the anesthesia machine, ventilator and monitors into an “anesthesia workstation” in which all modalities were displayed in one place, with alarms coordinated and prioritized. But the cost of the new machines could approach \$ 100,000.

Engstrom (later Datex-Engstrom and then General Electric) released the Anesthesia Delivery Unit (ADU), incorporating a new form of the variable bypass vaporizer, in 1995. This was the first anesthesia machine where gas flows through the bypass versus the vaporizer sump were controlled by a computer. The computer control-module was separate from the anesthetic sump. The former was programmed to deal with any of the anesthetics (including desflurane) while the latter (the sump) was specific to the anesthetic. Based on feedback from agent monitors, the computer-controlled flows were adjusted to deliver the agent concentration dialed on the anesthesia machine. Any anesthetic, including desflurane, could be used with this variable bypass vaporizer. As suggested in the previous paragraph, the vaporizer was integrated into a complete anesthesia machine, the ADU.

In 1981, Schwilden supplied an analysis that suggested the feasibility of a computer-controlled infusion of an anesthetic or anesthetic adjuvant drug in a manner that achieved a targeted concentration at the effect site of the drug, wherever that might be [50]. By the 1990s, several investigators had applied Schwilden’s approach (e.g., see Raemer et al. [51]

¹ Information may be accessed at update.anaesthesiologists.org/.

and Shafer et al. [52]) By 1995, machines to provide a Target Controlled Infusion of propofol (e.g., the ‘Diprifusor’) [53] were approved in much of the world...but not in the US.

SIM 1 the first computer-controlled anesthesia-dedicated mannequin simulator was made for use at the University of Southern California in the 1960s [54]. Although it appeared promising, it was never released commercially. In the 1980s, David Gaba at Stanford University [55], and Michael Good and JS Gravenstein at the University of Florida created simulators for investigating human performance, training and safety in anesthesia [56]. And from the late 1990s through to 2010, training and recertification with computerized simulators grew rapidly despite limited evidence of sustained efficacy. In 2000, there were less than 200 computerized mannequin simulators, but by 2011 this had increased to more than 7000 (see Chapter 37).

How do Anesthetics Work?

Our appreciation of the mechanisms underlying the action of inhaled anesthetics advanced in the 1990s. In 1993, to the surprise of many anesthetists, Antognini and Schwartz [57], and Rampil [58] reported that the spinal cord and not the brain mediated the immobility produced by inhaled anesthetics. And in a further blow to the notion that inhaled anesthetics acted by altering the lipid bilayer, Koblin et al. reported in 1994, that many polyhalogenated and perfluorinated compounds disobeyed the Meyer-Overton correlation [59]. If not lipids, then perhaps proteins were the site of anesthetic action—as Franks and Lieb argued [60]. In support of that notion, Lysko et al. found stereospecific effects of isoflurane isomers on MAC [61], and, similarly, Franks and Lieb showed stereospecificity for actions of isoflurane on nerve ion channels [62].

Also in the 1990s

Increasingly, the anesthesiologist, sometimes deliberately and sometimes by chance, has become a perioperative physician with responsibilities that extend beyond the operating room [63]. Consistent with this concept was Fischer’s 1996 argument that anesthesiologists should establish and supervise clinics for the preoperative evaluation and preparation of patients for surgery [64].

In 1998, a mandated increase to 2.5 years duration of training was imposed on US Nurse anesthesia training programs and all graduates had to earn a master’s degree. Further increases were programmed for the future, including a requirement that graduates earn a doctorate. For now, that development has been postponed to 2025.

In 1983, Gualtieri et al. suggested that drug addicted anesthesia residents should seek work in another specialty because of the poor success rate for re-entry into anesthesia [65]. A 1991 study by Pelton and Ikeda suggested however that up to 70% of health care professionals, including anesthesiologists, successfully return to medical practice [66]. Paris and Canavan reported a similar finding in 1999 [67]. No evidence indicated that anesthesia providers in recovery returning to anesthetic delivery posed an increased risk to patient safety.

Reprise

The 1990s advanced safety, control and understanding of clinical anesthesia. Two new, poorly soluble inhaled anesthetics, sevoflurane and desflurane allowed a more precise control over the anesthetic state. Sevoflurane did so without cardiorespiratory stimulation. Both protected the heart from hypoxia. An older anesthetic, isoflurane, could reverse mental depression. We learned that all these anesthetics acted on central pattern generators in the ventral spinal cord to make patients immobile despite ongoing surgery. We also learned that the Meyer-Overton theory correlating lipophilicity and anesthetic potency didn’t always work, indirectly suggesting that inhaled anesthetics operated on proteins. Two new muscle relaxants, rocuronium and cis-atracurium added to safety by acting more rapidly and for shorter times. On the other hand, the historically “safe” local anesthetic lidocaine, was found to be mildly or severely neurotoxic, particularly when given through an intrathecal microbore catheter. In another blow to local anesthetics, higher doses of bupivacaine produced cardiovascular collapse. We dealt with this problem by giving less bupivacaine (helped by the development of ultrasound guidance which allowed more accurate placement of the bupivacaine) and giving it more slowly. We might switch to the less toxic enantiomer of bupivacaine, ropivacaine, and if all else failed we treated toxicity with intravenous lipid which swept up the local anesthetic. More to safety, we applied checklists to decrease infection. We prevented hypothermia, and that, too, decreased infection. In Europe and other places outside the US, we used machines to give target controlled infusions to maximize the kinetic advantages of propofol. It was a good decade for anesthesia.

Summary

The dramatic scientific and technologic advances of anesthesia in preceding decades slowed in the 2000s, with maturation of the specialty and associated subspecialties. Certificates attesting expertise in anesthesiology and subspecialties now require or will require recertification.

Except for sugammadex, no new anesthesia-related drugs were released for use, and few new drugs are on the horizon. New uses for old drugs were found such as administering ketamine to lessen postoperative dependence on opioids, and substituting intrathecal 2-chloroprocaine for lidocaine to avoid lidocaine-associated transient neurologic syndrome. The 2000s saw technical advances such as the GlideScope, the first of many video-laryngoscopes, and increased adoption of ultrasound-assisted regional anesthesia. Several societies recommended ultrasound guidance for insertion of central venous catheters.

Fears that increased risk precluded outpatient surgery for ASA PS III patients were shown to be unfounded, and approximately 80% of elective surgical and diagnostic procedures in the US were performed on an outpatient basis. However, office-based sedation appeared to increase risk relative to that in free-standing ambulatory surgery centers (ASCs), probably because of less oversight and training of those delivering sedation. The Lifebox Foundation promoted the 2004 Global Oximetry initiative of the WFSA, to make oximetry and capnography available and thereby diminish mortality in low-income regions of the world.

Three major worldwide instances of plagiarism, fraud, and lack of informed consent by anesthesiologists were revealed, resulting in retraction of a record number of publications, and prosecution and incarceration of at least one investigator.

The percentage of women anesthesia residents in the US increased from 27% in 2000 to 38% in 2010, women increasingly chaired Departments of Anesthesia, and 9 of 22 SAMBA Presidents were women. In the 2000s, governing agencies in the US and Europe progressively limited duty hours of residents in all specialties. In 2005, Pandit noted that only 6 of 23 UK universities sustained departmental or divisional structures for anesthesia.

Several analyses suggested that anesthesia safety reached new heights with death rates attributable to anesthesia of less than 1:100,000. If immediate mortality has reached an irreducible minimum, future efforts may aim to decrease long-term morbidity and mortality and associated health care costs. Consistent with this thought, Mark Warner as President of the American Society of Anesthesiologists in 2011 described the “Perioperative Surgical Home” proposing that anesthesiologists coordinate all matters relating to the in-hospital care of surgical patients. Now that would be a game changer!

World Events Shaping the 2000s

The decade began with the controversial 5:4 ruling by the US Supreme Court, delivering the US presidency to George W Bush. On 11 September 2001, commercial airliners became weapons of mass destruction (WMDs) deliberately destroying the World Trade Center in NYC, killing more than 3000 people. The subsequent “War on Terror” produced the US invasion of Afghanistan in search of Osama bin Laden and presaged the 2003 Iraq War justified by a search for never-to-be-found WMDs. SARS and Bird flu epidemics interfered with world travel in 2002 and 2006. Hurricane Katrina and

the Indian Ocean Tsunami convincingly demonstrated the power of Mother Nature, nearly destroying a city of 500,000 and killing more than 240,000. In 2008, at the Beijing Olympics and again in 2012 in London, Usain Bolt and Michael Phelps became household names. So did Lance Armstrong after winning the Tour de France for seven consecutive years. In 2012 he was banned for life from racing for using banned substances. Barack Obama became the first African-American US President. In the early months of his presidency, the deregulated finance industry's ability to create mortgages for people who could not afford them, and then sell the debt for a profit, led the housing market "bubble" to burst, bringing near collapse of the world's economy. Bernard Madoff created the largest ever "Ponzi" scheme cheating investors out of 60 billion dollars. China and India developed into new economic powerhouses epitomizing the best and the worst of globalization. Google became the search engine of choice, and Facebook and Twitter emerged, creating a vast industry called "social media". The smart phone revolutionized communications and Apple became the world's most valuable company. Finally, in the US in 2010, proponents of the Affordable Care Act overcame enormous political opposition, providing access to medical care to 30 million previously uninsured American citizens, the US joining the rest of the developed world in offering (nearly) universal health care.

Pharmacology: Where are the Drugs?

One new medication pertinent to anesthesia, sugammadex, gained approval for clinical use in the 2000s in much of the world, but was not approved for use in the US. In contrast, at least 6-to-13 new medications had appeared in each of the six previous decades (Fig. 13.1).

Released for clinical use in the late 1990s, the ultra-short acting non-depolarizing neuromuscular blocking agent rapacuronium received an enthusiastic reception because the time to onset of action was similar to that of succinylcholine, succinylcholine-like side effects were absent, and neostigmine easily antagonized residual neuromuscular block. It was considered advantageous for use in patients at risk of aspiration and requiring a rapid sequence induction. However, Organon voluntarily withdrew rapacuronium from the market in 2001, due to concern regarding unexplained fatalities and severe bronchospasm occurring during post-marketing surveillance.

In the 2000s, Organon developed a radically new approach to reverse neuromuscular blockade. By "surrounding" a molecule of a neuromuscular blocking drug (particularly rocuronium), the cyclodextrin sugammadex could inactivate the action of the relaxant. A major advantage of sugammadex was the ability to immediately antagonize "deep" neuromuscular block, including that following rapid sequence induction. Like rapacuronium however, sugam-

Fig. 13.1 Six to thirteen new anesthesia related drugs were introduced in each decade between 1940 and 2000. But from 2000 to 2013 only a single medication, sugammadex was introduced (while not available in the US, it was approved in more than 50 countries worldwide.)

madex was also associated with occasional cases of hypersensitivity reactions [1, 2], and while available throughout much of the world, as of 2013 it had not been approved by the FDA for clinical use. Interestingly, case reports describing the use of sugammadex to successfully treat severe rocuronium-induced bronchospasm (presumably by inactivating the molecule provoking the anaphylaxis) provided support for an otherwise unintended use of the drug in patients with anaphylaxis from rocuronium not responsive to other treatment [3].

A neuromuscular blocking drug, gantacurium, is in phase three trials. Like atracurium, gantacurium produced a non-depolarizing blockade, but rather than undergoing Hofmann degradation, inactivation occurred by adduct formation with L-cysteine. Exogenously administered L-cysteine could accelerate inactivation, independent of blood pH, temperature, or depth of block [4].

Reasons for the dearth of new anesthesia related medications in the 2000s included the enormous cost of drug development and the relatively small market for anesthesia related medications. Increasing cost controls placed by third party payers and/or governmental decision makers may have also exerted an effect. But the primary limitation may have been the proven efficacy and safety of already available drugs. Improving on the excellence of presently available anesthetics and anesthetic adjuvants proved difficult. Contrast these circumstances with those in the 1950s to 1970s, a period of considerable drug development. The increasing use of electrocautery reduced the suitability of ether and cyclopropane, and an appreciation of the importance of decreased blood solubility and lesser metabolism, stimulated synthesis of new inhaled agents, first halothane, then methoxyflurane (a mistake) then enflurane, isoflurane, sevoflurane, and desflurane. While none were perfect, it is difficult to imagine development of additional volatile agents. The same might

be said of propofol, the intravenous induction/maintenance drug that replaced thiopental, or the anxiolytic drug midazolam that replaced diazepam, or the present array of opioids. Neuromuscular blocking drugs in the 1950s included d-tubocurarine, metacurine, decamethonium, gallamine, and succinylcholine, all relaxants with notable limitations that led to the “oniums” and “uriums” of the 1960s–1990s. While also not perfect, these drugs advanced the field so far that safety and efficacy were less problematic, and other than searching for a faster-shorter-acting non-depolarizer, further “tinkering” would seem to have a low benefit/cost ratio.

Thus safety and pleasantness of anesthetic delivery, rather than newness remained the principal concerns of the anesthesiologist. Improving safety might not depend upon newer and better medications. Instead of developing new drugs, newer applications of older drugs occurred in the 2000s. These included administration of small doses of ketamine at induction of anesthesia and at intervals during surgery to supply analgesia, especially in patients with chronic pain who otherwise required large doses of opioids [5].

Postoperative nausea and vomiting (PONV) has long concerned patient and anesthetist. In the 2000s and before, anesthetists increasingly appreciated the factors predisposing to PONV. Various remedies had been shown to be effective up to a certain dose, beyond which further doses added little to a reduction in PONV. Apfel et al. added another dimension, in 2004 showing that combining 2 or 3 such remedies increased their antiemetic effect [6]. The implication of this finding was not that more drug was effective, but that PONV resulted from effects on multiple receptors. Thus the use of remedies influencing multiple receptors was more effective than increasing the dose affecting a single receptor.

In the 1980s, 2-chloroprocaine (CP) was nearly abandoned because of concern regarding spinal cord injury associated with inadvertent intrathecal injection of a large dose for epidural anesthesia [7]. CP use at much lower doses returned for spinal anesthesia in patients undergoing relatively brief surgery [8]. However, such delivery represents an off label application, and the difficulty of “obtaining FDA approval or exemption to study the use of spinal CP in a randomized-controlled manner, (means that) the safety of CP will likely be determined by large scale clinical practice”[9].

Awareness during anesthesia has long been acknowledged as a risk in severely injured patients not tolerating the circulatory effects of amnestic concentrations of inhaled anesthetics [10]. A parallel concern has arisen from the increased use of total intravenous anesthesia (TIVA), especially for patients receiving neuromuscular blocking agents in doses that prevent movement reflecting pain or awareness. Providing an end tidal anesthetic concentration slightly exceeding MAC-Awake is considered sufficient to prevent awareness in most patients [11]. With TIVA, a surrogate matching MAC-Awake has been sought, developing an advocacy for

so-called awareness monitors [the bispectral index (BIS) or entropy monitors] to assure the presence of amnesia [12]. The value of these devices continues to be debated.

Ultrasound-Guided Procedures in Anesthesia—I Can See it Now!

Ultrasound technology has had a place in anesthesia since the 1980s with the introduction of transesophageal echocardiography [13]. Its origins as an adjunct to anesthesia-based procedures began in the 1990s [14, 15], but in the 2000s the promise of ultrasound assisted techniques blossomed. Anesthesiologists with their roots in the 1960s remember the anxiety associated with “walking the needle along the first rib” while performing supraclavicular brachial plexus blocks (pray, don’t let me pierce the dome of the pleura!), or drawing lines on the buttocks before sciatic-femoral blocks (where were those nerves anyway?) Remember too, instructing an inexperienced resident in the use of surface landmarks to cannulate the internal jugular vein (especially nerve racking in a small child and still more problematic when the surgeon was nearby). Such terrors receded in the 2000s. More than 95% of the 1200 papers published describing ultrasound assistance for regional blocks, jugular vein and other vessel cannulation (and all papers describing training in these techniques) appeared after 2000.

The 2000s’ use of ultrasound guidance in regional anesthesia increased the ability to observe intravascular or intraneural injection of local anesthetic, lessened local anesthetic systemic toxicity (because a smaller volume of local anesthetic was needed, particularly advantageous in smaller children), and decreased patient discomfort relative to the previous method of nerve identification (paresthesias from nerve stimulation). Studies comparing landmark vs. ultrasound assistance for internal vein cannulation showed that ultrasound assistance led to a more rapid completion of the procedure, a greater frequency of successful performance, fewer attempts, and less morbidity (carotid puncture or hematoma formation) [16]. Recommendations from several societies including the Society Of Cardiovascular Anesthesiologists [17], and the American Society of Anesthesiologists [18] regarding its use, have recently emerged.

While these advantages appeared to indicate the usefulness of ultrasound assistance, many studies used as part of a recent American Society for Regional Anesthesia—Evidence Based Assessment were too small and the complications too infrequent to provide statistically significant evidence of superiority [19]. They relied on surrogate measures such as onset time and number of nerves anesthetized rather than more clinically relevant criteria including the ability to complete surgery without block supplementation or general anesthesia. Furthermore, experts performed many of

the randomized control trials included in this assessment and their results may not reflect the success rate of anesthesiologists occasionally using regional anesthesia. As this clinical area matures, a specific period of training and experience may be expected, perhaps similar to that currently required for certification in trans-esophageal echocardiography. 3-D simulation trainers, with tactile feedback, are being developed.

Scientific Misconduct

The known frequency and magnitude of scientific misconduct increased enormously in the 2000s. Plagiarism and fraud accounted for most of these reports, the latter composed of “made-up” data and patient-related research lacking patient consent and/or Investigational Review Board (IRB) approval. Plagiarism detection probably increased because of newly available software that laid bare the use of another’s words without proper attribution. Shafer, described a taxonomy of plagiarism varying in seriousness from Intellectual Theft (use of ideas, analysis, and large blocks of words without proper attribution—unacceptable) to Self Plagiarism (use of one’s own words to describe perhaps a technical analysis or method not easily lending itself to restatement—OK) [20]. As Shafer stated, “it is unrealistic to expect an author working in a field to generate a novel description every time he or she chooses to write about it (but) extremes of self plagiarism including that approaching duplicate publication are clearly unethical and may be subject to manuscript retraction.” (see cited references as an example) [21, 22].

Shafer also described “Plagiarism for Scientific English” used by authors uncomfortable expressing their thoughts in English. While understandable, this is not justifiable and if excessive may also be grounds for retraction [23]. Given that scientific journals increasingly screen every submission for plagiarism, the frequency of retraction for plagiarism will probably approach but not reach zero because plagiarism can escape detection by the detection software [24]. It is tempting to speculate on the incidence of plagiarism before the “plagiarism detection software” era. This remains for others to explore.

Alas, no scientific fraud-detecting software comparable to plagiarism-detecting software exists. In the 2000s three major scandals revealed fraudulent anesthesia-related research published over the past several decades. First, Scott Reuben an investigator at Baystate Medical Center in Springfield Massachusetts published numerous papers describing the benefits of postoperative multimodal pain management. In 2009, more than 20 published papers and abstracts were retracted when individuals in his institution discovered that Reuben fabricated the data in these reports. Importantly, the falsity of the results cast doubt on recommendations regard-

ing several clinically important treatments [25]. Reuben was sentenced for health care fraud to 6 months in prison, fined \$ 50,000 and ordered to repay more than \$ 300,000 to several pharmaceutical companies.

German investigator Joachim Boldt published more than 200 papers over the past 25 years, many comparing efficacy and safety of colloids, including hydroxyethyl starch and albumin, in humans. In early 2010, several readers noted suspicious data appearing in a paper published in 2009 [26]. The data, particularly the variability in the measurements of several cytokines and of blood gas data was too small. This led to an investigation revealing that no study had been performed! Further investigation of all of Boldt’s research resulted in retraction of 88 papers, most for lack of evidence that patient consent had been obtained. At the time, this comprised the greatest number of retracted papers by a single author.

But wait! Not to be outdone, Yoshitaka Fujii a Japanese anesthesiologist has been accused of falsifying data in 172 (126 supposedly randomized control studies) of 212 papers published between 1993 and 2011. Fujii’s credibility had been questioned in a 2000 Letter to the Editor [27] commenting on one of his published papers [28], that the data were “incredibly nice”. In March 2012, John Carlisle a British anesthesiologist reported that the likelihood “of the data from all of Fujii’s published papers being generated experimentally—as opposed to by fraud—(was) implausibly small, in the order of $1:1 \times 10^{30}$ [29].” Using a meta-analysis, Carlisle subsequently assessed the impact of deleting Fujii’s research papers on our understanding of the impact of several antiemetics, showing far less antiemetic effect and a lack of synergy between these medications [30].

Assuming that the concerns regarding Fujii’s reports hold up, of the 2,200 papers retracted from the literature since 1970, anesthesiologists authored nearly 13%. In addition to diminishing the credibility of our specialty, such fraud could adversely affect patient care, if clinicians were misled by the recommendations emanating from the fraudulent papers.

Anesthesia Safety Through the 2000s: Is it a Snake or a Tree?

Defining anesthetic safety is akin to the parable in which blind men touch an elephant and describe what they have touched. “It is like a snake” says the man grabbing the tail. Oh no, says the man hugging the leg, “it is just like a tree”. Context is important in describing the shape of an elephant and in describing the past and present history of anesthesia safety.

Anesthesia-related death rates of 1:500 to 1:2,000 were reported in the 1920s 1930s and 1940s (Fig. 13.2) [31–33]. We and others argue that by the 2000s, the safety of anesthesia

Fig. 13.2 Observational data describing anesthesia related death rate suggest a progressive decrease in mortality of two orders of magnitude during the history of modern anesthesia

had dramatically increased. Today's low mortality probably represents the cumulative result of multiple factors.

In 1954, Beecher and Todd published their landmark report of anesthesia-related mortality in a surgical journal [34]. Some fellow anesthesiologists dismissed the study [35]. Nonetheless, it illustrated some of the forces leading to today's amazing record of safety. Beecher and Todd prospectively studied 600,000 patients receiving various anesthetics. The mortality attributed to anesthesia as the primary cause was 1:2680 and contributory in 1:1560. The authors indicted curare as an important cause of death, finding many more deaths in patients receiving curare, with the greatest incidence of anesthesia-related death occurring in patients given both curare and ether (1:250). A plausible explanation of the greater mortality in this latter group is that patients reached the recovery room still partially anesthetized (because of the high blood solubility of ether), partially paralyzed (by curare and the synergistic effect produced by residual ether and hypercapnia secondary to hypoventilation), and breathing room air rather than air supplemented with oxygen. That is the explanation Cecil Gray supplied in an interview at Oxford in 1996:¹

"... when he (Beecher) published the paper it was quite obvious these patients were returned to bed still curarised, and lying there. Now, the secret was when they were still curarised, breathing ineffectively, not only was that not good for them, from the point of view of the collapse of the lung and so forth, but also they accumulated carbon dioxide. Their carbon dioxide tension went up, which potentiated any residual curare, so it became a thing called residual curarisation, which was a thing unknown to us".

¹The Royal College of Physicians and Oxford Brookes University, Medical Sciences Video Archive MSV A 145, Professor Cecil Gray CBE KCSG FRCP FRCS FRCA in interview with Dr Max Blythe, Oxford, 25th November 1996, Interview Two.

Gray also explains the difference between the results with curare in the US and England:

"Now, the Americans were frightened of prostigmine because of its effect on the heart: give enough of it and it will just stop the heart, you see. But if you give atropine, atropine blocked that action but didn't block the action on the muscles, the reversal of the tubocurarine. And we worked out the technique in which we were giving atropine and prostigmine, feeling our way until we got the right sort of dose. Then over the months, I suppose it was—yes it was certainly months—we came to give it absolutely routinely, because there was no trouble."

Further to the elimination of the problem, monitoring of neuromuscular block began in the 1960s and became increasingly routine by the 1970s.

Subsequent observational studies (counting bodies) in the 1970s and 1980s reported anesthesia related death rates approaching 1:10,000 [36], decreasing further in the 1990s and 2000s to between 1:100,000 and 1:200,000 [37, 38]. In 1994, Lucien Leape commented "Whereas mortality from anesthesia was one in 10,000–20,000 just a decade or so ago, it is now estimated at less than one in 200,000. Anesthesiologists have led the medical profession in recognizing system factors as causes of errors in designing fail-safe systems in training to avoid errors [39]." The Institute of Medicine singled out the specialty for its success in reducing anesthesia related mortality [40].

Not all parties (including the authors of one of the essays in this book) accepted a two orders of magnitude decrease in anesthetic related mortality [41, 42], and many factors (including variations in surgical care, severity and number of co-morbidities and use or non-use of antibiotics) make comparisons of death rates between different eras difficult. But other measures—perhaps only surrogates of quality—lend support to the conclusion that a remarkable improvement has occurred, attributable to what we do and how we do it. For example, liability insurance rates—corrected for inflation—have decreased by forty percent over the last 40 years (Fig. 11.1).

Several factors may have decreased mortality over the more than 6 decades of outcome data portrayed in Fig. 13.2. Most of these factors would produce a gradual, progressive improvement. They include better training programs incorporating the use of simulators, recruitment of higher quality trainees, successive introduction of inhaled anesthetics, hypnotics and opioids with more favorable pharmacokinetic and dynamic profiles, the application of specific antagonists of neuromuscular blocking drugs, more effective preoperative and postoperative management, and the increased use of electronic medical records. They might also include the invention of monitors with proper alerts, anesthetic machines preventing delivery of hypoxic gas mixtures, and the influence of national and international patient safety organizations. Some factors such as perioperative "check lists"

Fig. 13.3 Anesthesia-related deaths in England from 1908 to 1968 increased to a peak in the late 1930s and then dramatically decreased by nearly an order of magnitude. (Data from Scurr et al [43])

(time outs), response to malpractice liability crises (including adoption of monitoring standards), analysis of outcomes from malpractice cases (closed claims studies), and publication of evidence based practice parameters, guidelines, and advisories, might impose more immediate, step-like decreases in mortality because they are rapidly adopted.

Consider the anesthesia-related deaths data from England from 1908 to 1968 (Fig. 13.3). Consistent with an increasing number of operations (data not provided), deaths increased during the first thirty years, reaching a peak in the late 1930s. The number of anesthesia-related deaths declined over the next 30 years, doing so by nearly an order of magnitude. It seems unlikely that this would be explained by a decrease in the number of surgeries per year; if anything, the contrary would be likely. During this latter time, departments of anesthesia arose, anesthesia attracted better students, and halothane with a precision vaporizer for delivery was introduced [43]. None of these explanations provide a provable cause and effect relationship, but we submit that together they provide a compelling story supporting an actual improvement in patient safety meriting the comments of Leape and the Institute of Medicine.

In the 1930s, mortality from anesthesia might have killed 1:1000 patients anesthetized. If that applied to an annual delivery of 50 million anesthetics, anesthesia would have killed 500,000 patients, a mortality demanding attention. But assuming a present mortality of 1:100,000 to 1:200,000 and again an annual delivery in the 2000s of 50 million anesthetics, only 250-to-500 people would die in the US from anesthesia-related causes. In contrast, 400,000 people die yearly from smoking, alcohol-related automobile accidents and gunshot related deaths, 800–1,600 times the number of anesthesia-related deaths. Should additional resources be expended to achieve further decreases in anesthesia-related mortality when other more pressing health care re-

lated issues have the greater need? In 2009, Daniel Sessler commented:

“An unfortunate consequence of our improvement is that some consider anesthetic safety a more-or-less solved problem. At the very least, the number of intraoperative deaths is now so small that policymakers might reasonably conclude that resources would be better invested elsewhere. This thought process may contribute to the dimly small amount of funding that the National Institutes of Health provides for anesthesiology research” [44].

Sessler also noted that compared with anesthesia-related deaths as defined by death within days following surgery, “mortality in the year after surgery is about 10,000 times more common than preventable anesthetic mortality.” Increasingly anesthesiologist-directed initiatives and research efforts should focus on factors influencing long-term surgical outcomes. An early example was the 1996 study of Manganò et al. demonstrating a beneficial effect on long-term outcome of beta blockers in patients undergoing non-cardiac surgery [45].

Similar to the remarkable safety record in hospital-based surgery, outpatient surgery experienced a safety record greater than that originally anticipated. Dillon in 1967, opined that ASA PS III patients with diabetes, vascular insufficiency and anemia were unsuitable for surgery in an outpatient center [46]. But in 1976, as described by McGoldrick (Chapter 59), “Reed and Ford reported on 33,000 cases without a single death or malpractice suit [47], and in 2004 Ansell and Montgomery reported that ASA PS III patients had no obvious increase in morbidity or mortality relative to ASA PS I or II patients [48].”

Why should this be a surprise? Assuming a quality of care in an ambulatory surgery center similar to that in a tertiary care hospital, no reason suggests that the death rate for the two should differ. Of course this depends upon proper patient selection, upon suitable patient care at home, and upon availability of transport to a tertiary care facility if needed. And the patient treated at an outpatient surgery center may be at less risk of encountering infections.

On the other hand, office based surgery, another surgical site favored by patients and surgeons because of convenience and lower cost, may have a greater rate of both mortality and morbidity than that associated with ambulatory surgery centers [49]. Reasons for this seem obvious: a lack of oversight resulting in excessive sedation by the surgeon performing surgery while simultaneously providing sedation; lack of training (as well as practice) of the surgeon in airway management and other emergency procedures; limited familiarity with the consequences of the administration of potent opioids and sedative hypnotics; and poor selection of patients undergoing what may be lengthy and painful procedures. Consistent with this reasoning, mortality decreased by 58% in the year following implementation of a standard

that required an anesthesiologist in attendance for any case during which either general anesthesia, deep sedation, or regional anesthesia was used [50].

Perioperative Medicine and More

Originally proposed as a term defining the “job description” of anesthesia departments [51], Mark Warner reintroduced perioperative medicine as the Perioperative Surgical Home.^{®2} In this role, anesthesiologists would manage and coordinate all in-hospital care related to the surgical patient. This differs from the current practice in many hospitals wherein surgeon, anesthesiologist, primary care physician, hospitalist, physician assistant, nurse practitioner, and intensivist (as needed) independently (and not necessarily in a coordinated manner) provide perioperative care.

More specifically, Warner states “The Perioperative Surgical Home is proposed as a demonstration project to evaluate whether anesthesiologists supported by Medicare, Medicaid and private health plans will be able to achieve the following goals:”

- “Reduce unjustified variation in utilization and expenditures.
- Improve the safety, effectiveness, timeliness and efficiency of health care.
- Increase the ability of beneficiaries to participate in decisions concerning their care.
- Provide delivery of care that is consistent with evidence-based guidelines in historically underserved areas.
- Decrease unjustified variation in utilization and expenditures under the Medicare program.”

“If anesthesiologists’ efforts reduce length of stays, numbers of transfusions and the complications that accompany them, and improve patient satisfaction and safety, it is logical that the medical center and facility administrators will find value in this extension of anesthesia practice”. For example, anesthesiologists understand and are in a position to manage the factors underlying surgical site infections (SSIs), a complication estimated by Edmiston et al to be responsible for more than 1.6 billion dollars in cost, and 3.7 million extra hospital days [52]. As Mauermann and Nemergut point out, factors influencing SSIs and under the control of the anesthesiologist include the maintenance of body temperature [53], the amount and timing of antibiotics, the FiO₂ (greater than 80%) [54], intravenous fluid administration, decisions regarding blood transfusions, and prevention of hyperglycemia [55]. Additional long term outcomes in the anesthesiologist’s purview include cognitive effects of

inhaled anesthetics in infants and small children [56], and the effects or lack of effects of inhaled vs regional anesthesia on cancer recurrence [57, 58].

An extended role for the anesthesiologist as envisioned by The Perioperative Surgical Home has counterparts in other countries. In France for example, anesthesiologists have via SAMU (Service d’Aide Médicale Urgente), assumed control of all emergency out of hospital care. In the 1970s, anesthesiologists Cara, Huguenard, Lareng and Serre, developed SAMU, reasoning that “in emergencies the hospital should go to the patient and not the contrary.” Doctors (anesthesiologists) “dispatch and control the emergency response teams and unlike many emergency medical services, SAMU is an extension of the hospital service itself.” And in 2006 “The development of SAMU demonstrates the widening borders of anesthesiology, a specialty only relatively recently recognised in France. In 2006, the SAMU received 15 million calls” (Chapter 27).

But is the Perioperative Surgical Home preempted by today’s Hospitalist? The arguments for The Perioperative Surgical Home seem cogent and compelling, but may compete with the present implementation and control of patient’s hospital care by Hospitalists. Hospitalists, a growing arm of medicine, already govern the care of patients entering hospitals, facilitating patient care from entry to departure. Can and will anesthesiologists compete with this group?

Kapur in her 2011 Rovenstine lecture addresses this question this by listing qualifications needed by anesthesiologists to assert the dominant role envisioned by Warner [59].

1. “Determine quality benchmarks and equal or exceed them”.
2. “Oversee and solve perioperative, periprocedural, intensive care, and pain issues throughout the health system, utilizing a cost-effective mix of providers appropriate for the severity of the cases”.
3. “Facilitate procedural through-put at all levels, including critical care”.
4. “Become integral to the management of all areas where acute care and pain services are being delivered”.
5. “Become the acute care go-to people, the acute care solution, for each of our clinical sites”.

Further, Kapur comments that as “Miller and Hannenber stated in 2005 [60], None of the existing medical specialties is fully equipped to provide comprehensive care in all of these areas, but anesthesiology is a strong contender for the best qualified”. We regret that we will not be part of this evolving role for this specialty but look forward as observers to the fulfillment of the exciting possibilities described above.

Regarding the anesthesiologist’s role as a perioperative physician, Merlin Larson commented that “the perioperative period is the ideal time to counsel patients about bad habits such as smoking and over-eating. The perioperative

²As Taken from a report [310-3.2] submitted to the ASA House of Delegates on Aug. 21, 2011, by then ASA President Mark Warner, M.D., entitled “Surgical Home Draft Proposal.”

period initiates a major disruption in patient's lives and it provides the ideal time for them to change how they live. We should take full advantage of this time—and use our special skills to help them recover with elation instead of depression. If we don't as a specialty look closely at how to help patients during this stressful period in their lives, then we will always be turning around to see if someone (such as a CRNA) is catching us". (Personal communication October 10, 2012).

Accordingly and in furtherance of the objectives of the Surgical Home is the recently announced program instituted at Monash University in Melbourne Australia and providing a Masters Degree in Perioperative Medicine (<http://masters.periopmedicine.org.au/>). As stated in the program description

"Surgical patients are getting older and sicker. Many clinicians caring for surgical patients are challenged by the growing complexity of these patients, particularly their perioperative management. Pre-admission clinics are responding, and perioperative medicine is becoming an emerging field. This course will be conducted by Monash University (Academic Board of Anaesthesia and Perioperative Medicine and Department of Epidemiology and Preventative Medicine), in conjunction with the Alfred Hospital's Department of Anaesthesia and Perioperative Medicine (Director Prof Paul Myles).

Key objectives of the perioperative medicine component are:

1. Provide clinicians with information to care for the growing complexity of surgical patients.
2. Provide a greater understanding of the importance and functioning of the pre-admission clinic.
3. Equip the perioperative physician to risk stratify and optimize care of the patient in the perioperative period.
4. Collaboratively manage the patient in the perioperative period, in particular the perioperative management of patients with acute medical, cardiac, and other organ dysfunction.
5. Equip the perioperative physician with the managerial skills to lead a multidisciplinary perioperative management team.
6. Equip the perioperative physician with basic research skills to further perioperative medicine research."

These objectives mirror the qualifications outlined by Kapur in her 2011 Rovenstine lecture [59], suggesting that worldwide support for this concept may be building.

Some Reflections

Over the previous 60 years (and more), the quality of personnel needed to deliver anesthesia, and their skills, tools, and medications have vastly improved. So has anesthesiology's position in the medical hierarchy. We increasingly occupy senior positions in our medical schools, hospitals, and medical societies and participate at all levels in national and international initiatives reforming medical care and extending this miracle of anesthesia to less developed areas of the world. Worldwide, anesthesia continues to grow. The numbers of anesthesiologists increase, and surprisingly, there seems to be no decrease in the rate of addition of anes-

Fig. 13.4 Fifteen more anesthesia societies arose between 2000 and 2010, there seeming to be no decrease from the rates of addition in previous decades

thetia societies (Fig. 13.4). Is further advancement needed; shall we declare victory and go home; or should we seek new challenges?

And what might those challenges be? Here's one. Although we might think we know how anesthetic agents produce unconsciousness, we have but a vague idea of the mechanisms underlying injected drugs and a still vaguer notion of how inhaled anesthetics act to produce unconsciousness, unawareness, and immobility. Why pursue that challenge? Because it might tell us how the brain works.

Lawrence J. Saidman, Rod N. Westhorpe and Edmond I Eger II

“The future ain’t what it used to be.”—Yogi Berra, famous American baseball player and manager

We asked each editor-in-chief of 16 anesthesia journals to supply a 500-word (or less) essay predicting their respective vision of local or worldwide anesthesia in 2023. Each was asked to ignore the great risk of being wrong. They were enjoined not to use “may be” or “might be” but to make definitive statements (“will be”). Some took this to heart and made grand, adventuresome predictions while others were more cautious. The reader will have to judge the likelihood of each being correct. In 10 years we all will know for sure... maybe.

Allan Basbaum, PhD, Editor-in-Chief, *Pain*

Plus ça change, plus ça reste. In 2023, NSAIDs will remain the treatment of choice for pain associated with tissue injury and inflammation. Despite the generally unavoidable side effects of morphine and other opioids, I also predict that they will still be the drugs of choice to treat the most severe pain, particularly the most intractable pain (e.g. in cancer). For the near future, gabapentoids will remain the first line approach for neuropathic pain, despite the accepted mantra that the efficacy is roughly 30% relief of pain in 30% of patients. However, given the focus of basic and clinical research on neuropathic pain, I expect that new entities will appear and replace gabapentoids by 2023.

Paralleling the continued use of NSAIDs, is the likely introduction of antibodies directed against nerve growth factor (NGF), which in clinical trials proved remarkably effective against osteoarthritis. I expect that before 2023, these antibodies, or some variation, will overcome the serious limitations that arose during their development, namely deleterious effects on non-target joints. I do not expect that these antibodies will be routinely used for pain induced by tissue injury, including post-operative pain, but they will be introduced and be effective for severe arthritic conditions—possibly even for back pain. Most importantly, studies of anti-NGF provided what I consider the most convincing evidence that animal models used to study clinical pain conditions are predictive of the clinical condition. Unfortunately, many large pharmaceutical companies doubted the utility of animal models and accordingly decreased their discovery efforts. That decision will slow the development of new entities, which of course will contribute to the continued use of existing analgesic therapies.

Crystal balls are hard to come by, so predictions must also be based on the many new targets that molecular and genetic analyses revealed in recent years. Unfortunately, despite the discovery of numerous molecules that predominate and, in some cases, reside exclusively in nociceptors, I am not optimistic about the development of effective antagonists against these highly localized channels/receptors. The problem is that blockade of a single entity will not effectively silence the nociceptor, which is required to produce generalized pain control. My skepticism is not because of lack of efficacy or selectivity of the antagonists, but rather because of the heterogeneity of the nociceptor channels that underlie the generation of pain. Thus, I believe that a more generalized blockade of “pain” transmission is required, which is precisely what occurs with existing agents, notably those acting at sodium or calcium channels. For the same reason, I expect that a drug targeting the NaV1.7 subtype of voltage gated sodium channels will be in use by 2023. Whether it will be targeted with a small molecule or a virus carrying an

siRNA that knocks down NaV1.7 messages is not known, but development of a successful drug is likely.

Mario J. Da Conceicao, MD, MSc, PhD, Editor-in-Chief, *Brazilian Journal of Anesthesiology*

Anesthesiologists have increasingly moved beyond the operating room to a more diversified role in the perioperative care of surgical patients. They play central roles in delivering analgesia, and lead acute pain control teams; they deliver and provide guidelines for sedation services for diagnostic and therapeutic procedures outside the operating room, and at times outside the hospital as part of home care services. They have assumed roles in hospital administration and critical care services. These activities will expand in the next decade.

Molecular biology has increased our understanding of the mechanism of action of anesthetic drugs, particularly facilitating investigations of the role of receptor subunits in anesthetic end points. GABA_A, glycine, NMDA, and acetylcholine receptors are likely targets for various anesthetic prototypes. The creation of animals lacking particular receptor subunits (“knockouts”) or possessing subunits that act normally except for their response to anesthetics (“knock-ins”) will find increasing use in studies of anesthetic actions.

There may be advances in treatment of local anesthetic overdose with lipid or hypertonic saline solutions, but other than this we are unlikely to see many advances in anesthetic drugs or devices. Drug and device development requires enormous investments, with few new products reaching the market in a process that can take as long as 20 years—other markets are more attractive than the anesthesiology market.

Important *in vitro* pharmacological effects require confirmation *in vivo*. And important *in vivo* findings in animals must be confirmed in humans. One important question that requires an answer is: “Are anesthetics dangerous to developing brains?” They seem to be in rodents. Is *in vitro* apoptosis a danger in animals and more importantly in humans? This issue will be resolved in the next decade by epidemiological outcome studies. I predict that the findings will indicate minimal danger to humans.

Thousands of papers are now submitted to dozens of journals dedicated to anesthesia. I do not foresee a decrease.

Finally, unlike many South American countries, Brazil prohibits delivery of anesthesia by non-physicians. However, economic and supply issues preclude continuation of this practice. Reimbursement of anesthesiologists by insurance companies and salaries of public health care providers are under increasing pressure, decreasing the attractiveness of a career in anesthesia and thus the number of anesthesiologists. Consequently, non-physician-delivered anesthesia will arise in the next decade in Brazil. This will be a still greater

problem in other South American countries, especially those lacking training programs.

James Eisenach, MD, PhD; Editor-in-Chief, *Anesthesiology*

My guess is that anesthesia research in 2023 will continue the existing model of a relatively small number of investigators, either singly or in small, local groups, examining highly focused physiologic/ pharmacologic questions. This model will incrementally increase our knowledge and care of patients, particularly with technology-focused research, such as implantable devices, portable imaging approaches to procedures, and targeted drug delivery. A dearth of commercial interest in developing better drugs for anesthesia might be countered by academic development, exemplified by recent work on etomidate derivatives. I predict that in 10 years we will only rarely apply genetic testing clinically, confining it to a few highly specific circumstances.

We will see the universal application of electronic medical records and the development of large clinical registries and databases. Whether these will revolutionize our practice is unclear but complications (unexpected difficult airway management, malignant hyperthermia, position related injury) from prior anesthetics and surgeries will be more easily and uniformly made known. We will have greater confidence in the prevalence and antecedents of both common and rare clinical problems, and the findings from these approaches will generate more hypotheses than they will test. Disparities across hospitals and practice systems will trigger interventions, oftentimes with arguably weak scientific evidence.

On a positive note, I am encouraged by the number of anesthesiologists around the globe who partner with others in and outside the specialty to organize large, multi-center observational and interventional clinical trials. We arrived to this approach late compared with our medical colleagues. Major problems in perioperative morbidity and mortality, problems arising nearly exclusively outside the operating room, can best be approached using methods that collect information on large populations, and we will increasingly apply such methods.

In summary, we have a modest chance of advancing technology and, perhaps, pharmacology in anesthesiology over the next 10 years. By 2023 we will have recognized that perioperative and acute critical care periods remain dangerous. We will replace an emphasis on the cult of safety regarding rare morbid events from anesthesia delivery in the operating room, with a focus on more frequent major perioperative problems. We will be guided by results from multi-center, large clinical trials that use electronic, registry, and database findings in a responsible and scientific manner to address

problems like perioperative myocardial infarction, stroke, and renal impairment, as well as postoperative cognitive dysfunction and chronic pain.

Neville M. Gibbs, MBBS, MD, FANZCA, Chief Editor, *Anaesthesia and Intensive Care*

In 10 years, anaesthesiologists will scan their patient's identification number and procedure code into their hand held computer or phone, and obtain a list of anaesthesia risks specific to the patient. Risks considered will include the likelihood of anaphylaxis, awareness, post-operative cognitive dysfunction, tumour recurrence, thrombosis (and other cardiovascular events), pain, and postoperative nausea and vomiting. Links to evidence-based data will support each item. Advice on risks and their management will consider the patient's physiological, biochemical, pharmacological and pathological data, including genomic information, all accessed wirelessly from linked databases. These data will inform the options, also delivered wirelessly, for optimal anaesthetic management, including the best options for prevention of untoward effects. Other links will offer instruction on specific aspects of anaesthesia care, including vascular access, airway maintenance, and regional blocks. A phone-based video camera may be used to obtain advice from a colleague or supervisor at a different site, and to record procedures into the medical record. Algorithms that consider intraoperative data will automatically collect such data, apply trend analysis, take into account pre-operative patient data, and will supply early warning of potential complications.

Anaesthesiologists will routinely use their ultrasound imaging equipment and skills to guide vascular access, perform nerve blocks, assess the patient's airway, and confirm airway device position. Transthoracic echocardiography using portable or hand held devices will be used routinely for real-time simple and complex hemodynamic assessments.

The role of the anaesthesiologist will not change significantly, but the procedures requiring anaesthesia services will continue the current trend to less invasive procedures performed more often outside the traditional operating room. Subspecialisation will become essential to ensure adequate training and maintenance of skills, and to meet expectations in relation to accreditation, expertise, and safety. This will prompt the development of novel methods for competency assurance and assessment, with greater emphasis on both simulation and multi-rater feedback.

Anaesthetic research will emphasize risk stratification, pre-operative optimisation and postoperative care. Research into risk stratification will include the identification of biomarkers or genotypic predictors of adverse outcomes (e.g. postoperative cognitive dysfunction, major cardiovascular

events) to better inform patients, and to prompt consideration of lower risk alternatives where necessary. There will be a focus on decreasing human error to improve safety rather than on a search for safer agents. Pharmacological research will develop shorter acting drugs, drugs offering novel reversal mechanisms (e.g. cyclodextrins), and drugs that minimise adverse responses to tissue injury (e.g. inactivation of mediators by monoclonal antibodies).

Accessibility to safe anaesthesia will increase in less developed countries and remote areas through: collaborative education programmes that increase the skills and numbers of physicians and non-physicians providing anaesthesia in these areas, sponsorship of essential monitors and equipment (e.g. pulse oximetry, and purpose built simple/inexpensive/portable anaesthesia machines) and greater use of telemedicine for teaching and advice regarding individual patients.

Overall, changes will be related more to rapid advances in technology and better application of knowledge than to paradigm shifts in basic science concepts...but paradigm shifts are inherently unpredictable.

Ghassan E. Kanazi, MD, Editor-in-Chief, *Middle East Journal of Anesthesiology*

In the next decade, anesthesiologists will assume greater roles in the preoperative evaluation and perioperative management of surgical patients. Preoperatively, they will work to improve the ability of patients to withstand the impact of surgery and improve surgical outcome, often doing so without the aid of consultants—the anesthesiologist becoming the “medical” consultant. Technological advances will allow anesthesiologists to monitor intraoperative care from a distance. Nurse anesthetists who will provide bedside monitoring and immediate intervention will replace anesthesiologists in the operating room. Postoperatively, anesthesiologists will be charged with the responsibility for pain management. Improvements in anesthetic-surgical outcomes will be accomplished by application of outcomes-based research led by anesthesiologists.

There will be quantum leaps in monitoring. Blue tooth technology will supplant hard wiring and tangled monitoring wires. Non-invasive monitoring will largely replace the need for percutaneous catheters for arterial and central venous blood pressure measurements. Non-invasive monitors will also routinely provide measurement of tissue perfusion, and oxygen delivery and extraction during anesthesia.

Closed loop systems that monitor and titrate anesthetic and adjuvant drug delivery (as anesthetic depth and hemodynamic requirements prescribe) will displace human control. Such increased automation will ultimately (perhaps in 2 decades rather than 1) eliminate the need for the presence of either an anesthesiologist or nurse in the operating room.

The anesthesiologist will provide supervision and intervene to manage critical incidents.

Debate will continue concerning the use of inhalational versus intravenous agents as the mainstay for maintenance of anesthesia. Need will prompt the development of safer and better inhalational agents (e.g., one that does not produce postoperative agitation or laryngospasm on induction of anesthesia) and/or intravenous agents. I think that both will continue to be used. Evaluating depth of anesthesia will be seen to potentially influence morbidity and mortality. Accordingly we will develop monitors that will enable titration of anesthetics to minimize overdose, improve emergence and decrease cost, as noted above, using such monitors in closed loop systems.

The role of anesthesiologists will continue to expand outside the Operating Room especially for moderate and deep sedation for office-based procedures, endoscopies, magnetic resonance imaging procedures and more. There may be an expansion in the role of hypnosis as a technique that anesthesiologists will use as a less expensive and safer alternative to pharmacological sedation.

Anesthesiologists will increasingly resume the postoperative care of critically ill patients and will have a large role in Critical Care Medicine. The anesthesiologist is the most suitable person for the application of pharmacological advancements for the treatment of chronic pain and palliative care and will continue to be involved in Pain Medicine and palliative care.

Ailun Luo, MD, Editor-in-Chief, *Chinese Journal of Anesthesiology* (with Professors Qinchen Jin, Jing Zhao, and Zhonghuang Xu)

In 2011, the Chinese Society of Anesthesiology promulgated 5 goals: 1) assure patient safety; 2) develop “healthcare with comfort”; 3) improve hospital efficiency; 4) coordinate relationships among different departments; and 5) achieve community awareness of the importance of anesthesiology. Directly and indirectly, these goals will dictate developments in the next decade.

In the twentieth century, large differences between rural and urban economies produced an uneven distribution of medical development, and in much of China, anesthesia did not catch up with the rest of the world until the twenty-first century. Although acupuncture and traditional Chinese medicine are still applied in China, most anesthetic theories, techniques and drugs are now the same as those found in western countries. Remaining differences are predicted to decrease.

In ten years, Chinese anesthesiologists will increasingly act as perioperative physicians with active roles in ICU and pain management. In addition to caring for patients undergoing surgery, they will support more patients outside of the

operating room undergoing cardiac catheterization, endoscopy, interventional radiology, and arrhythmia surgery. Improvement in the Chinese economy, and an accompanying increase in the number of anesthesiologists will promote healthcare with comfort (e.g., painless upper endoscopy under general anesthesia.)

Over the past 30 years, an imposed family planning has decreased the birth rate and increased the percentage of patients older than 60 from 10.3% in 2000 to 13.3% in 2010 with further increases predicted. In ten years surgical (e.g., transplantation) and anesthetic (e.g., ultrasound guidance for nerve blocks and TEE) techniques widely available in the West will be commonly adopted in China. Similarly, newer anesthetic techniques (e.g., general anesthesia combined with regional anesthesia, the latter also used for postoperative pain control), short-acting drugs producing rapid onset and relative hemodynamic stability (e.g., sufentanil and rocuronium), and other drugs recently introduced in the West (e.g., levobupivacaine, parecoxib sodium, and new analgesics) will become widely available.

In ten years, we will widely use fiberoptic and similar techniques in airway management. Reliable noninvasive or minor invasive techniques will increasingly replace invasive techniques. Anesthesia will increasingly adopt TIVA, prompting improved monitoring of anesthesia depth, leading to closed-loop (auto-control) delivery of anesthesia.

Presently, anesthesiologists in major cities such as Beijing and Shanghai provide modern anesthetic delivery, but differences in delivery in other regions can be huge. Establishment of standard requirements for anesthesia monitoring will minimize regional differences and will lead to the use of automatic anesthesia data input systems and related databases.

China’s huge population and increasing amounts of surgery have caused shortages of allogenic blood despite increasing donation of blood. Within ten years indications for transfusion will be stricter, component transfusion will be broadly applied, and new plasma substitutes will be developed and used. Prevention of blood-borne transmitted diseases will receive extensive attention because of an increasing incidence of hepatitis C and AIDS.

In summary, China’s current level of medicine, including anesthesiology, has unevenly approached that in advanced countries. The remaining differences are expected to narrow or disappear in ten years.

Donald R Miller, MD, FRCPC, Editor-in-Chief, *Canadian Journal of Anesthesia*

Globalization notwithstanding, in 2023, large inter-country and inter-continental variations will persist within anesthesiology. One example of variations that will continue is

differences in the scope of practice of anesthesiologists as perioperative physicians. Increasing funding constraints and accountability within publicly funded systems will profoundly impact clinical practice. A 6–7% annual increase in health care expenditures in Canada, or elsewhere, cannot be sustained. An increasing burden of illness in aging, obese, or more medically compromised patients undergoing increasingly complex (and expensive) operations must be served. One result will be less taxpayer funding and increased privatization with proportionately more anesthesia services provided outside publicly funded hospitals. Although some will bemoan a loss in autonomy in elements of clinical decision-making, perioperative decisions will be governed by funding constraints, increasingly stringent guidelines and/or evidence-based clinical care maps supported by pharmacoeconomic data, optimization of human resources, and shortest possible hospital length of stay. Routine pharmacogenetic testing will support evidence-based guidelines for drug dosage, improving therapeutic efficacy and enhancing patient safety.

To enhance operating room efficiency, anesthesiologists will increase their roles as operating room managers. Parallel processing will be increased to maximize OR efficiency. Examples include induction of anesthesia while surgical trays are being prepared, and use of centralized induction and block rooms to minimize case turnover time. Anesthesiologists will continue to deliver anesthesia services as a medical act, with increasing support by anesthesia assistants. Technological advances and cost constraints will prompt hospitals to become “critical care and emergency towers” offering short (ambulatory) stays for 85% of patients undergoing major elective and emergency cases requiring delivery of complex anesthesia care. Electronic anesthetic/medical records will become ubiquitous, having established their value for critical incident review and quality assurance. Technology and data processing advances will produce wireless, smart and compact monitoring systems and iPad-like devices and will provide online algorithms for patient management.

Team-based, interdisciplinary research will replace the individual researcher in most academic health science centres. Such research will produce new intravenous, and/or local anesthetics with higher therapeutic ratios (LD50/ED50) and fewer side effects than existing drugs provide. Results of studies of anesthetic mechanisms will facilitate development of drugs imposing minimal postoperative respiratory depression and postoperative neurocognitive dysfunction. New insights into neuronal network behaviour will result in an improved monitor of anesthetic depth.

Despite the many challenges, the future of the specialty is bright, albeit qualitatively and quantitatively changed. By 2023, anesthesiology will emerge from relative under-supply. High ranking medical students who routinely extend their training through fellowships, and postgraduate degrees in education and clinical epidemiology will continue

to apply to this competitive specialty. The scope of clinical practice will continue to expand beyond the operating room and intensive care unit, for example, by provision of home care services for chronic pain, regional blocks and infusion therapy. Medical simulation will be integrated into anesthesia education, certification and re-certification. By 2023, hard copy publications of anesthesia journals and textbooks will have disappeared, and participants at scientific congresses will view presentations in the comfort of their home or office.

**Joseph M. Neal, MD, Editor-in-Chief,
Regional Anesthesia and Pain Medicine
(with James P. Rathmell, Associate Editor-
in-Chief for Pain Medicine)**

Although anesthesiologists and pain medicine specialists both treat pain and use regional anesthetic techniques, within a decade anesthesiologists will assume sole responsibility for managing acute postoperative pain, while pain medicine specialists will focus on the care of patients with chronic and cancer pain. Rather than continuing as a subspecialty of parent disciplines (including anesthesiology, physical medicine, neurology, psychiatry), pain medicine will become an independent specialty in the US, as it has in many parts of the world.

Indications for thoracic epidural analgesia will decrease as advances in minimally-invasive surgery, multimodal analgesia, and receptor-specific opioid antagonists negate its traditional benefits, and potent irreversible anticoagulants limit its applicability. Peripheral regional techniques will replace neuraxial approaches, and development of sustained release, sensory neuron-specific local analgesics, will allow single-injection to replace continuous techniques. The “ultrasound revolution” will evolve to 3-dimensional ultrasonography with exquisite image resolution. Both anesthesiologists and pain medicine specialists will use new imaging modalities such as light impedance to accurately identify vascular and neural structures, and both will use new radiologic guidance-systems.

Minimally invasive methods will be developed to treat many painful disorders now requiring open operative intervention. The first to appear will be those to treat chronic spinal pain. Targeted biologic therapies will attain common usage, including monoclonal antibodies directed against specific inflammatory mediators that sustain pain, and specific growth factors and ion-channel inhibitors that directly influence the establishment and maintenance of neuronal plasticity that leads to persistent pain. These treatments will require precisely placed drug or devices accurately deployed percutaneously to get therapeutic agents to their site of action in high concentrations. Several future biologics (e.g., monoclonal antibodies against tumor necrosis factor alpha) will

work poorly when given systemically, but will be effective when placed next to their target (e.g., a nerve root inflamed from disc herniation). Similarly, accurate device deployment will increase the likelihood of effective therapy. The roots of pain medicine specialists in anesthesiology and their expertise in image-guided intervention place them ideally to lead the application of these minimally invasive techniques.

Intense pressure to control increasing healthcare costs will profoundly impact both regional anesthesia and pain medicine. We will use approaches that decrease hospitalization and accelerate recovery. A present case in point: we combine numerous modalities (we decrease the amount of local anesthetic; add a long-acting opioid; arrange for early involvement of physical therapy, and ensure assistance at home on day two) to decrease recovery time after total joint arthroplasty from 4 days to 2 days. In 2023, the disciplines of regional anesthesia and pain medicine will supply more effective care at a lower cost.

Benoît Plaud, MD, PhD, Editor-in-Chief, *Annales Françaises d'Anesthésie et de Réanimation*

Imagination... is the preview of life's coming attractions—
Albert Einstein

When I began my anesthesia residency in the 1980s, my mentors suggested that the greatest challenge confronting the specialty was to decrease anesthesia-related mortality and severe morbidity, particularly permanent brain damage. They succeeded in this enterprise in France, and so did anesthesiologists worldwide. With an associated mortality of approximately 1:200,000, anesthesia is one of medicine's safer endeavors. To further improve upon this by 2023 will require control of human factors by methods similar to those applied in commercial aviation. Because of its direct influence on outcome, the anesthesia team rather than a new drug or new device will be of primary importance. By 2023, we will have improved perioperative health status and life expectancy simply by applying protocols defined by evidence-based safety rules. Further, we will have decreased surgical mortality by increasing cooperation between treating physicians, using multifaceted medical team training, simulation, ongoing coaching, and checklists to trigger operating room briefings and debriefings.

As with the rest of the population, aging of the medical population will decrease the numbers of physician and nurse anesthetists who in turn will care for a greater number of older patients requiring more complex care. Cost controls will be accomplished by anesthesiologists who will delegate care of less difficult cases to yet better trained non-physicians under the supervision of anesthesiologists. With a proper evolution of the roles of anesthesiologists and nurse anesthetists, this will not decrease the attractiveness of our specialty.

Anesthesiologists have contributed to the safety of the perioperative process through better pre-operative evaluation, and better delivery of anesthesia and postoperative care. We will not have new anesthetic drugs or adjuvants in 2023. The key to improving outcome will be to apply evidence-based guidelines to current drugs and monitoring.

Although research is the cornerstone of the specialty, research in anesthesia will decrease because of governmental fiscal constraints. However, by 2023 we will have an understanding of the genetic basis for inter-patient variability that will provide improved outcomes... via tailoring individual medical strategies... to specific patient genotypes. These strategies will apply to the entire anesthesia process, including preoperative evaluation, anesthetic management, and postoperative care.

Lars Rasmussen, MD, PhD, Editor-in-Chief, *Acta Anaesthesiologica Scandinavica*

Anesthesia will adapt to surgical advances and changing patient characteristics. By 2023, a greater proportion of procedures will be performed endoscopically, percutaneously, or via small surgical incisions. These less invasive techniques may be implemented in combination with robotic surgery, leading to less tissue trauma, less fluid shifts, and minimal blood loss. The result will decrease the need for fluid administration, postoperative opioids, and extensive monitoring. Infiltration anesthesia and light sedation will suffice for many procedures, reducing the need for general anesthesia.

In 10 years, patients having elective surgery will rarely stay in hospital overnight afterwards. Non-opioid analgesia will suffice for many patients, reducing opioid related postoperative complications. Preoperative identification of high pain responders will be identified by genetic profiling. They will be offered regional anesthesia for pain relief.

Titration of anesthetic drugs will be facilitated by improved monitoring of brain function, by rapid spontaneous degradation of injected drugs, by specific reversal agents, or by the rapid pulmonary elimination of poorly soluble inhaled anesthetics.

The proportion of elderly surgical patients will increase, and they will actively contribute to decisions about their anesthesia management. Because of their greater knowledge of medical care and of their own health status and medications, they will expect to choose the type of anesthesia such as general versus regional technique, and elements of their postoperative care. Fewer older patients will retire from work, and most will expect to resume usual activities—including a return to work—soon after surgery. The decreased impact of surgery and anesthesia on their general physical status, and a shortened recovery period, will facilitate the fulfilling of this expectation. This will demand that anesthetists adopt

regimens that allow early mobilization and discharge. Invasive anesthetic techniques, such as neuraxial blocks and peripheral nerve blocks that produce motor block and urinary retention, will be disadvantageous in this respect.

The mismatch between demand for anesthesia services and provider capacity will necessitate more widespread implementation of nurse anesthetists or anesthetic assistants. This will enable anesthesiologists to focus on the challenging cases but it will also require good communication skills and team management capability.

Charles Reilly, MB ChB (Glasgow), MD (Glasgow), FRCA, Editor-in-Chief, *British Journal of Anaesthesia*

Projecting what may change in anaesthesia by 2023 might begin with a reflection on the changes I have seen in my years as an anaesthetist, appreciating that this carries the temptation to think that the big developments have already happened. Maybe they have. By the 1980s we had in practice nearly all the agents we use currently, and in the 1980s and 1990s we added major developments in monitoring. Current trainees find it hard to believe that in 1990, automated non-invasive blood pressure measurement was not customary, pulse oximetry was a new experimental monitor, and transoesophageal echocardiography was far from routine.

I do not foresee further developments in general anaesthesia drugs. However, an increased understanding of the cellular and molecular mechanisms of pain and of the inflammatory process will lead to the invention and introduction of specifically targeted analgesic agents and agents for the treatment of sepsis.

By 2023, we will devise a reliable, universally accepted monitor of depth of anaesthesia. While the manufacturers of the BIS and entropy instruments should be applauded for their efforts, their devices have considerable limitations, are unevenly accepted and used, and compare poorly with the example of pulse oximetry which in a few years went from development to acceptance as a minimum standard. Results with new depth monitors will provide real-time values that closely correlate with gold-standard measures of anaesthetic depth. They will find particular application when end-tidal analysis cannot be used to certify adequacy of anaesthesia.

At present, we might predict that the perioperative complication rate and mortality for a *group* of patients undergoing surgical procedure X is Y% and Z%. In 2023, preoperative assessment of the cardiovascular and respiratory systems will enable the anaesthetist to say with accuracy that this *individual* patient has a 1 in A risk of specific complication B. This process follows closely from our current interests in preoperative optimisation, fast-tracking and multimodal analgesia. In 10 years' time we will increasingly play

the role of a perioperative physician who co-ordinates the preoperative preparation, intra-operative care and postoperative management for each patient.

Making predictions is a risky business, with a greater chance of getting it wrong than appearing prescient. Perhaps the most certainly correct prediction is that the now large gap between anaesthesia provision in developed and underdeveloped countries will widen. This will include differences in availability of trained personnel, choice of drugs, and type of equipment. I hope that the anaesthetic community will respond to these disparities with the ingenuity and intelligence that it has shown in meeting challenges in preceding decades.

Professor Dr. Rolf Rossaint and Professor Dr. Bernhard Zwißler, Co-Editors-in-Chief, *Der Anaesthetist*

By 2023, the present focus of German anesthesiologists on anesthesia, intensive care, out-of-hospital physician based emergency systems, and pain management will be expanded. For example, anesthesiologists will increasingly assume responsibility for all surgical intensive care patients. Moreover, the anesthesiologist will direct the immediate perioperative phase of patient treatment. Increasingly, anesthesiologists will manage Emergency Departments and/or Departments of Palliative Medicine.

Although nearly 900 physicians complete anesthesiology training every year, the additional clinical activities indicated above will lead to a shortage, in part because German law dictates that physicians must provide anesthesia (nurse anesthetists may support but not replace anesthesiologists). The shortage may even be great enough to threaten the existence of some hospitals. Compounding the problem, 70% of medical students are females who will demand and receive new working time options. To overcome this shortage, as is the case today, university anesthesiology departments will continue to aim to be ranked by medical students as the best teaching departments, in part by a continuing investment in and the use of simulators in teaching.

Due to stricter legal requirements and related insurance costs governing clinical studies, anesthesia research in 2023 will emphasize basic investigations, using modern molecular biology techniques in animals or in vitro, often involving topics at boundaries with other disciplines. National or international research foundations will fund this basic research. The resulting papers will be of higher quality than today's papers, and will follow the requirements of specific writing guidelines such as those found in CONSORT (Consolidated Standards of Reporting Trials) and PRISMA (Preferred Reporting Items for Systematic Reviews). In 2023 there will be fewer innovations in devices or drugs, and

those that are developed will be evaluated in hospitals with good infrastructures for performing clinical studies, and will be financed by industry. In 2023, clinical researchers will supplement the fewer, well performed Research Clinical Trials with observational studies and studies using comparative effectiveness research methods. Comparative effectiveness research will allow for a holistic view (i.e., more than just anesthesia) of our patients to reduce morbidity and mortality. Examples are management of anemia with preoperative intravenously administered iron, and improvement of long-term cancer outcome using particular anesthesia techniques.

By 2023, improvement in patient outcomes will result by adopting clinical pathways developed from guidelines that avoid/reduce medical errors. Avoidance of medical errors will require use of computerized checklists reflecting the most important items of the guidelines. Finally, by 2023, there will be centers for telemedicine where specialized physicians (including anesthesiologists) will care for patients with out-of-hospital emergencies or emergencies in smaller ICUs, or will support anesthesiologists in the operating room.

Steve Shafer, MD, Editor-in-Chief, *Anesthesia & Analgesia*

Anesthesia in 2023 in the US will look like anesthesia today. Four factors weigh against the introduction of new drugs and drug delivery systems: small market size, high cost of development, lack of regulatory enthusiasm, and complacency within the anesthesia community because of the high quality of drugs and devices currently available. We will provide general anesthesia with propofol, sevoflurane, fentanyl, succinylcholine, rocuronium, vecuronium, and nitrous oxide, with minor amounts of ketamine, desflurane, remifentanyl, dexmedetomidine, and cisatracurium. However, some “standard” generic injectable drugs will vanish due to the small market and high regulatory burden for such drugs. These factors will also make drug shortages more common. Our European colleagues will continue their transition towards intravenous anesthesia because of the availability of target controlled drug delivery, a technology unavailable in the United States.

We will see minor improvements in monitors of ventilation and oxygenation. Oximetry-based monitoring of total hemoglobin, carboxyhemoglobin, and methemoglobin will become routine, as will plethysmographic monitoring of intravascular volume. Brain function monitoring will not improve, a consequence of our inexplicable opposition to EEG monitoring. Nearly every operating room will be equipped with ultrasound monitors. These will be routinely used for placing peripheral and central venous, arterial, and spinal and epidural catheters. Small, inexpensive TEE devices may become common.

Our practice will be less fun. In years past I challenged residents to induce anesthesia with the smallest possible volume containing intravenous agents. The winner was a 1 ml “dart” holding 0.5 mls (50 mg) of ketamine plus 0.5 mls (25 µg) of sufentanil which was used to draw up 10 mg of vecuronium. I taught residents how to induce anesthesia with isoflurane via mask, and how to titrate ketamine and methadone. Future administrators will be less tolerant of “let’s try this today”. Our employers, our payers, and our patients will expect practice uniformity.

Our research will focus on outcomes driven by public demand for the best healthcare for the least money. Preoperative screening and triage will improve. Less expensive anesthesia providers will care for low risk patients, allowing anesthesiologists to focus on high-risk patients.

Our practice will become increasingly transparent. Anesthesia information management systems and video recorders will capture every drug, dose, and clinical decision. Algorithms will assess our care in real time. Although our vigilance may lapse, the supervisory software in our information management systems will not—and will alert us to deviations in vital signs or clinical practice that presage a problem. Algorithms will identify areas where our skills need to improve.

Information management systems will document our compliance with “best practices”, which will be reviewed by our employers and payers. Practice incentives will be structured to compel us to provide anesthesia in a manner that enforces best practices. We will chafe at the lack of autonomy, but ensuring conformity with standards of care will likely enhance care.

Koh Shingu, MD, Editor-in-Chief, *Journal of Anesthesia*

In the next decade, Japan must confront physician shortages in anesthesia, emergency medicine, pediatrics, and obstetrics, and must face problems of mal-distribution, especially in provincial areas. The revised resident training system initiated in 2004 may compound the problem. Previously, most residents trained in hospitals associated with the universities from which they graduated. In 2003, these represented 72.5% of new residents. In the new matching system, residents may choose any hospital certified by the government for training for 2 years. In 2010, the percent of new residents trained in the university hospitals from which they graduated decreased to 47.2%. They now tend to select residencies in larger cities and in departments imposing less burdensome schedules.

The Japanese government has increased the capacity of medical university faculties to train the greater number of physicians needed to care for an increasingly aged

population. The intake of medical students increased from 7,625 in 2006 to 8,923 in 2011. In 2021, this will raise the number of physicians per 100,000 patients to 260—from 215 today. But will this 21% increase keep pace with demand? I think not. In 2011, 7,000 anesthesiologists will administer about 2,000,000 general anesthetics in Japan. Over the next decade, an aging population will require an increased number of procedures. An increased need for critical care facilities and pain clinics will further raise the need for anesthesiologists. Combined with a low birth rate (i.e., a decreasing support base) an increased financial burden will be imposed upon Japanese society (peaking in 2035), further limiting the ability to pay for more anesthesiologists. Ironically, the resulting increasing burden on anesthesiologists will hinder recruitment of new trainees.

I predict that a financially feasible solution to meeting this impending shortage of anesthesiologists will require introducing nurse anesthetists having competencies similar to those in other countries. The Japanese Society of Anesthesiologists proposes “perioperative nurses” directed by anesthesiologists. These perioperative nurses will enable anesthesiologists to make greater use of their abilities in anesthesia, including research, training, and education, over the coming decade.

**Martin R. Tramèr, MD, DPhil, Editor-in-Chief,
*European Journal of Anaesthesiology***

Three major changes will affect the anesthetic world in the forthcoming decade: a change in patient demographics, a change in surgical techniques, and an increase in out-of-theatre care. These changes will significantly increase workload.

Anesthesiologists will adapt to increasing numbers of older and sicker patients. Such polymorbid high-risk patients taking a multitude of drugs will need care during the entire perioperative period, starting with preoperative risk assessment allowing for rational preparation and triage. Intraoperative care and postoperative rehabilitation will focus on prevention and therapy of the main complications of surgery and anesthesia such as infection, postoperative cognitive dysfunction, and pain including acute and chronic post-surgical neuropathic pain. To reduce perioperative mortality, anesthesiologists will focus on postoperative care. Intermediate care units will be mandatory to achieve that goal.

Surgery will move towards minimal invasive approaches combining multidisciplinary interventions, and the use of high-tech aids, like robots. Thus, surgical interventions will become still more complex and lengthy. Surgeons will increasingly perform surgery from outside the operating theatre, connected wirelessly to a patient. As a consequence, anesthesiologists will work in huge, dark, hybrid theatres, caring for increasingly older and sicker patients requiring increasingly prolonged anesthesia. Communication with

surgeons will become more difficult as they increasingly perform surgery without entering the operating theatre. Anesthesiologists will become theatre managers, key players in controlling this most expensive environment in healthcare. They will facilitate communication between surgeons, will organize smooth transitions between operations, and will ensure perioperative safety.

Anesthesia workload for non-surgical tasks outside the theatre will continue to increase, with obstetricians, radiologists, cardiologists, gastroenterologists and chest physicians as regular customers of anesthesiologists. Patients will expect comfort, safety, and professional care during labor, cerebral aneurysm coiling, colonoscopic polyp resection, catheter-based renal sympathetic denervation for resistant hypertension, and implantation of lung volume reduction coils for the treatment of severe emphysema. The anesthesiologist’s main dilemma will be to match an ever-increasing workload with limited human resources. Workload will increase about 30% during the next 10 years. Not all anesthesiology departments will be able to respond to all exigencies. Intraoperative care of low-risk surgical patients will often be delegated to nurse anesthetists who work under the supervision of anesthesiologists. Non-anesthesiologists will perform out of theatre sedation. Countries that have practiced anesthesia with doctor-nurse anesthesia teams will be better prepared to face this challenge. To ensure safety, anesthesiologists will define standards of care and will teach and supervise non-anesthesiologists and nurse anesthetists.

I believe that pharmacogenetic research and high-tech monitoring will not significantly affect our working environment in the next 10 years—perhaps in 20 years or more, but not in 10. The main challenges by the end of the next decade will be logistic in nature; the anesthesiologist team will have to cope with a changing, challenging working environment and an increasing workload.

**Steve M. Yentis, BSc, MBBS, FRCA, MD, MA,
*Editor-in-Chief, Anaesthesia***

Bah humbug

Many changes I foresee in the UK over the next decade relate to organisational factors, particularly how services are delivered. As I write, a severe financial ‘squeeze’ grips much of the world, and the British Government is currently on a mission of cost-curtailment, from which healthcare and science are anything but immune. Concurrently, the National Health Service (NHS) is embarking on a major and controversial reconfiguration, accompanied by decreased public sector pensions and pay, and increased retirement age. Such gloomy realities influence my predictions.

Service delivery

Over the last decade or two, hospital care in the NHS has moved from a largely consultant-led but trainee-delivered service, to a consultant-delivered service (conflicting with the need to control costs). Anaesthetists have been among those leading this trend. However, continued expansion in consultant numbers is not considered sustainable. Accordingly, a major shortfall in hospital consultant positions will occur within the next decade—one possible outcome being a sub-consultant grade or its semantic equivalent, with (lower) salary to match. Anaesthetists may be especially vulnerable because everyone who isn't an anaesthetist sometimes still views them as technicians not requiring consultant (let alone medical) status. Unlike some countries, the UK has no tradition of anaesthesia provision by non-medical personnel, and the Physicians' Assistants programme, developed over the last decade to solve the predicted shortage of specialists, is unlikely to be sustained. Instead, the merging of NHS services is becoming the preferred option (despite the accompanying and politically unpalatable closure of departments or even hospitals that this brings).

Training

The traditional UK model of apprenticeship, by which consultants closely supervise junior trainees who assume increasing responsibility as they acquire and develop appropriate skills and attitudes, is likely to continue, as is the recent trend towards earlier subspecialisation. Whilst the latter may be cheaper and therefore more 'efficient', it also produces practitioners with a narrower range of experiences (and perhaps capabilities). Restrictions on working hours imposed by the European Working Time Directive exacerbate this trend: trainees do less (which may not be a bad thing) but can do less (which probably is).

Research

The most obvious current trend is a reduction in time, resources, and enthusiasm to pursue the clinically-orientated research that has fuelled our specialty's development. An increasing emphasis on fewer, larger, 'proper' (and very expensive) randomised trials compounds this limitation. Many feel this is short-sighted. Support for the development of new anaesthetic drugs, machines, and devices will continue but will be limited and will be more targeted than in the past (probably an improvement). Fewer UK studies are likely to fill our journals.

The Only Way is Up

I was attracted to anaesthesia because anaesthetists seemed more capable and nicer people than those in other specialties. I see no evidence that this is changing, and am encouraged by the continuous inflow of enthusiastic, clever, conscientious people into our specialty. *Dum spiro spero.*

A Synthesis of Opinions from Editors of Sixteen Anesthesia Journals

Table 14.1 summarizes the points made by 4 or more of the editors-in-chief. The number of editors who made a comment is given in the second column and the percent of those agreeing with the stated item appears in the third column. Thus, four editors thought that research funding for anaesthesia would decrease over the next decade. Twelve editors weighed in on whether new drugs will be made for use by anaesthetists, but only half of these thought they would be made, the other half suggesting that they would not or that at best but a few would be made. The following discussion supplies further detail.

New Drugs, Devices, and Safety

Fifty percent of editors discussing drug development predicted (item 3) a continuation of the 2000s when only one new drug (sugammadex) was introduced, pointing to the huge costs associated with new drug development, the relatively small market for anesthetic drugs, and of greatest importance, the proven efficacy and safety of currently available volatile agents, opioids, hypnotics, and neuromuscular blocking agents.

These medications are safe in trained hands. Future increases in safety will not be achieved by developing new drugs but by improving training, especially training of non-physicians, and by supplementing that training with devices that guide the less-trained individual. A case in point concerns a device (Sedasys System) available in Europe but not the US facilitating the safe administration of propofol for patients undergoing endoscopic and other out-of-operating room procedures. The Sedasys System links a propofol infusion to the pulse oximeter, capnograph, and blood pressure signals, and patient responsiveness.

Some editors would apply the information revolution to enhance safety. The ubiquitous ID band worn by hospital patients will more than just identify the 2023 patient. When scanned, the band will reveal drug allergies and the patient's prior incidence of postoperative cognitive dysfunction, nausea and emesis, deep venous thrombosis, and difficult airway. It will provide risk stratification and suggestions including optimal anesthetic management for each problem.

Table 14.1 Editors' Predictions of Changes over the Next Decade¹

Item	Number with a Comment	Percent Agreeing
1. Research funding will decrease	4	100%
2. Clinical research will focus on outcome trials	4	100%
3. New drugs will be made	12	50%
4. New devices will be made (esp brain function)	9	56%
5. Molecular biology will be used in research	5	100%
6. The perioperative role of the anesthesiologist will increase	7	100%
7. Particularly in pain management	6	100%
8. A shortage of anesthesiologists will exist	8	88%
9. More non-anesthesiologists will deliver anesthesia	7	86%
10. Genetic testing will be used preoperatively	6	67%
11. Non-invasive monitoring will increase	5	100%
12. Checklists will guide clinical care	4	100%
13. Anesthetists will use electronic records	4	100%
14. Differences among countries in the quality of anesthesia will decrease	4	50%

¹ Putting the editors' comments in particular categories sometimes required interpreting what they meant. Thus, the results in Table 14.1 probably should be considered but semi-quantitative. And, of course, the table ignores imaginative comments made by several editors because we only summarized those comments where four (25%) or more editors had addressed a particular issue.

Anesthesia Personnel, Scope of Practice, and the Cost of Care

The editors predict an increased use of less trained individuals (i.e. more non-physicians; item 9) in locations and patients requiring a lower intensity of care. Three factors underlay this prediction: First, the increasing cost of medical care associated with new technology. Second, a demand for greater care by a vulnerable subset of patients such as those found in an aging population having greater co-morbidities. And third, an increasing number of patients in developed as well as less developed countries requiring care. The use of non-physicians to care for less vulnerable patients will allow physicians trained in perioperative medicine to care for those requiring a higher intensity of care such as patients in critical care units, emergency rooms, and pain management centers. Thus, even in countries presently providing anesthesia services using only physicians, acceptance of non-physicians as supervised assistants is predicted to accommodate the increasing need for diverse services such as care in endoscopy and radiology suites, infusion services, home care of patients with implanted regional block catheters, and preoperative assessment clinics.

The anesthesiologist will increasingly take on the role of perioperative care manager (item 6), especially where patients have many or complex co-morbidities.

Research

Some editors predicted fewer investigators pursuing highly focused laboratory based projects, and more globally-united investigators pursuing both observational and interventional large-scale clinical trials (item 2). And rather than concentrating on decreasing the vanishingly small number of

perioperative deaths, these studies will use comparative effectiveness methods to examine the impact of anesthesia and surgery on long-term outcomes including stroke, myocardial infarction, cognitive dysfunction in the elderly patient and small children, metabolic dysfunction, and cancer recurrence. A few editors predicted that we will look to biomarkers or genotypes to control outcome, cautioning, however, that genetic testing in 10 years will be applied in only a few highly specific circumstances (item 10).

Pain Management

Because of their limited efficacy in the treatment of neuropathic pain (efficacy of 30% in 30% of patients), gaba-pentenoids will be replaced by 2023 by a drug yet to be created. NSAIDs will remain the treatment of choice in the treatment of pain associated with tissue injury and inflammation, especially important because increased minimally invasive surgery (robotic and laparoscopic) should lessen the need for opioids. There will be fewer thoracic epidurals (because of concern regarding concomitant use of anti-coagulants) and greater use of multi-modal analgesic techniques. By 2023, targeted biologic therapies against specific inflammatory mediators that sustain pain including monoclonal antibodies directed against nerve growth factor (proven effective against osteoarthritis in clinical trials) will be available. "High pain" responders will be identified and offered regional anesthesia techniques permitting earlier mobilization and discharge. Finally, Pain Medicine as a primary specialty will assume management of patients with chronic painful conditions. Anesthesiologists will represent one of several specialties that compete in this arena. However, anesthesiologists will likely dominate in the arena of acute pain management as follows surgery (item 7).

International Outreach

The editors suggested that the international community would address the uneven availability of medical resources throughout the world. This is presently an intra- and inter-national issue depriving huge populations of even basic anesthesia and surgical care. For example, non-availability of obstetric anesthesia support for high risk pregnancies increases fetal and maternal mortality and morbidity (e.g., urogenital fistulae). And lack of cosmetic surgery for children born with disfiguring congenital abnormalities condemns this cohort to a life of abuse and exclusion. Programs and international organizations providing expert patient care and training of indigenous personnel will greatly increase by 2023. This may be accomplished by the use of non-physician anesthesia providers and telemedicine educational programs. While half of the editors raising this issue thought that such measures would decrease differences among countries in the quality of anesthesia (item 14) half had the opposite view.

Reprise: two views of the future

Given the diversity of their interests and locations, not surprisingly, our editors provide sometimes common, sometimes dissimilar views of the future (Table 14.1). Some opt for a pessimistic (“Bah, humbug”) view of things to come. They foresee less support for research and clinical enterprises with a resulting decrease in the development of new information and new investigators essential to academia. They believe that fewer (if any) new drugs or devices will appear. Shortages of highly-trained professionals and increasing clinical demands (more surgeries in diverse places for sometimes prolonged procedures) will force reliance on less expensive anesthetists with more limited training to give clinical anesthesia to an older, sicker, fatter patient population. To sustain

the safety that modern anesthesia has so carefully cultivated will mandate anesthesia dictated by mind-numbing checklists. Adding insult to injury, departments of anesthesia may be subsumed by larger enterprises, the name “anesthesia” sometimes disappearing and programs directed by someone with no immediate expertise in anesthesia. We will lose, or have now lost, control of areas of medicine we developed (e.g., intensive care medicine; management of chronic pain.) This has already occurred in some parts of the world.

Not so fast says the optimists. The anesthesiologist has and will evolve into the leader of Perioperative Medicine, the physician best equipped by history and training to manage the perioperative care of the surgical patient from admission through procedure (sometimes surgical, sometimes not) and postoperative care in the PACU or ICU and home again. We will continue to control the management of acute pain and with that advantage, compete with other specialties for the management of chronic pain. We already vie for control of intensive care medicine, particularly as it deals with surgical care. Our immediate relationship with our surgical colleagues stands us in good stead there. With superb drugs and devices already at hand, we need but a few new devices (e.g., a 3-D ultrasound device; a more precise depth monitor) and fewer drugs (perhaps ones that guarantee reversal of paralysis or ones that supply anesthesia with neither circulatory depression nor stimulation). Cutting edge bench research employing molecular biology will be applied in a limited number of institutions as has been the case in the past. We will increase safety, but not by adding to what already is a marvelous record for the immediate intra and postoperative period, one that admittedly must make use of those checklists. The gold for increasing safety lies in avoiding problems weeks, months or years after surgery. Thus, clinical research will increasingly shift to multicenter long-term outcomes research. No need to think doom and gloom. Although demanding, the future is bright.

Part II

Individual Stories

William Silen and Elizabeth A. M. Frost

Summary

Long before the advent of anesthesia, operations relied on a detailed knowledge of anatomy gained by dissection of the dead. Morton's demonstration of ether anesthesia on 16 Oct 1846 made planned surgery possible, that is surgery in a silent motionless patient. Thus began the era of the great surgeons of Europe (Billroth, Kocher, Torek) and the US (Sims, Halsted, Cushing). Supporting discoveries added to the advances: Lister used antiseptics with carbolic acid spray (1867); Macewen intubated the trachea (1870s); Roentgen discovered X-rays (1895); Landsteiner identified blood groups (1900) and Domagk synthesized sulfonamides (1932).

For a century, the anesthetic properties and simple methods of delivery of ether, chloroform and nitrous oxide sufficed for most surgical needs. By the 1950s however, surgical advances demanded manipulation of vital functions such as controlled ventilation and deliberate hypotension. Advances such as electrocautery and cardiopulmonary bypass machines required the safe nonflammable anesthetics developed in the 1950s and later. The 1950s and 1960s saw the initiation of immunosuppression making organ transplantation feasible. None of this reflected the myriad expansions of other kinds of operations—orthopedic, gynecologic, urologic, bariatric, orthodontic and more. The perturbations produced by surgery became enormous—and anesthesia had to contribute more. That's another story.

More recently, the demands of surgery changed in ways few had foreseen. Surgeons fearlessly tackled problems in unfit patients—obese, elderly, debilitated, and diseased. Surgeons in the 1980s practiced in new venues, ambulatory care centers or even in their offices, again demanding more of anesthesia—quicker awakening and fewer side effects. Some operations are not done by surgeons—radiologists now intervene in many vital organs, and cardiologists stent coronary arteries. Less invasive operations such as laparoscopic procedures (Muhe performed a laparoscopic cholecystectomy in 1991), and robotic surgery place sometimes less and sometimes just different, demands on anesthesia. Surgery is a brave new world.

Introduction

The reader may wonder at the inclusion of a history of surgery in a book detailing the history of anesthesia, thinking that the story of surgery runs parallel to but is separate from the story of anesthesia. Not so: Surgery existed long before the demonstration of anesthesia with most surgeons doing little to assuage the pain resulting from their work. But surgeons (including dentists) discovered general (Horace Wells and William Morton) and local (Carl Koller) anesthesia. They became the first anesthetists, quickly morphing into directors of anesthesia, usually both performing surgery and controlling the delivery of anesthesia. They developed various aspects of the safe delivery of anesthesia, including air-

way management, and they devised diverse approaches to regional anesthesia. They were the captains of the ship, the leaders of the operative enterprise. Anesthesia initially was a surgical subspecialty or “competence”. Surgeons reluctantly relinquished their direction of anesthesia, only surrendering control more than a century after Morton's demonstration. As surgeons advanced their reach they demanded more of anesthesia, and the resulting advances in anesthesia facilitated the growth of surgery. So did the genius of anesthetists who independently made advances that supported surgery. The resulting complexity of anesthesia made it impossible for surgeon to be both surgeon and anesthetist. And yet, the two specialties always were joined at the hip, part of the same enterprise.

Mythology

Chiron the Centaur, born in Thessaly, celebrated for applying herbs to wounds, is presumed to have been the father of surgery. Aesculapius, the son of Apollo, thought by some

to be Chiron's pupil, and by others his predecessor, may have outdone Chiron. Of course, perhaps neither existed. Apollo, himself the son of almighty Zeus, was the original Greek God of Physic and Healing, but he resigned in favor of his son, Apollo God of the Sun, whose temples became the repository for all medical and surgical knowledge. Even Celsus testified that Aesculapius was the most ancient authority in surgery. Homer's *Iliad* immortalized Podalirius and Machaon, the 2 sons of Aesculapius, as they followed Agamemnon to the Trojan wars and cared for the sick and wounded. Podalirius was reputed to be the first phlebotomist.

Ancient Civilizations

The first surgical operations probably took place in the Mesolithic period (10,000 BCE–5,000 BCE). Skulls with rounded, often multiple defects suggesting trephination have been excavated from graves in all countries of the world except China, Japan, the Malay Peninsula and Australia. Many intact skulls showed evidence of healing, without infection, indicating deliberate surgery [1]. What prompted these interventions? Perhaps it was for epilepsy, headache, a passage into manhood or spiritual or religious reasons. Trephination persisted in primitive civilizations in some form until the early 20th century [2]. How was pain minimized for these operations? Coca leaves were widely used in Peru. Perhaps an early anesthetist was the assistant who chewed the leaves and spat in the wound, a technique used and described for centuries in South America—but the concentration of cocaine in such saliva may have been too small to be effective [3].

Despite its advanced culture and influence, little physical evidence indicates that Babylonians practiced surgery. However, the Code of Hammurabi, perhaps the first law book, defined physician practice, (not unlike what may happen today). Laws 215–223, set out rewards and punishments for surgeons. “If a physician make a large incision with an operating knife and cure it, or if he open a tumor (over the eye) with an operating knife, and saves the eye, he shall receive 10 shekels in money.” This sum decreased to 5 shekels if the patient was the son of a plebian, to 2 shekels if the patient was a slave (fee to be paid by the owner). However, “if a physician make a large incision with the operating knife, and kill him, or open a tumor with the operating knife, and cut out the eye, his hands shall be cut off.” If he killed a slave, then he had to replace him. Broken bones and soft tissue injury repair were to be compensated with 5 shekels [4].

The Edwin Smith papyrus is the earliest written record of surgical practice, and is an incomplete copy of an earlier treatise composed about 3,000 BCE. It describes 48 cases that may have been records from the Egyptian architect-

physician, Imhotep. Fifteen cases concerned head injury, 12 related to facial wounds and fractures, and 7 to vertebral injuries. The remaining 14 cases involved pathology of the thorax. The author described healing of wounds, and advised placing traumatized skin edges together, and using fresh meat for its hemostatic value as the usual dressing for the first day. It might be a stretch to say that this recommendation anticipated the tissue clotting factors discovered in modern times. The author recognized that the injury caused pain and that movement and examination exacerbated the pain. But the physician was advised to “palpate his wound although he shudders exceedingly.... cause him to lift his face; if it is painful for him to open his mouth, his heart beats feebly” (from case 7, a depressed skull fracture.) [5] The author was probably differentiating injuries that could and could not be treated. The feeble pulse and shuddering suggested a fatal wound, and the physician could not make it worse. As the patient with a fatal wound was most likely not responsive, then the response to palpation would help the clinician to decide whether or not the wound was treatable.

Several medical records survive from ancient Egypt (circa 2000–1600 BCE). The Ebers manuscript (University of Leipzig) describes medical recipes and incantations. It also identifies peripheral arterial aneurysms, recommending the following: “treat it with a knife and burn it with a fire so that it bleeds not too much.”

Greeks, Romans and Jews

The Homeric poems, the *Iliad* and the *Odyssey* (800 to 700 BCE) [1] provide the first Greek allusions to surgical subjects. They presented realistic descriptions of battle wounds and attempts to treat them. Between 800 BCE and 700 BCE, “schools” of medicine and associations of philosophers, priest-physicians and practitioners arose throughout Greece. Hippocrates (circa 460–370 BCE) “the father of modern medicine,” born on the Greek island of Cos, worked to disentangle medicine from religious mysticism. He rejected the prevailing thought that credited supernatural and divine forces as the cause of disease, claiming instead that environmental factors, diet and living habits caused illness. Stimulated by Hippocrates, several authors compiled some 72 works, the *Corpus Hippocraticum*. The Hippocratic School (actually two schools, the Knidian and Koan Schools) focused on patient care and prognosis rather than diagnosis. The Koan School believed that an imbalance of the 4 humors (blood, black bile, yellow bile and phlegm) caused illness. These teachings contrasted with those of the Knidian School, which sought diagnoses and specific treatments. Surgical sections from Hippocrates' writings [6] describe the treatment of hemorrhoids, fistulas, wounds, injuries of the head, and fractures, as well as prognosis of various wounds. For example,

“Only wine should be used to moisten the wound unless it is on a joint. Sparse food, and no drink but water, are important for all injuries—and more so with fresh wounds than old, with wounds that have somehow become or risk becoming inflamed, with joint injuries, or when cramps may occur but also with abdominal wounds and most of all, with injuries of the head or thigh bone or any other bone.” [6]

Trephination was recommended for skull fractures, epilepsy, blindness and headache. The practitioner was advised to avoid suture lines and the temporal area for fear of arterial (? middle meningeal artery) damage, which might cause contralateral convulsions. Advice also directed that the inner table of the skull should be preserved to protect the dura.

Cornelius Celsus (25 BCE–CE 50) in his *De Medicina* described the characteristics of inflammation, including redness, swelling, heat and pain (rubor, tumor, calor and dolor) and the use of the ligature to control bleeding [1, 7]. He also wrote of the signs and symptoms of head injuries, noting that fractures of the base of the skull were usually fatal. He recommended incinerated egg yolk as a styptic powder for treatment of meningeal hemorrhage [7].

The famous Roman (but of Greek ethnicity) Galen (CE 129–199) is generally regarded as second only to Hippocrates as a physician [1], and he repeated much of the latter’s teachings. He was an accomplished technical surgeon who served for many years as chief surgeon to the Roman gladiators. Galen carried out detailed anatomical dissections in pigs and apes rather than humans (human dissection was forbidden). His detailed discussion of pathologic swellings and inflammation is probably his greatest contribution. It came close to modern views of such lesions. Galen had a pugnacious personality and presented his views and ideas with a force that convinced many, including the Church and its leaders, of their veracity. Galen treated blindness due to opaqueness of the lens by performing cataract surgery. Perhaps he loosened the opaque lens from its bindings and displaced it into the vitreous rather than extracted the lens. Indeed, it is difficult to see how the lens might be extracted without destroying the eye. However, Galen was far from the perfect physician. He practiced venesection (blood letting or bleeding), perhaps to rebalance the humors, to the detriment of untold numbers of patients. Because of the respect for his authority, blood letting continued for nearly two thousand years. He became wealthy by performing uvulectomies (removal of the uvula in the back of the throat) for chronic cough, an irrational, ineffective—and painful—procedure.

By this time, many surgical instruments were developed. Scalpels were made with blades of steel and handles of bronze. Probes, directors, guards and elevators were known. Tissue and bone forceps, drills (whirled by a thong) chisels and gouges were part of a surgeon’s armamentarium [8].

It is difficult today, to conceive of Galen and other surgeons performing uvulectomies, cataract extractions, cae-

sarean sections, or amputations in unanesthetized patients. What enabled patient tolerance of these procedures—and others? The ancients knew of the hypnotic and analgesic effects of alcohol, herbs, including mandrake, henbane, cannabis and opium, and the saliva from the chewing of coca leaves as mentioned previously. The speed and dexterity of the surgeons must also have played a part. Anecdotal reports suggest that they performed these procedures in 2–3 minutes or less, although it is difficult to imagine that extensive trephinations could have been performed in less than 30 minutes.

Pedanius Dioscorides (40–90 CE), a Greek surgeon in Nero’s army in the 1st century CE, described the use of many herbs. His work, *De Materia Medica*, was the standard pharmacopeia for some 1500 years. He wrote “sleeping potions such as opium or mandragora are applied to such people as shall be cut or cauterized...for they do not apprehend pain because they are overcome with dead sleep...but used too much they make men speechless (i.e., dead).” He described how wine made from mandragora could induce “anesthesia”, an absence of sensation in people about to undergo surgery. The Greeks may also have recognized that pressure on the carotid artery causes loss of consciousness (Karoun, from which carotid is derived, means “to fall into sleep”). Dioscorides’ use of the word “anesthesia”, anticipated Holmes’ recommendation to Morton by almost 1800 years [9].

The Talmud (200–500 CE) describes many surgical procedures undertaken by the ancient Jews including the suture of wounds, reduction of dislocations, amputations, and Caesarian sections [1]. The care of wounds also received attention: “To treat a wound, one applies cotton or lint, and sponge as well as garlic and onion peels which are secured by a thread (Tosefta Shabbat 5:3–4)”. That such advice was *avant garde*, is supported by a recent clinical study demonstrating the benefits of a gel of onion extract on the appearance of post-surgical scars [10]. The Talmud discussed the relief of pain for many conditions. For example: “If one’s loins pain him, he must NOT rub them with wine or vinegar, but he may anoint them with oil, yet not rose oil”.

The Middle Ages

The Middle Ages began with the fall of Rome to the Goths in 476 CE, and continued until the Turks conquered Constantinople in 1453 CE. Widespread ignorance and lack of social progress in the early Middle Ages (476–814 CE), caused it to be named the Dark Ages. The high esteem accorded surgery during Greco-Roman times disappeared during this period.. In the 12th century, the Roman Catholic Church declared that shedding of blood was incompatible with holy office (the Ecclesia abhorret a sanguine edict of 1163), thereby

prohibiting monks (the “educated class”) from performing surgery. The clergy treated surgeons with contempt because they believed that incising or cutting another human body, and touching such wounds with one’s hands was unclean and unholy. Enter the barbers as surgeons. The barbers had shaved the monks and cut their hair according to styles of specific religious orders. They had also assisted the monks in the performance of surgical procedures. The withdrawal of monks from surgery left a vacuum that the barbers filled. They used the training they had received by assisting the monks, and applied it in the performance of operations for hernias, bladder stones (seemingly violating the Hippocratic oath stating, “I will not use the knife, not even on sufferers from stone”), and even cataracts.

Although these barber-craftsmen ensured the survival of surgery, the shift in responsibility from monks to barbers, diminished the craft of surgery in the 12th and 13th centuries. There was a relatively transient resurgence in Western Europe at the School of Salerno near Naples (founded in the 9th century CE), sparked by an important surgical manuscript, the Bamberg Surgery, which covered in detail the management of all types of wounds (Corner GW. Salernian surgery and especially the “Bamberg Surgery” with an account of a previously undescribed manuscript of the Bamberg Surgery, in the possession of Harvey Cushing) [11].

By the end of the 13th century, Italian leadership in surgical education had declined substantially because of civil war. During this war, Matteo I Visconti exiled a leader in Italian surgery, Guido Lanfranc of Milan (1250–1306), in 1290. Lanfranc went first to Lyons and later to Paris. There he completed his *Practica Quae Dicitur Ars Completa Totius Chirurgiae* (Practice and Art of All of Surgery) in 1296, a compilation of teachings from the Arab world and his master, William de Saliceto. The work became the foundation of French surgical teaching for many years, and reached 70 editions. Lanfranc made an interesting observation regarding the diagnosis of skull fractures (some 500 years before the invention of X rays): He would place a violin string between a patient’s rear molars. Plucking the string caused the skull to vibrate with a musical note. If the sound was bright and clear, the skull was intact and healthy. If the sound was dim and muffled, it indicated the presence of a fracture. He also argued against the separation of surgery and medicine (advocated since the time of Avicenna), noting that a good surgeon should also be a good physician. In France he associated with the Confraternity of Saints Cosmos and Damian, named after twin brothers who were martyred in 287 CE and who were recognized as the patron saints of surgery for services to the needy—they did not accept payment for their services [1].

In addition to the Confraternity, a guild of Parisian barber surgeons came into existence. Lanfranc bitterly criticized the barber surgeons [12]. A great jealousy arose between them and the Confraternity, leading Phillip IV of France to order,

in 1311, that only “masters of surgery” who passed a royally authorized examination could practice surgery in Paris. The edict disenfranchised the barber surgeons. Unwelcome in the Confraternity, the barber surgeons obtained a royal charter in 1372, legalizing their position. They received the designation “barber-surgeon”, but were not allowed to treat any wounds thought to be non-mortal! Such would seem a pyrrhic victory. A desire to protect ill-defined professional territorial boundaries (turf) underlay the evolution of the Confraternity and guilds of barber-surgeons. How much does this differ from modern times?

A contemporary of Lanfranc, Henri de Mandeville (1260–1320), became prominent as a strong opponent of surgical quackery. In his book, *Chirurgie*, he describes as quackery, the barber-surgeons’ practice of placing noxious and corrosive substances in wounds, rather than cleaning them. As Mandeville’s career came to an end, the University at Montpellier in France began to rival Paris as the center of European medical and surgical education. The most prominent of its graduates, Guy de Chauliac (1300–1380), authored a 7-part work, *Inventarium Sive Collectorium Chirurgie* (Inventory of the Complete Works of Surgery), published in 1368, describing methods dominating surgery in France, and to some extent in England, for the next three centuries. The texts dealt with tumors and sores as well as fractures, antidotes and drugs [1, 12]. Of special importance were descriptions of splinting and traction for fractures of the limbs. Because the work was written in Latin, it was not immediately accessible to the less educated barber-surgeons. Over the next century, it was translated into English (about 1425 CE), French and other languages, allowing the non-Latin-educated barber-surgeons access to surgical teachings, aiding their struggle against the more educated university surgeons.

English surgery during the Middle Ages lagged behind that in France and Italy. In 13th and 14th century London, guilds or companies were established to control various trades. Initially, barber-surgeons were allowed almost exclusive control of the practice of surgery in the City, and this antagonized the smaller number of military surgeons, causing them financial harm. The barber-surgeons and military surgeons fought economic and political battles for the right to supervise anyone practicing surgery. The London city corporation sided sometimes with one group and sometimes with the other, creating recurring indecision.

The Renaissance

An understanding of anatomy underlies modern surgery. Fundamental changes in the study of anatomy, changes enabled by the weakening of the Church’s ban on human dissection in the 14th century, prompted a resurgence of surgery during the Renaissance. Removal of impediments to dissection and

Fig. 15.1 From Vesalius' *De Humani Corporis Fabrica*. (lane.stanford.edu/portals/history/vesalius.htm; lane.stanford.edu/.../vesaliusSketchfull.jpg)

autopsy enabled Andreas Vesalius (1514–1564) to become proficient in human dissection. His work at the University of Padua, as Professor in Anatomy, culminated in his publication in 1543 (at the age of 29) of *De Humani Corporis Fabrica* (On the Fabric of the Human Body; Fig. 15.1). Many errors arising from Galen's reports from dissections of animals, or simply from baseless misconceptions, were revealed and corrected [1, 12]. Vesalius was in good company. Italian surgeons, unlike their less literate German and Swiss counterparts, were often university educated, and some achieved academic distinction. Vesalius' friend, Bartolomeo Eustachius, described the inner ear and the process of dentition. He also discovered the adrenal glands in 1563. Guido Guidi (1508–69) described many anatomical structures, such as the Vidian artery, nerve and vein [3]. Gaspare Tagliacozzi (1547–99), perhaps the father of plastic surgery, provided detailed methods for treating mutilating injuries in his *De Curatorum Chirurgia per Insectionem Libri Duo* (1597; Fig. 15.2).

The last great Italian Renaissance surgeon, Hieronymus Fabricius ab Aquapendente (1533–1620) became so popular as a teacher, anatomist, and surgeon, that he felt compelled to build (at his own expense) in Padua, the first known permanent amphitheater for anatomy demonstrations [1, 12]. Contributions to the development of surgery by Fabricius include techniques in tracheostomy, thoracocentesis, and urethral stricture repair, and the development of many surgical instruments. Perhaps his most important discovery was that of venous valves, later used by his pupil William Harvey to explain the circulation of blood. Also from the University of Padua, Johannes Vesling, professor of anatomy, published *Syntagma Anatomicum*, which became the most widely used illustrated anatomical book of the 17th century. He also corresponded with Harvey, and

his manual was one of the first to accept the circulation of blood impelled by the heart.

Other countries contributed to the renaissance. European surgery owed much to two Frenchmen, Pierre Franco (1500–1561) and Ambroise Paré (1510–1590) [1, 12]. Their achievements were noteworthy because both had risen from poverty, and neither was university educated. Itinerant lithotomists and herniotomists trained Franco, whereas Paré emerged from a barber-surgeon apprenticeship. Franco acted to remove surgery from the grip of charlatans, and to place it under the auspices of trained practitioners. He successfully repaired hernias and removed bladder stones. In 1541, Paré passed an examination to become a “master barber-surgeon” and a member of the guild. Despite protests over his background as a barber's apprentice and his vernacular rather than Latin speech, and with the support of an academic French surgeon Jacques Dalechamps (1513–88), Paré was granted membership of the College of St. Como (1554). This membership was important because it facilitated a later union of the barber-surgeons and the academic surgeons. Paré rose to become the official royal surgeon to Henry II, Francis II, Charles IX and Henry III. He was instrumental in moving surgical practice towards the modern model and helped abolish some erroneous techniques of the ancients, such as the use of the cauterizing iron to stop hemorrhage, encouraging the use of ligatures, especially of arteries. He designed a “bec de corbin” or crow's beak which was a predecessor to the hemostat. He treated wounds with egg yolk, oil of roses and turpentine rather than with boiling oil [13]. In his famous statement, “I treated him. God cured him”, Paré demonstrated great humility.

The struggle between university surgeons and the barber-surgeons mounted. The barber-surgeons moved beyond the

Fig. 15.2 “Gaspar Tagliacozzi, (1546–99) professor of surgery and anatomy at the University of Bologna, published *De Curtorum Chirurgia* to instruct surgeons on all they needed to know about reconstructing noses and ears. It is the first published work on plastic surgery. The work’s twenty-two plates depict every step of the process of rhinoplasty and are among the best-known illustrations in the history of medicine. Shown here is the patient, immobilized in a vest of Tagliacozzi’s devising, waiting for the skin graft taken from the arm to adhere to the nose. The process was supposed to take two to three weeks.” [1, 12] (From *De Curtorum Chirurgia per Insitionem* Venice, Bindoni, 1597.)

legal limitations that had earlier been placed on their practices. They became known euphemistically as the “surgeons of the short gowns”, in contradistinction to the “long gowns” or academic surgeons (cf residents and senior physicians). Barber-surgeons grew more numerous than their “long-gown” counterparts probably because of the elitist and exclusionist attitude of the latter. For the average Parisian, the “short-gown” barber surgeon was more accessible, cheaper, and more pleasant than his academic counterpart. Although the barber-surgeons had a lesser social status and academic rank, the public eventually recognized them as having superior skills, fewer complications, and lower morbidity and mortality.

The Seventeenth Century

In the 17th century, experimentation began to replace speculation, and the scientific revolution changed the history of medicine. William Harvey (1518–1657) discovered the fundamental anatomy and physiology of the circulation of the blood [11]. His book *Exercitatio Anatomica De Motu Cordis Et Sanguinis In Animalibus* (*An Anatomical Exercise on the Motion of the Heart and Blood in Living Beings*; 1628) may be the most important book in the history of medicine. We now take for granted his great insights, but at the time, they were revolutionary. In addition to Harvey’s contribution, Marcello Malpighi (1628–94) described the capillaries and their function in 1661.

However, surgery did not progress in the 17th century as rapidly as did anatomy, physiology and internal medicine. Despite their limitations, barber-surgeons in France were given the legal right to treat all wounds. In the second half of the 17th century, the barber-surgeons continued to favor their own union for financial reasons; and began to command higher fees than their academic counterparts (shades of modern surgery). Because it was difficult to make a living practicing only “surgery”, barber-surgeons provided “barber work” such as bloodletting and mundane wound care. By the end of the 17th century, the activities of barber-surgeons and academic surgeons diverged, and this disjunction produced alterations in the character of surgery that became more evident in the 18th century. Although the surgeons of the late 17th century, particularly the barber-surgeons, developed increasing technical proficiency and surgical dexterity, they contributed little to fundamental advances in knowledge. Rather, medical and herbal therapies were developed. One of the first medical texts in English, *The Physician’s Practice*, was published in 1639: “wherein are contained all inward diseases from the head to the foot by that famous and worthy Physician, Walter Bruel”. Surgery was not recommended and gave place to bleeding from the nose to let the evil out, leeches to the temporal artery, bathing in water from flayed foxes, and diuretics. What wonderful fun.

The Eighteenth Century

Anatomic research by academic surgeons continued during most of the 18th century. By the end of the century, surgeons rose above their past station as technicians, and received ever more acceptance as professionals equal to physicians. At the beginning of the century, surgical training in France increasingly included the teaching of an accepted body of knowledge in courses and schools. The establishment of the Royal Academy or College of Surgery in 1731, together with a Royal Declaration in 1743 forbidding master surgeons to work as barbers, transformed French surgery from a craft to a profession.

The French Revolution (~1780–1793) profoundly changed medicine and surgery. In 1792, by law, the Faculty of Medicine and College of Surgery were abolished, and in 1794 the creation of the *Ecole de Sante* (School of Health) inextricably united medicine and surgery [1, 12]. Educational requirements to practice either medicine or surgery were now identical, and only one degree, that of Doctor of Medicine, was awarded. The first surgical periodical, *Journal de Chirurgie*, appeared in 1791, edited by Pierre-Joseph Desault, an anatomist and surgeon trained in part by barber surgeons. Desault established a school of anatomy in 1776, and became surgeon major to the *Hopital de la Charite* in 1782. A renowned lecturer, he developed the journal as a means for his students to publish their most interesting cases. These 18th century events came about in part because surgeons and others had shown the importance and interdependence of pathological anatomy and pathophysiology.

In 1745, the British Parliament passed a bill forming an independent Company or Corporation of Surgeons, thereby divorcing surgeons from the barber guilds. Unfortunately, the Company failed to uphold standards for admission and to adequately organize surgical education. Despite these limitations, by the last decade of the century, Britain displaced France as the most important European center for surgical education and training.

This transition occurred largely because of Percivall Pott (1714–1788) and John Hunter (1728–1793) [1, 12]. Pott's reputation as a fine clinician exceeded that of his pupil, Hunter. Sustaining a compound fracture of his femur in 1756 (not the injury subsequently called Pott's fracture), Pott prevailed on his attending surgeons to splint his leg rather than amputate it. He recovered completely and published his own experiences and observations in 1769, in an influential work translated into French and Italian [14]. He described the anatomy of congenital inguinal hernias in a "Treatise on Ruptures", arthritic tuberculosis of the spine (Pott's disease) and was an enthusiastic advocate of early operations for incarcerated hernias [15]. Perhaps most importantly, he observed an association between exposure to soot and a high incidence of scrotal cancer (later identified as squamous cell carcinoma). His 1775 *Chirurgical Observations*, an essay five pages long, discussed cancer among chimney sweeps—the first identification of an environmental carcinogen. His investigations contributed to epidemiology and the Chimney Sweeper's Act of 1788. (Bernardino Ramazzini had published "Diseases of Workers", [16] a work anonymously translated into English in 1705 as *Diseases of Tradesmen*. Chimney sweeps and occupationally induced cancer were not described.)

John Hunter, the youngest of 10 children, was born at Long Calderwood, 10 miles from Glasgow. He followed his brother William, who was also a surgeon and anatomist, to London and served an apprenticeship with the latter for many years before being appointed as surgeon to St. George's Hospital. He had a large practice and was considered a dexterous

surgeon, but his main contributions to medicine and surgery were his lectures and writings, especially those concerning the pathophysiology of surgical diseases and comparative anatomy. He studied animals from leeches to elephants. He had difficulty overcoming a natural dislike of speaking and although he gave extensive courses, he "never gave the first lecture without taking 30 drops of laudanum to take off the effects of his uneasiness". [17] [The source for this is found in Mr. Home's introduction in John Hunter's book [17]. Home had lived and worked with Hunter for most of Hunter's life.] In addition to observations on malignant tumors, he studied the development of collateral circulation after occlusion of major arteries leading to improved treatment of aneurysms. He also wrote extensively on the development of the teeth [18].

Hunter had angina pectoris and frequent transient ischemic attacks. He said "my life is in the hands of any rascal who chooses to annoy and tease me". His prediction was accurate. He went to St. Georges Hospital on 16 October 1793 in his usual state of health (Mr. Home p lxi) and "meeting with some things which irritated his mind, he withheld his sentiments, in which state of restraint he went into the next room and turning round to Dr. Robertson, he dropt dead". He was 65. An autopsy indicated severe valvular disease and evidence of several old myocardial infarctions. A contributing factor may have been his self-inoculation with syphilis because he was sure he could cure himself, believing that no two diseases could coexist in one organism. Both Pott and Hunter dignified surgery by stressing the importance of making it a scientific discipline, one largely based on precise anatomical dissection and understanding. The Hunterian Museum at the Royal College of Surgeons in London has retained a large collection of Hunter's anatomical dissections.

The London Company of Surgeons encouraged the study of anatomy, and from 1752, was granted the corpses of all executed felons. The Surgeons' Hall dissections were formal affairs and students were relegated to the role of spectators [19]. This encouraged the development of private anatomy instructors, securing bodies from alternative sources. In his book "The London Tradesman" Robert Campbell wrote in 1747 of the young surgeon that "it is not sufficient for him to attend anatomy lectures, and to see two or three subjects cursorily dissected; but he must put his hand to it himself, and be able to dissect every part, with the same accuracy that the Professor performs."

The medical school in Edinburgh began to outshine those in England. In 1726, Alexander Monro (1697–1767), a surgeon trained in Leiden, was appointed as professor of anatomy. His son, Monro II (1733–1817), and grandson Monro III (1773–1859), followed him, thus holding the chair in the family for 120 continuous years. Training in Edinburgh focused on educating a doctor to be well-rounded in surgery and medicine. In 1778, the school of surgery became the Edinburgh Royal College of Surgeons. In England, most medical

education took place outside the universities, and the Hunterian anatomy school was one of many similar schools training surgeons. The London Company of Surgeons eventually secured legitimacy by being granted a Royal charter in 1800.

Military and socioeconomic strife prompted inconsistent surgical practices in Germany. Formal surgical education and training were limited, and local barbers and quacks dispensed most surgical treatment. In North America, medicine and surgery made minimal advances from 1600 to 1750. Few actual physicians or surgeons existed, and self-educated “physicians” served most medical needs. By the late 18th century, society began to hold physicians in higher regard, and increasing numbers of Americans obtained their medical degrees in Europe, returning to the colonies with valuable clinical acumen and technical skills. By the end of the 18th century, the role of surgery within the overall context of medicine became clearer. An increasing interdependence of internal medicine and surgery followed the parallel development of 18th century pathological anatomy and experimental physiology. For thousands of years, surgeons attempted to connect disease to an objective anatomical diagnosis. With the advent of the understanding of pathology, surgeons could regard disease from a viewpoint long prevalent among physicians, one that considered disease processes and their physiologic consequences, rather than the effect of these on anatomy.

However, meaningful gains in surgery required the advent of anesthesia and antisepsis. By contrast, 18th century internal medicine yielded more impressive results in diagnosis and treatment. A better understanding of both anatomy and pathology, allowed surgeons to conduct procedures more expeditiously and accurately, but with the suffering that only anesthesia would abolish.

The Nineteenth Century Before the Discovery of Anesthesia

During the first half of the 19th century, the scope of surgery slowly increased. Surgeons treated simple fractures and dislocations, drained abscesses, sutured wounds, and performed amputations. Stimulated by the improved education and training described above, surgeons could ligate major arteries, treat aneurysms and excise some superficial tumors. Some treated anal fistulae, hernias and cataracts. Compound fractures (the broken bone extending through skin) remained mostly unmanageable because resulting severe infections produced a staggering morbidity and mortality, and were thus still treated mainly by amputation, which itself had a high mortality rate. Trephination continued in vogue. In the textbook “The Principles of Surgery”, published by Lea and Blanchard, Philadelphia in 1848, [20] no mention is made of pain relief during operations. Only 1 page of Malgaigne’s

Operative Surgery addresses pain control, [21] and the operator is encouraged to use narcotics. Malgaigne notes that animal magnetism does not work, and that it is better to distract the patient, work quickly or crush or cut the nerve to the area (pp 42–3).

The anticipation of pain caused some patients to refuse surgery, but some (many?) were amazingly stoic. John Hunter was summoned to Downing Street by the Prime Minister, William Pitt the Younger, in 1786, to excise an “encysted tumour” (perhaps a sebaceous cyst) Pitt would not allow Hunter to tie his hands as was the custom, asserting that he would not move during the operation. He asked how long the operation would take, and Hunter gave an estimate of six minutes. Pitt fixed his eyes on the Horse Guards’ clock, and remained motionless until the operation was over, whereupon he remarked: “You have exceeded your time by half a minute.” [22]

Changes in the education and training of surgeons were among the most important advances during the early and mid-portions of the 19th century. By the mid-19th century, Germany, Austria and soon after, the US, supplanted France as centers of surgical knowledge. William Halsted (1852–1922) adopted the German “pyramid” system of clinical training for interns and residents at the Johns Hopkins Hospital. Surgical journals such as *Archiv fur Klinische Chirurgie* (1860), *Annals of Surgery* (1885), and other periodicals supplemented the textbooks and treatises that had been the foundation of medical writing.

The Royal College of Surgeons of Ireland was founded in 1784 by charter from George III, with a supplemental charter from Queen Victoria in 1844. The College was formed along the lines of the *College de St Cosme* in Paris, created by Royal charter from Louis IX in 1255. Surgical organizations followed in Britain (The Royal College of Surgeons 1815), Germany (*Deutsche Gesellschaft fur Chirurgie* 1872), and the US (American Surgical Association 1880) [23]. The US Civil War (1861–1865) introduced many physicians to the basic principles of surgery and the limited use of anesthetic agents. American surgical practice evolved expeditiously with on-site education and training.

Mid-Late Nineteenth Century and Early 20th Century

In the last half of the 19th century, surgical practice changed more abruptly than in all of its previous history. Pivotal events, namely the discovery of anesthesia and the establishment of antisepsis, enabled an amazing transformation.

In 1844, Horace Wells (1815–1848), a dentist from Hartford Connecticut, discovered the anesthetic effects of nitrous oxide, but failed in an attempted public demonstration of those effects. He shared his findings with another dentist, William Morton (1819–1868). On 16 October 1846, Morton

gave the first public demonstration of the effects of sulfuric ether anesthesia on Gilbert Abbott from whom, John Warren (1778–1856), professor of surgery at Harvard Medical School, removed a vascular tumor of the neck. Greatly impressed with the new discovery, Warren uttered his famous words: “Gentlemen, this is no humbug”. A new epoch in surgery had begun. Operations could be performed more efficaciously, and haste was no longer of primary concern [23].

Word of the discovery of the use of ether to allow for painless surgery spread around the world in weeks. James Simpson in Edinburgh heard of this and applied it in his practice. He found the pungency less than desirable. In a search for something better than ether, he enticed his colleagues to sniff several vapors after dinner, including chloroform. They all fell asleep. Simpson used chloroform the next day in his obstetrical practice. (4 November 1847). Six days later, he reported to the Edinburgh Medico Chirurgical Society on more than 30 painless deliveries [24].

The Scottish Church opposed the use of chloroform, for God said, “Unto the woman, I will greatly multiply thy sorrow and thy conception; in sorrow thou shalt bring forth children; and thy desire shall be to thy husband and he shall rule over thee.” (Genesis 111:16) In Edinburgh in 1591 A young lady, Euphemia Maclean, had asked a midwife, Agnes Samson, known as the Wise Woman of Keith, for relief from labor pains. She was publicly burned by order of King James as a warning to any woman who wished to be relieved of God’s judgment.

Simpson was denounced from some Scottish pulpits and in pamphlets. One clergyman proclaimed that “Chloroform is a decoy of Satan, apparently offering itself to bless women; but in the end it will harden society and rob God of the deep, earnest cries which arise in time of trouble for help.” [25] Simpson countered in “Answers to the religious objections against the employment of anesthetic agents in midwifery and surgery” in 1847. He argued that the Hebrew word “sorrow” could be translated as “toil” or “labor”. Because of their erect position, childbirth in humans is much more laborious than in animals and the Bible was only recognizing a physiologic fact [25].

Queen Victoria scuttled this thinking when she insisted, on the advice of her physician, James Clark, that the surgeon/anesthetist, John Snow, administer chloroform for the birth of Prince Leopold in 1853. The lady was obviously satisfied and invited Snow back in 1857, to attend during the birth of Princess Beatrice. Snow, who had studied at the Hunterian school, was admitted to the Royal College of Surgeons in 1838. Snow figured in the initial safe development of anesthesia and was arguably the greatest anesthetist that ever lived. His broad use of both ether and chloroform led to his publication of two books which, incidentally might be said to describe office based anesthesia [26, 27]. He was also known for his insights as an epidemiologist, one leading to

Fig. 15.3 Frederick Treves. (From Wikipedia.)

control of the cholera epidemic in Soho in London. His study led him to believe that the Broad Street well was contaminated. He assisted in halting the epidemic by persuading the City Council to remove the handle from the Broad Street water pump.

In 1900, Frederick Treves (Fig. 15.3) described the impact of the discovery of anesthesia on surgery and surgeons [28]:

“The changes that the discovery has wrought in the personality of the surgeon, in his bearing, in his methods, and in his capabilities are as wondrous as the discovery itself. The operator is undisturbed by the harass of alarms and the misery of giving pain. He can afford to be leisurely without fear of being regarded as timorous. To the older surgeon every tick of the clock upon the wall was a mandate for haste, every groan of the patient a call for hurried action, and he alone did best who had the quickest fingers and the hardest heart. Time now counts for little, and success is no longer to be measured by the beatings of a watch. The mask of the anaesthetist has blotted out the anguished face of the patient, and the horror of a vivisection on a fellow-man has passed away. Thus it happens that the surgeon has gained dignity, calmness, confidence, and, not least of all, the gentle hand.”

“Anaesthetics have, moreover, greatly extended the domain of surgery by rendering possible operations which before could only have been dreamt about, and by allowing elaborate measures to be carried out step by step.”

In 1886, for the first time, a surgical textbook dedicated an entire chapter to anesthesia [29].

A Century of Surgical and Other Giants

James Sims (1813–1883), was one of the first “giants” in surgery [23]. He is thought of as the father of modern gynecology. After many unsuccessful attempts to repair vesicovaginal fistulae (a tunnel between bladder and vagina), he achieved a cure on November 12 1849, in a patient who had undergone thirteen prior unsuccessful procedures. He attributed his success partly to positioning the patient on her left side with the thigh bent upward toward the abdomen, which allowed excellent visualization of the fistula. This position is now known as the Sims position. Sims’ surgical expertise became famous, his practice grew, and he initiated research on menstrual problems, sterility, and artificial insemination. He founded the Women’s Hospital in New York in 1855, with the aid of several prominent citizens, in particular their wives. Sims’ interests extended beyond gynecology. He performed the first successful cholecystostomy for gallstone removal, in 1878. In 1882, Carl Langenbush performed the first successful cholecystectomy (gall bladder removal).

Theodor Billroth (1829–1894; Fig. 15.4), was born in Rugen on the Baltic coast. Billroth liked music more than books as a youngster. However, after his father died, his mother persuaded him to study medicine. He settled in Vienna at the completion of his training, because of Vienna’s reputation in music. But nary a patient came in the first two months. Then he stumbled upon a job assisting the greatest surgeon of the day, Bernhard von Langenbeck (1810–1887), the founder of *Archiv für Klinische Chirurgie*. Billroth used a microscope to examine the large collection of tumors at the Charite Hospital, classifying them and writing a dissertation on his findings. He was made an associate professor of surgery and histology in 1856, and four years later, his scientific and clinical skills became renowned throughout German-speaking lands. He was appointed professor in Zurich. Interested mainly in infection and healing of wounds, he was the first to use regular temperature measurement post-operatively, and to recognize that a rising temperature is often the initial sign of complications, an observation of vital importance to this day.

Billroth returned to Vienna as the professor of surgery when the chairman retired. He created one of the finest schools in the history of surgery and his legacy continues. Billroth performed the first total removal of the larynx for cancer (1873), the first hemipelvectomy (1891), the first

Fig. 15.4 Theodor Billroth (1829–1894) (From Wikipedia.)

perineal prostatectomy for cancer (1867), and the first suprapubic removal of a bladder tumor (1875). His boldness and technique made him a pioneer in abdominal surgery. On 29 January 1881, Billroth performed the first removal of a cancerous stomach in an operation taking one hour and thirty minutes [30]. The operation attached the remaining proximal stomach to the duodenum and became known as the Billroth I procedure. Unfortunately, the cancer returned, causing obstruction at the junction of the stomach and duodenum. Billroth recognized that he needed to connect the stomach with the intestine in a position less likely to become obstructed, even with recurrence of the tumor. On 15 January 1885, he removed another stomach cancer, closing the duodenum and connecting the stomach with the jejunum. This “Billroth II” procedure is used today.

Theodor Kocher (1841–1917; Fig. 15.5) greatly influenced American surgery in the second half of the 19th century, not only because of his impact on the understanding and treatment of thyroid disease but also because Halsted studied with him. Halsted returned to the US, bringing Kocher’s precise, gentle and meticulous technique. Kocher was born and educated in Bern, Switzerland, where he became professor at the

Fig. 15.5 Theodor Kocher (1814–1917). (From upload.wikimedia.org/wikipedia/commons/thumb/...)

age of 31. Bern was the center of the goiter district, and the prevalence of goiter spurred Kocher to investigate the regulation of thyroid function. In 1850, the mortality rate for thyroid surgery was about 50%, usually from uncontrolled bleeding. With his meticulous technique, Kocher decreased the mortality rate to 0.2% in some 4000 thyroidectomies. For this and his other contributions he received the Nobel Prize in Medicine in 1909. Good surgeons obey Kocher's rule: "a surgeon is a doctor who can operate and who knows when not to." [11]

The recognition of antisepsis, without which major surgical procedures often ended in infection and death, equals the discovery of anesthesia in importance to the advancement of surgery. *Joseph Lister* (1827–1912), Professor of Surgery at the Royal Infirmary in Glasgow, recognized that air-borne microorganisms caused surgical infections. In wards next to the cemetery where bodies awaiting burial were tossed from the windows (tale heard by EAMF as a student), the infection rate was higher than in the wards at the opposite end of the hospital. The Glasgow necropolis is immediately adjacent to the Royal Infirmary. In 1867, after two years of testing his theory, Lister described the use of a carbolic acid spray to minimize infection (Fig. 15.6). Gradually, Lister's principles of antisepsis gave way to those of asepsis, the complete

elimination of bacteria. Ernst von Bergmann (1836–1907), developed steam sterilization (1886) that ensured the sterility of instruments, an essential ingredient of asepsis. Other antiseptic rituals such as the use of masks, operating gowns, hats, and sterile gloves evolved rapidly thereafter [23].

Another Scot and successor to Lister at the Royal Infirmary in Glasgow, advanced both surgery and anesthesia by developing tracheal intubation. *William Macewen* was Medical Superintendent of the Glasgow Fever Hospital where he dealt with many deaths from respiratory obstruction due to diphtheria. He developed metal tubes that could be inserted into the tracheas of cadavers, following the observations of Desault some 100 years previously. He reported the case of a Glaswegian who rushed up to his flat after work. Boiling water had just been poured from the potatoes prepared for his dinner, and he picked one up and popped it into his mouth. The potato lodged in his throat and was expelled with great difficulty. A few hours later and after some libation, he had trouble breathing. A note from a Dr. McMillan read "Urgent case, probably requiring operation." Rather than proceeding to tracheostomy, Macewen passed a gum elastic No 12, and successively larger catheters into the man's trachea, thereby relieving the obstruction. The catheters were maintained for 36 hours and the patient went home on the 6th day [31].

On July 5th 1878, Macewen passed a tube into the larynx of a patient, before induction of chloroform anesthesia, for removal of an epithelioma from the base of the tongue [32–33]. He was also dedicated to the teaching of anesthesia, unlike Lister, who vehemently opposed the emergence of specialists devoted to anesthesia, believing that his own clerks were superior to other chloroformists [34]. Macewen mandated practical instruction and certification in anesthetics for students and residents who worked in his wards. After an anesthetic death and much national publicity, the Board of Managers at the Glasgow Royal Infirmary adopted a resolution (Board of Managers Reports Glasgow Royal Infirmary 1882–3 Archives, University of Glasgow) on 7 March 1883, that required training in anesthetics for all medical students and clerks [35].

Macewen was offered the Chair of Surgery at Johns Hopkins in 1889. He refused the offer because the trustees would not grant him supervision and training of nurses, instead electing to wait for appointment as the Regius Professor at the University of Glasgow in 1892. He might have added considerably to American surgery—and anesthesia [36].

Victor Horsley (1857–1916), Macewen's concurrent neurosurgical counterpart in London, investigated the effects of several anesthetic agents on himself. While a house surgeon to John Marshall at University Hospital, London, he had his friends anesthetize him or he self-administered anesthetics some 50 times. He devised several means to monitor and record his sensations, developing pain charts linked to the percentage of anesthetic administered. The hospital authorities

Fig. 15.6 An operation in which Joseph Lister uses his carbolic acid spray

reported that the amount of anesthetic used increased during his apprenticeship. He recognized the value of hypotension obtained with increasing concentrations of chloroform. Ether was not to be used as it caused hypertension, increased blood viscosity, produced excessive bleeding, and resulted in severe postoperative vomiting. While he initially advocated a combination of chloroform and morphine, he later abandoned morphine because of its respiratory depressant effects. Chloroform was administered at that time by applying a cloth on which the liquid had been sprinkled. Insisting that control of the concentration was essential, Horsley used a vaporizer developed by a physical chemist, Vernon Harcourt. He added oxygen, believing that oxygen would reduce capillary bleeding [37, 38].

William Halsted (1852–1922; Fig. 15.7) influenced surgical development in the US. He began his work in 1889, in the newly opened Johns Hopkins Hospital in Baltimore, advancing surgery by emphasizing physiology as well as anatomy (and what might have happened had Macewen accepted the post—see above?) He was a meticulous surgeon who moved surgery from the heroic operating “theater” to the relative sterility of the operating room and the privacy of the research laboratory. His development of radical mastectomy for breast cancer, in 1898, became the gold standard for the treatment of that malignancy [39]. In the late 1970s, when local excision and radiotherapy were found to yield equivalent outcomes, those who advocated the less radical option had to overcome considerable doubt, sometimes including doubts concerning their surgical skill. While less mutilating

Fig. 15.7 William Halsted (1852–1922). (From en.wikipedia.org/wiki/File:WilliamHalsted.jpg)

procedures have supplanted radical mastectomy, Halsted's teachings on the spread of malignancies to regional lymph nodes (in this case, axillary nodes) guides today's practice.

Halsted's training program was patterned on the German model that required a dedication to meticulous care of the patient with graded and increasing responsibility over a period of at least five years—or until the professor deemed the trainee to be an independent and safe surgeon. Today this is called a pyramid system, a system in which five or six candidates begin at a first year level, but with only one or two completing the full five years. The aspiring resident surgeon lived in the hospital for 24 hours a day, hence the terms “resident” and “residency”. Graduates of Halsted's training program were highly regarded, and increasingly populated teaching hospitals, promulgating Halsted's principles. The “Halstedian” residency became the standard for training. Modifications are imposed now by limited-hour work-week rules, rules passed by the Residency Review Committee, and its equivalent elsewhere, as a result of concern regarding resident fatigue and consequent errors. The successful trainee in a 5 or 6 year program who ultimately achieves the esteemed status of chief resident, is well prepared for a career as an independent physician and surgeon. He or she may now also be married during training.

A German obstetrician, Walbaum, described a hand cover for operations in 1758, [40] However Halsted deserves credit for popularizing the use of gloves throughout the world. His interest in gloves was accidental. The mercury-bichloride solution used to sterilize instruments had produced an incapacitating eczema on the hands of his favorite nurse—who happened to be his fiancée. He urged her to try rubber gloves. They worked and were soon adopted by him and his staff. “Venus had come to the aid of Aesculapius.”

Halsted began self-experimentation with cocaine when he learned of its topical anesthetic properties, and became addicted. He was treated with morphine and then struggled with addiction to morphine for much of his life.

Surgeons immediately applied the 1895 discovery of X-rays [11] to the diagnosis and location of fractures, dislocations and the removal of foreign bodies. *Wilhelm von Roentgen* (1845–1923), whose name was given to these rays, actually belonged to the world of physics. Educated in Holland and Switzerland, he held professorships at Strasbourg, Gies-sen, and Wurzburg, studying heat and electricity. In November 1895, while experimenting with current through a vacuum in a tube, he made a chance observation of a greenish glow from a screen on a nearby shelf. This glow continued even when he stopped the current. He found that the screen was painted with a phosphorescent substance, and it was this that glowed when struck by invisible “rays” from the vacuum tube. He proved that the invisible rays generated by his tube could pass through wood, and other materials, unlike light and heat waves. Sometimes he noticed an image of his

Fig. 15.8 Roentgen's image of his wife's hand. (From www.cs.brown.edu/.../cs024/images/canon/37.jpg)

own hand on the phosphorescent screen. Being an avid photographer, he set up a film before the screen, laid his wife's hand on the plate, and produced the world's first X-Ray picture, showing bones and a wedding ring (Fig. 15.8). Weeks later, he reported to the scientific academy in Wurzburg, “On a New Kind of Radiation”. Few discoveries, apart from anesthesia, spread as fast as this one. He refused a Bavarian title but accepted the first Nobel Prize in physics in 1901, and lived on as a professor in Munich [11].

Roentgen's discovery profoundly altered surgery, but in more subtle ways than anesthesia and antisepsis. Before X-rays, doctors had to rely on their five senses. The advent of X-rays facilitated more precise diagnoses and therefore more definitive therapy. Soon it was realized that soft organs could be visualized by X-rays using a “contrast material”, such as that developed by Graham and Cole for imaging the gall bladder. Injection of such material into the nipples of amputated breasts demonstrated how cancer changed them. X-ray mammography, without injection of contrast material, became an important tool in the diagnosis of breast cancer in 1962. It is difficult to envision modern medicine and surgery without X-rays.

Harvey Cushing (1869–1939; Fig. 15.9) was another American pioneer of surgery—and anesthesia. He studied at Yale and Harvard, and trained at Johns Hopkins Hospital

Fig. 15.9 Harvey Cushing operating. (From l.murugan.tripod.com/Murugan/id22.html.)

with Halsted. During his residency with Halsted, he became interested in neurosurgery and determined to give it better diagnostic methods, becoming one of the first in American surgery to employ X-rays.

As a medical student in the 1890s, Cushing was asked to stand in for the anesthetist Frank Lyman, in the process killing the patient he had been instructed to anesthetize [41]. This terrible event illustrates the then low state of anesthesia in the US: an orderly directed a third year medical student (Cushing) in the administration of an anesthetic to a seriously ill patient (a different arrangement from that in Great Britain where physicians gave the anesthetic). Cushing never forgot about it. Moreover, to the benefit of anesthesia, he did something about it [42]. The disaster led to the development of closer attention paid to the anesthetized patient. It led to Codman and Cushing's development of the anesthetic record under the urging of his chief, FB Harrington, and the setting down of the patient's heart rate and blood pressure in that record at five minute intervals, still a standard in anesthetic records (Fig. 15.10). Cushing had seen blood pressure measured in Europe when he visited the Ospidale di St Matteo in Padua where he was impressed with an adaptation of Scipione Riva Rocci's device. Later, in 1930, Cushing was to write:

"...I am not so sure that the general use of a blood pressure device in clinical work has done more good than harm. Just as Floyer's pulse watch led to two previously unknown diseases, tachycardia and bradycardia, so the sphygmomanometer has led to the uncovering of the diseases (God save the mark) of hypertension and hypotension, which have vastly added to the number of neurasthenics in the world." [43]

Cushing barely tolerated the weaknesses of lesser individuals. Consorting with females, and certainly marriage, were not allowed among his (male) residents. (Dr. Davidoff, wife of the neurosurgeon, Professor Davidoff, told EAMF, how she had to creep into her husband's quarters to see him. Both lived in fear that their marriage would be discovered). A Johns Hopkins nurse told a second anecdote. An inexperienced student nurse was substituting for the anesthetist. At a tense moment, Cushing ordered her to take a blood pressure. A few moments later he felt a tug on his pants as the nurse place the pneumatic cuff around his leg [43].

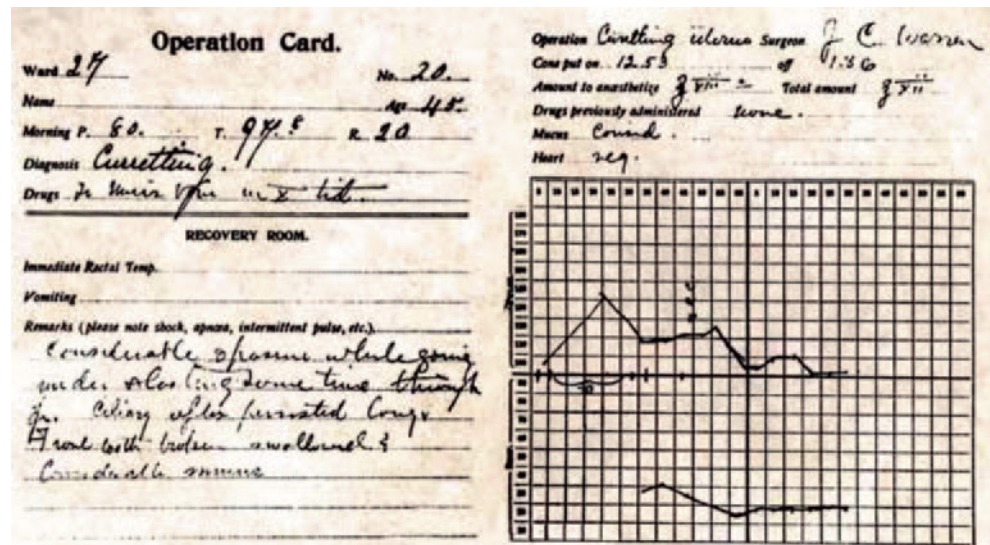

Cushing became professor of surgery at Harvard Medical School (and chief of surgery at the Peter Bent Brigham Hospital in Boston) in 1912. A perfectionist, he brought to neurosurgery the ultimate refinements in pre-operative preparation and operative technique. He introduced silver clips to occlude blood vessels in tissues (the brain) that could not be ligatured or pressed to staunch bleeding. He played an important role in the development of the Bovie electrocautery, a standard method today, of halting bleeding. Cushing's skill reduced the mortality rate in patients undergoing brain operations, from 50–60% to about 10%, by 1930 [44].

Inspired by Halsted's work with local anesthesia and by observations of deaths under ether anesthesia, Cushing applied local infiltration of cocaine for hernia and thyroid operations in 1898, [45] and for amputation somewhat later [46]. He kept meticulously detailed records of all of his work, insisting that records similar to current anesthetic records (see above) be maintained on his patients. He wrote extensively on his studies of brain tumors and developed a classification for these lesions, especially meningiomas. His finest work was "The Pituitary Body and Its Disorders" (1912), describing the syndrome which now bears his name. He developed the present operation for removal of pituitary tumors by an approach through the nose (trans-sphenoidal hypophysectomy), [47] entering the brain at its base rather than the more dangerous approach, traversing the brain from above.

Cushing was also a bibliophile. Antique book dealers everywhere knew of—and doubtless profited by—his friendly race with the Swedish surgeon Erik Waller, to collect the world's best library of medical history. Whether Waller or Cushing won may be debated. Later in life, he wrote a biography of William Osler (1849–1919), a Canadian and teacher whom he worshipped. His biography of Osler won Cushing the Pulitzer Prize in 1926.

Alexis Carrel (1873–1944), a Frenchman who came to the US in 1905, was another major innovator. He worked first in Chicago, and from 1906–1939 at the Rockefeller Institute for Medical Research in New York City. He revolutionized surgery of the vascular system with his technique for suturing blood vessels end-to-end with fine needles and suture material. He investigated grafting of organs, including the transplantation of organs from animal to animal; he replaced

Fig. 15.10 An anesthetic record kept by EA Codman in November 1894. (From Beecher HK. The first anesthesia records (Codman, Cushing). 1940. *Surg Gynecol Obstet* 71:689, with permission.)

arteries with veins. In 1938, he crowned his long research on transplantation by keeping organs alive outside the body with a pump built by Charles Lindbergh (1902–1974). His work provided the foundation for today’s organ transplantation, and for the treatment of arterial occlusive disease, of aneurysms, and of coronary artery disease. He well deserved his 1912 Nobel Prize in Medicine but failed to mention Charles Guthrie (1880–1963), an important collaborator during a two-year period at the Rockefeller Center.

Carrel developed the “Carrel-Dakin” solution used in World War I, an antiseptic still used. He also wrote, “Man the Unknown” (1935), arguing that a “utopia” run by geniuses should replace democracy. He played a role in French politics, particularly with the fascist Parti Populaire Francais during the 1930s, and may have helped implement eugenics policies in Vichy France. He was accused of helping the Nazis—whose physicians tarnished the reputation of medicine by performing inhumane experiments on individuals in concentration camps. He died in 1951, before his trial for collaboration. His suture technique came into practice three years later when his countryman, Charles Dubost, removed an aneurysm and sutured the two cut ends together [48].

The introduction of anesthesia profoundly altered the practice of surgery. Painless surgery was regarded as bold therapy, and the theatricality of the event was not lost on increasing numbers of surgeons who were emboldened to devise new and more technically complex operations. Some of these procedures provided little more than a poor excuse for the act of surgery. Thoughtful members of the surgical community became alarmed with what was considered to be the exploitation of surgery for financial gain. John Watson (1807–1863), a well known New York City surgeon, expressed concern more emphatically. “Surgery.....is a good thing, a useful, an excellent thing in its way, but too much of it is a great evil. And the sooner you find this out for yourself, the better for your patients”.

Rudolph Matas (1860–1957) of New Orleans, was an imaginative surgeon who performed the world’s first known aneurysmorrhaphy (correction of a ballooning of an artery) in 1888 [49]. Matas’ activities and his innovations impacted on more than vascular surgery. During the 1890s, he performed some of the earliest successful pre-planned attempts at intraspinal cocainization (spinal anesthesia) [50]. With 3 colleagues, Larue, Gessner, and Allen, he successfully used intrathecal cocaine for a hemorrhoidectomy in a 32 year old Argentinian, on 18 December 1899. Earlier attempts on November 10, using intrathecal eucaine B to relieve pain in a man with a tuberculous knee joint, did not succeed.

At the turn of the century, Matas developed a test to determine the adequacy of the collateral circulation before performing surgery on the great vessels. He is also credited with introducing tracheal insufflation (blowing gases, particularly oxygen, into the trachea), a technique perfected by Samuel Melzer and John Auer in 1909 who, working on a suggestion made by Vesalius 350 years previously, applied positive pressure to the lungs, allowing the chest to be opened.

Notwithstanding these wonderful contributions, American physicians were slow to separate surgery from general medical practice. Some surgeons such as Samuel Gross (1805–1884) of Jefferson Medical College in Philadelphia, himself highly regarded by colleagues and patients, wrote and campaigned against specialization [23]. Influenced by Gross, the 1866 Committee on Medical Ethics of the American Medical Association carefully considered the advantages and disadvantages of specialization, and concluded that the disadvantages could only be overcome if the specialist were to begin his career as a generalist physician-surgeon, and slowly adopt his new specialty. Consequently, in the US, the rise of surgery as both a scientific and well-regulated profession did not begin in earnest until the late 1880s. At that time, it became evident that theoretical concepts and valid

applications would be necessary to demonstrate the scientific basis of surgery, not only to non-surgical medical colleagues, but especially to the lay public. Surgeons needed to allay society's fear of the surgical unknown, and present surgery as an accepted part of the established medical armamentarium. The results obtained by surgeons treating the wounded in World War I, played an important role in convincing the public of the value of surgery in the treatment of non-war related conditions.

Evarts Graham (1883–1957) performed the first successful pneumonectomy for lung cancer in 1933, on a patient who himself was a physician [51]. Years later, Graham, a heavy smoker, recognized the role of cigarette smoking in the pathogenesis of carcinoma of the lung, and to the surprise and dismay of conservative physicians and surgeons, he openly decried smoking during conventions and meetings. Today, such a stance is standard, but in the 1950s, it was unusual. Graham succumbed to cancer of the lung some years later. His first patient, the physician with the same disease, outlived him.

Graham was not only a pioneer in pulmonary surgery, but also in X-Ray studies of the gall bladder. In 1924, he and a young resident in his surgical training program, Warren Cole, collaborated with Mallinckrodt Chemical Works in St. Louis, to develop a compound excreted and concentrated in the bile, enabling the gall bladder to be visualized by X-Ray. This test is still used today.

Graham loved music and wrote that

“... surgery is like music, which has its great artists and its great composers. The great musical artists are like the great surgeons. They often perform before large audiences with great technical skill, and they have large incomes. But what they accomplish is the work of the composers, the creative men who have made it possible for them to perform and who often have received only modest economic rewards. What our present surgeons need is more men of the composer type”.

Antibiotics Greatly Impact Surgery in the Twentieth Century

Paul Ehrlich (1854–1915), a German bacteriologist, was the first to employ “antimicrobial chemotherapy”. He synthesized several “magic bullets” that would target specific disease-causing organisms, and was responsible for the development of arsenicals to treat syphilis. For those discoveries, he shared a Nobel Prize in Medicine in 1908.

In the early 1930s, *Gerhard Domagk* (1888–1964) invented a red dye which protected mice against streptococcus bacteria, and which was patented as Prontosil in 1932. Although Prontosil was effective in mice, it was not clear that the same effect would be obtained in humans. Domagk's daughter fell seriously ill of a streptococcal infection, and in desperation, Domagk gave her Prontosil. She recovered completely. Prontosil and its many relatives, known as sulfonamides,

proved to be effective against infections in wounds, lungs, urinary tract and other organs—earning for Domagk a Nobel Prize in Medicine in 1939. The Nazis forbade him to accept it and even arrested him. This bizarre outcome resulted because Carl von Ossietzky, who had won the Nobel Peace Prize in 1935, angered the Nazis by his criticism of the German government. German nationals were prohibited by law from accepting the prize [52]. Domagk finally received the prize in 1947.

In 1928, the Scot, *Alexander Fleming* (1881–1955), while studying staphylococcus bacteria, noticed that no bacteria grew around mold that developed in old culture plates. He inferred that the mold, *Penicillium notatum*, contained an antibacterial substance that he called penicillin. Nothing further was done until World War II when Howard Florey (1898–1968) from Australia, and Ernst Chain (1906–1979) from Germany, discovered how to obtain useful amounts of penicillin from the mold. All three were knighted and shared a Nobel Prize in Medicine in 1945. The discovery of penicillin is one of the most important breakthroughs in medicine.

Fleming's discovery inspired *Selma Waksman* (1888–1973), a world authority on microbes in soil, to look there for substances similar to penicillin, and he found streptomycin. In 1952, he too received a Nobel Prize in Medicine. Streptomycin provided the first medical cure for tuberculosis, which previously often required removal of portions of the lung containing an infected cavity, or which necessitated removal of multiple ribs to collapse cavities in the thorax infected with tuberculosis.

Antibiotics revolutionized surgery. They prevented surgical (wound) site infections after operations for appendicitis, diverticulitis, colonic and intestinal resections, and peritonitis, and are now given routinely before surgery. They had an unexpected effect on the common operation for peptic ulcer disease. In 1982, Australians *Barry Marshall* and *J. Robin Warren*, demonstrated that the bacterium *Helicobacter pylori* caused peptic ulceration [53]. Their finding was met with skepticism, a skepticism Marshall countered by drinking a culture of *Helicobacter* with resulting stomach inflammation. Antibacterial agents eradicated *H. pylori*, and with that, the need for operations to treat perforated ulcers and persistent ulcerative disease of the stomach and duodenum. Prior to this, stomach operations for intractable peptic ulcerations kept surgeons busy. Marshall and Warren were awarded the 2005 Nobel Prize in Medicine.

Later in the Twentieth Century

World War II greatly expanded surgery as a specialty, and increased the number of surgeons throughout the country. Many of these individuals, newly indoctrinated in the rigors of technically complex operations for trauma, became leaders in the construction and improvement of hospitals,

multispecialty clinics, and surgical facilities in their hometowns. Large urban and community hospitals established surgical training programs, and increasing numbers of students graduating from medical school sought surgical residencies. The trend toward specialization became so great that extinction of the general practitioner became a threat. The change in the demographics of the American doctor was most dramatic for the surgical specialties. In 1930, 10% of the medical profession considered themselves surgeons, but by 1975 over one third of all physicians were full time practitioners of either general surgery or one of the surgical specialties.

The greater number of surgeons loosened the indications for surgery. In 1970, John Bunker, an anesthesiologist at Stanford University, reported that not only were there twice as many surgeons in the average American city as in an English city, but twice as many surgical procedures were performed per capita—without any demonstrable short or long term health-related benefits [54]. Parallel studies undertaken recently showed similar results, and such findings are likely to profoundly change surgical practice and the delivery of health care in the US.

American Cardiothoracic and Transplant Surgery after World War II

World War II undermined the economies of most countries of the world. The diversion of resources to war undercut the growth of medicine, including surgery—but not the US. This ended European surgical superiority and North Americans became the leaders of world surgery. Two developments emphasized the importance of post-World War II American surgery: the maturation of cardiac surgery as a new surgical specialty, and the emergence of organ transplantation. As the first president of the US to undergo a major abdominal operation (ileotransverse anastomosis for intestinal obstruction due to Crohn's disease) Dwight Eisenhower (1890–1969) enhanced the fascination with surgery, especially since he experienced an uneventful postoperative course. This example of a leader setting an example for a country is similar to the popularizing of epidural analgesia in Japan after the Emperor underwent abdominal surgery, anesthetized in part with epidural analgesia (see Chapter 31 on the History of Anesthesia in Japan).

Robert Gross (1905–1988), at the Boston Children's Hospital, initiated modern cardiac surgery. While still a surgical resident, he successfully repaired a congenital defect, a patent ductus arteriosus (an abnormal opening between the left pulmonary artery and the aorta) in a seven year old girl [55]. In 1945, he resected a coarctation (narrowing) of the aorta and reconstructed anatomic continuity with an end to end anastomosis [56]. In 1948, Dwight Harken (1910–1993), a Boston based surgeon, and Charles Bailey (1910–1993) of Jefferson Medical College, independently carried out suc-

cessful operations for mitral stenosis (narrowing of the intra cardiac mitral valve). These procedures challenged the long-held medical myth of the heart as an organ so vital and complex that it could not withstand surgical intervention.

Yet, technically complex cardiac repair procedures could not be developed further until the operative field could be rendered free of blood, and the unrelenting beating of the heart could be stopped while circulation to the body was maintained. *John Gibbon, Jr.* (1903–1973), whose tenacity in the research laboratory became legendary, worked with engineers for six years to develop a heart-lung machine which he employed to successfully repair an atrial septal defect in the heart of an 18 year old woman, in May 1953 [57].

Substituting a healthy organ for a sick one is a surgeon's dream. Carrel's suture method caused a wave of enthusiasm for transplantation after initial experience with long-lived "auto-transplants" (i.e., take out a kidney and put it back into the same animal and the kidney and animal survive). Enthusiasm dimmed when it became apparent that a host animal would reject a guest organ from another animal! The body's immunity "defense mechanism" killed such foreign cells.

Peter Medawar (1915–1987) in London, showed during the 1940s, that a guest organ's life was shorter in a host animal that had previously received a graft from the same donor [58]. The same was true in a host previously receiving white blood cells from the donor. These prior "transplants" activated the immune system, preparing it for hostile action when confronted by invasion of similar subsequent transplants. The immune response protects us all from infections (e.g., once we have measles, the immune system defends us from a subsequent infection by the measles virus), but the immune system does not stop when faced with an organ transplant. Medawar discovered that cortisone could increase the life of the transplant, thus providing an "immunosuppressive" weapon against rejection. Medawar received the Nobel Prize in Medicine in 1960. Other investigators subsequently developed better immunosuppressive agents.

In 1954, Bostonians *J. Hartwell Harrison* (1909–1984) and *Joseph Murray* (1919–2012), performed the first successful human kidney transplantation between identical twins [59]. Identity of the twin's tissue types made chemical immunosuppression unnecessary. Harrison and Murray followed that feat in 1959, with a kidney from a non-identical twin. Whole body radiation was given to provide immunosuppression [60]. In 1962, a transplant was completed between unrelated individuals using drug immunosuppression, thus opening the door to such operations on a large scale [61]. The world has now seen hundreds of thousands of kidney transplants, allowing people with severe renal damage an alternative to chronic dialysis treatment. Over 85% of patients who receive cadaver kidneys live and function normally, albeit with suppressed immune systems.

In 1963, *Thomas Starzl* (1926–) in Denver began transplantation of human livers [62]. His progress report in 1981

heightened interest in the method, and today it is well established for adults with primary cancer or chronic inflammation of the liver, and for children born with narrowed bile ducts. Whole organ pancreatic transplantation for the treatment of diabetes soon followed, as did cardiac, intestinal and bone marrow transplants.

In New York, Adrian Kantrowitz practiced transplanting hearts in puppies for years. He had planned a human operation but was prevented at the last minute because the donor infant, an anencephalic, had not been declared brain dead. His next opportunity came on December 6th 1967, just 3 days after the first heart transplant performed at Groote Schuur Hospital in Cape Town, South Africa, by *Christiaan Barnard* (1922–2001). Kantrowitz' patient lived for 6.5 hours, Barnard's for 18 days. Kantrowitz found ways to supplement the work of the natural heart, developing the left ventricular assist device (1972), the intra aortic balloon pump (1967), and the implantable pacemaker (1962; designed with General Electric).

Gender and Race in American Surgery

Gender and racial bias have affected the evolution of American surgery. African-Americans and women were innocent victims of prejudice well into the mid-twentieth century, forcing unending struggles to attain competency in surgery. Fortunately, these barriers have been largely erased, and today, women and African-Americans hold important positions, including chairmanships of departments of surgery, throughout the US. Overall, of those who consider themselves to be general surgeons, roughly 10% are women of whom 90% are under 44 years of age. African-American general and thoracic surgeons constitute 1.7–3% of general surgeons in the US but these percentages continue to increase [23].

Blood Transfusion: A Pillar of Support for Today's Surgery

The idea that blood transferred from a healthy person to an old or sick person can convey youth and vitality is ancient, noted in Egyptian medicine as early as 2000 BCE. We do not know when the first blood transfusion from one human to another was successfully accomplished. In the early-mid 19th century, the London physiologist and obstetrician, James Blundell, began the process that led to modern transfusion. Animal experiments convinced him that transfusions could save the lives of bled-out patients, and that this could help women in childbirth. His success was limited because he did not understand that blood from one person might or might not be transferable to another. Successful transfusions—

those without reaction—probably resulted from good luck, but by 1868, transfusions had caused many deaths, and the practice disappeared.

The turning point came with *Karl Landsteiner's* (1868–1943) discovery of blood groups. In a modest article in 1901, in his native Vienna's *Klinische Wochenschrift*, [63] Landsteiner and his group at the Rockefeller Institute argued that humans had one of three blood groups, called A, B, and O. A year later, a fourth group (AB) was discovered. They proved that blood normally contains antibodies (antibodies are proteins that combine with and incapacitate other specific proteins called antigens) that are directed at antigen proteins in particular types of blood cells. If blood with the wrong antigen is given to a person possessing antibodies directed against it, the red blood cells clump together (agglutinate) and are destroyed. By giving blood of the person's own blood group, this great danger can be avoided. Landsteiner also found that type O blood cannot be agglutinated (no one has type O antibodies) and thus can be given to anybody—the universal donor. He was awarded the Nobel Prize in Medicine in 1930.

Early transfusions transferred blood directly from one individual to another. There were no bottles or bags of blood. A pioneer in direct transfusion, George Crile (1864–1943) of Cleveland, described his method in 1906 [64]. His stature and advocacy continued person-to-person transfusion until the blood banks that evolved in the mid 20th century made this obsolete. The availability of banked blood enormously impacted on surgery. Complex operations for vascular conditions, malignancies and many surgical procedures, including organ transplantation, could scarcely have been accomplished without this remarkable development.

Entering the Twenty-First Century

Over 100 years ago, Georg Kelling described the establishment of a pneumoperitoneum, and placement of a trochar through which a cystoscope could be introduced into the abdomen for viewing (laparoscopy) of the abdominal contents. Heinz Kalk, in the early 1930s, popularized laparoscopy using room air to create a pneumoperitoneum [65]. Initially employed by gynecologists, it was not until 1991, that general surgeons began to use laparoscopy. *Erich Muhe* (1938–2005) carried out the first laparoscopic cholecystectomy (gallbladder removal) in Germany [66]. CO₂ replaced room air to create the pneumoperitoneum, CO₂ providing greater safety than air by avoiding catastrophic gas embolism.

As surgeons became more adept with laparoscopic cholecystectomy, the use of laparoscopy for nearly every intra-abdominal operation grew explosively, and it is now the preferred approach for almost all surgeries, including bariatric procedures. Even resections of the liver, which in the

absence of cirrhosis can be carried out by open techniques with a mortality rate as low as 3 %, are now done laparoscopically. Clearly, well-controlled prospective trials to compare open with laparoscopic treatment are required, and many are ongoing today. The primary advantage of laparoscopy is that multiple tiny incisions replace the larger incisions of open procedures, which cause greater post-operative pain and incisional complications such as dehiscence (wound edge separation) and herniation. Lessened post-operative pain is the clearest advantage of laparoscopy and thoracoscopy, often allowing earlier discharge from the hospital and return to work. On the other hand, laparoscopic procedures may be longer and are more costly than open procedures. Robotic surgery has now entered operating rooms and, perhaps driven by marketing, is the method of choice for prostatic surgery. Evidence based medical reports have not uniformly supported better outcomes [67]. It is too early to determine its ultimate role in surgery.

The goal to use ever-smaller incisions has impacted surgeries such as thyroid and parathyroid procedures. Scientific studies are needed to determine whether these are superior to more conventional approaches, or whether their increased use is simply a reflection of the “macho” surgeon.

Anesthesia has increasingly affected surgical practice—and vice versa. Advances in anesthesia made possible the move from in-patient to out-patient and office-based surgery. Advances in anesthesia have enabled performance of even the most difficult surgery in the sickest patients. Drugs with evanescent effect have been developed, drugs that allow precise control of the anesthetic state, including a fast recovery that would have seemed miraculous to the 19th century surgeon—and anesthetist. Computerized records ensure accurate and contemporaneous collection of patient data. Intraoperative monitoring, especially with continuous pulse oximetry and capnography, has ensured an amazing level of safety [68].

Other changes may not be viewed by members of the surgical and anesthetic communities as advances. Increasingly, it seems that surgical practice is dictated by insurance carriers and the legal profession. How these trends will affect the public and medical profession remains to be seen.

Although we cannot describe all who significantly contributed to the development of surgery in the late 19th and 20th centuries, certain important events require mention. These are summarized in Table 15.1.

Integration of Surgery and Anesthesia

Anesthesiologists, in concert with surgeons, have revolutionized post-operative care, especially for patients requiring the special services of an intensive care unit. Anesthesiologists contribute to the origination, development and management

Table 15.1 Surgical Developments in the late 19th and 20th centuries

Date	Contribution	Surgeon/Scientist
1849	Repair, vesico-vaginal fistula	James Sims
1867	Antisepsis	Joseph Lister
1867	Perineal prostatectomy for cancer	Theodor Billroth
1871	Esophagectomy	Theodor Billroth
1873	Total removal of the larynx for cancer	Theodor Billroth
1875	Suprapubic bladder tumor removal	Theodor Billroth
1878	Tracheal intubation	William Macewin
1881	Gastrectomy for stomach cancer (Billroth I)	Theodor Billroth
1882	Radical mastectomy for breast cancer	William Halsted
1882	Successful open cholecystectomy	Carl Langenbush
1882	Drainage of a pancreatic cyst	Carl Gussenbauer
1885	Gastrectomy for stomach cancer (Billroth II)	Theodor Billroth
1886	Asepsis/steam sterilization	Ernst von Bergmann
1888	Repair of aneurysm	Rudolph Matas
1889	Improved inguinal hernia repair becomes the gold standard	William Halsted
1889	Use of surgical rubber gloves	William Halsted
1891	Hemipelvectomy	Theodor Billroth
1894	First use of the anesthetic chart	Codman & Cushing
1895	X-rays discovered	William Roentgen
1901	Discovery of human blood groups	Karl Landsteiner
1901	Visualization of the abdominal contents through a tube	George Kelling
1906	Direct blood transfusion	George Crile
1908	The magic bullet for syphilis	Paul Ehrlich
1909	Development of surgery for thyroid disease	Theodor Kocher
1909	Tracheal insufflation for aeration	Matas & Melzer & Auer
1910	Pituitary tumor removal through the nose	Harvey Cushing
1912	Nobel prize for suturing of blood vessels	Alexis Carrel
1913	Resection of cancer of the esophagus	Franz Torek
1923	Treatment of aortic obstruction	Rene Leriche
1924	X-ray visualization of the gall bladder	Evarts Graham
1928	Observation of effect of penicillin	Alexander Fleming
1932	First sulfonamide	Gerhard Domagk
1933	Pneumonectomy for cancer	Evarts Graham
1935	Resection for pancreatic cancer	Allan Whipple
1939	Closure of a patent ductus arteriosus	Robert Gross
1941	Hormonal influence on prostate cancer	Charles Huggins
1943	Streptomycin discovered	Selman Waksman
1945	Resection of an aortic coarctation	Robert Gross
1946	Endarterectomy for arterial occlusions	J. Cid Dos Santos
1948	Repair of a mitral valve	Harken & Bailey
1951	Resection and graft replacement of aortic aneurysm	Charles Dubost
1953	Successful cardiopulmonary bypass	John Gibbon
1954	Successful transplant of a kidney between two humans	Harrison & Murray
1963	Human liver transplantation	Thomas Starzl
1967	Human heart transplantation	Christiaan Barnard
1983	Cause and treatment of peptic ulcer discovered	Marshall & Warren
1991	Laparoscopic cholecystectomy	Erich Muhe

of intensive care units. Similarly, successful pain management is integral to the early return to normal daily living, and anesthesiologists, again in concert with surgeons, have made major contributions in this area.

Roughly 50–60 years ago, most anesthesiologists were members of a department of surgery, or were hired by surgeons or surgical departments to carry out their work. This lack of independence seriously hampered their ability to rise academically. It became apparent that for anesthesiology to realize its potential, independent departments led by excellent scientists and clinicians were necessary. Many chairmen of surgical departments fought this trend, and when one of the authors of this essay (WS) at the Harvard Medical School elected to recruit a first-class professor of anesthesia, to establish an independent department of anesthesia at the Beth Israel Hospital in 1966, an eminent colleague at another Harvard hospital chastised him for his effort. The attitude exemplified by that surgeon and others, slowed the progress and development of anesthesiology. Fortunately, more thoughtful surgeons properly concluded that the life of the patient was as much in the hands of the anesthesiologist as in those of the surgeon. Today, surgeons and anesthesiologists in separate administrative departments, work effectively in a collegial and supportive manner to the benefit of all, most importantly for the patients they serve.

Summary

Women came slowly to medicine and anesthesia. The first modern woman physician, Elizabeth Blackwell, received her degree in 1849. The University of Zurich Medical School enrolled women in 1867. To increase their opportunities, American women founded 17 medical schools and 7 hospitals in the 19th century, but the move to scientific medicine prompted by the Flexner Report caused closure of all but one after 1910. Men avoided anesthesia because it offered minimal pay and status in the 19th century, but that presented an opening for women such as Herb in Chicago and Botsford in San Francisco at the turn of the century. In 1916, women constituted 19% of the American Association of Anesthetists (AAA) membership, but only 3.6% of physicians were women.

American women physicians were rejected for service as regular officers in both World Wars. In 1920, 3 women chaired anesthesia departments, and the first anesthesia resident, Mary Ross, completed training at the University of Iowa in 1923. Between World Wars, men were favored over women for internships and residencies. Only 4% to 5% of physicians were women. Waters established his residency program in anesthesia at the University of Wisconsin in 1927. Of his first 6 trainees, 3 were women, and one, Apgar, published her eponymous Score, in 1953. Marx entered anesthesia in the late 1930s, becoming the “Mother of Obstetric Anesthesia.”

The Armed Forces in World War II drafted male physicians into anesthesia, many finding that they liked it, leading to competition with females after the war. Industry provided free health insurance during World War II, making anesthesia financially attractive, and further increasing competition from males. And then the tide slowly changed, equalizing the competition. Title IX of the 1972 Higher Education Act banned discrimination in admissions. Female medical students increased from 824 in 1964–65, to 1,295 in 1970–71 and 3,392 in 1974–75. In 2000, 27% of residents in anesthesia were females, but in 2010, 38%.

In 2004, 5 of the 7 major medical specialty organizations (not anesthesia) had female presidents. The ASA's only woman president, Stephenson, served in 1991, but the President elect for 2013 is Jane Fitch. In the 1980s, 6.5% of female anesthesiology faculty, but 17.7% of male faculty, were full professors, a difference not materially changed in the 2000s. Comparing the 2000s to the 1980s, the number of female American Board of Anesthesiology examiners increased. By 2010 the number of female Directors of the Board had increased to 3/12. Women became editors of modern anesthesia journals in 1980 (*Anesthesia and Analgesia*) and 1987 (*Anesthesiology*). By 2011, 4 were editors at *Anesthesia and Analgesia* and 2 at *Anesthesiology*. In 2010, women chaired anesthesia departments at more than a dozen prestigious medical schools. One became dean at the University of Iowa in 2012. This US-focused history had its counterpart in other developed countries, particularly the UK and Australia where women sometimes played greater and earlier roles in governance of anesthesia than did women in the US.

Introduction

No women were physicians when surgical anesthesia was demonstrated in 1846, and few existed as anesthesiology initially developed. By the 20th century however, lack of manpower combined with acceptance of female anesthetists provided an opening that women physicians filled. They be-

came leaders; three women served as presidents of national anesthesia organizations from 1922–1930, when women could not belong to many specialty societies. In 2013, more women than men graduated as physicians, and although an increased number now selected anesthesia, proportionately fewer women became leaders. This story illustrates how history and society affected the place of women in the practice of medicine and anesthesiology. The chapter focuses on the US, because in the modern era, women first became physicians in the US, and because more information documents women's activities in anesthesiology.

A Brief History of Women in Medicine

In 2700 BCE, Egyptian Merit Ptah is said to be the earliest recorded woman physician. For the most part, universities excluded women, although some mediaeval Italian universities trained female physicians. The first modern woman to be awarded a medical degree, US citizen Elizabeth Blackwell (1821–1910), received her degree, in 1849 after a long and difficult struggle [1]. This set the pattern for future women in medicine [2]. Women battled against perceptions of lesser physical and mental competence (smaller brain size), difficulties during menstruation, and conflicts with their traditional roles as wives and mothers. In the 19th century, women felt that they might improve a profession that applied foolish remedies such as bleeding and purging. “Why not prevent disease?”

Women also entered medicine for economic reasons; medicine offered an alternative to a career as a poorly paid teacher, their other major option. Early women physicians were usually unmarried, and they paid for their medical education by teaching. Women could pursue medicine as a career because the youthful US lacked the rigid traditions of European medicine [3]. Medical schools, particularly the many marginal ones, in mid-19th century America had lax admissions policies. It was also easy to establish a medical school. American women founded 17 medical schools and 7 hospitals in the 19th century, providing opportunities for women in medical education that included internships, which became important after the turn of the century [2]. Because these schools and hospitals facilitated the entry of women into medicine, they also facilitated women physicians’ entry into anesthesia. There was geographic skewing of the distribution of women physician anesthetists, California having the most through the 1930s, in no small part because of Mary Botsford (1865–1939), who pioneered the development of anesthesia in the San Francisco Bay Area from 1910 to 1930 [4].

The opportunities for women in America’s medical institutions became known worldwide, and hundreds came to the US for medical training. Such competition may have motivated changes in Europe. In 1867, the University of Zurich became the first modern European school to enroll female medical students. L’École de Médecine in Paris followed in 1868. Such openings prompted some American women to train in the scientifically superior European schools [3].

Regardless of the school’s location, women studying medicine were isolated. Separate lectures for women and men were common in “coeducational” schools, as was social segregation [3]. Women were usually unable to join medical societies. Their professional lives *had* to center on the women’s medical institutions where they had studied.

The Flexner Report of 1910 affected all medical schools and was a crucial factor leading to subsequent closure of all but one of the women’s medical schools (the Woman’s

Fig. 16.1 Overall we see two periods of rapid growth in women physicians as a percentage of the total number of physicians. The first began in the latter part of the nineteenth century and peaked at approximately 1910. The plateau lasted for a half century. Growth increased dramatically with the evolution of the feminist and civil rights movements in the 1960s

Medical College of Philadelphia, now Drexel University College of Medicine, survived) [2]. This report documented the deficiencies of existing medical schools, prompting the transformation of American medical training into the present science-based institutions. Most women’s medical schools could not provide the laboratories, equipment (such as microscopes), or faculty necessary to teach scientific medicine. Few of the remaining medical schools accepted women, and the proportion of women physicians decreased from 6.0% of the physician population in 1910, to 4.4% in 1930 and only returned to 6.1% in 1950 (Fig. 16.1) [2]. During this time, anesthesiology became a specialty. One of the editors of this book (LJS) remembers 9 women in a University of Michigan class of 209 in 1961.

1846 to the End of World War I

The Suitability of Women for Anesthesia

Medical specialization languished until the end of the 19th century, and anesthesia offered minimal attraction. Few operations were done, and anesthetic agents hadn’t changed in a half century. In the US almost anyone (untrained physicians, nurses, medical students, and orderlies) could—and did—give anesthesia. Because anesthesia seemed like a nurse’s job, it had low status and reimbursement was poor. It was difficult therefore, to interest physicians in anesthesia. These issues were summed up in the discussion after a 1918 talk on professional anesthesia by Ralph Waters (1883–1979),

who would lead the move to modern anesthesia. An audience member stated:

“If you get a nurse to give an anesthetic, there is really no inducement for a doctor to make a specialty of it...The reason we have not better men or a larger number of good men giving general anesthetics is that we do not see that they are properly paid.” He added: “I think the main reason that we are having nurses give anesthetics...is the question of money...I am going to pay out anywhere from one hundred to one hundred and fifty dollars a month for anesthesia (by physicians), and if I can hire a girl who will keep my instruments clean, and who will do my office book-keeping, work, etc (as well as give anesthesia), I can get her for about sixty-odd dollars a month.” [5]

Some surgeons thought that women physicians combined the desirable characteristics of nurses—submissiveness and acceptance of lower pay—with the medical knowledge needed to improve surgical outcomes. Albert Ochsner (1861–1943) wrote in his 1920 surgical text that: “The best anesthetics are conducted by women at the present time, because it is possible to select women with the highest degree of intelligence and judgment for this work, while medical men possessing these qualities can almost never be induced to elect anesthesia as a specialty [6].”

It gets worse. Hugh Cabot, Professor of Surgery at the University of Michigan, and Surgeon-in-Chief at University Hospital, Ann Arbor, Michigan, closed the 1927 American Surgical Association meeting with

“I would lay particular stress upon the importance of the selection of (anesthetists). They should always be good-looking... Half of the anesthetic effect, when no anesthesia is used, depends upon the appearance of the anesthetist....” [7]

The First Women Physician Anesthetists

Two women physicians, Isabella Herb (1863–1943) (Fig. 16.2) and Mary Botsford (1865–1939) (Fig. 16.3), committed themselves to anesthesia in the 1890s. Botsford graduated in 1897 from the coeducational Medical Department of the University of California (now the University of California at San Francisco, UCSF), one of 8 women in a class of 59 [8]. She then studied at the Children’s Hospital of San Francisco (CHSF) founded by women physicians in 1875 [5], first as one of 6 interns, and later as a resident [9]. By 1898, she held the title of Anesthetist [10].

Herb graduated in 1892 from the Woman’s Medical College of Chicago. She interned at the Mary Thompson Hospital (founded in 1865 by women physicians), remaining there in various roles, including Superintendent, until 1897 when she moved to the Augustana Hospital in Chicago to practice anesthesia and pathology [11]. The hospital’s surgeon was Oschner, as noted above, an advocate for female anesthetists. By 1900, 13.0% of Chicago’s physicians and 13.8% of San Francisco’s physicians were female, training or practicing at

Fig. 16.2 Isabella Herb was the first woman physician known to specialize in anesthesia. She began her career in 1897 and was the first physician anesthetist at the Mayo Clinic, 1899–1904. (Courtesy of the Olmstead County Historical Society, Rochester, MN.)

the women’s hospitals. Nationally, only 5.6% of physicians were female [2].

As a student rotating to San Francisco’s City and County Hospital (the medical school did not have its own hospital then), Botsford was appalled by the illness that patients suffered with chloroform. Interning at CHSF, she saw equally bad results with ether. A close friend wrote:

“...Botsford...followed me in the surgical service (at CHSF)... She saw patients return from the operating room so saturated from ether that they were ill for a week from the effect of the anesthetic. She told one of the surgeons that she was going to specialize in anesthesia. He replied that she was crazy and could never make a success of it.” [12]

Few operations were done then. For example, CHSF did only 3 operations in December 1903 and 4 the following month [13]. Both women pursued other medical work to survive. Herb practiced pathology, and Botsford maintained a general medical practice [14]. Herb was a widow [11], and Botsford separated from her physician-husband before entering medical school. Until her death, Botsford supported her niece and grand-niece [15].

Fig. 16.3 Mary Botsford, the second known woman physician specializing in anesthesia, at left, instructing an intern at CHSF. (Courtesy of The Bancroft Library, University of California, Berkeley. Call number 1989.058-pic ctn 1)

Herb began her anesthesia career at the Augustana Hospital in 1897, working with Lawrence Prince (1859–1946), a pioneer of open drop ether and chloroform. She was also the hospital's pathologist [11]. She probably earned no income from giving anesthesia because Augustana Hospital was a charitable institution [16]. Similarly, Botsford earned no anesthesia fees from her first five years in practice [12].

Herb published the first paper on anesthesia by a woman physician in 1898 [17]. In 1899, she became the first physician anesthetist (and the pathologist) at the Mayo Clinic. She left anesthesia to pursue pathology in 1904, studying in Europe and conducting research in Chicago, but in 1909 she was appointed chief anesthetist at Presbyterian Hospital and Rush Medical College in Chicago. Arthur Bevan, another surgeon-advocate for women physicians in anesthesia, was chief of surgery. Herb was the first woman on the medical school faculty [11].

No one taught Botsford anesthesia. Making careful observations, she learned by herself what was safe and effective. In 1910, Botsford became "Assistant in Surgery" (responsible for anesthesia) at the new UCSF hospital in San Francisco [18], the city's only officially appointed anesthetist. This, the most prominent hospital in the state, had a single operating room. She received no salary from her academic position, but did develop a lucrative practice among San Francisco's elite at a nearby private hospital. She also continued as anesthetist at CHSF. Unlike many at that time, she recognized the need to add supplemental oxygen to nitrous oxide, and specialized in nitrous oxide-oxygen anesthesia

[19]. She published her first article, on nitrous oxide-oxygen anesthesia, in 1916 [20].

Internships became more important, but after 1900 few hospitals accepted women interns, channeling female medical graduates into the few hospitals that did, primarily the women's hospitals. Working in such institutions, in a specialty "suitable" for women, Herb and Botsford attracted these interns. After anesthesia training with Herb in Chicago, women interns later assumed faculty positions at Rush and the University of Chicago. Anesthesia training with Botsford led interns to positions at UCSF, Stanford, or private hospitals in the San Francisco Bay Area. Stanford, then Cooper Medical School, had a Botsford-trained physician anesthetist, Caroline Palmer (1867–1947), from 1909 [21]. By the 1920s, Botsford or Palmer had trained women physician anesthetists for all but one of the major San Francisco Bay Area hospitals [4]. Herb's and Botsford's efforts attracted a disproportionately large number of women physician anesthetists to Chicago and San Francisco, a skewing of geographic distribution that continued until the 1940s (Fig. 16.4) [4].

Herb and Botsford were also active in the development of local, state, and national anesthesia societies. In 1922, Botsford led the effort to found the Anesthesia Section of the California Medical Association, and was the first president. She successfully lobbied for a state law requiring all interns to learn anesthesia [4]. In 1922, Herb became president of the first nationwide anesthesia society, the American Association of Anesthetists (AAA, founded in 1912 by Francis McMechan) [11]. and in 1930, Botsford was president of the Associated Anesthetists of the United States and Canada, an

Fig. 16.4 The number of women physician anesthetists increased in the figured states after World War I. Note that Herb taught in Chicago and Botsford in San Francisco

organization that evolved from the AAA [4]. Eleanor Seymour (1877–1961) of Los Angeles, was another woman AAA president, in 1922–23 [22]. A 1903 University of Southern California medical graduate, Seymour interned at CHSF in 1903–1904, where she would have been influenced by Botsford. Like Herb, she had also practiced pathology [23]. She led a bitter legal fight in California against nurse anesthetists, and organized the first anesthesia society in Los Angeles, the Southern California Society of Anesthetists [24, 25].

Herb and Botsford were widely known, respected, and a little feared. When considering a move from Indiana to California in 1928, Arthur Guedel (1883–1956) asked Ralph Waters if he should go to Los Angeles or San Francisco. Waters replied,

“Now about San Francisco. I can give you a bit of dope. San Francisco and all the territory around is the private property of Botsford. It’s female and doubtless will remain so, but as I understand it, extremely well handled. She is a bit of a czar on her throne at least that is the impression I have...make friends (but) don’t try to invade her territory.” [26]

Guedel wisely went to Los Angeles.

The Women of the First Anesthesia Organization [27]

A woman physician, Emilie (also Amelia) Schirmer (1872–1951) of Brooklyn, was present in 1905, at the first general meeting in Brooklyn of the Long Island Society of Anesthetists (LISA), the predecessor of the present American Society of Anesthesiologists (ASA). Schirmer practiced pathology as well as anesthesia until the late 1940s. Four more women joined LISA early enough to be Charter Members. All five graduated from a women’s medical college or trained at a

women’s hospital and then practiced at a women’s medical institution. Reflecting the America of that time, all were immigrants (two from Germany, and one each from Austria, Sweden and England). Three were married.

As evidenced by their accomplishments, these were inquisitive and talented, self-taught women. In 1923, 6 months after the discovery of ethylene’s anesthetic properties, Schirmer gave a clinical demonstration of ethylene anesthesia at a joint meeting of East Coast anesthesia societies. Charter member Alma Vedin (1863–1925), was the first female officer of LISA, elected to the Executive Committee in 1918 and later serving as vice president—the first woman officer of a professional anesthesia society. She graduated in 1899 from the Women’s Medical College of the New York Infirmary (NYI), founded by Elizabeth Blackwell, the first modern woman physician. She served as anesthetist at the NYI and, after 1915, at the New York Hospital. That year, she reported 115 cases of endotracheal anesthesia, including thoracic cases [28], at a time when endotracheal anesthesia was seldom used and chest surgery was rare. How she learned these advanced anesthetic techniques is unknown.

The Women Physician Anesthetists of World War I

As measured by membership in professional anesthesia organizations, increasing numbers of woman physicians practiced anesthesia in the decades before World War I. The need to pay membership dues endorsed their commitment to professional anesthesia. Other women physicians also practiced anesthesia, therefore numbers from membership directories probably underestimate the actual number of female physician anesthetists. The American Medical Association’s (AMA) annual directories of physicians began recording who was an AAA member in 1914, when 8 women were AAA members, 9% of AAA membership. Two years later, 15 women were members, 19% of AAA membership [29]. In 1915, only 3.6% of all physicians were women [30]. These data illustrate the relative popularity of anesthesia for women physicians, a popularity confirmed by a survey undertaken by the Council of National Defense’s Committee on Women Physicians, in preparation for World War I. Among women, only gynecology was more popular than anesthesia [31].

World War I revealed an ambivalence concerning recruitment of women physician anesthetists. By 1916, the Army and the Red Cross had organized base hospitals centered at major university hospitals where the staff worked together daily. Surgical units, with nurse or physician anesthetists, were the core of these base hospitals. When the US entered the war in April, 1917, 33 base hospitals were nearly ready; 6 sailed for Europe that month [32]. However, there were no physician anesthetists in the Army [33]. Although women physicians wanted to serve, the Army’s Judge Advocate

General ruled in August 1917 that the term “citizens,” used in 1916 legislation to expand the Army Medical Corps, did not include women. Because they could not vote, they were not considered to be citizens, and because they were not citizens, women could not be commissioned medical officers [31].

Increasing casualties made the Army desperate for anesthetists. Male physician anesthetists were still rare. Nurses were trained in anesthesia as rapidly as possible, but these efforts were insufficient. In March 1918, the Army reconsidered its position, and women physician anesthetists were offered employment as “contract surgeons,” medical specialists hired temporarily. This lowly position had no rank or benefits, no command authority and the pay of a first lieutenant [31].

The Army advertised that: “women between the ages of 23 and 45, born in the United States, who are graduates of reputable medical schools and who are skilled in the administration of anaesthesia, are eligible for employment....” Recruitment was actually broader. If not trained already, women physicians could be sent to “an intensive course of instruction in the administration of anesthetics [34].” Only five of the 16 women physician anesthetists recruited had practiced anesthesia before the war. Only 2 were sent for training, one to the Mayo Clinic and the other to an Army general hospital. Eleven went overseas, at least 2 to forward combat units. Anesthetists were the only female contract surgeons sent overseas [31].

Anne Tjomsland (1880–1968) and Frances Haines (1882–1966) were the first female physician anesthetists to go overseas, both with units formed in 1916: Tjomsland for Bellevue’s Base Hospital No. 1 and Haines for Rush-Presbyterian’s Base Hospital No. 13. Both of these essential members of their units were refused commissions because they were female. Their Base Hospitals’ chief surgeons battled Army bureaucracy to no avail, and both women had to sign on as contract surgeons [31].

There is little information on Tjomsland, but Haines wrote of her war-time experiences. A 1913 graduate of the University of Nebraska College of Medicine, she interned at Chicago’s Mary Thompson Hospital and became an anesthetist in Herb’s department in 1916 [35]. Arriving in France on June 10, 1918, she oversaw anesthesia at a 1,500 bed hospital in Limoges [36]. Ether was in short supply and to conserve the agent, she developed a technique that used its analgesic effects only, something not normally done at the time. This was done with open drop ether, demonstrating Haines’ considerable skill:

“One night in Limoges at 10 PM, I began the anesthetic for the removal of the entire left lung of a soldier whose large arteries, wounded in battle, bled whenever the sterile gauze packing was even partially removed. His heart kept actively beating, right in the field of operation. Had he taken one sudden deep breath, the surgeons’ instruments could have slipped and punctured more blood vessels. I kept the patient breathing quietly and smoothly throughout the operation. The surgeons commended me. The patient recovered.”

Haines also trained enlisted men and corporals to give anesthesia. She served for 16 months as a contract surgeon, the second-longest serving female contract surgeon [31]. Haines published her anesthesia experiences in collections of World War I anesthesia articles [37]. Reports in the medical women’s literature [38], and testimony at Congressional hearings [39] document the expertise of these female physician anesthetists.

After her return, Haines practiced anesthesia in Chicago. She served as president of the Mid-Western Association of Anesthetists in 1926 [40]. Poor health ended her anesthesia practice, and a 1964 radio show on her effort to get an Army pension described a surreal tragedy:

“...Dr. Haines still maintains a tiny, cramped office in downtown Chicago, where, if she’s lucky, she may treat two patients a day. Often she earns as little as a dollar a day. These small fees are hardly worth her making the long bus trip from her small north side apartment each day. But she has no choice. If she doesn’t, she will starve.”

Her Army pension was denied, and she died destitute in 1966 [41].

Finally convinced of women physician anesthetists’ usefulness, the Army established Anesthetic Unit I in September 1918, the only time such a unit title was used. Once overseas, its 7 women physician anesthetists and 2 male medical officers relieved anesthesia staff in various units, especially Base Hospital No. 15 stationed in the Argonne [31].

On home territory, the women contract surgeons were assigned to various Army hospitals, where they gave anesthesia and taught others (primarily nurses) to give anesthesia. Botsford served as a contract surgeon at San Francisco’s Letterman Army Hospital, in addition to teaching anesthesia at the Medical Department of the University of California [42]. This assignment allowed her to continue her private practice and provide for her two dependents. Another woman physician, Rose Bowers of Indiana, was ordered “to report to the Surgical Unit as Anesthetist” at Camp Grant in Rockford, Illinois, just as the 1918 influenza epidemic hit. Within 6 days, the number of hospital beds increased from 610 to 4,102. All military functions ceased, and Bowers spent the rest of the war caring for patients with influenza [43].

World War I provided opportunities for the women physician anesthetists to prove their skills, and they did. Many of these women continued in anesthesia after the war.

1920 to World War II

World War I opened a 19 month window of opportunities for American women to enter medical school and pursue internships, opportunities that lessened with the end of the war. Several other factors also decreased the number of women physicians after the war. American medical schools decreased from 166 in 1904, to 76 by 1930, as marginal schools

closed in the accelerating move to scientific medicine. Most schools imposed a quota, usually 5% or less, for women and minorities such as Jews and African Americans. Admission increasingly required baccalaureate degrees, and the cost of medical education increased, making it unaffordable for many women. In 1920, 5.0% of physicians were women; by 1930, this had decreased to 4.4% (Fig. 16.1). When World War II began, the US had 7,708 women physicians, fewer than in 1910 [44]. And women had trouble obtaining the increasingly required internships. In 1921, 40 of 482 AMA approved hospitals accepted women interns. In the 1930s, 250 female medical graduates competed annually for the 185 internships open to women, while 4,844 male graduates competed for 6,154 positions [30].

Discouraging though this inter-war period was for most women physicians, it seemed attractive for women physician anesthetists. Women were there at the founding of anesthetic institutions and served as leaders in those institutions. Three chaired anesthesia departments in 1920: Herb at Rush, Botsford at UCSF, and her trainee Palmer at Stanford, and these important leaders influenced the geographic distribution of women physician anesthetists, as previously noted (Fig. 16.4). But women physician anesthetists spread throughout the country, appearing in smaller towns, from Oregon to Texas to New York [45].

One change having little immediate effect was passage of the 19th amendment to the Constitution of the US on August 26, 1920, giving women the right to vote. In 1918, the Senate refused to pass the amendment, but women began feeling their power. The National Woman's Party responded by attacking anti-suffrage Senators, suggesting that they should not be re-elected. In 1919, the Senate passed the amendment by 56 votes to 25.

First Resident: Mary Ross of Iowa

Anesthesia residencies as we know them today did not officially exist until 1927, but some physicians sought training in anesthesia. The year after her 1922 medical school graduation from the University of Iowa, Mary Ross (later Gillespie, 1895–1980) trained in anesthesia with Louis Harding (1866–1959), the self-taught physician in charge of anesthesia at Iowa. She received a Certificate of Residency Training in Anesthesia in 1923. This training is considered to be the first formal residency in anesthesia [46].

Dorothy Diamond (also spelled Dimond) (1896–1975), a 1922 medical graduate of the University of Minnesota, interned in 1922–1923 at CHSF, where she would have been taught by Botsford [47]. In 1924–1926, she followed Ross' example of training with Harding. Diamond replaced Harding in 1930 as chief of anesthesia at Iowa, until September 1937. Stuart Cullen, assumed the chair (a Division of Surgery) at Iowa in 1938 [46].

Residents: The Women of Wisconsin

Ralph Waters, considered the father of academic anesthesia in the US, began the residency in anesthesia at the University of Wisconsin (UW) in 1927. This pivotal residency, directly or through its heirs, trained most future leaders of academic anesthesia in the US and several other countries. In the years Waters reigned, women made up 16.4 percent of the anesthesiology residents, a percent exceeded only by women in pediatrics (Fig. 16.5). Waters' first 2 trainees were women, and 3 of the first 6 were women. At the time, this differed from other UW departments which had nearly all male trainees, except for pediatrics [48]. The first 2 anesthesia trainees were single but married while in practice, and could not be traced further in anesthesia [49]. As then expected, they probably stopped practice after marrying.

The third woman trainee, Martha Kohl (1901–1985), illustrates the difficulties then faced by married professional women. She was accepted because of an outstanding recommendation from Waters' close friend, pharmacologist Chauncey Leake (1896–1978), who had recently moved from Madison to San Francisco to chair the pharmacology department at UCSF. After 2 years at the University of Wisconsin medical school, Kohl got a masters' degree in pharmacology working under Leake [50]. She then transferred to Rush in Chicago for her remaining years of medical school and her internship. (Internship was required at Rush before the MD was granted [51].) She wrote to Waters to say that, she was "on the anesthesia service as an intern at Presbyterian Hospital under the direction of Dr. Isabella Herb for four and a half months. I have arranged for at least a month of work in my present internship (at CHSF) in anesthesia under the direction of Dr. Mary Botsford... [52]." She obtained her MD in 1931 [51].

Leake's recommendation also indicated that Kohl had a husband and a child, something not mentioned in Kohl's own letter. She reached Madison on April 4, 1931, but left on July 1, 1932. Writing to Leake in June 1932, Waters observed "she is somewhat uncertain about her family affairs..." and asked if there were opportunities for Kohl in San Francisco [53]. Leake reported that Botsford had 3 good opportunities [54], but Kohl went instead to Eau de Clair, Wisconsin, to general practice, some anesthesia and lots of obstetrics [55]. She had a second baby in November, 1933 [56]. She disappeared from anesthesia directories after 1935. The 1940 AMA directory of physicians listed her as specializing in obstetrics and gynecology [57]. She was licensed in California in 1944, practicing general medicine [58] and divorced her husband in 1945 [56].

A 1942 letter, gave Waters' impression of Kohl:

"...during her service I was considerably disappointed in Leake (for his recommendation). She is good-looking and has brains and is capable, but she proved to be extremely nervous and easily upset...She, however, did a fairly good year's work in

Fig. 16.5 Female and total residents in various specialties at the University of Wisconsin Medical School from 1927 through 1949

spite of physical handicaps...the last time I saw her, she said her husband was in the military service and the care of the children was pretty much up to her..." He also noted she was found to have "some disturbance of the internal secretions and got better with treatment." [55]

Speaking of Kohl again, Waters revealed his aversion to women, including competent women:

"I have a woman resident who has been with me a year and a half who, as women go, is as good as any. Neither you nor I like women, so I presume you would not consider her. She knows, however, inhalation anesthesia in all its phases...with the possible exception of endotracheal work. She can however, do endo and work reasonably well. She can take care of major blocks, has done hundreds of spinals and a significant number of transacrals. She likes to teach, and I think is a good teacher. The only serious objection I have to her is that she is a woman...." [59]

These first 3 female residents were an inauspicious start for the Wisconsin department, failing to elevate Waters' attitude towards medical women. In a letter to Guedel, he wrote "...M.D. ladies...are useless in the profession. I am through with them. Ladies are nice socially but not (as) professionals [60]." Another 5 years passed before a fourth woman trainee came to Madison. Fortunately, she was outstanding.

Virginia Apgar

Virginia Apgar (1909–1974), a unique, charming and charismatic character became America's best-known anesthesiologist, male or female (Fig. 16.6). A 1933 graduate of Columbia University's medical school, she wanted to be a

Fig. 16.6 Anesthesiologist Virginia Apgar attends one of her patients. Her Score ("the Apgar"), published in 1953, easily identified which newborns needed resuscitation. (From National Library of Medicine, <http://profiles.nlm.nih.gov/ps/retrieve/Narrative/CP/p-visuals/true>)

surgeon. But Alan Whipple, chair of surgery at Columbia wanted medical anesthesia at Columbia (only nurse anesthetists gave anesthesia at Columbia then). He saw Apgar as the best candidate to accomplish this, and persuaded her of the wisdom of that course. Apgar wrote to Francis McMechan (1879–1939) (then organizing national and regional anesthesia societies), asking about places to train [61]. McMechan wrote to Waters: "She seems to be an unusually ambitious

person and might prove to be an excellent find for the specialty irrespective of her sex. Do what you can for her [62].” She stayed at Columbia, working with nurse anesthetists during the 2 ½ years it took her to find anesthesia training. She finally came to the University of Wisconsin as a “visitor,” arriving on January 2, 1937 [63]. (“Visitors” were common then; only a few 3-year “resident” positions with room and board were available because of limited state budgets caused by the Great Depression).

Apgar faced the usual problem of housing for women physicians. House staff were poorly paid (Eger remembers getting \$25 per month as an intern in 1955), and free room and board made survival possible. Lack of housing was used to explain the rejection of women house staff, although plenty of housing seemed available for nurses. Apgar initially slept in Waters’ office for 2 weeks and, after moving several times, found a room in the maids’ quarters. She recorded in her diary of being excluded from dinners after anesthesia meetings: “Stag dinner—MAD!” [61] Botsford also recorded her anger at exclusion from similar events.

In September 1937, Apgar returned to New York City as a resident in the new Bellevue program under Emery Rovenstine (1895–1960). At this time, Waters sent his partially trained staff to Rovenstine, to help Rovenstine succeed in a difficult situation. Rovenstine, a Waters’ trainee and former UW faculty member, had rejected Apgar for a training position in April 1936 [64]. Her training with Waters must have made her acceptable this time around. Apgar wrote to Waters as she ended her time at Bellevue, “Did a small bird tell me you are risking two positions on women this next year? I hope you will not be disappointed...please don’t expect anything less of them and make them work like the devil, for there is nothing worse than a poor woman anesthetist [65].” Another woman physician, Mary Lou Byrd (later Cowan, 1911–1994), started residency at Bellevue as Apgar left, so Apgar’s performance must have been satisfactory.

On 1 January 1938, Apgar became Director of the Division of Anesthesia, and Attending Anesthetist at Columbia. Beginning the difficult job of developing academic anesthesia, she followed Waters’ plan, focusing first on medical student teaching, then clinical care, and lastly research. World War II imposed enormous difficulties. In spite of these, she attracted residents, wrote papers, and did research, some with surgeons [61].

Her first 3 residents were men, for she did not immediately want women, writing to Waters in 1938: “If you have any applications for residencies which you cannot use (not women yet) maybe they would like to get a breath of Madison in NYC [66].” She sought advice from Waters for years on the problems she faced as a prominent woman in this developing specialty [67].

Waters probably instigated Apgar’s 1940 selection as treasurer of the American Society of Anesthetists (later the

American Society of Anesthesiologists, or ASA), a position held from 1929 by the powerful but then ailing ASA founder, Paul Wood (1894–1963). Apgar contributed greatly to the stabilization of the fledgling ASA. The organization’s finances were poorly managed; there was no budget, a non-standard method was used for accounting, dues collection was erratic, and the launch of the journal *Anesthesiology* threatened to financially overwhelm the organization. Despite conflicts with Paul Wood, Apgar solved these problems, placing the ASA and the journal on a sound financial basis. Although it was clear that she had done a good job as Treasurer, she was the last woman officer to hold a significant ASA position for 27 years [27].

In the mid-1940s, a crisis arose concerning the state of anesthesia research at Columbia. As at other institutions, clinical demands exceeded the capacities of the available staff, precluding a sustained research focus. Apgar searched for a vice-chair for research, but there were few suitable candidates who wanted to be only a vice-chair. Ultimately, Emanuel Papper (1915–2002) came from Bellevue in 1949 as chief of the division. He became chair of a free-standing department at Columbia in 1952. After a year’s sabbatical leave and now freed from the burdens of administration, Apgar moved laterally into obstetric anesthesia, a neglected area in which she had always been interested [61].

A medical student asked the question at a casual breakfast in the hospital cafeteria: How do you evaluate a newborn baby? “Easy,” Apgar said, and in a moment, wrote down the “Apgar Score”. After testing for validity, it was published in 1953, becoming the world-wide method to evaluate how well newborns made the transition to extra-uterine life. The beauty and power of the Apgar Score was its simplicity; it could be determined easily and quickly, and required no fancy apparatus. She and her team documented that, contrary to previous thought, hypoxia and acidosis were abnormal after birth and should be treated. Low Apgar Scores meant hypoxia and acidosis and indicated a need for prompt resuscitation. Using the Apgar Score and other measures, they found that maternal and neonatal outcomes improved when regional rather than general anesthesia was used for delivery. Thus they began the move to regional anesthesia for obstetrics, incidentally comparing various methods of neonatal resuscitation [68].

In 1959, Apgar became director of the National Foundation’s (previously the March of Dimes) new effort to decrease the incidence of birth defects, later becoming Vice President for Research at the Foundation [61]. Because of her work on newborns, many thought she was an obstetrician or pediatrician, not suspecting that she was an anesthesiologist. Efforts led by the American Academy of Pediatrics and its Neonatal Section resulted in release of a US postage stamp in her honor in 1994, a fitting acknowledgement because Apgar was a dedicated stamp collector [69]. Since 1975, the section has maintained an annual Virginia Apgar Award in Perinatal

Pediatrics. The ASA's Distinguished Service Award, its highest honor, was awarded to Apgar, the first woman to receive it, in 1961 [70].

Another Successful Woman of the 1930s, Gertie Marx

A new source of US women physicians appeared in the 1930s: Jews fleeing Nazi Germany. Anesthesia training positions were available, and many of these immigrants found anesthesia to be their only opportunity. This small group included another notable woman, Gertie (Gesti in German) Marx (1912–2004), the “Mother of Obstetric Anesthesia.” At the University of Frankfurt in Germany in 1931, nearly 40% of her medical school classmates were women, however anti-democratic legislation in 1933 prohibited the graduation of Jews. She completed the final semester for her MD at the University of Bern in 1936, and moved to the US in 1937. She had trouble finding an internship because of the so-called housing problem for women physicians. She found a rotating internship at Beth Israel in New York City when a male intern candidate withdrew and a room then magically opened for her in the student nurses' quarters. Her first rotation was surgery, but this tiny person was too weak to hold retractors. She was instead assigned to anesthesia for the next 4 months, and loved it. Anesthesia became her life's work.

Her long career (she practiced until age 85) focused on obstetric anesthesia. She reintroduced spinal anesthesia for obstetrics, documented the problems and treatments of aorto-caval compression in pregnant patients, advocated epidural analgesia for labor, and in 1969 co-founded the Society for Obstetric Anesthesia and Perinatology [71]. She received the ASA Distinguished Service Award in 1988 [85], and is remembered with great affection as a terrifyingly effective teacher who, Eger says, could skewer you with a question.

Women Chairs End for a While

Apgar and Marx established themselves just as the early women physician anesthetist leaders finished their careers. Botsford retired in 1932 and died in 1939. Herb retired in 1941 and died in 1943. Francis McMechan, the pivotal leader of the AAA, who had strongly supported women physicians in anesthesia, died in 1939. These deaths marked the end of that early era of professional anesthesia. There were still remnants however, women chairs of anesthesia departments, such as they were at the time. In 1940, 4 women chairs were in place: Isabella Herb at Rush, Dorothy Wood (1894–1963) at UCSF (soon to be replaced by Waters-trained Hugh Hathaway), Huberta Livingstone (1905–1980), another Herb trainee, at the University of

Chicago and Virginia Apgar at Columbia. This was down from 5 in 1932: Herb at Rush, Botsford at UCSF, Palmer at Stanford, Livingstone at the University of Chicago and Diamond at Iowa. Julia Arrowood (later Mason, 1900–1984) would be appointed Acting Chair at the Massachusetts General Hospital (MGH) from 1943–45, replacing Henry Beecher (1904–1984), who left for war service [72]. Hers was a difficult position, as MGH epitomized the white male establishment hostile to women. Harvard admitted no female medical students until 1945, and MGH only rarely employed female faculty and interns.

One might argue that these women did not chair free-standing departments, separate from the surgery department, but that was the usual situation then. All but one or two early departments were divisions or sections in surgery. As late as 1965, 40% of US anesthesia “departments” were sections of a surgery department [73]. All the divisions/sections-departments headed by women were organized for didactic and clinical teaching of students, interns and, in some cases, residents. Men replaced the women chairs just before or during World War II, leaving only Apgar at Columbia until 1949, Huberta Livingstone at the University of Chicago until 1952, and Alice McNeal (1897–1964), another Herb trainee, at the University of Alabama at Birmingham from 1948 to 1961. Then there would be none until 1974, when Dola Thompson became chair at the University of Arkansas. A 1949 University of Arkansas medical graduate, she interned with her surgeon-husband at CHSF [74].

World War II

Despite the anticipated need for more anesthesiologists as World War II approached, many anesthesia residencies per-versely excluded women. Residency lists by specialty published in the AMA's annual *Directory of Physicians* did not note exclusion by gender until 1940. That year, 33 hospitals were approved for an anesthesia residency, and only half accepted women applicants. New York City, a major center for academic anesthesia, had 8 approved residencies, but only 3 accepted women. All 3 approved California hospitals accepted women, likely reflecting Botsford's legacy. Women headed 3 residency programs (Stanford, the University of Chicago and Columbia) [75].

In preparation for war, the Army began ordering male medical officers to anesthesia training programs [76]. A Subcommittee on Anesthesia of the National Defense Council was formed in 1940, enlisting prominent male chairmen and ASA leaders. It developed short training courses and the necessary didactic material. In July 1942, the Surgeon General appointed Ralph Tovell as consultant in anesthesia for the European Theater [77]. As in World War I, base hospitals were organized at major hospitals, and these units

planned to include their usual female physician anesthetists, for example Apgar at Columbia (Base Hospital No. 2) and Alice McNeal at Rush-Presbyterian in Chicago (Base Hospital No. 13). (McNeal was a 1921 Rush medical graduate working in Herb's department [78]) And, again as in World War I, women physicians would not be commissioned officers, only less-prestigious and less-paid contract surgeons. Surgeon General James Magee proclaimed in 1942 that "Women should not belong [31]."

Medical women fought back, their argument focusing on the importance of women physicians in anesthesia. Writing to Magee on February 18, 1942, Emily Barringer, president of the American Medical Women's Association (AMWA), used women physicians' status as anesthetists as the main reason to commission medical women:

"The field of anaesthesia is one in which women physicians have excelled and a field where many of the objections to a woman physician do not apply. At the present moment there are two anaesthetists who have applied to your office for permission to serve in the Unit from the Hospital to which they are attached. I refer to Dr. Alice McNeal of Chicago and Dr. Virginia Apgar of New York City. And I am asking you to please be willing to change your mind and appoint these two women in the Medical Reserve Corps, and let them go forward with their Units...By appointing these two outstanding women you will hearten all the women physicians of America...." [79]

Magee resisted, and the units left without their physician anesthetists. The *New York Times* and *Time* magazine reported McNeal's situation to the public [80]. (It is not clear why Apgar's situation was not also publicized.) A nation-wide lobbying campaign for commissions for medical women, especially anesthetists, drew support from unions and charitable organizations. Success came on April 16, 1943, when President Roosevelt signed the Sparkman-Johnson Bill, allowing women physicians to serve in the Army and Navy Medical Corps [2].

However, only 4 women physicians became Army anesthesiologists in World War II, out of 76 women commissioned as medical officers. Two of the 4 attended the new war-time short courses in anesthesia at Bellevue and Walter Reed. The Navy commissioned 57 female physicians, but only 2 were anesthesiologists. Only 1 of the 6 women, Bernice Walters, continued in anesthesia after the war, becoming a career Navy medical officer. She was the first woman physician assigned to a Navy ship in war time, during the Korean War [31]. Another woman doctor, Louise DeVore, was in Honolulu visiting her sister when Pearl Harbor was bombed. She rushed to Tripler Army Hospital to help, and gave anesthesia there for the next nine months as a "United States civil service worker attached to military service." Despite requests from her commanding officer, she was never commissioned [81].

In contrast to World War I, the military did not recruit female anesthesiologists for World War II. Although the numbers of soldiers and sailors serving in the armed forces in

World War II exceeded those in World War I by 4 to 5-fold, only 6 female anesthesiologists served in World War II, in contrast to 16 in World War I. One went overseas (to England), compared to 11 in World War I, when women were placed in front-line situations.

The war-time shortage of men increased medical school, internship and residency opportunities for the available women. In addition to filling slots in established residencies, women became the first residents in new anesthesia programs that were to develop modern, post-war anesthesiology. Margo Deming (1914–1998) was the first resident at the University of Pennsylvania (HUP), beginning in October, 1942 [82]. In 1946 she became the first chief of anesthesia at Children's Hospital of Philadelphia and was a pioneer in pediatric anesthesia. Later she was chief of anesthesia at Philadelphia General Hospital. She was never acknowledged by the department as the first HUP resident [83]. Three women became the first residents at Charity Hospital, New Orleans, in 1941 when John Adriani became chair [84].

World War II changed American anesthesiology to a recognized, prestigious, more affluent and desirable specialty [77]—that left women behind. Many of the men trained in anesthesia by the armed services sought further anesthesia training after the war and filled positions previously held by women. And, the aging, earlier generation of women physician anesthetists was not replaced because fewer women became medical students and physicians. As noted above, men moved into anesthesia after World War II because they had been pressed into service as anesthetists and discovered that they liked the specialty. In addition, the war prompted employers to provide health insurance (wage controls meant they could not attract workers with increased wages). Anesthesiologists got paid just like the professionals they were—he/she sent a large bill. And, the insurance company, not the patient, paid the bill.

1950–2000

The civil rights movement and the Vietnam War began in the mid-1950s and both escalated in the 1960s, affecting many areas of American society, particularly medicine. Laws and legal actions increased the flow of women into medical schools. They included: The Civil Rights Act of 1964 (banning discrimination on the basis of color, religion or national origin), a sex-discrimination law suit against every medical school in the country in 1970, an amendment to the Public Health Service Act (banning employment discrimination in medical and other health professional schools), and in 1972, passage of Title IX of the Higher Education Act (banning discrimination in admissions and salaries in institutions receiving federal funds). Within two years after Title IX passed, women's applications to medical schools

tripled. The number of women accepted to medical schools increased from 824 in 1964–5, to 1,295 in 1970–71 and to 3,392 in 1974–75 [30].

In 1964, the year the Civil Rights Act passed, Apgar described women's status in anesthesiology in a pamphlet published by the American Medical Women's Association for women medical students. It documented the situation for women in anesthesiology as the 1960s began. The final section, "Anesthesiology as a Career for Women," revealed what today might be considered patronizing and sexist stereotypes:

"women were ideally fitted for this specialty because tact and diplomacy are part of their nature (with a few exceptions). Team work comes easily. Manual dexterity is a by-product of those who are expert at sewing or knitting." Apgar discussed the potential problems for women of her time, especially those with children: "Married women anesthesiologists with children are not, in general, popular as members of a group practice. They are, of necessity, less dependable than men."

She noted that women did much of the low-prestige medical student and intern teaching and held few of the higher prestige administrative positions. She ended with statistics: Women constituted 11% of the ASA membership in 1963, but comprised only 6% of the physician population [85], implying that anesthesiology continued to be an attractive specialty for women.

Women medical students and graduates progressively increased in numbers without a parallel increase in acceptance. Ten years after Apgar's pamphlet, Mary Howell, the first woman serving as a dean at Harvard Medical School, wrote a pivotal article, "What medical schools teach about women [86]", on what was happening in medical schools and residencies. The article profoundly influenced women physicians, especially older ones. They realized, many for the first time, that the issues they faced did not have to happen. Memoirs by two women anesthesiologists documented the situation in anesthesiology from the 1960s [87, 88].

As the number of women medical graduates increased, the total number of women in anesthesiology residencies and practice increased, in part a "mass effect" from the increased total numbers of female physicians. From the time of Apgar's observation to the present, the percentage of anesthesiologists who were women has progressively increased (Fig. 16.7). However, on a percent basis (percent of total women physicians who are in anesthesia), entry of women into anesthesia has actually fallen [89]. To many, it seemed that there were no problems for women in anesthesiology, but that was not quite the case.

In the 1980s and 1990s, women anesthesiologists worked to correct the limited presence of women leaders in the organizations that represent anesthesiologists. In 1983, Anne Barlow, then medical director at Abbott Laboratories and president of the American Medical Women's Association

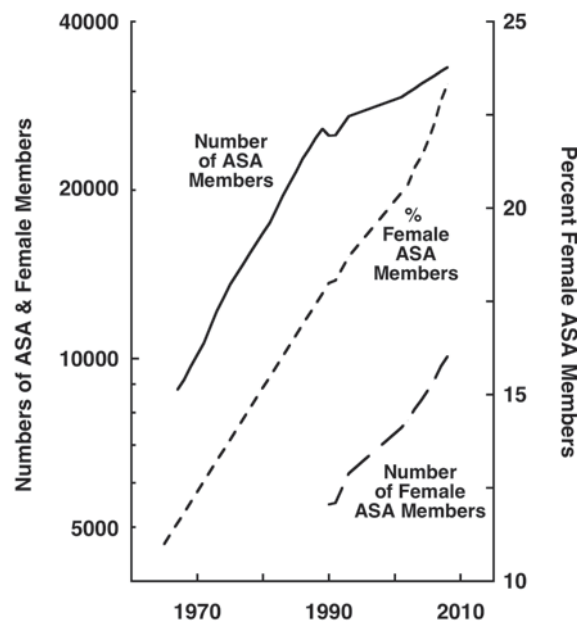

Fig. 16.7 Anesthesia as a specialty in the US grew progressively in the last half of the 20th century. Women anesthesiologists vigorously participated in this growth, females contributing an increasing percentage of the membership of the American Society of Anesthesiologists. (Data from ASA archives generously supplied by Karen Bieterman, MLIS, Manager of the Wood Library-Museum of Anesthesia, Park Ridge, IL.)

(AMWA), convened a group of 20 women anesthesiologist leaders during an ASA meeting. All agreed that a committee on women's issues was needed in the ASA and that male-specific organizational bylaws were a concern.

The next year, Caryl Guth of California surveyed other specialty organizations which were represented in the American Medical Association's House of Delegates and which were the same size as the ASA (then 18,000). All seven had committees on women's issues and had revised their bylaws to be gender neutral. The ASA had neither committees on women's issues nor gender neutral bylaws. Guth wrote to the ASA president-elect in 1986, requesting formation of an ad hoc committee on women and that the ASA sponsor a panel each year on women's issues at the ASA meeting. (Two informal sessions had already been held.) Both requests were denied [90].

In 1986, Wilkinson and Linde published the first analysis of women in academic anesthesiology [91]. This documented the lower academic advancement of women compared to men, and the lower board-certification rate. As Apgar noted 20 years earlier, women were more involved in teaching and patient care, with fewer research and administrative duties. There were 3 women academic chairs, less than there were in 1940.

At the 1986 House of Delegates meeting during the ASA meeting, Texan Betty Stephenson (1927–2006), presented a resolution to degender the language of the ASA's Bylaws.

ASA's Executive Secretary said it would be too burdensome to undertake, and the issue was referred to the bylaws committee (all male), asking, "Do the bylaws need to be degendered?" The answer was "no," reasoning that a footnote on page 1 of the bylaws stated that all masculine pronouns were to be considered gender-neutral. Stephenson became ASA president in 1991, the first and only woman ASA president. Other unsuccessful attempts were made, and the issue festered until ASA President Peter McDermott acted:

"In October 1992, I became ASA president and issued an order degendering the language of ASA bylaws and other documents. It would have been embarrassing to have the issue debated by old white men. I also selected the first woman Rovenstine lecturer—Betty Bamforth—and established the women's forum at the ASA annual meeting that morphed into the Committee on Professional Diversity. My first partner, Kay Belton, sensitized me to gender discrimination, and my three daughters take no prisoners when it comes to asserting the importance of women." (Private communication to S. Calmes and E. Eger, July 28, 2010).

At the 1993 ASA meeting, the California delegation to the House of Delegates proposed formation of an ad hoc committee on women's issues, and it passed. The committee was formed in 1994 as the Committee on Women's Issues [90], renamed the Committee on Professional Diversity in 1996 [92]. It now focuses on all issues of diversity. No other committee or activity in the organization focuses on women.

2000 to the Present

A 2004 survey [27] found that 5 of the 7 major specialty organizations (not anesthesia) had a woman president that year. Two had women immediate past-presidents, and 1 had a woman president-elect. Only the American College of Surgeons had not had a woman president by 2004, but did in 2005–6 [93], and in 2011 has a second woman president [94]. The ASA's single woman president served in 1991, 20 years ago. However, Jane Fitch is the President-Elect for the ASA in 2013. As in Guth's 1984 survey, female contributions to ASA governance differed from that of other equivalent size specialty organizations, making the ASA unique among medical specialty organizations.

A 2008 article on the situation for women in academic anesthesiology [95], the second on this subject, compared 2006 data (the most recent available at that time) to 1985 data, and reported a mixed picture. The percentage of women anesthesiologists progressively increased (Fig. 16.7). Other areas of improvement included the number of female chairs (a 100% increase in a decade) [96], an increased presence of female American Board of Anesthesiology examiners, and an increase in women serving in leadership positions in the increased number of subspecialty anesthesia organizations. These new subspecialty areas led to more opportunities for

women to be leaders. For example, women anesthesiologists have been important leaders in the move to out-patient surgery. Nine of the 22 presidents of the Society for Ambulatory Anesthesia, founded in 1974, have been women [97].

Women first joined editorial boards of the modern anesthesia journals in 1978 (*Anaesthesia and Intensive Care*), in 1980 (*Anesthesia & Analgesia*), and in 1987 (*Anesthesiology*). By 2011, 4 women were editors at *Anesthesia and Analgesia* and 2 at *Anesthesiology*. Nonetheless, a study of the gender of specialty and editorial boards reported found anesthesia was 1 of 6 specialties, out of 21, in which women were significantly under-represented compared to the number of women in the specialty [98].

Of female anesthesiology faculty in 2006, 6.5% were full professors, compared with 17.7% of male faculty. This had not changed significantly since 1986. No other specialty had a lower percentage of women full professors [95]. On the other hand, in 2010 women occupied many prestigious chairs in anesthesia, including those at the Massachusetts General Hospital (Harvard), University of Washington (becoming Dean at the University of Iowa in 2012), Columbia, UCLA, Yale, and SUNY Upstate Medical Center, as well as the University of Arkansas, University of Texas at Houston, Syracuse, Northwestern, University of Nebraska, University of Oklahoma, and New York Medical College. And in 2000, 27% of residents were females; this increased to 38% in 2010.

Contributions by Women Outside the US

The striking differences among countries in opportunities for women in medicine and the differences in the development of professional anesthesia among countries make a world-wide view of this subject difficult. Several consultants outside the US supplied their assessment of the leadership roles women have assumed outside the US. Information was difficult to collect, and some major countries, such as Japan and India, did not contribute. But the numbers in such roles appear to have been limited. As one consultant put it, "...considering the number of women practising anaesthesia in Europe at the present time, there have been very few women of note in the history of anaesthesia outside of the USA." To describe those who have made contributions, we have taken an exemplar approach, citing the contributions and when they were made.

1950–1980

Australia–New Zealand In 1935, Mary Burnell (Fig. 24.9; 1907–1996) became the first female member of the Australian Society of Anaesthetists. In 1953, she was elected president of the Society, the first woman attaining that position.

Fig. 16.8 Pat Mackay was a founding member of the Australian Patient Safety Foundation and President of the Australian Society of Anaesthetists from 1966–1968. She was Chairman of the Victorian Consultative Council on Anaesthetic Morbidity and Mortality from 1991 to 2005, and named 2001 Woman Doctor of the Year. (Courtesy of Dr. Patricia Macay, OAM)

She served as Dean of the Faculty of Anaesthetists, Royal Australasian College of Surgeons in 1966–67, the first female Dean of the Faculty. She had a sense of humor as indicated in a story told by Gwen Wilson: On one occasion,

“after an hour’s fruitless argument and nit-picking over a minor issue, a firm voice said, ‘Mr Chairman, I’ve had a lot of committee experience and I know this committee is both tired and hungry. I propose we go to lunch’. The meeting broke up laughing, and on return after lunch, the matter was settled in less than five minutes.”

Professor Tess Cramond (née Brophy) (1926 -) was the first female Fellow of the Australian Medical Association (AMA). She formed the Pain Clinic at the Royal Brisbane Hospital in 1967 where she directed the Multidisciplinary Pain Centre, now the Professor Tess Cramond Multidisciplinary Pain Centre. She was Dean of the Faculty of Anaesthetists of the Royal Australian College of Surgeons from 1972–3. From 1978 to 1993, she was Professor of Anaesthetics at the University of Queensland, the first female professor of anaesthesia in Australia. Accolades include an Order of the

British Empire (OBE) in 1977, the Gold Medal of the Faculty of Anaesthetists of the Royal Australian College of Surgeons in 1982, an Advance Australia Award in 1986, Officer of the Order of Australia (AO) in 1991, a Red Cross Long Service Award 1994, and the AMA Women in Medicine Award.

Neridah Dilworth established paediatric anaesthesia in Western Australia. She became the first Director of Anaesthetics at Princess Margaret Hospital for Children in December 1960, remaining Director until her retirement in 1992. With Peter Brine, she started the first ICU in Perth. “Physicians and the medical superintendent, who were unable to accept that anaesthetists could care appropriately for critically ill patients” opposed their efforts. The Australian Society of Anesthesiologists Western Australian Section named an award in her honour in 1988. She was awarded a Member of the Order of Australia (AM) in 1993, for services to medicine, particularly in paediatric anaesthesia, subsequently receiving the Australian Society of Anesthesiologists Medal.

While in London in the 1930s, Margaret (Greta) McClelland (1905–1990) documented the adverse interaction between trichlorethylene and soda lime. She returned to Melbourne in 1946, and became the first director of paediatric anaesthesia at the Royal Children’s Hospital. She was President of the Australian Society of Anaesthetists in 1964, and received the OBE in 1975.

Patricia Mackay (nee Wilson; Fig. 16.8) was a founding member of the Australian Patient Safety Foundation. She was Secretary, then Treasurer of the Australian Society of Anaesthetists, becoming President from 1966 to 1968. In 1984, she was appointed Chairman and Head of the Department of Anaesthesia at the Royal Melbourne Hospital, a position she held until 1992. She established the first acute pain management unit in Victoria. She received the Order of Australia Medal (OAM) in the Queen’s Birthday Honours on 9 June 2008, after serving as Chairman of the Victorian Consultative Council on Anaesthetic Mortality and Morbidity (VCCAMM) from 1991 until 2005. As Chairman of VCCAMM she authored the 5th, 6th, 7th and 8th Reports of the Council (in 1993, 1996, 2000 and 2004). In 2000, she was awarded the Australian and New Zealand College of Anaesthetists Medal and shortly later received an award as the Woman Doctor of the Year by the Australian Medical Association.

Gwen Wilson (1916–1998) was one of the first female physicians to specialize in anesthesia in Australia. She has fame as a historian, having authored two books, one on the Australian Society of Anaesthetists, and another on anesthesia in Australia-New Zealand, “One Grand Chain”. She was the first Laureate of the History of Anesthesia awarded by the Wood Library Museum [99].

Israel Florella Magora contributed to the development of intrathecal opioids for the management of pain, being a

Fig. 16.9 Elena Damir was appointed chair of one of the first Russian departments of anesthesiology in 1959. She trained more than 15,000 students in the “Damir School” and was a member of the WFSA Executive for more than 20 years. (Courtesy of Kester Brown.)

co-author of the first report of epidural opioid for the management of postoperative pain [6].

The Netherlands Affectionately known as “The Missus,” Doreen Vermeulen-Cranch (Fig. 16.10; 1915–2011; Amsterdam) trained in the UK during World War II at University Hospital, London, with experience with chest cases at the Brompton Hospital. She was asked to improve anesthesia at Amsterdam’s University Hospital. She was the first trained anesthetist in the Netherlands, convinced the surgeons of the need for professional anesthesia, especially for chest cases, and was appointed Professor of Anesthesiology in 1958. This was the first chair of anesthesiology on the Continent, and the first ever held by a woman in anesthesiology in Europe [100].

Russia Elena Damir (Fig. 16.9) was one of three leaders of Russian anesthesia during the 1950s to 80s, the only prominent woman known at the beginning of Russian anesthesiology. After anesthesia training in Moscow, she went to Copenhagen for the World Health Organization training course. She chaired the Dept of Anesthesia at Botkin Hospital in Moscow from 1959–1998 and was active in the World Federation of Societies of Anesthesiology (WFSA).

Fig. 16.10 Doreen Vermuelen-Cranch was appointed Professor of Anesthesiology in 1958 at Amsterdam’s University Hospital, the first chair of anesthesiology on the Continent, and the first ever held by a woman in anesthesiology in Europe. (Courtesy of Dr. Christine Ball.)

United Kingdom Margaret Manford (1914–2007) focused on pediatric anesthesia at St Helier Children’s Hospital in the 1950s and 60s, doing so when this was not a time of specialization in anesthesia. She had numerous trainees and published a variety of papers with them. She had an affection for the underserved, doing work in the late 1960s in Vietnam and Bangladesh, and after retirement she worked with disadvantaged families in Kent.

1980–Present

Australia–New Zealand Kate Leslie (1962–), Associate Professor at the Royal Melbourne Hospital at the University of Melbourne, is known for her collaborative work on awareness during anaesthesia. She was President of the Australia–New Zealand College of Anaesthetists from 2010 to 2012.

Jeanette Thirlwell (author of this book’s essay on the History of Anesthesia Journals) has been the backbone of the journal, *Anaesthesia and Intensive Care*, since it began under the first editor, Ben Barry, in 1972. She was appointed as As-

sistant Editor in 1978, and remains as the executive editor, supervising all printing and publication.

There is a notable prominence of women as leaders in anesthesia organizations. In 2013, the incumbent president of the Australian and New Zealand College of Anaesthetists is the third woman in a row to hold the position (a two year term), with the current Vice-President (and likely next President), also a woman.

China Ailun Luo, was elected President of the Chinese Society of Anesthesiologists in 1997, She was subsequently elected as a fellow of the Royal College of Anesthetists.

Greece Helena Askitopolou from Heraklion in Crete, is active as a historian of early Greek contributions to anesthesia [101].

Mexico Estella Melman is Professor and Chair; Dept of Anesthesia, Hospital Infantil de Mexico, Mexico, D.F. She has played a prominent role in pediatric and regional anesthesia since the 1970s and authored one of the essays in this book.

United Kingdom Aileen Adams (1923-), an early neuroanesthetist, worked at Cambridge and made several political contributions. She was Dean of the Faculty of Anaesthetists, Royal College of Surgeons of England from 1985–1988. She also was President of the Section of Anaesthetics in the Royal Society of Medicine from 1985–1986 and President of the Section of the History of Medicine from 1994–1995. She was President of the History of Anaesthesia Society from 1990–1992 and the British Society for the History of Medicine from 2003–2005.

Griselda Cooper was recently Vice-President of the Royal College of Anaesthetists (RCA). She was awarded an OBE recently for services to obstetric anaesthesia.

Jean Horton (1924-) is a neuroanesthetist, who worked at Addenbrooke's Hospital, Cambridge. Her teaching in Hong Kong and Lagos improved anesthesia care in those areas. She was a founding member of the History of Anaesthesia Society and was President in 1997–1999.

Judith Hulf, on the faculty at Middlesex Hospital and University College Hospital, London, recently completed her term as President of the RCA.

Jennifer Hunter is currently Professor of Anaesthesia, University of Liverpool where she studied the pharmacodynamics and pharmacokinetics of neuromuscular blocking drugs in health and disease, especially in critically ill patients, and in patients with chronic renal failure and liver disease. She was Editor-in-Chief of the British Journal of Anaesthesia from 1997–2005 and subsequently was made Honorary Chairman of the Board of the Journal.

Jean Lumley at Hammersmith Hospital, London, is presently Vice-President of the RCA.

Reflections on the History of Women Anesthesiologists Outside of the US

These exemplars suggest that female anesthesiologists have made greater progress in the United Kingdom and Australia than in other countries. We cannot say whether this reflects differences in interest or opportunity. It does correlate with the origins of anesthesia and, perhaps with an earlier acceptance of anesthesia as a specialty in the countries of origin. If so, the increasing worldwide acceptance of anesthesia as a specialty suggests that the worldwide prominence of female anesthesiologists will increase in the future.

Concluding Thoughts

In the first few decades of the 20th century, women physicians contributed definitively to anesthesiology in the US, and in some parts of the country women physician anesthesiologists flourished. In part, this resulted from the efforts and vision of two physicians, Mary Botsford and Isabella Herb. In part, it resulted from a perception by surgeons that anesthesia was well-served by the psychic makeup of women. In part, it resulted from an unfavorable view of anesthesia, a specialty not worthy of a male physician's attention.

But there were concurrent opposing factors. Changes in medical education, the decline of women's medical institutions, and increasing technology (adding interest) contributed to the end of anesthesia as "women physicians' work." So did the increased interest in anesthesia by male physicians, exemplified by the great Ralph Waters, who despite his greatness failed to understand the potential of women physician anesthetists. Perhaps that should be surprising. Botsford and Herb had views in the 1900s and 1910s and 1920s that antedated but paralleled those expressed by Waters in the 1930s and 1940s on the development of anesthesiology. All emphasized clinical care, teaching, research, and the development of professional organizations. Botsford and Herb were committed to, and convincingly espoused the critical issues for anesthesia of the time. They were important leaders who were comfortable in their roles as leaders at a time when women were not leaders in any other medical specialty. The two women published articles describing complications, recorded clinical effects of various anesthetic techniques, and analyzed how care might be improved. Both advocated preoperative visits by physician anesthetists and got surgeons to agree. They argued that an understanding and observation of the operation should guide the conduct of anesthesia. Both were charismatic teachers who had medical school faculty appointments (the first ones for anesthesia in their schools), and they educated medical students, interns and residents. Their recruitment of women physicians into anesthesia attests to their ability and charisma.

World War II produced changes that further shifted dominance in anesthesia towards men. Male, but not female, physicians were drafted into the armed services and forced to become anesthetists, like it or not. Many did like it, and they swelled the numbers of male physician anesthetists. The war made anesthesia financially rewarding by providing workers with health insurance benefits that allowed payment to anesthesiologists, and, insult to injury, women physicians couldn't enlist and be trained at no charge as anesthetists, as commissioned officers, until the end of the war. Too late! Most women couldn't benefit from (didn't have a chance to earn) the GI Bill of Rights. Thus male physician anesthetists increasingly dominated anesthesia in the 1940s and 1950s, despite the great contributions of a few women physician anesthetists such as Virginia Apgar.

Then came the 1960s and the 1970s and the confrontation of bigotry. There was and is a good side to bigotry. The anger, sometimes rage, that it generates, the sense of injustice, prompts women and men to civil disobedience and other acts that have transformed the world, a transformation that continues to this day. The primary vehicles of transformation in the US were the 1960s civil rights movement and the feminist movement. These changed the face of anesthesia in the last third of the 20th century and into the 21st century. Some changes are obvious. Women now equal, sometimes exceed, men in medical school admissions (well, they are smarter, and they get better grades, don't they?) As anesthesiologists, they still lag although they've gained ground. Perhaps anesthesiology is less sought after by women, or perhaps until recently there were fewer role models. But that is changing now that women hold the chairs at some of the most prestigious departments in America.

Anesthesiology today differs qualitatively and quantitatively from that developed by Botsford and Herb in the early 1900s. These women from an earlier, simpler time left a legacy that influences today's vastly different specialty which still, however, focuses on teaching, clinical care, and research. It wouldn't hurt to remember that Herb and Botsford led the way a century ago.

Summary

Historically, anesthesiologists have played pivotal roles in medical ethics by developing and applying technology that posed ethical dilemmas, and by their leadership in answering ethical questions and posing new ones. In 1853, Queen Victoria's demand for chloroform for her labor undermined the religious demand that women must suffer the pains of childbirth. In the 1950s, Pope Pius XII consulted with anesthesiologists concerning humane and ethical pursuits centered in anesthesia. In 1957, the Pope supported the treatment of pathologic pain, even though such treatment might shorten life (the "double effect"). In 1973, John Bonica proposed that relief of pain is a basic human right.

Horrible abuses by Nazi physicians during World War II attacked the moral traditions of medicine and medical research. These and subtler unethical actions of honorable researchers led anesthesiologist Henry Beecher in the 1960s to support the development of institutional review boards and informed consent protections for human subjects of research. In 1968, Beecher again advanced medical ethics when his Harvard-based committee defined death in permanently unconscious patients. Robert Truog and other anesthesiologists continue to opine about ethical repercussions of the practice of anesthesiology by the dead donor rule, organ donation after cardiac death, and terminal sedation/anesthesia.

Dutch anesthesiologist Pieter Admiraal has made an ethical case for physician assisted suicide and euthanasia since the 1980s. In 1982, an anesthesiologist recommended what soon became the preferred lethal drug recipe for state-sponsored executions. However, in 2006 the American Society of Anesthesiologists (ASA) condemned physician participation in execution as unethical, and in 2010 the American Board of Anesthesiology threatened rescission of board certification for such unethical behavior.

Throughout the last 25 years, the ASA Committee on Ethics has advanced the cause of ethical medical care by anesthesiologists, particularly through its 1995 *Guidelines for the Ethical Practice of Anesthesiology*. The 1993 *Ethical Guidelines for the Patient with Do-Not-Resuscitate (DNR) Orders or Other Directives That Limit Care* argued for the routinely-neglected ethical right of a surgical patient with an existing DNR directive to refuse resuscitation should a cardiac arrest occur under anesthesia. Other specialties (e.g. the American College of Surgeons) used these documents to develop their ethical guidelines.

In the first decade of this century, a cluster of notorious cases of research and publication fraud by anesthesiologists prompted a coordinated response from the specialty to rectify these unethical breaches.

In their reach across specialty boundaries (pain medicine, critical care, and transplantation) anesthesiologists have contributed to the evolution of medical ethics in the US and abroad, in anesthesia in particular, and medicine in general.

Introduction

The School of Hippocrates [1] advised that the relationship of physicians with their patients should be gentle and pleasant, comforting and discreet. The traditional Hippocratic Oath also suggested the obligations of physicians to their patients—benefit the sick and do them no harm; keep confidences; refrain from exploitation; and show concern and caring—even at a cost to the physician's health and wealth. Then and now, physicians must justify their worthiness of social trust and demonstrate that they deserve so-

cial authority and reward. Societies expect that a physician's primary concern is that of their patients' well being. These three themes—personal character, interpersonal duty and social responsibility—are recurrent topics of ethical reflection, and they constitute the threads that bind medicine and morality, what has become known as medical ethics.

This chapter examines some of the ethical dilemmas unique to anesthesia and considers contributions that anesthesia and anesthesiologists made to the advancement of modern medical ethics as a whole. Because of the specialty's broad scope, with connections to most aspects of medicine, anesthesiologists have played critical roles in the major ethical issues of our age: Should pain be relieved even if treatment may hasten or cause death? Is it ethical to relieve the pain of childbirth? Should anesthesiologists participate in legal executions? How should ethical research be carried out on human subjects?

Anesthesiologists and the Ethics of Birth, Pain, and Death

The ethical history of anesthesiology goes beyond the responses of anesthesiologists to the shifting moral and ethical demands of society, to how they produced and promoted moral change. One example is the role of anesthesia and anesthesiologists in changing Western attitudes towards the pain of childbirth, and the implications of that change for the role of women in society. Another addresses the question of whether relieving pain by administering potentially fatal doses of medication is morally acceptable. A third considers patients who want to forgo life-sustaining medical interventions and the evolving definition of the principle of 'beneficence'¹ in biomedical ethics. These examples touch on fundamental problems: where does life begin and end; when does a person cease to be a person; and is it moral to withdraw life-sustaining therapies at the end-of-life?

Moral Questions About Pain Relief

Labor Analgesia

Traditional stories blame Woman (Eve) for introducing knowledge (sin) into the Garden of Eden. The pain of childbirth served as eternal punishment for this: [2]

¹Beneficence is a moral obligation to act to benefit the patient, to promote the patient's best interests. Originally interpreted to mean "preservation of life," from the late 20th century onward, this obligation was interpreted to mean promoting a 'good quality of life,' and acting with the patient's desires and goals in mind.

Genesis 3:16 Unto the woman He said, "I will greatly multiply thy sorrow and thy conception. In pain² thou shalt bring forth children; and thy desire shall be to thy husband, and he shall rule over thee." [3]

Western culture used these passages to justify the subjugation of women (as the originators of sin) and to rationalize suffering during childbirth. To relieve labor pain neutralized God's justice and repudiated God's dictum that women should be subordinate to men.

Violations of this concept in Western society could have capital consequences. Although efforts to relieve the pain of labor date to the dawn of historic times in Egypt and Persia, [4] in Christian-dominated society, those acting to relieve pain for laboring women might lose their lives. Even requesting labor analgesia could be heresy. In the 16th century CE, Euphemia McCalyean and Agnes Sampson were burned at the stake because Euphemia asked Agnes for something to relieve her labor pains [5, 6].

Fast forward to 1847, a momentous year in a quiet revolution for women. On 19 January, James Simpson, Professor of Midwifery at the University of Edinburgh, became the first physician to use ether to relieve labor pain in the UK [7]. Less than a year later, Simpson discovered the anesthetic property of chloroform and, having determined it to be a superior anesthetic agent, immediately employed it in his obstetric practice. The parents of the first baby he delivered under chloroform, in gratitude, baptized the child 'Anaesthesia.' Some representatives of the clergy criticized this practice as against the will of God. Simpson responded by famously quoting Biblical text supporting anesthesia as a divine invention:

Genesis 2:21 So the Lord God caused the man to fall into a deep sleep and while he was sleeping, He took one of the man's ribs and closed up the place with flesh [3].

The bold actions of three famous families on both sides of the Atlantic Ocean quickly followed Simpson's treatment. On 7 April 1847, Fanny Longfellow, wife of Henry Wadsworth Longfellow, received ether administered by her physician, Nathan Keep, to relieve the pain of labor [8]. The belief that relief of labor pain was against God's will was prominent in rural America in the 19th Century [7], but there was a reason why Fanny would defy Christian edicts. The Longfellows belonged to a precursor of the modern Unitarian Church, which did not believe in original sin, did not believe that relief of labor pain opposed God's will, and held enlightened views of the role of women in society. This would become the leading edge of women's rights in the US, and an early step in a movement that would reach beyond the labor suite.

²Many theologians argue that this translation of the Hebrew text is incorrect, and that the proper word in the second sentence is 'sorrow,' and not 'pain,' as it was originally phrased in the King James Version of the Bible.

In July of the same year, Charles Darwin administered chloroform to his wife, Emma (who also held Unitarian beliefs) [9] for the birth of their seventh child, Elizabeth [10]. And on 7 April 1853, Queen Victoria received chloroform from John Snow for the birth of Prince Leopold [11]. The acceptance of labor analgesia by the monarch, who was also the head of the Church of England, promoted the widespread acceptance of labor analgesia in England and beyond.

Anesthesia arose in an age of evolving liberal views, and obstetrical anesthesia appeared at a time ripe for liberalization of society's view of women. The development of anesthesia and labor analgesia not only resulted from—but also fostered the growth of—enlightened ideas regarding humanism, compassion, and the worth of human life [7]. In 1956, the Pope of the Catholic Church accepted that Christian women could seek pain relief for childbirth, although they should not do so “with exaggerated haste.” [12]

The Moral Acceptability of Pain Relief, and the Principle of Double Effect

The religious imagery of global cultures, including Western civilization, accepts pain as divine punishment. Eastern faiths such as Hinduism describe pain as the result of wickedness in previous lives, and the Abrahamic religions (Judaism, Islam, and Christianity) draw direct relationships between pain and punishment.

Medieval Christian theology glorified martyrdom and man's obligation to accept suffering imposed by God. Was induction of unconsciousness in the pursuit of pain relief a sin against God? And was it morally acceptable to seek to relieve pain if the treatments intended to accomplish relief also risked an unintended shortening of life—the principle of ‘double effect’? At the 1957 Congress of the Italian Society of the Science of Anesthetics, the president, Piero Mazzoni, posed these questions to Pope Pius XII [13]. The Pope affirmed that Christians legitimately used pain treatments, “in accordance with the Creator” to bring suffering under man's control. The Pope agreed that producing unconsciousness for surgery was acceptable, but enjoined that deprivation of consciousness (sedation) in a dying patient for reasons other than to relieve pain was not morally acceptable.

Pain Relief as a Human Right

As advances of modern medicine prolonged lifespan, chronic pain and its attendant suffering became a key factor in determining the quality of life, particularly in the developing world which has less capacity to control pain. The medical profession experienced a heightened ethical impetus to treat pain and suffering, “to develop those dimensions of practice

that seek to heal what cannot be cured ... the physician is both a therapeutic and moral agent, given that any (if not all) clinical decisions affect the vulnerability of the patient, reflecting the asymmetries of knowledge and power between physician and patient, and (thus) impact trust within the medical relationship.” [14]

The founding father of the field of pain medicine, and the driving force in establishing the International Association for the Study of Pain (IASP) in 1973, was John Bonica, professor and chair of the Department of Anesthesiology at the University of Washington (1960–1978) [15]. This visionary figure achieved recognition of the importance of pain as a fundamental element of human suffering, and established the specialty of pain medicine as an international, multidisciplinary scientific effort. His preeminent contribution to medical ethics lay in his championing of pain relief as a human right. In 2004, with the support of the World Health Organization, the IASP issued the first international call for pain relief as a human right, and not merely as a medical issue [16]. Alex Cahana continued carrying Bonica's torch, by advocating at both a national and international level for the consideration of pain as a distinct phenomenon, and not a symptomatic byproduct of disease. He has advocated for the appropriate, measurement-based and safe administration of opioids for chronic pain, and for an enhanced appreciation for the impact that psychosocial elements of pain have on patient outcomes [17, 18].

Ethical Issues at End-of-Life

Forgoing Life-sustaining Medical Interventions

The rapid advances of anesthesia and intensive care in the mid-20th century prompted a succession of moral questions. War and plague contributed to advancements in medical care and ethics. The development of open-chest cardiac massage in World War II (with subsequent modification to closed chest massage and cardiopulmonary resuscitation—CPR), and the need for long-term ventilation of patients suffering from respiratory paralysis brought about by polio, led to further medical and theological dialogues—this time between the World Congress of Anesthesiologists and Pope Pius XII.

Mechanical ventilation had existed before the polio epidemics of the 1940s and 1950s. “Iron lungs” (tank respirators) were intermittent negative pressure chambers in which the patient was placed with their head outside the chamber. The negative pressure expanded the chest, passively drawing gas into the lungs. Long-term therapy was possible—as of 2008, approximately 30 patients still depended on iron lung therapy, one having lived this way for more than 60 years [19]. However, such therapy was expensive, and the limited access to the patient hindered their care.

A crushing polio epidemic struck Copenhagen in 1952, when hundreds of patients succumbed from respiratory paralysis, spurring a search for a new therapy. Anesthesiologist Björn Ibsen suggested supplying manual positive pressure ventilation via tracheal tubes placed through tracheotomies, and delivered by diverse personnel [20]. Over two hundred medical students (backed up by anesthesiologists and dental students) provided “hand ventilation” around the clock to support as many as 75 patients at any one time [21]. The success of their efforts encouraged the development of positive pressure ventilators and intensive care units.

CPR and artificial respiration raised potential moral implications. Were patients or physicians obliged to institute or continue such therapy in hopeless situations? Should such therapy be withdrawn if the family of the patient wished to discontinue it? And when, exactly, was an unconscious patient dead: when they were unable to breathe on their own, or when their heart had stopped beating? Bruno Haid, chief of anesthesia at the surgical clinic of the University of Innsbruck Hospital, posed these questions to Pope Pius II, on behalf of the World Congress of Anesthesiologists in 1957. The Pope’s response acknowledged the broad role of anesthesiologists in medicine, in the relief of pain, and in end-of-life care. In answer to the specific questions, he stated:

“The doctor has no separate or independent right where the patient is concerned. In general he can take action only if the patient explicitly or implicitly, directly or indirectly, gives him permission.” [22]

Further, he said that doctors were not obliged to use modern artificial respiration apparatus, and that the family could morally act only in accordance with the known will of an unconscious patient who is ‘of age.’ He stated that a definition of death “could not be deduced from any religious and moral principle” and “does not fall within the competence of the Church ... It remains for the doctor, and especially the anesthesiologist, to give a clear and precise definition of death ...” [22]

Out of this dialogue would come discussions of how to define death, socially and medically. Henry Beecher, first chair of Anesthesiology at the Harvard School of Medicine would lead these discussions.

Defining Death

In 1968, Beecher received permission to use the Harvard Standing Committee on Human Studies, to examine the issue of declaring death in the permanently unconscious patient. Within a year, his committee published their definition of death in terms of a neurologic standard, in the “Report of the Ad Hoc Committee of the Harvard Medical School to Examine the Definition of Brain Death.” [23] The sole refer-

ence listed in this Committee’s original report was a speech by Pope Pius XII. This Ad Hoc Committee’s Report cited two primary purposes for defining irreversible coma, with no discernible central nervous system activity as a new criterion for death:

“1) Improvements in resuscitative and supportive measures have led to increased efforts to save those who are desperately injured. Sometimes these efforts have only partial success so that the result is an individual whose heart continues to beat but whose brain is irreversibly damaged. The burden is great on patients who suffer permanent loss of intellect, on their families, on the hospitals, and on those in need of hospital beds already occupied by these comatose patients. 2) Obsolete criteria for the definition of death can lead to controversy in obtaining organs for transplantation.” [23]

Beecher had to repeatedly dispute allegations that securing a better supply of organs for transplantation had provided the primary motivation for his committee [24]. His emphasis was antithetical to this contention; instead it developed stringent objective criteria to determine that the patient had died, thus enabling the physician to pronounce a patient dead. While the criteria for brain death promulgated by Beecher’s committee would be modified over the next fifty years, these guidelines have remained the bulwark of the present day’s definition of death.

Physician-Assisted Suicide and Euthanasia

After World War II, physician involvement in euthanasia³ was closely scrutinized because of abuses of prisoners and vulnerable patients by physicians employed by the Third Reich. Expanding medical technology in the latter half of the 20th century also forced a medical profession that had previously been dedicated to preservation of life, at almost any cost, to confront the ethics of end-of-life care. The seemingly endless new means of prolonging life raised ethical and

³“Euthanasia” refers to another party ending a patient’s life at the patient’s request. Currently, it is only legal if it occurs at the patient’s request. It differs from withdrawal of life-supportive therapy or refusal of life-supportive therapy, in that it is active (not passive). “Physician-assisted suicide” (PAS) refers to the use of powers and privileges restricted to physicians and a few other health-related professions (for example, prescriptive privileges) to provide a patient with the means by which they may, at a time of their choosing, end their life. Distinguishing between the two partly relies on asking which party “acted” last. If the physician acts last to inject a lethal substance, then they have committed euthanasia. If the patient acts last to voluntarily ingest a lethal substance, then they have committed suicide. A physician who uses common powers not related to health care (for example, a physician might purchase a gun with which a patient then uses to commit suicide) to assist a suicide is not providing PAS, but merely “assisted suicide.” The differences are significant in that PAS raises questions related to the ethics of the physician’s role in suicide, while assisted suicide does not.

legal debate about patient rights to forgo life-saving medical therapies, and about the role of physicians in end-of-life management. “Euthanasia”, the active ending of a life at the request of the patient, became an issue because unregulated physicians in many Western countries were, quietly and compassionately, actively assisting patients to die.

The Netherlands became one of the first countries to accept the practices of euthanasia and physician-assisted suicide (PAS), ironically so because among occupied countries during World War II, it alone refused to participate in the Nazi euthanasia program [25]. However, by the 1980s, Dutch physicians, like those of many other countries, undertook covert euthanasia in patients who were suffering from incurable disease, and who requested it. The first official study of the Dutch practice of euthanasia—the 1991 Rummelink Report [26]—indicated that PAS and “voluntary euthanasia” (where the patient requests euthanasia) had occurred in about 2,700 patients during the previous year, and “involuntary euthanasia” (where the physician ended a patient’s life without their request) had occurred in 1,300 patients during the same time. Another 8,100 patients died of narcotic overdose that physicians intended to hasten death. All in all, in 1990, physicians deliberately assisted about 9.1% of deaths in the Netherlands.

A prominent Dutch anesthesiologist, Pieter Admiraal, became the major international advocate for euthanasia and PAS, as he pioneered the field of voluntary euthanasia [27, 28]. He was President of the Dutch Society of Anesthesiology, the first president of the Dutch Society for the Study of Pain, and a member of the Committee of Pain and Committee of Euthanasia of the Dutch Health Council. In 1994, he received the royal decoration, Officer Oranje Nassau, and in 2000 he was awarded the Janet Good Memorial Award from the US Hemlock Society. In 2000, partly as a result of his advocacy, the Dutch Parliament legalized euthanasia and PAS under strict conditions, becoming the first Western country to legalize both. Belgium, Lichtenstein and several other countries have since followed suit, and liberalization of laws in Britain, Germany and France is being debated. As in many countries, physicians in the US, such as anesthesiologist Lawrence Egbert, often pushed the legal boundaries to actively assist patients in dying [29].

The Ethics of Research and Publication

Rights of Human Research Subjects; Obligations of Human Subject Researchers

Following revelations of experimentation by Nazi physicians in German prison camps, the world rebelled against abuses in human experimentation. The physicians were tried and convicted at Nuremberg, and the Nuremberg Code

[30] was created, emphasizing the importance of informed consent and voluntariness of human subjects of experiments. The Code forcefully addressed the need to protect human safety, to not experiment frivolously, and to only allow experimentation by qualified researchers. Indeed, the influence of the Code marked “a new beginning in the moral traditions of medicine, a beginning that would become bioethics.” [21] These regulations primarily addressed “physician-researchers” who were not in a therapeutic relationship with their subjects, and therefore, were to be distinguished from “physician friends.” Interestingly, the Nuremberg Code had, over the next decade, little effective influence on American investigators performing research upon human subjects [31].

In the 1950s and early 1960s, US funded research was initiated in earnest, and included both ‘volunteer’ subjects and ‘subject-patients’. Not being patients, volunteers failed to qualify for the fiduciary responsibilities traditionally provided by physicians, and subject-patients risked being harmed by their well-meaning physician’s experiments. Thus, again, the awareness of a distinction between the moral quality of the researcher-physician, and the treating-physician arose [32]. Was the good will of the investigator sufficient to safeguard the rights and welfare of all experimental subjects?

Henry Beecher’s interest in the ethics of human experimentation dated from 1947, when he requested information about Nazi medical experimentation from the Office of the Surgeon General at the War Department [33]. In 1959, Beecher prepared an essay that appeared in the *Journal of the American Medical Association* (JAMA) [34] and broadly distinguished the motives and practices of research from those of therapy, but it received little attention and stirred minimal controversy. He continued to write on informed consent and ethics in human investigations in 1962 and 1963 [35–37].

In 1964, James Shannon, the Director of the National Institutes of Health (which over two decades, had increased the funds available for research by over 600-fold to nearly half a billion dollars yearly) [38], appointed a committee to review the ethics of human experimentation. It concluded that “the judgment of the investigator is not sufficient as a basis for reaching a conclusion concerning the ethical and moral set of questions in that relationship,” thus repudiating a traditional, century-long view. Shannon then declared that the researcher’s judgment must be subject to prior peer review to ensure an independent determination of risks and benefits [39].

In 1966 in a paper published in the *New England Journal of Medicine* (after its rejection by the JAMA), Beecher described examples of abuse in human experimentation [40]. This landmark article contained 22 anonymous but concrete examples of what he considered to be unethical experimentation, many by leading investigators at respected academic institutions (including his own). He did not specifically cite the

examples “for the condemnation of individuals,” but rather with the hope that “calling attention to (the examples) will help to correct abuses present.” [33, 37] While he stated that “thoughtlessness and carelessness, not a willful disregard of the patient’s rights, accounted for most of the cases encountered,” his article nonetheless shocked the medical community by offering an unfavorable exposure of the practice of human experimentation. The fact that this ethical indictment came from such a renowned scientist, and was published strategically in perhaps the most respected medical journal of its time, testified to Beecher’s extraordinary “courage” [31]. In fact, Beecher’s report had a great impact, and without that report,

“the movement to set new rules for human experimentation would have proceeded on a much slower track. Few others had the scientific knowledge and ethical sensibilities to call into question, researcher’s ethics.” [31]

Because of Beecher’s publication, and others, a Presidential Commission was formed to examine the behavior of US medical researchers, and the rights of human subjects. The resulting Belmont Report reiterated the rights of human subjects and proposed formal independent oversight of research, giving birth to the concept of Investigational Review Boards (IRBs) [41]. In 1966, the National Advisory Council of the NIH issued a policy requiring reviews of research proposals by IRBs, a mandate that presently must be followed in all institutions conducting human research.

Beecher kick-started a transition from an insulated research community with minimal internal or external oversight to a medical community requiring informed consent and public oversight of both standard and research medical procedures. His report ultimately overthrew a naïve conception that placed ethical decision-making in the purview of an insular research profession, whose paternalistic practitioners made moral decisions based on their professional training and personal integrity, but not necessarily based on a formal understanding of rules governing morality. However, Beecher believed that the best interests of patients involved in research investigations was served, not necessarily by a code of ethics—or even informed consent (which he thought was an absolute necessity)—but rather by “the presence of an intelligent, informed, conscientious, compassionate investigator.” [40]

The Oaths of Hippocrates and Lasagna

After obtaining his medical degree from Columbia University, Louis Lasagna became a research fellow and then an associate in Beecher’s anesthesia laboratory at the Massachusetts General Hospital. Later acknowledged as the father of clinical pharmacology, Lasagna worked with Beecher in

the early 1950s, on the placebo effects of medications, including the study of the psychotomimetic (not psychedelic) effects of lysergic acid diethylamide (LSD), at that time a legal drug, to investigate subjective responses [42]. This and other army-sponsored research that Beecher, in retrospect, believed to have been unethical, may have prompted his advocacy for the ethical treatment of human research subjects [43, 44]. Lasagna authored the popular Oath of Lasagna, commonly referred to as the contemporary version of the Oath of Hippocrates, and first presented in 1964 [45] while he was at Johns Hopkins. This holistic and humanistic oath had no prohibition against abortion, nor a promise of the physician to abide by the ethical principle of nonmaleficence,⁴ nor an admonition against prescribing a “lethal medicine.” It includes:

“avoiding those twin traps of overtreatment and therapeutic nihilism ... that warmth, sympathy, and understanding may outweigh the surgeon’s knife or the chemist’s drug ... if it is given me to save a life, all thanks. But it may also be within my power to take a life; this awesome responsibility must be faced with great humbleness and awareness of my own frailty ... I do not treat a fever chart, a cancerous growth, but a sick human being, whose illness may affect the person’s family and economic stability.” [45]

Beecher’s thoughts, ideas, and opinions were complex, and occasionally seemingly contradictory and enigmatic, yet inevitably open to his own reconsideration and public deliberation, while participating in the groundbreaking work that was integral to the foundation of clinical ethics. As already noted, he advocated the ethical treatment of human subjects, but he had engaged in potentially unethical work on hallucinogens. Perhaps he was led to champion the ethical treatment of human subjects because of such personal experiences. Another enigma: Beecher knew of the Nazis’ forced experimentation with psychoactive drugs, but in 1959 he opposed the application of the Nuremberg Code to American medical experimentation, and even at that juncture he questioned the concept of informed consent [34]. Yet, nearly a decade later, his evolving bioethical perspective supported a more stringent view of ethical violations in human experimentation, one that ultimately produced IRBs and applied informed consent. Nonetheless, he continued to adhere to the belief that the ethical obligation of scientists might better serve society if it rested with investigators rather than their institutions or standardized regulations.

⁴Abstaining from whatever is deleterious; *primum non nocere* (Latin: “first do no harm”). In modern times beneficence coupled with non-maleficence are considered to be maximizing ethical principles—not simply doing good and avoiding harm, but providing the greatest good and the least amount of harm for the patient.

Research and Publication Fraud

Physicians have a social contract with the public that they serve—a contract that includes the spirit of sacrifice and service to society. They are expected to collectively and individually exercise moral integrity, this behavior fostering the public trust and serving as a structurally stabilizing and protective force. We are aghast and angry when they fail us. In return, physicians retain considerable authority and privilege to control key aspects of the practice of medicine. The medical profession has an obligation to expel those physicians who fail to maintain technical and intellectual competence and the ethical norms of professional integrity. Fraudulent research and publication practices divert and undermine the search for truth, corrupt the scientific literature, and damage the image of scientific investigation as a noble enterprise. Publication of scientific research serves the medical profession's ethical obligation to advance knowledge that benefits patients (beneficence), and discredits harmful or ineffective treatments (nonmaleficence). Falsification and fabrication of data increases the potential for delivery of ineffective or even harmful treatments, and the loss of beneficial treatments. False information can divert other researchers from productive paths of inquiry.

Sadly, in the last decade, several anesthesiology researchers provided some of the largest individual acts of research fraud and misconduct ever detected in the medical literature. An audit in 2008, revealed fraudulent research by American anesthesiologist Scott Reuben, promoting the routine use of postoperative pain medications with theoretically detrimental effects on bone healing in orthopedic patients [46]. After the Baystate Medical Center in Springfield Massachusetts, (the institution in which the fraud had been conducted) announced the fabrication, Steven Shafer, editor-in-chief of *Anesthesia and Analgesia*, listed 21 journal articles (ten from *Anesthesia and Analgesia*, three from *Anesthesiology*) that had been based on that data, and then correctly predicted the retraction of most if not all of them [47]. Reuben was fined and imprisoned.

German anesthesiologist, Joachim Boldt misrepresented key aspects of a published study, including probable fabricated data, on the use of hydroxyethyl starch as a priming solution for cardiopulmonary bypass [48]. The article contained other egregious ethical transgressions, such as failure to gain IRB approval and to obtain informed consent. In an unprecedented international collaboration, the editors of sixteen journals published a collective letter acknowledging that 89 (now corrected to 88) of 102 studies by Boldt had not received IRB approval [49]. Subsequently, the hospital at Ludwigschafen announced its findings in August of 2012 [50], adding that no evidence indicated patient harm consequent to the research. However, of 91 articles examined, study files were incomplete or missing in most; nearly all

had not received IRB approval; and most had no record of informed consent. False data were published in at least 10 of the 91 studies. Boldt was stripped of his professorship, and faces both fines and potential imprisonment, under direction by the State Medical Association of Rhineland-Pfalz which has jurisdiction over such physician misconduct in Germany [51].

More recently, in what may be a record number (approximately 172) of fraudulent publications by a single investigator [52], retractions were announced of virtually all research published by Japanese anesthesiologist, Yoshitaka Fujii. Whereas questions were initially raised about the integrity of his research in 2001 [53], serious investigation did not commence until approximately 2010 [54]. Allegations included lack of IRB approval, failure to follow ethical standards for research, and questions about the veracity of data presented in the papers. Moreover, in some cases, listed co-authors were unaware of being listed, and it is alleged that submission letters to journals contained forged signatures. Once again, a bevy of respected editors from prominent anesthesiology journals, including Shafer, Steven Yentis (*Anaesthesia*) and Donald Miller (*Canadian Journal of Anesthesia*), successfully pursued appropriate investigation at the host institutions, as well as correction in the published literature. Fujii was dismissed from Toho University and almost all of his research retracted. Indeed, the international community of editors for anesthesiology journals is “completely engaged with the process of coordinating our efforts to identify and reduce research fraud. ... It is a team effort. ... Everyone is on board.” [55–57] Importantly, anesthesiologists introduced statistical methodology as a novel tool to identify unnatural patterns of categorical and continual variables in order to identify fabricated data [58, 59]. This expands the armamentarium of editors to detect research and publication fraud far beyond acts of plagiarism [60].

Ultimately, as Beecher stated, the integrity of medical knowledge and advancement of patient care relies on the honest pursuit of ethically designed research, and therefore on the integrity of individual researchers [40].

Anesthesiologists and the State

Lethal Injection

Physicians receive financial benefits and social as well as professional prestige for their skills and their adherence to rules that prevent them from taking advantage of vulnerable persons or using their skills in immoral ways. For most of the history of medicine, the physician has had a role similar to that of a priest or shaman, and hallowed tenets of the medical profession forbid the use of a physician's skills for personal or political purposes or gains.

Use of a physician's expertise for non-medical, state-sponsored activities such as torture, medical incarceration, or executions is forbidden. Physicians may swear ancient oaths to "keep patients from harm or injustice." [1] From ancient times, individual physicians have ignored these principles, and governing states have employed execution for the most serious of human crimes. Ritualistic, even "religious" overtones of executions unite a community in virtue, and separate the condemned from society. Until recently, protracted torture was also a common element of executions that exacted retribution.

Execution methods have evolved to ensure that society's laws and punishments are humane (not 'cruel or unusual'), to prevent prisoners' suffering during the execution process. Physicians have contributed to the development of many modern methods, such as the guillotine (Antoine Louis and Joseph Ignace-Gillotin), hanging (Samuel Haughton) and the gas chamber (Allen McLean Hamilton).

When macabre aspects of many modern execution methods rendered them repugnant to the public, Jay Chapman, a medical examiner, and Stanley Deutsch, an anesthesiologist at the University of Oklahoma, introduced a recipe for a lethal intravenous injection—combining a hypnotic (e.g., thiopental or pentobarbital), a paralyzing agent, and potassium—for the execution of prisoners [61]. This formula was first used in 1982, and became the preferred method of execution in most of the US. It continues to be the subject of ongoing, acrimonious debate among the public, and among physicians in the US.

Participation of individual physicians in state executions is debated as an issue of beneficence (providing a 'humane death' for the prisoner) versus a violation of the principle of nonmaleficence, and an erosion of the physician's professional ethic. However, social action in pursuit of social justice in other Western countries has demonized and eliminated the death penalty. In fact, such actions have reached beyond individual country boundaries. When a shortage of the hypnotic thiopental occurred in the US in 2009, Hospira Inc. exited the market for barbiturates, under pressure from death penalty abolitionists in the European countries where the company's manufacturing plants were sited [62]. An initial attempt by the US to obtain the drug from DreamPharma in the UK, was thwarted when Great Britain banned the export of thiopental for use in lethal injections [63]. More recently, prisons have turned to the use of pentobarbital, a drug also used in veterinary euthanasia [64].

In 2006 anesthesiologists were drawn into the national debate on lethal injection. In California, death row inmate Michael Morales successfully argued that lethal injection might go awry and be cruel, leading Justice Jeremy Fogel to rule that a physician had to be present at all executions to prevent mistakes [65]. Two anesthesiologists, Robert Singler and another identified subsequently as "Anesthesiolo-

gist 2," initially volunteered [66], thinking that they would only monitor the prisoner and declare death. They both withdrew when they learned that, in the event of a mishap, they might have to administer drugs to execute the prisoner. Both claimed that, in contrast with their feelings about declaring death, 'active' participation in the execution itself violated their medical ethical principles. In that same year, a federal judge in Missouri ordered that a board-certified anesthesiologist be present at all lethal injections [67]. The then President of the American Society of Anesthesiologists (ASA), Orin Guidry, declared that:

"Clearly, an anesthesiologist complying with the Missouri ruling—and despite the court's position on ethical obligations—would be violating the AMA position which ASA has adopted. It is my belief that the court cannot modify physicians' ethical principles to meet its needs." [68]

This reflected the ASA's Committee on Ethics statement that executions were not medical activities, that execution by lethal injection is not the practice of medicine (particularly anesthesiology) [69], and that participation in executions would constitute a violation of the ASA's ethical code. Later that year, the mandate for an anesthesiologist's presence at executions in Missouri was reversed, although in 2008, an anesthesiologist who demanded anonymity joined the Missouri execution team, thus violating the ethical guidelines of the ASA [70]. It is not known whether that anesthesiologist is even a member of the ASA. In any case, no disciplinary action could be pursued by the ASA, presumably because the identity of the physician was never released.

Years before the California and Missouri cases, the ASA adopted principles upheld by the American Medical Association [71], which were expounded by Robert Truog's article in the *New England Journal of Medicine* [72]—indicating that participation in lethal injection, including prescribing tranquilizers, monitoring consciousness or vital signs, attending or observing the execution, rendering technical advice or assistance, selecting injection sites, starting IV infusions, preparing the drugs, supervising the injection of lethal drugs, inspecting or maintaining equipment used in the execution, and consulting with or supervising execution personnel, was unethical and violated foundational medical ethical principles. In fact, all medical professional organizations in the US hold that physician participation in state executions is unethical, although as of 2010, no US physician organization had outlined punitive action against any member for providing the means for—or carrying out—state executions.

In 2010, the American Board of Anesthesiologists (ABA) made the historic announcement that not only was participation in lethal injection unethical, but doing so by a board-certified anesthesiologist would be investigated, and that punitive action could result, which might include rescission of board certification [73]. In so declaring, the ABA became

the first physician organization to indicate that it would actually punish physician members who violated its ethical code regarding physician involvement in executions.

Despite a steady opposition by professional medical societies, and anesthesiologist-ethicists, to physician participation in the death penalty [74, 75], some anesthesiologist-ethicists have questioned the ABA edict. David Waisel argues that, whether physicians support the death penalty or not, perhaps anesthesiologists are best positioned to provide humane ‘*euthanasia*’ and should be permitted to do so under specific circumstances. Waisel argued further that humane euthanasia should be available to any individual, regardless of whether or not death is ordered by the state [76, 77].

The future of lethal injection, and of executions in general in the US, is uncertain: for the first time in history less than half of Americans favor capital punishment if life-long incarceration is assured for certain crimes [78]. Whatever the ultimate outcome of the debate, anesthesiologists will continue to have a major role in the debate regarding physician participation in executions—from formulating methods of execution, to potentially being the first specialty to punish its members should they participate.

The American Society of Anesthesiologists Committee on Ethics

The history of the Committee on Ethics of the American Society of Anesthesiologists (ASA) is best understood by reviewing the content of the original “*Guidelines to the Ethical Practice of Anesthesiology*,” dating to the 1960s. These guidelines appropriately included an anesthesiologist’s responsibilities to patients, other physicians, hospitals and nurse anesthetists. It also addressed financial aspects of anesthesia practice, such as fee-for-service rules, billing, and hospital contracts [79]. Credibly, those guidelines, also ruled against exploitation of patients, healthcare personnel and other anesthesiologists; warned against inappropriate prevention of qualified anesthesiologists from securing staff appointments; and promoted billing of reasonable fees, only for services personally rendered. These “ethical” guidelines notwithstanding, in 1977, the Federal Trade Commission (FTC) issued a proposed complaint against the ASA, alleging that the provision in its “ethical guidelines” that prohibited ASA membership by most employed physicians (i.e., those not practicing on a fee-for-service basis) impaired competition and thus violated antitrust laws. In truth, aspects of these guidelines, *at least* in part, were intended both to prevent exploitation of anesthesiologists by institutions, and to protect the best interests of patients from institutional economic interests. The ASA was forced to abandon that so-called “ethical” standard [80].

In the 1960s, the ASA had no committee on ethics, and its *Guidelines to the Ethical Practice of Anesthesiology* received no input from ethicists. In the late 1980s, some anesthesiologists and medical ethicists declared as unethical the common practice of automatically suspending existing Do-Not-Resuscitate (DNR) orders of surgical patients coming to the operating room. The need for the ASA to resolve this issue of not honoring a *patient’s informed refusal* for resuscitation, as well as to decide upon other ethical matters (both past and into the future) led the ASA, in 1992, to establish a formal Committee on Ethics, chaired by Robert Stoelting. The following year and for the next decade, Stephen Jackson assumed the chairmanship, and he was succeeded, chronologically, by Susan Palmer, Gail Van Norman and Jeffrey Jacobs. The Committee on Ethics, a distinguished group of anesthesiologist-ethicists, has over a period of two decades, contributed to medical ethics well beyond its reconstruction and expansion of the ASA’s ethical guidelines for anesthesiologists.

ASA Guidelines for the Ethical Practice of Anesthesiology

The 1992 formal Committee on Ethics re-wrote the ASA *Guidelines for the Ethical Practice of Anesthesiology* [81] to reflect ethical, rather than economic, issues. Guided by the American Medical Association’s Principles of Medical Ethics and by ethical guidelines of other medical as well as non-medical professional organizations, Susan Palmer led the committee in composing guidelines that recognized physician responsibilities to patients, to colleagues, to health care facilities, to themselves and to the community. In so doing, the Committee empowered the ASA to be among the first medical organizations to declare such obligations to include the duty to provide health care to patients regardless of their ability to pay, to advise colleagues whose ability to provide care had become impaired to cease practice, to assist in the rehabilitation (when possible) of impaired colleagues to return to work, and to modify or cease practice if the anesthesiologist’s physical health or ability to practice was in doubt [82].

ASA Ethical Guidelines for Patients with Do-Not-Resuscitate (DNR) Orders or Other Directives that Limit Care

The passage in the US Congress of the Patient Self-Determination Act of 1990 [83] responded to public concerns regarding the lingering authoritarianism and paternalism in the medical profession for decisions about life-sustaining therapies. The law stated that patients have the right to consent to

and to refuse medical therapy, that health care institutions accepting government funding must both recognize those rights and inform patients of them, that institutions cannot then discriminate against patients because they have executed advance directives, and that the institutions must then see that such advance directives *are implemented to the extent permissible under state law*. This important Federal Law focused on a patient's right to refuse medical therapy, including life-sustaining therapy, tacitly recognizing that, without informed refusal, there cannot be *informed consent*.

Federal legislation to the contrary, until the early 1990s, the routine and essentially noncontroversial exception to this covenant was the surgical patient with preoperative DNR orders. As a universal institutional culture, pre-existing DNR orders were automatically suspended upon the patient's entrance into the operating room. Both bioethicists and patient-rights advocates vehemently challenged this violation of patient autonomy, and a flock of commentaries virtually unanimously declared that automatic suspension of DNR orders could not be ethically justified [84–95].

An early task for the newly established ASA Committee on Ethics, therefore, was to develop opinion and guidelines relevant to DNR orders. Led by Perry Fine and Joseph Layon, a task force of the committee created the *Ethical Guidelines for the Anesthesia Care of Patients with Do-Not-Resuscitate Orders or Other Directives that Limit Treatment* [96] that the 1993 ASA House of Delegates adopted, including:

“policies automatically suspending DNR orders ... may not sufficiently address a patient's rights to self-determination in a responsible and ethical manner. Such policies ... should be reviewed and revised.” [96]

These guidelines required reconsideration and renegotiation of the DNR order [97, 98].

At the ASA's prompting, the American College of Surgeons [99] and the Association of Operating Room Nurses [100] soon followed suit with documents that paralleled the ASA's guidelines, advocating for the fundamental right of competent patients to define and limit what treatment would be provided to them in the operating room.

Whereas the original “DNR-in-OR” guidelines detailed specific procedures to avoid in the operating room, in 1998, the ASA Committee on Ethics revised the guidelines to incorporate a goals- and values-directed approach, in which the patient's goals would be outlined, and the anesthesiologist would be allowed more procedural flexibility. The revised guidelines recognized that the context of a cardiac arrest would play a larger role in determining the clinical response that it generates [101–103]. These efforts have gone a long way to draw the anesthesiologist into understanding the autonomous rights of patients in the operating room, but questions remain as to whether the quest for honoring patient autonomy is best served by a goals-directed process that may

introduce, rather than eliminate, ambiguities in decisions about therapeutic interventions [102].

The ASA's “DNR-in-OR” ethical guidelines also considered the moral views of individual physicians, and a means of resolving conflicts that might arise from conscientious objections [96, 104] of the physician to aspects of patient care. Indeed, in order for these guidelines to be ethically whole, anesthesiologists, surgeons and nurses must agree about how to manage ethically and emotionally perplexing scenarios.

Unequivocal enthusiasm did not greet the early efforts by the ASA Committee on Ethics to establish ethical, rather than economic, guidelines for physician behavior. The first proposal of the *Guidelines for Ethical Practice of Anesthesiology* was met with skepticism and at least one comment that the committee ‘Must be made of West-Coast tree-huggers’ (although only 3 of the 13 members of that committee hailed from west of the Rockies) and ‘moon-beamers’ (referring to a past—and present—governor of California).⁵ After publication of the *Ethical Guidelines for the Anesthesia Care of Patients with DNR or other Directives that Limit Treatment*, a proposal was put forth to rescind the guidelines after the question of a lawsuit was raised against an anesthesiologist-member, who had resuscitated a patient against their will.⁶ Despite these political hurdles, both guidelines remain cornerstones of the Committee's work. To this day, the only formal criterion for potential expulsion from ASA membership is failure to observe the guidelines of the Committee on Ethics. This growing role of medical ethics in shaping the specialty of anesthesiology was underscored by the 1999 ASA Annual Rovenstine lecture delivered by anesthesiologist-intensivist-ethicist Carl Hug Jr entitled ‘Patient Values, Hippocrates, Science and Technology.’ [105]

Ethics of Medical Tests

The ethical implications of medical tests, such as genetic testing, have been widely discussed in the literature. However, until recently, professional societies have not formally addressed the ethical implications of routine testing despite the ethical dimensions—those of beneficence and nonmaleficence as well as implications for patient autonomy, privacy, and social justice.⁷ [106]. Preoperative testing for pregnancy,

⁵Personal communication to the then chair of the ASA Committee on Ethics, Stephen Jackson.

⁶Letter of protest to the ASA Committee on Ethics.

⁷Social justice is the distribution of the limited resources made available by society for health care such that the burdens and benefits are borne fairly by others in society. In contradistinction to an individual patient's autonomous medical choices (self determination), distributive justice does not require serving the immediate good of the patient (beneficence). Thus it underscores a physician's obligation to society as well as to the individual.

HIV and hepatitis can introduce complex social implications and potential harms [107, 108]. The ethics of medical testing became of particular concern to the ASA Committee on Ethics when, despite the absence of supportive scientific evidence, the ASA published a Practice Advisory on Pre-anesthetic Evaluation in 2002 that buttressed the practice of unconsented routine pregnancy testing. Citing issues ranging from women's rights to women's autonomy and privacy, and the lack of evidence of medical benefit accruing from routine mandatory pregnancy testing, the ASA Committee on Ethics objected to this unsubstantiated advisory, finding that routine mandatory pregnancy testing may be unethical. The ensuing discussion between the *clinical practice* and the *ethical* arms of the ASA led to an amended Practice Advisory that recommended *offering* pregnancy testing with informed consent [109]. The change reflected both the limited existent scientific information and the ethical considerations involved with preoperative pregnancy testing [107]. In so doing, the ASA took an ethical leadership role that both questioned and limited a heretofore-paternalistic approach in routine medical care.

Council of Medical Specialty Societies' Contemporary Ethic of the Practice of Medicine

The Council of Medical Specialty Societies (CMSS) was created in 1965 to provide an independent, yet collaborative forum for the discussion by medical specialists of issues of national interest and mutual concern. In 1996, as an organization of then 17 (currently 39) national specialty societies, the CMSS established a Task Force to examine the traditional professional ethic of medicine—the attitudes and behaviors of physicians as ethical professionals—in modern healthcare delivery. This effort responded to the question of whether the traditional ethic should be abandoned, or adapted to fit the current realities of health care that, while having become more scientifically deciphered, also had fallen siege to potentially corrupting influences of the profession by public and commercial entities. Moreover, whereas the traditional ethic was rooted in the relationship between physician and patient, contemporary pressures had begun to shift physician responsibility from individual patients to patient populations (and only secondarily to individual patients), and thereby produce the greater good for the greater number of people. As with every ethic, this was likely to overlap with moral guidelines and the law.

It was envisioned that statements or concepts representing a consensus framework for ethical medical practice could be developed for consideration by each specialty society, and serve as a direction and stimulus for further initiatives, as well as a reference for practicing physicians. As the ASA's representative of that Task Force, Stephen Jackson intro-

duced the Task Force to the ASA's recently adopted *Guidelines for the Ethical Practice of Anesthesiology* [81]. The ASA Guidelines became the framework for the consensus statement that the CMSS adopted in 1999 [110]⁸. This document, as with the ASA guidelines upon which it was built, acknowledged that it introduced only some of the values and principles governing the relationship between physicians and their patients, colleagues, organizations/institutions, and the larger society in which they practice. It remains to be determined whether one consensus ethic could guide the entire health care enterprise, as it did in the past, and whether any contemporary ethic based on the physician-patient relationship, would be sufficiently sensitive to the ethical demands of the greatly modified contemporary work environment.

Ethics and Anesthesiologists and the Shape of Things to Come

Anesthesiologists continue to be engaged in the evolving field of medical ethics. Robert Truog has challenged the dead donor rule (DDR), guiding principles in the transplantation of vital organs from one patient to another. He has also raised questions surrounding established practice concerning brain death and the declaration of death in patients providing organ donation after cardiac death (DCD) [111–115]. He brings us, once again, back to Beecher's work [23] on revising the definition of death such that some patients with devastating neurologic injury become ethically and legally suitable for transplantation of their organs under the DDR. Indeed, individuals diagnosed as brain dead “maintain an extensive range of biological functioning of the organism as a whole.” [116–118] Maintaining that the DDR has necessitated “unnecessary and unsupportable revisions of the definition of death,” Truog also opines that the arguments supporting why these patients should be considered dead have never been “ethically convincing.” Indeed, DCD challenges the reliance on the DDR because DCD patients are not brain dead, but rather undergo an orchestrated withdrawal of life support that leads to a cardiac asystole, for which a decision has been made to *not* attempt resuscitation. As the cardiac definition of death incorporates the irreversible cessation of cardiac function, that irreversibility is the consequence of a choice to *not* reverse, and indeed, these patients' hearts have been successfully transplanted. Truog does conclude that “characterizing the ethical requirements of organ donation in terms of valid informed consent [from patients or surrogates] under the limited conditions of devastating neurologic injury is ethically sound,” and even that it is ethical to retrieve vital organs *before* death in such patients, provided that anesthesia is administered.” [119]

⁸ Steve Jackson's personal observation.

The prominent French bioethicist, Sadek Beloucif, has focused on ethics in informed consent for procedures with special societal implications—such as psychosurgery (e.g., lobotomy) and electroconvulsive therapy [120]—as well as patient rights with regard to pain relief, organ transplantation, and issues of self-determination at end-of-life. Beloucif has explored the preeminent ethical issues relating to psychosurgery: their scientific validity, the unique ethical intricacies of the process of informed consent for such interventions, and the potential conflict between the interests of the patient and those of society, particularly for violent individuals. He emphasizes that human dignity is deeply embedded in the concept of free will, as he advocates for ethical safeguards to protect the rights of mentally afflicted patients who present for psychosurgical techniques and functional psychiatric interventions.

The first textbooks of ethics for anesthesiologists, published in 2003 and 2011 [121, 122], addressed topics beyond anesthesiology, and they have relevance to “the domain of other physicians and surgeons,” [123] reflecting the broad reach of the specialty. As one surgeon wrote,

“Although there is room for discussion and disagreement about how truly distinct the ethics of anesthesiology should be from, for example, the ethics of surgery [or any other medical discipline], there should be no disagreement over the importance of addressing ethical issues from the perspective of specific disciplines ... the field of clinical medical ethics requires attention from all specialties in medical practice.” [124]

The specialty of anesthesiology touches on issues from birth to death involving clinical care and research, and even human rights. Medical ethics continues to evolve, shaping the nature of medical care and the kind of practitioners who will care for us in the years to come. Anesthesiologists will continue to shape debate about the intersection of medical science and moral obligations.

Christopher D. Kent and Karen B. Domino

Summary

Heroes from the early history of anesthesia, Davy, Wells, Glover, and Halsted, all displayed a sometimes fatal addiction to inhaled anesthetics, cocaine, or opioids. Even before the 1900s, society debated whether addiction was a disease or an immoral weakness of will. In the 1890s, states (but not the Federal US government) passed anti-morphine laws to stem addiction. Observations at this time indicated that physicians might be at increased risk of addiction. In 1906, the Federal Pure Food and Drug Act banned importation of potentially harmful drugs, and the 1914 Harrison Narcotic Tax Act required the Treasury Department to enforce the law. In the 1930s, the US Public Health Service established drug addiction treatment hospitals having features consistent with a view of addiction as both disease and vice.

In his 1955 treatise on drug addiction among physicians, Marks estimated that roughly "...one out of every hundred physicians in the United States has been, or is, addicted to narcotics...", and several (but not all) observers considered that anesthesiologists were at greater risk than other physicians. In 1975, the Georgia Medical Association funded an Impaired Physician Program to treat impaired physicians. In 1983, it found that anesthesiologists comprised 9.6% of its first 507 patients but made up only 4% of the physicians in the US. Studies from 1983 and 1984 corroborated the Georgia data. Surveys in the 2000s revealed that anesthesiologists frequently abused synthetic opioids, with propofol also emerging as a drug of abuse.

In the 1980s and 1990s, the anesthesia community responded to the addiction "epidemic" with tools for preventing drug abuse, for early detection of abuse, and for assisting in recovery. No study has shown that these tools are effective.

A retrospective survey of anesthesiology program directors in 1983 found a large incidence of relapse with death in anesthesiology residents using parenteral opioids, concluding that such residents should be redirected to an alternative career. However, a 1984 review of addiction among anesthesiologists by Spiegelman and colleagues suggested that 60–80% of addicted physicians sustained recovery after a return to practice, with the same recovery success as that of other physicians. Estimates from treatment programs in the 1990s suggested that up to 70% of addicted health care professionals successfully returned to medical practice, with a sustained recovery among anesthesiologists similar to that of physicians working in other areas. Independent reviews in 1994 and 2005 did not reveal that any patient injury resulted from errors made by impaired anesthesiologists.

The problem of addiction in anesthesia is real and substantial. Although much of the discussion applies to anesthesiologists, parallel problems and solutions appear for nurse anesthetists. For both groups, the history of addiction's causes and management indicates that it is a soluble problem.

Introduction

"It's a poor sort of memory that only works backwards."
—Lewis Carroll from *Through the Looking Glass and What Alice Found There*

Despite what Jefferson Airplane may have implied in their song *White Rabbit*, no evidence indicates that drug use in-

spired the fantastic scenes from Lewis Carroll's stories. This introductory quotation merely reminds us that we need to project what we learn from our memories and history onto the future.

Discoveries and innovations in anesthesia and patient care are largely triumphs of hard work and celebrations of brilliant insights. But much might be learned from darker stories. The history of drug addiction in anesthesia reveals few triumphs, but does provide opportunities for insight, and perhaps redemption, in the stories of the lives affected and sometimes ended by this occupational hazard. Our burden of this disease has made us leaders in the struggle against it. By facing the problem of addiction in our profession, we better

C. D. Kent (✉) · K. B. Domino

insure that our patients do not become additional victims of the disease.

Perhaps no other story in the history of anesthesia evokes such powerful emotional responses from anesthetists. At its heart are fundamental human questions; what are the limits of free will and of responsibility for choices affected by environment and genetics. It raises questions specific to our role as self-regulating professionals. How should we respond to the violation of professional trust? How do we simultaneously protect our patients while assisting and providing a safe second chance for each colleague in recovery? This chapter reviews the history of addiction, particularly as it broadens our understanding of the history of addiction among anesthetists. The review focuses on the medications used in daily anesthetic practice, those to which anesthetists have direct and sometimes unique access. We examine the stages of our recognition, as a specialty, of our problem with addiction, and the history of our evolving response to it.

Some terms we use require clarification. Drug addiction, drug abuse, and chemical and controlled substance misuse can be found in source materials on this topic but are not synonymous. Aside from alcohol, the substances most abused and the primary focus of addictions among anesthetists are opioids, so we frequently employ the terms opioid abuse and opioid addiction. The term narcotic originally meant any drug that produces narcosis or sleep, but now this term refers to substances whose use is legally restricted and includes activating substances such as cocaine, so the term is avoided except in direct quotation.

Finally, we note that the problem of addiction extends to all of the anesthesia community. The present chapter focuses on the problem in physicians. Nurse anesthetists and organizations such as the American Association of Nurse Anesthetists have confronted the same problem (see Chapter 22).

Pioneers in Discovery and Addiction

The story of addiction and anesthesia coincides with the discovery of inhalational anesthesia. In 1795, building on the work of Joseph Priestley, Humphry Davy isolated, contained and inhaled nitrous oxide. He briefly noted nitrous oxide's potential as an anesthetic agent, but as the center of a group of creative luminaries such as the potter Josiah Wedgwood, and the poets Samuel Coleridge and William Wordsworth, Davy focused much of his attention on its recreational use. From 1798 to 1800, Davy inhaled nitrous oxide compulsively, providing evidence for an addiction in this description; "I ought to have observed that a desire to breathe the gas is always awakened in me by the sight of a person breathing, or even by that of an air-bag or an air-holder." Although he eventually controlled his use of the drug and went on to unparalleled success as a chemist (e.g., he discovered the

element sodium), Davy seems to have suffered short term health consequences from its use and the consequent inactivation of methionine synthase from prolonged exposure to nitrous oxide: "increased sensibility of touch: my fingers were pained by anything rough, and the tooth-edge produced from slighter causes than usual. I was certainly more irritable and felt more acutely from trifling circumstances [1]."

Fifty years later, Horace Wells in the U.S. and Robert Glover in the U.K. were not as fortunate as Davy. They lived out parallel stories of thwarted recognition and addiction that led to their deaths. Wells considered himself to be the discoverer of inhalational anesthesia. He provided a proof of concept with nitrous oxide use in his dental practice, and a partially successful demonstration with nitrous oxide in 1845 at the Massachusetts General Hospital. But William Morton's triumph at the same site eclipsed Wells' efforts on what became known as Ether Day in 1846 [2]. The perception that Wells' anesthetic was "humbug" while Morton's was a miraculous success plagued Wells, as he vied, largely unsuccessfully with Morton and Charles Jackson, for recognition as the discoverer of anesthesia. Similarly, Glover felt cheated by James Simpson from the recognition of his (Glover's) discovery of chloroform's anesthetic potential. Glover had published the results of his studies with chloroform in animals 5 years before Simpson's reports of chloroform anesthesia in humans [3].

The greatest tragedy in the lives of Wells and Glover was not the lack of recognition of their roles in the discovery of anesthesia, but their lack of recognition of the consequences of self-experimentation with chloroform. Wells was among the first practitioners to use it in the US but failed to appreciate the hazards that might result from its frequent use. Upon moving to New York City in 1848, Wells advertised his arrival in the *Herald*:

H. Wells, Surgeon Dentist, who is known as the discoverer of the wonderful effect of ether and various stimulating gases in annulling pain, would inform the citizens of New York that he has moved to this city, and will for the present attend personally to those who may require his professional services. It is now over three years since he first made this valuable discovery, and from that time to the present, not one of his patients has experienced the slightest ill effects from it; the sensation is highly pleasurable [2].

Wells asserted that breathing chloroform was "highly pleasurable", a view arising from his frequent personal use of the anesthetic. What may have started as "scientific" experimentation to master the use of chloroform changed to something more sinister. Wells turned from its use as an anesthetic to its use for pleasure.

In an incident in the days leading up to his death, Wells recounted helping a male acquaintance obtain revenge upon a woman by providing sulfuric acid used subsequently to attack her. Three days later, after a prolonged chloroform

binge, Wells apparently went on his own sulfuric acid rampage. Allegedly, he threw acid on two women. He claimed his chloroform-induced delirium impaired his memory of what happened. Wells was arrested and imprisoned. He was tortured by guilt over the effect that his actions would have on his personal and professional reputation, and the reputation of his family. He was escorted to his home to obtain toiletries for his stay in prison, and while there surreptitiously obtained chloroform and a razor. After returning to his cell, Wells wrote to his wife and others outlining his actions and remorse over the events of the preceding days. Then in the desperate isolation of his cell, Wells soaked a handkerchief with chloroform, secured it in his mouth, and slashed an artery in his left thigh. His death was reported as “suicide while under temporary insanity.”

Confounding our ability to make sense of the circumstances surrounding Wells’ death is the contemporaneous report of a police officer who could not find evidence of any women injured in an attack with acid. Nor could the officer find anyone who corroborated the initial testimony of the accusers appearing in court when Wells was arrested [1]. Did Wells die in part as a result of the guilt and shame over hallucinatory experiences produced by chloroform intoxication? Wells’ death tragically parallels the deaths of others who desperately thought that they were trapped by the consequences of their drug use.

Glover’s equally tragic death from addiction was less dramatic and more protracted. He appears to be the first physician with documented poly-substance abuse. He became addicted to both opium and chloroform after treating himself for symptoms associated with dysentery acquired during the Crimean War in 1856. His death followed a slow decline over the next three years from heavy chloroform and opium use and was ruled an “accidental death by overdose of chloroform ingested to produce intoxication.”

William Halsted: Addiction to Cocaine and Morphine

In the first century after the introduction of ether, few physicians dedicated their practice to the delivery of anesthesia. Many who practiced anesthesia were surgeons like William Halsted. While he was a faculty member at Columbia University, Halsted experimented with the use of cocaine as a local anesthetic, demonstrating its capacity to block superficial nerves [4]. He produced plexus anesthesia by direct application of cocaine to the nerves after open dissection and exposure, a lengthy process that should put in perspective present complaints by surgeons about delays associated with peripheral nerve blocks. While developing this expertise, Halsted became addicted to cocaine. The severity of his addiction prompted his closest friend and fellow physician,

William Welch, to take Halsted on a long sea voyage to attempt a cure [5]. Halsted demonstrated the depth of his addiction first by sneaking a stash of cocaine on board and then by breaking into the Captain’s locked medicine chest when his supply ran out.

Following this unsuccessful treatment, Halsted checked into a psychiatric hospital where in addition to the holistic treatments of “seclusion, fresh air, exercise, a healthful diet, and a gradual withdrawal from cocaine” he received morphine to treat the symptoms of cocaine withdrawal—thereby starting his lifelong addiction to morphine. In the first two years of his battle with morphine addiction, he re-entered the treatment facility and struggled to re-establish his reputation as a physician. Despite signs that he secretly used morphine and possibly cocaine for the rest of his life, Halsted became the Chief Surgeon at Johns Hopkins, recognized as both a great surgeon and pioneer in patient safety. In a diary unsealed in 1969, William Osler recounted having seen Halsted suffering from extreme chills. His conversation with Halsted on this subject led Osler to write, “[Halsted] has never been able to reduce the amount to less than three grains [of morphine] daily, on this he could do his work comfortably and maintain his excellent physical vigor.... I do not think that anyone suspected him... [6].” An entry in a letter from Halsted to Osler illustrates Halsted’s good fortune relative to some other colleagues, “Poor Hall and two other assistants of mine acquired the cocaine habit in the course of our experiments on ourselves—injecting nerves. They all died without recovering from the habit [7].”

Addiction: Moral Failure or Disease?

Halsted acquired his first addiction—to cocaine—through self-experimentation with a substance unrecognized as addictive, and his second addiction—to morphine—as treatment for the first. His life-long secrecy on the matter suggests that neither his accidental path to addiction nor the fact that opioids were widely and legally available in patent medicines could mitigate his shame in this matter. The recreational use of opioids in the US in the 19th century was primarily thought to be confined to opium smoking, a practice symbolically associated with Chinese immigrants. The most common path to opioid addiction, however, was through prescription and non-prescription medical use. Opium and its derivatives were used to treat acute and chronic pain, stress, insomnia, and menstrual pain [8].

Although 19th century control over opioid importation and distribution was limited, addiction to opioids appears to have been stigmatized. Some medical literature characterized opioid addiction as a loss of “moral will” or a problem that affected susceptible, weak individuals in the lower social

classes [8, 9]. In a brief chapter on the “Morphia Habit” in his textbook of 1892, Osler wrote, “Persons addicted to morphia are inveterate liars, and no reliance whatever can be placed upon their statements. In many instances this is not confined to matters relating to the vice [10].” Osler’s words have a moralizing tone absent from those used by his contemporary JB Mattison, the medical director of a home in Brooklyn for treatment of opiate addiction. Mattison wrote in 1894, “it is easy to moralize on the weak will—as many, mistakenly, are wont to put it ... but talk about weak will as a reason why strong men succumb to morphia ... is twaddle [11].”

The idea that addiction, starting with alcohol and later encompassing other drugs, is a disease rather than a sign of moral intemperance is more than 2000 years old. References to chronic drunkenness as a sickness of the body and soul, and the existence of specialized roles to care for people suffering from “drink madness” appear in writings from ancient Egypt and Greece [12]. Benjamin Rush (1745–1813), a prominent American physician, advanced this idea, asserting that alcoholism was a disease in which alcohol is the causal agent, loss of control over drinking behavior the characteristic symptom, and total abstinence the only effective cure [13]. Since the 1930s, the successful treatment approaches used by Alcoholics Anonymous and Narcotics Anonymous incorporate the idea that addiction is a disease requiring multi-faceted treatment [14, 15].

In contrast, many societies and individuals, including physicians, held and continue to hold conflicting views as to the idea of addiction as disease. Physicians surveyed by the Treasury Committee’s 1919 report *Traffic in Narcotic Drugs* were almost evenly divided on whether drug addiction was a disease or a vice [16]. This idea of addiction as something other than disease has persisted, as apparent in this statement from a 1962 review article by a psychiatrist purportedly specializing in addiction: “Addiction is caused far more by human weakness than the drugs themselves and from the psychiatric point of view is essentially a symptom of personality maladjustment [17].” Even recently, psychologists and psychiatrists expressed dissenting opinions in response to the Recognizing Addiction as a Disease Act of 2007. This act was intended to change the name of the National Institute on Drug Abuse to the National Institute on Diseases of Addiction and the name of the National Institute on Alcohol Abuse and Alcoholism to the National Institute on Alcohol Disorders and Health. Some may consider this an empty battle over semantics, but therapists resisting the change assert that the disease terminology is bad for the public’s “mental health literacy” and is excessively fatalistic and disempowering, implying that users cannot fully free themselves of their drug or alcohol problems [18].

These opposing viewpoints underlie the conflicting responses to societal and individual problems associated with opioid addiction in US governmental policies, policies that

have sometimes focused on the restriction of access to opioids and enforcement of legal penalties for abuse, while at other times centered on treating a disease. In the 1890s, although no federal laws restricted opioid distribution, various states began to pass anti-morphine laws, ostensibly to stem the rapidly increasing numbers of addicted individuals [8]. Federal regulation of narcotics started with the passage of the Pure Food and Drug Act of 1906 which banned importation of any drug that could be considered harmful to the health of the people [8]. But no practical means of regulating narcotic distribution existed before the 1914 Harrison Narcotic Tax Act that made the Treasury Department responsible for enforcement of the law. This required that physicians, pharmacists, dentists and veterinarians register to dispense certain opioids and cocaine. It made possession of these drugs illegal without a license or a prescription from a licensed professional. Initially, the Supreme Court ruled that the Harrison Act regulated a vice, and that professionals could not dispense opioids solely for the maintenance of an opioid addiction in the absence of another reason such as chronic pain [8].

Although there is a long history of private hospitals, retreats, and homes in the U.S. for the treatment of drug addiction, treatment at the federal level started in the 1930s with establishment of drug addiction treatment hospitals by the US Public Health Service in Fort Worth, Texas and Lexington, Kentucky. Having features of hospitals and prisons, these facilities manifested the divided view of drug addiction as both vice and disease. Drug-addicted individuals convicted of other crimes could be remanded involuntarily for treatment while persons without a criminal record but with a drug addiction could also apply for treatment [8].

Addiction as an Occupational Hazard for Anesthesia Providers

The stigma attached to drug abuse and addiction may compromise our ability to measure the incidence of addiction, particularly among health care professionals. In 1892, Osler noted that physicians who used morphine via hypodermic injection to control pain had a greater incidence of morphine addiction, perhaps the first suggestion of a physician-occupation risk for addiction to opioids [10]. In 1894, Mattison reported that 70% of the morphine-addicted patients in his Home for Habitues were physicians [11]. Of the male morphine addicts treated between 1883 and 1900 in an Ontario treatment center, 35% were physicians [19]. In 1955, Jan Marks published *Doctor Purgatory*, a treatise on the problem of drug addiction among physicians. He provided what appears to be the first estimate of the incidence of addiction among physicians: “It is estimated roughly that one out of every hundred physicians in the United States has been, or

is, addicted to narcotics... [20].” In the United Kingdom, the Home Office recorded the proportion of its citizens known to be drug addicts, in part to establish eligibility for maintenance treatment. According to its records, 21 % of the addicts in 1947 were physicians [21], and in 1956 this figure was 23 % [22], both figures far exceeding the proportion of physicians in the population. Despite these data, some authors writing more recently have concluded that the incidence of drug addiction among physicians remains unknown [23, 24], while others suggest that the prevalence is similar to that in the general public [25].

Some “circumstantial” evidence from the 1990s suggests that anesthesiologists are at greater risk for addiction and abuse than other physicians. This evidence comes from surveys of anesthesiologists, reports from chairs of anesthesia departments, and records from treatment centers, particularly those specializing in treating drug abuse and addiction among physicians. Problems with the surveys include the likelihood of underreporting by affected physicians, and the possibility that the memories of anesthesia chairs may be biased. In contrast, at least one report indicates that resident anesthesiologists do not have a greater incidence of drug abuse than residents in other specialties [26]. The apparent overrepresentation of anesthesiologists in treatment may not be related to an increased prevalence of addiction in the specialty, but to the choice of abused substance [27]. The incidence of deaths related to drug abuse in anesthesia may be greater than in other specialties because the drug of choice, an opioid, has a high addictive risk and low therapeutic index. These factors lead to a relative risk of drug-use-related death of 2.79 in anesthesiologists when compared to a cohort of matched internists, with the greatest frequency of deaths occurring in the first 5 years after graduation from medical school [28].

If anesthesiologists do have a higher risk of addiction, why might that be? Theories include the stress of a demanding career, easy access to addictive substances, and a sense of invincibility stemming from an innate sense of control over our destinies or an exaggerated sense of personal control over potent substances as a result of working with them every day [29]. A 1988 report from providers in treatment programs suggested that individuals predisposed to drug abuse by previous experience and exposure may select anesthesiology for the access to drugs that it provides [30]. Some investigators in the 2000s suggested that exposure to potent opioids through aerosolization and subsequent inhalation primes craving in the anesthesia provider and thereby leads to abuse [31]. Vaporized fentanyl in parts per billion may exist in the air surrounding an anesthetized patient’s head [32]. That such a concentration could exert a subtle but significant long-term priming effect in susceptible individuals seems fantastical; we might equally blame the release of endorphins.

With regard to the written history of drug abuse and addiction specifically among anesthetists, nothing appears

to have been published from the time of Halsted’s story in 1884 (we count Halsted as an anesthesiologist as well as a surgeon), until an article by Bloomquist in 1959 [33]. Bloomquist focused on the problems associated with providing anesthesia for patients with addiction. He also raised concerns about the addiction potential of anesthesia medications, opining that “anesthesiologists are advised to refrain from sampling anesthetic drugs for any reason.” He particularly advised against teaching anesthesia trainees to smell anesthetic gases to check their concentration and content, asserting that this might bring on addiction in susceptible individuals. He reported what might be the first case of a patient harmed by an anesthesia provider’s addiction: a 2 ½ year old child who died while under the care of an anesthesiologist impaired by the inhalation of nitrous oxide and halothane [34].

In 1962, at the request of the American Association of Nurse Anesthetists, John Lundy, an anesthesiologist, and Florence McQuillen, a nurse anesthetist, wrote a review acknowledging (1) the hazards of addiction in the anesthesia work environment; (2) the lack of published information on the topic; and (3) the then reliance on anecdotal reports [35]. The authors surveyed the experience of the American Association of Nurse Anesthetists regarding drug abuse among perioperative personnel. There was a low rate of return on their questionnaires, limiting their value as a comprehensive review of the problem. Notwithstanding this limitation, the survey identified 25 individuals with drug abuse problems: 6 nurse anesthetists, 2 physician anesthesiologists, and 17 other allied health professionals. The most frequently abused medication was meperidine. This corroborated the reported use of meperidine as an abused drug among health professionals from the Lexington Public Health Hospital: 50% of the patients at Lexington addicted to meperidine between 1955 and 1958 were either physicians or allied health professionals. In the Lundy-McQuillen survey, neither of the two addicted physician anesthesiologists and only one of the nurse anesthetists remained in the workplace.

Although problems with addiction among anesthetists surely occurred in the 1960s and 1970s, there is little or no published recognition of its impact. In 1975, the Georgia Medical Association (GMA) pioneered treatment for drug-addicted physicians, funding an Impaired Physician Program (IPP) for the treatment of impaired physicians throughout the country. In a 1983 editorial, Talbott and Farley noted that 9.6% of the first 507 patients in the GMA IPP were anesthesiologists [36], but anesthesiologists comprised only 4% of the physicians in the US [37]. In the same journal, Gravenstein et al. published the results of anonymous surveys sent to the chairs and clinical personnel in 31 academic anesthesia departments [38]. The chairs reported that 1–2% of anesthesia providers abused drugs, with at least 47 drug-abuse-related deaths between 1974 and 1979. Despite the

availability of synthetic opioids, there were still anesthesia providers addicted to inhalational agents (shades of Glover and Wells).

In 1983, Ward et al. [39] surveyed all anesthesia training programs in the US regarding their experience with resident and attending physician drug abuse. Seventy four percent of programs reported at least one incident of drug abuse among the residents or attending physicians during the 10 years under study. Their extrapolation from the number of attendings and residents in the programs surveyed indicated that the incidence of drug abuse among anesthesia providers was 1%. The most frequently abused drugs were meperidine, fentanyl, and morphine. Interestingly, droperidol made the list of abused substances despite reports that it could produce severe dysphoria. Perhaps this abuse was of Innovar, a combination of droperidol and fentanyl. Most impaired physicians in this study were referred for psychiatric care, with few needing detoxification. Detailed follow-up was available for about 40% of the reported incidents; 71 practitioners were offered a return to their original employment; tragically, 30 died of drug overdose.

Two other studies of physician drug addiction treatment programs from 1983 and 1984 corroborated the Georgia data on disproportionate numbers of anesthesiologists in treatment: 13.8% of physicians in the California Diversion Program [40] and 13% in the Depaul Rehabilitation Treatment Program [41]. In 1984, Spiegelman and colleagues published a comprehensive review of addiction among anesthesiologists suggesting that 60–80% of addicted physicians remained successfully in recovery after a return to practice [41]. Based on their personal communications with addiction treatment specialists, Spiegelman et al. suggested that despite their particular work environment, anesthesiologists had the same recovery success as other physicians. This review also provided the strongest statement to date on the impact of drug addiction on the specialty: “The 1979 survey [42] of the causes of death of anesthesiologists concludes that the high mortality rate for suicide appears to be the only major health problem among American anesthesiologists. In fact, it may be more accurate to say that the major health problem associated with the practice of anesthesia is chemical dependency.”

In a landmark study published in JAMA in 1987, updated data from the GMA IPP for the first 1000 patients in the program indicated that the trend first noted in their treatment program had continued—although anesthesiologists comprised only 4% of physicians, they again represented 13% of the physicians in the treatment program [43]. More remarkable were the data for residents in treatment: anesthesia residents constituted 4.6% of all residents, but 45% of the residents in treatment.

The published data on the incidence of drug problems among anesthesiology trainees and attending physicians has remained consistent in recent years. Menk et al. [44] and

Booth et al. [45] reported on the results of their surveys sent to academic anesthesia programs, finding that the incidence of residents with known drug abuse was 2% and 1.6% respectively. Booth also surveyed attending anesthesiologists and once again estimated the incidence of abuse to be 1%. Fentanyl was the most frequently abused substance, but other opioids, benzodiazepines, propofol, thiopental, and inhalational agents were also misused. Ominously, in Booth’s study 18% of the persons abusing drugs were identified by a drug overdose producing death or a near-death event.

Atypical, Emerging, and Reemerging Substances of Abuse

From surveys of anonymous practicing anesthesiologists and from reports of those in treatment, the most frequently abused substances are consistently opioids, especially synthetic opioids. Fentanyl surpassed meperidine as the most frequently abused drug in the 1980s. The history of drug abuse in anesthesia contains stories of abuse that are novel and perhaps surprising in both the manner of abuse and some of the substances involved, e.g., an individual in a motor vehicle accident who was driving while under the influence of enflurane inhaled from a soaked rag [46].

In 18% of departments recently surveyed, propofol emerged as a drug of abuse. This generates an incidence estimate of 10 per 10,000 anesthesia providers per decade [47], a fivefold increase from earlier surveys [39, 45]. Of 25 individuals reported to abuse propofol, 7 died as a result of the abuse, 6 of whom were residents. Volatile agents and propofol are especially problematic in that there is little or no provision for regulating and monitoring the diversion of these substances. Results of a 1993 study suggested the potential for the misuse of propofol, with 50% of the study participants reporting liking the drug [48]. In 2010, the federal government responded to the perception of a growing problem with propofol abuse by proposing to place it in Schedule IV of the Controlled Substances Act [49].

The Response from the Anesthesia Community; Tools for Enhancing Prevention, Early Detection of Drug Abuse, and Recovery

Efforts to prevent drug abuse and detect it before addiction becomes a career- and life-destroying force include provider education, enhanced controlled-substance dispensing systems, and improved drug testing. In 1986, Lecky and colleagues at the University of Pennsylvania developed and published a departmental policy aimed at increasing general awareness and directing actions effectively when dealing with physician impairment [50]. The policy outlined the im-

portance of education and specified that incoming residents receive an introductory lecture on the hazards of substance abuse. These efforts anticipated the mandatory requirement for formal education regarding drug abuse, instituted by the American College of Graduate Medical Education (ACGME) for all residency training programs. In 1993, a group led by Tom Hornbein, then Chair of the University of Washington Department of Anesthesia, supported the production of the video *Wearing Masks* (produced and directed by Dirk Wales), an emotionally powerful tool for increasing awareness of the problem of drug abuse among anesthesia providers and their spouses and partners. The Coalition for the Prevention of Substance Abuse in Anesthesia has continued this work, having produced the *Wearing Masks Series*, a collection of videos that addresses many aspects of the problem, including the issue of the recovering anesthesia provider returning to practice [51].

Lecky's protocol and the Hornbein-Wales films provide excellent and sometimes dramatic illustrations of attempts by the anesthesia community to decrease the numbers of addicted anesthetists and thereby, the number of associated deaths. We do not know, however, whether either is effective. No controlled study has examined whether the protocol or films decrease abuse or death. It is not enough to say that their application should or might be effective. We have had half a century or more to determine whether we can affect the problem of abuse and death. We have not yet done that.

Historically, one of the obstacles to effective intervention was the lack of a urine drug test for the most frequently abused [52] and arguably the most dangerous drugs of abuse for anesthesiologists: fentanyl and sufentanil. The American Society of Anesthesiologists funded the development of a urine drug screen for the detection of fentanyl. In addition, programs using statistical analysis of providers' drug acquisition from dispensing systems have been developed to improve the detection of unusual patterns that might indicate the diversion of controlled substances [53].

Controversy over Returning Recovering Anesthesiologists to Practice

The issue of a return to anesthesia practice for practitioners in recovery has elicited strong opinions and focused discussion. Opponents of the "one strike and you are out" approach suggest that this might discourage affected individuals from seeking early help. Other opponents suggest that the Americans with Disabilities Act mandates an opportunity to return to work with reasonable accommodation [54]. In the middle ground, between the extremes of return to work for all or none, are those investigators looking for predictors and optimization of monitoring and treatment programs to allow an individualized approach.

In the 1990s, the predominant belief was that the high rate of relapse with death in anesthesiology residents using parenteral opioids indicated that they should be redirected to an alternative career. This belief was based upon results from a highly publicized retrospective survey of anesthesiology program directors describing a poor success rate of reentry, with a high death rate for residents using parenteral opioids [40]. Treatment protocols and monitoring methods have changed markedly over the past 2 decades and now include frequent contact for behavioral assessment, random urine testing with observed micturition, and workplace surveillance [43, 55]. Treatment programs now estimate that up to 70% of health care professionals successfully return to medical practice [56], with similar rates of success among anesthesiologists to other physicians, despite their more widespread use of parenteral opioids [56, 57]. A family history of substance use disorder and a co-existing psychiatric disorder, such as depression or a personality disorder increase the risk of relapse [54]. The use of a major opioid only increased the risk of relapse in the presence of a coexisting psychiatric disorder, but not in its absence. These observations should be considered in the decision regarding return to anesthesiology practice of anesthesiologists with substance use disorders.

The concern regarding anesthesia providers in recovery returning to anesthesiology practice also extends to concerns over patient safety. Two separate reviews utilizing different types of databases did not reveal any incidents of patient injury resulting from lapses in vigilance or errors made by impaired anesthesiologists [58, 59]. A controversial article in Men's Health Magazine, and the online correspondence following the article, highlighted incidents of severe patient injury attributed to impaired anesthesiologists [60]. However, the problems described were not related to anesthesiologists with a known substance abuse problem in recovery and in a monitored work environment. Hence, there is little evidence to support the assertion that monitored anesthetists in recovery pose a danger to their patients.

Conclusion

Addiction has been the dark shadow companion of anesthesia since the earliest days of the discovery of the remarkable effects of its central actions. The recognition of the dangers that anesthetic medications pose to anesthetists has slowly developed, with accelerated growth in recent years. Although anesthetists have taken many steps to identify, prevent and treat addiction among the members of the profession, the stigma attached to addiction has added to the complex challenges associated with broadening and deepening our understanding of it. The evaluation of the effectiveness of treatment and monitoring programs for addicted practitioners is limited at best and may, by nature of the problems

faced, always be imperfect. The vigilance that anesthetists apply to their patient care must also include vigilance regarding the possibility of addiction among their colleagues to ensure that more anesthetists do not suffer the tragic fates of some pioneers in the profession.

The American Society of Anesthesiologists' Contributions to the Development of Anesthesiology

19

Peter L. McDermott

Summary

Eight Brooklyn physicians and a medical student founded the Long Island Society of Anesthetists (LISA) on 6 October 1905. LISA became the New York Society of Anesthetists (NYSA), and in 1936, in pursuit of AMA recognition, became the American Society of Anesthetists (ASA). The AMA rejected the ASA's effort. Two highly respected anesthesia leaders, John Lundy and Ralph Waters, asked the American Board of Surgery (ABS) to recognize the American Board of Anesthesia (ABA) as a sub-board. The ABA gained recognition in 1937 and the Advisory Board for Medical Specialties approved this action in 1938.

In 1940, the ASA established the journal *Anesthesiology*. In 1943, the ASA Committee on Fellowship revived the Fellowship process and in 1947, developed the American College of Anesthesiologists. In 1945, the ASA became the American Society of Anesthesiologists. Membership quadrupled between 1940 and 1960. In 1949, Paul Wood's collection of historical materials became the Wood Library-Museum (WLM), with a permanent home at the new ASA offices in 1963.

In 1950, with AMA support, the ASA threatened to deny membership to any salaried physician who allowed a corporation (e.g., a hospital) to offer their services for a fee. However, in 1978, the Federal Trade Commission required that the ASA sign a Consent Decree, agreeing "that an anesthesiologist is free to choose whatever arrangement he prefers for compensation of his professional services."

In 1962, the ASA House of Delegates authorized the ASA Medical Student Preceptorship Program, placing thousands of medical students with practicing anesthesiologists, until the program ended in 1983.

In the mid 1970s, malpractice claims increased and professional liability insurance premiums rose sharply. In 1984, the ASA began studies of closed claims—resolved litigated cases—to learn what underlay adverse outcomes and define solutions to those outcomes. By 1985, Ellison Pierce, ASA Immediate Past President, proposed the creation of The Anesthesia Patient Safety Foundation (APSF), a foundation dedicated to eliminating harm from anesthesia.

In 1985, the ASA established an ad hoc Committee on Industry Relations, to encourage anesthesia-related industries to support ASA activities. This led to the establishment of the ASA Foundation for Anesthesia Education and Research (FAER). In the 1980s, the ASA's Committee on Occupational Health of Operating Room Personnel developed programs for monitoring, education, and intervention that would protect patients and rehabilitate drug-impaired physicians.

Founding of the Society

The world's first anesthesia society, the London Society of Anaesthetists, was founded in 1893. A dozen years later, on the evening of October 6, 1905, eight young Brooklyn doctors and a medical student met to form the second—the Long Island Society of Anesthetists, LISA [1]. Adolph Erdmann (Fig. 19.1) was the driving force behind an American association dedicated to placing "the science of anesthesia

upon its proper plane with the other cognate sciences whose aim is to make man well [1]." From this beginning, through name changes and vast expansions of membership, arose the American Society of Anesthesiologists.

Erdmann was not the first to believe that safe and effective administration of anesthetic agents required knowledge of physical science and medicine, careful calculation of drug dosages and techniques of administration, and the development of equipment for airway management and drug delivery. John Snow had made similar observations a half century earlier but had not acted to form a society, because there were few anesthesiologists. Before LISA's inaugural meeting, Erdmann and his colleagues had concluded that conditions for successful surgery and improved patient

outcomes demanded improved education and training of those who administered anesthetics.

There may have been further motivations to form a society. Historians are wedded to context. In 1905, in America, surgeons directed anesthetic administration by diverse personnel, including nurses, medical students, janitors, secretaries, interns, orderlies – and sometimes physicians. Equipment generally consisted of a vaporizer made from a towel, gauze, or a rag [1]. The administrator’s eye, ear, nose, and fingertips served as monitoring devices. The anesthetist performed a task but hardly practiced medicine. Physicians practicing anesthesia might have wished to separate themselves from those less educated, and to establish qualifications for education and practice, but medical education in the US at the turn of the 20th century was unregulated, patchy, and sometimes almost fictitious. The American Medical Association (AMA) had little influence, and primarily existed during its annual meeting. In 1900, with 8,000 members out of approximately 120,000 physicians in the US, the AMA was an annual occasion rather than an institution. Remarkably however, in 1904, it established the Council on Medical Education which initiated the process of assessing medical schools and their curricula, leading to the revolutionary 1910 Flexner Report on medical education [2]. With support from the Carnegie Foundation, and publication nationally, Flexner’s report radically improved medical education.

No doubt, Erdmann and his colleagues dedicated themselves to promoting “the art and science of anesthesia”[3], but we need not accept this statement as explanation in full. A cynic of today, condescending to the past might ask—what art and what science? But there were techniques and tricks and a knowledge of physics and chemistry that could be shared. The same cynic might ask if Erdmann and his colleagues were driven by greed (money) and hunger for power, or unearned status or respectability? The historical record does not overflow with admissions of self-interest. We do know that physicians were modestly paid, their annual income averaging \$750 according to AMA surveys [2]. The profession lacked control over the practice of individual physicians, the respective states controlling the profession through licensure and review boards. Whatever interests physicians shared, whatever their competing loyalties, they were, perhaps unconsciously, discovering a new identity. E. P. Thompson, in his *The Making of the English Working Class*, describes the way in which awareness of belonging to a class or group follows the struggle to clarify relationships in terms of values and moral agency:

Class happens when some men, as a result of common experiences (inherited or shared), feel and articulate the identity of their interests as between themselves, and as against other men whose interests are different from (and usually opposed to) theirs [4].

LISA established its identity in the February 1907 issue of the *Long Island Medical Journal*, with eight articles on anesthesia practices and techniques, as revealed in the Table of Contents:

1. Spinal Anesthesia
2. The Techniques of Tubation of the Pharynx to Facilitate Administration of Anesthetics
3. Major Surgery with Minor Anesthesia
4. Conditions Governing the Selection of General Anesthesia
5. Nitrous Oxide and Gas-Ether Sequence for Inducing Anesthesia, with Special Reference to the Bennett Apparatus
6. The Chloroform and Ether Solution for Anesthesia
7. Ethyl Chloride and the Newer Anesthetics, Some Personal Experiences
8. Ethyl Chloride in Oral Surgery

As a final consideration concerning the circumstance of this newly created medical society: US courts had recently shifted in their interpretation of medical malpractice and standards of care. According to Paul Starr,

“physicians came increasingly to rely on each other’s good will for their access to patients and facilities. I have already alluded to the instrumental role of the rise of hospitals and specialization in creating greater interdependence among doctors. Physicians also depended more on their colleagues for defense against malpractice suits, which were increasing in frequency. The courts, in working out the rules of liability for medical malpractice in the late nineteenth century, had set as the standard of care that of the local community where the physician practiced [2].”

Such an argument provided an impetus for defining the practice of medicine, specifically the practice of anesthesia, by standards agreed upon by local practitioners.

A fire destroyed the early records of the society in 1911, the same year that the society changed its name to the New York Society of Anesthetists (NYSA) [1]. The charter of the new society proclaimed its commitment to the “science and art of anesthesia [3].” Erdmann became the first president of the new society and James Gwathmey succeeded him in 1912. In that year, Gwathmey reported that in the US “mortality rates for anesthesia were one death in 5,623 anesthetics, three-fold greater than in the United Kingdom where physician anesthetists by then were on duty in almost all major hospitals [5].” Gwathmey attributed this to the minimal training of US physicians in anesthesia and the use of nurses as anesthesia providers [5].

Other Societies Arose

During the next two decades, a spate of anesthesia societies sprang up in the US: the American Association of Anesthetists (1912), the Interstate Association of Anesthetists (1915), the American Society of Regional Anesthesia (1923), and the International Anesthesia Research Society (1925). These and a multitude of local and regional societies sought to define the education and practices of this developing medical specialty, and to create some certifying system for practitioners [6]. But such fragmentation or “Balkanization of anesthesia into fiefdoms and principalities” delayed agreement on LISA/NYSA’s goals of establishing criteria for qualification as a proficient anesthetist [6].

Physician vs. Nurse Anesthesia

During the 1930s, battle lines were drawn over the relationship between physicians and nurse anesthetists, and whether the NYSA should continue to seek recognition by the AMA. At the same time, a concurrent reality needed to be addressed. Profits were to be made by the administration of anesthetics, and hospitals, surgeons, and nurses competed with physician anesthetists for the rewards. In 1926, the NYSA supported legislation in the New York legislature that would have increased the number of physicians providing anesthesia while limiting the anesthesia practice of others. This unrealistic proposal, which would have created a serious shortage of anesthesia providers, engendered the opposition of surgeons, nurses, and hospital associations. It was not enacted but left bitter feelings against physician anesthetists [7].

As Douglas Bacon wrote:

“Because administration of an anesthetic was a profit center for surgeons and hospitals, physician specialists were struggling.

Surgeons could hire a nurse, or other individual, and have that person give the anesthetic. The surgeon charged an anesthetic fee, and the money collected was in excess of the salary paid to the ‘anesthetist.’ Hospitals likewise hired a nurse to give anesthetics and collected a fee that more than paid the nurse’s salary. Finally, general practitioners (GPs) often would refer surgical cases to surgeons who would in turn use the GP as an anesthetist, and by administering the occasional anesthetic the GP increased his/her income [7].”

Multiple forces drove the aspirations of physician anesthetists in the mid-1930s:

1. Formal recognition of anesthetist’s work as the practice of medicine (which would provide status and financial leverage);
2. Establishment of quality practice through education, performance standards, examinations, and certification by a recognized American accrediting authority;
3. Professional independence from the influence of others on clinical decision-making;
4. Freedom from economic exploitation by surgeons and hospitals.

Certification and Specialty Recognition

In 1930, the NYSA established a committee to revisit the issue of member certification. As I recorded:

“Simultaneously, the Associated Anesthetists of the United States and Canada (AAUSC), under Francis Hoeffer McMechan, recognized the need for a national certification.... As is generally the case with intelligent people who find themselves with a problem, the AAUSC created another committee. As is often the case when intelligent people find themselves in a committee, they failed to agree, leading to another two years of delay and indecision [6].”

During the 1930s, the NYSA began anew, the efforts to achieve specialty recognition from the AMA. That route was unproductive when, in 1912, Gwathmey requested and was refused AMA recognition for a section on anesthesia [7]. By 1935, the Fellowship Committee of the NYSA had established a certification process consisting of oral and written examinations, and a practical demonstration of clinical competence. Physicians from twenty-three states requested applications, but to obtain recognition by the AMA, would require a national organization “in name as well as in fact”. Thus, in February 1936, the NYSA Executive Committee recommended approval of a name change to the American Society of Anesthetists (ASA) [8]. In order to establish some mechanism for awarding fellowship status to qualified physicians, representatives of the ASA, the Surgical Section of the AMA, and the American Regional Society of Anesthetists, met in October 1936 to discuss formation of an American Board of Anesthesia.

In December 1936, the NYSA, having received membership applications from nine other states, officially changed

its name to the American Society of Anesthetists by action of its House of Delegates, meeting the AMA's requirement for a nationwide organization, at least in name. The ASA now had 487 members [9]. They sent John Lundy, head of anesthesia at the Mayo Clinic and a long-time consultant to the AMA, to meet with the Guiding Committee of the AMA and the Advisory Board of Medical Specialties [9]. Although these groups would not agree to a separate Board or Section for anesthesia, a "side-door for entrance into organized medicine" opened.

Erwin Schmidt, Chief of Surgery at the University of Wisconsin in Madison, and a friend of Ralph Waters, proposed an affiliate status for anesthesiologists within the American Board of Surgery (ABS). On January 10, 1937, two representatives of the ASA, Waters and Paul Wood, successfully argued for this proposal before the ABS [10]. In June 1937, the ABS officially recognized the American Board of Anesthesia (ABA). In February 1938, the Advisory Board for Medical Specialties approved this affiliation, thus officially recognizing anesthesia as a medical specialty [3].

While the ASA pursued board status, it concurrently sought recognition as a medical specialty within the family of medicine. In June 1937, in its pursuit of recognition by the AMA through the creation of a Section on Anesthesia, the ASA limited its membership to physicians who were members of the AMA. This removed dentists, scientists, and foreigners from membership [3].

The 1939 World's Fair in New York provided an opportunity for the ASA, through the Winthrop Corporation, to promote the specialty of anesthesia to the general public (Fig. 19.2). With the theme "The Physician Anesthetist of Tomorrow," an ambitious display was assembled including a simulated patient and operating theatre. Just how many of the 45 million visitors to the Fair took in the ASA display is unknown—it competed with over 60 foreign government exhibits, 300 priceless works of art from the galleries of Europe, an original copy of the Magna Carta, and an amusement section with a 10,000 seat amphitheatre.

State associations of anesthesiologists in California, Connecticut, and Indiana had established sections on anesthesia within their state medical societies, and offered educational programs and scientific displays. In May 1939, at the annual AMA meeting in St. Louis, the ASA presented a session on anesthesia, and leaders of the AMA increasingly supported recognition of anesthesia as a specialty [3]. Members of the Council on Scientific Assembly of the AMA, at their meeting in December 1939, recommended establishment of a Section on Anesthesia within the AMA. This recommendation was submitted to the AMA House of Delegates Annual Meeting in June 1940, and was approved unanimously. Anesthesiology was now recognized as a medical specialty by the AMA.

Publication of the ASA Journal, *Anesthesiology*

The process of legitimizing the specialty also required establishment of organs of communication. First came a monthly *Newsletter*, begun in April 1938, which reported items of interest to anesthetists, appointments, meetings, and activities [7]. Next came the journal *Anesthesiology*, in July 1940. Development of *Anesthesiology* had been suspended out of respect for Francis McMechan and his dedication to *Current Researches in Anesthesia and Analgesia*. *Anesthesiology* commenced publication shortly after McMechan's death in 1939. It thrived, becoming the pre-eminent journal for anesthesia-related articles.

On February 16, 1941, the ABA gained independent status. The process of organizing anesthetists, developing a corporate identity, defining standards of practice and education, and incorporating these activities within those of other physicians was complete. Anesthesia had arrived as a medical specialty.

World War II Accelerates ASA Growth

The entry of the US into World War II, late in 1941, profoundly changed progress in anesthesia. The expectation of great numbers of casualties and the unfortunate experience of World War I battlefield anesthesia by episodically supervised and diverse anesthetists (corpsmen, nurses, secretaries, and the occasional physician), caused the National Research Foundation to ask eminent anesthesiologists how to manage the anticipated demand. Ralph Waters headed this group of ASA leaders, including Emery Rovenstine, John Lundy, Henry Ruth, Henry Beecher, Paul Wood, Ralph Tovell, and Lewis Booth [10]. They developed an anesthesia training program for physicians that joined the educational and training potential of American anesthesiologists to the emergent demand. Hundreds of physicians received an accelerated program of instruction, at class 'A' medical schools with established departments of anesthesia having a chairman who was certified by the ABA. Certain military hospitals handling a large volume of surgical cases with adequate staff were also included, as well as the Mayo Clinic and similar institutions [10].

This program, supported by ASA, contributed to the rapid growth of the specialty after the war. To accommodate the credentialing demands of this new population of partially trained physicians practicing anesthesiology, the Committee on Fellowship of the ASA revived the Fellowship process in 1943, and by 1947, it expanded into the American College of Anesthesiologists. For returning physicians who did not qualify for ABA certification, or who practiced anesthesia part-time, fellowship offered an opportunity to certify skills

Fig. 19.2 This postcard (front and back) pictured the ASA/Winthrop Corporation's effort to inform the public, to convince them of the considerable advantages offered by the skills of the anesthesiologist

and knowledge of the practice of anesthesiology [6]. The post-war expansion in the number of residencies and positions indicates the accelerated growth of anesthesiology: in 1940 there were 37 residency programs with 108 positions, in 1950 there were 216 residency programs with more than 700 positions [11].

The ASA Changes its Name

In 1945, the total membership of ASA was 1,977. Of those, 739 (37%) served in the military [3]. As the war drew to a close, the ASA changed its name to the American Society of Anesthesiologists and held the first of its Annual Sessions.

Paul Wood, the 1945 first recipient of the ASA Distinguished Service Award, had made the suggestion for a name change the year before, citing correspondence from MJ Seifert of Illinois:

“In 1902, while teaching at the University of Illinois, I coined the word ‘anesthesiology’ and defined it as follows: The science that treats of the means and methods of producing various degrees of insensibility to pain with or without hypnosis. An Anesthetist is a technician and an Anesthesiologist is the scientific authority on anesthesia and anesthetics. I cannot understand why you do not term yourself the American Society of Anesthesiologists?”

Apparently the term anesthesiologist predated the society itself.

Fig. 19.3 World War II spurred the growth in ASA membership. Growth accelerated further starting at approximately 1970, in part perhaps because of ASA efforts to educate medical students concerning the important role played by anesthesiologists in the care of surgical patients

A Move to Chicago

In 1946, the ASA celebrated the centenary of the discovery of anesthesia, at its annual meeting in Boston, featuring the Morton Centennial Commemoration and the Ether Centenary celebration. It addressed part of the growing needs of the present and expanding membership, by hiring its first Executive Secretary, John Hunt, who was followed by John Andes in 1960. Need for more space and a more central location within the US prompted the movement of ASA offices to Chicago in 1947. Responding to the maturation of this new specialty, the ASA changed its constitution and bylaws [3]. The new governance structure created component societies at the state or regional level, a Board of Directors, a House of Delegates, and an Executive Committee. This model survives to this day. The House of Delegates first met in St. Louis in 1948. Refresher Courses, instituted at the 1950 Annual Session, continue to be offered today.

The 1940s saw an increase in membership from 538 to 3,393, and by 1960 it had increased to 6,785 [9]. Figure 19.3 indicates three phases of this growth: Slow before World War II; a steeper rise promoted by the war through 1970; and a still steeper increase thereafter, an increase that has yet to abate.

Founding of the Wood Library-Museum and Other ASA Foundations

In 1949, Paul Wood's collection of materials related to the history of anesthesia, officially became the Wood Library-Museum (WLM). George Bause admirably tells the

Fig. 19.4 In 1932, Paul Wood presented the ASA with the pictured seal of his design that became the Great Seal of the ASA. Bacon wrote [35] that this consisted of "... the pilot wheel, perfect circle, shield, stars, clouds, moon, ship, sea and lighthouse.... The patient is represented as the ship sailing the troubled sea with clouds of doubt, waves of terror, being guided by the skillful pilot (the anesthetist) with constant and eternal (stars) vigilance (*motto*) by his dependable (*lighthouse*) knowledge of the art of sleep (*moon*) to a safe and happy outcome of his voyage through the realm of the unknown. The perfect circle denotes unity of a closed group (the Society)* Quoting Wood, Bacon added that "the three dots after the founding date of 1905 were put there... to symbolize the name changes of the Society, from the original Long Island Society of Anesthetists, to the New York Society of Anesthetists, to the American Society of Anesthetists, and then the name under which the Society was incorporated, the American Society of Anesthesiologists." [36, 37] (Courtesy of the American Society of Anesthesiologists)

development and travels of this unique collection [12]. After being shuffled around New York for three decades, it found a permanent home at the new ASA offices in Park Ridge, Illinois in 1963. It now resides at the enlarged facility built there in 1993. This is the world's greatest collection of documents, letters, publications, memorabilia, and equipment related to anesthesia.

Wood gave the ASA something else. In 1932, he presented the ASA with a seal that became the Great Seal of the ASA (Fig. 19.4) [3]. Emblazoned on the shield is the patient as a ship on clouded troubled seas steered by the anesthetist (using the pilot wheel, a perfect circle suggesting the unity of the ASA) with stars and a lighthouse to guide the way, and a moon to reflect sleep. The three dots after "Founded 1905" symbolize the three successive societies – the Long Island Society of Anesthetists, the New York Society of Anesthetists, and the ASA. And above the shield lies the word "Vigilance", the motto of the ASA.

The WLM later achieved foundation status, but was not the first of the ASA's four foundations. First was the Anesthesia Memorial Foundation (AMF) established in 1956 to honor the passing of several prominent anesthesiologists who died that year—R. Charles Adams, Rolland Whitacre, Brian Sword, Robert Hammond, Henry Ruth, and Arthur Guedel. This foundation aimed “to loan or give money to deserving persons and to assist them in becoming specialists in anesthesia, or for research and study in the field of anesthesia and related fields.” In 1984, its name was changed to The Anesthesia Foundation (AF). Over the years its effectiveness has grown. It provides loans to residents, as many as 60 per year, in amounts up to \$6,000. It assisted in resident relief after hurricane Katrina hit New Orleans in 2005. Through its Anesthesia Foundation/Wellness Initiative Advisory Committee, it expanded its efforts to assist practicing physicians who experience hardship. Its assets exceed \$1,250,000, all of it “committed to individuals in the form of loans [13–15].”

The ASA Opposes the Corporate Practice of Anesthesiology

The 1950s were notable for more than organizational changes of the ASA. Increasingly, hospitals sought to control the practice of anesthesia, largely to generate revenue. The growth of health insurance companies in the 30s and 40s, and the provision of insurance coverage as an employee benefit during World War II, coupled with the increased power of the hospital industry, put pressure on anesthesiologists to become salaried employees of hospitals. The ASA needed to craft effective responses to this challenge. Since the 1940s, the ASA had issued statements asserting the professional nature of anesthesiologists' services to the patient, as opposed to the institutional services supplied by hospitals and their employees. Having required its members to maintain membership in the AMA (and the ABA having required that its candidates be members of the ASA), the ASA now sought AMA support against profit-based hospitals and their exploitation of physician anesthesiologists [16].

In 1950, the Committee on Corporate Practice of Medicine of the AMA, working with members of the ASA, produced a report on the corporate practice of medicine that was adopted by the AMA House of Delegates. The report included the statement:

“that the overall policy of the American Medical Association shall be that it is illegal... and unethical for any lay corporation to practice medicine and to furnish medical services for a professional fee which shall be so divided as to produce profit for a lay employer, either individual or institutional, including hospital and medical schools... The licensed physician is the only person legally qualified at the present time to render any individual medical service [16].”

The ASA quickly followed with a Statement of Policy threatening denial of membership through its component society system, to anyone working for a salary and allowing another entity to offer his services for a fee. It was rumored that residencies would be disapproved if their directors did not comply with this policy [16]. The intended consequence of this effort was to align the specialty with the private practice of medicine. The private practice of medicine was based economically upon fee for service payment. Over the next dozen years, the percentage of anesthesiologists practicing under salary from an institution, decreased from 25.7% to 8.8% [16].

Academic anesthesiologists, as salaried faculty in medical schools, increasingly feared that the ASA wrongly connected salary source and ethical behavior. Between 1950 and 1953, several prominent academic anesthesiologists formed the Association of University Anesthetists, later the Association of University Anesthesiologists (AUA), in part to challenge this connection. The division was real and deep, and threatened the corporate identity that anesthesiologists had obtained with such difficulty in creating the ASA. Despite ASA opposition, 37 academicians (all ASA members) formed the AUA, held their first meeting in 1953, and contemplated a life in opposition to the ASA [16]. Eventually, cordial and respectful relations developed between the ASA and the AUA, and as a multiplicity of special interest associations arose, the ASA pitched larger tents, made accommodations, and held together the specialty whose identity continued to evolve.

Founding of the WFSA

In 1955, 28 societies from around the world founded the World Federation of Societies of Anaesthesiologists (WFSA). The US, the post-war global super power, had just passed through a virulent communist scare and was engaged in the Cold War. The ASA was the largest and most prosperous anesthesia organization on earth and initially considered that the WFSA offered little benefit to ASA members. If becoming a member required the ASA to relinquish any of its hard won authority, caution was necessary before contemplating membership. Thus, initially, the ASA elected to remain an “observer”. Ultimately the ASA decided that WFSA membership had more advantages than disadvantages, and, perhaps that it had an obligation to the larger development of anesthesia implied by membership. In 1960, the ASA became a member of the federation that now has 116 member organizations [16].

Birth of the Relative Value Guide

The 1960s saw an economic revolution in medical care and government involvement in the production, delivery, and reimbursement for health care services. Even before the

enactment of Medicare in 1965, medical associations sought to devise some system to quantify the value of medical services. California led the way in 1953, with the creation of a Relative Value System. It was not a fee schedule, but a formula for calculating the relative value of specific medical services. From this, a dollar amount could be derived by application of a conversion factor. Joseph Failing developed a Relative Value Guide (RVG) specific to operative anesthesia services, and saw to its passage by the California Medical Association and the California Society of Anesthesiologists [17]. It was based upon the type of surgical procedure (e.g., gall bladder removal), pre-existing risk factors (e.g., heart disease and the extent of heart disease), modifying units for use of complicated modalities (e.g., hypothermia, extracorporeal circulation), and actual time for anesthesia services. The ASA adopted this RVG in 1962, which was therefore in place when Medicare came into effect [18]. Because the conversion factor varied with the prevailing cost of living and practice, it was not considered a fee schedule or a method of fixing prices. Despite legal challenges, the ASA-RVG survived and continued in use [18, 19].

Formation of the ASA Medical Student Preceptor Program

In 1962, the ASA House of Delegates authorized a systematic analysis of the practice of anesthesiology beginning with a survey of practice, research, and teaching [20]. Using the resources of a professional consultant, the ASA identified several areas deserving special attention. Medical student attitudes regarding the specialty led the ASA to include them in focused educational experiences—meetings, curriculum modifications, and the ASA Medical Student Preceptorship program. The last of these placed hundreds of medical students in direct contact with practicing anesthesiologists each year. Over the sixteen years before the program ended in 1983, thousands of medical students experienced the practice of anesthesiology first hand. Some then chose it as a specialty and many viewed it with increased favor [21]. Such recruitment to anesthesiology may explain a portion of the increase in numbers of anesthesia residents/anesthesiologists at this time (Fig. 19.3).

Support Programs for ASA Members Grow

Appointed in 1966, the ASA Council on Education developed guidelines for the inclusion of anesthesia education for interns, in the curriculum established by the AMA [20]. In addition, a heightened public education program was developed, including brochures, films directed at medical students, and similar materials directed at patients or the gen-

eral public. Anesthesiology became a separate section in the AMA, thereby increasing its status in the eyes of other physicians [20]. The recognition and respect that the ASA and its members desired from the public in general, required public education beyond that described above. Specifically, anesthesiologists wanted the general public to appreciate the distinctions between physicians administering anesthetics, and other anesthetic providers. To this end, the ASA called attention to the academic aspects of anesthesiology and mounted a public relations campaign. The emphasis on science focused on research funding and the assessment tools for continuing competence. The latter prompted the American College of Anesthesiologists (ACA) to develop the Self Education and Evaluation (SEE) program. Thus began periodic verification of practice competence, and assessment of the currency of member education, ultimately resulting in an ABA recertification mechanism. The ACA, in response to information gleaned from the SEE program, developed educational programs, regional refresher courses, and publication of the ASA Regional Refresher Courses—for many years the best selling publication of the specialty [6].

During the 1970s, the ASA developed further programs and support systems for its members. It established Ambulatory Surgery Guidelines in 1973 [18]. That same year the ASA, in conjunction with the ABA, mandated a resident in-training examination. In 1975, the ASA began assisting recovery room nurses in forming their own organizations, regionally and nationally. This resulted in the 1982 formation of the American Society of Post-Anesthesia Care Nurses (ASPAN) [19].

The ASA and the Federal Trade Commission

It would be wonderful to say that the ASA devoted all its resources and energies to the art and science of anesthesiology, but the 1965 Medicare and Medicaid legislation unleashed governmental agencies seeking economies in reimbursements that had overrun their predictive models. Membership in the ASA had been restricted to those who adhered to the ASA's approved methods of reimbursement. Punitive sanctions were pursued against those who deviated from the prescribed economic and ethical imperatives of the ASA.

“In September 1975, the Department of Justice filed an anti-trust suit against ASA charging that ‘the *Relative Value Guide* promulgated by the Association (sic)... which sets values on particular procedures...are used by the Association (sic) members to determine what fee to charge... (and) have the effect of raising, fixing, stabilizing, and maintaining fees.’” [18]

Two years later, the Federal Trade Commission (FTC) began an investigation of the ASA and its Guidelines to the Ethical

Practice of Anesthesia [22]. The Guidelines stated that “financial return from the private practice of anesthesia should be on a fee for service basis... Physicians should bill their own patients for the services and only the services they perform personally [18].” This, thereby restricted membership to those who demanded a fee for service. Whereas the ASA successfully defended its *Relative Value Guide* against the Department of Justice, it had to retreat on its Ethical Guidelines, accepting a consent decree with the FTC that agreed to stop “importuning or engaging in threats or actions of reprisal, coercion, or intimidation with purpose or effect of restraining or impeding anesthesiologists individually or as a class of practitioners from engaging in the practice of anesthesiology other than on a fee for service basis [18].” In the same year, 1975, the ASA established an advocacy presence in Washington D.C. [18] That presence continues today and enables advocacy on behalf of members and their patients with the federal government.

In August 1979, the FTC launched another investigation into allegations of anti-competitive practices, by anesthesiologists against nurse anesthetists. This matter was resolved within a year in favor of the ASA, but the FTC continued to threaten further action over the next decade [19]. The ASA faced more than legal challenges from the federal government. Bureaucracies instituted several regulatory activities in the early 1980s that threatened development of the specialty. The ASA began a series of activities to prepare anesthesiologists for some of the new realities of practicing in a highly regulatory environment. “Legislative Workshops” were begun—first in Chicago and then in Washington D.C. The Annual Legislative Workshop continues as a resource to component society leaders and their counsels [19]. In 1980, the ASA instituted a program on governmental affairs at its Annual Meeting, and through a *Key Contact* program, ASA members were encouraged to form personal relationships with legislators at both state and federal levels, in order to present concerns over pending legislation and regulatory rules. Establishment of a political action committee (PAC) was considered, but not pursued at that time.

The ASA Establishes a Full-Time Presence in Washington

In the early 1980s, the US Bureau of Health Manpower formed a Graduate Medical Education National Advisory Committee (GMENAC), to advise the Secretary of Health, Education, and Welfare on the proper number of physicians in each specialty. The GMENAC advocated increased numbers of primary care physicians and fewer positions in anesthesia residencies – despite studies indicating a shortage of anesthesiologists. By 1984, it became clear that a full-time presence in Washington was necessary: the Office of Gov-

ernmental Affairs (OGA) was opened with full-time staff, lobbying consultants, and legal counsel. In the following year, the ASA sponsored Grass Roots Political Education Seminars in five locations around the country. Recognizing that precedents could be set at a local level that affected the laws and regulations in other states, it became imperative that the broad range of possible threats to the specialty be communicated to component societies [19, 23].

It is numbing to relate the multitude of skirmishes and challenges that the ASA faced from the 1982 Tax Equity and Fiscal Responsibility Act (TEFRA). They included the congressionally mandated Prospective Payment System (PPS), the schedule of Diagnostic Related Groups (DRGs), the Physician Payment Review Commission (PPRC), efforts to bundle physician services with those of the hospital, or proposals to separate radiologists, anesthesiologists, and pathologists (RAPs) and their reimbursement from that of other physicians. Two critical contests were afoot: 1) the professional nature of the practice of anesthesiology, particularly its autonomy from institutional control; and 2) the economic survival of residency teaching programs. The ASA, in conjunction with the AUA, the Society of Academic Anesthesia Chairmen (SAAC), and the Association of American Medical Colleges (AAMC) defined reimbursable services for an attending physician who was concurrently directing two residents or interns [19]. As the government exercised increasing control over reimbursement for medical services, new problems arose. What is the value of the physician component of medical services when supervising nurse anesthetists? How many nurses could reasonably or safely be supervised at one time—two? four? eleven? How and when is the input of the physician in medical care appropriate? And, as a bottom-line, what is the service worth?

Other problems required consideration: What are the ethical implications of exclusive contracts between anesthesiologists and hospitals? Are they designed to maintain quality care or to keep out competition? Are clinical decisions influenced by the one who pays the bill? Is the exclusion of qualified practitioners from access to hospital facilities morally justifiable? As far as economic credentialing is concerned, should a medical staff or hospital administration grant exclusive privileges to practice based upon cost rather than quality of care? These issues have yet to be resolved as the quality of anesthesia services and the value of those services are considered in the broader arena of health care reform.

Establishment of the APSF and FAER

During the mid 1970s, professional liability insurance premiums rose alarmingly as malpractice claims increased. The crisis presented an opportunity, an ASA mandate to

reduce harm to the patient. In 1984, the ASA began a study of closed claims—litigated cases that had been resolved—in order to analyze problems with management decisions, practice methods, and their relationship with adverse outcomes. The Closed Claims Study eventually included thousands of cases. The ASA acted upon the information to focus educational programs on safety. The ASA also demanded better technologies, pharmaceutical agents and packaging, and developed guidelines and standards of care, peer review programs, and quality assurance programs for medical staff [19]. By 1985, Ellison Pierce, ASA Immediate Past President, had inspired creation of The Anesthesia Patient Safety Foundation (APSF), a foundation dedicated to a simple purpose—that no patient be harmed by anesthesia. Rather than focus on tort reform, it extended its hand to a coalition that included anesthesiologists, nurse anesthetists, nurses, pharmaceutical and equipment manufacturers, regulators, insurers, attorneys, and hospital representatives [24]. Actions of the foundation, together with the work of ASA committees on safety and standards, profoundly influenced the practice of anesthesia through development of standards for monitoring, promotion of alarm systems, use of simulators for training personnel, education in risk management, and information management and sharing [24, 25]. The result was that patient safety dramatically increased—and malpractice costs dramatically decreased. Sometimes good is rewarded.

At the same time the APSF was created in 1985, the ASA established an ad hoc Committee on Industry Relations, whose purpose was to obtain funding from anesthesia related industries to support ASA activities. This is called non-dues income, and, while priding itself on its frugality and efficiency in meeting its members' needs while keeping dues low, the ASA imagined treasure flowing into its general revenue account. The Committee, having reviewed the economic, ethical, public relations, and professional implications associated with multiple commercial marriages, identified two areas in which the ASA and industry shared respectable goals and interests—research and education. The committee then proposed the establishment of the ASA's fourth and last foundation, the Foundation for Anesthesia Education and Research (FAER), declared a victory, and vanished [26]. FAER has grown and fulfilled the expectations of its founders. King and Hug found that by 1998, "234 of the 296 FAER grant recipients then surveyed had received more than \$100 million in subsequent grant funding, from an initial FAER investment of just over \$5 million. I challenge you to find a better example of return on investment anywhere [27]." The emphasis on supporting post residency fellows and junior faculty also aided in the retention of academic faculty. FAER currently has assets of over \$20 million, awards grants in excess of \$2 million annually, and has organized an Academy of Mentors to encourage the exchange between senior academicians and those in the early stages of their research careers [28].

Substance Abuse

In the 1980s, the ASA addressed another significant problem: the plight of the impaired physician. Anesthesiologists used and abused addictive substances, including alcohol and other substances, more than did other specialists. This problem presented a need for investigation and intervention. The ASA's Committee on Occupational Health of Operating Room Personnel was charged with the responsibility for developing the programs of monitoring, education, and intervention needed to protect patients, and to rehabilitate physicians who could be rescued [19]. During the next three decades, other medical associations joined the effort to solve the problem. Did these and the ASA's activities produce remediation of physician impairment? There is no unequivocal answer, but hospital personnel with whom I've spoken seem confident that the problem is less severe than it had been. On the other hand, James Arens wrote (personal communication) that "Unfortunately there has been little to no change in the incidence of substance abuse in anesthesia residents." Thus, despite three decades of effort, we do not know whether remediation has occurred and, if it has, what specific efforts produced the remediation.

Public Relations

The ASA's forays into public relations programs dwindled after the 1960s. By the 1980s, the complex practice of anesthesiology had become sub-specialized and in need of renewed public understanding. The ASA Committee on Communications developed a program of Public Education, with a press information kit, spokesperson training, media tours, renewed medical student recruitment efforts, and video releases for television [19]. However, subsequent studies of the effectiveness of public education efforts indicated that the effort and funds expended on the program minimally affected the general public's appreciation of the role and importance of the anesthesiologist [19].

Bluntly speaking, no one was interested until they were about to have surgery. The ASA decided it was more effective to educate the decision-makers in government, the media, and other health care professionals. The ASA enhanced its presence at the AMA, developed stronger connections with other medical associations, and established annual media awards, presented to honorees at its Annual House of Delegates Meeting. The education of those in government was motivated by more than the economic interests of ASA members. Its efforts to limit the scope of practice of less qualified practitioners, and its determination to educate legislators and regulators on the consequences of their decisions cannot be reduced to mere lobbying. Lobbying, historically, signifies the pressure of self-interested groups on

those in government. The ASA has certainly represented the economic concerns of its members, but it has also been an advocate for the care of patients.

Subspecialization

As the 1990s began, sub-specialization within the practice of anesthesiology needed to be addressed: was the ASA to passively observe the fragmentation of the specialty or proactively adopt a supportive role? The Executive Office offered administrative support for the subspecialties as it had for the Foundations. Specifically, the ASA headquarters office helped with communications, membership services, meetings, and many of the needs of the new societies. By 1990, the House of Delegates had amended the ASA Bylaws to allow voting status to representatives from the American Society of Critical Care Anesthesiologists (ASCCA), the Society for Obstetric Anesthesia and Perinatology (SOAP), the Society of Cardiovascular Anesthesiologists (SCA), the Society for Pediatric Anesthesia (SPA), the Society for Ambulatory Anesthesia (SAMBA), the American Society of Regional Anesthesia and Pain Management (ASRA), and the Society for Neurosurgical Anesthesia and Critical Care (SNACC) [19].

Nicholas Greene had long been a volunteer with the overseas medical missionary project *Hope*. At his urging, in 1990, the ASA began an Overseas Teaching Program (OTP) in support of volunteer ASA members who would train anesthesia personnel in safe practices. In the past two decades the ASA-OTP has enlisted more than 100 volunteers for temporary teaching posts in Uganda, Zambia, Tanzania, and Kenya [29]. In 2009, it changed its name and mission. The new ASA Committee on Global Humanitarian Outreach (GHO) coordinates its activities with other organizations and specialties such as the WFSA, the World Health Organization (WHO), Health Volunteers Overseas, and the American College of Surgeons (ACS) [29].

Primary Care Growth Transiently Forces a Retreat

In 1991, the ASA, responding to the need for more effective representation of the political and economic interests of its members, approved the formation of a political action committee (ASAPAC). Some in the ASA had been reluctant to separate their representation at the federal level, from that of the AMA and its political action committee [23]. A gap had developed however, between the interests of the ASA and the AMA. There had been growing pressures on the AMA to represent the interests of primary care physicians and, within a short time, a federal Council on Graduate Medical Education (COGME), recommended an increase in

Fig. 19.5 This summary of match results for recruitment to first year positions in residency programs from 1980–2009 shows the considerable impact of the attempt of the Clinton Health Initiative in the early 1990s, to divert physicians from specialty to family care practice. The impact was large but relatively short-lived. (From Armin Schubert essay in the ASA newsletter 73, p 32, 2009)

the number of primary care physicians at the expense of specialty education. Specifically, anesthesiology residency positions would be reduced by 40% [30]. Such measures, combined with reaction to the Clinton health care initiative, the growth of managed care, the increase in exclusive contracts between hospitals and closed panels of anesthesiologists, and concerns over the numbers and qualifications of future anesthesia providers, dramatically decreased recruitment into anesthesia (Fig. 19.5). ASAPAC activities and increased programs to recruit medical students into anesthesia ensued, and recruitment into anesthesia residencies recovered. The sub-specialization in anesthesia and the expansion of clinical opportunities for general anesthesiologists, restored the demand and the specialty grew again. Subspecialties grew in number and membership, and the ASA responded by supporting them administratively and by incorporating them into the political structure of the ASA. In 1990, membership was 27,034. By 2010, it had grown to 44,599 [31]. The ASA's annual budget is approximately \$36 million.

Activities in the 2000s

As the century drew to a close, the ASA began another process of self-examination like that of the 1960s. In 1992, the ASA leadership convened a retreat/workshop consisting of the Administrative Council and other key leaders. Task forces were appointed to study and report upon the ASA's research and education efforts and the extent to which they responded to identified needs, set goals and priorities, and measured

outcomes. Another taskforce studied the structure and function of the society—leadership, governance, and administrative support systems. Others reviewed member services, economics and governance as they affected the strength of the society, and potential changes in the role of the anesthesiologist in the future. This process of planning and goal setting has continued, using facilitators, consultants, and other professional resources. Some results include an expansion of the Board of Directors to include representatives of all the component societies, representatives from subspecialty societies, related foundations, and academic organizations. The ASA House of Delegates continues to meet annually, and has expanded its membership to nearly 400. It has a reference committee format for handling reports and resolutions, a consent calendar for managing action and information, and a parliamentary structure for meetings.

The growing number of women entering the medical profession prompted an ASA workshop on women's issues in 1993, that evolved into a standing committee on diversity that addresses concerns of underrepresented sectors of the specialty and the particular interests that they might have. These sectors include medical students and residents, young physicians, uniformed services and veterans, anesthesia assistants, and anesthesia care team members. The ASA also established ongoing projects dealing with geriatrics, ethics, and practice management. The Annual Session added a subsection on history with panels, posters, and papers.

Formed in the mid 1980s, the Committee on Standards of Care produced a series of standards on monitoring, practice guidelines, and algorithms useful in dealing with special procedures. Practice parameters have been written based upon evidence or consensus. To date, the ASA has approved twenty evidence-based parameters [32]. They deal with such matters as preoperative evaluation, the prevention of intraoperative and postoperative complications, pain management, transfusion therapy, and postoperative care. The ASA has supported the development of anesthesia simulators, both in training and in maintaining proficiency in anesthesia practice. Concern for physician wellness, beginning as an awareness of the problem of substance abuse, has expanded to include active involvement in impairments of other kinds, including those related to aging, distraction, and unhealthy lifestyles. Other medical organizations and most medical staffs have embraced the ASA's concern, and instituted measures of detection and intervention to identify impaired physicians, and guide them toward recovery.

In response to an era of almost instant information dissemination, the ASA and its foundations and subspecialties have developed web sites and electronic alerts and bulletins, knitting the various anesthesia communities and their interests together. *Advocacy* has become a fashionable term, describing the duty of organizations to their members. To speak for ones members' interests is a laudable goal of an

organization. When that organization is a professional society however, it must behave as more than a trade association. Whatever member interests are advocated, they must also represent the best interests of the patients they serve and the collective good of society. The ASA has become the voice of most anesthesiologists in the US, representing them before the public, the government, industries, and the world. Despite diverse interests, anesthesiologists find common ground in socio-economic, public relations, scope of practice issues, and the improvement of patient care, as stated in the ASA's current Mission Statement:

The American Society of Anesthesiologists is an organization of physicians and other professionals dedicated to serving the best interests of its members and their patients. ASA supports patient safety by promoting improved quality, ethical behavior, discovery of new knowledge, and involvement of an anesthesiologist with every patient receiving anesthesia services, including perioperative care, pain management, and critical care [33].

One might argue that these goals cannot be realized, given the existence of dentists, veterinarians, and others doing their best to care for patients where anesthesia is required, but where there is no anesthesiologist. One might also argue that in some ways anesthesiology has become a victim of its own success. Improvements in practice have enabled application of more complicated and riskier procedures to sicker patients, but as a practice approaches fail-safe status, the virtuosity of the provider becomes a given. How relevant to or proportional to the outcome of the medical experience, is the investment in education and training of the provider? To answer this question, the ASA has established an Anesthesia Quality Institute, gathering data in preparation for the creation of a National Anesthesia Clinical Outcomes Registry [34].

The Specialty has Matured

In summary, over the past century, the ASA has developed a sustaining culture of shared values and assumptions that have advanced the progress of anesthesiology as a medical specialty. Its four foundations, jewels in the crown of the ASA, have shaped the development of the specialty. The ASA's educational efforts—meetings, communications, the most prestigious journal in anesthesiology—have informed and enriched generations of anesthesiologists. Awards and eponymous lectureships and scholarships have directed attention to the accomplishments of those whose contributions to the specialty have been noteworthy. The communities of anesthesiologists and those associated with the specialty rely upon a network of relationships, values, and communications; the ASA has provided these. The ASA can claim credit for creating an environment in which knowledge is shared and valued through education and research, and in which safe patient care is the primary consideration.

The Role of the International Anesthesia Research Society in the History of Anesthesia

20

Summary

The 10-decade old, 14,000-member International Anesthesia Research Society (IARS) was born and grew through the efforts of Francis McMechan (1879–1939) and his wife Laurette McMechan (1878–1970). By 1911, severe rheumatoid arthritis prevented McMechan from continuing his medical practice, and he turned his skills to the development of anesthesia organizations. In 1914, McMechan became editor of the *Quarterly Supplement of Anesthesia and Analgesia*. In 1919, he established the National Anesthesia Research Society (NARS) which in 1922, initiated publication of *Current Researches in Anesthesia and Analgesia*. The IARS succeeded the NARS in 1925. In 1957, the Journal became *Anesthesia and Analgesia...Current Researches*, and in 1979 it became *Anesthesia & Analgesia*.

Laurette acted as Assistant Editor, assuming greater responsibilities as illness increasingly disabled McMechan in the 1930s, leading to his death in 1939. In 1940, Howard Dittrick (Laurette's gynecologist) was appointed Directing Editor and Laurette continued as Assistant Executive-Secretary-Editor. Dittrick died in 1954 and Harry Seldon became Editor-in-Chief (1954–1976).

The fourth Editor-in-Chief (1976–1990), Nicholas Greene, improved scientific content, expanded circulation, and increased profitability, enabling the IARS research awards program. Greene was succeeded by Ronald Miller (1991–2006), who created a “journal within the Journal” for subspecialty societies, including the Society of Cardiovascular Anesthesiologists. Miller also appointed international editors, and inaugurated the Chinese Language Edition.

The sixth Editor-in-Chief, Steven Shafer (2006–), continued development of the electronic edition enhancing interactivity and facilitating continuing medical education and links to OpenAnesthesia.org. He led the charge in identifying and combating plagiarism and fraud in anesthesia publication.

The IARS provided logistical and financial assistance in the establishment of the World Federation of Societies of Anaesthesiologists (WFSA), which in 1955 elected Harold Griffith (Chair of the Board of Trustees of the IARS) as the first WFSA President.

IARS founders envisioned support of research and education as primary objectives, and from 1983 to the present, the IARS provided more than \$ 12,000,000 to support research. In 2009, responding to growing concerns that anesthetics may impair mental development in young animals, the FDA and the IARS launched a public-private partnership (Smart-Tots), to raise \$ 30,000,000 to support research needed to determine the safest sedatives and anesthetics for young patients. Finally, from 1997 to 2012, the IARS gave 21 anesthesiologists Teaching Recognition Awards totaling \$ 220,000.

Introduction

The International Anesthesia Research Society (IARS) arose concurrently with the accelerating development of anesthesiology that marked the beginning of modern anesthesia. Where other new anesthetic societies failed, the IARS succeeded, principally through the efforts of an extraordinary man, Francis McMechan (Fig. 20.1). He had a vision for an international society of specialists in anesthesia that would support research, organize meetings as venues to present research results, publish a journal, and provide a mechanism for specialty certification [1]. This

Fig. 20.1 Francis McMechan. (Courtesy of the Wood Library-Museum of Anesthesiology, Park Ridge, IL.)

chapter describes his role in the creation of the IARS, and the continuing contributions of that society to the advancement of anesthesiology.

The McMechans

McMechan's grandfather and father were physicians. While in college, McMechan (1879–1939) won gold medals for oratory and essay writing. He was attracted to dramatics and music. Too young to enter medical school after graduation from college, he worked for 3 years as a playwright, as the Director of the Shuster-Martin School of Acting in Cincin-

nati [2], and as a reporter for the Cincinnati Post. In 1900, he entered the College of Medicine at the University of Cincinnati. After graduating in 1903, he joined his father's general practice in Cincinnati. An interest in anesthesia led McMechan to approach surgeons known to his father and ask if he could administer anesthetics for them. They soon appreciated that McMechan possessed unusual skills as an anesthetist, and although he began his career as a general practitioner in Cincinnati, he established a successful anesthetic practice, evolving into one of the first full-time anesthesiologists in the United States [3].

Laurette van Varseveld McMechan (1878–1970) claimed to be a descendant of Baron Larrey, Napoleon's Surgeon in Chief. While detailed analysis of historic records does not support this claim, there is no doubt that Laurette had a major positive role in the development of the specialty of anesthesiology, earning the affectionate title "Mother of Anesthetists" [4]. She was a student at the Shuster-Martin School, displaying an interest that coincided with McMechan's [3]. They married in 1909.

Unfortunately, Francis McMechan developed rapidly progressing rheumatoid arthritis and by the age of 32, his skeletal deformities were so debilitating that he could not continue his medical practice. The disease eventually forced him to sleep while seated and to rely on assistance from others, particularly Laurette. Unable to practice medicine, a tenacious McMechan applied his considerable skills as physician, reporter, playwright and amateur actor, to written communications within the fledgling specialty, and to the development of its organizations. McMechan was the Editor and Executive Secretary of the IARS and had similar appointments in several affiliated organizations. Laurette became his assistant, increasingly assuming responsibilities for the conduct of these organizations as McMechan's health failed during the late 1930s. She continued with these responsibilities after his death. McMechan spent most of his adult life in a wheelchair, "a device which contained but never confined him" [5]. With the support of his wife and colleagues at the IARS, he remained productive until the late 1930s, traveling throughout the world on behalf of anesthesiology. The following provides the details of his story and the associated history of the IARS.

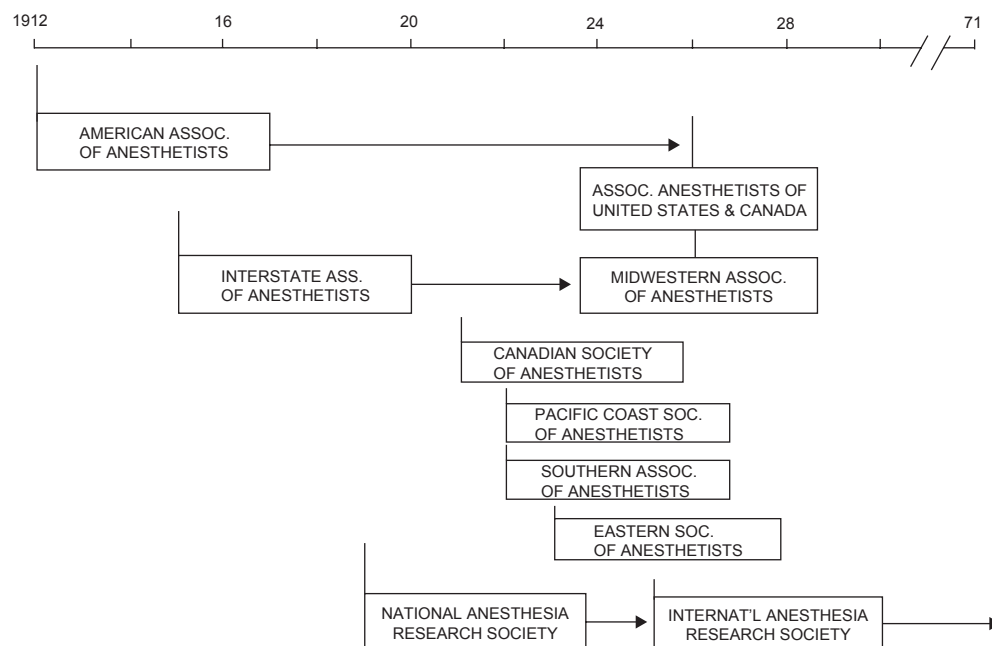

Formation of the International Anesthesia Research Society (IARS)

The London Society of Anaesthetists (1893), the Long Island Society of Anesthetists (1905) and its successor, the New York Society of Anesthetists (1911) constituted the world of formal organizations in anesthesia at the start of the 20th Century. Formal anesthesia training programs had

Fig. 20.2 A graphic depiction of the societies McMechan helped create and their approximate creation dates. (From Seldon TH: Anesthesia and analgesia—50 years of publication. *Anesth Analg* 1971; 50: 571–7, with permission.)

not been established for physicians¹, and no process existed to certify anesthetic practitioners. The specialty was truly in its infancy.

Two parallel streams of anesthesia organizations emerged in the United States. First, the New York Society became the American Society of Anesthetists (1936), to be renamed the American Society of Anesthesiologists (ASA) in 1945. Although the ASA initially included Canadian provinces as components, and one Canadian (Wesley Bourne) served as the ASA President in 1942, this arrangement lapsed and full ASA membership was then restricted to US residents.

Second, McMechan developed competing organizations in the US and Canada, some with international membership categories (Fig. 20.2). The American Association of Anesthetists (AAA, 1912), was linked initially with the American Medical Association, but through McMechan's influence, soon became fully independent. Additions to the AAA, included state and regional anesthesia societies within the US, and the Canadian Society of Anesthetists. A North American society (Associated Anesthetists of the United States and Canada) succeeded the AAA in 1926. McMechan led the establishment of the National Anesthesia Research Society (NARS) in late 1919. The announcement of the launching of NARS formed part of a report of the 8th Annual Meeting of the American Association of Anesthetists in New Orleans, April 26–27, 1920 [6]. NARS had a mandate to promote

research in anesthesiology and to communicate the results of this research, a mandate consistent with McMechan's vision of the importance of research for the future of anesthesia, and the need to link research with clinical practice. Members included both medical practitioners and industry representatives. However, the inclusion of members from industry prompted controversy and led to the decision to change both the society name and membership eligibility in 1925.

The IARS officially began on the 8th February 1925, by resolution of the "Professional Board of Governors (pro tem)" of the IARS, as the successor of the NARS. The IARS adopted the mission of the NARS, changing only the society name and society membership criteria (by excluding industry representatives). The IARS concurrently became the Publisher of *Current Researches in Anesthesia and Analgesia*, the first major anesthesia medical journal in the world, a journal started by the NARS in 1922 (Fig. 20.3). The 1925 Constitution and By-Laws of the IARS noted that the Society "...shall have the following Objects: 1) To initiate and foster research in all phases of anesthesia; 2) To establish and maintain the International Research Foundation; and 3) To extend the publication of the literature of anesthesia in so far as its resources may permit and its governing powers may direct" [7]. IARS membership was restricted to physicians, dentists and researchers with advanced degrees. The name change from NARS to IARS followed McMechan's belief that 'his' societies could and should have an international role, as evidenced by the IARS constitution listing its roles as the "official research and publications society of the International Federation of Anesthetists".

The Federation appears, from the limited information now available, to have been an entity under the IARS umbrella

¹ Agnes McGee established a school for nurse anesthesia at St. Vincent's Hospital in Portland Oregon in 1909. Agatha Hodgins and George Crile founded a school for nurse anesthesia at the Lakeside Hospital in Cleveland (part of the Cleveland Clinic) in 1915. (see Chapters 22 and 36 on the evolution of nurse anesthesia.)

Fig. 20.3 From left to right, covers of 1922, 1926, 1966, 1979, 1994 and 2005 issues of *Anesthesia and Analgesia* in various flavors. (From *Anesthesia and Analgesia*, with permission.)

which, at various points in time, included anesthesia societies in the United States, Canada and the United Kingdom. For example, the 1930 Directory of Anesthetists (accessed in the Wood Library-Museum of Anesthesiology) lists first the Associated Anesthetists of the United States and Canada, followed by the IARS and eight other societies based in the United States, plus one in Canada and three in the United Kingdom.

McMechan conceived the Federation as an organization that would certify specialists in anesthesia in the United States, Canada and the United Kingdom. However, when the certification process for anesthesia specialists was implemented, it was the International College of Anesthetists (not the Federation) that was the certifying entity. Medical and dental anesthesia specialists received the designation FICA—Fellow of the International College of Anesthetists. The IARS Board of Governors served as the review

committee of applications for certification. The 1941 certification requirements included 14 elements, ranging from professional qualifications through clinical anesthesia experience (minimum 2000 cases over 5 years), to IARS membership, and a pledge “to the ethical practice to the specialty of anesthesia”. Applicants were required to “present themselves to the Certification Board for questioning and for receiving certification” [8].

McMechan’s position on certification, as well as his condemnation of non-physician anesthetic practitioners, and those who taught them or worked with them, in part separated his organizations from ASA organizations. When invited in the late 1930s to join the ASA’s collaborative efforts with the AMA in the formation of the American Board of Anesthesiology (ABA), the IARS declined, responding that they already provided certification and that it should be “entirely separate from any other larger medical or surgical

organization and free from its domination or control” [9]. Thus, the IARS missed its chance to play a role in the formation of the ABA, and once the ABA was formed, the IARS certification gradually became irrelevant [10]. Newly developed specialty certification processes in Canada and the United Kingdom made the F.I.C.A. qualification irrelevant in those countries as well.

One historical discrepancy remains unresolved. The announcement in the April 1925 issue of *Anesthesia and Analgesia, Current Researches*, clearly states 1925 as the official start date for the IARS, succeeding the NARS. However, 1922 (the year of the first journal issue) is the date on the IARS seal. The seal was designed by, or under the authority of, the IARS Board of Governors, so the use of the year 1922 appears deliberate. The records now available do not further explain the seeming discrepancy. The year 1922 continues to be used as the official IARS start date.

Creation and Development of an Independent IARS Journal

McMechan recognized the importance of written communications to the development of anesthesiology. By 1914 he had convinced Joseph MacDonald, Managing Editor of the *American Journal of Surgery*, to publish a *Quarterly Supplement of Anesthesia and Analgesia*, with McMechan as editor. The Supplement continued until 1926, despite commencement of publication of *Current Researches in Anesthesia and Analgesia* in 1922 by NARS, with McMechan as editor. The latter publication coincided with the year in which MacDonald died.² The Editorial Foreword [11] of the first issue of *Current Researches in Anesthesia and Analgesia*, in August 1922, included the modest statement: “With this issue the former Bulletin becomes a regular Journal to carry on the organization and educational campaign of the National Anesthesia Research Society. As in the past, the Journal will print papers from the Transactions of the several Associations of Anesthetists, special and selected articles of pertinent interest, as well as abstracts from the current literature of anesthesia and analgesia.” A one-year subscription to the journal cost \$ 3.00, and single copies 50 cents.

With formation of the IARS in 1925, the Board of Governors of the IARS became the owners and governing body of the journal. McMechan continued as the Journal’s first editor until his death in 1939. His death precipitated a crisis for the IARS and its Journal, for the IARS Board of Governors had not prepared a succession plan. On 1 July 1939 the Board appointed Board member Emanuel Klaus to the acting positions of Executive Secretary and Editor, and Laurette

McMechan as Assistant Executive-Secretary-Editor, the positions she had held before her husband’s death. She continued in these roles until she retired in 1956. Thereafter, she was appointed Honorary Assistant Editor, a position she held until her death in 1970. A published summary of its 24 September 1939 meeting, noted that the Board had considered suggestions that the IARS should “amalgamate with other societies” [12]. In response, the Board approved an amendment to the IARS Constitution and Bylaws, requiring consultation with the membership via a mail vote for any proposal to change the status of the IARS as an organization. A change of IARS status required a two-thirds affirmative vote from at least two-thirds of the members. The IARS Board participated in initial discussions with an ASA committee but then withdrew, ultimately maintaining two societies, two journals (*Anesthesiology* was not launched until 1940), and two annual meetings [13].

In a further step toward editorial independence for the Journal, unlike two of three prior editors (McMechan and Seldon), Nicholas Greene, appointed as the fourth Editor-in-Chief of *Anesthesia & Analgesia* in 1977, declined to serve on the IARS Board of Trustees. This separation of the IARS governing board and the Journal editorial leadership, endured until 2012 when the IARS Board of Trustees (BOT) voted to invite Steven Shafer to participate in all BOT meetings (with certain exceptions) as a guest. This arrangement strengthened the communication between the IARS BOT and the Journal Editor-in-Chief, while maintaining the editorial independence of *Anesthesia & Analgesia*.

The history of the Journal, which became *Anesthesia and Analgesia...Current Researches* in 1957, and *Anesthesia & Analgesia* in 1979, may best be appreciated by a review of the contributions of the six Editors who have led it since 1922. In 1971, Seldon chronicled the Journal’s first 50 years [14], and in 1997, Craig and Martin reflected on the first 75 years [5]. We summarize those reviews below and add vignettes for Ronald Miller and Steven Shafer to bring us to 2013.

Francis McMechan (Editor from 1922–1939)

McMechan dominated the early years of the NARS/IARS and of the Journal (Fig. 20.1). As noted above, he had edited the *Quarterly Supplement of Anesthesia and Analgesia* of the *American Journal of Surgery*, from 1914 to 1926. As a former newspaper reporter and playwright he brought effective communication skills to these tasks. Through written communications, in an era when communication tools were basic by modern standards, and by extensive travel during which he promoted the specialty of anesthesiology and “his” societies, McMechan attracted authors, society members and journal subscribers. The Journal was successful and became a vehicle not only for scientific communication, but also for

² The British Medical Journal of 18 Feb 1922 reported MacDonald’s death on p 22.

NARS/IARS announcements. Some of these appear in the indexed pages of the Journal while others are ‘hidden away’ in the annual index, and are not highlighted on the index itself. Commercial advertising was introduced, with a note that “for permanent binding the advertising pages may be withdrawn, without discarding any of the content.” Laurette McMechan held an active position as Assistant Editor and influenced the operations of both the Journal and the various societies. During the 1930s, when chronic illness frequently disabled McMechan, Laurette increasingly assumed governance of Journal operations. This experience proved valuable following McMechan’s death in June 1939. Laurette’s contributions to anesthesia worldwide, including her recognition as the “Mother of Anaesthetists”, were included in tributes published following her death [15].

In 1937 Francis and Laurette were jointly recognized for their many achievements with the presentation of a loving cup trophy with the following inscriptions: “To F. Hoeffler McMechan, M.A., M.D., F.I.C.A. Editor, Secretary-General and Laurette van Varseveld McMechan Associate Editor, Secretary and hostess. In loving appreciation of devoted services and splendid achievements for the organization, economics, research, practice, teaching, journalism and fellowship of the specialty of anesthesia. For the world conquest of human pain in behalf of suffering humanity. Presented by the International Anesthesia Research Society and International College of Anesthetists. Sixteenth annual Congress of Anesthetists. 1937” [16].

Howard Dittrick (1940–1954)

As outlined earlier, the IARS did not have a succession plan ready when McMechan died in 1939. Assisted by Laurette McMechan and the IARS Governors, Emanuel Klaus, a member of the IARS Board of Governors, assumed editorial responsibility for the final three issues of 1939. The January–February 1940 issue announced Dittrick’s appointment as Directing Editor, reporting to the IARS Board (Fig. 20.4) [17]. Dittrick (1877–1954), a gynecologist, had a background in medical editing (Editor of the *Bulletin of the Cleveland Academy of Medicine*) and medical history. His appointment is thought to have been as a result of the IARS Board’s positive view of his academic credentials and international recognition, as well as Dittrick’s longstanding friendships with Klaus and both McMechans [18]. The first Journal issue for 1940 also confirmed the continuing role of Laurette McMechan as Assistant Editor and continued the IARS Board of Governors as the Editorial Board.

The 1940s were difficult years for the Journal. Dittrick functioned more as a copy editor than an Editor-in-Chief, and had a limited ability to recruit reports for the struggling Journal. Commencing in July 1940, the publication

Fig. 20.4 Howard Dittrick, second editor of *Current Researches in Anesthesia and Analgesia* shows one of the many surgical artifacts he collected. (From the Case Western Reserve Dittrick Medical History Center, Cleveland, OH.)

of *Anesthesiology* by the American Society of Anesthetists (becoming the American Society of Anesthesiologists in 1945) provided stiff competition for *Current Researches in Anesthesia and Analgesia*. The difficulties created by World War II, including the suspension of the IARS Congresses from 1942 to 1945 (a major source of papers published in the Journal), were also a negative factor. To the credit of the editorial team, the Journal continued bimonthly publication throughout the 1940s, but the numbers of society members and subscribers declined. Dittrick continued as Directing Editor until his death at age 77 early in 1954.

T. Harry Seldon (1954–1976)

After Dittrick’s death, Thomas Harry Seldon, (always addressed as Harry), a member of the IARS Board, assumed the Editor-in-Chief position, in addition to his full time clinical practice as an anesthesiologist at the Mayo Clinic (Fig. 20.5). Laurette McMechan’s appointment as Assistant Editor continued, as did the role of the IARS Board as the Editorial Board of the Journal. Seldon (1905–1991) recognized that the competition provided by *Anesthesiology* re-

Fig. 20.5 Thomas Harry Seldon. (Photo courtesy of Mayo Foundation for Medical Education and Research. Used with Permission.)

quired major changes to the Journal. The official title of the journal was changed in 1957 to *Anesthesia and Analgesia... Current Researches*. The appearance of the journal changed (Fig. 20.3). The page size was increased, color highlights were added, and new content features were introduced, all to make the Journal more interesting for the reader. These included short notes about new drugs and equipment, historical vignettes and the inclusion of photographs and biographical sketches of first authors. More significant was Seldon's legendary kindness and patience in helping first authors create publishable articles, through the revision and editing process. The Editorial Board was expanded to include non-IARS Board of Trustee members, a step with symbolic and practical importance. Credited to Harry Seldon, the decline in the status of the Journal was arrested, confidence in it increased [19] and *Anesthesia and Analgesia... Current Researches* was ready for the next phase.

Fig. 20.6 Nicholas M. Greene. (From Medicine at Yale website.)

Nicholas Greene (1976–1990)

The appointment of Nicholas Greene (1922–2004) as Editor-in-Chief began a new phase for the Journal (Fig. 20.6). He had served for 18 years as the Chair of the Department of Anesthesiology at Yale University, and had just completed a term as Editor-in-Chief of *Anesthesiology*. Greene offered a wealth of knowledge, experience and credibility as an editor and academician [20]. Tellingly, Greene declined an invitation to become an IARS Trustee. The Editorial Board was expanded, with most Editors not simultaneously acting as Trustees on the IARS Board. Thus, although the Journal was still responsible to the IARS Board, it gained increasing editorial independence. Another redesign was introduced in 1979 (Fig. 20.3), the Journal was renamed *Anesthesia & Analgesia*, and the following year it became a monthly publication.

Greene's authoritative approach to the scientific review process, and his kind but firm communications with authors had a salutary effect on the reputation of *Anesthesia & Analgesia* and the IARS, and the number of quality manuscripts increased. Elsevier Science Publishing (New York) was engaged as Publisher, replacing a complex set of in-house management steps that could be traced back to 1922.

Fig. 20.7 Ronald Miller. (From UCSF physician website.)

The enhanced scientific content and more efficient management process expanded circulation and increased profitability, which in turn supported the establishment of the IARS Research Awards program. When he stepped down as Editor-in-Chief in 1990, Greene left a legacy of a vibrant, scientifically based Journal, and a society that could now actively support anesthesiology research.

Ronald Miller (1991–2006)

Ronald Miller was a successful editor and academician before assuming the role of Editor-in-Chief of *Anesthesia & Analgesia* (Fig. 20.7). His textbook, *Anesthesia*, was in its third edition and was regarded as among the definitive textbooks in anesthesiology. Miller was Chair of the Department of Anesthesiology at the University of California San Francisco. While Editor-in-Chief, he was elected to the Institute of Medicine of the United States National Academy of Sciences. Miller moved the Journal Editorial Office to San Francisco, where it functioned relatively independently from the IARS Office in Cleveland, Ohio. The relationship between the Editor-in-Chief and the IARS Board of Trustees was similarly independent, with the interaction primarily that of regular reportage.

A crucial Miller legacy was his accomplishment of a “Journal within the Journal”, a publishing home for several anesthesiology subspecialty societies [21]. In 1993, the IARS changed publishers from Elsevier to Lippincott Williams & Wilkins (LWW), and in 1994, the Society of Cardiovascular Anesthesiologists (SCA) became the first and largest subspecialty society to adopt *Anesthesia and Analgesia* as its official journal. The IARS agreed to appoint an Associate Editor-in-Chief for Cardiovascular Anesthesiology, nominated by the SCA. This agreement strengthened the Journal by increasing its subscriber base and the number of manuscripts available for potential publication. Subsequently, Miller succeeded in negotiating with four more societies to affiliate with *Anesthesia & Analgesia* as their official journal: the Society for Pediatric Anesthesia (SPA) and the Society for Ambulatory Anesthesia (SAMBA) in 1996, the international Society for Anaesthetic Pharmacology (ISAP) in 2000, and the Society for Technology in Anesthesia in 2001. With the exception of SCA, affiliate society members were not required to subscribe to the Journal or join the IARS.

Miller advanced the worldwide influence of the Journal by appointing several international members to the Editorial Board, by creating the on-line edition of the Journal, and by inaugurating the Chinese Language Edition, published and distributed in China. The appearance of the printed Journal changed twice during his 15-year tenure (Fig. 20.3).

Steven Shafer (2006–Present)

In 2006, after an extensive and competitive search by the IARS Board of Trustees, Steven Shafer was selected as Editor-in-Chief (Fig. 20.8). Shafer is an academic anesthesiologist whose research focus is pharmacokinetics and pharmacodynamics. Shafer created a new look for the Journal in its printed and on-line versions. The covers of the printed versions contain original artwork: sometimes humorous, sometimes puzzling, but always arresting (Fig. 20.9). He further expanded the editorial content and correspondence sections of the Journal to amplify the significance of its content, and support subsequent debate. Dr. Shafer enhanced the interactivity of the on-line Journal using a multimedia approach, creating and encouraging links to innovative sites such as OpenAnesthesia.org. During Shafer’s tenure the impact factor of *Anesthesia & Analgesia* increased from 2.1 in 2006 to 3.4 in 2012, placing it in the top tier of anesthesiology journals. In 2013, the Journal stopped publishing Case Reports, instead creating a new online journal, *Anesthesia & Analgesia Case Reports*, naming Lawrence Saidman as Editor-in-Chief.

Shafer continued the recruitment of subspecialty societies and expansion of the editorial board. The Anesthesia Patient Safety Foundation (APSF) became affiliated with the Jour-

Fig. 20.8 Steven Shafer. (Courtesy of Dr. Pamela Flood.)

nal in 2007. In 2008, *Anesthesiology* decided to divest itself of subspecialty society affiliations. Shafer made a new home for the Society for Obstetric Anesthesia and Perinatology (SOAP), and the American Society for Critical Care Anesthesiology (ASCCA)—now called the Society of Critical Care Anesthesiologists (SOCCA).

A sad topical reflection on academic anesthesiology (and the scientific community as a whole) has been the increasing revelations of plagiarism and fraud in scientific publications. Shafer had to deal with three major such events in his first term, and many other minor ones. In every case he met the challenge head-on, with resolve, persistence and editorials (Fig. 20.9) [22–24]. Through his leadership, he brought together several national and international scientific journal editors to take joint action against academic fraud.

An important aspect of Shafer's role as Editor-in-Chief of *Anesthesia & Analgesia*, has been his active and ongoing dialog with the IARS Board of Trustees. He has engaged with the Board of Trustees in strategic planning, and has increased the exchange of ideas between the Board of Trustees and the Editorial Board. The move of the IARS Head Office to San Francisco and its amalgamation with the

Editorial Office (see below) further enhanced this relationship. Shafer was appointed to a second five-year term by the IARS Board of Trustees in 2011, and in 2012, he was invited to participate in BOT meetings (with certain exceptions) as a guest.

Creation and Evolution of the IARS Congress

McMechan initially convened his several societies as an annual “Congress of Anesthetists” at various locations in the United States and Canada. The first American Association of Anesthetists Congress took place in 1913. As new societies were formed, they participated in the Annual Congress, although with some inconsistency in sponsorships and inclusion—even the ASA co-sponsored the Congress for a short time. The first NARS Congress was held in Columbus, Ohio in 1922.

Since its formation in 1925, a major activity of the IARS has been its Annual Congress, renamed the Annual Meeting in 2009. Through this time the IARS has conducted 85 meetings, omitting only those coinciding with World War II (1942–1945) and the first WFSA meeting in 1955. Most meetings have been held in the United States (with a tradition of a meeting in Hawaii every five years), but other venues have included Puerto Rico, the Bahamas, Canada and England.

For many years two Trustees working with the IARS Head Office essentially ran the Annual Congress. This model developed into an Annual Meeting Committee, still led by two Trustees, but which reached outside the Board of Directors for new energy and ideas.

Rather than trying to compete directly with the ASA meeting, the IARS has positioned its Annual Meeting as a much smaller (1,000 attendees), interactive international forum with direct and easy access between faculty and registrants. The attractiveness of the Annual Meeting has been enhanced by innovations such as a half to full day thematic scientific symposium, and replacing the formal industrial exhibition by an interactive ‘table top’ gathering of sponsors and anesthesia expert opinion leaders. As a consequence, the IARS Annual Meeting continues to fulfill a unique, valuable role in enhancing the missions of the Society.

The IARS and the World Federation of Societies of Anaesthesiologists

The IARS played critical roles in the establishment of the World Federation of Societies of Anaesthesiologists (WFSA) and in the first World Congress, in Scheveningen, The Netherlands in 1955 [25]. Continuing the tradition of international cooperation established by McMechan decades

Fig. 20.9 Cover of March 2011 issue of *Anesthesia and Analgesia*

earlier, the IARS held its 1951 Congress in London, in joint session with the Association of Anaesthetists of Great Britain and Ireland. This meeting was followed by another international anesthesia congress in Paris, attended by IARS officers, during which the creation of a new world-wide anesthesia organization was proposed. Harold Griffith (at the time Chair of the Board of Trustees of the IARS) chaired the committee established to explore the issue. After soliciting reports about the numbers of anesthesiologists throughout the world, the committee met again in June 1953. The national organizations representing the specialty reported that there were about 7,000 practicing anesthesiologists and also confirmed interest in the development of a new international organization. The IARS represented the US on the planning committee since the ASA elected to remain an “Official Observer” rather than become involved at that point. Steps to establish the WFSA began, as did planning for the 1955 Congress. The IARS provided secretarial support and financial assistance for the Society and Congress planning processes, and later paid the full costs for the preparation and printing of the proceedings of the 1955 Congress, which were mailed to all IARS members and the 2,000 attendees. Griffith chaired the World Congress and was elected as the first WFSA President.

The WFSA Constitution, which was legally registered in the Netherlands in 1956, described the aim of the Federation as: “To make available the highest standard of anaesthesia to all peoples of the world”. McMechan’s vision of an international organization of anesthesiologists had been fulfilled, 15 years after his death [26].

By the time of the second World Congress in Toronto, Canada in 1960, the WFSA society membership criteria had been established, with each component national society required to be representative of all anesthetic practitioners in its own country. The IARS Board recognized and accepted that in the United States this role belonged to the ASA, not the IARS. The ASA, after its initial reluctance to become involved in 1955, became a strong and loyal supporter of the WFSA.

More recent IARS support for WFSA programs included the provision of 200 copies of the printed annual IARS Review Course book, from 1983 to 2007 (the last print edition) as well as major support for the costs of the Harold R. Griffith Symposium at the WFSA 9th World Congress in Washington, DC, in 1988.

IARS Governance

The Board of Governors of the NARS (1919–1924) and then the IARS (from 1925) included physicians, dentists, and scientists. These individuals ran the society, conducted the congresses, and starting in 1922, served as the editorial board of

the journal under the direction of McMechan. This unincorporated arrangement continued until 1952, when the IARS incorporated as a not-for-profit organization in the state of Ohio, to “foster progress and research in all phases of anesthesia.” The articles of incorporation charged the IARS Board of Trustees with all the responsibilities and authorities of the Society, including the management of its Journal. The title of the IARS Board members changed with incorporation from Governor to Trustee. A listing of all IARS Board members is available on the IARS website (IARS.org).

Initially, Board members were appointed without term limits. Later, the limit was set at 24 and then 18 years. Finally, in 1999, Stephen Thomas stepped down after twelve years, in an effort to push the Board of Trustees toward the twelve-year term, which has been in place since then. This term appears to have achieved the right balance between experience and innovation in the Board of Trustees. The Board has also become increasingly representative of women and minorities, as well as more international in character.

The listing of the IARS Board of Governors and the Honorary Officers and Advisory Board, in the 1930 Directory of Anesthetists (IARS Archives, Wood Library-Museum), reveals the international reach of the IARS, under McMechan’s influence. While 7 of 8 Governors were from the US, and one from Canada, the honorary officers were from (order and spelling as in Directory): United States, Germany, France, Holland, Sweden, Brazil, Cuba, England, Czechoslovakia, Scotland, Australia, Russia, New Zealand, and the Irish Free State—further evidence of McMechan’s international vision!

Except for the years 1962 to 1973, there has been at least one Board member from Canada. In 1999, the first European Trustee was elected to the Board of Trustees, followed in 2001 by the first Asian Trustee from Japan. These two seats have remained “international”.

The relationship between the IARS Board of Trustees and the Editor and Editorial Board of *Anesthesia & Analgesia* has undergone a continuous evolution. At its inception, the Board of Trustees essentially directed activities of the Journal. Greene’s decision to not become a Trustee initiated establishment of the editorial independence of the Editor-in-Chief and the Editorial Board, which developed further over the next three decades. Greene and Miller organized and directed the activities of the Journal through the Editorial Board and the Editorial Office, which moved to San Francisco during Miller’s tenure. The IARS Head Office remained in Cleveland, Ohio, with a local staff and limited interaction with the Editorial Office on the West Coast. The Editor-in-Chief had a largely reporting relationship to the Board of Trustees, which had little input into the day-to-day running of the Journal.

After the appointment of Shafer in 2006, this distant relationship started to reverse. Shafer brought new ideas for

discussion with the Board of Trustees. In 2007 the Board of Trustees hired a new Executive Director, Tom Cooper. In 2009, the IARS moved its office from Cleveland, Ohio to San Francisco, California, where it amalgamated with the Editorial Office with a new staff (save for Ms. Laura Kuhar, who has been with the IARS for 32 years!). The centralized office facilitated the productive integration of all the operational activities of the IARS—*Anesthesia & Analgesia*, the Annual Scientific Meeting, and support of research and education in anesthesiology and perioperative medicine. This development is consistent with the strategic missions of the IARS, and has enhanced teamwork between the editorial and IARS staff, increased operational efficiency and realized substantial cost savings.

Indicative of the enhanced interaction between the IARS Office and the Editorial Office, was the 2010 appointment of a Director of Publishing and Strategic Partnerships. In 2009, a Journal Strategic Planning Committee (JSPC) was formed that included the Editor-in-Chief, the Chair of the Board of Trustees, the IARS Executive Director, the Director of Publishing and Strategic Partnerships and a senior BOT member as Journal Liaison. This Committee has met twice a year to discuss financial issues of importance to both the Journal and the BOT, and steered the recent renewal of the Journal contract with Lippincott Williams & Wilkins. The JSPC also promoted the development and close association of the IARS and the Journal with OpenAnesthesia.org, an exciting on-line interface with great appeal to residents and younger anesthesiologists, as well as an iPad version of *Anesthesia & Analgesia*.

IARS Affiliation with Specialty Societies

In 1994, the IARS and the Society of Cardiovascular Anesthesiologists (SCA) reached an affiliation agreement in which the SCA made *Anesthesia & Analgesia* its official journal to be received by all its members. The IARS agreed to provide a “Journal within the Journal” for cardiothoracic and vascular related articles selected by the existing editorial process. In addition, the IARS agreed to appoint an Associate Editor-in-Chief for Cardiovascular Anesthesiology nominated by the SCA. This agreement strengthened the journal by increasing its subscriber base and the number of manuscripts available for potential publication. Subsequently, seven other societies, as listed in the section on Editors, established joint publishing relationships with the IARS and selected *Anesthesia & Analgesia* as their official journal. The subsequent affiliations strengthened the Journal, but the SCA affiliation remains the only agreement that required its members to subscribe to *Anesthesia & Analgesia*. In mid 2013, *Anesthesia & Analgesia* had 14,000 IARS member subscribers and 3,567 institutional subscribers.

IARS Support of Research and Teaching

Although the founders of the IARS envisioned support of research as a primary objective, a formal and sustained research awards program was not established until 1983. Before that time, the IARS recognized outstanding research by presentation of a “Scroll of Recognition for Meritorious Research in Anesthesia and Analgesia.” The IARS presented the first such award to Dennis Jackson in 1924. C McKesson (President), W Jones (Vice President) and F McMechan (Editor—Executive Secretary) signed the scroll. The IARS awarded two scrolls in 1925. It was not until decades later that the IARS contributed funds to support research: a \$ 10,000 donation to the ASA in 1976 and a \$ 5,000 donation to the Canadian Anesthesiologists’ Society in 1985, the latter in recognition of the many years of service of Canadian Trustees on the Board of the IARS.

In 1983, the IARS began its systematic support of research, establishing the BB Sankey Anesthesia Advancement Award (\$ 25,000) in recognition of Sankey’s long service to the IARS as Executive Secretary (1965–1983). The IARS Board of Trustees served as the review committee for these applications and subsequent awards noted below—with one exception. Applicants had to be IARS members and to submit formal research proposals. From 1983 to 1993, the IARS granted 45 Sankey awards, totaling \$ 1,078,495. From 1993 to 2004, the IARS provided seven individuals with \$ 143,237 (total) as the Ben Covino Research Awards, in honor of Covino’s pioneering work in regional anesthesia.

In 1988, the IARS Board determined that the financial success of *Anesthesia & Analgesia* permitted expansion of the IARS Research Awards Program. The Board reached two conclusions. First, it decided that the specialty needed larger awards (initially \$ 50,000, later \$ 80,000) focused on clinical research. To address this need, the Board created the IARS Clinical Scholar Research Award (CSRA) replacing the smaller Sankey award, a change made with Sankey’s consent. From 1994 to 2011, 62 individuals received Clinical Scholar Research Awards, including researchers from seven different nations (US, Canada, Germany, Israel, Netherlands, Switzerland, and the UK), totaling \$ 4,696,613. In 2012 the CSRA was replaced by the \$ 150,000 IARS Mentored Research Award, with four awards made in 2013.

Second, the Board concluded that anesthesiology needed a major award (initially \$ 500,000, currently \$ 750,000) to “foster innovation and creativity in anesthesia research by an individual researcher.” To address this need, the Board created the IARS Frontiers in Anesthesia Research Award. The Board appointed expert panels of scientists to review applications. From 1995 to 2012, this award has been granted nine times to researchers in four different countries (US, Canada, Germany, and Switzerland), totaling \$ 4,750,000. In 2009, in partnership with the Society of Cardiovascular Anesthesiolo-

gists (SCA), the IARS pledged \$ 1,000,000 over five years to the SCA Foundation in support of cardiothoracic and vascular anesthesia research projects. To date the IARS has provided over \$ 12,000,000 of support for research, including \$ 250,000 for the SmartTots Initiative discussed below.

In addition to research awards, the IARS provided recognition of excellence in education. From 1997 to 2012, 21 anesthesiologists have received Teaching Recognition Awards. Academic departments nominate and document the work of their outstanding teacher. The IARS Board selects the recipients and presents the awards at the IARS Annual meeting. Currently there are two awards (\$ 17,000 total), one recognizing Innovation in Education, the other, Achievement in Education. In total, the IARS has awarded \$ 220,000 in recognition of teaching excellence. A listing of all IARS awardees since 1983 is available on the IARS web site³.

The IARS-FDA SmartTots Initiative

In 2008 the US Food and Drug Administration (FDA) approached the IARS with a proposal to launch a private-public partnership to study the safety of anesthetics and sedatives in young children. This initiative was developed in response to a growing concern that anesthetics and sedatives may impair mental development in young animals. The FDA chose the IARS for this partnership because it considered the Society to be apolitical, independent and capable of garnering the scientific and financial resources required for this unique project.

After considerable discussion and planning, the partnership was unveiled in 2009 as SmartTots (*Strategies for Mitigating Anesthesia Related neuro-Toxicity in Tots*). (The program was introduced as SafeKids, but the title was changed when it was discovered that another entity was already using this name).

(<http://www.fda.gov/NewsEvents/Newsroom/PressAnnouncements/ucm149543.htm>).

Guided by a joint IARS-FDA Steering Committee, a multidisciplinary Scientific Advisory Board was formed to provide oversight for research strategy and proposal review as well as an Executive Board to lead fundraising. SmartTots appointed as its Executive Board Chair, Michael Roizen, a noted academic anesthesiologist, a well-known health advocate having a particular interest in the issue of neurotoxicity in the very young, and a proven expertise in gathering funds for such a major enterprise.

More than 250 physicians and scientists attended the SmartTots inaugural scientific symposium that took place at the 2010 IARS Annual Meeting in Honolulu. Guided by Roizen and his Executive Board, SmartTots (www.SmartTots.org) seeks to raise \$ 30,000,000 from private sources, to support the research needed to determine the safest agents to be used for the youngest patients requiring sedation or anesthesia. The IARS has donated \$ 250,000 to SmartTots thus far, and is leading the charge in soliciting donations from the anesthesiology community and the general public.

Tots.org) seeks to raise \$ 30,000,000 from private sources, to support the research needed to determine the safest agents to be used for the youngest patients requiring sedation or anesthesia. The IARS has donated \$ 250,000 to SmartTots thus far, and is leading the charge in soliciting donations from the anesthesiology community and the general public.

Conclusions

The IARS is a unique organization, now in its tenth decade as an apolitical, international medical society with a voluntary membership of 14,000 worldwide. The IARS has provided more than \$ 12,000,000 to support research, and many millions of dollars more to publish *Anesthesia & Analgesia*, the first major journal devoted to the profession of anesthesiology. Eight specialty societies have adopted *Anesthesia & Analgesia* as their official "Journal within a Journal." Over the lifetime of meetings organized by the IARS, approximately 50,000 professionals have attended an annual IARS meeting to participate in the presentation of research findings and educational sessions. Today, the IARS is pioneering discovery and improved patient care through its SmartTots partnership with the United States Food and Drug Administration. As it approaches completion of a century of activity, the IARS continues to fulfill its trifold mission to support research investigation and education in anesthesiology, and disseminate new information through its prestigious Journals and its Annual Meeting.

Acknowledgments The authors wish to thank Laura Kuhar of the IARS staff and the Wood Library-Museum of Anesthesiology for their help in providing material for this review.

Establishment of Anesthesia Certification and the ABA

21

Francis P. Hughes, and Myer H. Rosenthal

Summary

The NY Society of Anesthetists (NYSA) established a Committee on Fellowships in 1931, incorporating as the “American Board of Anesthesiology” (ABA) in 1935. The ABA certified only local practitioners, excluding recognition by the nationally-based American Medical Association (AMA). In 1936, the NYSA renamed itself the American Society of Anesthetists (ASA). Waters and Wood presented the need for formal recognition of credentialing by the ASA to the American Board of Surgery (ABS). The ABS instructed the ASA to form an examining board as a sub-board of the ABS. In 1938, the Advisory (later American) Board of Medical Specialties (ABMS) approved the ABA as a sub-board of the ABS. In 1939 the ABA awarded its first certificate. In 1941, the ABMS approved the ABA as a primary board with standing equal to that of other boards.

In the 1940s, the ABA evaluated each anesthesia residency training program application submitted to the AMA Council of Medical Education (AMACME). This became too burdensome for the 11 Board Directors, leading the AMACME to establish the Residency Review Committee (RRC) for anesthesiology in 1957. Similarly, the ABA abandoned the use of practical examinations and surveys of practice to define clinical competence in the 1940s, substituting yearly reports of competence by residency directors or preceptors, in 1946.

In 1940, the ABA defined two pathways for entry to its examination system: Two years of approved post-internship training followed by 3 years of 100% anesthesia practice, or 5 years of 100% anesthesia practice. In 1944, the ABA made two years of approved anesthesia training mandatory. From 1937 to 1947, the ABA allowed graduates of AMA-approved foreign medical schools to enter its examination system. In 1969, the ABA admitted Fellows of English, Irish, South African, Australasian and Canadian Colleges (of anesthesia) to its examinations, but the Faculty of Anesthetists of the Royal College of Surgeons of England barred US trained anesthesiologists from their examination system because their training demanded more years than did the US. The ABA mandated an increase in residency from 3 to 4 years in 1976, implementing the increase in 1984. In 1993, the ABA withdrew recognition of residency training in any foreign country except Canada.

In 1985, the ABMS authorized the granting of certification in Anesthesia Critical Care Medicine, with the first examination in 1986. In 1991, the ABMS authorized certification in Pain Management, with the first examination in 1993.

In 1994 and 1995, the ABA declared its intent to issue 10-year time-limited certificates for its primary certificate and for all current and future subspecialty certificates, to commence for all certificates awarded after January 2000. Pain Management certification was granted with a 10-year time limit at its inception in 1993. In 2009, a program for Maintenance of Certification in Anesthesiology (MOCA) replaced the recertification program in place since 2000.

The first US medical organization focused on anesthesiology was the Long Island Society of Anesthetists (LISA), established in 1905. T Drysdale Buchanan, later the first President of the American Board of Anesthesiology (ABA) and recipient of ABA certificate #1, graduated from the New York Homeopathic Hospital in 1897 and in 1898 became the first anesthetist appointed to the Flower Hospital Staff in New York City. In 1904, he became the first professor and head of the Department of Anesthesia at the New York Homeopathic Hospital (later the New York Medical College and Flower Hospital.) In 1912, the LISA combined with anesthetists from Manhattan, to become the New York Society of Anesthetists (NYSA). The NYSA established the Committee on

Fig. 21.1 Members of the New York Society of Anesthesiologists' Committee on Fellowships. (Courtesy of the New York State Society of Anesthesiologists, New York, NY.)

Fellowships in 1931 (Fig. 21.1), beginning a 9-year effort to develop a certification process for anesthesiologists.

Francis McMechan established the International Anesthesia Research Society (IARS) in 1922, and the International College of Anesthetists (ICA—which awarded the first certificate in anesthesiology in 1935), but circumstances militated against his efforts to establish a US based certification.

ICA certification required:

1. Documentation of graduation from medical school and type of anesthesia practice
2. Documentation of the candidate's practice for the previous 3 years, meetings attended, and papers published
3. Submission of 10 complete records including preoperative evaluation, with a discourse on that which was learned from each case.

McMechan, crippled with rheumatoid arthritis, would not tolerate dissent and rarely sought compromise. His adamant opposition to anesthesia practiced by nurses, placed him in direct opposition to surgeons and the American Medical Association (AMA) who favored non-physician anesthesia, demonstrating their allegiance to the nurses providing anesthesia in support of their surgeries. McMechan, an internationalist, married to a French woman, favored international over a more limited US certification. The AMA, the NYSA, and the ABMS established in 1933 by the AMA, opposed such an approach. McMechan's internationalism came at a time of increasing isolationist views in America. Having suffered over a million casualties, beginning with the Revolutionary War and continuing through the Great War (World War I), American society had turned inward, giving a deaf-

ear to McMechan's proposals. His uncompromising persona precluded reconciliation.

Paralleling McMechan, the Committee on Fellowships of the NYSA, with Buchanan as Chair and Paul Wood, (an Obstetrical Anesthesiologist at the 5th Avenue Hospital in New York City who famously created the Library-Museum bearing his name) as secretary, began developing its own certification process, a process that eventually established the ABA. The Committee formally incorporated in 1935 "under and by virtue of the laws of the State of New York, (and) the name...shall be the Examining Board, Committee of Fellowship, American Society of Anesthetists or American Board of Anesthesiology." Initial Committee members were Buchanan, Wood, and William Branhowe, E Leslie Burwell, Archer Bush, Simon Ehrlich, Bernard Eliasberg, Robert Hammond, and George Tong.

On 23 July 1935, approximately 1 year after McMechan's ICA awarded its first certificates, the Committee met for the first time. In 1936, Fellowships were granted to 88 members of the NYSA, "certifying on record only". The Committee's intent for establishing specific certification for anesthesiologists was that "the basic science for anesthesiology must, of course, stress pharmacology and physiology which, apparently, are less important to the operating surgeon".

In 1927, at the University of Wisconsin, Ralph Waters created the first academic Department of Anesthesiology. His protégés subsequently developed parallel anesthesia programs that enlarged the recognition of anesthesiology as a physician-led, independent specialty and thereby prompted the formation of a certification processes. One protégé, Emery Rovenstine, established the Department of Anesthesia at the Bellevue Hospital at New York University College of Medicine, in 1935. Rovenstine, Buchanan, Wood and Waters would join the first Board of Trustees of the new Examining Board.

Restriction of the certification by the Fellowship Committee of the NYSA to locally trained practitioners precluded support by the nationally-based AMA. In 1935, the NYSA extended membership outside New York, accepting anesthesiologists from 17 other states. Further to the national focus of the AMA, on December 10, 1936, the NYSA incorporated in New York as the American Society of Anesthetists (ASA). Reflecting McMechan's concerns regarding non-physician practitioners, the ASA by-laws stated that the purpose of the Committee on Fellowships was "to protect the public against irresponsible and unqualified practitioners who profess to be specialists in anesthesiology."

The ABMS rebuffed early ASA attempts to establish a primary certification process. The ABMS and the AMA considered anesthesiologists as "surgeons specializing in anesthesia". This hostile climate led the Committee on Fellowships to seek other options, leading to a discourse with the American Board of Surgery (ABS) which was organized on 1 Janu-

ary 1937. On 10 January 1937, Waters and Wood presented the ASA position to the ABS. The ABS instructed the ASA to form an "examining board in anesthesiology" as a sub-board of the ABS. A formal affiliation was established on 2 June 1937. The initial examining board consisted of 3 members nominated by the ASA, 3 by the ABS and 3 by the Section of Surgery of the AMA. A 10th member would be a representative from the ABS. The initial articles of incorporation specified that the Examining Board would establish criteria of fitness to practice anesthesia, and arrange, control and conduct examinations to determine the qualifications, and grant certificates to those who voluntarily apply and meet these required standards.

The initial Board of Trustees, as it was called, included the then giants of anesthesia (Fig. 21.2): Buchanan (NYC), Arthur Guedel (Los Angeles), John Lundy (Rochester, Minnesota), Rovenstine (NYC), Henry Ruth (Philadelphia), Ralph Tovell (Hartford, Connecticut), Waters (Madison, Wisconsin), Wood (NYC), and Philip Woodbridge (Boston). The surgical representative from the ABS was Arthur Elting from Albany, New York. Buchanan was designated Chair with Ruth as Vice-Chair and Wood as Secretary-Treasurer.

The Examining Board established criteria for entering the examination process:

1. Medical school graduation
2. Completion of internship
3. 2 years of training, including 18 months of practical training in anesthesia
4. 2 years in the sole practice of anesthesia
5. Membership in the AMA or a comparable approved national medical society (a change from the original criteria that required NYSA membership)

The Board developed categories for the first candidates for certification:

- I. Founders: Professors and Associate Professors previously elected to Fellowship in the ASA were to be certified without examination
- II. Group A: Those having practiced for 15 or more years were to appear before the Board and could be certified without examination
- III. Group B: Those practicing for 7.5 years or more or having administered anesthesia in at least 1500 major procedures could be certified following only an oral examination
- IV. Group C: Those who met the 5 "criteria for entering the examination process" listed above and submitted 150 of their cases for evaluation were allowed to enter the full examination system

Finally, certification required a positive vote of two-thirds of the Board of Trustees of the Examining Board and approval by the ABS.

Arthur Guedel did not fall under any of the group designations, and he was removed as a Trustee and replaced by

Fig. 21.2 The initial Board of Trustees of the American Board of Anesthesiology. (Courtesy of the American Board of Anesthesiology, Inc., Raleigh, NC.)

H. Boyd Stewart of Tulsa, Oklahoma. In 1943, recognizing Guedel's enormous contributions to anesthesiology, the Board of Directors of the ABA approved his certification without examination. Guedel said, "thank you".

The AMA initially resisted certification of the Founder's group of 40 anesthetists and suggested placing this group in Group A. The ABS rejected this proposal as it would have eliminated 95% of the candidates including Rovenstine, Wood, and Tovell. On 1 January 1939, the ABA awarded certificates to the Founders and 6 candidates from Group A (Fig. 21.3).

The ASA Trustees next sought independent recognition by the ABMS, and thus the medical establishment, for anesthesiology. In February 1938, the ABMS approved the ABA as a sub-board of the ABS, and on 23 March 1938, this new Board was incorporated in the State of New York. The final articles of incorporation began the separation from the ABS, as desired by the ASA Trustees, by replacing the 3 nominations previously assigned to the ABS with 3 nominations from the American Society of Regional Anesthesia (ASRA). The role of the ASRA in the nominating process ended with its merger with the ASA in 1939. These articles also identified the former Trustees as Directors.

Fig. 21.3 The second certificate given by the American Board of Anesthesiology. (Courtesy of the American Board of Anesthesiology, Inc., Raleigh, NC.)

An early issue faced by the new sub-board of the ABS was the status of nurse anesthetists and “non-professional” practitioners. (This could be almost anyone, including a first-year medical student such as Eger, who with his first anesthetic nearly killed a patient [1].) The National Association of Nurse Anesthetists (NANA—later the American Association of Nurse Anesthetists or AANA) asked the ABS to protect the position of nurse anesthetists. The ABS requested a meeting between the NANA, the ABS and the ABA to examine the feasibility of having the ABA sanction a training curriculum and certification for nurse anesthetists. They met on 27 November 1938. The minutes of this meeting indicated that the NANA wanted to “compile a pattern curriculum which we expect to have taught in the various schools of anesthesia for nurse anesthetists. After this has been introduced we expect to have examinations for the students with eventual certification.”

Discussions revealed mutual distrust and ABA apprehension concerning independent nurse anesthesia practice. Elting, the ABS representative to the ABA, attempted to encourage discussion, stating that “Just as the American Board of Surgery is perhaps in the relative position of the god-father of the American Board of Anesthesiology, so the American Board of Anesthesiology might perhaps be the god-father to the Association of Nurse Anesthetists or the nurse anesthetists of this country.” The ABA continued the dialogue to avoid offending the ABS, but expressed little en-

thusiasm for involvement with nurse anesthesia. At an ABA meeting in May, 1939, Buchanan related a conversation with an ABS surgeon who cautioned, “To be frank with you I want to state that Dr. Graham, Dr. Elting and I are very concerned about the way you are handling this nurse anesthetist question ... Frankly we feel that you are side-stepping it.” At this May meeting, Buchanan reported that he had told Elting and Rodman that he “would not consent to the American Board of Anesthesiology being sponsors to any nurse anesthetists and they both agreed with me that I was right.”

Thus the two protagonists—anesthesiologists and nurse anesthetists—missed an opportunity. Trained anesthetists—nurse and physician—were scarce, and the approaching World War indicated a great increase in the need for trained anesthetists. A formal teaching arrangement might have been established that would have benefited the nurse-physician relationship and the quality of care given to our patients. Anesthesiologists—especially those involved in certification—might have taken the opportunity to participate in nurse certification. The nurses asked for guidance and physicians rejected their overtures to the detriment of their relationship.

An October 1939 report to the ABA by John Lundy exemplifies the physician perception of nurse anesthetists: “The Committee has functioned perfectly. There have been many opportunities offered to the girls to come to us for advice on what would be the best books to read and the advice hasn’t been sought.” Several ABA discussions considered with-

drawing or not certifying physicians who were involved in training nurse anesthetists. Furthermore, when in 1950, the ABA added membership in “good standing” in the ASA, as a criteria for candidacy for certification, the board stated that “If a man signs a nurse’s training certificate he is not in good standing in the ASA”. However, we cannot find that the ABA acted against any physician working with or training nurse anesthetists. In a statement in 1976, the ABA demonstrated an attempt at accommodation with nurse anesthesia, in proposing to become involved in and accept responsibility “for examination and certification of non-physician anesthesia personnel.” Subsequently, the ABA refrained from involvement with nurse anesthetist certification, leaving such matters to the ASA as the representative of the practicing anesthesiologist. Anesthesiologists do contribute to nurse anesthetist education, participating importantly in training, but without the sanction of the ASA or the ABA.

The ABA relationship with its “god-father”, the ABS, was sometimes contentious. In October, 1939, Lundy reported on a conversation with the ABS’s Elting. Elting stated that “The first thing I want to tell you is that the American Board of Anesthesiology is not an independent Board. They cannot issue a certificate without our consent and while we haven’t bourn [sic] down on them previously, we may have to.” The ABA remained sensitive to their position as an affiliate of the ABS, and attempted to limit concerns raised by the ABS as evidenced by a Lundy statement at the October 1939 ABA meeting: “I too hope that this Board will keep those problems under their consideration and that they won’t do the thing that will offend that Board [ABS] and make them think that we are unsympathetic as to the problem they have to face.”

In March 1940, the ABMS with the support of the ABS, recommended ABA independence to the AMA. On 16 February 1941, the ABMS approved the ABA as a primary board with equal standing to others, including the ABS. Neither Buchanan nor McMechan lived to see this event. McMechan died on 26 June 1939, with some speculating that the AMA’s decision to establish the Section on Anesthesiology in June 1940 was not just coincidental. Buchanan died suddenly on 22 March 1940 and was replaced as President by Ruth, and as Director by Charles McCuskey, from Glendale, California. In recognition of his contributions in establishing certification for anesthesiologists culminating in the acknowledgement of anesthesiology as a primary specialty, the ABA directors paid tribute to Buchanan.

The by-laws of the ABA as a primary ABMS Board listed the following objectives:

1. To elevate the standard of anesthesiology
2. To familiarize the public with its aims and ideals
3. To protect the public from irresponsible and unqualified practitioners
4. To examine and certify

Fig. 21.4 The ABA seal (logo). (Courtesy of the American Board of Anesthesiology, Inc., Raleigh, NC.)

Organization of the ABA and its Directors

Achievement of a balanced national representation motivated selection of future directors. The merger of the ASRA and the ASA in 1939, eliminated the short-lived role of the ASRA in the nomination process. The seal (logo) of the ABA, designed in 1941 and still in use today, reflects this relationship of the ABA with the ASRA along with the AMA, ASA and ABS (Fig. 21.4). In 1942, the AMA provided four nominees (Lundy, McCuskey, Ruth, and Tovell), the ASA provided four (Rovenstine, Waters, Wood, and Woodbridge) and the Southern Medical Society provided one (Stewart). In 1944, the New England Society of Anesthesiology nominated a tenth (Meyer Saklad). Over the following decade, the ABA asserted increasing control over the selection process, assuming sole responsibility for the final selection of nominees, while expressing its desire for input from the nominating bodies. Notwithstanding that expression of desire, conflicts arose between the ABA and the nominating bodies. With Stewart’s resignation in 1946, the Southern Medical Society nominated John Winter. Winter completed Stewart’s term in 1949, by which time nominations by component societies (Southern and New England) had been assigned to the ASA. The ASA refused to re-nominate Winter, and instead nominated Harvey Slocum who was selected. When, in 1950, the ASA also refused to re-nominate Ruth and Lundy, expressing concern over their “heavy-handedness” and length of service, the ABA “in defiance of their wishes” re-elected the two and made it clear that if the ABA so desired, the AMA and ASA were compelled to nominate a specified candidate, thereby insuring the re-election of existing Directors and control by the ABA of its own makeup.

Differences between AMA and ABA continued into the 1950s. In 1955, the AMA refused to re-nominate Edward Touhy, appointed in 1951 to fill Ruth’s unexpired term. The last founding Director, Lundy, retired in 1955 after 18 years of service. Albert Falconer and Forrest Leffingwell replaced Ruth and Lundy.

The controversy over control of the nominating process was resolved when the ABA, AMA and ASA created a joint nominating committee, with 2 representatives from each organization. The ABA president served as the non-voting

chair of the committee. The ABA gained the control it desired when it was agreed that each ASA and AMA representative would have 1 vote and each ABA representative would have 2 votes. The ABA could not be out-voted. Established in 1961, this Triple Committee would nominate 3 candidates for each position, and the ABA would elect its Directors from this slate. As the work of the ABA increased, the number of Directors increased from 10 to 11 in 1950, and to its current number of 12 in 1973. Director's terms as a member of the Board were initially 6 years without term limits. In 1950, this changed to a maximum of two 6-year terms, and in 1957 to three 4-year terms, requiring re-nomination and re-election at each interval. Gender was also considered as a factor in discussions related to Director nominations in 1938, when Huberta Livingstone was considered "... as the probable female member of the Board when it was organized...", but the first female Director, Judith Donegan, was not elected until 1983. Gender equality continued to evolve slowly so that as of October 2012, there are three female directors.

Notoriety came to Emery Rovenstine, one of the original Board Directors. He was the second professor and chair of an academic anesthesiology program (at NYU), Waters being the first in both categories. Rovenstine was President of the ASRA. In the fall of 1947, a series of articles appeared in the *New Yorker Magazine* that favorably described his contributions to this new specialty, anesthesiology. At this time the medical profession abhorred any advertisement of services. The articles describing Rovenstine and anesthesiology in the New York area led to investigation of his role in the publications, and the material was found to be "self-serving and self-promoting" and therefore inconsistent with the standards of a medical professional. Rovenstine was censured and suspended from membership by the New York State Society of Anesthesiologists. He resigned as a member of the ABA Board of Directors on 19 July 1948, and in support of his good friend and colleague, Wood also resigned. Rovenstine fell victim to pressures of the times, but his reputation as educator and clinician, did not suffer among his colleagues.

The expanding activity of the ABA mandated increasing administrative support. In 1950, an administrative leadership position of Executive Secretary was established and occupied by Charlotte Hickcox, sister of ABA Director Curtis Hickcox. She served until 1979. With Ms. Hickcox's retirement, a new Executive Secretary was hired whose performance was deemed unacceptable. Litigation followed and after settlement, in 1981, search for a replacement resumed. As it had in 1974, the ABA considered asking a physician/former Director to assume this position, a direction consistent with that of other ABMS Boards. But the ABA reasoned that appointment of a former Director could concentrate responsibility and decision making processes in a single individual, diminishing the role of the entire Board. Accordingly, the ABA selected Francis Hughes, PhD as Executive Secretary

in 1982, a title changed to Executive Vice-President in 1994, and to Executive Director in 2000. Duties of the Executive Director position altered in 2007 due to both an increasing role of Board executive directors in the governance of the ABMS, and Hughes' impending retirement.

In June, 2008, Mary Post, MBA was appointed Executive Director for Administrative Affairs while Hughes assumed the new position of Executive Director for Professional Affairs. In this position, Hughes continued his involvement in the governance of the ABMS, serving together with representatives from the other ABMS Boards. As most other board representatives were physicians, Hughes opined and the ABA determined, that physician representation provided more credibility to the views expressed at the ABMS by the ABA. Consistent with its earlier views regarding a physician executive director, the ABA chose to designate a new position of Executive Director for Professional Affairs without involvement in the administrative functions within the Board office. Initially that position was filled by the appointment of a Former Director, David Chestnut to represent the ABA at meetings of the ABMS Board of Directors. The ABA presently intends that the Executive Director for Professional Affairs will be a sitting Director, acting for a maximum of 2 consecutive 3 years terms.

The tenure of Frank Hughes as Executive Director and Executive Vice President coincided with the development of the current written examination and the increased emphasis on validated psychometric tools. Hughes' background as a psychometrician proved invaluable to these processes, and the credibility of the ABA certification process. The reader is referred to Chapter 35 regarding Hughes' crucial role in the development of the certifying examination.

Anesthesia Training and Program Accreditation

The ABA was created to establish a certification process that would eliminate "irresponsible" practitioners, and to guarantee the quality of the educational processes leading to certification. Thus, the ABA would both certify practitioners and accredit programs. The initial articles of incorporation stipulated that the ABA should "increase educational facilities in medical schools and hospitals, and furnish lists of these, together with lists of individual instructors who give adequate instruction and training in anesthesiology". ABA criteria for candidacy for certification included "2 years of training of which 18 months should be practical training in anesthesia." Thus, the ABA was tasked with evaluating each anesthesia residency training application that an institution submitted to the AMA Council of Medical Education for approval. Members of the ABA acted as program inspectors. By 1943, there were 45 approved training programs in anesthesiology, increasing to 213 by 1950. Desire for accreditation exceeded

resident interest—in 1950, there were only 107 anesthesiology trainees. By comparison, in 2010, 132 accredited programs trained 5,556 residents.

The responsibility for evaluating and recommending programs became increasingly burdensome for the 11 Board Directors, leading to discussions with the AMA Council on Medical Education and the 1957 establishment of the Residency Review Committee (RRC) for anesthesiology. The RRC was composed of 3 ABA Directors and 3 appointees by the AMA who were recommended by the ABA. In 1981, the AMA, ABMS and the American Hospital Association (AHA) established the Accreditation Council for Graduate Medical Education (ACGME), retaining the RRC as an arm of the ACGME. The ACGME assumed responsibility for accrediting both internship and residency training programs. Concurrently, the ABA modified its requirements to include satisfactory completion of a residency in anesthesia at an ACGME accredited program. The ABA continues to nominate Directors to the RRC as does the Anesthesia Section of the AMA and more recently the ASA. These nominations are forwarded to the RRC/ACGME, who select the RRC members. Beginning in 1998, an anesthesia resident representative was (and still is) nominated by the ASA Resident Component Governing Council. With approval by the ASA Board of Directors, RRC and the ACGME, this resident becomes a member of the RRC. Survey and evaluation of programs by the RRC and accreditation by the ACGME eased the burden on the ABA. The ABA continued to determine the training necessary for admission to its examination and certification system, and therefore continued to influence the content and accreditation of training programs.

The Anesthesia Curriculum and Resident Evaluation

Since its formation, the ABA established education requirements, training curricula and evaluation procedures for certification of physicians in anesthesiology. These were guided by Committees on Education, Curricula, Residencies, Written Examinations, Oral Examinations, Practical Examinations, and Requirements and Credentials. The Committee on Education established “maximum and minimum suggestions for teaching purposes, undergraduate and post-graduate.” The work of the Curricula Committee was eventually “blended” with that of a similar committee of the ASA. The ABA Committee on Curricula would be responsible for approving the curriculum assembled by the ASA. The ABA also believed that multiple curricula should be approved to avoid implying “that’s all you have to know.” In 1947, through a process of elimination and consolidation, the Board reduced its committee structure to a Finance and Executive Committee, a Committee on Credentials and Residency, an Examinations

Committee, and the Committee on the Administration of Anesthetics in the US.

In March 1972, the Board determined that the Continuum of Education in Anesthesiology consisted of three post-doctoral years; 24 months devoted to approved residency training in clinical anesthesia, and 12 months devoted to internships or any combination of such, approved for the individual by the training program director. The program director, in consultation with each candidate, determined when during the Continuum, the candidate received training in clinical anesthesia and clinical experience versus training in an area or areas other than clinical anesthesia, but the Board urged that at least part of the latter should occur early in the Continuum. The Board also determined that candidates who passed the written examination would have to complete two years of anesthesia practice or an Optional Year of training, before appearing for oral examination.

The increase in information and ideas in the last half of the twentieth century affected all aspects of medicine, including anesthesia, and mandated (at least in the eyes of the Board) an increased duration of training. In October 1976, the Board eliminated the “Optional Year of training” and required all candidates to complete a four-year continuum. Two options in lieu of a fourth (i.e., specialized) year of approved training were added to the required 12 months Clinical Base and 24 months Clinical Anesthesia training: (1) two years of practice or (2) a year of residency in other specialties, or a year of anesthesia related research. This change could be implemented without the RRC having to revise the “Essentials” because all programs had to offer three years of anesthesia training. In 1987, the essentials were changed to require a fourth year of training for all anesthesiology residents.

Subsequently, the ABA convened two meetings of anesthesiology program directors, to inform and obtain input about implementation of a mandated fourth year of training. The ABA announced the continuum, mandating a fourth year of training, at a meeting of Program Directors in April 1984. The Board described three possible tracks for the mandatory fourth (or CA-3) year—Advanced Clinical, Subspecialty Clinical, and Clinical Scientist. The ACGME subsequently mandated a fourth year of training and required that each program offer all three CA-3 tracks. Over the ensuing 15 years, most residents selected the Advanced Clinical Track, spending more than the minimum number of months in subspecialty training—or devoting time to research. Consistent with these dominant choices, the Subspecialty Clinical Track was eliminated and the Clinical Scientist Track (CST) was modified to define opportunities for academic investigators. The CST consisted of 2 options. Option A allowed the candidate to complete 6 months of research at any time during the 48 month continuum. Option B was designed for academic investigators and provided for 18 months of clinical or laboratory research at any time during a 60 month continuum,

of which 12 months were devoted to clinical base training and 30 months to clinical anesthesia. In time, options for research during the residency replaced the Academic Investigator Track. These options required that the program director develop a plan with strict guidelines for research activity and “work product” oversight for resident’s research activities exceeding 6 months. Scholarly activities had to generate a specific permanent “work product.” A local Scholarship Oversight Committee assessed the trainee’s progress, and verified the completion of a permanent work product.

With one exception, until recently, the ABA had not stipulated duration of time spent in anesthesiology subspecialties, nor had it mandated the number of cases in any particular area of anesthesia. The exception was Critical Care Medicine. In 1983, the Board required that 2 months be spent in Intensive Care, in 2008 increasing that to 4 months, 1 of which might be in the Clinical Base Year (internship). With input from the ABA, the RRC has now, however, provided definitive expectations regarding specific experiences in both subspecialties types of cases and experience in the entire scope of perioperative care.

More recently, after several meetings with other ABMS primary specialty boards and with approval of ABMS, the ABA has established combined training programs with Pediatrics beginning in 2010, and with Internal Medicine in 2013. Completion of a combined program will result in eligibility for certification in both specialties in less time than that needed to complete each residency separately.

The Clinical Competence Certificate

From its inception, the ABA defined competence with more than grades in the written and oral examinations. Initially, the ABA used a practical examination and surveys of practice, but these proved too burdensome for the small Board. Recognizing that those who trained the candidates might be best able to evaluate competence, in 1946, the ABA mandated yearly reports by residency directors or preceptors. In April 1973, the ABA proposed “a new method for determining competency” to address “long-standing problems of the ABA ... related to judging the clinical competence of candidates desiring certification by the ABA.” The Board subsequently required appraisal of “satisfactory achievement as assessed by an Evaluation Committee within the candidate’s institution of training”.

In October 1973, the Board mandated “that a Certificate of Clinical Competence (CCC) be a requirement in the process leading to certification for all candidates who complete their training” In November 1973, Anesthesiology Training Program Directors were told

“...that candidates for certification who complete the two years of Clinical Anesthesia subsequent to December 31, 1974, will

be required to have a CCC on file with the ABA attesting to their having achieved at least satisfactory clinical competence” This did not eliminate any existing requirements. Program Directors had to “appoint a Clinical Competence Evaluation Committee... [that] is best chaired by someone other than the Program Director.”

The new procedure required that the Committee formally evaluate “the candidate’s performance in each of the categories,” make a judgment of overall clinical competence, and forward the completed evaluations to the ABA during June and December of each year of Clinical Anesthesia training. “The evaluation of overall clinical competence by this committee during the final six months of the two years of Clinical Anesthesia training will be the evaluation used by the Board in its final determination of eligibility for certification.” In time, the Board identified Essential Attributes in the semi-annual evaluation form and required that overall clinical competence be judged unsatisfactory if any “Essential Attribute” was judged unsatisfactory. By 2000, the Board required that programs extend Clinical Anesthesia training for residents receiving consecutive unsatisfactory evaluations of overall clinical competence.

Qualifications and Credentialing of Candidates

In its first Booklet of Information in 1937, the ABA identified the criteria for admission to the examination process.

1. Satisfactory ethical and moral standing
2. Membership in the AMA or other medical societies acceptable to the Council on Medical Education and Hospitals of the AMA
3. Practice limited to anesthesiology (as stipulated by the ABS)
4. Graduation from a Grade A medical school in the US or Canada recognized by the Council of Medical Education and Hospitals of the AMA or graduation from an approved foreign school
5. Satisfactory completion of 1 year or more of an approved internship
6. Duly licensed by law to practice medicine

Although in 1938, the ABS “stipulated” the requirement for practice to be limited to anesthesiology, ABA minutes of 1939 revealed that the ABS felt that the ABA was too strict in implementing this guideline. The ASA leadership expressed concern over the next two decades, regarding the rule limiting practice to anesthesiology. Failure to meet this requirement caused several Diplomates to lose certification. Non-anesthesia practice included general medical practice, surgery or other non-anesthetic specialty practice. The ASA represented many of these “part-time anesthesiologists” and brought pressure on the ABA to remove the 100% requirement. In response, a 1957 Board action removed the 100% requirement for those who already had certification but retained it as

a credentialing criterion for prospective candidates. In 1960, the Board eliminated the 100% practice requirement for certification, retaining it only during residency training.

The numbers of physicians entering the practice of anesthesia grew slowly in the 1930s, and this may have influenced the view of what constituted adequate training in anesthesiology. The approach of World War II and the potential need for greatly increased numbers of trained anesthetists may also have influenced that view. In June 1940, the ABA identified 2 entrance pathways for its examination system

1. Two years of approved post-internship training, followed by 3 years of 100% anesthesia practice or
2. 5 years of 100% anesthesia practice

The 2 years of training could be either in an approved program, or under the supervision of an ABA approved preceptor. In 1944, the ABA eliminated Groups A, B and C categories for certification identified at its creation in 1937. Pathway 2 above, the full practice option, was eliminated in 1945, thus making two years of approved anesthesia training mandatory—except that the Board allowed credit for military anesthesia practice: “In exceptional instances the Board may, in its discretion, accept for examination, candidates who have met all the preliminary requirements, and have clearly demonstrated their identity as an anesthetist over a period of years, but whose formal training does not comply with the full requirements to be exacted in the future.” In 1950, the Board again modified their requirements, allowing candidates to take the written board examination (the first examination phase for certification) following the second year of practice, however, final certification would still not take place until after 3 years of practice.

In its 1937 Booklet of Information, the ABA stated that effective from 1 January 1944, requirements for entrance to the examination system would be 3 years of post-internship anesthesia training plus 3 years of anesthesia practice. Although the Directors favored such a plan, it was not implemented. Again in 1957, the ABA voted to increase training to 3 years post-internship, beginning on 1 July 1963, and to only admit those with this option after 1 July 1965. Furthermore, the ABA indicated its plans to withdraw recognition of any training program that did not offer the 3 years after 1 July 1964. However, program directors and the ASA criticized this decision. Led by John Dillon and Robert Virtue, this opposition caused the ABA to hold a special meeting with program directors on 8 December 1959 and again on 5 October 1960. Subsequently, the ABA again rescinded its plans for the required 3 years of residency. As an alternative it created the “optional 3rd year”.

In 1962, the ABA announced two pathways to certification beginning 1 July 1966:

1. Two years of clinical anesthesia training post-internship plus a 3rd year spent in research in the basic or clinical sciences, pathology, internal medicine, surgery, advanced

anesthesia training or an anesthesia subspecialty. These 3 years would be followed by 1 year of practice

2. Two years of training post-internship of clinical anesthesia followed by 4 years of practice

In 1966, the Board granted credit for 2 years of the 4 year practice requirement in the second pathway, for 1 year of scientific work performed after completion of undergraduate training, 1 year of training in a medical specialty recognized by the ABMS, or pursuit of a PhD degree in a scientific field. In 1970, the ABA increased the credit for these activities to 3 of the 4 years of required practice.

Just as the ABA had accepted on-the-job expertise gained from military service during World War II, it accepted the value of anesthesia experiences during the Viet Nam conflict. Military personnel completing at least 6 months of formal anesthesia training could receive additional credit for military anesthesia experience on an individual basis evaluated by the ABA.

In 1973, the ABA revised its credentialing under the “optional 3rd year” program:

1. Clinical Base Year (CBY) plus 3 years of anesthesia training, or
2. CBY plus 2 years of anesthesia training and 2 years of practice

Credit towards the 2 years of practice in pathway 2 could include military experience, training in or practice of anesthesia in a foreign country, or any of those previously credited in 1966. In 1977, a candidate with a PhD in a related field or satisfactory completion of another ABMS specialty could apply for full credit for the third year in pathway 1.

In 1984, 47 years after first suggesting it, the ABA announced its decision to increase the required training to 3 years following the CBY. The Board identified the continuum of 4 years—CBY, CA-1, CA-2 and CA-3 (CA=clinical anesthesia). The new continuum was to be introduced for those beginning the CA-1 on 1 May 1986. Again the ABA met opposition but experiences with the optional third year supported the Board’s decision, and implementation took place as planned.

International Medical Graduates

Foreign medical graduates (FMGs) or, as more recently designated, international medical graduates (IMGs), presented two concerns for the ABA: Would acceptance of IMGs affect standardization of training; and could the ABA identify acceptable programs including medical schools, internships and residencies satisfying criteria leading to approval by identifiable regulating agencies such as state licensing boards? The Board sought assurance that only IMGs educated comparably to US physicians be admitted to the certification process, an often impossible task. From 1937 to

1947, the ABA allowed graduates of AMA-approved foreign medical schools to enter its examination system. In 1947, the Board deleted direct reference to FMGs in its Booklet of Information, favoring a statement indicating acceptance of Diplomates of the National Board of Medical Examiners (NBME). In 1961, after introduction of the Educational Commission of Foreign Medical Graduates' Examination (ECFMG), the ABA announced that the only acceptable screening organizations were the NBME and the ECFMG. In 1972, the Board added the Federal Licensing Examination (FLEX), and included in its Booklet of Information, the words "or any recognized licensing body".

The ABA first adopted a formal policy regarding IMGs in April 1969, after conducting a 2-year investigation of certification requirements of English, Irish, South African, Australasian and Canadian Colleges or Faculties (of anesthesia) that revealed them to be comparable to those of the ABA. The ABA subsequently admitted holders of the Fellowships of these Colleges or Faculties to its examinations if all other entrance requirements (except for training in an ACGME accredited program) were satisfied. The Board stated that "... dual certification was neither necessary nor desirable." Furthermore it discouraged the need for ABA certification for those with Fellowship status in the above Colleges, a position that had significant future implications when the ABA deleted reference to "equal and comparable" regarding the Colleges and the ABA's certification.

In 1969, the Faculty of Anesthetists of the Royal College of Surgeons of England indicated their appreciation for the equivalency statement by the ABA, however, adding that they would not admit US trained anesthesiologists to their examination system, because British anesthesia training required more years than in the US. The Canadian College sent similar correspondence. Over the next 14 years, the ABA continued to refine the acceptance qualifications for entrance to its certifying examinations for holders of these Fellowships in 1977, adding the requirement for 1 year of practice or training in the US. In 1982, all Fellows except for those from Canada were required to have a year of training in an ACGME accredited anesthesia training program. In 1986, the requirement was added for Fellows from Canada. The refusal of the various foreign Colleges to admit US residency graduates to their examinations certainly contributed to these policies.

In 1993, the ABA withdrew recognition of residency training in any foreign country except for the CBY from Canadian institutions affiliated with medical schools approved by the Liaison Committee on Medical Education (LCME). This change arose from the realization that the ABA could not objectively verify the comparability of any other organizations' certification nor could it verify the equality of training programs certified outside the US not controlled by the ACGME. The removal led to complaints from those with Fellowship certificates, who, because of the ABA's language

regarding "equality" in the past, elected not to take the examination. Sympathetic to this dilemma, the ABA allowed IMG holders of the Royal College Fellowships to apply through an alternative pathway, expiring in 1997, for entrance to the examination with either 1 year of US training or 2 years of practice in the US with the second year between 1 January 1992 and 31 December 1995.

The ABA continued to examine these policies, and review of their minutes indicates that consideration is ongoing regarding IMGs practicing in the US, with special emphasis on faculty in US academic training programs. A trial program limited to 2 faculty members from a given ACGME approved academic program, is currently in place. The program permits IMGs to eventually qualify to take the ABA certifying examinations. Subsequent evaluation of this trial program will determine future ABA policies for IMG anesthesia practitioners.

Doctors of Osteopathy

Initially, the ABA denied osteopathic physicians entry into the examination process. However, the decision by the California State Legislature to recognize doctors of osteopathy (DOs) as medical doctors, changed the ABA stance, and the ABA subsequently treated MDs and DOs equally. In 1981, the ABA accepted the clinical base year from a program approved by the American Osteopathic Association (AOA). Thus, the Board required all candidates to have satisfactorily completed residency training in an anesthesia program accredited by the ACGME, with the exception of those completing their CBY in either a Canadian institution affiliated with a medical school approved by the LCME, or an osteopathic program approved by the AOA.

The ABA and Anesthesia Subspecialty Certification

When initially confronted with the issue of subspecialty certification, the Board reacted negatively. In the early 1970s, referring to Critical Care Medicine (CCM) certification, the ABA indicated that it would not allow its credentialing policies to be used to limit the ability of its Diplomates to practice in certain subspecialties: "We cannot condone economic credentialing". Undeterred, in 1977, the Society of Critical Care Medicine (SCCM) initiated discussions with the ABMS Boards of Internal Medicine, Pediatrics, Surgery and Anesthesiology. These foundered on disagreements over guidelines and duration of training, but prompted ABA reconsideration. Recognizing the possibility of hindering the practice of ABA Diplomates in CCM if other Boards individually allowed certification, the ABA submitted an appli-

cation to the ABMS for authorization to grant certification in Anesthesia CCM. The ABA application was approved on 21 March 1985, with the first written examination on 27 September 1986. Recognition of Pain Management (PM) as a multi-disciplinary subspecialty, caused the ABA to request authorization to certify PM from the ABMS. Authorization was granted on 26 September 1991, with the first written examination on 11 September 1993.

In the early 1990s the ABA decided not to object to ACGME accreditation of subspecialties, if requested by their respective organizations. At that time, however, the ABA was still not favorably disposed to approve certification for subspecialties where patient care was restricted to anesthesiologists. Most recently in 2009, the ABA decided to begin the process to offer subspecialty certification in Pediatric Anesthesiology, and the first certification examination is scheduled for 2013. Furthermore, ABA subspecialty certification is now a reality for Hospice and Palliative Medicine with the first examination in 2008, and for Sleep Medicine in 2011. Recognition of these latter two subspecialties with certification available to anesthesiologists, was done in conjunction with several other ABMS primary boards and reflects, as with Pain Medicine and Critical Care Medicine, the ABA's efforts to protect its Diplomates practicing in areas recognized by other specialty Boards. Other subspecialties including cardiac anesthesia remain under consideration. The implications for intra-disciplinary competition, and the potential inability of rural hospitals to provide care in the absence of board certified anesthesia sub-specialists, remain unresolved.

Continuing Medical Education, Recertification and Time-Limited Certificates

In 1994, and again in 1995, the ABA declared its intent to issue 10-year time-limited certificates for its primary certificate, and for all certificates awarded after 1 January 2000. Pain Management certification was granted with a 10-year time limit at its inception in 1993.

Why had it taken so long? A 1932 report of the Commission on Medical Education noted that "The time may come when every physician may be required in the public interest to take continuation courses to insure that his practice will be kept abreast of current methods of diagnosis, treatment and prevention." In 1940, the Advisory Board of the AMA stated, "...as the certifying boards become better established and as they complete the examination of a large group of physicians already practicing the specialties, they may find it desirable to issue certificates that are valid for a stated period only." Thus, the seeds for CME and recertification were planted before the ABA existed. CME became increasingly popular with the advent of local, regional, national and in-

ternational meetings offering a plethora of reviews, updates and presentations. State licensing departments soon required continuing education as a condition of continued licensure. New Mexico became the first state (in 1971) to require CME for medical license renewal. While agreeing with the need for currency, the ABA determined that the responsibility for CME belonged to the ASA rather than the ABA. In 1949, the ABA recommended that the ASA establish a Refresher Course Program, a program offered first in 1950 and annually ever since. The ABA maintained that education is the purview of the ASA and its components, while certification is that of the ABA. However, the ABA proactively works with the ASA and others to promote educational opportunities in support of its certification examinations and the currency of its Diplomates.

In 1973, the ABMS called for all boards to adopt voluntary recertification, asking that a "... reasonable deadline [be established] when voluntary, periodic recertification of medical specialists will have become a standard policy of all medical boards." Thus began the ABA's prolonged assessment of recertification for its Diplomates. The first ABA proposal came in 1977 with adoption of a plan for voluntary recertification to be implemented in 1984. Although proposed to ensure public trust, maintain a high standard of practice, motivate CME and comply with the ABMS resolution of 1973, the ABA felt continuing concern over numerous issues, particularly the best tool for reassessment, and lack of evidence on how long it took to degrade knowledge and skill. Perhaps most importantly, the ABA believed it lacked proof of the validity of the initial certification certificate! As stated by one director "Board certifying procedures do not test clinical competence", a crucial concern since the maintenance of clinical competence underlay the enthusiasm for recertification.

Given increasing lack of confidence that the goals of recertification might not be met, the ABA reversed course in 1980 and rescinded its proposal for the 1984 implementation of voluntary recertification. Over the following 13 years the ABA continued to assess both the climate for recertification and evidence of its worth. Pressure from the ABMS and from government, both state and federal mounted, with most ABMS Boards implementing recertification procedures. State licensing agencies considered mandating recertification as either a requirement or an alternative pathway for licensure renewal, and the federal government began considering legislation to require recertification. Representative Pete Stark from California introduced proposals in Congress, calling for recertification of physicians, one of which appeared in the 100th Congress on 7 August 1987 as an amendment to the Social Security Act as the "Medicare Physician Competency Certification Act of 1987". It would "...require periodic competency certification of physicians as a condition of participation under the Medicare program."

Pressure built for the ABA to join other ABMS Boards in offering recertification. Publications began to appear, including those of Silber and Slogoff in the 1990s, validating certification as a means to predict and assess satisfactory clinical care [2, 3]. Experiences of other boards suggested the value of reassessing knowledge and performance. During that period a joint committee of the ABA and ASA met to define the best way to proceed with recertification. The Committee recommended both a credentialing process and examination to provide Continued Demonstration of Qualifications (CDQ). The ABA adopted this proposal, with implementation in 1993. Having taken the first major step in recertification, the remainder of that decade witnessed the continued maturing of recertification, renaming CDQ to simply Recertification in 1996. As a final step, the ABA proposed to the ABMS, with acceptance on 21 March 1998, the issuance of only time-limited certificates, beginning on 1 January 2000. Consistent with the policies of several ABMS Boards, the ABA “grandfathered” all those with non-time-limited certificates. Such holders would remain certified without requiring recertification except that all Associate Examiners and Board Directors of the ABA had to be recertified within 10 years of their original certificate, and every 10 years thereafter.

From 2000 to the present, the ABA continued to emphasize education and credentialing beyond that provided in its written examination. This philosophy led the ABA and the ASA to develop an educational based approach to recertification which “includes a commitment to continuing education, an assessment of the quality of practice in the local environment, and an evaluation of knowledge.” In 2009 the recertification program in place since 2000 was replaced by a program for Maintenance of Certification in Anesthesiology (MOCA). MOCA originated from a concept of maintenance of certification (MOC) approved by the ABMS in 2000, and endorsed by the 24 ABMS Member Boards. The ABA also plans to complete the transition from its current subspecialty recertification examinations to a MOCA-SUBS process in 2017. The 2010 ABA Booklet of Information describes MOCA as “a 10-year program of ongoing self-assessment and lifelong learning, continual professional standing assessment, periodic self-directed assessments of practice performance and quality improvement, and an examination of cognitive expertise.” The program begins immediately following the awarding of an ABA certificate.

Although it took the ABA what many may have thought an inordinately long time to recognize the appropriateness of its final decision regarding recertification and time-limited certification, the Board believed that the depth and resulting duration of its assessment was appropriate. The ABA recognized that such a major philosophical change with significant impact on its Diplomates required a cautious and thoughtful approach. Having issued 49,877 primary certificates, 1,616 for Critical Care Medicine 4,739 for Pain Medicine, 59 for Hospice and Palliative Medicine, and 5 for Sleep Medicine as of 30 November 2012, the ABA continues to examine several complex issues. These include subspecialty certification, recertification and the role of simulation, the relationship to IMGs practicing in the US, modification to the anesthesia curriculum and its existing examinations to ensure currency, the appropriate emphasis on research, and scholarly activity, as part of the continuum.

At the time of preparation of this chapter the ABA has served as the specialty’s primary certification board for 70 years. During that period the Board has met its responsibilities to the public, the specialty and its Diplomates in its decisions impacting the education, training and continued excellence in clinical care. Whether it was duration of training, components of the anesthesia curriculum, certification for subspecialists, or more recently, recertification, the ABA has persisted in rigorous evaluation and reevaluation prior to implementation. The ABA’s demonstrated capacity to establish educational standards, to certify trainees and their training programs, and to work productively with other anesthesia societies and organizations will be essential to the continued growth of physician led anesthesia.

The Evolution of Nurse Anesthesia in the United States

22

Bruce Evan Koch

Summary

From 1870–1890, many US surgeons asked nurses to provide anesthesia. The Mayo brothers trained Alice Magaw and Florence Henderson, who perfected smooth and safe anesthesia with ether. In 1909, Agnes McGee opened the first school of nurse anesthesia in Portland Oregon. In 1915, supported by surgeon George Crile, Agatha Hodgins opened a more influential school at Lakeside Hospital (later the Cleveland Clinic), spawning 54 schools by 1950.

In the early 1900s, legislative efforts and lawsuits unsuccessfully sought to preclude nurse anesthesia, arguing that it allowed nurses to practice medicine. Subsequent state statutes legalized nurse anesthesia practice but specified physician supervision of nurse anesthetists. The second Bush administration modified a federal corollary to these statutes, allowing states to “opt out” of the supervision requirement. By 2011, 17 of 31 eligible states had opted out.

Hodgins, Helen Lamb, and Gertrude Fife saw the need to protect nurse anesthesia through a formal organization that would certify competence of its members, leading in 1931, to the American Association of Nurse Anesthetists (AANA). The first AANA qualifying examination was administered in 1945, leading in 1956, to the Certified Registered Nurse Anesthetist (CRNA). The AANA implemented recertification in 1978. By the end of the twentieth century, nurse anesthesia training had increased to >2 years and will increase to 3 or more years after 2015.

In 1955, the Dept. of Health, Education and Welfare recognized the AANA as the accrediting agency for nurse anesthesia educational programs. In 1974, the US Office of Education (USOE) required that an independent organization supply accreditation and the AANA proposed establishment of an autonomous Council on Accreditation of Nurse Anesthesia Educational Programs (COA) composed of CRNAs, anesthesiologists and members of the public. In 1976, the USOE granted the COA the authority to accredit nurse anesthesia training programs.

In 1978, Swiss nurse anesthetist Hermi Löhnert discussed the potential for international cooperation with AANA President Ron Caulk. In June 1989, representatives from 11 countries founded the International Federation of Nurse Anesthetists. Nurse anesthetists are an essential part of world health. A 2011 survey of 107 countries found that nurse anesthetists usually delivered 70 to 89% of the anesthetics.

In the past 20 years, volunteer nurse anesthetists have increased access to anesthesia care in underdeveloped countries and began to formalize nurse anesthesia education. Also in the past 20 years, the AANA has faced up to the epidemic of drug abuse and addiction among nurse anesthetists.

Social Factors and Anesthetic Delivery Between 1850 and 1900

Three revolutions changed the status of women in the eighteenth and nineteenth centuries. The American and French Revolutions caused women to believe that they were entitled to the rights enjoyed by men [1]. The Industrial Revolution forced women to seek work outside the home. Because medical schools would not accept them, many women entered

nursing. Florence Nightingale (1820–1910) elevated nursing from custodial care to a profession, based on hygiene and nutrition [2]. During the Civil War (1861–65), surgeons used nurses to meet the need for anesthesia care, [3, 4] generating the first US group of nurses to practice anesthesia.

In the second half of the nineteenth century, the US economy expanded rapidly westward. Small Midwestern towns accumulated wealth, established hospitals, and attracted physicians eager to operate on patients anesthetized with ether or chloroform. For half a century or more after Morton’s 1846 demonstration of ether anesthesia, “midwives, first-year medical students, husbands, chauffeurs, and inexperienced general practitioners were all pressed into service” [5] to provide anesthesia. Deaths inevitably resulted from the poor care that they provided. According to Gunn and Thatcher,

[3, 6] anesthesia came to be regarded as a “failed promise” [6] or “not an unmixed blessing” and Thatcher (pp. 49–52) [3] and Bankert (pp. 21–24) [7] reported that descriptions of late nineteenth century anesthesia contained words like “barbaric,” “reckless,” and “dangerous.”

The experience of Harvey Cushing (later the father of neurosurgery), giving anesthesia in 1894 as a student at Harvard, illustrates the problem. He reported, that in the course of his administration of ether anesthesia to an older man with a strangulated hernia, the patient vomited, aspirated the vomit, and died. An orderly had directed Cushing’s administration of the ether, and this was Cushing’s first administration of anesthesia. “To my perfect amazement, I was told it was nothing at all, that I had nothing to do with the man’s death, that he had a strangulated hernia and had been vomiting all night anyway, and that sort of thing happened frequently” [8].

Referring to nineteenth century anesthesia, Helen Clapesattle, the historian of the Mayo family of physicians, wrote that “only the most courageous patients would submit to it” [9]. Concern for their patients and professional standing led surgeons to seek skilled inexpensive anesthetists who would remain attentive. Both Thatcher (p. 53) [7] and Bankert (p. 16) [3] wrote that the job required intelligence and acceptance of a subordinate role that would not compete with that of the surgeon.

Then Matters Improved

In 1877, some Midwest surgeons turned to nurses, particularly Catholic Sisters, for anesthesia service (p. 54). [3] First taught by surgeons, they added intuitive skill to the delivery of anesthesia. Sister Secundina Mindrup

“devised her own method for judging when more ether or chloroform or an alcohol-chloroform-ether mixture should be given—a decade of prayers on the rosary and it was time to give a little more. In an apron with two split pockets she carried everything that anyone in the hospital might want, and in one of the pockets she secreted a bottle of chloroform. This she quietly and judiciously used to supplement the ether anesthesia when the surgeon required more relaxation” (Thatcher, p. 55). [3]

Sister Secundina embodied a change from most previous anesthetists. She added anesthesia to her other duties, yet was innovative (e.g., devising her own means of knowing when to re-dose), and proficient with three anesthetics.

By the late 1880s, Catholic hospitals throughout the Midwest turned to sisters/nurses like Sister Secundina for anesthesia. Thatcher documented over 90 by name (p. 285–6) [3]. The practice spread to other hospitals. Between 1884 and 1888, the Missouri Pacific Railroad established hospitals for its employees in Illinois, Indiana, and Missouri, and Thatcher noted (p. 54) [3] that the Hospital Sisters of St. Francis provided the nursing and the anesthesia.

Records describing the earliest nurse anesthetists are scant, but what began in Catholic Hospitals spread to other institutions. The earliest example was the Augustana Hospital in Chicago where Lotta Frejd, the Matron: “acted as cook, laundress, anesthetist, janitress, and carried patients up and down stairs” [10].

These pioneer nurses advanced anesthesia, in part by mastering the difficult and sometimes perilous inhalation induction of anesthesia. The difficulty and danger arose in the phase from wakefulness to deep sleep. In this phase, inhibitions and the ability to swallow are diminished, but involuntary movements can result in struggling, coughing, vomiting and aspiration (recall Cushing’s patient). The phase could last several minutes, or longer in unskilled hands.

Magaw and Henderson Advance Anesthesia Beyond the Mayo Clinic

The employment of nurses as anesthetists developed at St. Mary’s Hospital (The Mayo Clinic) in Rochester, Minnesota. Clapesattle wrote [9] that “The Mayos had given the job to Miss (Edith) Graham and then to Miss (Alice) Magaw in the first place through necessity; they had no interns. And when the interns came, the brothers decided that a nurse was better suited to the task because she was more likely to keep her mind on it, whereas the intern was naturally more interested in what the surgeon was doing.” Magaw and her star student, Florence Henderson, perfected the induction of anesthesia with ether in the 1890s. Magaw and those she taught used an Esmarch mask covered with two layers of gauze. They administered ether continuously, drop by drop, onto the gauze. They initially held the mask a short distance from the face and gradually lowered it, applying the ether slowly at first and then faster as the patient accepted the smell. This graded approach minimized the sense of suffocation and limited the struggling [9]. The anesthetist would observe the face for flushing (vasodilation) and sought evidence of relaxation, both changes denoting the onset of anesthesia. Support of the lower jaw and turning the head helped maintain an open airway. Turning the head might also facilitate the discharge of regurgitated gastric contents and thus lessen the likelihood of aspiration. These techniques resulted from an awareness of the importance of upper airway management [11]. The pioneer surgeon William Mayo praised Magaw as “The Mother of Anesthesia” [12].

Magaw and Henderson applied different techniques to gain a patient’s confidence and cooperation. Magaw wrote that “one must be quick to notice the temperament, and decide which mode of suggestion will be the most effective in the particular case: the abrupt, crude, and very firm; or the reasonable, sensible, and natural” [11]. Harris and Dean wrote (p. 11) [13] that Henderson was gentle, and made patients feel they were in control of the anesthetic.

Magaw and Henderson applied other measures to improve the patient's experience, including inducing anesthesia within the operating room, and warming the patient. To decrease stimulation and suggest sleep during the induction, they enforced silence. At all times they displayed self confidence. Henderson wrote that: "If the administrator is nervous or loses the confidence in her ability to secure a rapid narcosis, it invariably affects the patient." Writing of her work between 1899 and 1906, Magaw described her experiences in over 14,000 cases, all "without an accident, the need for artificial respiration, or the occurrence of pneumonia or any serious results" [11, 14] Testimonials by physicians visiting the Mayo Clinic reflect the esteem that Magaw and Henderson enjoyed. Henry Munro observed that: [13]

"... it is quite the common occurrence for an anesthetist who does not understand the use of suggestion to use from ten to twenty times the amount of ether in anesthetizing a patient that is used by Alice Magaw and Miss Henderson, who make use of suggestion in every possible way in a given operation." And "there is no period of excitement, no struggling of the patient that demands restraint, comparatively little stertorous breathing, no feeling of the pulse, and no hypodermics administered in the course of the operation, and more yet, an unbroken record of approximately seventeen thousand cases of anesthesia without a single death from the anesthetic."

First the Midwest, and then larger regions adopted the methods developed and refined by Magaw and Henderson. Nurses came to St. Mary's from hospitals in New York, Philadelphia, Seattle, New Orleans, and Denver, returning to teach others. And those who learned, passed the word to hospitals in Illinois, Oregon, Maryland, Iowa, Upstate New York, California, Michigan, Virginia and Minnesota. According to Thatcher (p. 77), [3] by the second decade of the twentieth century, a wide spectrum of institutions in the US had "capitulated to nurse anesthesia."

Nurses Introduce Nitrous-Oxide/Oxygen Anesthesia in World War I

World War I Opens a Door and Hodgins Walks Through

The contributions of US nurse anesthetists during World War I were important in numbers and in the introduction of new techniques. In Europe, nurse anesthetists provided anesthesia in the American field hospitals for almost three years before the 1917 entry of the US into the war. The hospitals, known as "ambulances" (from the French), were shipped in their entirety from the US.

One of these was led by the surgeon George Crile (Fig. 22.1) from Lakeside Hospital (associated with the Cleveland Clinic), assisted by nurse anesthetist Agatha Hodgins (Fig. 22.2). Crile had learned the use of nitrous

Fig. 22.1 George Crile Sr. who was one of the founders of Cleveland Clinic. (Courtesy of the American Association of Nurse Anesthetists Archives.)

oxide-oxygen ("gas-oxygen") from the dentists John Stephan and Charles Teter. With Hodgins' help, Crile conducted experiments on animals, determining that nitrous oxide produced less cardiovascular depression than chloroform or ether, and from that surmised that nitrous oxide might be better suited to wartime trauma surgery.

Hodgins described her work as a nurse anesthetist in the early war years (Bankert, pp. 44–5): [7]

"The unit... in the charge of Dr Crile, left in December, 1914, for service in the American Ambulance in Neuilly, Paris, France. Attached to this unit were three anesthetists—the writer and two members of her staff. The assignment of this anesthesia unit was to introduce gas-oxygen in war surgery, from that base hospital. The fortunate result was that of being able to successfully accomplish this assignment both on this special unit, and later, on the French surgical division of the American Ambulance Hospital."

Nitrous Oxide/Oxygen for Trauma Victims

In 1915, Hodgins returned to the US to direct one of the earliest formal nurse anesthesia educational programs. Other

American nurse anesthetists continued to provide nitrous-oxide/oxygen anesthesia until the armistice in 1918. Crile and Hodgins added pre-operative injections of scopolamine or atropine and morphine prior to nitrous-oxide and oxygen administration. The combination produced a “dissociated” mental state that Crile termed anoci-association, a state in which patients did not perceive pain. This was a forerunner of balanced anesthesia. Anoci-association, but particularly the administration of nitrous oxide with limited concentrations of oxygen and no oxygen monitor, required special skills.

Alice Hunt, a nurse anesthetist on the Yale faculty, described her approach.

“The technique calls for careful attention to detail in several ways, as follows: (1) an endeavor to gain the patient’s confidence and cooperation and to allay apprehension; (2) adequate narcotic premedication for relief of pain; (3) rinsing out of all diluting air from the lungs and tissues of the body; (4) avoidance of painful manipulation during the induction period; and (5) gentle surgical handling of the body tissues throughout the operation—a strong plea for this anesthesia, for it is a well-recognized fact that an important contributing cause of surgical shock is trauma to the tissues.” [15]

Crile also knew that the technique demanded observant care.

“Oxygen is a pilot light to keep the flame of life burning safely. If the light burns too high, the patient immediately comes out

from the anesthesia, if too low, the patient is too deeply submerged; if it is turned out, the patient dies. Yet with a steady flow of gas under constant pressure, the patient is carried easily through the narrow zone of anesthesia. Miss Hodgins made an outstanding anesthetist for she had to a marked degree both the intelligence and the gift.” [16]

Personal accounts reveal some unusual stresses of wartime experiences. Sophie Winton (1887–1989), who worked with James Gwathmey wrote that she averaged twenty-five to thirty anesthetics a day. “As soon as they were through operating on one patient, I would have the next patient anesthetized....Many a night I had to pour ether or chloroform on my finger to determine the amount I was giving, because we had no lights except the surgeon had a searchlight for his work, so the only sign I had to go by was respiration” [17].

From “The History of the Pennsylvania Hospital Unit”:

“Throughout the British Army, anesthetics had hitherto only been administered by doctors and when shortly after our arrival our women began their work they (the British) were greatly astonished. The skill and care which was displayed soon caused their amazement to yield to admiration. The idea was soon adopted by the British authorities, and in the early spring of 1918, classes were formed of British nurses who received instruction at our hospital and at several others, and before the end of the war a number of British nursing sisters were performing the duties of anesthetists in various hospitals throughout the British Expeditionary Forces....” [18]. In 1936, Crile reflected that: “if the Great War had gone on another year, the British army would have adopted the nurse anesthetists right in the middle of the war.” [19]

Accolades accrued to Winton and her colleagues: “All the nurses in Winton’s unit were awarded the Croix de Guerre. Bankert reported (p. 48) [7] that Winton herself was also awarded six overseas service bars as well as honors from the Overseas Nurses Association, the American Legion, and the Veterans of Foreign Wars.” They were paid \$ 60 per month. But as they were associated with the Red Cross nurses, they “did not receive full military rank, nor the pay and allowances equal to male military personnel. Veterans’ compensation was also denied them” [20].

Thatcher (p. 97) [3] traced two other changes to World War I. The Army and Navy both began to formally train nurses for duty as anesthetists for war service, a practice that continues to this day. The other change stemmed from the increased popularity of nitrous oxide: a “booming demand” after the war for trained nurse anesthetists” familiar with the technique of nitrous oxide anesthesia.

Success Triggers Opposition

The success of nurse anesthetists during World War I and afterwards, triggered opposition among the growing number of physicians entering anesthesia. According to Thatcher

(p. 108) [3]. “The rapid growth of postgraduate schools of anesthesia in which nurses were trained, as well as the increasing enthusiasm for the trained nurse anesthetist during and after World War I, did not escape the attention of physician specialists in anesthesia, and during the 1920s resentment against the nurse anesthetist culminated in attempts to legislate her out of existence.”

The movement began in New York as early as 1912 with an article by attorney Lawrence Irwell entitled “The Case Against the Nurse-Anaesthetist”. “The moment that a nurse of her own volition, in consequence of symptoms observed by her, increases or decreases the amount of an anesthetic, which is being given to man, woman or child, she unquestionably and beyond doubt practices medicine in the legal sense of the words and violates the law of New York, Ohio, or Illinois, as the case may be.” He snidely concluded his article urging: “self respecting nurses to turn their attention to other matters—perhaps urinalysis” [21].

Bankert considered that Frank McMechan, the founder of the Interstate Association of Anesthetists, was “probably the most virulent” opponent to nurse anesthetists. In an editorial in the American Journal of Surgery, [22] he inveighed: “The nurse anesthetist must go, because she is unlicensed, and because her employment is as much an economic crime against the profession and public as *fee splitting* (emphasis original).” McMechan threatened: “to bring an end to the administration of anesthetics by unlicensed persons in every state in the middle West in which such can be secured” [22].

In 1916, McMechan attempted to close the Lakeside School, a high profile source of nurse anesthetists. Through the Interstate Association of Anesthetists, McMechan petitioned the Ohio Medical Board to adopt a resolution that stated in part, “it has been charged by many well-known and reputable physicians, that the law regarding the administration of anesthetics by others (sic) than licensed physicians has been systematically violated by Lakeside Hospital, Cleveland, Ohio, and that courses in anesthetics are given nurses in Lakeside Hospital.” Thatcher wrote (p. 113) [3] that together with physicians Albert Freiberg and J Baldwin, McMechan: “denounced in no uncertain terms the administration of anesthetics by nurses.”

More subtle opposition came from giants in anesthesia. Ralph Waters, the father of academic anesthesiology, held nurse anesthetists in low esteem:

“I hear that some surgeon in this state is using a nurse or an office girl—I’m not sure which—to administer anesthetics to his patients. Do you know why? The only honorable reason he could give is because he believes that she can give an anesthetic better than any practitioner of medicine available in his community. Surgeons with this handicap can be found in many communities in the United States today.” He believed that: “A nurse’s training is not sufficient foundation for becoming an anesthetist of value to both patient and surgeon.”(Bankert, p. 56). [7]

Program closures occurred or were threatened. A program had been established at the Johns Hopkins Hospital in 1917. In 1931, Olive Berger became its director, and in 1941 the pioneer thoracic surgeon Alfred Blalock, became the Chief of Surgery. According to Bankert (p. 199), [7] Berger:

“managed the anesthesia department, administered anesthesia, and trained at least four nurse anesthesia students a year. She administered the anesthesia for the first total pneumonectomy at John Hopkins and, with Helen Lamb, developed an endotracheal technique for intrathoracic surgery. She was the first nurse anesthetist to administer anesthesia to infants for tetralogy of Fallot.”

In 1941, Blalock invited Austin Lamont, an alumnus of Ralph Waters, to open a residency at Hopkins. “Lamont’s concept of an anesthesia department that included physician anesthesia, residency training and a resident research program was forged by the model presented in both Wisconsin and New York” [23]. But Lamont and Blalock “came to a parting of the ways”. Lamont wrote that his resignation was “due to Blalock’s opposition to my wish to increase the number of physician anesthetists and decrease the number of anesthetic nurses” [23]. The Johns Hopkins program survived until 1985, a time when numerous programs closed (see below).

Attempts to Outlaw Nurse Anesthesia

During the first half of the twentieth century, two lawsuits unsuccessfully argued that nurse anesthesia practice was illegal. In *Frank v. South* (Kentucky, 1917), surgeon Louis Frank, together with nurse anesthetist Margaret Hatfield, sued the Kentucky State Board of Health to test the contention that Hatfield was practicing medicine. The court ruled that both nurses and physicians could practice anesthesia without breaking the law (Bankert, p. 116) [3].

In *Chalmers-Francis v. Nelson* (California, 1936), the Los Angeles County Medical Association and its Anesthesia Section sued nurse anesthetist Dagmar Nelson for allegedly practicing medicine. Nelson however, with support from surgeon Verne Hunt, convinced the court:

“(1) (that) the giving of drugs upon the direct or understood instruction of a physician was a recognized practice and within the limits of the definition of nursing, (2) that the recognition and the reporting of changes in a patient’s condition and acting accordingly under the direct or understood supervision of a physician was within the province of nursing, (3) that nursing education as accepted by law gave instruction in the administration of anesthetics and the recognition of the signs and stages of anesthesia and (4) that it was an established practice within the law for registered nurses to give anesthetics as a nursing duty” (Bankert, p. 146). [3]

Acting with the backing of these two rulings, nurse anesthetists sought legislation in some state legislatures to legalize their work. “A number of states adopted statutes recognizing

the practice of nurse anesthetists. Typically, these statutes followed the formulation in *Frank v. South*, and provided that nurse anesthetists were to work under the ‘supervision’ or ‘direction’ of a physician” [24]. Stoll wrote (p. 86) [25] that “Any nurse anesthetist would have been convicted of practicing medicine without such direction and supervision.” Ultimately, twenty-three states enacted a supervision requirement either in their medical practice act, nursing practice act, or hospital licensing requirements [26].

Attempts to Control Nurse Anesthesia

Decades later, the concept of required supervision would be turned against nurse anesthetists. In 1985, H Ketcham Morrell, president of the American Society of Anesthesiologists (ASA) wrote: “...the operating surgeon or obstetrician who purports to provide medical direction of the nurse, in the absence of an anesthesiologist, carries a high risk of exposure, on a variety of legal theories, for the acts of the nurse” [24].

Additionally, two federal (Medicare) payment schemes, the Tax Equity and Fiscal Responsibility Act (TEFRA-1982), and the Prospective Payment System (PPS-1983), disadvantaged Certified Registered Nurse Anesthetists (CRNAs). TEFRA and PPS were accountability measures meant to ensure that an anesthesiologist oversaw no more than 4 CRNAs at once, and personally performed certain services as part of a given anesthetic, to qualify for payment. However, the PPS inadequately compensated the physician/nurse team. Rita Rupp, a policy expert who was Special Assistant to the Executive Director at the AANA, concluded that: “Simply put CRNA services were, for all practical purposes, non-reimbursable” [11]. The PPS and TEFRA rules were misconstrued as a standard of care, despite the government’s caution that they were not (Bruton-Maree and Rupp, pp. 361–3) [27].

CRNAs sought legislative and then regulatory relief. Medicare rules were the logical place to request removal of the supervision requirement, because they impacted all the states where *state* laws did not impose supervision (p. 408) [24]. Efforts by the AANA and the ASA to renegotiate TEFRA ended after “the ASA had second thoughts” about agreed upon revisions (Bruton-Maree and Rupp, p. 363) [27]. The Clinton administration removed the other supervision requirement. This was overturned by the GW Bush administration, with a proviso that states could “opt out” of supervision if the governor so chose. To date, Governors in 17 of the 31 eligible states have done so (Table 22.1).

Other activities pertinent to education included ostracism of anesthesiologists participating in training programs,

Table 22.1 States in which the governor has opted out of the federal CRNA supervision requirement, and the date

(see for example, John Adriani below; Bankert, p. 154) [7] and an attempt to control school accreditation (also discussed below) [28]. Like the preceding lawsuits and attempts to legislate restrictions, both of these efforts failed.

What prompted the opposition to nurse anesthesia? Bankert argued (p. 57) [7] that economic factors were key. She cited C McCauley, a colleague of Ralph Waters: “I think the main reason that we are having nurses give anesthetics, at least up in this country, is the question of money.” Thatcher wrote (p. 135): [3] “Undoubtedly, it was the economic pinch of the depression that led the California physician anesthetists to renew their attack against nurse anesthesia in October, 1933, leading to the trial of Dagmar Nelson...” Stoll, citing (p. 200) [25] Hodgins (1935) wrote that opposition was greatest against nurse anesthetists who worked on a fee for service basis, at a lesser price than anesthesiologists.

Bankert added (p. 62 and p. 95) [7] that surgeons like Louis Frank and Verne Hunt, recognized the limited resources of nurse anesthetists, and financially supported the pursuit of their claims or defense. Attempts to control the activities of nurse anesthetists prompted them to form state associations for self protection (e.g., Ohio in 1931, New York in 1933, and California in 1935 and others) (Thatcher p. 162) [3]. Closer ties developed between the AANA and other nursing organizations (Stoll, p. 200) [25]. Finally, efforts to improve education, which lagged between the mid 1950s and the 1970s, were reignited when anesthesiologists moved to control the accreditation of nurse anesthesia schools (Stoll, pp. 128–38) [25].

Nurse Anesthesia Education

Teaching the Art of Anesthesia

Surgeons taught nurses to administer anesthesia in the 1870s and 1880s. By the mid to late 1890s, nurses began to train other nurses. As noted earlier, the first formal training in anesthesia took place in the 1890s at St. Mary's Hospital (the Mayo Clinic) with Magaw and Henderson doing most of the teaching. Initially they learned from surgeons, adding education by trial and error, supplemented with keen observation. They knew little pharmacology or physiology, and offered no theories, but they understood how to deliver chloroform and ether effectively and safely. They gave their students guidance, plenty of time, and individual oversight. Thatcher wrote (p. 62) [3] that "Sometimes the nurses (students) stayed for 2 or 3 months and learned to give ether under supervision." Education was tailored to the learning style of each student, and respectful of the need for oversight for patient protection. Such early nurse education in anesthesia differed from most education of anesthesiologists, which historian AJ Wright described (p. 15) [5] as: "on the spot training of any person available."

From Technical Training to Professional Education

As the twentieth century began, Thatcher described (p. 93) [3] the training of nurses in anesthesia as taking three forms:

- (1) that given by graduate nurses in a hospital in which they were to be employed as anesthesiologists;
- (2) that provided gratuitously to visitors-physicians and nurses-who went to a hospital to observe and sometimes give anesthetics under supervision; and
- (3) that given by the manufacturers and the demonstrators of gas machines, who often traveled round the country to sell and teach the operation of machines to anyone who would buy."

Although better than training by trial and error, these methods lacked uniformity or a didactic component. They were technical and only addressed the need to cover service requirements.

The recognition of the importance of asepsis in the 1890s, underlay the expansion of surgery, and this, in turn increased the need for safer, better, more consistent anesthesia. According to Thatcher (p. 48) [3] "The new (aseptic) surgery, combined with the new knowledge of other practical aspects of bacteriology, stimulated organized efforts to set standards of education and service in all phases of medical care."

In 1910, Medical Education Changed, and Nurse Education Followed

Publication of the Flexner Report in 1910, contributed to the closure of many inadequate medical schools. Medical education became university based, science-driven and research oriented [29]. Nursing education needed to change to keep pace.

"Early on, before anesthesia education was regulated, there were a lot of substandard schools. They needed to be improved or closed to ensure *safe patient care*. Our profession took on that responsibility." (April 2011 personal communication, Betty Horton, AANA Education Director from 1990–2002.)

The First Schools of Nurse Anesthesia

Agnes McGee graduated in 1907, from St. Joseph's Hospital School of Nursing in Chicago, and received anesthesia training in Heidelberg, Germany, before settling in Portland, Oregon. In 1908–09, Good Samaritan and St. Vincent's hospitals in Portland used interns to deliver anesthesia, but the interns rebelled, resolving that 'they were not going to spend their internship giving anesthetics.' Their revolt opened the way for McGee, and in 1909, at St. Vincent's Hospital; she opened the first school of nurse anesthesia in the US. [30–31]

According to Brown, the school "expanded and flourished under McGee's leadership" [31]. The initial course occupied four months. It was extended to one year in 1939. The students studied the "anatomy and physiology of the respiratory tract, pharmacology of anesthetic agents and techniques of administration of anesthesia" [31]. St. Vincent's curriculum was the first to contain both didactic and clinical components. The program continued until 1956, training 142 students over its life span. Other programs followed at St John's Hospital, Springfield, Illinois (1912); the New York Post-Graduate Hospital, New York City (1912); and the Long Island College Hospital, Brooklyn (1914). For her pioneering work, McGee received the AANA Award of Appreciation in 1953.

A second pivotal event for nurse anesthesia education took place in 1909: the twelfth annual convention of the Nurse's Associated Alumni of the US, in Minneapolis. The meeting was to feature a presentation on the nurse as anesthesiologist by Henderson, and a response by Hodgins. Instead, nurses in attendance took over the agenda, and expressed their desire for formal specialty training programs in anesthesia. Thatcher wrote (p. 91) [3] that Hodgins was said to have gone home: "with a bee in her bonnet", perhaps remembering J Baldy's

Fig. 22.3 Distribution of the 54 schools of nurse anesthesia listed by the AANA, that produced graduates qualified to take the certifying examination in 1948

declaration the year before, that: “At present there is no place to my knowledge where a nurse or anyone else could apply for a training in anesthesia.” Hodgins and Crile began their school at the Lakeside Hospital in Cleveland, thinking their program was the first. Regardless, the meeting in Minneapolis produced the Lakeside program, a program from which 54 other institutions developed six-month-long postgraduate training programs—modeled on the one at Lakeside. Hodgins and Crile trained nurses, doctors, and dentists in the administration of nitrous-oxide-oxygen anesthesia. Founded in 1915, the school became known for this anesthetic approach, just as the Mayo Clinic had evolved as a center for teaching ether anesthesia. In 1916, 11 nurses, 6 physicians, and 2 dentists graduated. In 1917, the Lakeside school was closed by the challenge from the Ohio Medical Board described above. Thatcher reported (p. 106) [3] that it reopened in 1918, and by 1919, 54 nurses and 2 physicians had graduated.

The Lakeside School was housed within the anesthesia department. From 1915–1933, Hodgins directed and was the driving force behind both. As reported by Thatcher (p. 76) [3] “One now famous surgeon, who as a student went to Cleveland to learn the technic (nitrous oxide-oxygen anesthesia), was admonished by his chief: ‘George (Crile, the surgeon) will talk a lot, but you watch Agatha’.” The curriculum lasted six months, tuition was charged, and a diploma was granted. Hodgins gave the classroom instruction (added in 1918), and she had up to three assistants to help supervise the students. To widen clinical experience, students rotated to operating rooms in hospitals around Cleveland (Thatcher, p. 106) [3].

The Lakeside School had considerable influence. In her 1948 presentation of a posthumous award to George Crile, for his support of nurse anesthesia education, AANA President Lucy Richards noted: “Living memorials to him are the 54 formal schools for the training of nurse anesthetists in registered hospitals in this country. Because of his vision and his confidence, the anesthesia service in over 75 per cent of the nation’s registered hospitals is being conducted by nurse anesthetists educated in schools patterned after the one of which he was the founder” [32]. Three-quarters of the 54 schools established by 1948 were centered in the mid-west (39%) and Northeast (35%) (Fig. 22.3).

Anesthesia education improved during this era. Classroom instruction began to supplement on-the-job training. But as Thatcher described (p. 96), [3] “while these pioneer educational ventures started a shift of emphasis from service to education, the service requirements of hospitals remained paramount in the majority of the training programs that sprang up during World War I and the postwar period. All other considerations were secondary to that of turning out anesthetists who had technical proficiency.”

Assuring Quality in Anesthesia Education

Between 1931 and 1955, Hodgins, Helen Lamb, and Gertrude Fife changed anesthesia education by organizing a national nurse anesthetists’ association, promulgating educational standards and agitating for their acceptance. These pioneers fought to accredit schools, determine curriculum standards, certify graduates by examination, educate educators, and initiate continuing education for practicing nurse anesthetists.

In 1931, many programs were deficient. Requirements for opening a school were lax, consisting “merely of obtaining the consent of the hospital and the surgeons and a willingness on the part of the instructor to impart knowledge and techniques to the student apprentice.”(p. 103) Some schools did not keep pace with scientific and technical advances. Thatcher reported (p. 96) [3] that “the courses represented all shades of adequacy depending on the native intelligence and the teaching ability, experience and education of the instructor.” Certification was needed to ensure that graduate nurse anesthetists met an acceptable standard. Hodgins appreciated that achieving this goal required a coordinated nationwide effort.

Birth of the American Association of Nurse Anesthetists (AANA) and Education Standards

The National Association of Nurse Anesthetists (NANA—changing its name to the American Association of Nurse Anesthetists, or AANA, in 1939) was born in 1931, at a

meeting convened by Hodgins, of members of the Lakeside Alumnae Association. The organization was the culmination of her life's work, and became a singular force for bettering anesthesia education [3, 33] Membership was to be contingent upon certifying that the applicant's practice and capabilities met set standards. Applicants for membership either had to have practiced anesthesia more than 3 years, or graduated from a program of nurse anesthesia that met standards set by the AANA. Certification of a nurse anesthetist or a school by the AANA would signify quality in education. Thatcher wrote (p. 209) [3] that the accomplishment of these intended goals would "place the association in the position of a pioneer among nurse specialty groups."

An Education Committee was formed to define and achieve these goals. Its work became "the main plot development in the story of the national organization," and Lamb chaired the Education Committee. After training at the Lakeside School under Hodgins, Lamb had been recruited by Evarts Graham to the Barnes Hospital in St. Louis. There, she founded a program of nurse anesthesia in 1929, remaining as its director until retiring in 1951. With Graham, Lamb pioneered endotracheal anesthesia, and collaborated with the engineer Richard von Foregger on the design of anesthesia equipment. She administered anesthesia for the world's first pneumonectomy (Thatcher, p. 158, and Bankart, p. 202) [7]. She was an exacting teacher, and is today remembered annually by an award in her name, bestowed by the AANA upon an outstanding nurse anesthesia educator.

Lamb "could size people up very quickly (Kelly JW: personal communication, 2011)," "and looked into the future with sharper vision than had anyone else up to that point" (Thatcher, p. 189) [3]. Her career overlapped those of McMechan who opposed nurse anesthesia, [23] and Waters who resisted the presence of nurse anesthetists in academic centers [34]. Observing these men and their actions, Lamb probably suspected that nurse anesthesia would be threatened if it failed to keep up with the progress made by physicians.

The Education Committee first surveyed existing schools to determine the current state of anesthesia education. From the survey results, the Committee published minimum curriculum standards for schools in 1933, making these increasingly stringent in 1935, 1936 and 1948 (Fig. 22.4). The Committee then established and maintained a list of "accredited" schools that met those standards. These were the first universal standards in nurse anesthesia education.

Defining adequate schools was only one of the AANA's educational goals. Beginning in 1933, the Association published a journal; it has subsequently been in print continuously. The Education Committee also established a certifying examination that all graduates would have to pass to obtain AANA membership (see also Chapter 36). World War II delayed implementation of the examination by several years. In the interim, the AANA established an Education Department in 1935, with Lamb as its first director.

Fig. 22.4 Course requirements for nurse anesthesia programs markedly increased between 1931 and 1948. (Data from Stoll DA: The emerging role of the nurse anesthetist in medical practice (dissertation). Evanston, IL, Northwestern University, 1988)

In her 1934 address at the annual meeting in Memphis, Fife articulated the AANA's intention to become the sole authority on nurse anesthesia education: "The Association will serve as a pace-maker for the better schools and will influence the poorer schools to meet the required standards. The Association will secure for (accredited) schools on its list a recognition throughout the United States such as could not be secured in any other way, and will make possible the acceptance of guiding principles in matters pertaining to the education of the nurse anesthetist" (Thatcher, p. 210) [3].

Hodgins vs. Fife: How Should Certification Be Achieved?

To accomplish these goals, the Association had to arbitrate a dispute between Hodgins and Fife over how certification should be achieved. Hodgins favored state registration. Bankert wrote (p. 97) [3, 7] that "her reasons for doing so may have been the result of her conviction that the work fell under neither the category of medicine nor of nursing, and that nurse anesthetists needed the protection of a separate legal status. She may also have been affected by years of listening to the charge leveled by physician-anesthetists hostile to the existence of nurses in the field, that they were 'unlicensed' practitioners."

Fife took the position that national certification would be more practical.

"Furthermore, every anesthetist should be required to pass a National Board examinations (sic). I do not believe that state board registration for nurse anesthetists is either practical or possible. Quicker and more direct action can be obtained through

a National Board, and more uniform methods of teaching will result from the establishment of universal rather than sectional standards" (Bankert, p. 211) [7].

This "contest of wills" ended only after Hodgins' death, with the eventual implementation of national certification.

Strengthening the AANA by Affiliation with Other Organizations

Other matters diverted attention from the move to establish standards. Organized physician groups filed law suits—the two discussed above and several in other states—challenging the right of nurses to practice anesthesia. To confront the lawsuits of organized physicians, maintain standards in the face of the government's wartime needs, and keep up with expanding marketplace needs was daunting. And the AANA was weak, having fewer than 1,000 members, each paying only \$ 5 in annual dues. However, the AANA persevered.

Hodgins, Lamb, and Fife, and their fellow organizers affiliated the AANA with the American Hospital Association. Philosophical differences hindered attempts to work with other associations. Hodgins had written to the American Nurses Association (ANA) seeking affiliation as a subsection, prior to establishing the NANA: "Our reason for asking affiliation with the ANA, is simply recognition of the primary fact that we are registered, graduate nurses, qualified for and pursuing a special work" (Bankert, p. 70) [7]. The ANA stalled and finally rejected the request, creating a rift that would not be healed until the 1970s.

At the sixth annual meeting of the NANA, Lamb spoke of efforts to enlist support from the American Hospital Association: "The (Education) Committee's most important activity centers around the movement now under way to enlist the endorsement of the American Hospital Association...for the inspection of schools of anesthesia for nurse anesthetists; and upon the basis of inspection to eventually approve those schools whose curriculum proves to be the equivalent of the standard already adopted by our Association" [35].

Before settling on the American Hospital Association, the NANA held "numerous conferences" with other organizations. Thatcher listed (p. 233): [3] "a talk by Miss Lamb on the association's educational aims before the American Board of Surgery in St. Louis...a meeting of the entire Board of Trustees with members of the American Board of Surgery and the newly organized American Board of Anesthesiology in New York City on November 27, 1938, and subsequent conferences with representatives of the American Hospital Association and the American Board of Anesthesiology."

The specifics of those meetings are unknown. For the American Hospital Association (AHA) to contemplate imposing new standards on a school must have been politically

delicate. Thatcher would conclude (p. 233): [3] "The conferences pointed to the facts that the AHA would be the most desirable sponsoring body, but that a more detailed plan should be prepared for formal submission to that organization and that the association could effect a raising of standards in schools of anesthesia by having definite rather than nonspecific requirements for admission to membership."

Liaison with the AHA was instrumental in this formative stage. As John Garde observed: "By 1933, the NANA had still not held its first national meeting, and suffered from general disarray organizationally" [36]. The AHA, recognizing the value of nurse anesthetists to their hospitals, invited the NANA to hold its first national meeting in conjunction with them [36]. The relationship was a success, and the AANA (renamed from the NANA in 1939) and the AHA held their annual conventions together for 43 years, from 1933 to 1976.

Other imperatives trumped the educational aims of the association. Stoll wrote (p. 6) [25] that "While it may be rationalized that the primary reason for the support from administrators and surgeons was based on the proven capabilities of nurse anesthetists, the reality of this support was the need for an inexpensive provider of anesthesia services. It is important to state that when serious challenges to nurse anesthetists' right to work began, these organizations and individuals provided the necessary peer and professional support required to ensure that nurse anesthetists remained in practice."

World War II Delays Educational Advancement

The demands for trained anesthesia personnel posed by World War II were a challenge. The need for nurse anesthetists was so great that the Army pressed them into service after as little as three months training, some within "earshot of battle." This compounded a severe shortage of civilian nurse anesthetists. The AANA wisely (it would turn out) did not resist the accelerated training programs, although these emergencies delayed implementing the leaders' plans for a national certifying examination and a school accreditation program. Fife articulated the AANA's position, including its attempt to maintain minimum standards of competence, in a recruiting brochure published in 1942:

"The need for nurse anesthetists both in civilian and Army hospitals is becoming increasingly urgent. In order to meet the situation many Schools of Anesthesia have increased the student body. The degree of expansion is limited, however, because in order to qualify for membership in the AANA, each anesthetist must have administered a certain number of anesthetics during her training. The AANA has been opposed to lowering the standards by allowing the student to be graduated with less clinical experience than necessary to prepare her properly for work in active surgical clinics" [37]. Instead of resisting the accelerated training, Bankert wrote (p. 124) [7] that the AANA: "encouraged the establishment of schools in hospitals equipped to offer training in this field."

With the war's end, the AANA renewed its education program. Bankert reported (pp. 130–5) [7] that opposition from anesthesiology organizations reappeared as threats of sanctions against anesthesiologists who were involved in training nurse anesthetists. John Adriani directed a major school of nurse anesthesia at Charity Hospital, in New Orleans. In 1947, the Board of Directors of the American Society of Anesthesiologists “adopted a statement in its bylaws to the effect that it was unethical for an anesthesiologist to participate in the training of nurses” and “precluded giving lectures at the annual meeting for the AANA.” “In addition, Adriani was personally informed by Dr. Paul Wood, secretary of the American Board of Anesthesiology, that the board was ‘seriously considering’ the revocation of certification of any anesthesiologist who trained nurse anesthetists.” “Promising to respond with a federal lawsuit to any revocation of his certification, Adriani heard no more and continued his work.” The bylaw was not rescinded until 1964. Its effect on other anesthesiologists cooperating with nurse anesthesia education was never assessed.

The first qualifying examination was administered in 1945. The wartime contributions of trained nurse anesthetists indirectly sped the move to accreditation of schools of nurse anesthesia. In 1947, the Education Consultant for the Army Nurse Corps, Lt. Col Katherine Balz, explained that “World War II conclusively demonstrated the need for nurses trained in anesthesia, both for battle-front duty and for service in Army hospitals caring for military personnel. The very fact that the Army has founded schools for the training of nurses in anesthesia is confirmatory evidence of the value of the nurse anesthetist to the armed forces” [38]. Balz next observed that the Army planned training programs at five hospitals, ensuring that “upon completion of the course, the Army nurse will be prepared to take the qualifying examination and become a member of the Association” [38]. The endorsement of civilian hospitals followed the Army's acceptance of the AANA plan, and the accreditation of programs and certification of graduates became universal after the Korean conflict.

The aftermath of the war in Korea added to the pressure to accredit programs. Federal education benefits for military personnel could not be obtained for training at unaccredited schools. In 1955, the AANA successfully appealed to the United States Office of Education to recognize the AANA as the accrediting agency for nurse anesthesia educational programs (Bankert, p. 138) [7]. Unaccredited programs then gradually disappeared, but were more than replaced by accredited programs (Fig. 22.5).

Between 1953 and 54, just before the accreditation mechanism was approved (1955), the number of programs nearly doubled within one year. Stoll explained (p. 98) [25] that “only the schools which adhered to AANA educational guidelines were counted prior to 1952, and after the United

Fig. 22.5 Number of active nurse anesthesia programs adhering to AANA guidelines from the 1940s

States Office of Education approval, those non-recognized programs that met requirements, received accreditation status, and were added to the approved list.”

A continuing expansion ended with a peak of 213 programs in 1973, and an equally rapid descent between 1978 and 1988. Half the programs closed, and graduates decreased by one third [39]. Concurrently, “the number of anesthesiology residents nearly doubled” [39]. Sandra Maree-Ouellette, a former AANA President recalled: “As a profession we thought we were dying on the vine” (personal communication July 2011).

DePaolis-Lutzo suggested diverse reasons for the striking decrease in the number of programs, with the main problems being funding, cost, competition from anesthesiology residents (subsidized by the US government), and the lack of anesthesiologist support within joint departments [40]. Similarly, Denise Martin-Sheridan attributed closures to: “lack of financial support from the hospital, university, and anesthesiologists; changes in state and federal reimbursement, and reconfiguration of the delivery of healthcare services under managed care systems...” [41] Jeffrey Beutler contrasted third-party payment policies for anesthesiologists teaching residents, and CRNAs teaching student nurse anesthetists, finding that they “burden CRNAs and nurse anesthesia students with financial disincentives and payment exclusions...” [42].

By 1989, fears for professional survival prompted AANA President Richard Ouellette to appoint a 17-person commission of nurse anesthetists, anesthesiologists, and administrators of educational institutions and health systems, to study school closures and recommend what should be done. Sandra Maree was the chair.

The commission reached several conclusions. Program closures had caused a CRNA shortage, ranging geographically from 10–20%. Access to anesthesia had become limited in rural areas where CRNAs practiced alone. Anesthesia had grown more expensive as demand outstripped the supply of providers, and where anesthesiologists had displaced CRNAs. Quality was compromised because untrained (non-anesthesia) providers were substituted to administer intravenous sedation. Resolution of these problems would require the training of 25,000 additional CRNAs by 2010 [43].

Where nurse anesthesia educational programs shared facilities with anesthesiology residencies, the lack of sufficient cases posed a major obstacle to training more CRNAs. Nurse anesthesia programs resolved this problem by diversifying. Some developed relationships with community hospitals. Additional remedies separated nurse anesthesia training programs from other training (residencies), or even from schools of nursing [44]. Some nurse anesthesia training programs affiliated with allied health departments, and some found ways to co-exist happily within schools of nursing [45–53]. Horton and Brunner described how programs became more numerous and complex between 1992 and 1997, a period in which the number of clinical sites rose from 266 to 577 and the number of graduates recovered from 669 in 1990, to almost 1100 in 1996 [54]. These efforts restored the independence and vitality of nurse anesthesia as shown by the stabilization of the number of accredited training programs in the late 1980s (Fig. 22.5). In the end: “Almost a third of the nation’s 6,000 hospitals participated in the education of nurse anesthetists” (personal communication Sandra Maree-Oullette July 2011. Sandra Maree and Richard Ouellette married in 1994).

Will We Soon Call a Nurse Doctor?

In 2004, the American Association of Colleges of Nursing (AACN) recommended that by 2015, all advanced practice nurses earn a doctoral degree. A 2006 AANA task force explored the consequences and concluded that: “it is essential to support doctoral education...” [55]. But a 2015 deadline would deprive existing programs of sufficient time to prepare. Consequently, the task force proposed delaying the doctoral requirement to 2025, and the AACN (which accredits colleges of nursing, some of which contain anesthesia educational programs) has not objected.

For differing reasons and for some time, doctoral education has been a goal of nurses. According to Sandra Edwardson, Professor and Director of the Doctor of Nursing Practice Program at the University of Minnesota: “From the beginning, the primary reason for wanting doctoral preparation in nursing was to develop the knowledge necessary for practice and to gain credibility within the academy” [56].

The AACN, referring to a National Academy of Sciences recommendation, says: “the growing complexity of the healthcare environment, coupled with the rapid expansion of knowledge required for practice” demand higher degreed nurses (<http://www.aacn.nche.edu/media-relations/factsheets/dnp>). Phelps and Gerbasi examined why 14 health care professions adopted doctoral education. Most pointed to: “changes in the scope of practice relating to increasing responsibility and/or independence of practice...” [57]. Doctoral education has become a trend.

But what type of doctoral degree should student nurse anesthetists earn? Phelps and Gerbasi compared accreditation requirements of doctoral programs in clinical laboratory sciences, dentistry, medicine, nursing, nurse anesthesia, osteopathic medicine, pharmacy, physical therapy, podiatry, and psychology [57]. They found a swing away from universal educational standards, which are considered by many administrators as “unnecessarily prescriptive.” Instead, almost all accrediting agencies identify essential competencies that graduates should obtain.

Thus, the AANA did not prescribe a type of doctoral degree, allowing nurse anesthesia educational programs to offer research-based or practice-based degrees. The doctor of philosophy (PhD), doctor of education (EdD), doctor of nursing science (DNSc or DNS) are research-based. The doctor of nursing practice (DNP or DrNP), doctor of nurse anesthesia practice (DNAP), and doctor of management practice in nurse anesthesia (DMPNA) are practice-based [58].

However between the degrees there are: “subtle although uncertain distinctions” [56]. One distinction is the requirement for a thesis. Mary Marienau who is Program Director at the Mayo Clinic Nurse Anesthesia Educational Program, and Chair of the Council on Accreditation of Nurse Anesthesia Educational Programs, noted that: “Just like other professional (practice-oriented) degrees, including the MD degree, a thesis is not a requirement.” Instead; “A capstone project is an expectation, which still requires a rigorous in-depth investigation into a research question, but it does not necessarily need to be a thesis” (personal email communication, October 2011).

Eight essentials for a practice doctorate in nursing have been identified: 1) Nursing Science & Theory: Scientific Underpinnings of Practice; 2) Systems Thinking, Healthcare Organizations, & the Advanced Nurse Practitioner; 3) Clinical Scholarship and Evidenced Based Practice; 4) Information Systems/Technology Systems, and Patient Care; 5) Health Care Policy for Advocacy in Patient Care; 6) Inter-professional Collaboration for Improving Patient and Population Health; 7) Clinical Prevention and Population Health for Improving a Nation’s Health; and 8) Ethics [59].

The minimum time required to earn a doctoral degree has also been assessed. Upon graduation, a nurse anesthetist with a DNP degree will have spent a minimum of 8 years

in training (4 undergraduate, 1 ICU, and 3 graduate years). Mary Marienau, explained that: “Four years of baccalaureate (nursing) education, plus one year of ICU experience (as a nurse), plus three years of doctoral education is comparable to other doctoral degrees....Possibly we should be calling the ICU experience an RN-ICU Internship so that it equilibrates to the MD model of internship time.”

However, even with the postponement of implementation to 2025, and near universal support, the transition to doctoral education may prove difficult. The diluting affect of nursing “essentials” on the anesthesia component within the curriculum will be assessed. Mary Marienau noted that some within the AACN would like to see more classroom time devoted to non-anesthesia topics—but that the Council on Accreditation will fight “tooth and nail” to retain and in fact expand the time devoted to anesthesia. It is too soon to predict if doctoral preparation will increase nursing’s presence within the academy, but AANA Executive Director Wanda Wilson recently reiterated Helen Lamb’s hope (noted below) that: “nurse anesthetists with doctoral degrees could participate more fully in university life” (personal communication, June 2011). Finally, no one has ventured to predict whether doctoral education leads to better or more cost effective anesthesia.

Support for the Safety of Nurse Anesthesia

The increasing complexity of surgery and anesthesia in the 1950s did not diminish the role of nurse anesthesia. Training and numbers of nurse anesthetists increased (Figs. 22.4 and 22.5). “There had been a constant market for nurse anesthesia services, and surgeons had provided them with support and acclaim. There were no major indicators demonstrating any significant problems, although there was little question that studies demonstrating accountability in terms of patient outcomes were on the horizon” [6].

In 1954, Beecher and Todd [60] published the first major multi-institutional study assessing anesthesia outcomes among anesthesia providers. Their study showed that in patients at comparable risk: “although the physician specialist anesthetizes only half as many patients as the nurse, he is charged with an equal number of anesthesia deaths.” The authors speculated that this finding was due to the “complexities of the situation” and the “common observation” that the physician “cares for the patient faced with the more trying and difficult operation...” Without citing evidence they concluded that: “to deny the greater difficulty of the physician specialists’ cases is to reduce the matter to an absurdity where one would be obliged to argue that the physician’s learning was a dangerous thing.” Perhaps the nurses’ learning had also amounted to something.

This issue resurfaced in the 1990s. Between 1992 and 2003, anesthesiologists published five studies [61–65] that the AANA critiqued. Four supported the view that “CRNAs should be anesthesiologist-supervised, and that such supervision improves anesthesia outcomes.” The fifth found that: “office surgery may not be as safe when an anesthesiologist is not present.” The AANA review concluded that “Anesthesia-related accidents are infrequent; those that do occur tend to result from lack of vigilance rather than the level of education of the provider.... Studies to date have not demonstrated statistically significant differences in the safety of anesthesia care provided by CRNAs working alone, CRNAs working with anesthesiologists, or anesthesiologists providing care alone” [66].

Increasing Educational Demands on Nurse Anesthesia Increase University Affiliations

It was anticipated that an increased number of nurse anesthesia faculty with academic degrees, would promote college and university affiliations for nurse anesthesia programs [67]. In 1936, Lamb pointed to the desirability of this evolution towards university based education: “The School of Anesthesia should strive to secure the benefits which Universities have extended to other professional groups. Such University recognition and affiliation should eventually result in broadened facilities, both practical and cultural” [68].

But what Lamb urged took half a century to achieve. Stoll explained (p. 66) [25] the delay by noting that early nurse anesthetists “...had enough to do in beginning this organization (the AANA) and fighting to keep it viable that they could not address the issue of university affiliation which was beginning to consume the leaders of nursing”. CRNAs also resisted the imposition of greater educational requirements. Hudson reports (p. 15) [69] that John Garde recalled “...CRNA faculty standing up in 1975 stating: ‘if you think you are going to get CRNAs to have a bachelor’s degree to be a program director, you are not going to have any anesthetists in this country. We will be replaced by technicians because these people cannot teach, work all day and get baccalaureate degrees’”. Horton argued that advancing anesthesia education “could not have been done without” the “deliberate actions” of nurse anesthesia leaders. These included setting educational standards, approving curricula, inspecting schools, and developing an accreditation process [70].

In the last half of the twentieth century, advances in anesthesia education were accomplished, but not linearly. Until 1980, nurse anesthesia training concluded with possession of a certificate or a bachelor’s degree. Masters’ degree programs emerged in the 1980s. A bachelor’s degree

became the minimum requirement in 1990, and in 1998 the requirement universally increased to a masters degree. As noted above, a clinical doctorate will be fully implemented in 2025 [70].

Assuring an Absence of Conflict of Interest in Accreditation

In 1974, the US Office of Education (USOE) revised its standards for accrediting organizations. Of particular importance was “Standard 7. Avoidance of Possible Conflicts of Interest such as the separation of the decision making body responsible for the accreditation of educational programs and that body responsible for the certification of graduates of those programs.” In order for students (Korean War veterans) to be eligible for federal education dollars, the AANA would have to meet Standard 7. After decades as a de facto accrediting agency, the AANA would have to end its involvement in the accreditation process.

An ad hoc group of CRNA educators, led by Ira Gunn and Ruth Satterfield, pioneering educators who had developed anesthesia programs for the US Army, organized the changes that would be required to meet the new USOE requirements. Both Gunn (p. 11) [6] and Hudson wrote (p. 9) [69] that “it would be necessary to change the organizational structure of the AANA to assure the degree of autonomy for the accrediting element to maintain continued recognition as the accreditor of nurse anesthesia education.” They proposed an independent organization, to be called the Council on Accreditation of Nurse Anesthesia Programs, to undertake the work. It would be composed of CRNAs, anesthesiologists and members of the public, representing a ‘community of interest’ in anesthesia.

Anesthesiologists Compete for Control of Nurse Anesthesia Education

In 1975, anesthesiologists proposed a competing accrediting organization, the Faculty of Nurse Anesthesia Schools (FNAS). All existing nurse anesthesia faculty were invited to join. Hudson wrote (p. 2) [69] that if authorized by the USOE, the FNAS would “effectively (cede) control of nurse anesthesia education to anesthesiologists”.

At the same time, the ASA brought a 1972 manpower study to the USOE which the ASA claimed had support from the AANA (it did not; Bankert, pp. 156–8) [7]. The study concluded that the best interests of patient care would be served by: “more direct involvement of the anesthesiologists in establishment of policy relative to accreditation, curriculum, certification, and quality assurance for the nurse

involved in anesthetic care” [71]. Nurse anesthetists saw this initiative as a threat to the control of their profession.

Bankert (pp. 156–62) and Hudson (p. 11) [69] reported that concern increased further in 1976 when, in confidence, three leading anesthesiologists filed “letters of complaint against the AANA’s accreditation program with the USOE...”, questioning the competence, adequacy, composition, and autonomy of the Council proposed by the AANA. The AANA petitioned the USOE for copies of those letters, and the USOE mistakenly sent the AANA a letter meant for the physicians who had complained about the Council. Ira Gunn explained to Hudson (p. 21) [69] that John Profit (head of the Accreditation Unit at USOE) wrote to the three anesthesiologists indicating “that they probably didn’t need to worry (regarding the AANA petition) because they didn’t expect the AANA to come into compliance with the new criteria...Mr. Profit’s secretary at the USOE furnished us with that letter rather than the three complaints, and there is no question that prompted a strong willingness for the AANA to get involved.”

Disclosure of these letters to the AANA provoked outrage. Hudson noted (pp. 11–12) [69] that President Bernice Baum wrote that the letters contained “innuendo, misrepresentation, and out-of-context quotations to discredit the AANA accreditation program.” Baum observed that “While some of the allegations expressed may stem from sincere concerns about the anesthesia care in the United States, there can be little question that the real issues are: control, power, and economics....”

The USOE decision to recognize the Council on Accreditation or the FNAS was delayed, pending resolution of the complaints. In September 1976, in Washington DC, the AANA’s Council on Accreditation, the ASA and the FNAS presented their views to the USOE (Hudson p. 18) [69]. The AANA argued that “Individual professions must assume primary responsibility for quality assurance mechanisms relative to their membership while providing adequate input from the community of interest and the public.... The FNAS is neither representative of historical precedence, professional tradition, nor recognized by the USOE and has no experience in the accreditation of nurse anesthesia educational programs and certification of nurse anesthetists.” [72] The USOE sided with the AANA and granted the authorization to the Council on Accreditation.

“An Impetus to Formalize Nurse Anesthesia Education”

To Hudson (p. 9), [69] “the newly mandated standards gave the AANA an impetus to formalize nurse anesthesia education.” Gunn agreed, saying that as a result of this ordeal “It

also became apparent that this would be the best time to implement new standards not only incorporating USOE criteria but those which would also set the stage for movement of nurse anesthesia education in university frameworks” [73].

Other related education reforms took place concurrently. Standards of Practice were written in 1974, with subsequent periodic revisions. Mandatory continuing education was initiated in 1977, and recertification was implemented in 1978. Recertification required that for every two year period, nurse anesthetists must possess an active unrestricted license, earn forty hours of continuing education, and document that they remain “substantially engaged in the practice of nurse anesthesia” [73].

Global Improvements in Anesthesia Education

A dream and a conversation lead to international cooperation One day in August 1978, a Swiss nurse anesthetist travelled to Detroit carrying a dream. Hermi Löhnert had come to attend the AANA Annual Meeting. He shared this dream with President Ron Caulk. Might the AANA “be interested in co-sponsoring (with the Swiss Association of Nurse Anesthetists) an international symposium in Switzerland?” (p. 5) [74]. Caulk, who would become an enthusiastic co-founder of the symposium, learned much later “that the Swiss had not formed their (own national) organization yet.”

For Löhnert (p. 5), [74] attending the AANA Annual Meeting was a “tremendous experience...One take home message I will never forget: ‘be professional!’ I received all the support needed to strengthen and improve the situation of our Swiss Association of Nurse Anesthetists. The many discussions with nurse anesthetists at the congress triggered my interest for international cooperation.”

Achieving international cooperation was easier dreamed than done. Löhnert, together with Caulk, pursued it for eleven years. Under the auspices of the American and Swiss Associations, they sponsored two international symposiums (Lucerne 1985 and Amsterdam 1988) and numerous organizing meetings. The symposiums contained educational presentations, but were better remembered for overcoming provincialism. Pascal Rod, of France, recalled (p. 11): [74] “It was amazing how much each country was promoting its own education and practice as being the only one available.” Ron Caulk recalled (p. 9) [74] that being ‘more open’ entailed a “major adjustment”...in Finland “when we discussed business in the sauna...nude!”

On June 10th 1989, representatives from Austria, Finland, France, Germany, Iceland, Norway, Slovenia, South Korea, Sweden, Switzerland, and the USA signed a charter in St. Gallen Switzerland, and the International Federation of Nurse Anesthetists was born [75]. From the outset, the IFNA

faced problems that recalled the early years of the AANA. Pascal Rod recalled that advanced practice nursing was opposed in many nations, and not just by physicians. Nursing organizations looked at nurse anesthetists as “only technicians doing medical tasks.” Just as in the 1930s, nursing and medicine denied nurse anesthetists a home [74].

But the IFNA was anxious to announce its presence. The newly elected officers, Löhnert as President, Caulk as Vice President, Hanna Birgitsdottir of Iceland as Secretary, and Svein Olaussen of Norway as Treasurer, reached out to the International Council of Nurses, the World Federation of Societies of Anesthesiologists, and the World Health Organization. New member countries were recruited, especially from Africa and Asia. The officers vowed to convene a World Congress of Nurse Anesthetists every two to three years, which they did in Oslo (1991), Paris (1994), Vienna (1997), and Chicago (2000) [75] Today, preparations are underway for the 11th World Congress in Tunis in 2014.

They then tried to “find their colleagues.” No one, including the chief nurse scientist at the World Health Organization, knew the world-wide extent of nurse anesthesia. Sandra Maree-Ouellette reported: “When meeting with her (the chief nurse scientist) she said ‘why should we take nurses to do technicians work.’ The answer we gave her was: because nurses are administering anesthesia all over the world. She said ‘show me!’ And we did.” (email communication July 2011)

McAuliffe and Henry found that nurse anesthetists are an essential part of world health. They surveyed the education, practice and regulation of nurse anesthetists world-wide, reporting in 1996 that nurses administered anesthesia in 107 countries—the majority of member states of the World Health Organization [76]. Nurse anesthetists from 96 countries subsequently completed questionnaires about their practice, education and regulation. Respondents from 62 countries reported that educational programs to prepare nurses to give anesthesia existed within their countries. Of these, 81% indicated they had classroom instruction in anatomy and physiology, 87% in pharmacology including anesthetic agents and adjunctive drugs, 65% in chemistry and physics of anesthesia, and 91% in basic principles of anesthesia practice. 77–78 However, the duration of anesthesia training varied, ranging from 12 months or less to over 22 months, and clinical training varied from 5 months or less to more than 22 months. Only half of the respondents reported access to continuing nurse anesthesia education after completing their entry level education. McAuliffe further wrote that: “The data were reconfirmed with data collected over a (sic) 10 years, including repeat mailings of surveys to original study participants, recruitment of additional participants from international educational meetings, and in depth interviews of nurse anesthesia leaders throughout the

world.” (Personal email communication Maura McAuliffe, 6 October 2011).

Though groundbreaking, McAuliffe’s survey is but a pilot study that provides an incomplete view. Data were gathered from little more than half the countries of the world, and from only a minor fraction of the anesthesia providers. Given the potential importance of nurse anesthesia to the health of the world and given the apparently unequal distribution, contribution and education of nurse anesthetists, this survey bears repeating with greater control and in greater depth.

Notwithstanding the limitations of McAuliffe’s findings, they anticipated IFNAs’ next big endeavor: establish a committee to set international standards for nurse anesthesia education. Sandra Maree Ouellette chaired this Education Committee, and like the original Education Committee chaired by Helen Lamb, this one had to define what it means to be a nurse anesthetist. Between 1989 and 2001, the committee wrote (and the IFNA adopted) Educational Standards for Preparing Nurse Anesthetists, Standards of Practice, a Code of Ethics, and Patient Monitoring Guidelines. [75]

The IFNA grew. As many as 4200 registrants from 35 member countries attended its tri-annual World Congress meetings. Proceedings, which were translated into several languages, covered scientific, clinical, and educational topics. There were poster sessions and, of course, much socializing.

A forum for teachers of anesthesia began at the 1991 World Congress in Norway. Although it was “put together at the last minute, the room was filled to capacity, and the response to the presentation of educational issues was enthusiastically received.” An expanded forum is now a permanent part of the World Congress [74].

The IFNA has begun to “globalize” nurse anesthesia. Ouellette and Horton counted the ways: IFNA developed international professional standards; IFNA interacted with appropriate regional and international organizations and professions; IFNA examined and recorded the range of nurse anesthesia and its contributions to progress in anesthesia; and IFNA has developed a worldwide quality assurance program for educational programs [79].

The quality assurance program, known as the anesthesia program approval process or APAP, is the first international accrediting program for educational programs in nurse anesthesia. Starting in the early 2000s, it evolved through “a pilot project, a call for public comments, feedback from internal and external parties, and final approval of the documents and process by IFNA decision-making bodies in 2010.” [79] Ultimately, three increasingly stringent, but voluntary categories of approval were devised. Each acknowledged: “1. The diversity of nurse anesthesia programs throughout the world, 2. The economic stage of development of a country, 3. The resources available to individual programs, and 4. A

commitment of diverse programs to a common standard of educational quality” [79].

Today, anesthesia programs officially recognized by the IFNA can be found in: The Netherlands, US, Iceland, France, and Sweden. They and the details of the APAP program can be found at: (<http://ifna-int.org/ifna/news.php>, accessed July 16, 2011) Herme Lohmert’s dream has largely been realized.

Nurse Anesthetists from the US Contribute to World Health

With 80,000 licensed anesthesia providers (nurses and physicians) in the US, there may be a sufficient number to meet the country’s needs. Developing nations present a different picture. Richard Henker, the Program Coordinator of a nurse anesthesia training program in Bhutan, reported in 2011 (personal email communication February 2011), that 18 nurse anesthetists and 4 anesthesiologists serve that nation’s population of 700,000 people, a proportion roughly one-tenth of that found in the US. Similar situations exist in some countries of Africa, Southeast Asia, and Latin America [75].

CRNAs have provided assistance in developing nations for decades. Ruby Hills volunteered for physician Tom Dooley in Viet Nam in the 1950s [80]. Hundreds of volunteer CRNAs followed in Ruby’s footsteps. Sponsored by religious, military, or non-governmental organizations, they traveled as part of surgical teams to remote locations to establish temporary operating rooms, gave many anesthetics in a relatively short time, and returned home.

Such care was of limited value. Only surgeries requiring minimal postoperative care could be performed, and, because of the brevity of involvement, no local nurses received an education in anesthesia, and the host countries remained dependent on outsiders for anesthesia. (Personal communication: Suzanne Brown 2011).

How it Began

At the 1989 AANA Annual Meeting, an educational session on “Third World Anesthesia” drew a standing room only crowd. The strong interest among CRNAs prompted AANA support of volunteerism. However, overseas work demanded greater resources than the AANA could provide, leading in 1992 to affiliation of the AANA with Health Volunteers Overseas (HVO). (Personal communication: Clyde Tempel, 2010) HVO is a private non-profit organization headquartered in Washington, DC, coordinating activities of sponsors from various surgical specialties. Most importantly, HVO

Table 22.2 Teaching programs established by nurse anesthesia overseas (NAO)

Country	Year initiated	CRNA volunteers	SRNAs	MDs
Uganda	1993	9	20	0
Guyana	1994	28	6	0
Belize	2001	40	15	0
Cambodia	2003	17	7	0
Eritrea	2005	7	14	0
Bhutan	2009	17	8	3
Ethiopia	2010	7	13	0

Source: NAO 2011

facilitates training and education of local health care providers [81]. In 1992, CRNAs established a new organization within HVO, Nurse Anesthesia Overseas (NAO).

According to Suzanne Brown, a principle CRNA at NAO, teaching anesthesia to local nurses began with a few realizations. American standards might not always be attainable in foreign settings, but some set of standards would be needed if a program were to have legitimacy. A physical plant, a clinical setting, and legal recognition of graduates would also be required. NAO looked to the International Federation of Nurse Anesthetists (IFNA) for educational standards and recruited a local “champion” within each host country who could overcome cultural and legal barriers. (Personal communication: Suzanne Brown 2010) The IFNA had developed Educational Standards in 1994, that served as the cornerstone of the education plan.

An Example

Since 1994, teaching programs have been established in seven countries (Table 22.2). A representative example is the one developed in Belize, home to 300,000 people, and before 2001, dependent on transient foreigners for anesthesia. At the request of the Belize Ministry of Health, in 2001, 40 volunteer American CRNAs opened a school of anesthesia in Belize City, making numerous trips at their own expense. One volunteer described her experience as the greatest gift she could give another person and herself. The 2-year program conformed to curriculum standards established by the IFNA. Working through NAO and Belizean health authorities, the CRNAs selected top performing nurses for education as nurse anesthetists. Students spent seven months completing 73 didactic assignments in anatomy and physiology, biochemistry, physics, advanced pharmacology, and anesthesia case management. Frequent examinations kept them on track to succeed in the accelerated program. During the remaining 17 months, students devoted 1,000 hours to clinical rotations in Belize City hospitals, each student anesthetizing at least 450 patients. Students had to be trained to work alone since small rural hospitals serve most of the country. The program

taught more than clinical anesthesia. Students were trained to lead continuing education classes, administer tests, and obtain information from the internet that was not locally available.

The program aroused strong feelings. One student was “petrified on the first day,” and another expressed her devotion to the region she came from because “I have to go home and take care of my people.” In the final week, a student said that the volunteers “did an excellent job of preparing us for what we would face.” [82] These students became the first “generation” of CRNAs for their country. They made anesthesia available to more Belizeans.

Nancy Kelly MHS, the Executive Director of HVO believes that: “The Nurse Anesthesia Overseas program in Belize is an outstanding example of the HVO mission in action. (The) volunteers...transformed anesthesia care in Belize so that it is safer and more cost effective” [82].

Program descriptions and longevity vary from country to country. The program in Belize trained one generation of providers only. Similar, but ongoing, programs that train nurse anesthetists exist in Ethiopia and Cambodia. In Bhutan, the program focuses on continuing education of existing nurse anesthetists. The programs in Uganda, Guyana and Eritrea have completed their missions and closed.

CRNAs Combat Drug Abuse

A Tragedy Provokes Action

CRNA Jan Stewart had been the President of the AANA in 1999–2000. Her death at age 50, in 2002, caused CRNAs to confront drug misuse and addiction. Friends, loved ones, and colleagues believed she was happy, healthy and busy. Her daughter, teacher Sarah Gomes suspected otherwise. She knew her mom had been under a lot of stress, but believed she could handle it. Sarah learned too late that the medication Jan said she was taking for headaches was not Imitrex. In 2004, Sarah disclosed that her mom’s death had been caused by an overdose of sufentanil. In a tribute, Sarah lamented that there are

“...a lot of challenges facing nurse anesthetists, and nurses in general, who give so much of themselves... and often times forget to take care of themselves. It’s really important that we are able to talk about this openly before, and after, someone dies. If we talk about it before hand maybe we can prevent the drug use from even starting. If we talk about it while someone is using drugs, perhaps we can get them help so that they do not die. And if we talk about it after they die, unfortunately like I’m doing, we can learn the realities of what drug abuse does to families, individuals, and how easily death comes” [83].

Jan’s death and Sarah’s admonition to ‘talk more openly encouraged AANA leaders to alter the way addiction was

handled. The AANA Board of Directors commissioned a “Blue Ribbon Panel” to explore establishment of a wellness initiative. The panel’s recommendations led to the AANA Wellness Program.

Almost a Disease: 1846–1975

Drug misuse and addiction in anesthesia has a long history. Ether frolics and nitrous-oxide parties, the recreational use of these drugs, preceded the discovery of anesthesia. Addiction to chloroform contributed to the suicide of Horace Wells, one of several claimants to the discovery of anesthesia, in 1848. One newspaper obituary described his affliction as “amounting almost to disease” [84].

However, many considered drug abuse a moral failure rather than a disease. In 1910, Flexner likened alcohol and drug use to vice and moral turpitude. Congress and the states passed laws criminalizing drug use and depriving addicted physicians of licensure. Similar laws governing nurses followed. Some recognized the need for a different view. In 1962, anesthesiologist John Lundy and nurse anesthetist Florence McQuillan, described addiction as “an occupational hazard within the anesthesia community” deserving greater medical attention. [85] Still, few if any studies examined addiction among nurses before 1975.

Investigations of drug misuse among nurses revealed its considerable dimensions. State boards of nursing reported in 1984, that drug addiction among nurses was “significant and rising.” Of all nurse disciplinary actions, 67% were drug-related. At that time, there were approximately 1,800,000 nurses in the US, [86] 20,000 (1.1%) of whom were CRNAs. But CRNAs accounted for an astonishing 75% of drug abuse cases. Denial and self-delusion made meaningful data on incidence hard to obtain. Drug misuse by nurses was a secret epidemic. Addiction often resulted, and CRNAs were at greatest risk [87].

Enlightenment and Rehabilitation after 1975

To prevent negative publicity, hospitals might discharge addicted CRNAs. Databases, like the National Practitioner Data Bank kept the names of those discharged, so it might be difficult for a recovered CRNA to find work. The 1980s produced more enlightened attitudes toward addiction. It received a new name, chemical dependency, and was designated as a psychiatric disorder in the Diagnostic and Statistical Manual of Diseases. Essentially all states decriminalized addiction for doctors, but only 30 states did so for nurses. The American Nurses Association passed a resolution advocating treatment before discipline. Self help support networks and rehabilitation hospitals emerged. CRNAs led by

Diana Quinlan, Rusty Ratcliffe, and Art Zwerling brought an “alternative-to-discipline” program to nurse anesthesia, Quinlan spearheading these efforts for more than 20 years. She worked with a nationwide network of peer assistance advisors, and established education materials, resource lists, and guidelines. Peer assistance advisors served in every state to facilitate recovery of CRNAs suffering from addiction and their re-entry into the workplace [88].

The alternative-to-discipline approach appeared to decrease the problem. Addicted nurses were removed from work faster. They were helped to recover, to retain a nursing license, and in some cases to remain in or return to practice. In 1996, alternative programs were found to double the recovery rate relative to that found in discipline programs (68% versus 37%) [89]—although this assertion is difficult to evaluate because states with purely disciplinary programs were generally unwilling to share outcome data for fear “it would cast the program in a negative light” [90]. Because alternative-to-discipline programs removed impaired nurses from practice faster, they were said to improve patient safety. Quinlan attributed success to a 12-step program, support group attendance, random drug screening, and the use of recovering CRNAs to serve as mentors/sponsors for other recovering CRNAs [91]. However, none of the studies cited above pertained specifically to CRNAs.

Causes and Epidemiology: Drug Abuse as a Gender Problem

In the 1990s, the first publications by CRNAs, about CRNAs, suggested causes for drug misuse. John McDonough found that student nurse anesthetists have “excitement seeking” traits that place them at greater risk of developing addiction disorders than other graduate nursing students. McDonough urged anesthesia educators to prepare students for this danger [92]. He also echoed what others had stated: CRNAs are at greater risk of addiction due to easy access to addictive drugs and time spent alone. In 1995, Quinlan suggested a link between job-related stress and the risk of addiction among CRNAs [93]. In her 1996 review, Quinlan pointed out that addiction remained a criminal offense for nurses in 20 states. Substance abuse was a greater occupational hazard than either hepatitis B or HIV infection [94].

In 1999, Donald Bell et al. [95] surveyed 10% of CRNAs, finding that 9.8% of respondents reported “anesthesia drug misuse” of inhaled anesthetics, narcotics, sedatives, and other drugs. Sixty-two percent of those misusing drugs were male, consistent with Quinlan’s 2001 observation that: “Although men account for more than 40% of the CRNA population, they represent about 80% of the callers (to the AANA peer assistance hotline) with addiction...” (pp. 431–2) [87]. Bell’s 9.8% prevalence matched results from a similar study

of anesthesiologists, [96] but because it was self-reported, the incidence may have been artificially low. Bell also found that CRNAs were more likely to misuse drugs ten years after graduation.

The Wellness Program Attacks Stress

These studies shed light on the problem, but did nothing to mitigate it. The AANA Wellness Program had as its premise the possibility that some people resort to drugs in response to stress. Tony Chipas, a nurse anesthesia education program director, said: "It's not just about addiction; It's about reducing stress...Practicing anesthesia is stressful. Sources of stress include: the expectation of perfect outcomes, long work hours, disrupted sleep patterns, emotional exhaustion, and the lack of control over the workplace." (Personal communication March 2011). Bell concurred: "Benjamin Rush called alcoholism a disease almost 250 years ago. Yet, today we are still trying to find a means of derailing the disease without fully understanding its biological basis. We hope that by addressing stress as an environmental precursor, we can reduce the overall incidence of chemical dependency and abuse" (Personal communication March 2011). Finally, CRNA Sandra Tunajek, who led the Wellness Program for six years, wrote: "CRNAs recognized the detrimental effect that stress plays in their lives." [97]

The AANA Wellness Program began by subsuming and building on existing peer assistance activities. An annual lecture named for Jan Stewart was begun at the AANA Annual Meeting in 2004. Topics have included aging, stress management, substance abuse and workplace issues. Subsequently other elements were created. A variety of resources are housed on the internet, at <http://www.aana.com/Resources.aspx?id=6088&linkidentifier=id&itemid=6088>.

A monthly column in the AANA News Bulletin entitled "Wellness Milestones" began in 2005. Written by Sandra Tunajek, it addressed topics not usually found in professional journals. Some were intangible like harmony, compassion, fatigue, and spiritual dimensions of wellness. In 2011, the effect of stress on learning formed part of revised nurse anesthesia curriculum standards. It had been recognized that stress threatens learning. Twenty learning modules, all evidence based, were developed. They are to be implemented in 2012.

Have Good Intentions Succeeded?

Considerable effort has gone into the several studies and programs attempting to address the problem and the tragedies caused by addiction, but we have little evidence, yet, of their success. Alternative-to-discipline treatment did not appear

to decrease diversion, addiction, or mortality. Bell found that in 2006, abuse rates and death rates among CRNAs had not changed since his 1999 study (Unpublished manuscript, Personal communication, 2011). Measuring outcomes from the Wellness Program has not yet happened. Sandra Tunajek recently said: "Evidence to support conclusions is not there. It's very difficult to measure the ability of people to cope with or manage the pressures of anesthesia practice (personal communication 2011)." It remains to be seen if drug misuse and its adverse results can be reduced, and if stress is a major factor leading to misuse. Thus far, the plausible notion that stress may contribute to the problem of addiction, is just that. Eger is fond of quoting from a poster that was in the laboratory of his hero, John Severinghaus: "For every question there is an answer: neat, plausible, and wrong." (personal communication to EK, 31 Oct 12).

Conclusions

Nurses provided the earliest substantial numbers of professional anesthesia practitioners in the US. They paid attention to details of anesthetic administration and used positive suggestion to lead the patient smoothly through the induction process. They made anesthesia safe, and facilitated the evolution of the "Golden Age" of surgery. Nurses provided the first formal training programs and the first formal educational programs in anesthesia. They progressively increased the quality of education by accrediting schools. They assured quality practitioners by certifying graduates. Nurses established education for anesthesia educators, and mandated continuing education for practicing CRNAs. They supported surgery for the trauma imposed during World War I and played crucial roles in every war thereafter. Nurse anesthetists helped improve anesthesia globally by writing standards through the IFNA, volunteering in developing nations, and establishing volunteer run training programs. Finally, nurse anesthetists have established a wellness program with the hope of combating substance abuse and other stress related diseases that affect CRNAs. Taken together, these contributions define what nurses contribute to the care of patients under anesthesia.

Acknowledgments I wish to thank Sandra Maree-Ouellette and Rita Rupp for fact checking. I'm also grateful to Edmond Eger, Larry Saidman, and Rod N. Westhorpe for editing, and to Kathy Koch (no relation) for help with the reference list. And finally, I thank my wife, Loree Peery, who did everything else while I composed this paper.

Summary

The Royal Veterinary College, London, adopted anesthesia soon after Morton's 1846 demonstration. However, reports of accidents and deaths hindered widespread veterinarian acceptance of anesthesia, especially with large animals. In the late 1800s, anesthesia was used more to restrain than to alleviate pain. In 1875, Humbert described the oral, rectal and intraperitoneal administration of chloral hydrate to horses, usually as an adjunct to local or inhalation anesthesia. Later studies in Western Europe supported intravenous chloral hydrate in horses. In 1915, Hobday published the first English textbook devoted to veterinary anesthesia. In 1919, the British Parliament enacted an Anaesthetics Bill for Animals, specifying that anesthesia must "...prevent the animal feeling pain".

In his first edition of *Veterinary Anaesthesia* in 1941, Wright laid the foundations of *modern* veterinary anesthesia. The 1950s saw the first veterinarians who exclusively practiced anesthesia. From 1960–1979, the number of faculty and trainees in university-based programs increased in both Europe and the US. Alphaxalone, azaperone, droperidol, fentanyl, halothane, enflurane, ketamine, and xylazine appeared, and their effects were defined in species of interest to veterinarians. Growth of new university-based programs in the US and UK paralleled the growth in numbers of veterinary anesthesiologists. By the early 1980s, 25 faculty positions were assigned to teaching and research programs in the US, with 2 in Canada.

Established in 1964, the Association of Veterinary Anaesthetists of Great Britain and Ireland (reduced to AVA in 1991) awarded its first Diploma of Veterinary Anaesthesia (DVA) in 1967. The European College of Veterinary Anaesthesia and Analgesia (ECVAA) incorporated in 1995, and was registered in the Netherlands in 1997. The ECVAA Diploma became the primary certification as a specialist in veterinary anesthesia in Europe, and the DVA was phased out.

Founded in 1970, the American Society of Veterinary Anesthesiology (ASVA) was immediately recognized by the American Veterinary Medical Association (AVMA). In 1971, the ASVA facilitated establishment of the American College of Veterinary Anesthesiologists (ACVA), to credential specialists in veterinary anesthesiology. The AVMA recognized the ACVA in 1975. Two organizations were not needed, and the ASVA was dissolved in 1981. Presently, there are 222 ACVA diplomats, with 16 approved residency programs of veterinary anesthesia in the US, and 4 in Canada.

The International Congress of Veterinary Anesthesia was established in 1985 "...to promote veterinary anaesthesiology within the international community of veterinarians, through...triennial World Congresses of Veterinary Anaesthesiology".

Introduction

The reviews of Hall [1], Smithcors [2, 3], Stevenson [4], Wright [5], Westhues & Fritsch [6], Weaver [7], and Jones [8], provided material for the present discourse. I will briefly describe the early years of veterinary anesthesia, focusing more attention on events occurring during my lifetime, a period that most impacted clinical practice and fostered the evolution of veterinary anesthesia as an organized discipline

E. P. Steffey (✉)

of veterinary medicine. I choose this tack because information from the last half century is incomplete or unpublished, yet is known to me from personal experiences in teaching, research and clinical practice.

The Early Development of Veterinary Anesthesia

"...the history of anesthesia is a disturbing account of 'what might have been'..." [3]

Why was the use of anesthesia to relieve the pain of surgery in animals delayed? Despite knowledge of the discovery of

Fig. 23.1 John Wright (Photograph of a painting of Wright; painter unknown. Photo taken by Robert Pearson and sent to EPS by Ron Jones)

anesthesia, progress in veterinary anesthesia lagged behind that in humans, and reliance on mechanical restraint persisted [1, 3, 9].

Mid-1800s

The use of nitrous oxide, ether, chloroform, and even carbon dioxide in laboratory animals, antedated William Morton's 1846 public demonstration of ether as a general anesthetic, at the Massachusetts General Hospital [3]. An absence of a veterinary journal published by a veterinary anesthesia association hinders a determination of anesthesia's first clinical use. Several historians cite Charles Jackson's 1853 account of his experiences with "Etherization of Animals" [10], as one of the earliest (if not the first) published accounts of general anesthesia in animals [2–4]. Even this might be questioned as this shameless self promoter also claimed to have invented the telegraph. John Wright (Fig. 23.1) noted that, "Almost immediately after publication of Morton's use of [ether] in

human surgery (1846), it was adopted in the Royal Veterinary College, London [5]"

In 1847, Edward Mayhew reported in the *Veterinarian*¹ on the use of ether for "minor surgery" in cats and dogs [2, 3]. Despite the absence of evident pain, the excitatory stage of the anesthesia disturbed him:

"The results of these trials are not calculated to inspire any very sanguine hopes. We cannot tell whether the cries emitted are evidence of pain or not; but they are suggestive of agony to the listener, and, without testimony to the contrary, must be regarded as indicative of suffering. The process, therefore, is not calculated to attain the object for which in veterinary practice it would be most generally employed, namely, to relieve the owner from the impression that his animal was subject to torture..." [2]

In response to Mayhew's perception that the animals' cries reflected pain, Percivall, an editor of the journal with credentials as both a physician and veterinarian published a contrary view:

"... after perusing Mr. Mayhew's interesting cases, we ... augur more favourably of the inferences deducible from them than he would seem to. To us it appears questionable whether the cries emitted by the animals during experiments are ... 'evidence of pain'" [2]

This in turn prompted Mayhew to test his convictions, by convincing his dentist to 'etherize' him multiple times over the next 2 days, to have a *dens sapienta* extracted. Although he noted that the inhalation of ether was pleasant, he apparently was completely unaware of his excitatory state—and that each administration resulted in unsuccessful attempts at the extraction he had requested. After multiple attempts on the first day and another attempt the following day, the dentist and his assistant refused to continue. Nonetheless Mayhew "... concluded that ether did have a place in veterinary surgery, but warned, 'We should be cautious lest we become cruel under a mistaken endeavor to be kind' [2]" Smithcors described as unfortunate, Mayhew's suggestion that the principle use of anesthesia in veterinary practice would be to relieve the owner's perception of pain. Consideration for the patient's suffering appears to have arisen later [4, 11].

Chloroform's use in the horse in the UK quickly followed Simpson's discovery of chloroform anesthesia in humans [5]. WJ Goodwin, veterinary surgeon to Queen Victoria, administered chloroform to a horse at the Royal Mews for a neurectomy associated with navicular arthritis. Wright, in his review continues [5]:

¹The 'Veterinarian' was a journal launched in 1828 by William Percivall in the UK. It conveyed information concerning veterinary medicine in general (i.e., it was not a specialty publication). It likely was the earliest such publication in veterinary medicine but was independent of any organized veterinary association. It ceased publication in 1902 probably because the *Veterinary Record* was launched in late 1888 by the British Veterinary Medical Association.

“In the same year, William Field reported (that) ... ‘However satisfied I may feel about the power of chloroform over the horse as an anaesthetic agent, I cannot think of using it for casting in lieu of hobbles...the fall of the animal is too uncertain to admit of restraint or limitation and consequently violent injury may result in the struggles and staggerings preparatory to its fall, as well as in the fall itself.’”

Over the next few years, reports of accidents and deaths of animals subjected to anesthesia militated against veterinarian acceptance of anesthesia, especially with large animals. Only later in the nineteenth century and early in the twentieth century, when Frederick Hobday developed better techniques for agent delivery, did veterinarians accept anesthesia.

In the US, the physician George Dadd, was perhaps the first to use ether and chloroform for surgical procedures in animals. Dadd moved from human patients to veterinary practice soon after ether’s introduction by Morton, and his familiarity with medical developments likely prompted his use of inhalation anesthesia in animals. In his 1854 book, *Modern Horse Doctor* [12] (beginning page 252):

“...we recommend that, in all operations of this kind, the subject be etherized, not only in view of preventing pain, but that we may, in the absence of all struggling on the part of our patient, perform the operation satisfactorily, and in much less time after etherization has taken place than otherwise. So soon as the patient is under the influence of that valuable agent, we have nothing to fear from his struggles, provided we have the assistance of one experienced to administer it. We generally use a mixture of chloroform and chloric ether in our operations, and consider it far preferable, so far as the life of the patient is concerned, to pure chloroform.”

Thus, as in humans, this veterinarian recognized the greater safety of ether.

The Later 1800s

The difficulties accompanying inhalational anesthetic administration in large domestic animals, prompted a search for better anesthetics. Liebig discovered chloral hydrate in 1832, and after experimenting in animals, Pierre-Cyprien Oré used it intravenously to produce anesthesia in humans in 1872. Humbert described its use in horses in 1875, at doses of 30–70 gm. It was given by mouth or via the rectum, and occasionally by intraperitoneal injection, usually as an adjunct to local or inhalation anesthesia. The later intravenous use of chloral hydrate in full anesthetic doses in the horse is credited to experiments conducted in Western Europe. Degive, a prominent Belgian professor, described this method of administration in horses, in 1908. Degive wrote (as quoted by Wright [13]):

“Chloral hydrate injected into the jugular vein of the horse ... produces in 1 to 2 minutes complete general anaesthesia without causing preliminary excitement in the animal [as commonly seen with chloroform]. The method is most valuable when prac-

ticed with full aseptic precautions but it has been followed by several accidents which have put its value into doubt.”

Later, Wright wrote:

“It is a drug the value of which is continually being rediscovered. ... Half a century later I ... arrived at the same conclusion except to say that provided adequate technical care is exercised the doubt he [Degive] expresses becomes removed. In fact even today, with the great advances in our knowledge of anaesthesia and anaesthetics, it is my opinion that chloral hydrate by intravenous injections is the best method of inducing general anaesthesia in the horse ...”

Organized veterinary medicine had but limited interest in anesthesia through much of the last quarter of the nineteenth century. In his review of the *History of Veterinary Anesthesia* [3], Smithcors notes:

“In the first volume of the ‘American Veterinary Review’ (1877), ... there is but one reference to anesthetics, and none in volume 2....Early advocates of anesthesia, mainly Dadd and his colleagues, worked outside the pale of urbanized veterinary medicine. Perhaps one had to be a maverick to stray far from conventional practice.”

And in his *Manual of Operative Veterinary Surgery* Alexandre Liautard wrote [14]:

“In veterinary surgery, the indication for anesthesia has not, to the same extent as in human, the avoidance of pain in the patient for its object, ... the administration of anesthetic compounds aims principally to facilitate the performance of the operation for its own sake....”

1900–1939

In the 1915 edition of *The Principles of Veterinary Surgery*, Louis Merillat echoed the above sentiments but noted a trend to a use of anesthesia to relieve pain [11]:

“Anaesthesia in veterinary surgery today is a means of restraint and not an expedient to relieve pain. So long as an operation can be performed by forcible restraint without imminent danger to the technique, the operator or the animal, the thought of anaesthesia does not enter in the proposition. But, on the other hand, when a certain technique requires perfect repose of the surgical field, or when there is danger of personal injury or injury to the animal, it is **sometimes** (sic) administered, minority reports to the contrary notwithstanding.”

“(However, it is a matter of fact that practitioners who once begin the practice of administering inhalation anaesthetics for their operations soon find it indispensable to the success of their work. As they become more and more confident in their ability as anaesthetists they resort to this in all kinds of operations, minor and major, and the result is always the enlargement of their scope of usefulness as surgeons.)”

Humanitarian concerns for animals led to legislation in Great Britain (Cruelty to Animals Act, 1876), to restrict the use of animals in experiments to those persons who were licensed

and had Home Office permission for particular procedures (later succeeded by the Animals [Scientific Procedures] Act of 1986). In 1913, the British Parliament discussed and later enacted an Anaesthetics Bill for Animals [15],—the Animals (Anaesthetics) Act of 1919 (reproduced in the appendix of Wright's textbook [16]). It specified that general or local anesthetic must be used in specific surgical procedures in a horse, dog, cat or a bovine, and that the anesthetic must be "...of sufficient power to prevent the animal feeling pain". Any person subjecting, or causing, or procuring, or being the owner of the animal subjected "... to an operation contrary to the regulations ... shall be guilty of an offence under this Act" and liable upon conviction, for a fine and/or imprisonment. Its focus on general anesthesia inhibited the development of regional anesthesia until 1954. The 1919 Act was a precursor to legislation of the present day Act, i.e., The Protection of Animals (Anaesthetics) Act of 1954 and 1964 [7]. The 1964 version allowed veterinary surgeons to choose the type of anesthetic as long as it produced "adequate anaesthesia" [8].

In 1915, Hobday published the first English textbook devoted exclusively to veterinary anesthesia, *Anaesthesia and Narcosis of Animals and Birds* [15]. In his Preface he wrote that "The progress of anaesthetics in veterinary surgery has not been as rapid as it ought to have been, and it is in the hope that a small textbook specially devoted to the subject may be helpful in his direction."

Wright laid the foundations of *modern* veterinary anesthesia. He qualified and spent the early part of his career as a veterinary surgeon in the Department of Surgery at the Beaumont Hospital of the Royal Veterinary College, London. He moved to the veterinary school at the University of Liverpool in 1941, where he established the Field Station. Like Hobday, Wright's interest in anesthesia lay in his desire as a surgeon to avoid pain, to provide a safe anesthetic, and to ensure a proper environment for the performance of surgery. He published his first edition of *Veterinary Anaesthesia* in 1941. In 1961, Wright and LW Hall (of Cambridge University) co-authored the 5th edition. In 1966, the 6th edition appeared as *Wright's Veterinary Anaesthesia and Analgesia*, with Hall as the single author. No textbook of veterinary anesthesia has been published for a longer time, and it recently reached its 10th edition (now authored by Hall, KW Clarke and C Trim).

Two major advances occurred in the decade before World War II [4]: the introduction of barbiturates and epidural anesthesia to clinical practice. In America, Kreutzer [17] reported the first use of pentobarbital (administered intraperitoneally; IP) in veterinary anesthesia. Two years later in Britain, Wright published his own experiences with IP pentobarbital in 100 dog and cat patients. Humans were given barbiturates intravenously, and this route was soon applied to animals [18]. Some veterinarians thought that this method, particu-

larly for anesthetic induction was "...infinitely superior to the accepted methods of inhalation anesthesia; in fact by its introduction canine surgery became revolutionized [19]." Shortly thereafter, thiopental and later thiamylal were found to be more satisfactory for many common needs of veterinary medicine, like short periods of deep sedation and anesthesia for minor surgery [20]. Following intravenous barbiturate anesthetic induction, the needle was maintained in situ in the vein, and the attached syringe taped to the (usually) patient's foreleg for ease of added drug dosing as needed.

Such a technique was common in a small animal-focused clinical practice, when I entered the profession in 1967. Until I purchased my first inhalation anesthetic machine (with in-circuit glass vaporizer) from a regional General Services Administration (federal agency disposing of obsolete/unwanted medical equipment) auction in 1968, most anesthetics I administered in general veterinary practice were barbiturates. The notable exception was the use of diethyl ether for short-term anesthetic management of cats undergoing routine castration or abscess incision and drainage. Why ether? Part of the problem was poorly socialized, especially rural and semi-rural cats. In addition, the re-used needles of that time had varying degrees of sharpness. Accordingly, it was easier for the veterinarian and cat to place the fasted cat into a top-hinged wooden box with glass panel. The lid was quickly closed after a few milliliters of diethyl ether were poured onto the box floor. If additional anesthetic time was needed, more ether was administered using an open-drop technique.

Short and ultrashort acting barbiturates which appeared in the 1930s remained two of the most widely used anesthetic drugs (as a sole agent) in both small and large animal practice until late in the twentieth century. Their use as a sole agent however, required large doses to eliminate movement in response to pain. Accordingly, recovery times were undesirably prolonged.

To deal with the prolonged recovery time, during the 1970s, the increasing use of halothane and the newly introduced enflurane supplanted pentobarbital. In the 1980s, the introduction of ketamine and isoflurane as primary agents, either alone or in various species-related anesthetic drug cocktails, and then propofol (especially in small animals), gradually replaced the ultra-short acting barbiturates. In the past decade, a few investigators have used desflurane to accelerate recovery from anesthesia in large and fractious animals. Sevoflurane has seen an expanded, but still small clinical application for companion animals and horses. Cost has limited a broader application of both anesthetics. Isoflurane remains, by far, the primary inhaled anesthetic in veterinary medicine.

The development of local and regional anesthetic techniques for human patients fostered similar developments in veterinary medicine. For example, since the late part of the nineteenth century, local anesthesia has been used to

Fig. 23.2 Leslie Hall and Barbara Weaver. (EP Steffey photograph, 1994.)

assist diagnosis of the cause of lameness in horses. In the US, in 1924, Bemis and colleagues published a summary of regional nerve blocks in contemporary use with horses [21]. Regional anesthesia achieved only limited popularity in veterinary medicine because both local and regional anesthesia require a cooperative patient. Smithcors notes, “It remained for veterinarians Retzgen of Berlin [and also Pape and Pitzch] in 1925, and Franz Benesch of Austria in 1926, to demonstrate in horses and cattle respectively, that epidural anesthesia with the needle introduced distal to the spinal cord proper, was a safe technique. [3]” In 1940, Farquharson described paravertebral blocks of thoracic and lumbar nerves for abdominal operations (eg, rumenotomy and exploratory laparotomy) in standing cattle [22]. In 1953, Larson introduced the internal pudendal (pudic) nerve block for anesthesia of the penis and relaxation of the retractor penis muscle in bulls [23].

1940–1959

Veterinary anesthesiology did not exist as a discipline before 1950. Surgeons and general practitioners gave anesthesia as part of their care. The first veterinarians devoting their practice exclusively to anesthesia and its clinical development were Barbara Weaver and Leslie Hall (Fig. 23.2). Weaver qualified from the Royal Veterinary College (RVC) in 1949, and was appointed House Surgeon, then Lecturer at the RVC Beaumont Animals Hospital, London. Hall qualified in 1950, also from the RVC. After three months in general practice he was awarded a Veterinary Education Trust research training scholarship to work under E. Amoroso in the Physiology Department of the RVC. He was awarded a PhD degree from London University in 1957 for an investigation of the control of arterial blood pressure under general anesthesia.

Hall and Weaver’s paths repeatedly crossed. They began meeting with medical anesthesiologists in 1951, meetings that facilitated the application of knowledge and skills of anesthetic management of humans to animals. Weaver wrote:

“In the 1950s when Leslie and I became interested in anaesthesia, realizing we were some 50 years behind the ‘medics’ we adapted human techniques for our patients in the Beaumont Animals Hospital, mainly dogs and cats and an early trial in the horse. We introduced ‘Balanced Anaesthesia’ with three phases, i.e., premedication, induction and maintenance. For maintenance, using semi closed systems without absorption, we maintained anaesthesia with nitrous oxide, oxygen and trichloroethylene (trilene). Endotracheal intubation was carried out and intermittent positive pressure ventilation was also carried out to assist or control ventilation as necessary. Muscle relaxant agents were used with care, facilitating the control of ventilation when necessary.” (Weaver, personal communication, 2010)

In 1952, early in his PhD studies, Hall was appointed to a faculty surgery post in the new veterinary school at Cambridge University. He taught ophthalmology, gastrointestinal and thoracic surgery—and anaesthesia. Appointment of more teaching staff allowed him to focus on anesthesia teaching and research. After 8 years at the RVC, Weaver moved to the University of Bristol (5 November 1957) with a special remit to establish a division of anaesthesia within the Department of Veterinary Surgery. There she introduced balanced anaesthetic techniques in the management of small animals, and facilitated further development of inhalation equipment for anesthesia in adult horses and cattle [24, 25].

Weaver and Hall worked closely with physician and basic science colleagues (including William Weipers, William Mapleson, Brian Marshall, and Michael Halsey). Both were recognized by physicians for these interactions and their many contributions. For example, Hall was elected President of the East Anglian Society of Anaesthetists, and Weaver was elected President of the Society of Anaesthetists of the South Western Region. In 1977, Hall became the first veterinarian to be awarded the Faculty Medal of the Faculty of Anaesthetists of the Royal College of Surgeons of England, the highest award given by the Faculty. A few years later, Weaver was similarly honored, as Ronald Jones was still later, (discussed below), and all three were elected Fellows of the Royal College of Anaesthetists in 2001.

Veterinarians used and sometimes misused neuromuscular blocking agents, as a substitute for or as an adjunct to veterinary anesthesia. Wright credits William Sewell at the University of London, as the first person to experiment with curare as a remedy [13]. In 1935, Sewell used it to treat tetanus in a horse and a donkey, by implanting an arrow head coated with curare in the fleshy part of the afflicted equine shoulder, publishing accounts of this, years later. We aren’t told of the results, but they were likely no better than those of similar trials in humans (see Chapter 50 on Neuromuscular Blockade by J Caldwell).

Fig. 23.3 Ronald Jones. (Courtesy of Ronald Jones.)

Clinical veterinary use of neuromuscular blocking drugs followed more than a decade after Griffith and Johnson's 1942 report of curare in the anesthetic management of human patients [26]. In 1954, Hall and Weaver introduced "balanced anesthesia", including curare, to the clinical management of dogs and cats [27]. Peculiarly, Weaver did not find the bronchospasm in dogs that had discouraged Stuart Cullen from extending his studies to humans: "I did not find bronchospasm a serious problem in dogs. I was aware that it was a concern and so was prepared for it." (personal communication to E Steffey) By the early 1970s, 3 major textbooks of veterinary anesthesia discussed muscle relaxant pharmacology and the clinical use of relaxants [28–30]. However, their application in veterinary medicine remained modest. For example, the use of neuromuscular blockade to facilitate atraumatic tracheal intubation or intermittent positive pressure ventilation, both common to the management of human patients, is unnecessary with most veterinary patients. Thus, current use is focused largely on particularly delicate and/or complicated surgeries in small companion animals and in horses, e.g., some ocular operations, open reductions of large bone fractures, and specialized cardiovascular or intracranial surgeries.

1960–1979

In the next two decades, the number of faculty and trainees in university based programs increased dramatically in both Europe and the US. Alphaxalone (Althesin, Saffan), azaperone, droperidol, fentanyl (or Innovar, a combination of droperidol and fentanyl), enflurane, ketamine, and xylazine appeared, and their effects were defined in species of interest to veterinary medicine. Anesthetic and monitoring equipment, developed for use in humans, subsequently entered veterinary practice.

Ronald Jones (Fig. 23.3) was the third academic veterinarian appointed in the U.K., and in 1962, became the first person designated as a lecturer in veterinary anesthesiology, in the veterinary faculty of the University of Liverpool. He became the first full professor in veterinary anaesthesia in the UK in 1990. At Liverpool he overlapped tenure with Wright (just before Wright's retirement), but spent most of his time in the medical school's department of anaesthesia in association with Cecil Gray, Jackson Rees, John Utting and Jennifer Hunter. Indeed, he was influenced by and in turn influenced the medical anesthesia community. He served as Chair of the medical school's Department of Anaesthesia (the only veterinarian to my knowledge to hold such an honor), and was a reviewer and later Assistant Editor (1993–2001) of the *British Journal of Anaesthesia*. Like Hall and Weaver, he mentored numerous trainees, many of whom contributed to veterinary anesthesia programs elsewhere.

As documented by the careers of Hall, Weaver and Jones, collaboration and encouragement by physician anesthesiologists facilitated the progress of veterinary anesthesia in Great Britain. Weaver recently wrote to Steffey (personal communication), "The 'medical' anaesthetists have been hugely supportive of what we were trying to do for veterinary anaesthesia. I found their support and encouragement indispensable and no doubt was a major contribution to my lasting interest in comparative anaesthesia studies."

A parallel growth, similarly facilitated by physician involvement, occurred in North America (Table 23.1). Most of these first generation academicians trained in medical school anesthesia residency/fellowship programs. Lawrence (Larry) Soma (Fig. 23.4) graduated from the University of Pennsylvania School of Veterinary Medicine in 1957. After an internship at the Animal Medical Center in New York City in 1958, he returned to the University of Pennsylvania in 1960, training for three years in human anesthesia under the direction of Robert Dripps.

Soma recounted to me, his start with Dripps. Immediately after receiving his VMD, Soma applied for a newly established fellowship in veterinary cardiology under David Detwiler at Penn (another example of the many clinical disciplines new to veterinary medicine gaining its start at Penn). However, before a decision on his application was made, Soma enlisted in the US Army veterinary corps, and

1975	William Muir	Ohio State University	Ohio State University

^aYear starting at indicated institution devoted to veterinary anesthesia as a member of the faculty

spent 2 years in research at Walter Reed Medical Center. During this time, a valuable racing thoroughbred at Penn's veterinary hospital required major surgery. The then Veterinary Medicine Dean, Mark Allam asked Dripps to consult on the anesthetic management of this horse. Dripps reportedly replied,

"Thank you for inviting me but I can't do anything. You need a veterinarian trained in anesthesia! You select him and I'll train him."

In 1960, after completing his army service, Soma phoned Robert Marshak, then Chair of the Department of Clinical Studies, asking if he had any vacant positions. "Marshak replied, 'Go see Dripps'." Soma did, and the rest is history. Upon completion of training with Dripps, Soma joined the veterinary faculty at Penn with the charge by Allam to develop anesthesia as a distinct discipline in the veterinary

Fig. 23.4 Lawrence Soma. (Courtesy of Lawrence Soma.)

school; the first such program in the world. He published his *Textbook of Veterinary Anesthesia* in 1971, with contributions by Dripps and 11 other prominent anesthesiologists. Others quickly followed Soma's lead (Table 23.1).

Two of the earliest individuals helping to create veterinary anesthesiology as a discipline in North America, established their credentials in anesthesia to improve the quality of their results as surgeons. The first, William Lumb, was an established veterinary surgeon who directed a National Institutes of Health funded surgical training/research laboratory, at the veterinary school at Colorado State University, beginning in 1963. In 1963, he also published the first US veterinary anesthesia text, *Small Animal Anesthesia*, and then, with co-author E Wynn "Ginger" Jones, published a broader species based text, *Veterinary Anesthesia* in 1973. E. Wynn Jones qualified at the RVC in London and then came to Cornell University, for advanced clinical training in large animal surgery and completion of an anesthesia-related PhD dissertation. In 1954, he was offered and accepted a faculty post in large animal surgery in the veterinary college at Oklahoma State University. Research with disease-free swine at Oklahoma in the early 1970s involved him in early studies of the pathogenesis of malignant hyperthermia (MH), and subsequent development of a susceptible strain of swine for use as a model. Jones and Lumb are Charter Diplomates of both the American College of Veterinary Surgeons (est. 1967),

^aYear (approximate) starting as faculty in veterinary anesthesiology at the indicated institution

and the American College of Veterinary Anesthesiologists (more on this below).

Some others during this time established credentials in other ways. Following his Comparative Pathology PhD program at the University of California, Davis (UCD), JR Gillespie completed a respiratory disease fellowship at the Cardiovascular Research Institute of the University of California, San Francisco. He then returned to UCD in 1965, to establish the first clinical teaching program in respiratory system physiology/pathophysiology, and the first pulmonary function laboratory in a school of veterinary medicine. He set the stage for the later anesthesia program at UCD. For approximately the first decade of his career after his post-doctoral training in neurosciences, Jim Heavner worked with Rudy DeJong at the University of Washington, investigating basic and clinical actions of local anesthetics.

At this time, individuals dedicated to veterinary anesthesia appeared in Western Europe and other parts of the world (Table 23.2).

1980–to Date

Growth of new university-based programs in the US and UK paralleled the growth in numbers of veterinary anesthesiolo-

gists. Before 1960 in North America, no veterinarians were recognized as anesthesiologists, and no academic anesthesia programs existed in veterinary medicine. Both Lumb and Jones were surgeons. However, by the beginning of 1980, 25 faculty positions were assigned to teaching and research programs in colleges and schools of veterinary medicine in the US, and there were 2 in Canada.

Veterinary schools now add courses in anesthesia to both core and elective curricula. For example, the DVM curriculum at the University of California at Davis mandates an introductory 15 hours of lectures, 2 laboratory sessions on principles of veterinary anesthesia at the end of the second year, and a laboratory course on applied techniques of anesthesia at the beginning of the third year. In the third year it also mandates at least one of 3 species-specific elective courses, and the fourth year requires a 2-week clinical rotation in anesthesia.

A parallel growth in postgraduate professional training in veterinary anesthesia occurred. For example, beginning in 1966 as a single 2-year residency position in anesthesia at the University of Pennsylvania (held by Alan Klide, with Soma as director), by the 1980s there were 16 positions throughout North America. Five of the then 11 postgraduate clinical training programs, progressed from 2 year to 3 year training programs. This timing did not include a pre-residency internship year requirement after obtaining the DVM/VMD degree. According to American College of Veterinary Anesthesiologists (ACVA; described below) records, in 2010 there are 46 individuals at various stages of training, within 20 residency programs in North America (16 in the US and 4 in Canada).

Organizations of Veterinary Anesthesiology

The first formal society of veterinary anesthesia was the Association of Veterinary Anaesthetists (AVA; until 1991 it was the AVA of Great Britain and Ireland). The constitution of the AVA paralleled the Constitution of the Association of Anaesthetists of Great Britain and Ireland (AAGBI), and was written with the assistance of physician colleagues active in the AAGBI. The first general AVA meeting was held in 1964, and bi-annual meetings of the association followed with increasing national and international attendance. By 1968, there were 46 members of whom 9 were Corresponding Members including those from North America. Postgraduate specialist qualifications were subsequently established and recognized by the Royal College of Veterinary Surgeons, with particular enthusiasm and encouragement from William Weipers. The AVA awarded the first Diploma of Veterinary Anaesthesia (DVA) in 1967. Weaver has prepared a detailed account of the formative years of the AVA [31].

On January 1995, the European College of Veterinary Anaesthesia and Analgesia (ECVAA) was incorporated, and

Fig. 23.5 Charles Short. (Courtesy of Charles Short.)

was registered in the Netherlands in May 1997. The ECVAA regulates the standards of specialization in veterinary anesthesia and certified specialists in Europe. The DVA was phased out because the Diploma of the ECVAA became the primary route for certification as a specialist in veterinary anesthesia. The AVA evolved into an organization focused on regional political issues, organized scientific meetings for the specialty, and supported educational opportunities.

The American Society of Veterinary Anesthesiology (ASVA), with Charles Short (Fig. 23.5) as first president, was founded in 1970, and was immediately recognized as a professional society by the American Veterinary Medical Association (AVMA). In 1971, President Larry Soma appointed an ad hoc committee to investigate the establishment of a specialist college, the American College of Veterinary Anesthesiologists (ACVA), that would credential specialists in veterinary anesthesiology. The AVMA Executive Board recognized the ACVA in 1975, with JC Thurmon serving as the College's inaugural 2-term president. Because two organizations were not sustainable at the time, the ASVA was dissolved in 1981. Seven Founding Charter Diplomates and 13 additional Charter Diplomates attended the first ACVA meeting. The number of awardees progressively increased (Fig. 23.6) [32]. To date there are 222 ACVA diplomates and 16 approved residency programs of veterinary anesthesiology in the US, and 4 approved in Canada. In 2010, in the US and Canada, 41 and 5 individuals respectively, are training in these graduate clinical programs.

Fig. 23.6 ACVA Diplomate numbers progressively increased since the inception of the examination process

The World Congress of Veterinary Anaesthesiology (WCVA), was established in 1985 (changed from the International Congress of Veterinary Anesthesia in 2004) "...to promote veterinary anaesthesiology within the international community of veterinarians, through...triennial World Congresses of Veterinary Anaesthesiology". Hall was the inaugural president. Nine World Congresses followed the first Congress in Cambridge, England, with 4 subsequently hosted in Europe, 3 in North America, and 1 each in Australia and South America.

Reprise

The history of veterinary anesthesia has paralleled but lagged behind that of anesthesia for human patients (Fig. 23.7). The two have been intimately intertwined, each contributing to the advancement of the other. The introduction of veterinary anesthesia was delayed by the misperception that the induction of anesthesia in animals was painful—and unnecessary—one needed but to hobble the animal. Fortunately this misperception gave way to reality, and led to the governmental demand for the application of anesthesia to relieve the pain of surgery in animals. The conduct of anesthesia in animals today, as does surgery in animals, is remarkably similar to that in humans, particularly in the US, Great Britain, and Europe.

Acknowledgments I particularly acknowledge S Allweiler, RB Heath, S Luna, I Segura, LR Soma, and BMQ Weaver who supplied their first hand knowledge of names, locations and activities for this essay. Special thanks to RS Jones for my repeated botherings, and Dennis Sylvain for timely and accurate library searches.

Rod N. Westhorpe

Summary

Before Europeans arrived in Australia and New Zealand, neither of the indigenous peoples, aborigines or Maori, used any form of anaesthesia. The news of anaesthesia arrived in Britain's furthest colonies in May 1847. Australians William Pugh and John Belisario independently gave ether on 7 June 1847. In New Zealand, an instrument maker gave the first surgical anesthetic on 27 September 1847. Chloroform arrived in 1848. Portable and non-flammable, it was the ideal agent in a country of widely scattered rural communities. In the late 1870s, the risks inherent to chloroform became increasingly apparent and ether and nitrous oxide replaced chloroform.

By the end of the 19th century, physicians administered most anaesthetics. The lowly status of anaesthetists limited the attraction of young doctors to the specialty. Not until 1934, did Geoffrey Kaye convene a meeting in Hobart to found the Australian Society of Anaesthetists (ASA). Kaye assisted in the founding of the New Zealand Society in 1948.

Anaesthesia training until the 1940s consisted largely of observing senior anaesthetists. In 1944, a diploma course began at Sydney University, followed by another at Melbourne University in 1946. 1946 also saw publication of "Anaesthetic Methods" the most important anaesthesia textbook in Australia and New Zealand.

In 1952, the Faculty of Anaesthetists, Royal Australasian College of Surgeons was inaugurated, and examinations began in 1956. Successful candidates became Fellows and could claim the specialist status accorded by the post-nominals FFARACS. The Faculty Fellowship soon replaced the diplomas as defining the position of the specialist anaesthetist. Over the next fifty years non-specialist anaesthetists gradually disappeared, except for remote rural communities. In 1994, the Faculty separated from the College of Surgeons, and became a College in its own right, the Australian and New Zealand College of Anaesthetists. In 2011, there were 4000 Fellows of the College.

The ASA initiated publication of *Anaesthesia and Intensive Care* in 1972. In ensuing years it became and presently continues as a major international journal. In 1996, the ASA hosted the largest medical congress ever held in the southern hemisphere, the World Congress of Anaesthesiologists, in Sydney. In Australia and New Zealand, doctors administer all anaesthetics. They have established a proud tradition of safety and quality care.

Pain Relief Before Anaesthesia

Excluding indigenous aborigines, the 1847 population of Australia was around 300,000. Most lived in New South Wales (NSW) or Tasmania, and consisted of settlers, convicts transported from Britain, and government and military personnel. No accurate record indicates the number of aborigines. Bringing diseases and weapons, the European pioneers had decimated the aborigines, and by 1847 the number of aborigines in NSW had declined from an estimated 50,000 to 20,000. In New Zealand, the indigenous Maori outnumbered the 14,000 settlers 5 to 1. The great gold rush had not yet begun.

R. N. Westhorpe (✉)
Melbourne, Australia
e-mail: westhorpe@netspace.net.au

Pain relief before European settlement was rudimentary. Neither the aborigines nor the Maori conducted surgery except for tribal rituals—circumcision, skin scarification and tattooing, all without pain relief. They did however, use some plant preparations for relief of toothache, arthritis (a common complaint), and other ailments. They also had access to a drug, "pituri", that produced mild euphoria, enabling them to endure strenuous activity for long periods.

Aboriginal medicine was closely linked to their culture and beliefs—the "dreamtime", and their knowledge of the land and its flora and fauna. Many aboriginal bush medicines contained pharmacologically active compounds, but none produced anaesthesia. There were no measured doses or specific times of treatment. Since most were applied externally, there was little danger of toxicity [1].

The most widely known aboriginal herbal preparation is "pituri". Joseph Banks, the botanist accompanying Cook

on his voyage of 1770 “...observed that some, tho few, held constantly in their mouths, the leaves of an herb which they chewd as a European does tobacco or an East Indian Be-tele. What sort of plant it was, we had not an opportunity of learning...[2].”

When the starving John King, only survivor of the ill-fated Burke and Wills expedition to central and northern Australia, was rescued in 1861, he had Wills’ diary. It told how aborigines had fed them fish, bread and a

“stuff they call bedgery or pedgery; it has a highly intoxicating effect when chewed even in small quantities. It appears to be the dried stems and leaves of some shrub”. King described it as “nasty dirty-looking balls of chewed grass (producing) much the same effect as two pretty stiff nobblers of brandy.” [2, 3]

Joseph Bancroft immigrated to Brisbane from England in 1864, becoming the first resident surgeon at Brisbane Hospital. He studied the use of native plants in medicine, introducing many into his practice “thanks to the beneficent rule of this colony (Queensland), where no law prevents professional men from experimenting....” He found that infusions of minute amounts of pituri caused respiratory arrest and death in frogs, rats, cats and dogs [3, 4].

Duboisia hopwoodii and species of *Nicotiniana* supplied the active ingredient of pituri, *d-nornicotine*. Its use was generally confined to adult men, and its preparation and source were jealously guarded. Only men whose beards were grey were taught the secret of preparation [5].

The then small and scattered population of Australia/New Zealand merited little surgery. William Bland, a former naval surgeon, had been sentenced to seven years penal servitude in Australia after killing a fellow naval officer in a duel. Arriving in Sydney in 1814, he was pardoned almost immediately by Governor Macquarie because of the urgent need for qualified doctors in the colony [6]. In 1832, Bland attempted to ligate a subclavian artery aneurysm on William Mullen, a convict. Mullen’s wife had paid Bland the princely sum of 20 pounds. The patient died after 18 days, presumably from infection. Bland attempted another operation in 1837, the patient remaining on the operating table for five and a half hours [6].

The News of Anaesthesia Arrives

The news of Morton’s 16 October 1846 demonstration spread to England within a few weeks of the momentous event, coming as a personal letter aboard the *Acadia*, which left Boston on December 2, arriving in Liverpool on December 16. From there, in 100 days, the news journeyed to Australia and New Zealand, arriving in March 1847. Ironically, in both Australia and New Zealand, reports of anaesthesia rated only minor mention in newspapers [7].

Fig. 24.1 Diagram from the 9 January 1847, issue of The Illustrated London News, showing the apparatus used for several anaesthetics in London during December, 1846. Both Belisario and Pugh are said to have copied their apparatus from this diagram. (Courtesy of R. Westhorpe.)

The news could have come directly to Sydney from Boston. The *Robert Pulsford* sailed from Boston on 21 October, just five days after Morton’s demonstration, reaching Sydney on 5 February 1847. She carried the latest Boston newspapers, but no reports, either from them or by word of mouth from crew or passengers, appeared in local newspapers. The British admiralty regulated the transport of cargo to and from Australian ports under the English Navigation Laws of 1651, in order to keep out the Dutch. Non-British ships were unwelcome in Australian and New Zealand waters, and the *Robert Pulsford* was one of only two American ships to visit in 1847. No, the news had to come circuitously from Britain [7].

On 21 December 1846, Robert Liston performed painless surgery in London, and English Newspapers published news of Morton’s discovery. The *Mount Stuart Elphinstone* left England on 23 December carrying Bell’s Weekly Messenger of 21 December, describing anaesthesia. The ship reached Sydney Cove on 28 April 1847, afterwards proceeding to New Zealand. Sydney newspapers made no mention of anaesthesia, apparently sceptical or thinking little of the news. The *Maitland Mercury* in Stroud, 130 miles away, thought differently and published an account on 8 May [7].

More ships came with published articles, and from 17 May, major newspapers extracted details from various English publications. Taking from the *Lancet* of 2 January, the *Illustrated London News* of 9 January described the apparatus that Francis Boott used to supply ether (Fig. 24.1). This led to the first anaesthetics in Australia.

The “January Mail” for New Zealand reached Wellington on board the *Waterwitch*, on 4 July, 1847. On 7 July, the Wellington Independent reported “It appears by the London papers that the use of Sulphuric Aether, inhaled by vapour, by patients about to undergo painful operations, has reduced them to a state of unconsciousness while the operations were performed. Cases are given in which the most serious operations were performed without causing pain to the patient”.

Fig. 24.3 John Belisario, dentist of Sydney, who used ether for dental extractions on 7 June 1847. (Courtesy Geoffrey Kaye Museum of Anaesthetic History, Australian and New Zealand College of Anaesthetists, Melbourne.)

The First Anaesthetics in Australia

On 7 June 1847, William Pugh (Fig. 24.2) administered ether for surgery in Launceston, Tasmania, and John Belisario (Fig. 24.3) gave ether for dentistry in Sydney. Both Pugh and Belisario based their apparatus on the sketch in the *Illustrated London News*. In the *Sydney Morning Herald*, 8 June, 1847, below a list of auction sales, there appeared: “Painless Surgery—We had an opportunity yesterday of witnessing, at Mr Belisario’s, the extraction of teeth from persons who had inhaled ether, and in two cases the effect was as described in recent papers from England, almost miraculous....”

Further, on 16 June, the *Herald* published:

“...In the first case, a Mr Yarrow inhaled by means of a tube communicating with a vessel containing the ether, until from the entire relaxation of his whole frame, and the deathly expression of his physiognomy, we began to apprehend that the proceedings were taking a turn towards manslaughter, and that our curiosity was leading us into a scrape. As soon as Mr Yarrow was fairly off, as it was called; that is, as soon as his eyes closed,

his arms dropped and his body fell back as he sat...the tube was withdrawn from his mouth, and several persons in the room proceeded to satisfy their curiosity upon the patient, each in his own way. One pinched him in the arm, another in the leg, a third squeezed the top knuckle joints of the patient’s hand violently together...but the patient gave no sign whatever of the sensation.”

The report continues: “...He concluded by asking like Oliver Twist ‘for more’, which however was not given to him, as another patient stepped in...” This patient had two painful decayed stumps removed while under the influence of ether, and interestingly, “he had on a previous occasion undergone...extraction under the ether application....” When and where had this patient had his previous anaesthetic? Was it in Sydney, or in England—the mystery remains?

Pugh probably obtained the ‘*Illustrated London News*’ on 29 May via coach from Hobart where the *Lady How-*

den had berthed on 27 May. This gave him time to prepare the ether and apparatus, and plan the surgery. He also had willing patients who had previously undergone unsuccessful attempts at surgery. He proceeded to give two successful ether anaesthetics at St John's Hospital, in the presence of an audience that included the editor of the Launceston Examiner.

So, both Belisario and Pugh gave anaesthetics on 7 June 1847, but who was first? Belisario may have used ether previously, but no record has been discovered. He reportedly performed anaesthesia on 40 patients by 9th June, his successes leading him to advertise his services in the newspaper. David Thomas performed anaesthesia in Melbourne on 2 August, followed by Benjamin Kent in Adelaide on 30 September.

The First Anaesthetic in New Zealand

The first anaesthetic in New Zealand took place on 27 September 1847. That morning, Dr. John Fitzgerald and Mr. James Marriott went to the Wellington Gaol, "where a prisoner was anxious to have a decayed tooth extracted". Marriott was an engraver with a talent for constructing mathematical and scientific instruments. He had constructed an inhaler for ether, although the particulars are not known [8]. Marriott administered the ether, and Fitzgerald extracted the tooth. That afternoon, Fitzgerald removed a fibromatous lesion of the shoulder from Hiangarere, a Maori chief, at the Colonial Hospital. Marriott was the anaesthetist, and several Maori tribesmen observed the operation [8].

Good News?

Was anaesthesia welcomed? Recall that the public in general and the medical profession in particular, considered that pain and surgery were inseparable partners.

On 7 June, Pugh wrote to the recently established *Australian Medical Journal* which published his letter on 18 June:

"As it may be of interest to your readers to receive local testimony in addition to the published reports of cases, in which surgical operations have been divested of the usual suffering attendant on such procedures by the use of ethereal inhalation, I beg to furnish you with the results of a trial of this novel discovery made at St John's Hospital today, the results which, although to a certain extent incomplete, were so far so satisfactory as to justify an opinion that large amount of suffering hitherto experienced by the patients may be superseded, and that many operations can be performed during the stage of unconsciousness which is so readily induced."

"I employed part of Nooth's apparatus in the manner delineated in the illustrated London News of the 9th (January) and I found it in every respect suited to the purpose."

The Journal responded with a long editorial that included: "...we have no hesitation in predicting for this process a transient popularity. It will have its day, ultimately to be abandoned as useless and/or injurious...."

The editor's stance mellowed modestly in the next issue:

"Since our last publication, accounts of the effects of the sulphuric ether inhalation have poured in upon us from all quarters; and loud have been the blowing of trumpets and great the jubilation and overwhelming the nonsense uttered and invited thereupon...it may for a time serve interested parties as a medium for puffing themselves and for mystifying the public by enveloping the matter in a cloud of pseudo-scientific balderdash; but the simple fact is, that to inhale the sulphuric ether is neither more nor less than a mode of getting drunk;"

"Do not let us be misunderstood. We do not say that it ought entirely to be eschewed; all we contend for is that it should be used not indiscriminately, but with caution; and only under the superintendence of medical practitioners, who, instead of allowing themselves to be run away with by the novelty of the process, should use it and investigate its effects coolly and philosophically, so that it may not, if calculated to be really useful, come as many other therapeutic means have come to a premature end through the discredit thrown upon it by its abuse...."

Chloroform or Ether?

Ether was the sole anaesthetic used in Australia, until chloroform arrived. On 31 March 1848, the Sydney Morning Herald reported:

"We have now to state that a new anaesthetic agent has been discovered by Professor Simpson of Edinburgh. It is a substance called chloroform. It is applied similarly to ether, that is to say, the patient is made to inhale it, and the advantages over ether are so great, that it is said the latter will be entirely superseded."

On 12 April, 1848, the following report was published:

"Chloroform. This new agent, for rendering the operations of surgery painless, was yesterday, in the presence of some visitors, most successfully tried by the Surgeons of the Sydney Infirmary. The subject, a little girl had to submit to a most tedious, difficult and hitherto excruciating operation. Dr McEwan operated, Mr Nathan administered the anaesthetic."

The Sydney Hospital surgeon who administered the anaesthetic was Charles Nathan, who had assisted Belisario in the first ether anaesthetics the previous year. Chloroform soon displaced ether as the agent of choice.

Gold was discovered in Victoria on 10 June 1851. By 1860, the non-indigenous population had more than doubled to exceed one million. Hundreds of the new settlers practiced medicine, many without qualifications. Most surgery was performed in makeshift surroundings, and chloroform was the most suitable anesthetic. Anaesthesia required a dropper bottle, a handkerchief and a small volume of sweet smelling

chloroform. And chloroform didn't catch fire, a particular advantage in a tent.

The first patient death under chloroform was reported just three months after its introduction to Australia [7]. It was not until the late 1870s, that ether challenged the dominance of chloroform, and until 1900, the word "chloroformist" was synonymous with "anaesthetist". Chloroform had other uses. An entry in the 20 September 1848 issue of the Sydney Morning Herald says "Chloroform is recommended as excellent for scolding wives. A husband who has tried it says—'No family should be without it'".

William Purdie, one of Simpson's classmates, brought the benefits of chloroform to New Zealand. Purdie had been a regular attendee at meetings of the Obstetrical Society in Edinburgh, where he had commenced practice. Having arrived in New Zealand in late 1849, with a supply of chloroform, he set up practice in Dunedin [8].

Nitrous Oxide

Nitrous oxide emerged as an alternative, for dental surgery in particular, at about the same time as the re-emergence of ether. It must have been known in the early scientific circles of the colonies. In the Sydney Morning Herald of Monday, 21 July 1845, JS Norrie advertised his lecture on chemistry that evening on "*The simple substances and the metals. At the conclusion of the lecture the effect of the laughing gas will be exhibited.*"

There is no further reference to the use of nitrous oxide until Colin Buchanan of Port Stephens, wrote in July 1847 of his administration of ether for the repair of a popliteal aneurysm. He wrote "...not being aware of the kind of apparatus used for the inhalation of ether, I tried the simple bladder with mouthpiece, similar to what is used in the inhalation of nitrous oxide, or laughing gas, which answered the purpose admirably (I must tell you that I first tried it on myself, which convinced me as to its efficacy)." We presume that Buchanan used nitrous oxide for recreational purposes [7].

Recreational use of nitrous oxide appears in a contribution to the NSW Medical Gazette, a letter perhaps stimulated by the introduction of nitrous oxide into dental practice around 1870:

"Gentlemen... perhaps it would interest some of your readers to know the effects (nitrous oxide) produced upon me when taken on two different occasions, several years back. I inhaled it first in Sydney, at the residence of one of my friends.

"I had breathed about three quarts when the landlady of the house entered the room, and looked in an angry manner at me, to reprove me for being so ridiculous as to have the opening of a bullock's bladder in my mouth, like the figures in an old fashioned caricature; this look and the gas together caused me to have a violent fit of laughing; I laughed in the chair that I was

sitting on, then I fell on the floor and rolled over and over on the ground still laughing, and this state lasted about five minutes. I then recovered perfectly without any unpleasant after-effects. I believe however; I made an enemy of my friend's landlady ever afterwards as she never spoke to me again."

"I am, gentlemen, yours sincerely, A subscriber." Sydney August 20th 1870 [9]

In his "*History of Dentistry in South Australia 1836–1936*" Arthur Chapman writes that in the 1850s "*the introduction of laughing gas must have been greatly appreciated by those able to avail themselves of it [10].*" This presumably also refers to recreational use, because Chapman describes Lionel Blackmore, who arrived in Adelaide in 1870, as probably the first to use nitrous oxide for dental anaesthesia in Adelaide. The Sydney Morning Herald of 24 October 1870, reported that "*Mr E Reading, Dentist, 128 Phillip Street, administers the nitrous oxide gas on Tuesday, Wednesday, Thursday and Friday.*" By the end of the 1870s, Chapman notes that "*we find gold, platinum and vulcanite in use for artificial denture bases, and nitrous oxide gas largely employed for extractions [10].*"

The Australian Medical Gazette was the first Australian journal to include an article on nitrous oxide anaesthesia, in 1870 reprinting a paper from the 1869 *Lancet* by Charles Fox, Dental Surgeon to the Dental Hospital in London. Having learnt techniques from Gardner Colton, his paper extolled the virtues of nitrous oxide anaesthesia, citing his experience of its administration to M. Blondin for "*extremely severe dental operations*" whereupon the patient "*performed all his most difficult feats on the high rope 430 feet long within three hours after I had given him the gas [11].*"

The NSW Medical Gazette of 1871 noted in the "Miscellanea" section, that nitrous oxide was likely to supersede chloroform for short operations [12]. However, for the remainder of the nineteenth century, medical journals scarcely mention nitrous oxide, although it continued to be used regularly by dentists (Fig. 24.4).

The Adelaide based FH Faulding and Company, a pharmaceutical company founded in 1845, published Faulding's Medical Journal.¹ The quasi-scientific journal of news and reviews of scientific papers included advertisements for dental anaesthesia such as the "*New York Dental Institute*" of Grenfell Street, Adelaide, offering in the May 1900 edition "*teeth extracted painlessly with Cocaine, Eucaine, Laughing Gas or Aether [13].*"

Evidence of the establishment of local manufacture appears in the British Journal of Dental Science in 1898:

"Australian Nitrous Oxide Gas—In addition to making their own dentists, Australia is beginning to make its own nitrous oxide, for an Australian Nitrous Oxide Gas Company has been

¹ FH Faulding and Company was taken over in 2010 by Mayne Group, and following a demerger in 2005, is now part of Symbion Pharmacy Services.

formed and a complete plant for the manufacture of the gas has been imported....The price will be lower than that of the imported gas, as the risk and expense of carriage as deck cargo is avoided, while the cylinders will be of uniform size. Advance Australia!" [14]

No record can be found of an Australian Nitrous Oxide Gas Company. If it was FH Faulding and Company, they didn't mention it in Fauldings' Medical Journal. Still, it is likely that they were manufacturing nitrous oxide by 1900, as they supplied apparatus and pre-filled cylinders according to advertisements in their journal.

Nitrous Oxide in New Zealand Before 1900

The story of nitrous oxide in New Zealand is similar to that in Australia. The December 1878 Napier newspaper reported: "*Our Dentist, Mr H C Wilson, is about to commence the use of nitrous oxide (laughing) gas for producing insensibility to pain during dental operations... we believe that Mr Wilson is the first dentist in the Colonies who has introduced the use of this anaesthetic into his practice: and we must add that we are glad to see Napier taking the initiative in this advance of science.*" [15]

Septimus Solomon Arthur Wellington Daniel Myers registered as a Dentist in 1880, and is thought to have intro-

duced nitrous oxide in Invercargill. He then established a dental company in Dunedin, opening a Christchurch branch in 1888 [16].

An issue of stamps in 1893 with advertisements on the back indicates the expansion of nitrous oxide in New Zealand. Denominations ranged from one penny to one shilling, each stamp in a sheet bearing a different advertisement. The one advertising S Myers and Company noted that painless extractions are available using nitrous oxide gas. These stamps were withdrawn soon after issue due to a rumor that the ink, when licked, was injurious to health [16].

Deaths Under Chloroform

By 1870, the words anaesthesia and chloroform were virtually interchangeable. The deaths reported each year from 1848 had little influence on practice [17].

The July 1868 Australian Medical Journal, described a previously healthy 33 year old woman receiving chloroform at the Melbourne Hospital for surgery to her anal fistula and haemorrhoids. In the absence of the resident House Surgeon or Physician, the attending surgeon administered the chloroform. The patient struggled and died shortly thereafter. Although post mortem examination did not reveal the cause of death, kidney disease or impure chloroform was implicated.

It was recommended that the hospital appoint a full-time chloroformist. The proposal went unsupported [18].

In February 1891, the Australian Medical Journal reported another death in a patient receiving chloroform at the Melbourne Hospital with the City Coroner recommending “...that there ought to be some specially qualified gentleman in the hospital for the administration and teaching of the use of chloroform.” The suggestion was put to the Medical Staff Committee who took no action [19].

In May 1891, a young man of 32 died during chloroform administration at the Melbourne Hospital. The “resuscitation” over 20 minutes included artificial respiration, hypodermic injections of ether, and intravenous ammonia. At inquest, the City Coroner declared that an expert should supervise chloroform administration. “It appeared to him, that cases of death under chloroform occurred far too frequently at the Melbourne Hospital. Students were allowed to give chloroform without any supervision. The wonder was not that deaths should occasionally occur, but that they did not happen more frequently [20, 21].”

In an editorial entitled “Anaesthetics at the Melbourne Hospital”, the Australian Medical Journal argued for the appointment of a specialist anaesthetist to administer chloroform and other anaesthetics, and to supervise and instruct residents in the practice of anaesthesia. The Melbourne Hospital Medical Staff dealt with the issue by passing motions of confidence in whoever administered the chloroform [22, 23].

At this time, physicians (internists) controlled most medical affairs, with surgeons not far behind and exerting increasing influence. Anaesthetists ranked poorly, anaesthesia being entrusted to junior staff or students. But when things went wrong, it was a problem with the patient or the chloroform, and not the administration or the administrator.

Non-Medical Anaesthetists

Non-medical anaesthetists gave many anaesthetics, particularly in rural Australia. The medical profession condemned such practices but did nothing to remove the problem by advancing the establishment of anaesthesia as a specialty.

In 1884, the Australasian Medical Gazette reported that a patient had died while receiving chloroform at Tamworth Hospital in central NSW. Mr Goodwin, a local chemist, had administered the chloroform. The journal asked why the surgeon, Eustace Pratt, did not use the anaesthetic services of another medical man. In the next issue, Pratt attacked the editor for his audacity, and chastised him for forwarding copies of his editorial to the local Tamworth papers and several prominent citizens. He described how “hundreds of men, not legally qualified, have to give chloroform in the bush.” He described the Medical Gazette as a moribund and poverty stricken organ of a small clique of mutual admirers [24, 25].

Chloroform was easy to administer with a minimum of equipment. The status of the chloroformist was negligible, and surgeons regarded their anaesthetists as dependents rather than colleagues. Nonetheless, non-medical anaesthetists gradually disappeared, and by 1900, hospital residents or family doctors, gave virtually all anaesthetics. Until the mid-twentieth century, the family doctor who referred a patient to a surgeon would commonly provide the anaesthesia.

1900—The Beginnings of a Specialty

In 1901, the Legislative Council considered a Dental Act which would establish a Board registering Dentists with appropriate qualifications and would permit only those holding the Diploma of one of the American or British Dental Colleges to administer nitrous oxide. In November, Faulding’s Medical Journal commented that

“it can hardly be claimed that (this) provision has been inserted for the benefit of the public, for it means that to less than one dozen dentists in South Australia is granted the sole right to administer this anaesthetic. The members of this privileged class are all with high class practices, who charge high fees. It is therefore obvious that the poorer classes will be practically denied the comfort and benefit of nitrous oxide when undergoing dental operations...”

In 1909, four honorary anaesthetists were appointed to the Melbourne Hospital, to instruct and supervise residents. The resident doctors, who covered all disciplines during their work, had to view 20 anaesthetics before attempting one. Although this was a major step forward, the honoraries did not normally attend cases out of hours, when residents provided anaesthetics. This led to a furore after a death in September 1912.

An extremely ill 66-year-old man presented for surgery at 6am. The unfortunate duty resident administered ethyl chloride and ether, whereupon the patient immediately succumbed [26]. One of the honorary anaesthetists, Rupert Hornabrook (Australia’s first full-time specialist anaesthetist, and an advocate for the ethyl chloride—ether sequence) made a personal representation to the Coroner, leading to a public enquiry. Hornabrook argued that residents should not have to deal with such cases, and that a senior anaesthetic resident should always be present. He proclaimed, “Anaesthetic work should be more respected than it was.” The Coroner added fuel to the fire by stating “there appeared to be a feeling among medical men that the anaesthetist’s work was not as necessary as some might think.” The hospital was outraged, claiming that Hornabrook’s action was disloyal to the hospital and to the residents [26–28].

In the March 1914 Australian Medical Journal, Hornabrook wrote “The anaesthetist should be placed on the staffs of hospitals... on equal footing with other members of

the staff. It is useless to expect good men to come forward unless they are given some status.” [29]

But things didn't change. Physicians and surgeons controlled public hospitals. Surgeons depended on referrals from general practitioners in their private practices, and often engaged those practitioners as assistants or anaesthetists. Surgeons may have wanted anaesthetists to provide services, but they were not prepared to give them more than a passing acknowledgement. The traditional relationship between the surgeon and the “chloroformist” was hard to break, and the idea of the surgeon collecting the fee on behalf of the anaesthetist was firmly entrenched.

Thus, competing factors influenced the establishment of specialist anaesthetists. There was tacit recognition of the desirability of specialisation, but difficulty in attracting doctors into anaesthesia because of low status and poor remuneration. Their paltry remuneration forced anaesthetists to rely on activities such as general practice to survive. They had no time for research, and they were not unified.

There were exceptions. Edward Embley championed the cause of anaesthetists. He had gained worldwide recognition for determining that the cause of death from chloroform was cardiac and not respiratory [30]. His suburban general practice supported his unpaid weekend research at Melbourne University.

Hornabrook, recognised for his enthusiasm in experimentation (Fig. 24.5) and in teaching anaesthesia, was an outspoken advocate for patients and anaesthetists, and saw the need for anaesthetists to unite. He suggested in the April 1913 Australian Medical Journal, that a Society of Anaesthetists be established [31], also noting that:

“...more consideration should be shown by some surgeons towards their patients and the anaesthetist. Some gentlemen seem to have no idea of punctuality—half or three quarters of an hour late in the time of starting an operation seems to be nothing to them, they never appear to think of what that extra half hour or so must mean to the patient, in many cases it must be perfect hell.”

He went on to say how the lateness impacts on staff and other hospital arrangements. His forthright approach is obvious:

“On one occasion, after waiting an hour for a well-known surgeon, I walked out of the operating theatre as he walked into it. He remarked that he was ready to start, and I told him that if he was, I was not, and that if he wanted the patient put under an anaesthetic he had better get someone else to do it...” [31]

In the May 1914 Australian Medical Journal, he wrote of

“Some of the difficulties the anaesthetist has to contend against... One of the greatest difficulties the teacher has to contend with is the inborn idea that any fool can administer an anaesthetic.” He related the remark of a senior Melbourne surgeon that *“a drayman could administer chloroform”* [30]

Fig. 24.5 Rupert Hornabrook, self administering ethyl chloride via a nasal inhaler, while submitting himself to an incision in his forearm, followed by suturing. He said pain only occurred during the suturing of the last half inch of the two inch wound, when he became diverted from anesthetic delivery by his conversation with the operator. (Courtesy Geoffrey Kaye Museum of Anaesthetic History, Australian and New Zealand College of Anaesthetists, Melbourne.)

It gets worse:

“A few years ago, I was stopped one morning and asked by a surgeon if I was not busy on the following day could I come to a certain private hospital and be present while he did a big abdominal operation. The patient was a lady who had been sent to him by Dr X. Dr X had sent him a case before, and on that occasion he had asked him to assist at the operation; that he had found Dr X to be such a fool at assisting that he had this time asked him to give the anaesthetic.”

“For the next few minutes the air was electric” [30]

The situation did not improve for another 40 years. In 1927, a senior surgeon at the Alfred hospital told Geoffrey Kaye, when contemplating a career in anaesthesia, *“Why waste your opportunities”*. Kaye recalled that anaesthetics was poorly regarded as a specialty, the province of the physically handicapped or those who had failed in other branches of medicine. The surgeons of the day found that the best anaesthetists were the medical orderlies of the 1914 War, *“because those blokes did as they were told”*. [32]

This attitude was not peculiar to Australia and New Zealand. John Lundy recalled in 1946 that *“There was a tendency for only those physicians who were incompetent in*

general practice or in other branches to limit themselves to the practice of anesthesia.” [33]

Francis McMechan’s Visit

In 1929, only Hornabrook and Fred Green in Melbourne, and Gilbert Brown in Adelaide, were full time anaesthetists. Notwithstanding their limited numbers, they, with several others and the young and enthusiastic Kaye persuaded the Australasian² Medical Congress to establish a section of anaesthetics in 1929. Accompanied by his wife, Laurette, Francis McMechan (Fig. 34.3) visited that Congress, having previously written to anaesthetists in Australia and New Zealand, encouraging them to convince the medical establishment to formally recognise anaesthesia. An editorial in the 1930 Australian Medical Journal stated: “The anaesthetist is a specialist in the truest sense. The time has come when he should be recognised as such”. The suggestion fell on deaf ears.

Specialisation seemed similarly stalled in New Zealand, although formal instruction in anaesthesia began at the Dunedin School of Medicine in 1892. McMechan visited New Zealand after the 1929 Australasian Medical Congress in Sydney, and it is likely that he further encouraged anaesthetists to join forces. At the February 1930 BMA annual conference in Christchurch, there was a Section of Anaesthesia.³ The Section of Anaesthesia met again at the 1932 Annual Conference in Auckland. A Society seemed to form but died without trace. In 1949 F Fullerton recalled: “*We elected a President, a Secretary and a Treasurer, and we handed over 5 shillings each as our modest contribution to expenses. Well, if you’ll believe me, that was the last we ever heard of the Society. No further meeting was ever called...and I don’t know what became of our 5 shillings.*” [8]

The Influence of Geoffrey Kaye (1903–1986)

Australia had better luck, but it depended on the 26 year old Kaye, whose enthusiasm for anaesthesia research impressed McMechan. Kaye had a small private income enabling him to travel to England and Germany at the end of 1929, and McMechan convinced Kaye to visit North America. Kaye remembered McMechan’s “quite electrifying” description of the American approach to anaesthetics: anaesthetists trained in basic sciences, keeping anaesthesia record charts, and looking after their patients [32].

So in late 1929, Kaye returned to London briefly, as an Honorary research worker at St Thomas’ Hospital, before continuing on an extended tour of the US, Canada, and Germany. Prior to returning to Melbourne in early 1931, Kaye took several courses, including one with Elmer McKesson in Toledo, Ohio. McKesson, who trained as a physiologist and became an anaesthetist and manufacturer, advocated clinical measurements. McKesson’s technique of rebreathing and secondary saturation after intentional hypoxia from 100% nitrous oxide impressed Kaye who, however, later recognized the dangers of this approach. McKesson induced in Kaye a lifelong interest in engineering and metalwork. Kaye studied regional anaesthesia with Gaston Labat in New York, and spent time with Paul Wood, John Lundy, Wesley Bourne, and Ralph Waters, who more than anyone else shaped and encouraged Kaye’s development as a teacher and researcher. Kaye attended anaesthetic society meetings in Canada and the US, including the IARS meeting in New York in October 1930 [32].

On returning to Melbourne, Kaye assumed editorship of the first Australian textbook on anaesthesia. *Practical Anaesthesia* appeared in 1932, the collated work of several anaesthetists at the Alfred Hospital. McMechan wrote the introduction. Kaye joined in the organization of anaesthesia, becoming secretary of the Victorian State Section of Anaesthetics, under the auspices of the British Medical Association. He was instrumental in developing a Section meeting at the 1934 Australasian Medical Congress in Hobart, the venue of the second meeting after the eventful 1929 Sydney meeting. The 1934 Congress was to have been held in Perth in 1932, but the great depression delayed the meeting. With the advantage of his private income, Kaye devoted his energies to correspondence with several anaesthetists preceding the 1934 Congress. He convened a meeting of 6 prominent anaesthetists from various States, together with a local representative of the BMA, at Hadley’s Hotel where, in January 1934, the Australian Society of Anaesthetists was born, with Gilbert Brown elected as President, and Kaye as secretary [34, 35].

The first years of the Society were difficult times. Non-anaesthetists did not appreciate the necessity of a separate society; the BMA did not take kindly to the establishment of a group “in opposition” to the State Sections of Anaesthetics; the members of the Executive were idealistic in their expectations of the Society; and the general members struggled to make a living. Nevertheless, Kaye’s dogged efforts as secretary ensured that the Society survived.

From 1931 to 1939, while continuing to provide clinical anaesthesia (Fig. 24.6), Kaye published regular “memorandums” on new drugs and subjects of interest, and at least 16 scientific reports. One publication, for which he did not claim authorship, deserves particular mention. The June

² Australasia refers to Australia and New Zealand, as in the Royal Australasian College of Surgeons.

³ Until 1962 in Australia, and 1967 in New Zealand, the local medical associations were branches of the British Medical Association.

Fig. 24.6 Geoffrey Kaye administering ether, 1932. (Courtesy Geoffrey Kaye Museum of Anaesthetic History, Australian and New Zealand College of Anaesthetists, Melbourne.)

1938 “Anaesthetic Number” of the Medical Journal of Australia included the results of a survey of Anaesthetic fatalities presented at the 1937 Australasian Congress in Adelaide. Kay collated the data from nearly 400,000 anaesthetics at 14 hospitals from around the country, finding a mortality from anaesthesia of 1:1000 [36].

He also designed a demand flow anaesthetic machine, similar in principle to the McKesson. The DM machine was widely used in various forms for many years [37]. In 1938, Kaye again travelled overseas to Europe and America, this time because “it seemed inevitable that Europe was going to be shot up before long.” [32]

He went via Canada and the USA, renewing his acquaintance with Waters. Believing he had a mission to complete in Australia, Kaye declined a thinly veiled invitation by Waters to stay in Wisconsin. Had he accepted, anaesthesia in Australia would have been critically altered. In Rochester, he met with Lundy who was jealous that he had visited Waters first. This was an unintentional slight—Kaye had timed his visit to coincide with the meeting of the Anaesthesia Travel Club at the Mayo Clinic.

He visited F Clement in Toledo, who then drove him 800 miles to the IARS Congress in New York where Kaye presented a paper comparing carbon dioxide absorption and positive pressure techniques of gas anaesthesia [32, 34]. McMechan also attended the Congress but was too ill to attend the programme. He summoned Kaye to his room. Kaye gave the following account.

“He asked me if I knew why I had been so well received...on my previous visit to Europe and North America.”

“I said that I had possibly been a personable young man.”

“No”, he said, that was not the reason: I was being “vetted” as his possible successor as Secretary General of the IARS. He indicated the requirements of the post, the incumbent had to be an anaesthetist, internationally known, capable of handling meetings and secretarial work, not at a loss in Congress ante-rooms or in private homes, and fluent in English, French and German.”

“But now”, said McMechan, “it will not do. The world is sliding into war. When that war ends, the only country possessed of money will be the United States, and they will want an American Secretary General. Therefore, go back to Australia and do the best you can. If you survive the war, do your best to bring the anaesthetists of the world together again”. [34]

World War II Intervenes

World War II deferred progress towards an organised specialist Society, and the ASA went into hibernation as did progress in New Zealand. At the 1946 BMA Conference, a proposal to establish a New Zealand Society revived the New Zealand BMA Section of Anaesthesia. Eric Anson, the director of anaesthesia at Auckland Hospital, led the movement and sought Kaye’s advice on the process of establishment. Under the auspices of the BMA, The Society was formally established in 1948, with Anson as the first President [8].

Surgeons and patients appreciated the new intravenous barbiturates and more efficient apparatus developed by the 1940s, but these did not change their perception of the anaesthetist. And perhaps rightly so: There was no formal training or qualifying examination. “You simply followed around after senior anaesthetists and copied their tricks as best you could”. [32]

In 1939, Kaye had tried unsuccessfully to convince the President of the Royal Australasian College of Surgeons, of the need for an Australian Diploma in Anaesthetics similar to the British Diploma. In 1943, after serving as advisor to the Australian Army during World War II, Kaye returned to the University of Melbourne University, where he pursued his plans for the establishment of formal training of specialist anaesthetists [34].

Diplomas in Anaesthesia

Kaye sought, and failed, to establish a Diploma conjointly awarded by the Royal Australasian College of Surgeons and the Royal Australian College of Physicians. In 1944 however, the University of Sydney established a DA, and in 1946, the University of Melbourne followed. Kaye wanted the DA to be based in Melbourne, and later claimed that he had really envisaged an inaugural College of Anaesthetists. It was

Fig. 24.7 Geoffrey Kaye lecturing to medical students at Melbourne University, c1950. The first display of his museum collection may be seen in the background. (Courtesy Geoffrey Kaye Museum of Anaesthetic History, Australian and New Zealand College of Anaesthetists, Melbourne.)

not to be. What eventuated were two DAs in the two major cities of Australia [34].

Kaye threw himself into his teaching responsibilities at the University, supported by newly allocated teaching space, and facilities for a library and museum (Fig. 24.7). On 16 October 1946, the Centenary of Morton's demonstration, Kaye led the celebration of the official opening of his new teaching "Centre" for anaesthesia, in the Physiology Department at the University of Melbourne. With the introduction of the DA in Melbourne, and having got the ASA on its feet, the 43 year-old Kaye resigned as secretary of the Society, believing it time for a "younger man". [34]

1946 also saw the publication of the second Australian textbook on anaesthesia. "Anaesthetic Methods", a popular practical guide for both the specialist and non-specialist anaesthetist was written by Kaye, Orton, and Douglas Renton, all from the Alfred Hospital. The book was dedicated to Waters.

Orton and Renton assumed the task of sorting out the chaos resulting from two different DAs, further complicated by the credentials of anaesthetists who had obtained an English DA or held the FRCS or FRCP [34]. In 1946, the ASA created the Education Subcommittee, which would play a major role in the establishment of the Faculty. Organization of two more subcommittees. International Relationships, and

Standards, quickly followed, and in 1948, the State Sections of the Society were established [34].

The Faculty of Anaesthetists—Early Negotiations

In 1947, as President of the Australian Society, Harry Daly again approached the Royal Australasian College of Surgeons and the Royal Australasian College of Physicians, seeking the creation of a Federal Diploma of Anaesthesia. To no avail. In the meantime, Daly was awarded a Fellowship of the English Faculty on the occasion of its inauguration in 1947. Wishing to accept this honour in person, he and his wife set off to London in 1949 via cargo ship. On returning, their ship docked in Adelaide, and the Dalys stayed for several days with Mary Burnell. A meeting at Burnell's home was arranged with Ivan Jose (later Sir Ivan), a member of the RACS Council. This meeting led to negotiations with the RACS—and ultimately to the establishment of the Australian Faculty of Anaesthetists [34].

In 1949, Kaye travelled to Scandinavia, Great Britain and North America to review anaesthesia training in these countries, and particularly to seek some parity between the Australian DA, or at least one of them, and the English DA. Like Daly, Kaye had been elected to Fellowship of the Faculty of

Fig. 24.8 The “DM” or “Dental Midwifery” machine in use, c1950. (Courtesy Geoffrey Kaye Museum of Anaesthetic History, Australian and New Zealand College of Anaesthetists, Melbourne.)

Anaesthetists of the Royal College of Surgeons (England) without examination, giving him some influence. Having sensed dissatisfaction among some members of the new Faculty of the RCS, he returned home with a plan [34].

Kaye’s Experiment

Kaye considered that the US led the world in research and organisation, but Britain offered the best clinical anaesthesia. He also believed that the apparatus used in Australia equalled that found elsewhere (Fig. 24.8). [34]

He participated in the negotiations by the Society with the RACS to establish an Australasian Faculty. Renton and Orton, assisted by others on the ASA Executive continued their negotiations with the RACS. By mid 1950, Kaye again became Acting Secretary of the Society, owing to the illness of the incumbent, thrusting him again into the centre of the action. Kaye really wanted a College of Anaesthetists to be established in Melbourne. Behind the scenes he sought a suitable building to house his dream of a “centre” of anaesthesia. At the time, the membership of the Society stood at around 100.

In his retiring address as president of the ASA in 1949, Orton reflected on what would improve the status of anaes-

thesia in Australia: Anaesthetists should be properly trained, with higher qualifications required for senior appointments; and surgeons should be convinced of the advantages of modern anaesthesia. There was one unsaid factor: anaesthetists needed access to larger fees, and payment for public hospital work. Finally, Orton suggested that the anaesthetist should provide preoperative assessment and preparation, intravenous fluid therapy, and postoperative care [38].

The Faculty is Established

In October 1950, the College of Surgeons approved the establishment by the Society of an interim Board of Faculty that would become the Faculty of Anaesthetists. Concurrently, Kaye proposed a “Headquarters” of the Society, the establishment of his dream—a centre of excellence for Australian anaesthesia. Kaye was a man of vision—and incredible optimism. He purchased a substantial property in Melbourne and renovated it, converting the downstairs to include a meeting room, library, museum, laboratory and darkroom, and retaining the upstairs for his accommodation. Robert Macintosh officially opened the Centre in March 1951 [34, 35].

On 25 August 1952, the Faculty of Anaesthetists of the Royal Australasian College of Surgeons was inaugurated—in the same week that the ASA held its Annual General Meeting in Kaye’s mansion. All were impressed by what they saw, but did they appreciate what it meant? Kaye must have had an inkling that his “experiment” might not succeed: He inserted a clause in the five-year lease to the Society that its extension was at his discretion. Although he continued to arrange scientific meetings and invite overseas speakers, Kaye’s mansion primarily became a venue for the monthly meeting of the Victorian Section of the Society. Kaye managed the library and museum, and single-handedly produced the Society newsletter. He wrote some 15 papers for the newsletter for distribution to all members, eg, explosions, oesophageal thermometry, and anaesthesia for snakes. He encouraged young anaesthetists to learn engineering skills, and had them help in the sectioning⁴ of apparatus for teaching purposes [35].

The Experiment Fails

The experiment abruptly ended in 1955, when Kaye withdrew the lease. He lamented to his colleague Daly, “*our own members, who tread cigarette ends into the carpets, burn holes in the linoleum, ignore the washing up and generally*

⁴ Sectioning refers to the use of a lathe and other engineering equipment to cut apparatus in different planes, so as to demonstrate their internal construction and operation.

leave the place a pigsty when they depart” [35]. He later wrote:

“In backing the experiment at “49” (49 Mathoura Road, Toorak), I was gambling in “anaesthesia futures” for heavy stakes. The premises, and their rebuilding for the Society’s purposes, cost me £12,000, my entire fluid capital. The scientific equipment which I put into the pool was the collection of years, assembled for such a purpose. The upkeep of house and grounds has absorbed my surplus income for five years, abolishing all freedom of movement. Finally, the Society appeared to hold itself entitled to a blank cheque upon my physical energy”. [35]

Kaye was years ahead of his time, but did not comprehend the needs of the ordinary anaesthetist. The new specialists of the infant specialty in the immediate post war period had young families to support in a new environment. Their goals did not extend to scientific development. In contrast, Kaye, was unmarried and had an independent private income from his father. He “hated private practice”. This may reflect his reputation as an anaesthetist, where he had a tendency to exasperate his surgical colleagues by always trying new things.

In 1955, Kaye sold “49” and severed his relationship with anaesthesia. The museum and library were gifted to the Faculty of Anaesthetists at the Royal Australasian College of Surgeons in Melbourne. Only reluctantly did he, in 1958, agree to have his name associated with the museum.

Kaye joined the Department of Electrical Engineering at Melbourne University, where he designed and developed electrometrical equipment. His most ambitious project was the construction of a “Patient Watching Machine” which might monitor multiple parameters, and was reputedly the size of a large refrigerator. In 1965, the university refused to continue funding the project and, despite having contributed \$16,000 of his own money into it, he was forced to abandon it.

He shifted to his other passion, collecting objets d’art. However, his own financial status came under threat and he was forced to earn a salary. At the age of 62, he spent some five years working in the development section of Commonwealth Industrial Gases (CIG), the Australian equivalent of the British Oxygen Company (BOC). Once his finances improved, he resumed his passion, establishing a substantial collection of artwork, decorative arts, furniture and tableware.

He became an acknowledged expert on “Old English Glass”, “Chinese Monochromes of the 18th Century”, and “Antique English Silver”. In 1984, at the age of 81, he gave an opening address at the fiftieth anniversary meeting of the Australian Society of Anaesthetists. He died in 1986.

Specialization and Recognition

The establishment of the Australian Society in 1934, the New Zealand Society in 1948; the offering of Diplomas in both Sydney and Melbourne, in 1944 and 1946; and the

founding of the Australasian Faculty in 1952, laid foundations for a specialty with status in both Australia and New Zealand.

In the 1950s, despite many enlightened surgeons, especially those involved in the RACS, surgeons and anaesthetists were uneasy partners. Each needed the other, but neither used the benefits of the relationship to enhance the status of anaesthesia. There was a lot of tradition to overcome.

Stuart Marshall, President of the ASA in 1951–1952, and a member of the interim Board of Faculty 1951, wrote “Problems which surgeons create for anaesthetists” in the Australian Medical Journal in 1954 [39]. This appeared soon after the first Commonwealth Medical Benefits Schedule, where, as Orton might have predicted, the rebates for surgery services far exceeded those for anaesthesia. They were, of course, based on the fees commonly charged at the time.

“The outmoded idea that the anaesthetic is any fool’s business still persists, not only in responsible medical circles, but also among hospital authorities, government officials and the public as well. Surgeons in general are apparently not averse to other perpetuation of these anomalies, and thus play a major part in creating serious economic problems for anaesthetists.”

“None can deny the enormous benefits of good anaesthesia, yet there are surgeons who seek to preserve a degraded status for anaesthetists; who decry their achievements; who ridicule their knowledge and skill...”

In concluding the paper Marshall wrote “Contrary to widespread surgical and lay belief, the acquisition of reasonably comprehensive knowledge and skill in specialised anaesthetics is not a matter of a few weeks training, but of at least two to three years’ intensive postgraduate study and practical work. Fortunately many surgeons, both senior and junior, have a lively appreciation of the situation...The recent establishment of the faculty of Anaesthetists of the RACS marks a great step forward in this respect.” [39] And it indeed it was!

Early Days of the Faculty

The RACS had established an eminent interim Board in January 1951, including Daly, Renton, Len Travers, and Gilbert Troup. Troup, Daly, and Renton had been Presidents of the ASA, Renton in the immediate period leading to the establishment of the faculty. Travers had been a respected surgeon, until a serious skin disorder of his hands ended his surgical career. He then became a skilled anaesthetist who retained a strong influence in surgical circles.

The interim Board, acting under the auspices of the College of Surgeons Council, admitted several Foundation Fellows, and asked for recommendations from each State section of the ASA, and the New Zealand Society. This process caused disquiet, as there were approximately 100 members of the ASA and 60 in the NZSA, but the College Secretary invited only 36 anaesthetists to join the 5 interim Board members as foundation Fellows of the new Faculty. They included Kaye, and Renton was elected as the first Dean.

Having established the list of foundation Fellows, the Board then sought applicants for Membership to the College. Fellows would be admitted by election, and Members by application. Both had to be practising anaesthetists, with a Diploma in Anaesthetics (or similar). There was liable to be disquiet again because of the potential for discrimination. Regulations were required! The Chairman of the Executive of the College of Surgeons, Henry Searby took this in hand, drafted the regulations, and presented them *fait accompli* to the Board.

Notable among the regulations were the following clauses:

“Subject always to the approval of the Council (of the College of Surgeons), the Board shall govern and control all of the business of the Faculty”, and “...if it (the Faculty) does not accept what the College wants, then it ceases to exist” [34]

A great start! Well, at least we knew who the boss was.

Sixty Members were invited to join the Faculty, ensuring an initial Faculty of 100 anaesthetists. Thereafter a maximum of five recommendations for election to Fellowship, and two applications for Membership would be considered per year. Not surprisingly, some anaesthetists were upset at not being grandfathered into the Faculty, straining relationships with the Society. Following inauguration, Fellowships were conferred by election, but once examinations were instituted, they were also gained by successful examination. A Fellowship gave the holder the entitlement to place the letters FFARACS (Fellow of the Faculty of Anaesthetists, Royal Australasian College of Surgeons) after their name. Memberships by application were discontinued in 1959, once the examination process was established.

Of the seven candidates taking the first Fellowship examination in 1956, four were women. Six of the seven passed, becoming the first Fellows (by examination) of the Faculty. The two part examination began in 1957, with the first Primary examination. The Diplomas became increasingly irrelevant, with the Sydney DA discontinued in 1974, followed by the Melbourne DA in 1985.

The 1950s, Time of Change

As the Faculty consolidated its role and began training new specialists, the ASA entered a turbulent time. Besides Kaye selling its headquarters, there were financial concerns. The Society disaffiliated from the BMA in 1951. The timing may have been unfortunate, as the Minister for Health in the recently elected Government introduced the “Commonwealth Medical Benefits Schedule”(CMBS).⁵ Even the BMA had

⁵ The Commonwealth Medical Benefits Schedule (CMBS) is an indexed list of medical procedures and consultations to which the Commonwealth Government ascribes a “fee” that determines the basis of

Fig. 24.9 Mary Burnell (1907–1996), the first woman member of the ASA (1935), the first woman President of the ASA (1953), and the first woman Dean of the Faculty of Anaesthetists, Royal Australasian College of Surgeons (1966). (Courtesy Geoffrey Kaye Museum of Anaesthetic History, Australian and New Zealand College of Anaesthetists, Melbourne.)

difficulty resolving issues with Government over anomalies in the schedule, and the Society’s concerns fell on deaf ears. In 1959, the Minister responded to BMA requests for amendments to the Schedule, saying he would consider them “if they did not involve too much arithmetic”. Anaesthetists remained the “poor relations” in the operating room, receiving an income less than that of surgeons for many years [34].

Mary Burnell (Fig. 24.9) became the first woman President (1953–54) of the ASA, and Patricia Mackay (nee Wilson) served as treasurer/secretary (1955–61), later becoming President (1966–68). This indicates the major role women played in the ASA from its inception. In 1966, Burnell became the first woman Dean of the Faculty

reimbursement to patients of medical fees paid. All Australian citizens are entitled to a refund of 75% of the CMBS “fee”, and optional private health insurance can be taken to cover the remaining 25%. The “fee” is indexed each year. However, indexation at minimal rates over the years has seriously eroded the value of the refunds paid, and in many cases, they now fall far short of medical fees actually charged. Nowhere has this been more evident than with anaesthesia fees.

The New Zealand Society arose in the 1950s, in the process becoming a voice for specialist anaesthetists, important because New Zealand specialists had minimal representation in the new Faculty. Not having an established home, the headquarters of the Society rotated every two years between the major cities, similar to the ASA's situation once Kaye sold 49 Mathoura Road. A regular newsletter was begun, and regular meetings held. Patricia Mackay became Secretary/Treasurer in 1954, before moving to Melbourne and fulfilling the same role for the Australian Society. Of great concern, few doctors entered the specialty because of the lack of suitable full-time and registrar posts in public hospitals, and private practice was poorly remunerated. The importance of anaesthetists charging patients directly (rather than via the surgeon) was raised with the College of Surgeons, and a scale of fees drawn up. A meeting called by the Director General of Health was attended by hospital superintendents, surgeons, and Society members, resulting in an increase in hospital posts, and ultimately, independence from surgeons in the setting of fees. This long preceded similar changes in Australia. By 1959, New Zealand, with a population of just over 2 million had 147 physician anaesthetists, quite an achievement [8].

The 1960s

In Australia, the 1960s saw the aftermath of the introduction of the CMBS, and the gradual introduction of sessional payments for specialists in public hospitals. Under the old "honorary" system, specialists gave their time free of charge in the treatment of non-private patients in public hospitals, their income being derived entirely from their private practice. Such a system was fine for surgeons and other well established specialists, but anaesthetists received far less remuneration than their colleagues. It was not uncommon for the anaesthesia fee to be a quarter or less of the surgical fee, and the 1960s anaesthetist in private practice followed the surgeon to operating rooms in diverse small private hospitals, carrying their own apparatus and drugs, even nitrous oxide and halothane (Fig. 24.10).

At the end of the 1950s, academic anaesthesia had not recovered from the aftermath of World War II. No-one had taken up the initiative that Kaye had started. It was John Lowenthal, Professor of Surgery at the University of Sydney, who initiated establishment of an academic appointment. Driven in part by self-interest, his proposal would ensure the availability of specialist anaesthetists for his surgical practice, and for expansion of the Department of Surgery. In 1960, he proposed the appointment of an Associate Professor in the Department of Surgery, and sought financial assistance from the Nuffield Foundation [34].

Fig. 24.10 Portable “Midget Anaesthetic Machine”, typical of those used in Australia in the 1960s by anaesthetists in private practice. The anaesthetist carried this machine, as well as all drugs and other equipment, to each hospital. The hospital provided only oxygen. (Courtesy Geoffrey Kaye Museum of Anaesthetic History, Australian and New Zealand College of Anaesthetists, Melbourne.)

The similarity of events, to those in Oxford some 22 years previously, was uncanny. Having obtained a grant of £20,000 from the Nuffield Foundation, the advertisement was placed, stipulating that “the successful applicant will work under the direction of the Professor of Surgery”! Harry Daly was having none of it! As inaugural Vice-Dean of the Faculty and former President of the ASA, the prominent Sydney anaesthetist prevailed upon his friend, Robert Macintosh, and sought a meeting with Lord Nuffield, who was visiting Sydney at the time. A polite exchange of letters followed, resulting in an increase in Nuffield's grant to £50,000, in order to fund a full academic chair in anaesthesia (similar to that of Nuffield's funding the first professorship in anaesthesia in Great Britain. See also Chapter 30) Douglas Joseph became Australia's first Professor in May, 1963 [34].

Opinions differed as to whether the ASA or the Faculty should represent anaesthetists on medico-political-economic matters. The argument began in the State of Victoria, prompted by the Government's establishment of a committee to determine salaries and conditions for doctors in public hospitals. The debate continued over several years, however Gwen Wilson recalled that if both organisations had looked closely at their history, constitutions, and previous legal judgements, the issue might have been resolved more quickly. At the height of the disquiet, in 1963, the Society had 460 members compared to the Faculty's 248 Fellows. The ASA affiliated with the Australian Medical Association

in 1965, and ultimately, became recognised as representing anaesthetists on all matters related to fees and conditions of employment, while the Faculty concerned itself with training and standards of practice. This separation of roles has continued, and both bodies support education and research. A similar relationship exists in New Zealand [34].

Over the late 1950s and the 1960s, the ASA and the NZSA increasingly co-operated, particularly on matters of education and overseas aid. That relationship has continued, with each represented on the other's Board/Council meetings, and with joint support of congresses.

Low anaesthesia fees continued as an issue, with the Government schedule for anaesthesia fees priced at a fraction of the recommended surgical fee for the surgical procedure performed. After a visit to the US in 1970, Brian Pollard and Brian Dwyer introduced the "relative value" concept. After 30 years, and countless hours of lobbying by Pat Maplestone, Peter Hales, John Lodge, Greg Deacon and others, the Australian Government agreed to adopt the Relative Value Guide so that anaesthesia fees and rebates were determined by the anaesthesia service, and not by what the surgeon did [35].

The 1970s and Beyond

The 1970s also saw the first publication of *Anaesthesia and Intensive Care*. The proposal to publish a Society journal was raised in 1954, but interstate differences caused an 18-year delay. The first editor-in-chief was Ben Barry, and Neville Gibbs is now the fifth. Jeanette Thirlwell has been assistant and then executive editor of the journal since its beginning.

In 1970, the ASA established a permanent secretariat with a full time staff first housed in the offices of the private anaesthetic practice shared by several Sydney anaesthetists. In 1985, the Society moved to its current permanent headquarters in Sydney.

The 1970s and early 80s was a consolidation period for the specialty in Australia and New Zealand. Non-specialist, general practitioner anaesthetists diminished in numbers or vanished, as surgeons, hospitals, and eventually the public, increasingly appreciated the safety and quality of anaesthesia provided by trained specialists. Non-specialists were (and still are) required in remote rural parts of Australia. The Society and Faculty continue to support them with education and advocacy.

Over the 40 years from 1952, the Faculty grew in strength and numbers, as more doctors saw specialist anaesthesia as a fulfilling career. The relationship with the College of Surgeons was a necessary step at the time, and although Kaye dearly wanted an independent College established in 1951, the College of Surgeons provided the specialty with infrastructure and political clout that it would not have had as an indepen-

On the left, standing on wattle, the Australian national flower, is Vesalius with bellows signifying "ventilation". On the right, standing on the New Zealand silver fern, is William Harvey, who described the circulation of the blood. The Latin motto means "to care for the body and its breath of life". (Courtesy Geoffrey Kaye Museum of Anaesthetic History, Australian and New Zealand College of Anaesthetists, Melbourne.)

dent entity. Nevertheless, to many, the subordinate status of the Faculty sustained prejudices established over 100 years. Finally, in 1992, the Faculty separated from the surgeons to become the Australian and New Zealand College of Anaesthetists (ANZCA; Fig. 24.11). In 1994, the College moved to its current premises in Melbourne, a grand Victorian mansion now adjoined by a modern multi-story office building.

The Societies also prospered. They developed co-operative programs with the Faculty and with one another. The New Zealand Society began the first Conference of Anaesthetists of New Zealand (CANZ) in 1978, this becoming a major regular educational event. CANZ soon became a joint venture of the Society and the Faculty. In 1986, the Continuing Education Committee of Anaesthetists of New Zealand (CECANZ) was established as an educational arm of the Society, with a funded Director. CECANZ ultimately embraced the CANZ meeting and other educational meetings, refresher courses, and incident reporting. In 2004, CECANZ was re-

placed by NZAEC, the New Zealand Anaesthesia Education Committee, a formal joint educational program with the Australian and New Zealand College of Anaesthetists.

The NZSA and ANZCA acted to overturn a peculiar “medical manslaughter” law in New Zealand. Under this legal aberration, medical practitioners responsible for the death of a patient might be liable to criminal prosecution for manslaughter, regardless of whether or not the death had been due to negligence. A lengthy and enthusiastic representation finally resulted in passage of the Crimes Amendment Bill in 1997. No longer could doctors be charged with manslaughter after a medical error, unless gross negligence could be proven.

The NZSA has supported anaesthetists in the Pacific islands since the 1970s, and today the ASA is also closely involved. The ASA funded the establishment of the lecturer in anaesthesia at the University of the South Pacific in Fiji, and continues to fund the Pacific Fellowship.

Promulgation of Faculty policy documents was initiated in the 1980s, producing statements defining standards of facilities, training, assistance, and routine monitoring. These lay the basis for anaesthetists to argue for better conditions and facilities for the safe care of patients. Regularly reviewed and updated, such policies have become, by default, the standards by which hospitals and facilities are now judged. In 1987, Bill Runciman and colleagues established the Australian Patient Safety Foundation, placing Australian and New Zealand anaesthetists at the forefront in patient safety. (see History of Patient Safety in Anaesthesia-Chapter 41)

A landmark event for Australasian anaesthesia, was the 1996 staging of the World Congress of Anaesthesiologists in Sydney, hosted by the Australian Society of Anaesthetists. The largest medical congress held in the southern hemisphere up to that time, it attracted some 10,000 delegates.

Anaesthesia in Australia and New Zealand has made enormous strides in the last century. Anaesthetists now play significant roles in Australian and New Zealand health care. Intensive Care Medicine grew from the “hobby” of a few anaesthetists in the 1950s, to a joint specialty faculty of the College of Anaesthetists and the College of Physicians, now an independent College of Intensive Care Medicine. The Faculty of Pain Medicine was a world-first initiative in the training of specialists in chronic and cancer pain, and many hospitals now boast pain units for the management of post-operative and other pain.

Times have changed. In 1927, Kaye described the practice of anaesthesia.

“The care of patients was rudimentary in the extreme. Nobody ever dreamt of paying them a preoperative visit. Anaesthetists and patient met as strangers in the operating theatre. Nobody ever charted blood pressure, pulse or respiration during operations.” [32]

As noted earlier, in 1936 Kaye determined that anaesthesia mortality was around 1:1000. Australian mortality reporting has been amongst the most comprehensive in the world. Although reporting criteria have changed over the years, later mortality reports suggest enormous progress. Holland reported anaesthesia related mortality in 1960 of 1:5,500, reducing to 1:10,250 by 1970. This coincided with many general practitioners voluntarily leaving anaesthesia practice, and junior and untrained medical staff no longer providing the backbone of anaesthetic service. In 1984, the published anaesthesia-related mortality was 1:26,000, and the most recent figures suggest an incidence of less than 1:50,000, including patients classified as “high risk”. [40, 41] Australian and New Zealand anaesthetists take great pride in their achievements.

Summary

The first reported anesthesia in a territory that would become part of Canada (in 1867) was in the British colonial province of New Brunswick, in January 1847. In the late 19th century, Canadian anesthesia was linked primarily with that in the UK, leading to a physician-based practice, which continues to the present. In the early 20th century, US influence increased. By the 1930s a true Canadian identity began to emerge and, in time, to dominate.

The Canadian Society of Anaesthetists formed in 1920, but lapsed in 1929 with the start of the Anaesthesia Section of the Canadian Medical Association. The Montreal Society of Anaesthetists, established in 1930, became the Canadian Anaesthetists' Society (CAS) in 1943. The CAS was renamed the Canadian Anesthesiologists' Society in 1993. The CAS began a medical journal in 1954, an international education fund in 1967, and a research foundation in 1979.

McGill University established the first Canadian academic Department of Anesthesia in 1945, with independent departments evolving in all sixteen Canadian universities over the next 25 years. Important for these departments was the Royal College of Physicians and Surgeons of Canada (RCPSC), established in 1929, which oversaw the education curriculum in all specialty training programs and offered specialty examinations. In 1972, the RCPSC mandated that all specialty training programs operate under the auspices of a university. The Association of Canadian University Departments of Anesthesia (ACUDA) formed in 1976 to support academic departments and research. Canadian anesthesia researchers have contributed to many areas of medicine.

In the 1970s the focus on patient safety became increasingly important, and led to the CAS publishing Guidelines for the Practice of Anesthesia. The CAS assisted in creating and implementing new anesthesia gas machines standards of the Canadian Standards Association.

Since 1972, the Canadian universal healthcare system has provided patients in all provinces with comprehensive health services, including physician services. This unique system allows anesthesiologists (specialist or family-practitioner) to provide anesthesia services for all patients, regardless of their ability to pay.

In the Beginning

Canadian anesthesia began before the four eastern provinces formally amalgamated as the Dominion of Canada on July 1, 1867. Physicians, drugs and techniques from the neighboring United States (US) and the United Kingdom (UK) strongly influenced medical care in the provinces that would become Canada. According to the 22 Jan edition of the *Weekly Chronicle*, St. John, New Brunswick, the first reported anesthetic was on 17 Jan 1847, three months fol-

lowing the successful demonstration of ether anesthesia by William Morton in Boston. A visiting dentist from Boston (Samuel Adams) administered a "vapor of a compound of which aether appeared to form the chief ingredient" to a man to produce "complete sleep and insensibility" for removal of a tumor on his arm [1]. The proximity of St. John to Boston by sea explains how the news spread quickly. Other newspaper reports of the use of ether in Canada in early 1847 have been reviewed, [2] but none antedated that in St. John. A surgeon, Edward Worthington, provided the first medical report of the use of ether in Canada, in Eaton Center, Quebec, on 11 March 1847, describing a below-knee amputation [3]. Worthington was also the first in Canada to report (4 November 1847) the use of chloroform, soon after its introduction into surgical practice by James Simpson in Edinburgh.

Despite the proximity of the US, Canadian medicine in general and anesthesia in particular, were linked primarily to the UK during the second half of the 19th century. Many physicians then in Canada had completed their medical training in the UK before immigrating to a country that was part of

the British Empire. The pioneering anesthesia research in the UK by John Snow (1813–1858) also encouraged the long-term link between anesthesia in Canada and the UK. From the outset and continuing to the present, anesthetic practice in Canada has been physician-based, as in the UK. Although US influences on Canadian anesthesia became stronger by the early 20th century, a Canadian identity evolved and later dominated. This chapter charts the key steps in the development of that Canadian identity.

1899–1920: Origins of Anesthesia as a Specialty in Canada

From 1899 to 1920, anesthesia was performed as a ‘craft’, with a developing empirical base but little scientific evidence to guide its use [4]. Hospital appointments were an important step in recognizing anesthesia as a worthy profession. The appointment, in 1899, of William Hutton as an ‘honorary anaesthetist’ at the Winnipeg General Hospital in Manitoba, marks the beginning of the specialty in Canada [5]. Hutton graduated from the Manitoba Medical College in 1887 and was later appointed as Professor of Practical Chemistry and also Registrar of the College [6]. Other appointments soon followed, most notably William Webster (1865–1934) in Winnipeg, and Samuel Johnston (1869–1947) in Toronto [7]. Webster, born in Manchester, UK, came to Snowflake in rural Manitoba as a school teacher in 1888, then entered the Manitoba Medical College, graduating in 1895. After postgraduate training in Pathology in the UK, he returned to Winnipeg, working in both General Medicine and Pathology. Without further formal training, he began to include anesthesia in his practice, eventually on a full-time basis. In 1905, he was appointed Lecturer on Anesthesia at the Manitoba Medical College. He found that safe anesthesia relies on application of basic physiological and pharmacological principles [8]. His 1924 publication of *The Science and Art of Anaesthesia*, the only comprehensive anesthesia textbook written by a Canadian anesthetist, demonstrated his interests in teaching and research.

Johnston graduated from Trinity Medical College in Toronto in 1901. He began a general medical practice, but turned to full-time work in anesthesia. He later wrote: “I know I was the first physician in Canada to give up general practice and go into the specialty of anaesthesia.” (Personal Communication: Edward Shorter, Hannah Professor of History, University of Toronto. 2012.) Johnston was invited to organize the Department of Anesthesia at Toronto General Hospital in 1904, where he instructed house officers in anesthesia. In 1907, he was appointed Lecturer in Anesthetics in the Faculty of Medicine, University of Toronto. He spent 1908–09 in the UK, acquiring further training before returning to Toronto to his career in anesthesia. He taught medical

students about anesthesia and was probably the first anesthesiologist to do so in Canada. Canada’s ‘formal’ teaching track record in anesthesia therefore goes back to 1910.

Charles LaRocque, at Hotel Dieu Hospital, and William Nagle, at the Royal Victoria Hospital, both in Montreal, Quebec, joined Webster and Johnston as the only doctors in Canada at that time devoting themselves solely to anesthesia [9]. General practitioners, or interns and residents supervised by surgeons (in some of the teaching hospitals), provided much of the clinical anesthesia in Canada. Of interest, Margaret McCallum Johnston (wife of Samuel Johnston) was appointed as the first Chief of Anesthesia at Women’s College Hospital in Toronto in 1914, and is believed to be the first woman to practice anesthesia full-time in Canada.

Webster and Johnson travelled to the UK and the US to observe anesthetic practice, teaching, and the beginnings of anesthesia-related research. Although links to the UK had a greater influence on Canadian anesthesia in the first decade of the 20th century, influences from the US increased after 1910 because of mutual concerns about the quality of basic medical education resulting from Abraham Flexner’s comprehensive report [10]. The report, entitled “Medical Education in the United States and Canada”, transformed medical education in both countries. Academic-based training programs undertaken in Universities replaced the apprentice model, controlled by private practitioners.

Francis McMechan (1879–1939) of Cincinnati, Ohio probably created the most significant US link to Canada, from the late 1910s to the 1930s. Despite severe rheumatoid arthritis, which prevented him from continuing his anesthetic practice, he profoundly affected the organization of anesthesia in the US, Canada, and indeed worldwide. This included the creation of several anesthesia societies, which held annual scientific meetings, and his creation and editorships of both the Quarterly Supplement of Anesthesia and Analgesia of the American Journal of Surgery (1914–26), and Current Researches in Anesthesia and Analgesia, starting in 1922. Through his worldwide contacts with anesthetists, including Webster, Johnston and others in Canada, and Waters in the US, McMechan promoted academic anesthesia, with an emphasis on the link between the basic science laboratory and the clinical practice of anesthesia. Canadian anesthesia benefited greatly from McMechan’s promotion of anesthesia as a valid specialty.

Leaders in the specialty from both countries met regularly, including as the “Anesthesia Travel Club”, formed in 1929. Four of the 14 members at the initial meeting were Canadian—Easson Brown, Charles Robson, Harry Shields and John Blezard.

In 1933, Ralph Waters (1887–1979) was appointed Head of the first autonomous Department of Anesthesia, in Madison, Wisconsin. He created an academic department that pro-

vided exemplary patient care, undergraduate and postgraduate teaching, and quality research. Waters had a major impact on Canadian anesthesia, similar to his influence on American anesthesia.

In the subsequent decades, the scientific foundation for anesthetic practice established by Webster and Johnston, became the base for the evolution of anesthesia in Canada from that of a ‘service-oriented craft’, to a discipline recognized by others, and finally to a specialty based in science.

1920–1929: Canadian Society of Anaesthetists

The Canadian Society of Anaesthetists, Canada’s first formal association of specialists, [11] was founded mainly through the efforts of Wesley Bourne of Montreal as Secretary, and Samuel Johnston as the first President. They were encouraged and assisted by McMechan, who had established several anesthesia societies in the US and who had developed links with anesthesia organizations outside North America. The first annual scientific meeting was held in 1921 at Niagara Falls, Ontario, in conjunction with the Interstate Association of Anesthetists (Ohio, Kentucky), and the New York Society of Anesthetists (the precursor of the American Society of Anesthesiologists). The scientific program included presentations from Canadian, American and British anesthetists. HEG Boyle of London was the Honorary Chairman of the meeting and the Official Representative of the Anaesthesia Section, Royal Society of Medicine. Boyle’s participation demonstrated both McMechan’s far-reaching influence, and the different maturity of anesthesia organizations in the UK and Canada. By 1926, the Canadian society had over 100 members, but in 1928 the society Executive decided to terminate the Canadian society, and transfer its role to the Section of Anaesthesia of the Canadian Medical Association, thereby muting the voice of anesthesia. Although consideration was given in the 1930s to reviving the Society, no action was taken [6].

1930–1943: Montreal Society of Anaesthetists

The Montreal Society of Anaesthetists was established to facilitate interactions between and support French and English-speaking Montreal anesthetists. Its national importance emerged in 1943. Five members of the Society, with the support of colleagues in Toronto, applied to have the Society formally converted into a national entity – the Canadian Anaesthetists’ Society. The applicants were Wesley Bourne, Harold Griffith, M. Digby Leigh, Georges Cousineau, and Romeo Rochette.

1943: Canadian Anaesthetists’ Society (CAS)

A Memorandum of Agreement of 27 May 1943, signed by the five anesthetists, established the objectives of the new society, objectives that remain in place today:

“To advance the art and science of Anaesthesia and to promote its interests in relation to Medicine with particular reference to the clinical, educational, ethical and economic aspects thereof, to associate together in one corporate body members in good standing of the Medical Profession who have specialized in this particular science, to promote the interest of its members, to maintain a Society Library and Bureau of Information, to edit and publish a journal of Anaesthesia, to acquire and own such property and real estate as may become necessary to effectively carry out the purposes of the Society, and to do all such lawful acts and things as may be incidental or conducive to the attainment of the above Objects.”

On 24 June 1943, the Office of the Registrar General of Canada signed the Letters Patent confirming registration of the CAS in Canada as a “Body Corporate and Politic”. Canadian Anesthesia again had its own voice and this time had no intention of relinquishing it. The CAS office was initially sited in Montreal but moved to Toronto in 1946, where it remains. The CAS grew to its present size of 2000 members across Canada, with Divisions in each province. There are now 12 sub-specialty Sections within the CAS, reflecting expansion of modern anesthetic practice beyond the operating room, and advances in anesthesia for specialist surgical interventions. The Society name was changed to the Canadian Anesthesiologists’ Society in 1993. Although never officially recognized as such, the adoption of the US term anesthesiologist and the elimination of the diphthong (‘ae’) indicate the shift away from the early primary links of Canadian anesthesia with the UK. While a full description of CAS activities exceeds the scope of this summary, three Society programs deserve note, as do CAS roles in the World Federation of Societies of Anaesthesiologists (WFSA).

1954—Canadian Anaesthetists’ Society Journal

The Founders’ vision in 1943, that the Society publish a “journal of Anaesthesia”, was fulfilled in July 1954 with the first issue of the Canadian Anaesthetists’ Society Journal. The quarterly publication was distributed to the 500 Society members and a small number of subscribers. The first editor, Roderick Gordon of Toronto, held that post for 28 years (1954–1982). While the content initially consisted of papers presented at national and regional meetings in Canada, the Journal soon attracted manuscripts and subscribers from outside Canada. By 1961, 25% of the content originated from the US. In time, an increased volume of submissions prompted the publication frequency to increase to bi-monthly and then monthly. The title change in 1987, to *Canadian Journal*

of *Anaesthesia/Journal Canadien d'Anesthésie*, reflected the expanding international nature of submissions and readership. From the first issue, articles have been published in English or French, according to the language of submission. The inclusion of international Editorial Board members and Guest Editors also indicates the evolution of the Journal to a member of the international community of anesthesia journals.

Gordon (1911–1998) deserves recognition beyond his role as journal Editor. Within the CAS, he served as Secretary-Treasurer from 1946 to 1961, and President in 1963–64. He received the CAS Gold Medal in 1969. He was Professor and Head of the University of Toronto Department of Anesthesia from 1961 to 1977. The Dr. R.A. Gordon Research Award of the CAS continues to honor the man who influenced Canadian Anesthesia for decades.

1979: Canadian Anesthesia Research Foundation (CARF)

CARF was established as the Canadian Anaesthetists' Society Research Fund. The CAS Research Fund became the CARF in 1992, without changing its basic structure and mission. CARF is a Registered Charity in Canada and supports the Research Awards Program of the CAS. Led by a founding Trustee, Gordon Sellery of London, Ontario, CARF's resources grew until it could fund the first annual award in 1985, assisted by the CAS and its Journal. This award became a catalyst for additional awards in the CARF/CAS awards program, supported either by CARF or external sources. With total annual awards exceeding \$200,000, the CARF/CAS Program has become the largest provider of funds for Canadian anesthesia research, increasing from one award in 1985, to 12 in 2005 [12]. CARF supported 3 of the 12 awards in 2005, the remainder being externally funded. The seed planted in 1979 with the start of CARF grew to a single tree in 1985—and a small forest by 2005! The review also noted the important role of CAS new-investigator awards, [12] as the first step in successful long-term research careers of Canadian anesthetists. By 2012, the cumulative number of awards from the CARF/CAS Program had increased to more than 200—with the Program being the primary source of funding for new anesthesia investigators in Canada.

1967: CAS International Education Fund (IEF)

The IEF was established as the CAS Anaesthesia Training and Relief Fund, a Registered Charity, in response to a 1964 challenge from the WFSA for national societies to make modern anesthesia available worldwide. The Fund, led by

Rod Gordon, initially supported Canadian involvement with overseas training programs, principally in Nigeria, as well as supporting foreign trainees' short-term learning experiences in Canada. In 1993, the Fund was renamed and took on the mission of assisting anesthesia providers in developing countries to establish self-sustaining programs relevant to each country's needs. Canadians have helped Nepalese anesthesiologists, over a period of 15 years, to develop a training program in Katmandu. More recently, the main focus has been on a training program in Kigali, Rwanda. The Fund has also arranged visits by Canadian anesthesiologists to Ethiopia and Madagascar. The 1964 WFSA challenge continues to be recognized.

CAS and WFSA: 1955–2012

Harold Griffith of Montreal, the first CAS President (1943–1946) was elected in 1955, as the Founding President of the WFSA. (A fuller account of his WFSA roles can be found in Chapter 20). The second World Congress of Anaesthesiologists (WCA) was held in Toronto in 1960, and the 12th in Montreal in 2000. From the outset, Canadians have supported the WFSA through the CAS and through individual participation within the WFSA structure and at World Congresses. Angela Enright of Victoria, British Columbia, served as the WFSA President from 2008–2012, leading the WFSA component of the Lifebox pulse oximeter initiative. She was awarded the Order of Canada, the highest civilian honor, in 2010, and in 2012 was a recipient of the Queen Elizabeth II Diamond Jubilee Medal in Canada and the American Society of Anesthesiologists (ASA) Nicholas M. Greene Outstanding Humanitarian Award.

University Departments of Anesthesia (starting in 1945)

Anesthesia slowly became an autonomous academic specialty recognized by universities in Canada. Although Webster and Johnston were lecturers in anesthesia in Winnipeg (Webster) and Toronto (Johnston), their appointments were within the Department of Surgery (Webster) and Therapeutics (Johnston). The 1945 appointment of Wesley Bourne as Chair of the autonomous Department of Anaesthesia at McGill University was a key factor in the advancement of academic anesthesia in Canada. The McGill Department followed the creation of the first ever university anesthesia department in 1933, in Madison Wisconsin (Ralph Waters, Head), and the second in 1937 with the appointment of Robert Macintosh to the Nuffield Professorship of Anaesthetics at Oxford University. The founding of the McGill department deserves special recognition, both because it represent-

ed establishment of the first academic anesthesia department in Canada, and because it provides the opportunity to recognize three key members of the new department – Wesley Bourne, Harold Griffith, and Digby Leigh.

Bourne (1886–1965), the first Head at McGill, was nearing the end of a distinguished career. He had been an outstanding clinician, teacher, and investigator, holding an appointment in the McGill Department of Pharmacology. His honors included the first Henry Hill Hickman Medal of the Royal Society of Medicine, the first Gold Medal of the Canadian Anaesthetists' Society, and the 1942 Presidency of the American Society of Anesthetists (renamed the American Society of Anesthesiologists in 1945). Bourne was the only non-American ever to hold this position. An endowed Chair at McGill and the annual Dr. Wesley Bourne Lecture continue to honor this man.

Griffith (1894–1985) is best known for the first clinical use of curare in 1942, but his contributions to anesthesia at McGill (Head 1951–56), nationally and internationally, were broadly based and extraordinary [13]. An outstanding clinician and teacher, he made major contributions to the development of anesthesia organizations in Canada and beyond. He served as the first CAS President, as Chair of the Board of Trustees of the International Anesthesia Research Society (IARS), and as Founding President of the WFSA. Honors included the Hickman Medal, the 1959 Distinguished Service Award of the ASA, the CAS Gold Medal and appointment as an Officer of the Order of Canada. Griffith was also recognized in 1991 with a commemorative Canadian postage stamp bearing his image.

Leigh (1904–1975) was a University of British Columbia (UBC) undergraduate and a McGill medical graduate, who began training in surgery in Montreal, but was convinced by Bourne to change to anesthesia. He trained at the University of Wisconsin under Waters, returning to Montreal as a Research Fellow in Pharmacology, before becoming Head of Anesthesia at the Children's Hospital. He and Bourne established a two-year course in anesthesia at McGill, accepting candidates following a year of internship. Leigh elected to return to UBC, and later moved to Los Angeles Children's Hospital in California, where he developed a major pediatric anesthesia training program and remained as Chief for several years. In 1948, Leigh and Kathleen Belton authored *Pediatric Anesthesia* one of the first major pediatric anesthesia texts.

The University of Toronto Department became the second Canadian University Department in 1951. On 14 May 1951, in a letter to the President of the University, Dean MacFarlane of the Faculty of Medicine articulated the rationale for recommending an autonomous academic department of anesthesia: “anaesthesia has made considerable advances in the past 15 years” and “there is constantly a search for new methods of inducing anaesthesia which constitutes greater

measures of safety in seriously ill and injured patients”. The importance of establishing an independent body of knowledge as the basis for the specialty was recognized, and patient safety became a focus for the growth of anesthesia in other Canadian Universities. However, it took another 20 years to place independent departments in all 16 Canadian Faculties of Medicine.

The Royal College of Physicians and Surgeons of Canada (RCPSC)

Unlike other international colleges and boards, the RCPSC accredits training programs and examines candidates in all medical and surgical specialties. In addition, since 1974, the RCPSC has required all Canadian specialty training programs to be university-based and accredited by the RCPSC. Accreditors include anesthesiologists, who also review programs in Surgery, Internal Medicine, and the many sub-specialty programs. The RCPSC requirements have strengthened postgraduate medical educational programs across Canada.

The RCPSC was established in 1929 with a different mandate to that existing today. As originally designed, it provided a Fellowship diploma for physicians to confirm competence in special work. Initially, a limited number of these were conferred without examination, on physicians in academic posts. However, from 1931, the Fellowship has been awarded by examination. Regardless, from its inception, Fellows were expected to be grounded in basic sciences and in general medicine and surgery. The Fellowship, to quote, was “the hallmark of the academic man” and thus at that time was an academic qualification rather than a confirmation of specialist competence.

In the 1930s, about one third of Canadian physicians performed some form of specialist work, without holding a RCPSC Fellowship. Many physicians wanted recognition for their specialty, but not by means of the Fellowship. The RCPSC responded by creating an added RCPSC Certification program. Certification requirements were less rigorous than those for the Fellowship, but did confirm specialist status. Initially, Anesthesia was not one of the specialties recognized by Certification.

During the 1930s, anesthetists in Canada had other major issues to deal with. Many were salaried hospital employees while others were remunerated on a fee for service basis. Another concern was the emerging possibility of a National Health Insurance Program. These concerns, arising mainly in Montreal and Toronto, caused the Royal College to agree in 1942 to include Anesthesia in the Certification program.

However, the two-tier recognition of specialists, in all specialties, as either Fellows or Certificants, created further conflict within the College. A single standard of training and

examination, leading to a single qualification resolved this issue in 1971. The new form of specialist certification opened the way for Fellowship to all successful candidates, leading therefore to full membership in the RCPSC. In particular, this meant that the status of anesthesia was now the same as that for other specialties in Canada. Anesthesia candidates are certified in the RCPSC Division of Internal Medicine, not Surgery. This recognized that anesthesia residencies (requiring four years of clinical training after completion of internship), include one year of internal medicine, with an emphasis on intensive care.

The RCPSC enhanced independent Canadian-based research at the graduate level, by recognizing a Clinician-Investigator training program (CIP) in 1995. This program gave all residents access to funding and encouragement to undertake graduate research training as part of their fellowship. Prior to this program, no funding was available to support such research training during residency, and most anesthesiologists seeking research experience went abroad after their residency. This vital part of postgraduate education now allows residents to develop research skills during their residency, helping them to become successful career clinician scientists.

1976: Association of Canadian University Departments of Anesthesia (ACUDA)

A 1975 meeting instigated by Stuart Vandewater, then Chair of Anesthesia at Queen's University in Kingston, Ontario greatly advanced Canadian academic anesthesia. Previously, anesthesia department heads had met only informally. The Kingston retreat included representatives from all university departments of anesthesia, the RCPSC, the Medical Research Council of Canada and the Canadian Anaesthetists' Society. This hallmark meeting led to the formation of ACUDA, in June 1976. ACUDA's bylaws/goals caused academic anesthesiologists in Canada:

- To affiliate in a single organization, representatives of all Canadian University Departments of Anesthesia.
- To develop and promote undergraduate, postgraduate and continuing education by Canadian University Departments of Anesthesia.
- To advise in the training of allied health personnel as it relates to anesthesia.
- To promote the development of research and scientific progress in anesthesia.
- To represent the academic departments of anesthesia and to promote their interest within professional and learned societies, advisory boards and councils to government or public service organizations.

- To promote exemplary patient care and advise responsible bodies on matters concerning the standards of anesthetic practice.
- To support the interests of the profession through the objectives of the Canadian Anesthesiologists' Society.

ACUDA differed from the previous conference of department heads, in that it comprised all elements of the academic departments, rather than just department heads. Standing committees considered issues in undergraduate and postgraduate education, research, and departmental management.

Throughout this period it was essential that ACUDA and the Canadian Anesthesiologists' Society had a consistent and cooperative partnership. Emerson Moffitt, Department Head at Dalhousie University, Halifax Nova Scotia noted: [14] "the Society has many aims and functions but the responsibility for survival and development of academic anesthesia ultimately rests with the 16 University departments". During the 1990s, ACUDA provided a forum for the specialty to address human resource needs specific to anesthesia in Canada. The planning model used, [15, 16] allowed the specialty to lobby the government and universities in promoting the case for more providers.

Patient Safety and Quality of Care

In the 1960s and 1970s, anesthesia-related mortality of perhaps 1 in 5000 attracted the highest Canadian Medical Protective Association (CMPA) liability fees of any specialty in Canada. Following publication by the Canadian Anesthesiologists' Society, of the "Guidelines for the Practice of Anesthesia" in 1977, [17] Canadian anesthesiologists performed outcome studies in many institutions across Canada [18]. Reviewed annually, expanded, and renamed, the Guidelines are now published in an accessible on-line format [19]. Mortality has decreased to approximately 1 in 200,000 and anesthesia now has among the lowest CMPA fees.

Canada became the first country to have a comprehensive standard for anesthetic machines. The Canadian Standards Association published this in 1978 as a preliminary standard, followed in 1980 by the definitive standard [20]. Preceding the preliminary standard by one year was the June 1977 "Advance Standards Information" bulletin, sent to all Canadian hospitals. The stimulus for the bulletin, and for the publication of the preliminary standard, was the simultaneous presence in Canada of anesthetic machines of UK origin (oxygen as the left side flowmeter) and US origin (oxygen as the right side flowmeter). The new Standard, in addition to a number of other safety enhancements, required 'oxygen right'. In time, all clinical anesthetic machines met the new standard.

The importance of a national Guideline for the Practice of Anesthesia was further established when pulse oximetry and capnography were introduced into clinical practice. The CAS-approved Guidelines made these monitors de facto standards. This document supported efforts by anesthesia leaders, mandating that hospitals purchase this equipment to provide safe care. Later, the Guidelines dealt not only with technical aspects of monitoring equipment, but also the professional qualifications of providers, and eventually the role of members of the anesthesia care team appropriate to ensure patient safety.

In 1995, anesthetists developed Canada's first high-fidelity simulation-based education facility at the University of Toronto and Sunnybrook Health Sciences Centre. This was the third such centre in North America (after Stanford and Harvard Universities). Anesthesiologists from both Harvard and Stanford contributed their time and experience to train Canadian anesthesiologists in this emerging educational tool, and collaborated in research projects.

Research

Canadian research in anesthesia began in the 1920s and 1930s. Bourne had a faculty appointment in Pharmacology at McGill and was one of the early anesthesiologists to teach and conduct research. In Toronto, practicing physician Easson Brown, worked with George Lucas and Velyien Henderson to develop cyclopropane as an anesthetic agent. Henderson volunteered to receive cyclopropane in Lucas and Henderson's laboratory at the University of Toronto. In a later demonstration in the same laboratory, attended by members of the local anesthetic community, [21] the volunteer was Frederick Banting (later Sir Frederick Banting), who along with John Macleod received the 1923 Nobel Prize in Medicine for their discovery of insulin. This auspicious history notwithstanding, several unfortunate anesthesia-related deaths in Toronto and a fear of explosive agents led Samuel Johnston to forbid the use of cyclopropane on patients in Toronto. International relationships proved important, and the agent was supplied to Waters who introduced it into clinical practice.

In January 1942, Harold Griffith, and anesthesia resident Enid Johnson introduced curare into clinical practice at the Homeopathic Hospital of Montreal, publishing their results in the July edition of *Anesthesiology* [22]. They reported the use of Intocostrin (Purified Extract of Curare, Squibb) during 25 general anesthetics for a range of procedures from minor (curettage of the uterus, hemorrhoidectomy) to major (laparotomy, nephrectomy). This demonstration that curare could be used "safely" (although no reversal of blockade was done) was a major step forward and clinical anesthesia was forever changed for the better. Johnson moved to Dalhousie

University in Halifax after completing her training, and eventually became a Professor in the Department of Physiology at Dalhousie.

Research by pharmacologist Werner Kalow, at the University of Toronto, provided the first evidence of the importance of pharmacogenetics in anesthesia, with the discovery of the genetic basis for atypical plasma cholinesterases [23]. Later, in collaboration with clinical anesthesiologist Beverly Britt, Kalow described the genetic basis for malignant hyperthermia [24].

However, until the late 1960s or early 1970s, less research took place in anesthesia than in other specialties, such as internal medicine. At the Vandewater meeting in 1975 in Kingston, the head of the Medical Research Council of Canada, Malcolm Brown, pointed out that if Canadian anesthesiology were to produce research, they would have to do what other specialties had done: institute 'practice plans' that would free up time, allowing faculty to do research (protected time), and support investigators' training after the RCPSC fellowship. This launched research in many Canadian departments, and created a career path for the graduates of Clinician-Scientist training programs into the future.

Considerable input into the development of anesthesia came from other University departments. For example, Mark Nickerson (Pharmacology) and Reuben Cherniak (Internal Medicine) in Manitoba, promoted a 1963 report on anesthesia [25] at the University of Manitoba by Robert Dripps of the University of Pennsylvania. Dripps recommended establishing a University Department of Anesthesia (done in 1967) and pointed to the potential for anesthetists to do clinical research, a point he had made many years earlier [26]. Also at that time, with the advent of cardiac surgery and the advances in respiratory medicine, some anesthesiologists began to work in critical care medicine. Barry Fairley (anesthesia) in Toronto, and Cherniak in Winnipeg, were instrumental in this. Fairley worked with a pulmonary physiologist, Charles Bryan, recruited to the Department of Anesthesia in Toronto, on a series of classic experiments on lung volumes (FRC) and positive end-expired pressure (PEEP). Many clinical anesthesiologists trained in research with "Charlie", and this experience led to the elucidation of many important concepts that are still fundamental to clinical practice – including diaphragmatic function during anesthesia, [27] and mechanical ventilation using high frequency oscillation [28].

Alan Conn (1925–2010), Chief of Anesthesia at the Toronto Hospital for Sick Children (1960–71), recognized the need for a pediatric intensive care unit with specifically trained anesthesiologists. Conn followed in the footsteps of Charles Robson [29] (1884–1969), recognized as the "Father of Pediatric Anesthesia" (see chapter 65 on Pediatric Anesthesia for details). From 1971 to 1981, Conn directed the Intensive Care Unit. He was committed to both education

and research, and established the Dr. Alan W. Conn Lecture-ship in Pediatric Anesthesia and Critical Care in 1986.

At that time many young Canadian anesthesiologists went to the US for further research training at the University of California, San Francisco (UCSF), Boston, and the University of Washington. Their return stimulated research in many Canadian departments of anesthesia. Beverley Orser, who completed her PhD in neuroscience following her anesthesia fellowship, demonstrated benefits of training Canadian anesthesiologists as Clinician Scientists. Her studies in the basic molecular mechanisms of anesthesia were recognized in 1995, by the first "Frontiers of Anesthesia" research award (\$500,000) from the International Anesthesia Research Society. She was the first anesthesiologist to receive a Canada Research Chair, in 2003, under a Government of Canada program recognizing research excellence. Her success demonstrated that anesthesia had become a specialty in Canada which could train Clinician Scientists at the highest level. Graduate programs which were recognized by the Royal College in their Clinical Investigator Program, were established within the university departments to support such graduate level training for anesthesiologists.

In the 1970s, recognizing a growing clinical need in obstetrical units, especially in large hospitals, several Canadian anesthesiologists pursued obstetrical anesthesia fellowships in the US. In 1979, following the lead of the Society of Obstetrical Anesthesiologists and Perinatologists (SOAP) established in the US in 1968, several obstetrical anesthesiologists in Canada convinced the CAS Executive to create an Obstetrical Anesthesia section, the first subspecialty Section within the CAS. The Section arranged an Obstetrical Anesthesia clinical session at each CAS Annual Meeting and assisted members in research strategies and ways to improve obstetrical anesthesia in their individual hospitals. Following on the creation of this section, other anesthesiologists formed sections devoted to the anesthesia care of cardiac, neurosurgical, and pediatric patients. Today there are 12 such sections, which help the CAS to provide an Annual Meeting with excellent research and sub-specialty educational activities.

Clinical Anesthesia Across Canada

Canada is the second largest country in the world (after Russia) with a land mass of 3.8 million square miles, but a population of only 34 million. This is roughly 10% of the US population and 40% of the UK population. Although most Canadians live within 100 km of the US border, many are in rural and remote areas, some accessible only by air. Delivery of health care, including anesthesia services, presents major challenges as a result. Canada's universal healthcare system (Medicare) has been in place in all provinces and territories

since 1972. The federal Canada Health Act (1984) provides the basic guidelines for the Canadian Medicare system (universality, comprehensiveness, accessibility, portability, public administration), but the actual delivery of healthcare is the responsibility of the ten Provinces and three Territories.

Because of the geographic challenges and the requirement for physician-based anesthetic delivery, specialist anesthesiologists (see RCPSC section) or Family Physicians (FPs) with advanced training in anesthesia, provide all anesthetic services. The training of FP anesthesiologists has evolved over the years. In 2002, the College of Family Physicians of Canada (CFPC) formally accredited anesthesia for a third year of family medicine training, with a specified training curriculum within any of the 16 university Anesthesia departments.

The university departments of anesthesia and the CAS provide programs for ongoing anesthesia education for all practitioners in Canada. Anesthesiologists have become major contributors to patient care outside the operating room. In common with other countries, many Canadian departments now include "Perioperative Medicine" in their official titles. Many obstetrical wards have had anesthesiologists in-house providing epidural analgesia during labor, as well as anesthesia for patients undergoing elective and emergency cesarean sections. In the past two decades, pre-operative assessment clinics have been widely established. Management of both acute post-operative pain and chronic pain has become a special area of expertise. In all these areas, nursing staff and more recently physician assistants have allowed anesthesiologists to assume a supervisory role, helping reduce physician manpower requirements.

The Canadian Anesthesia Identity

The combination of the physician-based provider model from the UK, and the university-based clinical training system originating with Waters in the US, has resulted in a uniquely Canadian entity, operating within Canada's universal Medicare system and adapting to the geographical and political health service delivery challenges of Canada. It led to the development of the Canadian identity.

The CAS 'Guidelines for the Practice of Anesthesia', first published in 1977 was many years ahead of those of other nations, and improved the outcomes of anesthesia, while decreasing liability insurance premiums.

Until the 1960s, some anesthesiologists worked as hospital employees, but with the introduction of universal Medicare in the late 1960s and early 1970s, anesthesiologists became independent contractors. Since healthcare was a provincial/territorial responsibility, fees were negotiated separately in each province or territory. Initially, fees were less than attractive, but with time, they increased to levels of appropri-

ate remuneration. In many university departments, anesthesiologists organized into groups to provide opportunities for research, education and subspecialty clinical careers.

Reflecting the breadth of their clinical work, Canadian anesthesiologists accepted management positions in intensive care units, obstetrical care, pain clinics and other areas. Anesthesiologists became Vice Presidents of Medicine, Chiefs of Staff, and Chief Executives Officers of major health regions and hospitals, Deans of Faculties of Medicine, and Deputy Provincial Ministers of Health. Anesthesia has provided leaders in many of the medical associations at the Provincial and National level. They were instrumental in the 2003 formation of the Canadian Patient Safety Institute (CPSI), with John Wade of Winnipeg, Manitoba as the Founding Board Chair. Wade also had a major role in the early 1990s development of the Can Meds (Canadian Medical Education) system, by the RCPSC, which led to a revolution in the teaching of medicine at the undergraduate, postgraduate, and continuing education levels in Canada. Anesthetists have served as Registrars of provincial Colleges of Physicians and Surgeons, which regulate the medical profession, and as elected Presidents of the Colleges.

Over time, anesthesia emerged as a leading specialty in Canada and internationally, with leaders in research, education and patient care. The key factor in this evolutionary process was the development of a professional identity. Professionalism has been referred to as “the presence of individuals who have acquired knowledge by means of training and study and desire to pass on that knowledge to others” [30]. Combining the physician-based model from the UK with the positive influence of University-based departments of the US facilitated the development of the Canadian identity.

The History of Anesthesia in Mexico, the Caribbean Islands, and Central America

26

Estela Melman

Summary

Mexico and Cuba rapidly adopted anesthesia following Morton's 1846 demonstration, and US and Mexican forces used ether in the Mexican-American war in 1847. Ether was used in Cuba and Guatemala in 1847, but not until 1861 in the Dominican Republic, 1875 in Panama, and 1889 or later in El Salvador, Nicaragua, and Costa Rica. Surgeons in Cuba used cocaine for topical and local anesthesia in 1884. Spinal anesthesia appeared from 1899 (Mexico first) to 1910 in Mexico, Cuba, Guatemala, El Salvador, Nicaragua and Panama. At the Hospital General de Mexico from 1905 to the mid-1920s, Vázquez found a mortality of approximately 1:1,500 with spinal anesthesia and 1:440 with chloroform. In 1946, Cuban, Manuel Curbelo, performed continuous lumbar epidural anesthesia. Vicente García Olivera created the first center for pain treatment in 1948, in Mexico. Keith Holder followed, in Panama in 1975. In 1956, Mexican anesthesiologists assumed responsibility for obstetric anesthesia.

Tracheal intubation arrived in the 1930s–1950s in Cuba, Mexico, El Salvador, and Panama. Short-acting barbiturates, were adopted in the 1930s in Mexico, Cuba, Guatemala, and El Salvador while curare and succinylcholine came into use in the 1940s–1950s in every country. After Michael Johnstone's 1956 demonstration (Mexico), halothane rapidly replaced ether and cyclopropane throughout the region. Sevoflurane, given in oxygen, displaced halothane and isoflurane in most Central American countries in the 1990s. Desflurane appeared in a few countries (e.g., Panama and Mexico) at this time.

The Society of Anesthetists of Mexico developed in 1934, and societies formed between 1950 and 1993 in the remaining countries. The Mexican Society published a journal in 1951 (the second in Latin America), but except for the Cuban Society (which developed a journal in 2001) other societies were too small to publish a bulletin or journal.

Institution of specialty training in anesthesia roughly paralleled the development of societies, beginning in Mexico in 1957. 1974 saw the creation of the Mexican Board of Anesthesia. Residencies currently last for 3–4 years. Of all the countries in this region, only Mexico and Panama have recertification programs (every five years).

Initially, surgeons administered most anesthesia in Central America, but the shortage of physicians dictated that nurses and technicians also performed this task. Increasing numbers of anesthesiologists appeared after 1950, leading some countries to limit delivery of anesthesia to physicians: Panama, in 1971; Cuba, after 1978; and Mexico, 1998. Dominican Republic anesthesiologists currently provide anesthesia in even the smallest villages. Technicians still give most anesthetics in Guatemala, Honduras, El Salvador, and Nicaragua.

A Historical Perspective

Before Europeans came to North and South America, Mexico and neighboring countries were home to advanced Meso-American cultures. From the 1519–1521 Spanish conquest to Mexico's independence in the early nineteenth century, this region was part of the Viceroyalty of New Spain, embracing Mexico, the Spanish Caribbean Islands and Central

America as far South as Panama. A viceroy residing in Mexico City and appointed by the Spanish monarch administered the Viceroyalty.

Following the Mexican declaration of independence in 1810, protracted countrywide fighting erupted until independence was won in 1821. War left Mexico in disorder, but slowly Mexicans rebuilt the social and political infrastructure needed to support a republican government. The US invasion of Mexico in 1846 interrupted this process. Adding further to disorder and disarray, in 1848, Mexico was forced to cede California, Arizona, Nevada, New Mexico, Utah, Colorado, Wyoming and Texas to the US.

While under Spanish rule, Central America was a colonial backwater and lagged economically and culturally behind Mexico. However, fortunately Central America was spared the bloody wars that characterized the independence movements of Mexico and Spanish South America, and in 1821, Costa Rica, El Salvador, Guatemala, Honduras and Nicaragua proclaimed their independence from the Spanish Crown. In 1823, these five countries transiently formed the United Provinces of Central America, dreaming that they might achieve a united and prosperous independent Central American nation. This dream ended in 1841 when the five countries split apart. In 1821, the Dominican Republic gained its independence from Spain. However, Cuba remained a Spanish territory until 1898 when the US defeated Spain in the Spanish-American War. Cuba gained its independence from the US on 20 May 1902.

Mexico

Anesthesia Begins in Mexico

Anesthesia began in Mexico during the Mexican-American war [1]. Edward Barton, a University of Pennsylvania graduate, and surgeon to the 3rd Dragoons Cavalry Brigade, Twiggs Division, wrote to Thomas Lawson, US Surgeon General, in December 1846, citing Morton's recent demonstration of ether anesthesia. He urged Lawson to use Morton's agent for the relief of surgical pain in wounded soldiers. At President Polk's request, Barton joined General Winfield Scott in Veracruz, in February 1847 during Scott's siege of the port city. On March 29, 1847, Barton administered the first ether anesthetic in Mexico. A German teamster had accidentally discharged his musket, shattering both of his legs. On March 28, one leg was amputated, but the patient cried so intensely that amputation of the other leg was postponed. The next day, Barton, assisted by doctors Harney, Porter, and Laub, used ether during the amputation, administered with an apparatus that Barton had brought from the US (probably similar to Morton's). Barton described it as a complete success [1]. The patient became insensitive to pain and "the limb was removed without the quiver of a muscle."

Barton taught his aides, including John Porter who chronicled medical aspects of the Mexican-American war, including how to administer ether anesthesia [2]. Porter in turn, taught ether anesthesia to his Mexican counterparts, including Pedro Van der Linden, surgeon in chief to the Mexican Army (Fig. 26.1). During the Cerro Gordo's battle (Jalapa, Mexico), Van der Linden gave ether anesthesia to wounded Mexican soldiers. "Occasionally the physicians on both sides engaged in actual fighting, but more often they were kept busy, first attending their own compatriots, then the

Fig. 26.1 Pedro Van der Linden (standing), Surgeon in Chief to the Mexican Army, after performing his first amputation in a patient anesthetized with ether. Two soldiers hold the wounded soldier, perhaps still asleep (second from left), and a third soldier holds the amputated limb. This daguerreotype copy was taken at the Battle of Cerro Gordo, 18 April 1847 from reference 3 with permission from the publisher. (Courtesy of *Gaceta Médica de México*)

wounded enemy. The rule, rather than the exception, was that gallant and noble gestures were displayed by physicians on both sides" [2, 3]. The use of ether spread to other cities. On June 15 1847, Jose Sansores used it successfully for an upper limb amputation in Merida, Yucatan [4].

Pablo Martinez del Rio introduced ether into Mexico in 1848 (for general and obstetrical surgery), and then introduced chloroform in 1849. Years later (1878), he reported his experiences with chloroform in obstetric anesthesia [5]. He supported the use of chloroform anesthesia during general surgery, but advised against it in obstetrics in order to avoid massive blood loss and death, particularly in uterine dystocia. He suggested that it should be used only to achieve analgesia: "More than one mishap could have been avoided if the parturient would not have been under the influence of chloroform."

Fernando López Sánchez, a surgeon and ophthalmologist in the armed forces, was trained in Paris. In 1886, he returned to Mexico and began using cocaine topically, for superficial ocular surgery. During the 1890s, to avoid the use of general anesthesia with chloroform, he described a technique in which he injected 1% cocaine around the eyeball to perform enucleations and other major procedures [6].

In July 1900, in Oaxaca, Mexico, following a description published by Theodore Tuffier in 1899, Ramon Pardo used 15 mg cocaine hydrochloride injected at the 5th lumbar interspace to produce spinal anesthesia for amputation of a leg. He used a Pravaz syringe and a 9 cm long needle designed by

Fig. 26.2 Examples of the metal frames that were used to support the gauze onto which ether and chloroform were dropped. Two examples of the drip bottles used to deliver ether or chloroform also are shown. Table 26.1 Anesthetics Given at the Hospital General de Mexico, 1905–mid-1920s

	Number of Cases	%
Spinal anesthesia with cocaine	9452	100.00
Spinals completed with chloroform	687	7.27
Failed spinals	661	6.99
Deaths related to spinal anesthesia	6	0.06
General anesthesia with chloroform	8372	100.00
Cardiac arrests during chloroform	18	0.19
Deaths related to chloroform	19	0.22
Mixed anesthetics	401	
General anesthesia with ether	307	
Anesthesia with ethyl chloride	80	

Tuffier to obtain cerebrospinal fluid and inject the cocaine, achieving excellent anesthesia without side effects [7–9].

Bandera reported [10] that in the early 1900s, the most common anesthetic techniques used by surgeons in Mexico were local/topical anesthesia with cocaine for ophthalmic surgery, ethyl chloride for incision and drainage of superficial abscesses, and chloroform or spinal anesthesia for general surgery. Ether was reserved for very sick patients only. The consensus among surgeons was that chloroform was a potent and “toxic” anesthetic that could kill the patient instantly, or in the immediate postoperative period, by producing profound depression leading to coma, anuria and death [11, 12]. They considered that ether was a “safer” anesthetic, and was better tolerated than chloroform by sick patients [12]. Induction was said to be more pleasant with chloroform, which explains its continued use. However, they concluded that “it is about time to discard chloroform, but unfortunately we are immersed in a

Fig. 26.3 The ether inhaler designed by Louis Ombrédanne in 1908. (Courtesy of the Wood Library-Museum of Anesthesiology, Park Ridge, IL)

tight routine of spinal and chloroform for all patients....” Ether was available.

To deliver chloroform, a gauze mask was used. A similar mask could be used for ether, or alternatively, a Fowler, Clover or Allis’s mask or inhaler (metal frame, covered with leather and containing a folded cloth to absorb the ether) [13]. A dropper (Fig. 26.2) was also required, together with a mouth opener, and forceps to hold the tongue in case of a sudden respiratory arrest. Caffeine and strychnine were used to treat cardiac depression manifested by bradycardia and “cerebral anemia” (loss of consciousness or profound depression), and adrenalin was used for accidents occurring during spinal anesthesia. A report of anesthetics given at the Hospital General de Mexico, shows the greater popularity of spinal anesthesia (Table 26.1) and its lower mortality ($p < 0.0001$ —chi square analysis) [12].

In addition, the author compared the mortality occurring in the US at the time, with the same anesthetics: chloroform 1 death/2,500, ether 1/16,000 and nitrous oxide 1/200,000 cases [12].

In 1908, Louis Ombrédanne described an anesthetic apparatus for the simple delivery of ether anesthesia (Fig. 26.3), popularizing its use [14]. Nitrous oxide anesthesia, and carbon dioxide absorbers were introduced in the 1910s and 1920s respectively [10].

In 1932, Federico Vollbrechthausen, a trainee from the Mayo Clinic, came to Mexico to practice anesthesia, bringing ethylene, cyclopropane, and a closed circuit apparatus for their administration. He brought hexobarbital (later replaced by thiopental) for intravenous use, and procaine for spinal and local anesthesia. In 1941, an American thoracic surgeon, Leo Eloesser, and his anesthesiologist colleague William Neff, a former pupil of Ralph Waters, came to Mexico City to demonstrate thoracic surgery and anesthesia at the Hospital

for Tuberculosis Diseases. Neff used tracheal intubation and controlled ventilation with a closed circuit apparatus [15]. Jorge Terrazas and Martin Maquívar then employed it, reporting in 1944 on the first “19 cases of anesthesia with controlled ventilation for thoracic anesthesia” [16]. The 1940s also saw the introduction of curare, and the monitoring of vital signs. Cyclopropane became as popular as ether due to its capacity to produce a rapid induction, its potency, and the wide margin between anesthetic and lethal concentrations.

In 1956, Michael Johnstone came to Mexico to demonstrate the use of halothane, which then largely replaced ether and cyclopropane over the next decade [17]. A lesser proportion of the flammable anesthetics were replaced by methoxyflurane and enflurane. However, neither achieved great popularity. Their use was discontinued in 1980, with the arrival of isoflurane. Halothane continued in use until the 1990s, when Melman and Lozano introduced desflurane and sevoflurane into Mexico [18, 19]. The latter agents are those currently in use.

Regional Anesthesia in Mexico

As noted earlier, Ramón Pardo introduced spinal anesthesia in 1900 [7, 8]. Cocaine, amylocaine (Stovaine), and subsequently procaine hydrochloride were the commonly used local anesthetics, until displaced by tetracaine and lidocaine. In 1923, Leopoldo Escobar gave the first caudal anesthesia to a patient suffering from sciatica. In 1939, in Monterrey, Mexico, Rodolfo Rodríguez performed the first lumbar epidural block.

For almost two decades, obstetricians/gynecologists administered anesthesia for obstetrics, either intravenously with a combination of meperidine 50–100 mg plus promethazine 50 mg and promazine 25 mg, or as a spinal anesthetic with tetracaine. In 1938, surgeon Isidro Espinosa de los Reyes, used a catheter to achieve a continuous caudal epidural [20]. Two other surgeons (Mateos Fournier and Jose Rabago) [21] later introduced Robert Hingson’s and Waldo Edwards’s continuous caudal analgesia technique for obstetrics. In 1956, anesthesiologists Vicente García Olivera [22], Guillermo Vasconcelos [23], Fernando Rodríguez de la Fuente [24], and Carlos Martínez Redding [25] took obstetric anesthesia from the hands of the surgeons at the hospitals of the Social Security Institute. They replaced spinal (because of hypotension) and caudal (because of catheter contamination) anesthesia with lumbar epidural anesthesia. This practice, with its benefits for the parturient and the newborn, rapidly spread to other hospitals. Currently, unless contraindicated, lumbar epidural block is applied in 95–98% of obstetric cases (Marrón M. Personal Communication. Ob/Gyn Anesthesiologist. Former Director Division of Postgraduate and Continuous Education in Health. Secretaría de Salud, Mexico).

Epidural or subarachnoid anesthesia had not been used in children until Melman, Marrufo, and Penuelas, working at the Children’s Hospital in Mexico City (Hospital Infantil de México), compared the effects of subarachnoid versus epidural block, and from studies in cadavers and patients, Melman, Tandazo and Arenas, determined the doses needed to reach different dermatomes [26, 27]. Surgeons initially opposed the use of these techniques, but the benefits quickly overcame their reservations. Currently, at the Children’s Hospital, central neuraxial anesthesia is used in about 50% of cases and results in the earlier discharge of patients [28]. Epidural anesthesia in children is nowadays used throughout Mexico, having displaced spinal anesthesia because of the longer postoperative analgesia possible with continuous epidural anesthesia.

In 1945, Vicente García Olivera went to New York to train under E Rovenstine at the Bellevue Hospital in New York who had founded a Pain Clinic in 1936. García Olivera later attended a course at the Veterans Administration Pain Clinic in McKinney, Texas [29]. He was an enthusiast in regional anesthesia, in all its modalities, central neuraxial, sympathetic, and peripheral blocks. In 1948, he created the first center for pain treatment at the London Clinic, in Mexico City (Hospital Clínica Londres). In 1975 he organized the first Pain Clinic at the Hospital General de México, which in 1992 became the National Center for Training in Pain Therapy (Centro Nacional de Capacitación en Clínica y Terapia del Dolor) [29].

The Mexican Society of Anesthesiology

In 1934, led by physicians Emilio Varela, Federico Vollbreuthausen, Juan Morquecho, Francisco Fierro and Benjamín Bandera, the Surgical Society of the Hospital Juárez in Mexico City founded the Society of Anesthetists of Mexico (Sociedad de Anestésistas de México), the first anesthesia society created in Latin America. In 1948, the Society changed its name to the Mexican Society of Anesthesiologists (MSA), appointing members from other Mexican states [30].

In 1946, the MSA organized its first National Congress of Anesthesia, holding subsequent congresses every two years until 1974, when annual meetings were instituted. The MSA participated in the founding of societies of anesthesia in other states of Mexico, such as the Society of Anesthesiology of Jalisco in 1948, and the Society of Anesthesiologists of Monterrey, in 1954. In 1960, the societies assembled into a Federation of Mexican Societies of Anesthesia (FSARM). In 1955, the MSA participated as Mexico’s representative in the creation of the World Federation of Societies of Anesthesia (WFSA), and in 1962, in the Confederation of Latin American Societies of Anesthesia (CLASA). The MSA was appointed by the FSARM to

be the main organizer of the 6th World Congress of Anesthesiology held in Mexico City in 1976. In 1994 the MSA changed its name to Colegio Mexicano de Anestesiología (COMEXANE) to more effectively represent its members before government authorities [31]. The former Federation of Societies (FSARM) is now called FMCA, AC (Federación Mexicana de Colegios de Anestesia, Asociación Civil). The Mexican College of Anesthesiology, in Mexico City, has 1500 members. The total number of anesthesiologists in Mexico is approximately 12,000, with 8,000 board certified as of September 2011.

Goals of the Mexican College of Anesthesiology (Formerly Society)

1. *To promote information about anesthesia.* Aspects of the specialty are presented and discussed in monthly meetings. An Annual Meeting has been held with the participation of foreign and national speakers and professors since 1974.
2. *To promote research in anesthesia.* To further this aim, the “Benjamín Bandera Foundation” was created in 1976. A Trust Fund established with the profits from the 6th World Congress of Anesthesia held in 1976 in Mexico City, was used to support the Foundation.
3. *To improve clinical care:* anesthesia courses and workshops are conducted in different hospitals.
4. *To promote the countrywide development of societies of anesthesia.*

In 1960, the Society supported the founding of the Federation of Mexican Societies of Anesthesia (FSARM). State societies of anesthesia, one or two for each state for a total of 60, combined to form FSARM [32]. The Society (now College), also supported the founding and organization of societies of different anesthesia subspecialties including pediatrics (SAP), obstetrics and gynecology (SMAGO), cardiothoracic anesthesia, and pain [33].

Residency Programs in Anesthesia

The establishment of several major medical institutions in Mexico City in the 1940s facilitated the development of anesthesia training programs. They included the Children’s Hospital in 1943, the National Institute of Cardiology in 1944, the Institute for Medical Sciences and Nutritional Diseases (Instituto Nacional de Ciencias Médicas y Nutrición) in 1946, and the Hospitals in the Mexican Institute for Social Security. The training programs were supported initially by the Mexican Society of Anesthesiologists (MSA) and later by the National University of Mexico (UNAM) and the Mexican Board of Anesthesiology.

In 1957, the MSA organized the first postgraduate course in anesthesia, appointing members of the Society as professors. The 24-month course was held in Mexico City at the General Hospital (Hospital General de México). Physicians taking the course and training received a monthly salary enabling them to leave their former practice and devote their entire time to anesthesia. The MSA continued to organize these courses until 1962. The anesthesiologists thus trained, and others trained in Canada and the US, initiated residency programs in anesthesia in several Mexican hospitals.

In 1966, the MSA and the National University initiated a two-year residency program [19, 20]. A 3 year program was established in 1986 at the National University. This was achieved through the co-operation of the National Committee for Postgraduate Education, the Ministry of Health, the MSA’s Academic Committee in Anesthesia and the Mexican Federation of Societies of Anesthesia [21, 22]. Acceptance for subspecialty training in pediatrics, neuro-anesthesia, cardiothoracic anesthesia, critical care, obstetrics/gynecology, or pain, currently requires that the appointee be certified by the Mexican Board of Anesthesia. Subspecialty credentialing demands a further 2 years of training in the designated subspecialty [33].

Mexican Board of Anesthesia

In 1974, members of the MSA, as advised by the National Academy of Medicine, created the Mexican Board of Anesthesia (Consejo Mexicano de Anestesiología; Archivo del Consejo Mexicano de Anestesiología 1974). Candidates were certified after 3 years of a residency program in one of the hospitals appointed as training hospitals, and after taking a written and oral examination. The Board was also responsible for approving and certifying the congresses and the courses held as part of the continuing medical education programs. The Board also determined recertification of all anesthesiologists every 5 years, granting the permit to continue to practice anesthesia. This process of accreditation and certification by the Anesthesia Board, was equivalent to the process that was carried out by the 47 specialty councils recognized by the National Committee for Medical Specialties (CONACEM).

Practice of Anesthesia

As in many parts of the world, surgeons were the first to administer anesthesia in Mexico. However, the shortage of physicians also dictated that nurses and technicians perform these tasks. Nurses and technicians received one year tutorial courses from trained anesthesiologists; these courses ceased in the early 1970s. Finally, after a long campaign conducted

by Mexican anesthesiologists, the authorities and politicians in Mexico became convinced that anesthesia was a medical specialty, best administered by trained physicians. This was incorporated into Mexican law in 1998.¹

Revista Mexicana de Anestesiología (Mexican Journal of Anesthesiology)

The founding members of the MSA published the first anesthesia articles as a supplement called “Anesthesia” in the “Journal of Surgery of the Hospital Juárez” from 1936 until 1939. Subsequent anesthesia articles were published in “*Medicina*” [10, 31].

In July 1951, the first issue of *Revista Mexicana de Anestesiología* (RMA) was published, with Benjamin Bandera as the first director and Vicente García Olivera as editor [10]. It was the second anesthesia journal (after Argentina’s) published in Latin America. Since its first publication, it has appeared every three months. It is abstracted or indexed by standard databases (16 databases including Scopus, but not Medline), and is distributed to all members of the Mexican Society. It is the main anesthesia journal published in Mexico, and is the official publication of the Mexican College of Anesthesiology, (COMEXANE). The journal promotes the publication of clinical and basic research in anesthesia and perioperative medicine, critical care, and pain. The Editorial Board accepts papers submitted for publication by Mexican and Spanish speaking Latin American anesthesiologists.

Since 2006, the Colegio Mexicano de Anestesiología also edits quarterly, the Mexican Clinics of Anesthesia, with Raul Carrillo Esper as the current editor-in-chief of both publications [34]. Another Mexican journal “Anestesia”, edited by the Mexican Federation (FMCAAC), has had an irregular publication schedule; currently it is published online every 4 months.

Globalization has permitted the rapid spread of knowledge and technology. In Mexico the quality of medicine may now be comparable to that practiced in first world countries. The US Joint Commission on Health Care Accreditation, (JAHCO) has accredited several hospitals in Mexico City and other states in Mexico, as having standards comparable to those in the US (e.g., the American British Cowdray Medical Center).

Anesthesia in Caribbean Islands and Central America

Anesthesia developed unevenly in Caribbean Islands and Central American countries in the several decades after Morton’s historic demonstration in 1846 (Tables 26.2 and 26.3). This remarkable observation makes one marvel at the diverse conditions that led to a virtual absence of anesthesia in some countries until the last quarter of the nineteenth century, whereas other countries benefited from anesthesia within a year of its discovery. Of course, some of the information may overestimate how long it took to incorporate anesthesia into practice, since for some drugs, little data are available, while for others (ether-chloroform) we have sufficient information. Although a good explanation for the late arrival of anesthesia in many countries is lacking, socio-cultural and economic factors probably underlie the variability in the delay, but as Sherlock Holmes said: “it is a capital mistake to theorize before one has data.”

Cuba

Vicente de Castro used ether in Cuba on 11 March 1847, in a patient requiring surgical treatment of a bilateral hydrocele. Nicolas Gutierrez introduced chloroform in 1848 (It did not replace ether), and cocaine was first used for local anesthesia in ophthalmology in 1884. In 1900, Emilio Nuñez gave subarachnoid anesthesia with cocaine, later replaced with amylocaine by Gonzalez Mármol [35] (Personal Communication: Humberto Sainz Cabrera, Presidente Sociedad Cubana de Anestesia y Reanimación, 2011). Fournau had introduced spinal anesthesia, and Gonzalez Marmol used it in 100 obstetrical cases, reporting uterine inertia in five.

Luis Hevia, a physician who practiced anesthesia full-time, is considered to be the “founder of the specialty” in Cuba. He introduced nitrous oxide in 1918, ethylene in 1926, and cyclopropane in 1934 [35]. In 1938, he was appointed as Honorary President of the Anesthesia Research Society and the International College of Anaesthetists during the joint meeting with the Associated Anesthetists of the United States and Canada held in New York [36]. In 1939, he described the use of ether in the tropics [36].

In the 1930s, intravenous sodium amytal, hexobarbital, and sodium thiopental were used in Cuba to induce anesthesia, the last having the greatest popularity and remaining in use until recent times. Tracheal intubation was also introduced during those years [35], (Personal Communication: Humberto Sainz Cabrera, Presidente Sociedad Cubana de Anestesia y Reanimación, 2011) and epidural anesthesia was initiated in 1937 by Ferro [37].

In 1946, Manuel Curbelo performed continuous lumbar epidural anesthesia via a ureteral catheter inserted through a

¹ It appears as **NOM # 170 for The Practice of Anesthesiology** (Norma Oficial Mexicana #170-SSA1-1998 para la Práctica de la Anestesiología), which has been replaced by **NOM006-SSA3-2011**.

Table 26.2 Initial Use of Anesthetics in Mexico, Caribbean Islands and Central America

Country	Ether	Chloroform	Nitrous Oxide	Curare	Cocaine	Spinal	Epidural
Mexico	1847	1849	1910s	1942	1890s	1899	1923

16 G Huber tipped Tuohy needle. He was invited to demonstrate his technique in New York. The international anesthesia community acknowledged his contributions, electing him in 1955, as the first vice-president of the World Federation of Societies of Anesthesiology (WFSA) (Personal Communication: Humberto Sainz Cabrera, Presidente Sociedad Cubana de Anestesia y Reanimación, 2011).

Alberto Fraga introduced curare, succinylcholine and halothane for clinical use in the 1950s. Halothane rapidly replaced all other inhaled anesthetics (ether, ethyl chloride and ethylene) soon after its introduction in the late 1950s.

The exodus of many physicians after the 1962 Cuban Revolution, prompted initiation of a two-year residency program in anesthesia preceded by a one year rotating internship. No residency program, only tutoring, had existed previously. Physicians had practiced anesthesia as a part time specialty, supplementing income from other practices. The shortage of physicians and anesthesiologists, and the need to provide anesthesia services throughout the country, prompted the development of a one year anesthesia training program for registered nurses and, subsequently, for technicians. For more than a decade, these personnel provided most anesthesia services. In 1978, Sergio del Valle, Health Secretary, became aware of the considerable morbidity and mortality related to anesthesia, and determined that only trained physicians should administer anesthesia. Accordingly, the number of anesthesiologists increased from a few hundred in the early 1980s, to 1300 in 2012 (Personal Communication: Humberto Sainz Cabrera, Presidente Sociedad

Cubana de Anestesia y Reanimación, 2011). In 1986, anesthesia training increased to 4 years. The anesthesia training program was nationally designed and implemented by the Schools of Medicine. Trainees completing the program were awarded the title of specialist in anesthesia by the Ministry for Advanced Education (Ministerio de Educación Superior) (Personal Communication: Humberto Sainz Cabrera, Presidente Sociedad Cubana de Anestesia y Reanimación, 2011).

The shortage of resources and foreign currency due to the economic blockade of Cuba following the revolution hindered technical and scientific advancement. After the year 2000, globalization and the internet increased access to medical knowledge and thereby ameliorated this situation.

The Cuban Society of Anesthesiology (Sociedad Cubana de Anestesiología) was created in 1950. In 2000, the society was renamed Sociedad Cubana de Anestesiología y Reanimación (SCAR). It became the medical advisor to the Cuban Government and established national protocols for anesthesia practice throughout the country. SCAR has been an active member of CLASA since 1975 (Confederation of Latin American Societies of Anesthesia) and WFSA since its creation in 1955. It is also a member of FESACAC (Federation of Anesthesia Societies of Central America and the Caribbean), Humberto Sainz Cabrera from Cuba is the current President. Since 2001, the Cuban Journal of Anesthesia has been published online every 4 months, an initiative of Idoris Cordero, the current editor (Personal Communication: Humberto Sainz Cabrera, Presidente Sociedad Cubana de Anestesia y Reanimación, 2011).

Dominican Republic

Chloroform and ether anesthesia were introduced between 1861 and 1870, but were rarely used due to “complications”. “Aguardiente” (an anise-flavored liquor) was preferred. The first reports of the use of chloroform and ether appeared in the 1900s. Ether was initially used with Julliard’s mask, and later with Ombrédanne’s apparatus. There is no information as to why there was such an apparently long delay for anesthesia to emerge.

Francisco Puello, a general surgeon, reported the first spinal anesthesia in 1916. In 1923, he published an article describing 100 cases using “steraine with glucose”. He reported two deaths and sphincter paralysis, leading him to substitute procaine for the mixture thereafter.

Between 1947 and 1950, the first anesthesia apparatus, a Heidbrink machine,⁸ was brought to the island. It had a carbon dioxide absorber and a circle rebreathing system for administration of nitrous oxide and ether via a face mask. Tracheal intubation was not used. In 1951, Octavio Marmolejos went to Argentina to learn anesthetic techniques including selective bronchial intubation and cardiovascular anesthesia. Following his return to Santo Domingo he organized anesthesia services in clinics and hospitals, equipping them with Foregger anesthesia machines [38]. In 1953, he and Humberto Hernández initiated the use of tubocurarine. In 1957 Marmolejos also introduced epidural anesthesia with the “hanging drop technique” or Gutierrez’s method, which he had learned in Buenos Aires. (Personal communication provided by José Fanduiz the senior member of the SDA).

In 1970, Cosme Battle, founder of the Dominican Anesthesia Society, became its first president. In 1978, the Society created the first School of Anesthesia for physicians in the country. In 1993 CLASA incorporated the Sociedad Dominicana de Anestesiología (SDA) as one of its members, encouraging them to organize national and international anesthesia congresses, such as the XXV Latin American Congress of Anesthesia held in Santo Domingo in 1999. The SDA is also a founding member of the Federación de Sociedades de Anestesia de Centro América y el Caribe (FESACAC). The bylaws of the Society were updated, in 2006 [39].

In 1976, two anesthesia residency programs were created, one at the Salvador B Gautier Hospital of the Social Security system, and the other at the Hospital Dr. Darío Contreras, by the Health Ministry. Initially, residency programs lasted 2 years, but in 2009 they were extended to 4 years. Currently there are 12 residency programs in the country, two are in military hospitals, two in the Social Security Institute, one private and the remaining seven are with the Health Ministry. All are sponsored by the Universidad Autónoma de Santo Domingo (Autonomous University of Santo Domingo) (Lambertus Tomás E: Personal Communication. Dr. Lambertus is the Current Medical Director of the Department of Anesthesia at the Hospital Dr. Darío Contreras in Santo Domingo, Dominican Republic).

All hospitals have postanesthesia care units (PACUs). ICUs are available in the large hospitals with active participation by anesthesiologists in most. Anesthesiologists currently provide most anesthesia even in the smallest villages. Malpractice concerns ended anesthesia practice by all but a handful of technicians, some of whom are still in practice, but decreasing in number (Lambertus Tomás E: Personal Communication).

The Dominican Republic occupies almost two thirds of the territory of the Island of Hispaniola (48,442 km²); Haiti occupies the other third. Approximately 600 anesthesiologists serve this country with a population of more than 9.3 million inhabitants (Lambertus Tomás E: Personal Communication).

Guatemala

José Luna, a Guatemalan-born physician trained in Paris, used ether in November 1847, to anesthetize Urbano Paniagua in order to amputate his finger. A few days later, two medical students, Juan Cañas from Guatemala and Felipe Arana from El Salvador, volunteered to be anesthetized with ether by Luna in a public demonstration at the Hospital General “San Juan de Dios”. During induction they became excited and cyanotic and the experiment was suspended. On the next day, Luna amputated Marcelino Martínez’s right arm under ether anesthesia [40, 41].

Following these four experiences, chloroform, which permitted a smoother induction and emergence, replaced ether. Luna used it first on 21 February 1850 and thereafter for 50 years. He was probably afraid to use ether again [40].

In 1901, Juan Ortega, after training in Paris, used spinal anesthesia with cocaine (0.15 g) for a patient undergoing inguinal herniorrhaphy. He named this technique “raquico-cocainización”. It was used for the next 45 years for abdominal surgery [40].

In May 1913, surgeon Mario Wunderlich bought an Ombrédanne apparatus, for ether administration in Guatemala’s General Hospital. The associated decrease in morbidity and mortality, and the ease of the use of ether with the Ombrédanne led to the displacement of chloroform by ether [40, 41].

Ethyl chloride was first used in 1910, at the General Hospital. In 1926, Wunderlich used ethyl chloride combined with chloroform and ether as the Schleich mixture, for anesthesia in 100 cases.

In 1930, a Foregger “Gwathmey” model anesthesia apparatus was brought to Guatemala and used to administer ether for the first cholecystectomy in Guatemala performed under general anesthesia. The 40-bed American Hospital was opened, equipped with an Ombrédanne’s apparatus and an induction room for anesthesia [40, 41].

From 1935–1940, Mariano Herrarte and Enrique Penedo gave dibucaine/5% glucose (Nupercaine) intrathecally as “saddle anesthesia” This technique gained popularity for gynecological and urological surgery. Applying a technique developed by the Mexican anesthesiologist Efrén Fierro, Lopez Herrarte produced segmental spinal anesthesia for thyroidec-tomies and neck surgery (brave anesthesiologist; braver patient). Herrarte also used caudal anesthesia for labor. Ramiro

Gálvez gave caudal anesthesia for urological and rectal surgery, and paravertebral and regional blocks for abdominal surgery [40].

Wunderlich introduced sodium thiopental into practice in 1939. Pablo Fuchs performed the first tracheal intubation in 1945 for a thyroidectomy. He used a rubber rectal tube adapted to Ombrédanne's ether apparatus [40, 41].

In 1948, two Guatemalans trained in the United States: Gustavo Ordoñez at Chicago's Cook County Hospital and Roberto Perez at Yale University. In addition, Flaviano Velazquez trained at the Children's Hospital (Hospital Infantil) and the National Institute of Cardiology (Instituto Nacional de Cardiología) in Mexico City. These three returned to Guatemala and pioneered development and training in anesthesia. They created the first departments, and were soon followed by others trained abroad. In 1950, they created the Chair of Anesthesia at the University of San Carlos in Guatemala City [41].

In 1958, they also founded the Anesthesia Society of Guatemala, which in 1968 became a member of WFSAs, and in 1969 of CLASA. The society has been renamed as "Asociación Guatemalteca de Anestesiología Reanimación y Tratamiento del Dolor" (AGARTD). Guatemala's Society was also a founding member of the Federation of Anesthesia Societies of Central America and the Caribbean (FES-ACAC) (Personal communication from Dr. Eilin Valenzuela de Mazariegos, President of AGARTD).

In 1958, Samayoa de León started the first residency program in anesthesia, consisting of a 4-year training period developed by the University of San Carlos, the Health Ministry, Universidad Mariano Galvez, and the Institute for Social Security. At the end of the program, trainees were certified as anesthesiologists and became members of the Medical College of the University. They had to complete 32 hours per year of continuing medical education to remain active members, and to maintain the right to practice (Personal communication from Dr. Eilin Valenzuela de Mazariegos, President of AGARTD).

Although technicians still provide anesthesia in many parts of the country, in 1970, anesthesia was recognized as a medical specialty by the Medical College of Guatemala. The specialty has expanded into other fields such as ventilation therapy, peri-operative medicine, pain management, intensive care and other subspecialties. The AGARTD does not publish a journal or bulletin (Personal communication from Dr. Eilin Valenzuela de Mazariegos, President of AGARTD).

Honduras

Ether and chloroform both were first used in the early 1900s [42]. Initially, surgeons supervised the provision of anesthe-

sia by nuns, nurses or laypersons. In the 1930s, Sor Roswinda, a German nun, served as an anesthetist and taught local personnel for many years. She is remembered as one of the pioneers. No information indicates who introduced ether or chloroform.

Ether was administered with an Ombrédanne's apparatus from 1908 to the 1950s. Subsequently, modern anesthesia apparatus, vaporizers, anesthetics, ancillary drugs and techniques were slowly incorporated into the practice of anesthesia. Current practice in large government hospitals and in some smaller private ones, is comparable to that in many other countries in Latin America. However, small government centers may provide a lesser standard of care. Government institutions hire anesthesia technicians with high-school degrees (secondary level), and with limited training given in a government school, to provide unsupervised anesthesia services. They are hired in preference to graduate anesthesiologists. Honduras has approximately 300 technicians. In private hospitals, anesthesia is provided by anesthesiologists who have graduated from a residency program. [39] (Montes GN, Personal Communication. Dr. Montes was a former trainee at Hospital Infantil de México in Mexico City and is Executive Director of Hospital "Dr. Mario Catarino Rivas" in San Pedro Sula, Honduras).

The government controls 28 hospitals, and there are about an equal number of private hospitals. Only half of public hospitals have PACUs whereas all private hospitals have PACUs. Only 4 large government hospitals located in major cities have ICUs: Tegucigalpa—the capital city, San Pedro Sula and La Ceiba (Montes GN, Personal Communication). One editor of this book (LS) along with his wife Arlene spent two weeks in 1998 as a volunteer with a group from Interplast providing care in La Ceiba to children requiring cleft lip and palate repair. Arlene also assisted as the interpreter in preoperative preparation and postoperative observation. She refused to return the next year citing inadequate training for the job.

The University of Honduras was founded in 1847, and initiated its Medical School in 1881. In 1882, the first hospital opened in Honduras, the Hospital General San Felipe. Since then it has been the training site for medical graduates, specialists and technicians. In 1959, the Instituto Hondureño de Seguridad Social was created, and with it new clinics and hospitals with newly organized anesthesia departments. A formal residency program in Anesthesia, Reanimation and Pain was initiated in 1998, by Francisco Samayoa, who continues to be its academic coordinator. The National Health Department, the Social Security Institute, and the Universidad Autónoma de Honduras through its Post-graduate Division have supported this program since its creation [42].

The first Society of Anesthesia was founded in November 1960 by Napoleon Alcerro Oliva, an ENT specialist and

anesthesiologist (the first director of the Anesthesia Service at San Felipe's General Hospital), along with Zulema Canales, René Cervantes, Armando Rivera and Alejo Lara, all of whom had trained abroad. From 1995 to 1997, new bylaws of the Society were adopted and the Society changed its name to "Sociedad Hondureña de Anestesiología Reanimación y Dolor" (SHARD). Currently approximately 175 trained anesthesiologists serve a country of 5,500,000 inhabitants [42].

In 1974, the Society joined CLASA, and in 1976 joined WFSA. In 1994, the Society acted as a founding member of the Federation of Anesthesia Societies of Central America and the Caribbean (FESACAC). In 2002, the fifth congress of FESACAC was held in Honduras and in 2005, CLASA's XXVIII Congress of Anesthesia, was successfully organized in Tegucigalpa, Honduras, by Francisco Samayoa, acting as President of the organizing committee. Carolina Haylock, from San Pedro Sula, is the current president of SHARD. SHARD does not publish a journal or bulletin [42].

El Salvador

In 1870, 23 years following Simpson's 1847 discovery of the anesthetic properties of chloroform, Carlos Bonilla gave the first chloroform anesthetic in El Salvador. Surgeon Carlos Emilio Alvarez and his followers, pioneers of surgery as a specialty in El Salvador, used chloroform anesthesia for their surgical procedures. In 1886, Alvarez introduced the local anesthetic, cocaine. In 1899, surgeon Tomas Palomo brought ether to El Salvador for use by inhalation or rectally. In 1901, on a trip to Europe, he bought an Ombrédanne's apparatus, using it to administer Schleich's mixture of chloroform, ether and ethyl chloride [43]. Schleich's mixture was commonly used until 1920, when a modified Ombrédanne apparatus that delivered ether and oxygen, was substituted for the former one. Chloroform, which many surgeons had used was finally abandoned due to its toxicity [43, 44].

In 1902, Palomo used cocaine for spinal anesthesia in 28 cases, describing the symptomatic treatment used for spinal headache [44].

Medical students, who were responsible for bringing along a mask, and dripping chloroform onto it, provided anesthesia during the early twentieth century [43]. They also brought a mouth opener and a forceps to pull out the tongue in case of a sudden respiratory arrest (or perhaps airway obstruction).

In 1934, Carlos Leiva administered intravenous sodium hexobarbital to his brother for anesthesia, and Raul García Prieto induced obstetric analgesia with rectal paraldehyde.

In 1937, Raúl Argüello Manning convinced the board of the Hospital Rosales, of the need to improve the quality of medical care, and particularly anesthesia delivery to patients,

recommending the acquisition of the first two anesthesia machines in El Salvador. Two "Heidbrink" machines, each costing \$ 1,500 USD, were purchased. They could deliver nitrous oxide, cyclopropane, ethylene and oxygen. At the same time, Manning hired an American nurse anesthetist, from Chicago, Miss Doris Nuggett, to provide and teach anesthesia in El Salvador—and initiate the delivery of oxygen with nitrous oxide, cyclopropane, or ethylene. She stayed for two years, leaving one of her pupils, Mr. Joaquin Herrador Tejada, in charge when she left [44].

In 1941, Joaquín Herrador, working with the surgeon Carlos B González, used tracheal intubation and positive pressure anesthesia for a pulmonary lobectomy. Antonio Lazo Guerra and Roberto Cañas Rivas initiated the use of sodium thiopental and epidural anesthesia for obstetric and perineal surgery [43, 44].

In 1948, two US trained Salvadoran anesthesiologists (Joaquín Coto from the Mayo Foundation and University of Minnesota, and Armando Milla from the University of Chicago) returned to found the Anesthesia Service at the Hospital Rosales (the first public hospital). Other anesthesiologists who had trained abroad soon joined them. Tracheal intubation and muscle relaxants were introduced, and modern anesthesia began (Aguilar ME: Personal communication. Aguilar is a cardiovascular anesthesiologist and was the President of CLASA for 2009–2011).

Halothane and methoxyflurane were introduced in the 1960s, and the use of cyclopropane ceased in 1972, with ether finally disappearing in 1976. Enflurane was introduced in the last half of the 1970s, and isoflurane in 1983. Sevoflurane displaced all of these agents in the 1990s. Nitrous oxide has now been abandoned in favor of air-oxygen mixtures. (Aguilar ME: Personal communication).

In the 1950s, Joaquín Coto tutored 12 physicians in anesthesia. Some of them went to the US to continue formal training. Others trained nurses to become anesthetists. In 1977, Coto founded the School of Technicians in Anesthesia, which has graduated around 1000 technicians to provide anesthesia in different provinces. (Aguilar ME: Personal communication.)

In 1974, a 2-year anesthesia residency program was initiated at the Hospital Nacional Rosales. In 1987, the program increased to 3 years plus a year in surgery or medicine, or to 4 years of anesthesia. (Aguilar ME: Personal communication; Sandra Leal Aquino. Personal communication. Aquino is the current President of AMAES.)

Currently, about 100 anesthesiologists work in El Salvador (mainly in the capital city of San Salvador), a country with more than 5.7 million inhabitants. El Salvador has 32 hospitals (four with ICUs) and 8 hospitals supported by the Social Security Institute (four with ICUs). Anesthesiologists care for the patients in all of those units. All hospitals have PACUs. (Aguilar ME: Personal communication; Sandra Leal

Aquino. Personal communication.). Technicians/nurse anesthetists provide anesthesia in most provinces. The anesthesiologist to technician ratio is approximately 1:10. (Aguilar ME: Personal communication.)

The anesthesiologists returning to El Salvador in the 1950s founded the first Society of Anesthesia, but it disappeared after a short time. In 1967, Fernando Antonio Escobar re-established the former society and renamed it “Asociación de Médicos Anestesiólogos de El Salvador” (AMAES) which, in 1993, became a member of CLASA. In 2009, it was accepted by the WFSA as a member, finally ratified in 2012. It is a member of FESACAC (Federación de Sociedades de Anestesia de Centro América y el Caribe) and organized its 2nd congress in 1996. (Aguilar ME: Personal communication; Sandra Leal Aquino. Personal communication.) The Society has no journal or bulletin.

Nicaragua

There is no recorded description of anesthesia in Nicaragua before 1900. However, Juan José Martínez, a surgeon who trained for two years at the Bellevue Hospital in New York, probably introduced ether anesthesia when he returned to Nicaragua in September 1889. Although his autobiography [45] does not mention the use of anesthesia, he describes the surgeries he performed before 1900, probably done under ether anesthesia administered by nuns. He mentions his first surgery for removal of a cataract using local anesthesia with 5% cocaine in 1891, and his first spinal anesthesia with cocaine for a patient with an ankle fracture in 1900. He gave spinal anesthetics with cocaine in approximately 100 cases, mentioning that it caused a “horrible” headache. He therefore substituted amylocaine for cocaine, reporting its use in 500 additional cases. Later, he substituted procaine hydrochloride for amylocaine [45].

At the end of 1891, Luis H Debayle, a surgeon trained in Paris, arrived in Nicaragua. Since chloroform was commonly used for surgical procedures in France, Debayle probably introduced it into Nicaragua. No recorded description identified the year or the person responsible for introducing chloroform, although it is generally thought that chloroform was used before 1900 (Denis F. Nava. Personal Communication. Nava was the former National Director of Education in Anesthesiology and Past President of Asociación Nicaragüense de Anestesiología y Reanimación (ANARE)).

Lay providers continued to administer ether and chloroform anesthesia until 1956 when Cayetano Espinoza Valdés, an anesthesiologist trained in Chicago, returned to practice in Nicaragua. He organized the anesthesia department at the General Hospital in Managua, where he was joined by other anesthesiologists trained abroad. He introduced succinylcholine and halothane, thus ending the use of ether and

chloroform. Between 1964 and 1972, methoxyflurane was introduced and used. Enflurane was used for a short period in the 1970s. Halothane was used until 2000, when it was replaced by sevoflurane. Nitrous oxide was used in the first half of the 20th century but is no longer used. Sevoflurane-oxygen is currently the dominant anesthetic. (Denis F. Nava. Personal Communication.)

In 1960, Denis Nava, who had been trained in Mexico City, introduced epidural anesthesia. In the 1980s, 25 cases of arachnoiditis were reported after spinal and epidural anesthesia, probably attributable to the detergents used to sterilize reusable glass syringes and needles. Heat sterilization was then adopted as advised by Armando Fortuna from Brazil (who was lecturing in Nicaragua at the time), and this unfortunate complication has not recurred in any of the 25 hospitals serving the country. Regional anesthesia is still a popular anesthesia technique. No disposable equipment is available. Lidocaine and bupivacaine are the common local anesthetics used, with or without opioids. (Denis F. Nava. Personal Communication.)

A new private hospital, “Hospital Metropolitano Vivian Pellas” was opened in 2005, and has a gas sterilizer. It has been recognized by the JAHCO and is the most expensive hospital in Nicaragua. (Denis F. Nava. Personal Communication.)

The Ministry of Health (MINSa), and the National University of Nicaragua established a 3 year residency program in anesthesiology in 1982. Currently in Managua, the Antonio Lenin Fonseca hospital, the Berta Calderón hospital, the Roberto Calderón hospital and the Manuel de Jesús Rivera (pediatric hospital) offer anesthesia residencies, as does the Oscar D Rosales hospital in León. By 1979, 44 trained anesthesiologists provided anesthesia in Nicaragua, but with the overthrow of Anastasio Somoza, most of them emigrated, leaving only 18. At present, 190 anesthesiologists serve a population of almost 6 million inhabitants, leaving many vacant shifts covered by technicians, particularly in small provinces.

In 1993, the anesthesia community founded the Asociación Nicaragüense de Anestesiología y Reanimación (ANARE), which has been a member of CLASA and WFSA for the last 10 years. ANARE was also a founding member of FESACAC. In November 2009, the XXX Latin American Congress of Anesthesia, organized by CLASA and the VIth Nicaraguan Congress of Anesthesia and Pain were held at the same time in Nicaragua. No journal or bulletin has been published (Denis F. Nava. Personal Communication.)

Costa Rica

Anesthesia began in Costa Rica in 1875, with Carlos Duran’s arrival from Guy’s Hospital in London, where he had graduated in medicine and surgery, supervised by Joseph Lister, Queen Victoria’s private physician. At the Hospital

San Juan de Dios in San José, he performed surgery on patients anesthetized with chloroform, teaching other physicians the technique of its administration. He founded the School of Obstetrics, the School of Nursing, the Asylum for Insane Patients, and the Sanatorium for Patients with Tuberculosis—a remarkable man. Nuns ran the hospital and administered the anesthesia. Chloroform was dropped over 8 layers of gauze, 6 drops during the first minute, 12 during the second, 24 on the third and so on until they reached one drop per second [46, 47].

Physicians returning from medical studies in the US introduced ether in the late 1800s. To shorten the induction period they preceded ether administration with ethyl chloride administration. Ether continued in use until 1962. On 15 December 1909, surgeon Luis Paulino Jiménez used spinal anesthesia with amylocaine for the first time, in a 45 year old male with an inguinal hernia [47].

After many years of practicing both surgery and anesthesia, Ricardo Jimenez Núñez decided to devote his full attention to anesthesia. In 1940, he wrote a book in which he argued that “anesthesia should not be administered by nurses alone, they always have to work under the supervision of a medical doctor” [47].

Gonzalo Vargas Aguilar was the first trained anesthesiologist in Costa Rica. In 1941, he went to the Memorial Hospital in New York to train, returning in 1942. In 1947 he initiated the use of curare (Intocostrin, Squibb) for his cases. The introduction of anesthesia machines to Hospital San Juan de Dios, by Enrique Sotela in 1952, and their use by trained anesthesiologists, increased the popularity of neuromuscular blocking drugs, presumably because anesthetic machines allowed the support of ventilation [47]. In the 1950s, other physicians went to Mexico to train in anesthesia. On their return, they gave 9-month courses in anesthesia to nurses and technicians, who replaced a declining supply of nuns in the operating rooms. Such training continued for more than a decade, producing 130 technician anesthetists. The courses were suspended in 1981 [47]. Epidural anesthesia was introduced in 1962, by Luis Guillermo Hidalgo on his return from training in Denmark.

In 1974, there were 12 anesthesiologists in Costa Rica who had trained abroad. Supported by the University of Costa Rica, they initiated a two and a half year residency program, extended to 3 years in 1982. Physicians trained in residency programs have become the primary providers of anesthesia, and the few remaining technicians are used to monitor patients receiving intravenous sedation or to assist anesthesiologists. A subspecialty residency program in Pediatric Anesthesia is available at the Hospital Nacional de Niños “Dr. Carlos Saenz Herrera” (National Children’s Hospital), and lasts one year. Other subspecialty training must be accomplished abroad. All hospitals have PACUs, and larger hospitals have ICUs (Celia Hofman: Personal Communica-

tion. Hofman is former Director of the Anesthesia Service at the Hospital Mexico, Past President of AMACR and is the Coordinator of the European Foundation for Education in Anesthesia for Central America). Currently 200 trained anesthesiologists serve a country of 4,301,712 inhabitants (2011 census).

In 1987, Costa Rica converted to a partial barter system with England: coffee from Costa Rica was exchanged for new and modern anesthesia equipment to supply the country’s 57 hospitals.

In 1960, 8 anesthesiologists founded the first Anesthesia Society, but this ceased to exist after a few years. It was re-created in 1991 as “Asociación de Médicos Anestesiólogos de Costa Rica” (AMACR). It is a member of CLASA, WFSA, and FESACAC. In 1995, the Society promulgated Safety Standards for the Practice of Anesthesia based on international standards. These have been accepted by the Ministry of Health and are compulsory. In order to practice after finishing a residency program, regardless of the specialty, one must become a member of the Colegio de Médicos y Cirujanos de Costa Rica (College of Medical and Surgical Physicians) which acts as a board of certification and grants a permit to practice. AMACR has not developed a journal or bulletin (Celia Hofman: Personal Communication).

Panama

Geographically and historically, Panama was a part of Greater Colombia—from 28 Nov 1821 to 3 Nov 1903. After several insurrections, it became independent in 1903.

No precise record describes the development of anesthesia in Panama in the 1800s. In Colombia, ether and chloroform were widely used during the last quarter of the 1800s [48]. In 1846, the US signed the Bidlack-Mallarino treaty with Colombia, granting the US rights to build railroads in Panama and to intervene militarily. In 1855, the world’s first transcontinental railroad—across the Isthmus, from Colón at the Atlantic Ocean to Panama City at the Pacific Ocean—was completed. From 1880 to 1889, the French company that had built the Suez Canal, attempted to build a sea-level canal in Panama. They constructed dispensaries next to the railroad stations and large hospitals in the main cities to treat construction workers afflicted by accidents, yellow fever, malaria and cholera. French physicians, nurses and technicians served in these facilities. In September 1882, the 500 bed L’Hopital Notre Dame du Canal was established in Panama City, at a cost of 500 million francs [49, 50].

In 1904, during Theodore Roosevelt’s presidency, the US bought the rights from the French to build the abandoned project in a deal that included hospitals and dispensaries. The Panama Canal was then constructed. American and French medicine strongly influenced the development of medicine

in general and anesthesia in particular. There is no precise reference as to when or who introduced chloroform and ether, but both were widely used by French and American personnel who taught local personnel the art or technique of anesthesia [50]. (Solange de los Ríos, Personal communication: Former trainee at Hospital Infantil de Mexico, Mexico City. Jefe del Servicio de Anestesia, Hospital de Especialidades Pediátricas de la Caja del Seguro Social, Ciudad de Panamá, Panamá).

In the first half of the 20th century, surgeons provided spinal anesthesia while nurses cared for the patient during the surgery. Gabriel Sosa recalls that in 1938, amylocaine was used for spinal, and chloroform and ether were administered “open drop” by the nurses. Ramirez Duque bought an Ombrédanne apparatus ether inhaler from the US that “delivered ether more safely” (Solange de los Ríos, Personal communication) [49, 50].

In the 1950s, Augusto Ramos, an ENT specialist, traveled to Cuba to learn anesthesia, and tracheal intubation in particular. (Solange de los Ríos, Personal communication). In 1957, Rodrigo Bernal, the first anesthesiologist formally trained in Washington DC, arrived in Panama and was joined 2 years later by Dante Viggiano, who also trained in the US. Both worked at the Saint Thomas Hospital (Hospital Santo Tomás) supervising nurse anesthetists and administering anesthesia in more complex cases. Curare was introduced by Rodrigo Bernal in 1957 (Solange de los Ríos, Personal communication).

In 1962, the first anesthesia service was organized at the General Hospital of the Social Security (Caja del Seguro Social). Open drop ether and cyclopropane were the anesthetics used until 1975, when they were replaced successively by halothane, enflurane and isoflurane. In 1995, sevoflurane was introduced and two years later, desflurane appeared on the market (Solange de los Ríos, Personal communication).

Regional anesthesia has been widely used in adults and children. Rodrigo Bernal introduced epidural anesthesia in adults in 1970 (Solange de los Ríos, Personal communication). Central neuraxial anesthesia has been used in children since the 1980s when Solange de los Ríos, a trainee at the Children’s Hospital in Mexico City, returned to Panama and taught the technique. Lidocaine, bupivacaine, and occasionally ropivacaine are the local anesthetics currently used in adults and children (Solange de los Ríos, Personal communication).

In 1975, neurosurgeon Keith Holder developed the first Pain Clinic, followed in 1991 by Luis Pretto, an anesthesiologist who specialized in Pain Medicine (Solange de los Ríos, Personal communication).

Since 1971, administration of anesthesia by nurses or non-medical practitioners has been forbidden by law. A 3 year residency program was initiated in that year, at the Social Security and Santo Tomás hospitals by the Univer-

sity of Panama and the Ministry of Health. Training in subspecialties has been done abroad. Anesthesiologists work as generalists or as subspecialists in cardiovascular anesthesia, neuroanesthesia, intensive therapy, pediatrics, obstetrics, or pain. Presently, 300 anesthesiologists serve a population of more than 3.4 million inhabitants. The influence of American Medicine is still strong; it is the “raw model” to follow. Drugs not approved by the FDA in the US, are not allowed (Solange de los Ríos, Personal communication).

In 1964, Rodrigo Bernal and Dante Viggiano founded the Anesthesia Society, “Sociedad Panameña de Anestesiología, Reanimación y Algología” (SPARA). In 1977, it became a member of CLASA, and in November 2011, staged the XXXI Latin American Congress and the XIV National Congress of Anesthesia. It has been a member of WFSA since 1984 and of FESACAC since its foundation in 1994. SPARA does not publish a journal or bulletin (Solange de los Ríos, Personal communication).

Reflections

The use of anesthesia in Mexico, Central America, Cuba and other Caribbean islands variably followed Morton’s and Simpson’s demonstrations, Mexico and Cuba often leading the way with delays of up to decades in some of the other countries. Similarly, anesthetic advances in this region, advances in equipment, drugs, training, and anesthetic societies lagged behind those in more developed countries. All countries in this region now have anesthetic societies. Gradually, full-time anesthesiologists, usually trained for three or four years, have increased in numbers, doing so to the point where in several countries in this region (and subspecialists in a few countries) they now are responsible for most of or all anesthetic delivery. However, in several other countries in this region, technicians still deliver a substantial portion of anesthetics.

Summary

Peter Parker introduced ether anesthesia into China on 4 October 1847, using an apparatus supplied by Charles Jackson. A year later, he used chloroform after reading a pamphlet written by James Simpson. Open-drop ether or chloroform, and local and spinal anesthesia were used in China up to the mid-20th century. Physicians, students, nurses, nuns, and technicians—but few professional anesthesiologists—delivered clinical anesthesia. The People's Republic of China was founded in 1949 after the devastation of World War II and the civil war. Jone Wu and Xingfang Li from Shanghai and Deyan Shang, Rong Xie and Huiying Tan from Beijing then returned from the US and Europe, bringing back modern ideas concerning anesthetic delivery. In 1953, Rong Xie organized the first training course in anesthesiology, sponsored by the Peking Union Medical College and Beijing Medical Universities. Development of anesthesiology as a specialty, and the establishment of training programs began in the 1950s, aided by publication of two books, *Clinical Anesthesiology* by Jone Wu, and *Anesthesiology* by Rong Xie.

During the Chinese Cultural Revolution (1966–1976), research and funding were interrupted, and patient care switched to acupuncture and traditional Chinese medicine. Although the above techniques were later abandoned because of their poor performance on their own, acupuncture continued in use as a supplement to anesthesia and analgesia. At the conclusion of the Cultural Revolution, a few pain management programs and post-anesthesia care units and intensive care units were established. In 1979, 44 anesthesiologists were elected as inaugural members of the Chinese Society of Anesthesiology (CSA). The *Chinese Journal of Anesthesiology* (1981), *Foreign Medical Sciences (Anesthesiology and Resuscitation)* (1982), and *The Journal of Clinical Anesthesiology* (1983) began their publication.

A College of Anesthesia was established in Xuzhou Medical School in 1987. In 1989, the Ministry of Public Health formally defined the essential facilities and professional scope of a department of anesthesiology, thereby establishing anesthesiology as a clinical specialty. Chinese editions of *Anesthesia & Analgesia* (2002), *Anesthesiology* (2007), and *Anaesthesia* (2007) began their publication.

Chinese medical schools currently have 8-, 7-, and 5-year options for training in anesthesiology. Anesthesia given by nurses has not been established in China. Data obtained by Shuren Li, Emeritus President of the CSA, said that in 2007, more than 80,000 anesthesiologists were available in mainland China.

Anesthesia in Ancient China

Anesthesia in China dates back to 500 BCE, to the era of Bian Que (Fig. 27.1) the earliest known physician of ancient China. He and Hua Tuo are the most famous early Chinese physicians. Acupuncture, herbs and wine were used to provide anesthesia. Bian Que excelled in pulse taking and acupuncture therapy.

Documents from the Eastern Han Dynasty (25CE–220CE) and the Three Kingdoms (220CE–265CE) periods indicate that Hua Tuo (Fig. 27.2) was respected for his expertise in surgery, anesthesia, and acupuncture, and that he was the first person in China to apply anesthesia for surgery. His general anesthetic combined wine with herbs in a concoction called mafeisan (“boiled cannabis powder”). The Book of Sui Dynasty listed five books attributed to Hua and his disciples, but none survived and Hua's prescription for mafeisan has

Fig. 27.1 Portrait of Bian Que, the earliest known physician of ancient China. (Courtesy of the Chinese Society of Anesthesiology, Beijing, China.)

been lost [1]. Hua was also considered the first surgeon in China. He has been compared to Jivaka of India, who lived at the time of Buddha (about 500 BCE.) and was also renowned for surgery and anesthesia. Hua had no significant successors until modern times, when surgery and anesthesia were reintroduced by Western physicians [2]. Biographical information about *Hua Tuo* appeared in English in three works: an article in the *Journal of Traditional Chinese Medicine*; [3] a monograph in Chen's *History of Chinese Medical Science*; [4] and a report in the *Advanced Textbook on Traditional Chinese Medicine and Pharmacology* [5].

The Introduction of Western Anesthesia into China (1847–1949)

News of the 1846 public demonstration of ether anesthesia for surgery in the US [6, 7] spread to London in December 1846 and Paris in January 1847. Peter Parker, who received degrees from both the divinity and medical schools at Yale, introduced ether anesthesia into China on 4 October 1847, using an apparatus received from Charles Jackson of Boston. He anesthetized a middle-aged farmer for the separation of the eyelid from the eyeball (symblepharon) in Canton Hospital, Guangzhou. A year later, Parker used chloroform in 8–10 cases, after reading a pamphlet written by James Simpson [8].

Anesthesia, as demonstrated by Morton and Simpson, was quickly introduced into large cities including Beijing,

Fig. 27.2 Portrait of Hua Tuo from a Qing Dynasty print. He was the first person in China to apply anesthesia for surgery. (Courtesy of the Chinese Society of Anesthesiology, Beijing, China.)

Tianjin, Shanghai, and Guangzhou. Open-drop ether or chloroform, along with local and spinal anesthesia were used throughout the rest of the 19th century and up to the middle of the 20th century. During this time, physicians, students, nurses, nuns, and technicians might administer anesthesia. Although the anesthesia methods were simple, gastrectomy, cholecystectomy, and even some neurological surgeries were successfully completed. For example, in September 1938, a pituitary adenoma resection was completed in the Peking Union Medical College Hospital (PUMCH) using a combination of local anesthesia with procaine and rectal anesthesia with Avertin.

Modern anesthesiology in China developed formally with the founding of Peking Union Medical College (PUMC) in 1921, by the US Rockefeller Foundation. FC Mclean, a 28-year-old graduate of the University of Chicago, and professor of internal medicine, was appointed the Dean. PB Seam was assigned as the president of its subsidiary hospital, PUMCH. General surgery, orthopedics,

Fig. 27.3 Ma Yueqing, the first Chinese anesthesiologist in Beijing. (Courtesy of the author.)

urology, gynecology, ENT and other surgical departments were immediately established. Miss Helen Holland was in charge of anesthetic delivery. From 1938 to 1941, Yueqing Ma, a 1934 graduate from PUMC, worked in the department of anesthesia as the first Chinese anesthesiologist in Beijing [Fig. 27.3]. The PUMCH was equipped with US-made equipment. A Heidbrink anesthesia machine and a McKesson intermittent flow anesthesia apparatus, believed to have been used in the 1940s, were found in the storeroom of PUMCH in the 1950s,

Development of Anesthesiology in China (1949–1966)

World War II devastated China no less than Europe. The internal disruptions required to oppose the Japanese occupation were compounded by the Chinese civil war that followed. The Marshall Plan assisting reconstruction in Europe did not apply to China. Thus, anesthesiology, like all of

Chinese medicine, faced enormous economic and physical burdens. Anesthesiology as a clinical specialty and science had to begin at ground level, starting in the great cities and spreading from there.

Pioneers in Chinese Anesthesiology

Before World War II, anesthesiology in China strove to keep pace with that in America and Europe. Interns and junior surgical residents were trained to administer anesthesia, but no formal residency program existed, nor was there a professional society to promote the “art and science” of anesthesiology. There was neither a Chinese textbook of anesthesiology, nor a journal devoted to anesthesia.

After World War II, the Ministry of Education underwrote grants to send promising physicians to North America for training in anesthesia with the hope that these physicians would return with the knowledge and expertise to ensure the growth of the specialty in China. The following includes brief biographical sketches of some of these pioneers in Chinese anesthesiology.

Jone Wu (Fig. 27.4), a 1938 graduate of the National Shanghai Medical College, had pursued a career as an instructor in pharmacology at his alma mater for almost a decade. In 1947, he won a Ministry of Education Scholarship to study anesthesiology in the US, and from 1947 until 1949, he studied at the University of Wisconsin in Madison. Wu returned to China in 1950, and founded the Department of Anesthesiology in Zhongshan Hospital of the National Shanghai Medical College, and established the first blood bank in China. By 1954, Wu founded an independent academic department of anesthesiology, to provide a clinical service to the six hospitals affiliated with the medical school. He also helped develop the first Chinese ventilator and anesthetic machine [9]. In 1954, Wu published the first Chinese-language anesthesia text, with a second, expanded edition appearing in 1959. He was instrumental in establishing postgraduate training in anesthesiology and personally trained more than 150 residents.

Deyan Shang (Fig. 27.5) completed a 5-yr medical program in Lanzhou University in 1942. After graduation, he served as a surgeon at his medical school, becoming chief resident surgeon in 1945. Because there was no anesthesia service in Lanzhou at that time, the chief executive officer of Lanzhou Central Hospital persuaded young surgeon Shang to pursue anesthesia training in America, and sent him to the anesthesiology residency program at the University of Illinois (Chicago) in 1948. Shang returned to China in 1949 and established the first Department of Anesthesiology in China in the National Lanzhou Hospital. He began a research program in cardiac physiology, critical care medicine, and resuscitation.

Fig. 27.4 A photograph of Jone Wu taken in February 1986 at his residence in Shanghai. He holds three books that he wrote on anesthesiology. The middle one is mentioned in the memorial tribute to him published in 1954 in *Clinical Anesthesiology*. (Courtesy of Joseph Ruprecht, MD, PhD.)

In 1956, he moved from Lanzhou to the Fu Wai hospital in Beijing, a major teaching affiliate of the PUMC, where his career blossomed. In 1957, he established the first animal research laboratory in China, investigating issues associated with invasive cardiothoracic anesthetic management, hypothermic anesthesia for cardiac surgery, and resuscitative studies. Shang helped found the Chinese Society of Anesthesiologists (CSA) in 1979, and became its first president. In addition, he helped establish the Chinese Journal of Anesthesiology in 1981.

Rong Xie (Yung Shieh) (Fig. 27.6) graduated from the Tong Ji University School of Medicine in 1946. He traveled to America, and received training at the Detroit Receiving Hospital in Michigan, affiliated with Wayne State University. He received additional training in Pittsburgh, Pennsylvania, before returning to China in 1950. He first traveled to his

Fig. 27.5 Deyan Shang (1918–1985), the first president of Chinese Society of Anesthesiology. (Courtesy of the Chinese Society of Anesthesiology, Beijing, China.)

home province of Yunan to develop anesthesiology in the southwest region of China. In 1956, Xie started a collaborative relationship with Shang in Beijing. He was appointed associate professor at Peking Medical University in 1957, and succeeded Shang as the second president of the CSA, in 1984. He established the first Surgical Intensive Care Unit directed by an anesthesia department in China in 1985. He was also the founding editor-in-chief of the Chinese Journal of Anesthesiology.

Xingfang Li went to the US in 1947 for training in anesthesia. After returning to China in 1947, Li began work in the Renji Hospital at the Shanghai Second Medical School, establishing the Department of Anesthesiology there in 1954. Three years later, Li moved to the Ruijin Hospital, also affiliated with the Shanghai Second Medical School, where she established another Department of Anesthesiology following the anesthesia group established by the famous surgeon, Jixiang Shi. Li was an expert in hypothermia and cardiac anesthesia.

Huiying Tan graduated from Yunnan Medical School, and went to Europe in 1947, to study and work in the Department of Anesthesiology of the University of Paris. In 1956, she returned from France and pioneered “artificial hibernation

Fig. 27.6 Rong Xie (Yung Shieh), the second president of the CSA in 1984. He established the first SICU directed by an anesthesia department in China in 1985. therapy”, a state of deep sedation induced with pethidine and chlorpromazine (or promethazine).

These five pioneers are credited with elevating the national standard of anesthesia in clinical training, research, and education. They were instrumental in shaping Chinese anesthesia.

Progress in Anesthesia Methods and Machines

In the 1950s, most anesthesia practice consisted of open-drop ether inhalation, local infiltration anesthesia, and single-injection spinal anesthesia. Some anesthesia machines were in use, and nearly all equipment was imported, including Heidbrink machines from the US, Drager machines from Germany, and Boyle machines from the British Oxygen Company. Meanwhile, domestic manufacturers progressed from simple imitation of non-Chinese equipment to modification and improvement of machines built in China. Chinese brands included the Shanghai Tao Gen Ji (later the “Zhong Hua” brand, similar to the Heidbrink anesthesia machine); the Zhonghua compound anesthesia machine (with an attachment for pediatric anesthesia), a multi-functional anesthesia machine (with positive and negative pressure ven-

tilation), and the “103” closed circuit anesthesia machine. The first continuous-flow anesthetic machine was made in Shanghai in 1956, and the first artificial heart-lung machine was constructed, also in Shanghai, in 1957.

Most hospitals once used and are still using these products which combined quality and reasonable price. Chinese anesthesiologists were innovative and adaptive. If equipment was not ready-made, anesthesiologists used considerable ingenuity. For example, they might obtain smooth and slippery rubber tubing of appropriate diameter from grocery stores, and cut them into different lengths to make tracheal tubes. The distal end might be beveled and smoothed with sandpaper [10]. Meanwhile, other equipment was manufactured, including epidural and spinal needles, and laryngoscopes.

Anesthetic drugs, including ether, procaine, and succinylcholine were also manufactured in China, starting in the 1950s. Locally made procaine became available in 1955, and succinylcholine in 1964. During the 1950s and 1960s, epidural anesthesia, intravenous anesthesia with procaine, and nerve blocks became the most popular anesthesia techniques in China, largely because these techniques were simple and inexpensive.

Despite the problems of the times, major complicated surgery and related therapies by anesthesiologists were initiated in some major city hospitals. For example, the first mitral valvuloplasty was performed in 1954, in Shanghai, and the first interventricular septal defect repair using cardiopulmonary bypass, was performed successfully in 1958, in Xi’an. In 1958, steel worker, Caikang Qiu, suffered extensive burns to 89% of his body, and was thought unlikely to survive. But the efforts of anesthesiologists, internists, surgeons, and nurses resulted in his successful treatment in Ruijin Hospital in Shanghai.

Yuanchang Wang (1922–1998) from Tianjin Medical College is the world’s pioneer of external chest compression for cardiopulmonary resuscitation, providing what may be the first report of such therapy. In 1955, he used external chest compression successfully in 2 patients suffering cardiac arrest following epidural anesthesia. He published a report of “*Management of Complications in Epidural Anesthesia*”, in the *Chinese Journal of Surgery* in 1957. In his paper, Wang described external chest compression and its advantages in detail, emphasizing the importance of immediate recognition of arrest and action to restore cardiac function [11]. The following gives a summary of the two cases and the resulting conclusions:

Case 4: “Although 25 mg ephedrine was injected intravenously two times, the patient’s condition was not improved and cardiac arrest subsequently occurred. External chest compression was immediately performed. After one minute, powerful heartbeat reappeared and blood pressure returned to 140 mmHg.”

Case 5: “Pulse and blood pressure were undetectable, and the heart sound was not audible. External chest compression was performed at once, and ephedrine and Nikethylamide were also given intravenously. Five minutes later, the first chest compression operator tired and was then replaced by another person to continue the external cardiac compression. Within half a minute, regular and powerful heartbeats returned. Blood pressure returned to 150/70 mmHg and pulse to 140 beats per minute.”

In the Discussion, Wang wrote: “Cardiac massage should be immediately applied without any hesitation once heart beat stopped. Details of the methods are described in the literature. We performed external chest compression in two patients (cases 4, 5) in this paper. To do external chest compression, operator should stand on the left side of the patient, facing patients head. Palm with curved fingers is placed on the cardiac region of anterior chest wall, pressing the chest wall backwards like punching, about 70 to 90 times per minute. Such compression should be performed using the palm without moving fingers. External chest compression would not be effective if compression on the chest wall is not powerful.

The advantage of external chest compression is very simple, so that every health-care provider can do it. According to animal study, within one and half minutes of cardiac arrest, myocardium excitability and conductivity increase. Therefore, heart beat can easily return by cardiac massage during such period. External cardiac compression should be immediately applied when cardiac arrest occurs during epidural block. Because opening chest or abdomen is avoided, one may get precious time to save patient’s life. In addition, bleeding and infection caused by opening the chest or abdomen are also avoided by using this external cardiac compression. So far we can not get a final conclusion on the effects of the method due to limited experiences from the only two cases in this paper. But, at all events, whenever cardiac arrest occurs during epidural block, we should try our best to use this method.” [11]

Dexin Li, Chairman and professor of the Department of Anesthesiology, Nanjing General Hospital of Nanjing Military Command, led advances in brain resuscitation and blood gas analysis. In 1962, he combined selective head cooling with osmotic diuresis, to successfully resuscitate a patient who had been in cardiac arrest for more than 10 min. He also applied blood gas analysis to guide the monitoring and treatment of respiratory failure, and saved the lives of many patients with multiple organ failure.

Academic Development and Personnel Training

As indicated above, in the early 1950s, professional anesthesiology was established in the hospitals of major Chinese

cities. At that time, Anesthesiology was a sub-discipline of surgery, and consistent with the expansion of surgery, the number of professional staff engaged in anesthesia gradually expanded.

Early anesthesia practice focused on surgical operations, and was limited by the number and types of operations performed. With the expansion and increasing complexity of clinical work in sometimes severely ill patients, greater demands were placed on anesthesiologists to expand both basic knowledge and expertise. Training and education assumed increasing importance. Thus, in July 1953, Rong Xie chaired the first training course in anesthesiology, a course organized through the joint efforts of PUMC and Beijing Medical University. Support of the course included compilation of a “Clinical Anesthesiology Lecture”. The lecture systematically traced the development of modern anesthesia, including general anesthesia, spinal anesthesia, and blood transfusion. The course laid the foundation for future training and education [12].

Academic Activities in Anesthesiology

The earliest academic activities in Chinese anesthesiology were described in the first anesthesiology report to PUMC in 1951, by Rong Xie. Discussion included the significance and practical application of premedication, anesthetic techniques, and new anesthetics. After the Korean War (1950–1953), Deyan Shang trained many anesthesiologists for the army, significantly increasing their numbers. In February 1954, the Society of Surgery (Beijing Branch, Chinese Medical Association) organized a conference on epidural anesthesia at the PUMC. Dexin Li initiated the First National Conference on Anesthesia in Nanjing in 1964 (Fig. 27.7). The conference systematically reviewed the development and achievements of Chinese anesthesiology, including research on respiratory physiology, treatment of shock, cardiac arrest and resuscitation, and anesthetic management of heart and major vascular surgery. These early discussions lagged behind international standards for at least five years, but stimulated interest in technical development and scientific research. Gradually, academic activities became formalized under the imprimatur and name of the Chinese Society of Surgery—Anesthesiology Branch, and the Chinese Society of Anesthesiology. This support of academic activity has continued to increase [12].

Anesthesiology Books and Journals

Before the 1950s, there was no Chinese anesthesiology journal because Anesthesiology was a division of surgery rather than an independent specialty, and most research articles

Fig. 27.7 The First National Conference on Anesthesia was held in Nanjing in 1964 to systematically review the development and achievements of Anesthesiology. (Courtesy of the Chinese Society of Anesthesiology, Beijing, China.)

were published in surgical journals. Two books published in the 1950s played a major role in the development of Chinese anesthesiology and the training of practitioners. They were *Clinical Anesthesiology* by Jone Wu (Shanghai), and *Anesthesiology* by Rong Xie (Beijing). [12]

The Cultural Revolution and the Recovery Period

The Cultural Revolution in China (1966–1976) caused social, political and economic upheaval. Prominent intellectuals, especially professors, were persecuted, and this greatly impeded the development of anesthesiology and surgery. Scientific work either stopped or switched to acupuncture and Traditional Chinese Medicine. The limited research funding that existed was allocated solely to these two areas. Fortunately, China continued research on nerve growth factor and the endogenous opioid, endomorphin, as they were related to studies of acupuncture; and studies of the microcirculation were promoted. Only a few new drugs were developed, such as cissampelosime methiodide, for muscle relaxation. This drug was extracted from a Chinese Medicine called *Herbaccissampelotis*. Its structure and purity are not known to the present authors. In addition, domestic ketamine, fentanyl and haloperidol were produced, thus enabling the development and use of dissociative and neurolept anesthesia and analgesia. Except for these few bright spots, the Cultural Revolution significantly and adversely affected the development of Anesthesiology in China.

Because ties between China and the outside world were severed during this period, development of Chinese anesthesiology missed the halothane epoch. Routine anesthesia applied intravenous procaine plus ether inhalation, along with epidural anesthesia. Because of the special status of the Chinese People's Liberation Army (PLA), the anesthesia and resuscitation group that existed within the PLA were not subjected to the same restrictions as others, and thus became an important force in Chinese anesthesiology.

In 1976, the Cultural Revolution officially ended, and all that had been left undone now awaited attention. Anesthesiology was among those scientific fields to be reconstructed. Inspired by the National Science Conference held in 1978, Anesthesiology resumed its advance.

Anesthesiology and Anesthesiology Societies Develop (1979–1989), and Anesthesiology Becomes an Independent Academic Discipline

The pioneers mentioned above established the specialty of anesthesiology in some hospitals affiliated with medical schools. These became the bases for clinical work, scientific research, and education and training in China. In the 1950s, daily clinical anesthetic work was the principal focus. As time progressed, further areas of activity were developed. In the 1960s, these included cardiopulmonary and cerebral resuscitation. In the 1970s, a small number of hospitals began to develop pain medicine, together with the establishment of post-anesthesia care units and intensive care units. In the 1980s, consistent with the world-wide development

of new specialty areas within anesthesiology, the specialty achieved further recognition. However, anesthesiology was often viewed as a technical rather than a clinical department in domestic hospitals. In 1989, the Ministry of Public Health formally defined the facilities within the professional scope of a department of anesthesiology:

“The department of anesthesiology should be a clinical department rather than a technical department. More emphasis should be showed on personnel training, instrument and equipment. The working level should be improved to meet the demands of medical development.”

This established Chinese anesthesiology as a recognized clinical specialty, as opposed to a technical specialty in a supporting role for another clinical specialty, and therefore with a lower status [12].

As reform and open policies progressed, Chinese interchanges with the world increased. More advanced anesthesia equipment, anesthetic medications, and techniques were introduced from abroad. Anesthesia machines (Drager, Datex, Ohmeda) and modern volatile anesthetics, including isoflurane and enflurane, were eventually imported and employed in routine clinical practice.

The Chinese Society of Anesthesiology Is Founded In August 1979, the 2nd National Anesthesiology Annual Meeting of the Chinese Medical Association (CMA) was convened in Harbin, Heilongjiang Province. During the meeting, besides academic discussion and paper presentations, 44 anesthesiologists were elected as inaugural committee members of the Chinese Society of Anesthesiology (CSA) of the CMA. Deyan Shang, the chairman of the department of anesthesiology in Fuwai Hospital, Beijing, was elected as the first President. Rong Xie, Jone Wu, and Huiying Tan (from Beijing Soviet Red Cross Hospital, currently Beijing Friendship Hospital) were elected as vice-Presidents. In contrast to the order often followed in other countries, local Societies of Anesthesiology followed establishment of the National Society.

Following formation of the Society, international academic activities increased. In 1986, the Beijing International Conference on Anesthesia was successfully held. From that time, Chinese anesthesiologists began to communicate more with their international colleagues. At the first Sino-Japanese Clinical Anesthesia Symposium held in 1986, the CSA and the Japan Society for Clinical Anesthesia, represented respectively by Rong Xie and Kosaka Futomi, agreed to hold a symposium every 2 years. These symposiums promoted the modernization of Chinese Anesthesiology.

Journals Several journals were launched, including the *Chinese Journal of Anesthesiology* in Shijiazhuang in 1981, *Foreign Medical Sciences (Anesthesiology and Resuscitation)* in

Xuzhou in 1982, and *The Journal of Clinical Anesthesiology* in Nanjing in 1985.

Colleges of Anesthesia One of the most important indications of progress during this period was the 1987 establishment of the College of Anesthesia in Xuzhou Medical School by Yinming Zeng, who devoted his life to education in anesthesiology. This was the first College of Anesthesia founded in a medical school in China and represented a landmark in the history of Chinese anesthesiology. In effect, it was an enlarged anesthesia residency. Students underwent 5 years of study and training in anesthesiology, pain management, and critical care medicine to get their Medical Degree. This College of Anesthesia cultivated a greater knowledge and expertise in anesthesiology.

Many other Colleges of Anesthesia have been established, such as in Harbin Medical University, Hunan Medical University, and Tongji Medical University, all in 1988. By 2011, 54 medical universities had established Colleges of Anesthesia. This is a characteristically Chinese approach of anesthesia training. However, whether this approach should exist as an undergraduate major in medical school remains controversial.

The Rapid Development of Anesthesiology in China (1990-present)

The last 20 years have been exciting for Chinese anesthesia, largely because of the increasing opportunities that allowed the sharing of clinical and research experiences, making anesthetic practice safer and better than ever before. By 2007, China had 80,000 anesthesiologists (nurses do not provide anesthesia in China).

Advances in Anesthetic Equipment and Medications

More advanced anesthetic technology and medication were introduced into China from abroad. The manufacture of anesthetic instruments in China developed from imitation of foreign anesthetic machines and assembly of imported components, to the creation of original products. Improvements by anesthesiologists and technicians narrowed the gap between Chinese components and foreign ones in both quality and accuracy. In the 1990s, various anesthetic and adjuvant medications were available, and most new medications manufactured abroad were accessible in clinical practice. Indeed, some of our products now meet international standards.

During the last 20 years, Chinese anesthesiologists have advanced some innovative ideas and practices. The former president (2009–2012) of the CSA, Buwei Yu, has initiated

the concept of “ideal anesthesia”, which aims to monitor and control vital signs at predetermined “ideal” (normal) values, and achieve other desirable outcomes (e.g., minimizing post-operative nausea and vomiting). Hopefully, ideal anesthesia should provide patients with greater satisfaction and safety.

In addition, in the 2000s, Jin Liu from West China Hospital, Sichuan University completed a lot of animal studies and a phase I clinical trial on 130 human volunteers with emulsified isoflurane. These studies indicate that induction of and recovery from anesthesia with emulsified isoflurane is faster than with propofol, and provides stable hemodynamics. Therefore, it may be particularly suitable for rapid sequence induction and short and invasive examinations and therapies. In addition, it would reduce pollution (because may be equivalent to closed circuit anesthetic delivery), and is convenient to carry and use in the wild or on battlefields. As with inhaled potent anesthetics, emulsified isoflurane preconditioning has a protective effect against liver and lung injury, improves survival in hemorrhagic shock [13], and provides protection against cardiac ischemia reperfusion injury [14, 15].

The Chinese Society of Anesthesiology (CSA)

The CSA has built cooperative relationships with international associations, such as the American Society of Anesthesiologists, the International Anesthesia Research Society, and the Association of Anaesthetists of Great Britain and Ireland. Young Chinese scholars increasingly participate in major international meetings held in the US, Europe, Japan, and surrounding countries and regions. Famous professors from abroad (e.g., Ronald Miller and Edmond Eger) have visited China as keynote speakers. These activities enhance Chinese anesthesiologists’ familiarity with and contribution to international achievements and developments in anesthesiology. In return, these efforts make Chinese anesthesiology known to the world, and provide a foundation for the future development and international communication of Chinese anesthesiology.

The CSA plays a vital role in the progress of Chinese anesthesiology, acting as the conduit for official connections with many developed and developing countries; publishing many guidelines and recommendations on clinical practice; supervising the Quality Control Centers for Clinical Anesthesia; and establishing refresher courses for anesthesiologists from undeveloped regions.

Anesthesia Training Reforms that followed the cultural revolution enabled many young anesthesiologists to go abroad to receive training. In Chinese medical universities, there are now several training programs, varying in their lengths of study. Many are 8-year training programs, initiated by

famous medical schools at the end of the twentieth century. The first 8-year training program was established in PUMC, reflecting practice in the US (i.e., 4 years of medical school and 4 years of training devoted to anesthesia). There also are 7-year and 5-year programs. Most specialists in anesthesiology come from undergraduate and postgraduate programs. A system of nurse anesthesia training has not been established in China.

According to 2007 data from Shuren Li, Emeritus President of the CSA, more than 80,000 anesthesia professionals are available in mainland China which is a large number. However, the population in China is 1.3 billion, and at least 150,000 anesthesiologists are needed. In addition, economic and medical development has been uneven among regions. About 4000-to-5000 medical school graduates begin to study anesthesiology each year. However, no national standardized training system currently exists. Usually, anesthesia residents take 3 years for basic anesthesia training and 2 years for advanced sub-discipline anesthesia training, such as cardiovascular anesthesia, pediatric anesthesia, intensive care, and pain management. After these 5 years of training, they must pass a national examination before being certified as attending anesthesiologists.

Academic and Research Activities Since the 1990s, academic activities have been promoted both domestically and internationally. The National Conference on Anesthesia has been held annually since 2000, and symposiums attracting young scholars and specialists are held all over China throughout the year. In addition, international communications have been enhanced. Ailun Luo, after being elected President of CSA in 1997, advocated China’s integration into the world anesthesia community. She was conferred an Honorary Fellowship of the Royal College of Anaesthetists of the United Kingdom.

From the 1990s until today, research in Chinese anesthesiology has moved as fast as the economy of China would permit. Many well-known journals including, *Anesthesia & Analgesia*, *Anesthesiology*, and *Anaesthesia*, have been published in Chinese editions from 2002, 2007 and 2007, respectively, extending their influence among Chinese professionals. These localized journals become the window for communication in anesthesiology between China and the world. Moreover, with the progress of Anesthesiology, the numbers and qualities of research funds have been increasing. Clinical and basic studies have been conducted and increasing numbers of papers from mainland China have been published in international academic journals. In *Anesthesiology*, there were no Chinese studies published in 1999, and 5 in 2009.; In *Anesthesia and Analgesia*, the number rose from 1 to 14, and in the *British Journal of Anaesthesia*, the number rose from 0 to 4.

Conclusions

Anesthesiology in China has met many obstacles and opportunities during modern times. Several generations have striven to catch up with western countries, having had to contend with poverty, civil war, and great societal upheaval from the Cultural Revolution. Anesthesia practice today is performed by well-educated anesthesiologists using increasingly advanced anesthetic technology and medications. Academic and research activities are developing rapidly, as are anesthesia training and international communication. Future Chinese anesthesiologists will play an increasing role in the international arena. A bright future lies ahead.

Summary

The first trial of ether in France antedated use of the agent in England. During the next few years, France's Académie des Sciences examined the claims for the discovery of anesthesia, finally according it jointly to Morton and Jackson. By 1848, chloroform displaced ether despite inexplicable fatalities associated with its use. In 1908, ether spectacularly returned with the introduction of the Ombredanne inhaler, remaining popular in France to the 1960s.

As World War II began, doctors, pharmacists, dentists and medical orderlies might be briefly trained in anesthesia. Surgeons directed anesthesia, and article 45 of the 1947 code of practice gave the “*surgeon...the right to choose his operating assistants as well as the anaesthetist.*” Students completing a 6-week course, supervised by surgeons or physicians and supplemented by a 6-month hospital assignment, received a “Certificate of Anaesthesia”. The institution of examinations in 1948 led to the award of the Diplôme d'Anesthésie-Réanimation (Diploma in Anesthesia and post-operative care)

In 1934, surgeon Monod founded the Société d'études sur l'anesthésie et l'analgésie (SEAA). The Society published a review (*Anesthésie et Analgésie*) since 1935. In 1938, the Society became the Société Française d'anesthésie et d'analgésie (SFAA), but went dormant during World War II, reviving in 1946 with 117 members, mostly surgeons but including 17 anesthetists.

Until 1947, only surgeons received fees, giving about 10% to “assistants”. Anesthetists provided all supplies, promoting use of the least expensive approaches. From 1947, “Special anesthesia” by a qualified anesthetist warranted a separate fee. In 1958, a major reform of hospitals created full-time anesthesia posts and services. A 1960 Government decree recognized anesthesiology as a specialty, renamed in 1970 as Anesthésie-Réanimation, emphasizing the anesthetist's role in post-operative care. In 1979, the Conseil National de l'Ordre recognized anesthesiologists as medical specialists, independent of surgeons. From 1989, postgraduate medical education expanded to include anesthesia (previously restricted to older medical specialties), and 5 years of training led to the Diplôme d'études supérieures en anesthésie-réanimation (DESA). Concurrently, schools for nurse anesthetists opened, and examination led to the Certificat d'Aptitude aux Fonctions d'Aide Anesthésie. Like physicians, nurse anesthetists organized training programs and trade unions, and worked in accordance with statutes they devised. They competed with doctors, creating still unresolved antagonisms.

French anesthesiologists developed the prehospital emergency system, SAMU (Service d'Aide Médicale Urgente) in the 1970s, reasoning that in emergencies the hospital should go to the patient. In 1982, two previously disparate groups fused into la Société Française d'Anesthésie et Réanimation (SFAR), establishing the journal, Annales Françaises d'Anesthésie et de Réanimation (AFAR).

Introduction

Anesthesia in France initially developed in parallel with English speaking countries, but the details of that history are little known outside France. Nineteenth century French innovations reported in French often went unnoticed elsewhere. In addition, the development of anesthesiology as a specialty was slow. This chapter provides insights into the problems faced by anesthetists in France, from the middle of the 19th century to the end of the 1980s, when French anesthesia

could be regarded as being again in step with the progress of the speciality in other parts of the world [1–4].

The Early Years of Surgical Anesthesia (1846–1850)

France Adjudicated the American Quarrel about Discovery

From January 1847, the use of ether spread in France, as it did in England and throughout the rest of continental Europe. Charles Jackson (1805–1880), William Morton (1819–1868) and then Horace Wells (1815–1848) battled for recognition as the discoverer of anesthesia. They appealed to France to adjudicate, since for them a valid opinion could only come from Paris, at that time the medical capital of the world.

At the meeting of the Académie des Sciences, [4] on 18 January 1847 (six days after the first French communication about anesthesia to the Academy of Medicine), Christophe Ducros (1808–1849) claimed the discovery of anesthesia, recalling his paper of 16 March 1846 on the effects of sulphuric ether. His experiments carried out in 1842 showed the hypnotic effects of ether rubbed into fowls, and also mentioned similar effects in man. Accordingly, he claimed to have invented anesthesia, before the American who had recently suggested that the ablation of consciousness using ether could be of value in patients undergoing surgery. At the meeting, Léonce Elie de Beaumont (1798–1874), a geologist and a friend of Jackson requested that a sealed envelope¹ which he had delivered to the meeting of 28 December 1846, be opened. This contained three letters from Jackson which were read to the Academy. The first was dated 13 November 1846, and the second, 1 December 1846. The following are extracts from the letters:

‘I request permission to communicate to the Academy of Science through your intermediary a discovery which I have made which I believe to be important for the alleviation of human suffering and of great value for the art of surgery’ (...) ‘On learning that a local dentist was giving ether to patients requiring tooth extractions I asked him to go to the Massachusetts General Hospital and to give the vapour to a patient undergoing a painful surgical operation. The result was that the patient did not feel the slightest pain during the operation and was well afterwards.’ The letters claimed responsibility for the discovery and maintained that Morton had been but a technician. He did not even mention the latter by name.

Elie de Beaumont supported Jackson’s claim and his scientific credentials, and brought the discovery to the attention of

the Academy. After this lecture, the surgeon Alfred Velpeau (1795–1867) noted that:

‘The secret in question in the note which I have just read has not been a secret for long. The journals in America and England have revealed it since the month of November. I personally learned about it in a letter from Dr Warren in Boston over a month ago and Dr Willis Fisher, from the same town came to ask me to conduct a trial at the Charité (hospital) about the middle of last December’.

There followed a short narrative in which Velpeau cited the name of Morton, and related the results of his own experiments in anesthesia and those of others, about which he had learned in Paris.

At the 25 January 1847 meeting of the Académie des Sciences, Ducros again laid claim to the invention of anesthesia, but was ignored. For the moment, the French academics gave the credit for the discovery to Jackson.

Horace Wells, who had arrived in Paris at that time to start an engraving and painting business was welcomed by his friend and fellow Bostonian, Christopher Brewster (1799–1870), who practiced in Paris. Wells convinced Brewster that he was the inventor of anesthesia. Brewster introduced him to his circle of friends, and Wells lectured on nitrous oxide and ether. His presentation to the Société Médicale de Paris on the 17 February 1847 (*A history of the discovery of the application of nitrous oxide gas, ether and other vapors to surgical operations* [5]) propelled him to fame. He wrote to the Academy of Medicine (the meeting of the 23 February 1847) [4] and to the Academy of Science (the meeting of 8 March 1847) [4] to claim recognition for the discovery:

‘Reasoning from analogy, I was led to believe that surgical operations might be performed without pain (...) By these facts I was led to enquire if the same result would not follow by the inhalation of exhilarating gas (...) I accordingly procured some nitrous oxide gas, resolving to make the first experiment on myself, by having a tooth extracted, which was done without any painful sensations (...) This discovery does not consist in the use of any one specific gas or vapour, for anything which will cause a certain degree of nervous excitement, is all that is required to render the system insensible to pain.(...).’

There followed a lively discussion in the Academy, not just about who made the discovery but also on the use of nitrous oxide, which was contested by Matéo Orfila (1787–1853) and Pierre Boullay (1777–1869), since the gas appeared to them to be dangerous. Nicolas Gérardin (1790–1868) recalled that a London surgeon had written a letter bringing this topic to the attention of the Academy 17 or 18 years previously, when only Baron Larrey (1766–1842) had defended the use of nitrous oxide. This letter from Henry-Hill Hickman (1800–1830), read to the Académie de Médecine on the 28 September 1828, developed the idea that ‘*by introducing certain gases into the lungs the ability to feel could be*

¹A sealed envelope is a system whereby an inventor may guard his rights to an invention which are still uncertain. The latter is kept by the Academy and is not opened until requested by the depositor.

suspended'. This letter remained forgotten by the Academy of Medicine, and was finally lost.

The Academy of Science received a similar demand from Wells. The secretary added that this claim could not be considered until the documents proving the claims had been received. Jackson's friend, Elie de Beaumont, noted that the delays involved in examining the claim were unduly long and consequently diminished the value of the claim. He supported Jackson noting '*the true benefactor to humanity is the person who asked the dentist to pull a tooth from a person who was in a state induced by the inhalation of ether.*' Wells returned to Boston to collect documents proving his claims.

During the session of the Académie des Sciences [4] of 22 March 1847, Elie de Beaumont read a new, Machiavellian letter from Jackson, dated 28 February 1847. He noted a respiratory problem during an anesthetic given in Boston, and recommended the use of oxygen and precautions that should be taken before any anesthetic. This valuable scientific information brought honour on its author. In a second paragraph he justified the claim for a patent for anesthesia '*I was very opposed to the idea of taking out patents for anything that could reduce human suffering (...) but I decided to do so in order to establish my rights as author of the discovery and to be able to authorize others to use it*'. In a footnote he said that he had been obliged to include Morton in the patent since Morton had worked under his orders, but that he had been surprised to see him as sole owner of the rights six months later, although only for the US. These facts were proven to be false some months later, but the French Academies were not informed of this. The third paragraph contained an attack on Wells' requests. He finished with the final discovery he had made—dental cement—which confirmed his position as a man of science.

On the same boat that left Boston for Europe on 1 March 1847, Jackson sent copies of the Boston Advertiser of the 1st March 1847 to a hundred medical and other personalities. This contained the minutes of the meeting (written by him) of doctors in Boston where he had claimed his rights to the invention. In the minutes, he listed all the doctors and other persons who were present at the meeting. His carefully drafted text gives the impression that all present warmly favoured his claim. But the minutes are a fiction, since the meeting was not held until 2 March, after the departure of the mail boat for England! The honesty of Jackson had been placed in some doubt in Boston, but in Europe and particularly in Paris, the falsehood was accepted, and Jackson remained the discoverer of anesthesia.

Morton's response was to send a letter to the Académie des Sciences, which was received on 17 May, and a memorandum to the Académie de Médecine, mentioned in the Proceedings of 2 November 1847 under the title *Works received: 'Memorandum on the discovery of a new use of sulphuric ether by Morton'*.

Jackson continued to send legal documents supporting his claim to the Académie des Sciences (meetings were held on 5 May and 5 July 1847). The disregard of Morton's claim incensed the French consul in Boston. He wrote to the Ministère de l'instruction publique (Minister of Education), requesting him to kindly communicate the contents of his letter to the Academies. The letter was duly read to the Académie de Médecine on 21 September:

'I forward (some) publications sent by Mrs Gray and Warren (the son of John Collins Warren who had welcomed Morton) which put beyond doubt the fact that the honour for this discovery is due to Dr WTG Morton (following the receipt of the abstract of the brevet by Morton and the general attitude of Jackson). Jackson had so little confidence in the effectiveness of the 'ether' that he ceded all his rights to the discovery to Dr Morton for the sum of 500 dollars.'

The Académie des Sciences did not mention this submission until the proceedings of 18 October. On 13 December 1847, and 27 March 1848, Elie de Beaumont sent further notes by Jackson and announced an emissary (Mr Peabody), to confirm his priority.

On 24 January 1848, in a state of despair, Horace Wells committed suicide in prison while awaiting trial. Several days following his burial, a letter arrived in Hartford, sent from Paris by Brewster: "*My dear Wells I have just returned from a meeting of Paris Medical Society, where they have voted that to Horace Wells of Hartford, Connecticut, USA, is due all the honour of having first discovered and successfully applied the use of vapours or gases whereby surgical operations could be performed without pain.*" [6] But the Association des Médecins in Paris was not the Academy, and Wells had only obtained this recognition from the Société Médicale de Paris. The announcement of Wells' death arrived in Paris after this honour had been granted. In 1910, a statue of Wells was erected in the Place des Etats-Unis in Paris (Fig. 28.1).

On 24 April 1848, Morton announced to the Académie des Sciences that documents had been sent, which proved his claim and cited Dr. Bigelow as a witness. The Academy did not however receive these documents in April, and would indeed never receive them. They were contained in six cases which had been mislaid during Customs clearance. When Morton was informed after a delay of six months, he asked to whom in Paris he might send them. He requested the dentist Brewster (the friend of Wells) to assist. Brewster managed to clear the cases from Customs using money sent by Morton, but then held onto them for two years without responding to Morton's queries.

The Commission that was charged with the task of establishing who had made the discovery, took its time. On 16 April 1849, the Ministère de l'Instruction Publique (Minister of Education) sent a copy of a letter from Jackson to the Academy of Sciences on the occasion of his being awarded the decoration of Chevalier de la Légion d'Honneur. In the

letter, he expressed his gratitude to the Academy for the welcome he had received from it, following his discovery of ether anesthesia.

Morton re-sent a letter to the Académie des Sciences dated 16 March 1849, which was read at the 23 April 1849 meeting, concerning the question of ownership of the discovery. He reminded the Academy that the annual report of the Massachusetts General Hospital of 1848, formally accorded him the honour of having made the discovery. He added that, when the question was raised in the US Congress, the majority of the Congress reached the same decision.

The results of a Commission in charge of awarding a prize in Medicine and Surgery (the Prix Montyon), for the years 1847 and 1848, were announced by Dr Roux on 25 February 1850 [4]. *'A prize in the sum of 3000 francs² is awarded to Dr Jackson for his observations and experiments on the anesthetic effects produced by the inhalation of ether; (...) and a further prize of a similar sum is given*

²What corresponded to approximately one year of salary for a worker.

to Dr Morton for having introduced the method into surgical practice, following guidance from Dr Jackson. In the report concerning these prizes, read during the subsequent session (4 March 1850), [4] the Academy concluded that it could not determine who of the two, had made such a marvellous discovery. The prizes were duly reduced to 2500 francs.

The judgement was that of Solomon for some, but unfair for others. Jackson was unhappy to be associated with Morton, but still accepted the prize. For his part, Morton protested against the decision of the Academy and refused the prize. This caused a scandal in the Academy, since it was thought unacceptable that Morton had not received any reward because the Academy had received several documents favourable to his case over a period of time. After long discussions, the Commission decided to create a gold medal to the value of the prize. On one side of the medal was the Institut de France, surrounded by a Minerve (the Roman goddess of science and the official emblem of the Institut de France); and on the other side, the inscription 'Académie des Sciences, Montyon prize for medicine and surgery Concours of 1847 and 1848 WTG Morton 1850'. However the value of this medal was still less than that of the prize, so the Academy requested the maker to add a laurel wreath to make up the difference. All this enraged Jackson who had only a diploma, while the name of Morton appeared on the medal. Several years later, Morton had to sell the medal to provide for his family [6]. The fight between Jackson and Morton would continue in the US.

The Early Demise of Chloroform: A Clash of Two Personalities

The first death from chloroform in France occurred in 1848, several months after Hannah Greener died in England. The French Government ordered judicial and medical inquiries. The Academy of Medicine set up a special commission which arrived at contentious conclusions. The patient, a healthy 35-year-old woman, needed surgery for an abscess that had formed around a foreign body resulting from a riding accident. Within a minute of inhaling from a gauze pad onto which 20 drops of chloroform had been poured, she exclaimed *'I am choking'*, turned pale and died despite two hours of attempted resuscitation (involving insufflation of air into the airways) [7]. Malgaigne, who had presented his studies on ether anesthesia to the Academy one year earlier, led the inquiry. The Commission included Antoine Jobert (de Lamballe) (who had given the first ether anesthetic in Paris on December 15 1846), Alfred Velpeau (an adept enthusiast of surgical anesthesia), and Frédéric Blandin (author of a lengthy academic study on the effects of ether in 1847). Of the 13 Commissioners 7 were surgeons and the remainder veterinarians, pharmacists and chemists.

Fig. 28.2 Joseph-François Malgaigne and Jules Guérin. (Malgaigne image from <http://www.biusante.parisdescartes.fr/histmed/image?anmpx37x0163terb> Guérin image from <http://www.biusante.parisdescartes.fr/histmed/image?anmpx05x0189>)

Malgaigne presented the Commission's findings to the Academy in October 1848. They questioned the details of the report written by the surgeon who had conducted the anesthesia and operation, focussing on the dose of chloroform and the delay to the moment of death. They noted that the woman said *'I am choking'*, indicating in Malgaigne's view that the chloroform had not started to work. They suggested therefore that the sudden death was, without doubt, due to anxiety, or to a gas embolism (gas was found in the blood vessels at autopsy). Finally, the death was attributed to asphyxia (as Simpson had suggested for Hannah Greener). Other deaths occurred subsequently, but such cases were rare, being less than a dozen in one year out of several hundred chloroform anesthetics. Concerning the overall safety of chloroform, Malgaigne noted that *'one could not set up rules starting from exceptions. It was only necessary therefore to introduce certain precautions to avoid asphyxia'*.

This conclusion was not unanimously accepted, some members of the Commission noting that sudden deaths had occurred in animals as well as in humans. Blaming chloroform might mean abandoning general anesthesia itself, despite the successes with ether. Velpeau hoped that *'for the honour of chloroform'* the real cause of the deaths would be found. Jules Guérin (1801–1886) supplied the most virulent criticism, saying that to deny chloroform as the cause of death ran contrary to the facts and would render the Academy responsible for future accidents. He suggested a research program to establish the contributions of dose, setting, delay of action, and supply, through a program of animal experiments. This program had been preceded by intensive research

on many animals (mostly dogs, but also including rabbits, chickens, birds and frogs) conducted by chemists, veterinarians, and surgeons, including some members of the Commission. Guérin himself had studied the effects of chloroform on dogs, rabbits and frogs. However, Malgaigne remained content with clinical experience alone and thereby began a bitter dispute in which he denied the fact that Guérin had experimented on anesthetics. Further, he insinuated that Guérin had previously referred to *'non-existent results'*, inferring that Guérin was a liar. Guérin made no immediate response to this accusation but went on the attack the following day.

The confrontation had nothing to do with the anesthetic question. The real reason was a quarrel beginning ten years earlier. Both were surgeons, members of the Academy, and directors of medical journals—and their dispute had only been resolved a few months previously. In his journal, Guérin had reported on tenotomies for correction of club foot and spinal deformations. Of 750 operations, he described 650 cures or improvements. Thinking these results to be too good to be true, Malgaigne had attacked Guérin who then sued Malgaigne for defamation. Guérin won this case, but Malgaigne, having pursued the matter legally, attracted public attention by his eloquence. Guérin then asked for, and won the right for a Commission to judge the results of his new cases occurring during the following 3 months. The Commission judged that the results were consistent with those that Guérin had previously reported, and the Commission noted *'Mr Guérin had brought honour to science and to humanity'*. (Fig. 28.2)

During the following days, Guérin threw down the gauntlet declaring *'In deference to all I had to refrain previously*

from rising to this provocation. However, now you will no doubt be ready to provide the satisfaction that is normal among persons of honour'. Malgaigne refused the invitation to duel but also refused to withdraw his accusations.

The Academy, wishing to end this affair quickly, voted on 6 February 1849, to accept the conclusions of a new report about chloroform. The conclusions were identical to those of the first report, adding that rules could not be established 'on the basis of exceptions'. Chloroform was thus reinstated although, on 24 January 1849 in Lyon, another fatal accident was immediately reported in the journal, *L'Union Médicale*, with the objective of persuading the Commission to alter its conclusions.. After this latest accident, the surgeons of Lyon completely abandoned the use of chloroform, however they remained at odds with most other French surgeons who, as in England, used it successfully over much of the nineteenth century.

The Early Twentieth Century—The Ombrédanne Inhaler Reigns

Based on the work of Paul Bert (1833–1886), the use of nitrous oxide increased in the latter half of the nineteenth century, with ethyl chloride appearing at the end of the century. In 1908, the Parisian surgeon, Louis Ombrédanne (1871–1956) described his ether inhaler. It was a modification of Clover's inhaler, which he criticised "...as these are not provided with means of admission of fresh air, they rapidly produce cyanosis if one does not constantly raise the mask from the face." Ombrédanne's ether inhaler allowed the regulated admission of fresh air, and soon became the most commonly used apparatus in France, displacing the use of chloroform. It also became the usual means of anesthesia in many countries around the world, particularly Latin America.

Several other developments took place. Intravenous anesthesia, first used by Cyprien Oré (1828–1889) with chloral hydrate in 1872, was adopted from 1935 with the arrival of barbiturate compounds from Germany. Henri Laborit (1914–1995) described 're-inforced anesthesia' using other compounds, notably neuroleptics, antihistamines and morphine-like compounds, which had the ability to 'produce anesthetic states without using anesthetics'. His work also included the discovery of gamma hydroxybutyrate and its anesthetic effects.

Local anesthesia was largely the surgeons' domain. It started with simple infiltration (Paul Reclus 1847–1914), followed by nerve trunk blocks introduced by Victor Pauchet (1869–1936) and his pupil Gaston Labat (1876–1934). Finally, Théodore Tuffier (1857–1929) followed in the path of the German August Bier (1851–1949), and popularised spinal block. This new technique appeared shortly before caudal epidural anesthesia, which was discovered independently

by Fernand Cathelin (1873–1945) and Jean Athanase Sicard (1872–1929) in 1901.

In the late 1940s, Daniel Bovet (1907–1992) at the Institut Pasteur synthesized new muscle relaxants, used in clinical practice by Pierre Huguenard (1924–2006). Powerful opioids were discovered by the Belgian Paul Jansen (1926–2003) in 1961, and were tested by his fellow countryman Georges de Castro (1918–1990), who also worked in France.

The Slow Path to Professional Recognition in the Twentieth Century

Anesthesia in France was based almost entirely on the use of the Ombrédanne ether inhaler well into the twentieth century. The context of the times slowed professional progress. At the end of World War II, the French hospital system was essentially an antiquated nineteenth century structure. Doctors, surgeons and anesthetists were employed part-time, working on a voluntary basis in the mornings and earning their living in private practice in the afternoon. Surgeons reigned supreme and guarded their privileges.

In 1946, a dedicated anesthetist, Ernest Kern (who had obtained his Diploma in Anesthetics in England) reflected the stagnation pervading the medical services, in his book, *Mes Quatre Vies* [8]. He described several anecdotes that followed his return to France after the Libération:

- After asking for some modern anesthetic equipment, the director of a clinic replied 'we have used the Ombrédanne inhaler in France for 100 years to everyone's satisfaction. I do not see why we should change now to expensive foreign techniques. If you want other equipment you just have to bring it in yourself'.

- For one anesthetic he recalled 'I did not have curare available at the time and so used cyclopropane (which was at that time very expensive). This achieved perfect muscle relaxation and the surgeon thought the anesthesia was excellent. With total disdain the operating theatre sister threw me two 100 franc coins (the sum usually given to the theatre porter for giving the anesthetic). But this anesthetic had cost me five times as much...'

- In 1946, Kern presented a lecture to the Société Française d'Anesthésie et d'Analgesie (SFAA) on controlled respiration during thiopental and curare anesthesia. Afterwards, the President, surgeon Pierre Fredet (1870–1946), observed 'God caused man to breathe and God alone has the right to take away breathing. I challenge any man and any anesthetist to have this right; that would be sacrilege'.

First Step: Towards a Trade Union

Several anesthetists gathered together to defend their rights and establish a separate speciality. On 25 November 1941, Louis Amiot (1897–1978), Jacques Boureau (1909–2004), and Geneviève Delahaye (1906–1970) founded a 'co-operative of anesthetists' in Paris, made up of 19 Members (under the Vichy regime, trade unions were banned) with the

approval of the recently-formed *Ordre des Médecins*. After the Libération, the ‘co-operative of anesthetists’ (now with 23 members) changed its name to the *Syndicat des Anesthésistes Français*, and was officially recognised.

Second Step: Freedom from Surgical Domination

Professional Organization and Establishment of Qualifications (1947–1970) Other specialities saw anesthesia as a professional threat, resulting in confrontations with the *Ordre des Médecins*, hospitals, and universities—all organizations controlled by surgeons. Despite this, the scientific development of anesthesia progressed through congresses and publications. In 1947, the ‘new doctors’ who had arrived in the operating theatre, were controlled by an article of the code of ethics, (*Code de Déontologie*), written by the *Ordre des Médecins*, and officially published as a decree [9] stating that the ‘*surgeon had the right to choose his operating assistants as well as the anesthetist*’. In 1955, despite a revision of the code of ethics, this article (article 45, a pet hate of the anesthetists) was unchanged. Surgeons continued to control anesthesia, and the speciality could not financially support practitioners. Anesthesia was merely a ‘competence’ held by suitably qualified doctors with a university diploma (which did not yet exist) or who had passed a suitable hospital open examination (when they were indeed set up).

The situation changed gradually. Three Commissions to review qualifications were set up in 1950, with surgeons and anesthetists appointed by the Union and SFA, supervised by the surgeon Jean Baumann (1906–1981) and two anesthetists, Jacques Boureau and Louis Amiot. Little by little, the profession was recognised, which meant higher remuneration, better conditions and more consideration. On 18 November 1965, anesthesiology was added to the list of medical specialities, following a decree by the Minister of Health giving it official recognition. In 1970, the speciality became known as ‘*Anesthésie-Réanimation*’ instead of Anesthesiology, to recognize the role of the anesthetist in post-operative care. In 1979, when the Code was changed for the third time, the infamous article 45 was abandoned. The *Conseil National de l’Ordre* finally recognized the anesthesiologist as an independent medical specialist, no longer under the control of the surgeon.

The Problem of Fees

One major problem was the payment for providing anesthesia care. Before 1947, only surgeons received fees. Approximately 10% of these (at most!) were given to ‘assistants’, medical and non-medical. The anesthetist provided all drugs and equipment. Since doctors could not financially survive

as anesthetists, most continued to work as part time general practitioners. This situation led to the term ‘*docteur 10%*’. Some pioneers, such as Kern, paid for the new drugs and apparatus, but most stayed with ether and the *Ombredanne* inhaler.

From 1947 however, arrangements for payment for anesthetic services emerged. “Special anesthesia” given by a medically qualified anesthetist was paid for separately from the surgeon’s fee, and the surgeon’s fee was reduced, providing an incentive for surgeons to use anesthetic nurses. Whether the ‘*special anesthetic*’ was determined by the state of the patient, or by the nature of the surgery, was a decision left to the health insurance companies. In 1953, the payment for anesthesia services improved slightly. Every patient, regardless of their condition, was thought to benefit from a modern anesthetic without the anesthetist having to justify it. Finally in 1960, anesthesia was separated completely from surgery with the understanding that it was given personally by a medical practitioner. At last, the fee for anesthesia was completely separated from that of the surgeon.

Hospital and University

Creation of the Union did not necessarily confer status on the new speciality. In 1939, a project to create funded posts for anesthetists went unrealized. An ambitious programme of recruitment set up by the Paris hospital service in 1947 envisaged a chief anesthetist with posts for part time assistants. The programme was not formalized, but a competitive application was instituted for the post of hospital assistant, for 15 posts in Paris. The application specified that the post did not carry any remuneration. The greatest names in French anesthesia entered into this system but continued to earn their living by providing anesthesia in private hospitals.

In 1958, a major reform of French hospitals occurred when Charles de Gaulle returned to government. It had been formulated during World War II by the “*Conseil National de la Résistance*” of which Robert Debré was a member. Its authors were driven by a ‘generous mystic’, according to Debré’s word, who affirmed equality of all French people when faced with illness. When Debré’s son, Michel Debré, became the First Minister of the de Gaulle Government, he facilitated the implementation of the reform. It was financed in part by the Government (French state finances improved with the ending of the Algerian War) and partly by the *Sécurité Sociale* [10] (whose funds came from the contributions of salaried employees). The new structures united hospitals and universities. It led to creation of full-time posts and to the definition of future anesthesia services, giving the Union a new opportunity. A Government decree in December 1958, created heads of departments, although it took two more

years to include anesthetists as a recognized speciality. Anesthesia departments were instituted seven years later. Dual university and hospital appointments were created, and from that time specialists were trained, and posts created for them in large numbers.

Training in Anesthesia

Training in anesthesia in France, was formally organized after World War II. Until then, only a few private initiatives existed for training nurses. In 1939, at the outbreak of the war, training for doctors, pharmacists, dentists and medical orderlies was established to provide anesthetists for the Army.

In 1945, the surgeon Pierre Moulouquet (1890–1981), who held the newly created Chair of Surgical Techniques in Paris, assembled a formal training program for anesthetists, based upon modules used for teaching Army doctors and medical orderlies. The six week course started in 1947, and was supplemented by a six month hospital assignment supervised by members of the Société d'Etudes, either surgeons or internists. Students completing this course, received a 'Certificat d'anesthésie'. In 1948, a written examination was taken before entering the course, and a final examination led to the award of the Diplôme d'Anesthésie-Réanimation (Diploma in Anesthesia and post-operative care). Nurse anesthetists continued to receive the Certificate of Anesthesia, now awarded following a written examination. In 1951, doctors wishing certification had to be examined for the award of the Certificat d'Etudes Spéciales d'Anesthésie (CESA, the certificate of special studies in anesthesia). Faculties of medicine in major cities around the country organized the examinations, and the certificate became a national standard in 1956. By now the word 'réanimation' (post-operative care) had been dropped. However in 1966, CESA became CESAR with the addition of 'réanimation'. Holders of the CESAR could practice in both public and private hospitals, but not teach.

The growth in specialist medical anesthetists numbers was impressive. The 20 or so qualifications granted yearly between 1947 and 1951 increased tenfold, with a dozen city faculties introducing their own training. In 1966, there were 1000 trained anesthetists, and the number of trainees increased from 400 a year in the 60s and 70s, to 700 between 1970 and 1982. From 1989, anesthesia was included in immediate postgraduate medical education in Paris (the 'Internat'), previously restricted to the older medical specialities. However, the annual number of trainees in anesthesia was reduced by nearly 80% due to a quota system for the 'internat'. Successful students received the exclusive new diploma (Diplôme d'études supérieures en anesthésie-réanimation, DESA) at the end of five years of anesthetic training.

Anesthesiologists and Intensive Care Physicians and Precedence

During conversations with one of the authors, Maurice Cara (1918–2009) said that he had always insisted that anesthesiologists were capable of looking after patients with respiratory impairment, either pathological or from neuromuscular blocking drugs. It was an anesthetist, Björn Ibsen (1915–2007), who had convinced Henry Lassen (1900–1974) in Copenhagen in 1952, that polio patients required artificial ventilation [11].

Cara was a thoracic physiologist, and later an anesthesiologist. He was part of a specialist group working on silicosis for the European Coal and Steel Community (a forerunner of the European Union). In this group he met other European lung specialists including Benjamin Baudraz, who alerted Cara to what was happening in Copenhagen. On hearing the news, Cara immediately put himself at Ibsen's disposal. He noted that the Engstrom ventilator had been able to replace medical students who been used to squeeze bags to keep patients with respiratory failure alive. Cara finally met Carl Engstrom (1912–1987) in Stockholm, and the latter was obliging enough to lend him one of his machines. Cara had the opportunity to study the device at the Hôpital Necker—Enfants Malades in Paris, and he bought several for the Paris hospital service.

He used the device when the polio epidemic struck France in 1954. The first patient given intermittent positive pressure artificial ventilation was a child admitted to the hospital with polio at the beginning of 1954. At this time, Pierre Mollaret (1898–1987) had treated numerous adults afflicted with polio using cabinet ventilators (the 'iron lung'). To convince Mollaret of the value of mechanical positive pressure ventilation, Cara and a biochemist colleague ventilated a dog for a week (although they noted that patients had already been treated in this way in Denmark for more than two years). Finally convinced, Mollaret bought several Engstrom ventilators and opened the first 'respiratory resuscitation' service for adults at the Claude-Bernard Hospital in Paris in September. Numerous other French centers' duplicated this because of the concern about polio.

In 1955, under the aegis of SFAA, Cara convened a meeting of those with practical experience using mechanical ventilation, including French and Swiss practitioners who were anesthesiologists, physiologists, biochemists and medical intensivists. Mollaret was, of course, invited but his antipathy (jealousy?) towards Cara was such that he actually forbade Cara to attend, even though Cara had organized the meeting! For this reason, Louis Amiot, the President of the SFAA at that time, read the introductory address, drafted by Cara. Cara seems to have accepted the "diktat" without complaint, but never forgot it.

The dispute between anesthesiologists and medical intensivists, about who should control postoperative, and even

aspects of perioperative care, lingered. Surprisingly, anesthesiologists found allies in the surgeons who did not wish to see two doctors at the head of the operating table. Anesthesiologists increasingly realized that life support was important to their work. In 1957, not wishing to restrict their practice to the operating room, they asked authorities to increase training by 1 year (to a total of 3 years) devoted to ‘reanimation’ (post-operative and intensive care). They also modified the name of their society, to ‘*Société Française d’Analgésie d’Anesthésie et de Réanimation*’, and also the name of their journal which became ‘*Anesthésie Analgésie Réanimation*’.

Medical and Nurse Anesthetists: An Unfortunate Confusion of Identity

In 1946, nurse anesthetists received, in Paris, the same Certificate of Anesthesia as did doctors. From 1948 to 1973, nurse-anesthetist training schools trained 1500 students. From 1960 almost all cities with universities had a nurse-anesthetists school, and an examination was devised leading to the *Certificat d’Aptitude aux Fonctions d’Aide Anesthésiste*. During this period (1947–1965), nurse anesthetists advanced their own ideas about training. The word ‘anesthésiste’ presented a problem. It was used equally to describe doctors, nurses or auxiliary personal (including nurses) who had undergone any training in anesthesia. However, a legal ruling obliged nurses who were giving anesthesia, to put the word ‘Aide’ in front of ‘Anesthésiste’ (literally to describe them as anesthetic assistants).

The first nurse anesthetists were pioneers. Like medical anesthetists, they purchased their own equipment and drugs, and were entirely self-supported, including going abroad for further training. Like physicians, they organized trade unions and worked in accordance with statutes that they devised. With the support of surgeons they obtained the right to practice from the Ministry of Health. Thanks to close relations with the then Prime Minister, they obtained the exclusive right to practice as nurse anesthetists (Infirmière Anesthésiste Diplômée d’Etat or IADE) provided they had completed an official training program that they themselves had inspired. They organized their training programs, and thereby excluded other paramedical staff from giving anesthesia.

Far from being mere anesthetic assistants, they competed with the doctors, resulting in an antagonism. Anesthesiologists could not see (and some still cannot today) that the IADE were skilled technicians (rather like paramedics) who followed “cookbook” like protocols. They gave the anesthetic under the direct and exclusive supervision of a medical anesthesiologist, who could intervene at any moment. This mirrored systems used in Sweden and other countries. They could not work independently as was (but no longer is in many states) the case in the US.

Fig. 28.3 Robert Monod, surgeon and founder of the Société d’études d’anesthésie et d’analgésie (1934). (From reference [1], pp 591, with permission)

The Successive French Societies of Anesthesiology

Société d’Études d’Anesthésie et d’Analgésie (SEAA)

In 1934, surgeon Robert Monod (Fig. 28.3) founded the Society for the study of anesthesia and analgesia (Société d’études sur l’anesthésie et l’analgésie SEAA), with surgeon Antonin Gosset (1872–1944) as President (already President of the Society of Surgery). At the first meeting of the Society, Monod stated that ‘*its objective was not to become a society of anesthetists*’ (probably since surgeons held themselves superior to other physicians of the time) [12].

World War II and the Birth of a New Society

The society published a review (*Anesthésie et Analgésie*), with Monod as editor-in-chief, from 1935 until 1951. In

1934, the Society had 100 members from medical, physiological, pharmaceutical and veterinary disciplines, but only four anesthetic practitioners. In 1935, membership increased to 120. In 1938, the Society became the Société française d'anesthésie et d'analgésie (SFAA), but its activity and archives were suspended in 1939, following the outbreak of war. In 1946, the SFAA was reborn with 17 anesthetists out of a total of 117 members. The attraction of anesthetists towards the SFAA grew and was accompanied by the development of a trade union. As they were often anesthetists working with the surgeon-members of the SFAA, they were elected members of this society.

World War II had introduced modern anesthesia to France, but there would be a long battle to replace the Ombrédanne inhaler introduced in 1908. By 1948, anesthetic practice had progressed considerably from Fredet's notions. At a meeting of the general assembly on 15 January 1948, Monod (President of the society in 1947) [13] noted:

'We have been criticised, not without cause, for having created a society too much concerned with theory and research and not with practice. In this respect we have considerable work to do, since, despite the journal we publish, it is evident that anesthesia in France is not yet up to the standard found abroad, notably in America and Great Britain, a situation which is regrettable. I am speaking obviously as a surgeon and it has to be taken into account that really one of the reasons that surgery in this country is behind that of others is the fact that the practice of anesthesia is certainly not what it should be and does not have the degree of expertise it has achieved elsewhere'.

While some surgeons agreed with Monod about the primitive nature of anesthesia practice, and the need to catch up with that in the US and the UK, others did not. In 1946, almost everything remained to be achieved. Formal teaching needed to be established, and anesthetists needed to be recognized by surgeons and the general public, by health insurance, by the *Ordre des Médecins*, and by hospitals and universities. With the new generation of anesthetists, the SFAA and the French anesthetists' Union, the battle to establish French anesthesia began. It would last more than 20 years.

The Founding of the World Federation of Societies of Anaesthesiologists

Before World War II, an international congress originally planned for 1942 was arranged by the SFAA President, Monod, and the Vice President of the International Anesthesia Research Society (IARS), Francis McMechan (1879–1939). In 1951, this project was revived and an international congress of anesthesia was organized under the auspices of the International Congress of Surgery. The congress was duly held in Paris, and 32 countries took part. Lectures were presented by Maurice Cara (on graphical recording of physiological functions during anesthesia) and Pierre Huguenard

Fig. 28.4 Daniel Bovet, discoverer of synthetic muscle relaxants and winner of the Nobel Prize for Medicine. (From http://www.nobelprize.org/nobel_prizes/medicine/laureates/1957/)

(on the use of synthetic muscle relaxants). Daniel Bovet (1907–1992) (Fig. 28.4), a member of SFAA and a 1957 recipient of the Nobel Prize for medicine, reported on the chemistry of muscle relaxants.

The 1951 congress was a success, attracting great names from throughout the world of anesthesia, including Henry Beecher, Harold Griffith, Virginia Apgar, William Mushin and chemists and physicists such as Bovet and Robert Brinkmann. The idea of founding an international society linking the Société d'Etudes and the IARS of McMechan was considered. In March and May of 1951, Marcel Thalheimer, treasurer of the SFAA, set in motion the ideas for organization of such a society, and renewed them at the Congress of Anesthesia in London in September 1951. This British congress was held a week before the Paris meeting, bringing together English-speaking anesthetists and colleagues from the IARS in France. The participants debated whether it would be better to create a new society or to turn the IARS into an international society, not exclusively for research. The idea of a society open to several disciplines based on the model of the SFAA, was not popular with

Fig. 28.5 Jacques Boureau (1909–2004) President SFAAR 1958–1961 and Vice President WFSA (1965). (From reference [1], pp 575, with permission)

English-speaking anesthetists who had already founded a society of their own. Above all, they feared that the new society would be controlled by surgeons, as had occurred in France.

Representatives of the 32 societies present at the London conference elected an interim committee, charging the committee with the tasks of drafting statutes for a new international society, and organizing the next (1955) congress. Membership of the committee included Alexandre Goldblatt (Belgium), Torsten Gordh (Sweden), Harold Griffith (Canada), John Gillies (Scotland) and Jacques Boureau, (France) in his capacity as President of the French Anesthetists Union. There was also a representative of SFAA. Thus it was that the World Federation of Societies of Anaesthesiologists was born. In 1959, Boureau (Fig. 28.5), President of the SFAA (now called ‘Société Française d’Anesthésie, d’Analgésie et de Réanimation’, SFAAR), became one of the Vice Presidents of the WFSA. His many qualities included his struggle to assert the independence of anesthetists, his bilingual negotiat-

Fig. 28.6 Jean Lassner. (From www.histanestrea-france.org/SITE/Regards-sur-l-anesthésie-d-hi.)

ing skill, his overall knowledge, and his mastery of anesthetic techniques.

1960–1982: Division in French Anesthesia Societies

A controversy divided French anesthetists from 1960 to 1982. The problem lay with the concept of anesthesia. On one side was traditional anesthesia, dominated by inhalational anesthesia; quick and effective but often accompanied by untoward physiological reactions (e.g. nausea, hypotension). On the other side were the ‘Laboritiens’ who supported the views of Henri Laborit (1914–1995). He argued that the use of neuroleptic and other inhibitory agents protected the patient. The main actors in this drama were Jean Lassner (1913–2007; Fig. 28.6), Guy Vourch (1919–1988), and supporters of the English-speaking school of anesthesia on one side; and Pierre Huguenard (1924–2006) and other ‘Laboritiens’, mainly from Southern France (Louis Campan in Toulouse, Jean Bimar in Marseille and Jacques du Cailar in Montpellier), on the other.

The proposed election of a new member of the French Society of Anesthetists (SFAAR) started the division. The President, Jacques Boureau, following the rules of the parent

society SEAA founded 25 years earlier, wished to elect a pharmacologist. Huguenard, then secretary of the SFAAR and Editor-in-Chief of its journal *Anesthésie, Analgésie et Réanimation* (AAR), opposed the election. Several years earlier, Lassner (and his English-influenced school) who had founded a new journal, *Les Cahiers d'Anesthésie*, thought that the editor of AAR was biased, favoring the Laboritians. For his part, Huguenard thought the objectives of the *Cahiers* (whose motto was '*the method of giving an anesthetic was more important than what was given*') were too restrictive and blocked pharmacologic innovation. Huguenard left the SFAAR, and together with Bimar, founded l'Association des Anesthésistes Français (AAF) with its own journal, *Les Annales de l'Anesthésie Française*. Cara accepted the position of President, since he saw in the new society, a dynamism and capacity for innovation lacking in the old society. In fact, if the two journals are compared, new topics such as drugs, techniques and intensive care were more apparent in the AAF than the SFAAR journal. *Les Cahiers*, for its part, addressed more professional problems such as ethical questions, legislation, pain relief, and working relations with surgeons. The dispute continued until the end of the 1970s, when Lassner, in association with du Cailar, tried to bring the two societies together to form a united society, while Cara tried to reconcile the main protagonists of the two camps. However, anesthesiologist members remained distant from the discussions and still remained divided between the two societies.

The Société Française d'Anesthésie et de Réanimation (SFAR)

The divisions finally ended in 1982, with fusion of the two societies into a single organization (la Société Française d'Anesthésie et Réanimation (SFAR), with its journal, *Annales Françaises d'Anesthésie et de Réanimation* (AFAR). SFAR at present includes over 3500 doctors. The annual congress attracts more than 7000 participants making it the largest French-speaking congress in the world. The main activities of SFAR, then as now, concerned education, research, safety, ethics, professional life and relations with other specialities (including surgeons, intensivists, and nurse anesthetists).

In addition to training, central subjects for SFAR included the new organization of the national congress, editing successively professional guidelines from 1989, consensus conferences from 1993, meetings of experts from 1996 clinical standards from 1999, and an inquiry into postoperative pain from 2002. The training committee, created in 1992, became the Collège Français des Anesthésistes Réanimateurs (CFAR). This body linked all the key players in the profession including SFAR, the universities and the unions. In 1994, with Philippe Scherpereel as its first President, CFAR

undertook control of continuing medical education and the upholding of standards in the profession.

In 1990, SFAR helped research by organizing joint meetings with the 'Institut national de la santé et de la recherche médicale (Inserm). In 2001, SFAR financed the conduct of anesthetic research and in 2007, introduced the prize for multicenter research in anesthesia. Safety during anesthesia became a priority for SFAR, with an enquiry into morbidity and mortality in 1981, and establishment of the safety committee from 1989. A mortality enquiry was established in 1999, and a risk assessment and management committee from 2000. This Committee developed standards for anesthetic ethical considerations and established the scientific support Committee from 1999.

The professional conduct committee was formed in 1992. This regulates all aspects of professional practice. In parallel, SFAR has contributed to specific professional enquiries, notably the practice of anesthesia from 1996 and demographics from 1997. Professional relations have been clarified with the surgeons, intensive care physicians (through the interface between SFAR and the French language resuscitation society SRLF), and nurse anesthetists. Finally, SFAR communicates through its web site [14] set up in 1998, and internal journals: *La lettre de la SFAR* (1992–1997), and *Vigilance* (since 2004). Thus, SFAR became the definitive partner, and scientific point of reference for concerns regarding anesthesia by ministers and agencies involved in the management of health in France.

From Craft to Profession (1970–2000)

The Painful Path to Safer Anesthesia

Death on the operating table is anathema to surgeons, anesthetists, and the general public. Such accidents make front-page news and lead to corrective measures. In France, three dramas attracted media and judicial attention, and influenced the development of safety in anesthesia.

The Anesthetist Shares Responsibility with the Surgeon

On 10 July 1967, in Montpellier, the 29 year-old author, Albertine Sarrazin, died during surgery for tuberculous pyelonephrosis. The non-medical, unqualified 'anesthetist' first met Sarrazin in the operating theatre and was unaware of her serious medical history. Although this was likely to be a bloody operation, no provision was made for transfusion. The hypovolemic patient suffered a cardiac arrest during a change in position. The first inquiry (December 1970) acquitted the practitioners involved. At appeal, only the anesthetist was held responsible. A later hearing (June 1972) referred the case to the court of appeal in Toulouse (April

1973) which condemned the anesthetist for the superficial approach to the case, and the surgeon for not having realized the potential likelihood of major hemorrhage requiring transfusion. Both received a two month suspended sentence and a heavy fine. The separate responsibilities of the two practitioners were recognized for the first time.

Death Prompts a Study of Mortality from Anesthesia

On 11 July 1973, in Paris, a 20 year-old patient suffered a hypoxic-related cardiac arrest during a tonsillectomy. Recovery from anesthesia was improperly monitored, the patient returning directly from theatre to his hospital room. He died a few days later from the consequences of cerebral hypoxia. The anesthetist was deemed responsible, and the surgeon was acquitted at the initial hearing. At appeal, a higher court ruled that the surgeon was also responsible for improper patient observation postoperatively. Both practitioners left the hospital but resumed work elsewhere.

This accident prompted issuance of ministerial statements concerning anesthetic safety and procedures in the recovery room. In 1974, in a ministerial circular (a document without regulatory power) the Minister of Health recommended the establishment of recovery rooms, and specified the required equipment and personnel. However, the recommendations were ignored for reasons of cost. Two other circulars had equally little effect.

In 1976, the cumulative effect of the recommendations led to a major epidemiological enquiry into anesthetic deaths. At the request of the Society's president, Jean Lassner, Simone Veil, the Minister of Health, created a national commission on anesthesiology. This commission, chaired by Guy Vourc'h, organized the first epidemiological enquiry into anesthetic accidents, one similar to the Beecher-Todd report in 1954 [15]. The resulting INSERM inquiry (1978–82) [16] considered 200,000 anesthetics, finding a mortality of 1 in 13,000, and a greater incidence (60% of deaths) in the immediate postoperative period, in patients who had a moderate risk of respiratory insufficiency.

A Death Produces New Safety Standards

On 10 October 1984, in Poitiers, Nicole Berneron, aged 35 years, died at the end of an ENT procedure, possibly from switched nitrous oxide and oxygen pipeline supply to the anesthetic machine. The following trial raised great media interest. The accused practitioners were found not guilty, and the public hospital concerned paid damages to the victim's family.

Immediate measures were taken concerning the safety of anesthetic equipment in operating theatres, starting with a ministerial circular of 10 October 1985 on medical gases. The report of the Committee of public health on anesthetic safety (Nov 1993) [17] led to a Ministerial decree on 5 December

Fig. 28.7 Measures taken in the past few decades markedly decreased mortality from anesthesia in France. [15–20]

1994 (such a decree is the equivalent of a law in France). The decree established safety standards for anesthesia, including an obligatory preoperative anesthetic consultation more than 24 hours before elective surgery and to a final examination which had to take place the evening before or several hours before the start of anesthesia. This allowed verification of the pre-operative investigations, to find out whether there had been any change in medical condition since the consultation and to answer any further questions from the patient following the first consultation. Premedication was also prescribed at this time.

Conditions for the use of anesthesia equipment were also issued, and finally, the unbinding suggestions in the first ministerial circular of 1974 (i.e. 20 years before) were mandated. It was now an obligation that the patient be taken from the operating theatre to a recovery room. This revolution responded to several requests by anesthetists. All hospitals and clinics in France now had to be equipped according to these requirements, or risk being closed.

The recommendations of SFAR from 1989, meetings of experts, and risk management, changed anesthesia from a craft to a profession. A new study by SFAR and INSERM in 1999, showed the effectiveness of the measures. Anesthetic mortality had decreased to 1 death per 150,000 anesthetics (Fig. 28.7) [15–20].

French Research and International Recognition

Jean-Claude Otteni and Lassner, both German speakers, had special links with anesthetists in Germany, and frequently crossed the Rhine to give lectures, particularly after 1965. Other French anesthetists rarely visited Germany until 1977 (see next paragraph). Ernest Kern, Lassner, and Vourc'h created links with England and Canada, but these were essentially personal.

In 1977, Lassner created the European Academy of Anesthesiology (EAA) in Paris, sharing a common headquarters

with the Société Française d'anesthésiologie. Its aim was to promote meetings between European anesthetists, and thereby exchange ideas, notably on teaching methods. Out of the Academy came the European Journal of Anaesthesiology (1984) whose first editor was Mike Vickers. From this organization John Zorab proposed the idea of a European Diploma of Anesthesiology.

The arrival of two new anesthetic department heads in Paris, Jean-Marie Desmonts at the Bichat hospital, and Pierre Viars at the Pitié—Salpêtrière, would open French anesthesia to influence from North America. Desmonts had learned the technique of gas chromatography at Stanford University in California. Several contacts in that institution spent sabbatical periods in his department. In 1978, he produced the first publication from France in Anesthesiology on the cardiovascular effects of naloxone. His assistant, Philippe Duvaldestin was a known specialist in the use of muscle relaxants.

As part of the EAA Desmonts had close contacts with Vickers, Rozen and Fries. His research team travelled regularly to the US for the American Society of Anesthesiologists (ASA) conferences where they presented their work. He also maintained his relationship with the WFSA and was a member of the executive committee from 1992–2000, and Vice-President between 2000 and 2004.

Pierre Viars (1930–1998) followed a different path. He was committed to the advancement of French anesthesia. He sent his assistant Francois Clergue, to contact US anesthetists, and he invited American experts to lecture at his annual post-graduate education conference (Journées d'enseignement post-universitaire de la Pitié-Salpêtrière, JEPU).

Concurrently Viars guided French anesthetists towards the laboratory, and encouraged them to present PhD theses in pharmacology, pneumonology and cardiology. Thus, with an approach different from that in other countries, including the US where anesthetists usually were recruited after completing a PhD, he succeeded in moving anesthetists from a clinical to an academic environment. This explains the particular nature of the anesthesia related research of many French physicians.

Viars, a pharmacologist by training, understood the role of industry in developing new medicines and the need for rigorous research. The work of his department was among the first accepted by the FDA in the US from a foreign source. He sponsored attendance of his colleagues (particularly his pupils) at international congresses, notably the American Society of Anesthesiologists (ASA) Annual Meeting. He insisted that they publish in English noting that this language had replaced Latin in the medical world. However, writing for an American journal was not simple. Among the first to overcome this obstacle were André Lienhart, Kamran Samii, Francois Clergue and Pierre Coriat. Many others including Bruno Riou and Jean Jacques Rouby followed, and by 1988, more than 50% of communications to the ASA from outside

the US came from pupils of Viars. One of the editors of this book (LS) was Editor-in-Chief of Anesthesiology during this period (1986–96) and was impressed with the high quality of French research then submitted to and published in Anesthesiology.

Viars also co-founded the new European Society of Anesthesiology which, in 1991, brought together the EAA, the ESA and the European National Society of Anaesthesiology. Philippe Scherpereel from Lille, was initially an intensive care practitioner. He came to Paris as assistant in Viars's department to study anesthesia and later became chief of the anesthesiology department in Lille. With Johan Spierdijk from Leiden, he put in place the Foundations for European education in Anaesthesiology (FEEA) in 1986. From January 2009 this organization joined the European Society of Anaesthesiology. There still exists a joint initiative between the ESA and the WFSA for the operation of 110 training centres around the world.

Desmonts and Viars provided inspiration to anesthetists who followed them. French anesthetists now participate in all international activities and are recognized for the quality of their original research. The success of the world congress of the WFSA in Paris in 2004 was proof of this.

Following the work of the modern pioneers, French anesthesiology has developed into a speciality of perioperative care which covers all medical and surgical cases requiring special resuscitative care. Although in University hospitals there are medical and surgical special care units this is not the case in the smaller hospitals where resuscitation and intensive care are largely the responsibility of anesthetists.

Anesthetists Outside the Hospital: The Founding of SAMU

In the latter part of the 20th century, French anesthesiologists pioneered the development of the provision of prehospital emergency care. The French prehospital emergency system is known as SAMU (Service d'Aide Médicale Urgente) and is a medical and not a paramedical service. Anesthesiologists, Maurice Cara (Paris), Pierre Huguenard (Créteil), Louis Lareng (Toulouse) and Louis Serre (Montpellier) (Fig. 28.8) developed SAMU during the 1970s, reasoning that in emergencies the hospital should go to the patient and not the contrary. Consequently, medical teams (often including an anesthesiologist) go from hospitals in specially equipped ambulances to care for patients with life-threatening emergencies. Doctors dispatch and control the emergency response teams. Unlike many emergency medical services, SAMU is an extension of the hospital service itself.

Following the Algerian War in the 1960s, the health authorities asked anesthetists to organize emergency medicine and prehospital care in France. This urgent request was intended

to address the rising death rate from automobile related accidents, which had reached 13,000 per year and more than 290,500 injured, 90,150 of them seriously. The creation of mobile emergency units in the south (by Paul Bourret at Salon de Provence, and Louis Serre at Montpellier) began in 1957 and gradually grew. The first mobile medical emergency response units were created in 1965 (Service mobile d'urgence et de réanimation, SMUR). The treatment and transport of high-risk patients required the immediate provision of medical care,

and its continuation through transport to hospital. This was achieved using specially trained and equipped medical teams who could perform resuscitation and emergency care in emergency ambulances, helicopters or fixed wing aircraft. In 2006, this service conducted 1,890,439 missions.

A 1986 French law [21] specified that SAMU should act as a dispatch and reception center for all medical emergency calls, 24 hours a day. SAMU now operates under Government control throughout France in over 100 regional

subunits united in their training and equipment. Before the organization of SAMU, Fire Brigades (Sapeurs Pompiers) provided prehospital emergency medical care. This service still provides primary emergency care, especially in rural regions, and works alongside SAMU in large towns. The development of SAMU demonstrates the widening borders of anesthesiology, a speciality only relatively recently recognised in France. In 2006, SAMU received 15 million calls.

Epilogue

The discipline of anesthesia in France is now securely established. It has become reliable with a mortality rate approaching 1:150,000 to 1:300,000 for patients having an ASA Physical Status of 1–2. Qualifications of trained medical graduates in anesthesia equal those of other specialists, and the discrimination against anesthesia consultants present up to the 1990s has ended. At the end of training, the anesthetist can undertake research in the university in preparation for the Diplôme d'Etudes Approfondies (DEA), a qualification now essential for those wishing to hold a university chair.

As with all living organisms, anesthesiology continues to evolve. The struggle between anesthetists and medical resuscitators is over. The SFAR has woven links with the Société de Réanimation de Langue Française and the two are currently drafting the basis of ministerial decrees relating to the speciality. Anesthetists now provide preoperative assessment. Often in smaller hospitals, anesthetists also run the intensive care units, caring for a wide range of acutely ill patients. Anesthetists have taken charge of prehospital emergency medicine and created SAMU. Following the lead of Americans, they were the first in France to organize pain clinics.

But the path of anesthesiology is not always smooth. Sometimes it has lost control of structures it created such as SAMU and pain clinics. The demands of the 'internat qualifiant' examination has drastically reduced the number of practitioners, and uncertainty about the future weighs heavily on a profession which was the first speciality in France to make demographic projections. The risk at present, is the possibility of delegating specialist tasks to nonmedical personnel as was formerly the case, or relinquishing certain professional activities such as perioperative care to nonspecialists. To do so would be to negate what has been an intrinsic part of our

profession and part of the specific character of French anesthesia.

Michael Goerig

Summary

Heyfelder administered the first ether anaesthetic on 24 January 1847. For the next century, surgeons gave anaesthesia or directed its administration by a nurse or a less experienced person. To the 1940s, most surgeons-anaesthetists dripped ether or chloroform onto Esmarch or Schimmelbusch masks. In 1902, Roth described an anaesthetic machine produced by the Dräger brothers using compressed gases and reducing valves. In 1907, Dräger added its Pulmotor, a ventilator. In 1903, Fischer and von Mering synthesized barbitone, the first of the barbiturates. In 1905, Kuhn advocated Macewen's technique of orotracheal intubation and until the 1950s, tracheal tubes were usually inserted under local anaesthesia and digital control. In 1908, Küppers patented the rotameter, subsequently used by Neu in 1910 to deliver anaesthetic gases from the Rotameter Company's new anaesthesia machine, and ultimately used to control gas flow for much of the next century. Pharmacologist Straub produced the first electrically driven roller pump in 1911 to accurately infuse intravenous fluids and drugs during anaesthesia, and surgeon Martin developed today's drip-chamber. Schmidt introduced the Codman-Cushing anaesthetic records into Germany at the end of the 1920s. In 1932, pharmacist Weese described a new, water-soluble, ultra-short acting barbiturate, hexobarbital. In 1953, Frey devised an electronic device for continuous analysis of volatile agents.

Koller's 1884 discovery of cocaine's anaesthetic properties introduced local and regional anaesthesia. German surgeons became regional anaesthesia advocates. In 1899, Bier gave the first spinal "block". Some surgeons rejected cocaine because of its side effects, inspiring Einhorn to synthesize procaine in 1904. Bier described intravenous regional anaesthesia, and obstetrician Sellheim described paravertebral blocks in 1908. In 1911, Hirschel invented the axillary approach to the brachial plexus, while Kulenkampff described the supraclavicular approach. In 1912, Perthes used electrical stimulation to locate peripheral nerves. In the early 1930s Capelle prescribed continuous subcutaneous abdominal injection of local anaesthetic to facilitate deep breathing and decrease the incidence of postoperative pneumonia.

In the early 1900s, Gauss suggested use of scopolamine-morphine to enable pain-free childbirth but its dangers led to its abandonment after only a few years. Surgeon Hercher used hypertonic solutions for fluid resuscitation during World War I, and Schück and Simenauer revived this concept in the 1930s. In 1943, Weese invented 4% polyvinyl pyrrolidone to manage hemodynamic instability.

Increasing complexity of surgery and use of new anesthetics and delivery apparatus in the 1920s revived interest in anaesthesia specialization. But influential surgeons rejected the idea, and World War II stopped the discussion. US and UK advances in anaesthesia rekindled discussion after World War II, and in 1953, the German Society of Anaesthesia was founded.

In the Beginning

Little time separated the successful demonstration of anaesthesia in Boston on October 1846, from the first ether administration in Germany. Johann Heyfelder (1798–1869) gave ether at the Erlangen University on 24 Jan 1847 to facilitate incision of a gluteal abscess [1]. Few advances followed in

the next fifty years. Surgeons gave anaesthesia or directed a nurse or a less experienced assistant to drip ether or chloroform. Surgeons Esmarch and Schimmelbusch introduced apparatus and techniques, and their wire and gauze masks (see below). Medical, gynaecological or surgical journals reported observations on anaesthesia.

At the turn of the twentieth century, the first association of professional anaesthesiologists was formed in New York. Parallel developments in Germany might have occurred at the instigation of Carl-Ludwig Schleich (1859–1922; Fig. 29.1). He was among the first surgeons to condemn the existing state of anaesthesia, advocating specialization and

Fig. 29.1 Carl-Ludwig Schleich, father of infiltration anaesthesia, insisted that local anaesthesia could decrease or eliminate the need for general anaesthesia. He advocated training in anaesthesia. (The picture, taken around 1905, is from the collection of the author.)

training in anaesthesiology to improve quality and minimize risks. Schleich however, was “persona non grata” within the German Society of Surgery, and therefore (see below) his ideas went unheeded. Anaesthesia did not develop as a specialty in Germany until after World War II.

Nevertheless, many German surgeons, chemists and other physicians, produced anaesthetic innovations. These included the introduction of regional anaesthesia, development of the barbiturates, and invention of anaesthesia apparatus.

Local and Regional Anaesthesia

The 1884 discovery of cocaine’s anaesthetic properties by the ophthalmologist Carl Koller (1857–1944) of Vienna, introduced local and regional anaesthesia [2]. The same concentrations of cocaine used for topical anaesthesia were then used for injection, and such high concentrations sometimes caused fatal complications, leading other investigators, including Schleich, to dilute the solutions to produce “infiltration anaesthesia”.

Schleich described his techniques in a lecture to the 21st annual Congress of the German Surgical Society in 1891 in Berlin. After reviewing infiltration anaesthesia including indications, and the pros and cons, using humanistic,

legal and ethical arguments, Schleich denounced chloroform anaesthesia as dangerous, and denied the need for general anaesthesia for most surgical procedures. A tumult arose. Although the audience knew little about the new technique, nobody agreed with Schleich’s arguments, and he left the congress without further discussion. Schleich continued to perform major surgical procedures including hernia repair, laparotomy, and limb amputation under infiltration anaesthesia, stating that general anaesthesia was not needed. The initial negative response eventually subsided, and his method was later considered a “great feat in the discipline of surgery in Germany” [3].

In 1894, Schleich again inflamed his fellow surgeons by arguing, in his textbook “Schmerzlose Operationen” (Painless Surgery), that only specially trained physicians should perform anaesthesia, and moreover that the specialist should teach younger colleagues. This was then a revolutionary concept in Germany [4].

Regional Anaesthesia: Further Developments

At the end of the nineteenth century, the side effects of cocaine inspired the German chemist Alfred Einhorn (1856–1917), to search for a better local anaesthetic. In 1904, Einhorn and his colleagues produced procaine (Novocaine), which until the 1940s discovery of lidocaine by Swedes Nils Löfgren (1913–1967) and Bengt Lundquist (1878–1922), was the prototypic local anaesthetic.

In 1903, Heinrich Braun (1862–1934) of Leipzig recommended adding adrenaline to cocaine to decrease the speed of absorption. This allowed the safe administration of larger amounts of cocaine and more extensive surgery. Braun also realized that the simultaneous use of adrenaline would minimize procaine’s vasodilating properties, decrease the toxic side effects of procaine and prolong its anaesthetic properties. Not surprisingly, procaine became the most important local anaesthetic for decades, worldwide. In the 1920s, variants of procaine, such as isocaine and nirvanine were introduced, but failed to challenge procaine [5].

Specialized regional anaesthesia techniques including splanchnic, paravertebral, sacral-caudal and brachial plexus blocks, were developed subsequently and local anaesthesia increasingly displaced general anaesthesia. Braun described these new options in his famous textbook “Local Anaesthesia—Scientific Basis and Practical Use”, first published in 1905, with several editions following until 1951 [6]. A 1914 translation popularized local anaesthetic techniques in the English-speaking world [7].

Arthur Lāwen (1876–1958) trained with Braun, and in 1933 succeeded him as editor of the textbook. Lāwen enthusiastically supported local and regional anaesthesia. He provided a clinical evaluation of a bicarbonated procaine solution, which he developed in collaboration with his pharmaco-

cological colleague Oskar Gross (1877–1947) from Leipzig. This preparation had a faster onset, longer duration of action, and less potential for toxicity [8].

New Conduction Anaesthesia Techniques are Established

In 1911, Georg Hirschel (1875–1963) invented the axillary approach to the brachial plexus while Diedrich Kulenkampff (1880–1963) described the supraclavicular approach. Hirschel also published a textbook of local anaesthesia which gained world-wide recognition due to its excellent illustrations and detailed descriptions. Several editions were published in Germany. Translations into English, French, Spanish and Russian popularized local anaesthetic techniques outside Germany [1].

Spinal Anaesthesia

In 1899, August Bier (1861–1949; Fig. 29.2), a colleague of the Kiel surgeon, Friedrich von Esmarch (1823–1908),

administered the first spinal or regional “block” to adult patients. Bier sought to “render a large part of the body insensitive to pain for surgical purposes.” Using a fine hollow needle, as described by Heinrich Quincke (1842–1922), Bier performed a lumbar puncture with the patient in the lateral recumbent position. The puncture itself was made painless by local anaesthetic infiltration using Schleich’s method. Bier then injected 0.10–0.15 mg of cocaine into the lumbar subarachnoid space. Following an initial enthusiasm, German surgeons rejected the new method because of reports of severe side effects [9].

Bier himself called for caution in applying the method. The problem of an excessively high spinal block with its attendant side effects represented a major challenge, and the means to prevent these adverse reactions were often inadequate. Side effects such as the unsolved problem of post-operative nausea and vomiting, post spinal headache, and hypotension caused Bier to call for restricted use of the brand-new technique. Moreover, the analgesic cocaine was far from the ideal anaesthetic [10]. Thus, most physicians contented themselves with local infiltration and inhalation anaesthesia and only a few enthusiasts persisted in administration of spinal anaesthesia [11]. In the mid 1920s, new atraumatic spinal needles and hypo- or hyperbaric anaesthetic solutions renewed interest in spinal anaesthesia [12]. A better knowledge of physiology and newly developed vasoconstrictive drugs like ephedrine, further augmented enthusiasm [13].

In the 1930s, the Hamburg surgeon Helmut Schmidt (1895–1979) popularized Pitkin’s 20–22 gauge short bevel needle in Germany. This special needle, originally described by Georg Pitkin (1885–1943) of New Jersey in 1924, decreased the incidence of post-dural puncture headache (PDPH) to less than 5% [14].

With wider use of spinal anaesthesia in German speaking countries in the mid 1970s, the call for less traumatic spinal needles increased. This prompted the Würzburg anaesthetist, Günther Sprotte (1947), to develop a spinal needle, with a “pencil point” tip and aperture positioned slightly back from the tip. The design minimized trauma during perforation of the dura, further decreasing the incidence of PDPH to less than 2%. Since then the “Sprotte needle” has found world-wide acceptance among anaesthesiologists [15].

Unlike surgeons, obstetricians and gynaecologists persisted in advocating the use of spinal anaesthesia. After the London surgeon, Arthur Barker (1850–1916), described hyperbaric and hypobaric solutions in 1907, Freiburg obstetrician Carl Gauss (1875–1957; Fig. 29.3), assessed the use of gravity as revealed by experiments in Great Britain with a glass model of the spinal canal, evaluating the potential of hyperbaric/hypobaric solutions to control intrathecal spread [16]. Gauss recommended hyper- or hypobaric solutions in spinal anaesthesia for patients undergoing operative gynaec-

colony. However, his technique did not become popular until the mid 1930s [17]. In 1900, Oskar Kreis (1872–1958) of Basle used spinal anaesthesia to ameliorate labour pain, describing the parturients as remarkably alert compared with women receiving other forms of labour analgesia [18]. Later, spinal anaesthesia was often combined with a low dose of subcutaneously administered scopolamine for sedation, as recommended by the Austrian obstetrician Richard von Steinbüchel (1865–1952) in 1903 [19]. It was hoped that the scopolamine would also decrease the incidence of vomiting.

Paravertebral and Epidural Conduction Anaesthesia

Most regional anaesthetic procedures designed to avoid the adverse effects of spinal anaesthesia were developed during the early 1900s. Tübingen obstetrician Hugo Sellheim (1871–1936), described paravertebral anaesthesia in 1908 [20], but surgeons did not become interested until Max Kappis (1881–1938), of Hanover, published articles on

it [21]. Kappis suggested applying it to differentiate indistinct types of abdominal pain, a method approved by Lāwen [22]. Lāwen also advanced the use of epidural anaesthesia, particularly “sacral anaesthesia”, in urology and obstetrics [23, 24]. The initially inferior quality of epidural anaesthesia stimulated Lāwen’s efforts to improve the technique to one that allowed safe cholecystectomy, gastrectomy or nephrectomy [25]. To shorten the time of onset and to prolong the duration of anaesthesia, he used a new bicarbonated preparation of the local anaesthetic procaine [26]. He combined epidural and general anaesthesia in 1912 [27].

Safety First: Localization of Peripheral Nerves by Electricity

The increasing popularity of conduction anaesthesia in the twentieth century prompted development of techniques that located peripheral nerves using electrical stimulation. Georg Perthes (1869–1927) from Tübingen, described this method in 1912. Unfortunately his technique lay fallow until the 1960s, when it was rediscovered and became the “gold standard” until the twenty-first century when ultrasound became available for localization of peripheral nerves [28].

Quality Management in Regional Anaesthesia: Realized in 1910

In 1908, Bier described regional intravenous anaesthesia [29]. He injected up to 40 ml of 1% procaine intravenously into a limb previously made bloodless by an Esmarch bandage. Complete anaesthesia and motor paralysis could be achieved. Known as “Venenanästhesie” in German speaking countries, and “Intravenous Regional Anaesthesia” (IVRA) or “Bier’s Block” in Anglo-American countries, the method achieved limited popularity. Fear of local anaesthetic overdose, or the cumbersomeness and limited duration of the block may have hindered its use [30]. IVRA also may not have competed with new conduction techniques for blocking peripheral nerves and plexuses percutaneously. Fear of intravenous overdose inspired Bier’s colleague Fritz Momburg (1870–1939) to invent a double tourniquet, still applied today when IVRA is used [31]. Concerns regarding the side effects of IVRA prompted the development of a remarkable risk/benefit questionnaire [32] marking the beginning of quality control measurements in German anaesthesia.

Pain Therapy

The pioneers of local anaesthesia appreciated the adverse effect of acute and chronic pain upon daily life, and evaluated the possible role of local anaesthetics in pain management.

Fig. 29.4 This set of specially designed needles allowed the continuous application of local anaesthetics into the abdominal muscles for post-operative pain relief. (From Capelle W: Die Bedeutung des Wundschmerzes und seiner Ausschaltung bei Laparotomierten. *Dtsch Zschr f Chir* 1936; 246: 466–85.)

Surgeons Schleich, Braun, Läden, Kappis and Kirschner explored various regional anaesthesia techniques in the management of chronic pain. A lesser known pioneer was the Berlin surgeon Walter Capelle (1881–1950), who in the early 1930s suggested continuous subcutaneous injection of local anaesthetic. Specially designed needles (Fig. 29.4) were inserted into the subcutaneous tissue of the abdominal wall surrounding the surgical incision. He hypothesized that pain relief would facilitate deep breathing and decrease the incidence of postoperative pneumonia [33]. His contemporaries did not appreciate the importance of this concept and it seems that only his surgical colleague Ewald Fulde (1899–1971) in 1933 praised Capelle’s innovative concept [34].

Tübingen surgeon Martin Kirschner (1881–1942), introduced the modern treatment of trigeminal neuralgia [35]. In 1932, he used an electrocoagulating current to produce discrete lesions and to limit the spread of substances injected into the trigeminal nerve and Gasserian ganglion. Kirschner inserted the electrode through the foramen ovale into the ganglion. Decades previously, Georg Perthes had used a similar apparatus to localize peripheral nerves, and perhaps this stimulated Kirschner to invent a comparable device [36].

The Long Way to Painless Childbirth: The Medicated Birth

In the early twentieth century, childbirth moved from the home to hospital. Progress in anaesthesia, and the introduction of new anaesthetics, led women and their obstetricians to expect a painless birth through medication. Unlike surgeons, obstetricians and gynaecologists applied spinal anaesthesia widely from its beginning. By 1900, Gauss had suggested the use of combinations of scopolamine and mor-

phine to alleviate pain during childbirth. Although anaesthetic drugs affected the baby, physicians believed that the benefits of the combination outweighed the risks to mother and baby. Morphine relieved or dulled the pain, and scopolamine produced mental sedation and amnesia. There was the unproven perception that the drug combination enhanced the effectiveness of each single drug, thereby enabling a reduced dose of medication and a minimization of side effects. Labour might progress uninterruptedly without the pregnant woman being aware, or at least remembering, that she had suffered any discomfort. Gauss’ concept, known as “twilight sleep” attained transient popularity world-wide but its dangers to the baby and mother [37] rapidly led to its abandonment.

Later, caudal anaesthesia was recommended as a substitute for spinal anaesthesia. By the 1950s, epidural blocks, often performed via a catheter, became popular. This allowed more precise control over the extent of sensory loss and enabled the mother to assist in pushing during labour [38].

Early Intravenous Anaesthesia—Beginning with Intravenous Ether

Rectal and intravenous alternatives to the inhalation route were tried soon after the 1846 discovery of the anaesthetic properties of ether. In 1847, the Russian surgeon Nicolai Pirogoff (1810–1881) described such experiments in his monograph [39]. Decades later, French physiologist Cyprien Oré (1828–1899) attempted to popularize the intravenous injection of chloral hydrate, but failed due to inadequate analgesia and side-effects. Intravenous anaesthesia was forgotten for another thirty years, and rediscovered by the Würzburg surgeon Ludwig Burkhardt (1872–1922).

In 1909, Burkhardt reported that intravenous infusion of 4% chloroform or ether in a warmed saline solution could produce unresponsiveness and could sustain anaesthesia. He thought that intravenous infusion should minimize pulmonary complications because evidence of respiratory irritation such as coughing, laryngeal spasm, and cyanosis was markedly decreased. There were the added benefits of little or no excitement during induction, and intra- and postoperative cardiovascular stability, probably a consequence of the infusion of several litres of fluid. Burkhardt suggested that IV-ether was indicated for patients undergoing surgery of the head, face and neck, and especially for cachectic and hypovolemic patients [40]. Hamburg surgeon Hermann Kümmell (1852–1937) praised IV-anaesthesia as an “ideal narcosis” and recommended it for oesophageal surgery, gastric resection, craniotomy, and hypophysectomy. Intravenous ether was used during World War I, especially in hypovolemic patients [41].

But IV-ether never became popular. In the writer’s view, the technique died for two reasons: There was the problem of easily establishing reliable intravenous access; and few

Fig. 29.5 Hellmuth Weese invented hexobarbital in 1932, and the plasma substitute, 4% polyvinyl pyrrolidone in 1943. (The picture, taken around 1950, is from the collection of the author.)

experienced persons knew how to use IV needles (i.e., to avoid the need for cut-down access). Nevertheless, until the late 1920s, notable German surgical journals and textbooks of surgery discussed the use of IV-ether, recommending it in selected cases and calling for further research. The introduction of the short acting barbiturates, cyclopropane, and intubation techniques, made IV ether superfluous by the early 1930s [42].

From Intravenous Ether Anaesthesia to Balanced Anaesthesia

In the early 1930s, oral barbiturates became widely used for premedication. Berlin chemist Emil Fischer (1852–1919) winner of the 1902 Nobel prize in chemistry in collaboration with Josef von Mering (1849–1908) synthesized barbitone (Veronal)[®], the first effective sedative barbiturate, in 1903.

In the mid 1920s, others reported on water soluble preparations of limited value due to unwanted pharmacological properties [43]. Their pharmacological properties caused a deep sleep lasting for up to 24 hours. Moreover, respiratory and circulatory side effects were noted and often the patient's airway was compromised by the drug's action, producing life-threatening situations [44]. In 1932, Bayer pharmacist Hellmuth Weese (1897–1954; Fig. 29.5) reported his experiences with a new, water-soluble and ultra-short acting barbiturate that changed anaesthetic practice, Evipan[®] (hexobarbital) [45].

The pharmacological properties of hexobarbital created a breakthrough despite untoward effects, including life-threatening cardiovascular depression, induced respiratory depression with airway obstruction, local phlebitis and allergic reactions. IV hexobarbital anaesthesia offered considerable advantages, particularly a smooth induction which was then followed with an inhalational anaesthetic. Unlike ether, hexobarbital did not burn or explode with the use of cautery. Its portability recommended its application in war zones, if administered with caution, and as often suggested, "with an individual dosage" [46]. Cumbersome anaesthesia apparatus could be eliminated. These advantages plus changing surgical requirements led to the broad acceptance of hexobarbital.

Weese, Professor of Pharmacology at Dusseldorf and Director of Pharmacology at Bayer Wuppertal-Elberfeldt, was a major contributor to modern intravenous anaesthesia, illustrating a beneficial partnership between academia and industry [47]. In 1938, he was elected as an honorary member of the International Anesthesia Research Society, and became one of the first honorary members of the German Anaesthesia Society (DGA) on its founding in 1953 [48]. In the later 1930s, thiopental displaced hexobarbital. The Munich scientist, Alfred Doenicke (born in 1928), reported on a new hypnotic, etomidate, [marketed as Hypnomidate[®]] synthesized in 1971 and introduced in 1973. Its minimal depression of the circulation facilitated anaesthesia in hemodynamically compromised patients [49].

On the Way to Target-Controlled-Infusion (TCI)

In the 1960s and 1970s, pharmacokinetics and pharmacodynamics with new available hypnotics and analgesics became a topic of scientific interest in Germany [50].

The onset and elimination characteristics of drugs administered via precision infusions pumps were analysed. These tests identified dosages of the drugs for used for "target controlled infusion" (TCI). The invention of microprocessor controlled infusion pumps facilitated development of TCI. A group of anaesthetists guided by Horst Stoeckel (1930) in Bonn published the first paper on "closed-loop total

Fig. 29.6 Walter Straub (center and with cigar) produced the electrical roller pump for accurate infusion of liquids. Weese is third from left. (The picture, taken around 1930, is from the collection of the author.)

intravenous anaesthesia”, using the EEG as the feedback variable in estimating pharmacokinetic and pharmacodynamic values [51]. Of note, closed loop delivery of inhaled ether anesthesia had already been realized by the US physiologist Reginald Bickford (1913–1998) with his so-called Servo-Anesthesizer for the EEG-controlled dosing of ether in the early 1950s [52].

Rectal Anaesthesia

Pioneering anaesthesiologists found that rectal administration of pure ether produced excellent narcosis but adversely affected local tissues. The method was abandoned, but was revived early in the twentieth century by the American anaesthetist James Gwathmey (1862–1944) whose mixture of ether with olive oil produced satisfactory narcosis without injuring tissues [53]. It enjoyed some popularity in the US, especially for obstetric analgesia. In Germany it never became popular. Similarly, rectally administered paraldehyde was used as a basal narcotic in Great Britain, but was rarely given in German speaking countries.

Paraldehyde’s unpleasant odour, and the occasional violent restlessness associated with its use, caused German anaesthetists to prefer Avertin[®] (tri-bromoethanol), which became available in the mid 1920s. The surgeon Otto Butz-engeiger (1885–1968) observed that convenience, a smooth induction, and ready acceptance by patients recommended the use of Avertin[®] [54], particularly where calmness during preparation for anaesthesia was desirable (e.g., in children and patients suffering from thyrotoxicosis). However, adverse local tissue reactions were described shortly after

Avertin[®] introduction, leading to cautionary headlines in the lay-press and medical journals. With a revised dosage regimen, and administration restricted to selected patients, Avertin[®] remained in use until the middle of the 1960s.

Some Early Developments in Infusion Therapy

Experiences with IV anaesthetics stimulated the design of devices that administered precise volumes. In 1911, the pharmacologist Walter Straub (1874–1944; Fig. 29.6) produced the first electrically driven roller pump [55]. Straub suggested the use of his device to accurately infuse intravenous fluids, and drugs during anaesthesia, but only after the beginning of the 1950s were these pumps introduced into clinical practice. In German speaking countries, various models then became available, the most popular being the “Perfusor”[®], designed by the Braun Company, Melsungen, in the early 1950s. (Fig. 29.7). Even today, the term “Perfusor”[®] is colloquial for an anaesthesia IV pump in German speaking regions, even if it is a microprocessor-controlled computerized model [56].

Synonymous with the use of an intravenous infusion needle is the term “Strauss-Kanüle”, a needle made of steel and invented in the first decade of the twentieth century by the Berlin internist Strauss (1868–1944) [57]. A comparable model, made of polypropylene, became available in the mid 1950s. It was produced by the Braun Company, Melsungen, hence it is usually named “Braunüle”[®] [58].

The first appearance (in 1911) of today’s ubiquitous drip-chamber may be credited to the Cologne surgeon Emil Martin (1865-?) [59].

Fig. 29.7 An early model of Braun's infusion pump, named "Perfusor", used in clinical practice around 1955. (From the collection of the author.)

From Short-Acting Salt-Solutions to Volume Expanding Fluids

Early in the twentieth century, the importance of a sufficient intravascular fluid volume during anaesthesia became increasingly appreciated. Attempts were made to retain infused solutions within the intravascular space longer than normal saline by using a solution of gum acacia [60]. The research of the English physiologist Ernest Starling (1866–1927), suggested that a 3% solution might be best. His concept was correct, as shown by tests during World War I in wounded soldiers. But serious adverse effects such as allergic reactions, fever and even shock, led to tests of new approaches, such as the administration of hypertonic solutions [61]. Surgeon Friedrich Hercher (1881–1958) may have been the first to use such hypertonic solutions, giving them during World War I. He administered a "maximum of 50 ml of a 9% hypertonic solution" and praised its immediate cardiovascular stabilizing effects in several publications. Berlin surgeons Franz Schück (1888–1958) and Erich Simenauer (1901–1988) revived this concept in the 1930s. Schück noted the positive circulatory effects that appeared in 3–5 minutes. Why this revolutionary concept did not change clinical practice is unclear. One explanation is that both scientists were Jewish and emigrated to escape persecution. Their idea was temporarily forgotten, and rediscovered in the early 1980s. Today their concept is known world-wide as "small-volume resuscitation" [62].

A world-wide search for a solution with volume expanding properties proceeded in parallel to the studies of a concentrated saline or sugar solution. The lack of safe and effective blood-volume expanders became apparent during World War II. In Germany, Weese devised a non toxic, biocompatible solution with the desired blood-volume expanding properties, but without side-effects in 1943. This was Periston® (Polyvidone) [63], containing 4% polyvinyl pyrrolidone (PVP) with

an average molecular weight of 30,000. It was successfully tested as a plasma substitute in wounded soldiers, primarily during the campaign in France in 1940. Later it was not uncommon to administer Periston® into the sternal marrow of hypovolemic soldiers to manage hemodynamic instability. However it was generally infused intravenously during surgical procedures in anaesthetized patients. It was noticed that the pyrrolidone could bind with toxic substances like botulism and diphtheria toxins that were then renally excreted, thus being detoxified. Bayer subsequently developed a 6% preparation for this use, and this preparation was used to treat intoxication-hazards, such as barbiturate poisoning in suicide or in septic patients [64]. In the mid 1960s, pyrrolidone was withdrawn from the market, as better new synthetic colloids became available, especially modified fluid gelatins, dextrans and new preparations of starch solutions [65].

Around 1920, Straub developed an infusion of a "serum saline solution". Its use became widespread, since it could be prepared from hot water and a powder. A "Normosal-solution", manufactured at the "Sächsische Serum Werke" was available in ampoules by the middle of the 1920s. Some years later, other saline solutions, such as Tutofusin became available

Professional Developments in Surgical Pain Relief in Germany

Schleich's call to raise the quality of anaesthesia practice in the early part of the twentieth century fell on deaf ears. However the introduction of acetylene as an anaesthetic, the greater use of nitrous oxide, and the increased administration of intravenous or rectal anaesthetics in German speaking countries in the early 1920s, revived the idea of a specialty of anaesthesia. The development of complex apparatus for anaesthetic delivery, and more intricate operations increased the pressure for specialization. Physicians and state institutions favoured specialization, and the founding of a German Anaesthesia Society was discussed during the ninetieth Meeting of the German Natural Scientists and Physicians in Hamburg in 1928. But influential surgeons rejected the idea of anaesthesiologists. Most surgeons feared losing their place as the "captain of the ship" in the operating theatre. There was also an economic reason. Accepting the anaesthesiologist's important role in the treatment of patients during surgery would result in monetary requests to the patient, and this was not acceptable! In a popular textbook, Greifswald surgeon Friedrich Pels-Leusden (1866–1944) argued: "Fortunately, we do not have specialists in anaesthesiology like in the United States and hopefully they will never annoy us". Thus for decades, nurses experienced in the administration of anaesthetics were responsible for anaesthesia [66].

The enormous progress in anaesthesia in the US and UK during the 1930s and 1940s, rekindled discussion after

World War II. But major surgical circles continued to deny the need for specialization in anaesthesiology. Karl-Heinrich Bauer (1890–1978) argued: “For the training of anaesthesia physicians there is no urgent need; on the contrary, a better training of the anaesthesia nurses is more urgent” [67]. But the development of anaesthesiology as an independent branch of medicine could no longer be stopped. In 1953, the German Society of Anaesthesia (Deutsche Gesellschaft für Anaesthesie) was founded [68].

Because in Germany there was no educational program for nurses to specialize in anaesthesia, their role diminished as the medical specialty developed [69]. For decades, nurses have not been allowed to perform anaesthesia unless controlled (directed) by a physician [70]. In contrast to this situation in Germany and Austria, trained nurses in Switzerland are permitted to perform anaesthesia when an anaesthesiologist is nearby.

Journals and Textbooks Reflect the Increasing Importance of Anaesthesia

Publication of the first German anaesthesia-related journals “Der Schmerz” and “Narkose und Anaesthesie” in 1928, considerably preceded the founding of a professional specialty of anaesthesia. These journals merged to “Schmerz, Narkose und Anaesthesie” for economic reasons in 1929 and continued publication until 1944, interrupted then by the devastation of World War II. In the early 1950s, discussion by those working to form the German Anaesthesia Society led to publication of the journal “Der Anesthetist”. Indeed, the first issue of “Der Anesthetist” appeared in 1952 when the Austrian and Swiss Societies were founded. It is noteworthy, that this happened before the founding of the German Society of Anaesthesia! Der Anesthetist subsequently became the official organ of the German, Swiss and Austrian Anaesthesia Societies. In the mid 1960s, additional anaesthesia related journals appeared: Anästhesiologie und Intensivmedizin (Anaesthesiology and Intensive Medicine), Anästhesiologie-Intensivmedizin-Notfallmedizin-Schmerztherapie (AINS; Anaesthesiology, Intensive Care Medicine, Emergency Medicine, Pain Therapy) and these are still published [71]. The official journal of the German Society and Intensive Therapy of the former German Democratic Republic (DDR) merged with AINS after West and East Germany reunified in the late 1990s. Presently, all publications are official organs of the German Anaesthesia Society [72].

An increasing demand for information concerning anaesthesia encouraged publication of new textbooks for both the novice and the experienced anaesthetist. In the first decade of the twentieth century, German speaking authors Fritz Dumont (1854–1932) from Bern, Switzerland, Benno-Wilhelm Müller (1873–1947) from Berlin, and Max von

Fig. 29.8 Jean Henley at age 30. Reproduced from a photograph that accompanied her application for internship at Santa Barbara Cottage Hospital. In 1949, she wrote the first modern German textbook on anaesthesia. (From Zeitlin GK, Goerig M. An American contribution to German anaesthesia. *Anesthesiology* 2003;99: 496–502, with permission)

Brunn (1875–1924) from Tübingen published anaesthesia related monographs. Dumont’s textbook, “Handbuch der der allgemeinen und lokalen Anästhesie” [Textbook of general and local anaesthesia] appeared in 1903, Müller’s monograph “Narkologie—Narkosen und Methoden der lokalen Anaesthesie” [General anaesthesia and methods of local anaesthesia] followed in 1908. Max von Brunn’s monograph “Allgemeinnarkose” [General Anaesthesia] became available in 1913. In 1934, two monographs were published: Hans Killian’s “Narkose für operative Zwecke” (General Anaesthesia for Operative Surgery) [73] and Ludwig Lendle’s, Fritz Hesse’s and Rudolf Schoen’s “Allgemeinnarkose und örtliche Betäubung” (General Anaesthesia and Local Anaesthesia) [74].

After World War II, the American anaesthetist Jean Henley (1910–1993; Fig. 29.8) worked for several months at various hospitals in the American Sector of Germany. During the second half of 1949, she completed the first modern

German anaesthesia textbook, entitled “Einführung in die Praxis der modernen Inhalationsnarkose” (Introduction to the Practice of Modern Inhalation Anaesthesia) [75]. The textbook became a “best-seller” with more than 15,000 copies through 13 editions [76]. Henley’s textbook helped popularize modern anaesthesia techniques and endotracheal intubation in German medicine. She initiated the recording of preoperative assessment and postoperative complications. In 1981, the German Society of Anaesthesiology and Intensive Care Medicine (DGAI) awarded Henley an honorary membership [77]. Other anaesthesia related monographs by German authors soon followed publication of Henley’s book, reflecting the rise of anaesthesiology as a new German speciality. These publications underpinned the academic and scientific needs of the speciality.

Airway Management: from Tracheotomy to Endotracheal Anaesthesia

In 1869, Friedrich Trendelenburg (1844–1924) introduced a cannula surrounded by an inflatable cushion through a tracheotomy and delivered an inhaled anaesthetic through the cannula. In 1878, the Scot, William Macewen (1848–1924), pioneered tracheal intubation when he passed a tube by mouth into the trachea. His technique was initially unrecognized in its importance. Decades later the Kassel surgeon Franz Kuhn (1866–1929) “rediscovered” Macewen’s technique and praised orotracheal intubation [78] in a 1911 monograph [79] detailing the technique and its indications in anaesthesia and emergency medicine. His work led to the general recognition in Germany of the importance of tracheal intubation [80].

Kuhn never wearied of promoting the advantages of tracheal intubation. He repeatedly drew attention to the importance of an adequate airway during anaesthesia and of the avoidance of hypoxia. He demonstrated that intubation allowed provision of an adequate intrapulmonary pressure that would prevent pulmonary collapse when the pleural cavity was opened. Most of his German surgical colleagues did not realize the immense importance of intubation, perhaps being prejudiced by the influential surgeon Ferdinand Sauerbruch (1875–1951) who described positive pressure ventilation as “unphysiological” [81]. Another reason for the lack of interest in the intubation technique was the concurrently increasing importance of local anaesthesia in clinical practice. Some surgeons performed 70% of procedures under local anaesthesia, because the use of chloroform was thought to be (and probably was) dangerous [82]. In 1905, Kuhn designed an inflatable pharyngeal airway (Fig. 29.9), perhaps anticipating the development of the laryngeal mask airway [83]. We do not know why he discontinued this research.

Fig. 29.9 Kuhn’s inflatable pharyngeal airway (ca 1910) anticipated the laryngeal mask airway. (From Kuhn F: Perorale Tubage mit und ohne Druck. II. Teil Perorale Tubage mit Überdrucknarkose. Dtsch Zschr f Chir 1905; 76: 467–520.)

From “Autoscopy” to “Laryngoscopy”

Initially, tracheal tubes were inserted by digital guidance aided by topical cocaine-analgesia (Fig. 29.10) [84]. Later, the tube was passed orally under direct vision using a laryngoscope provided with distal illumination as described in 1895 by Berlin otolaryngologist Alfred Kirstein (1863–1922). Kirstein was among the first to develop a laryngoscope, but his intention was to visualize the larynx, trachea and oesophageal opening, and not tracheal intubation! Kirstein called his technique “autoscopy”, and the instrument an “autoscope” (autos = self, copia = watch) [85]. His laryngoscope was rarely used by anaesthetists. Thus, up to the 1950s, tracheal tubes were still usually inserted under topical anaesthesia and digital control, as Kuhn suggested in 1910 [86]. With the clinical introduction of muscle-relaxants in the early 1950s, laryngoscopes became more widely used in Germany [87].

Origins of Premedication in Germany

In 1900, Eduard Schneiderlin (1875–?) of the Psychiatry Clinic in Emmendingen described the positive effects of scopolamine combined with morphine, terming the combination “new anaesthesia”. He declared that he intended to prevent

Fig. 29.10 Insertion of a tracheal tube under digit control. The index finger pulls the tongue and the epiglottis forward, as the tube equipped with an introducer is inserted along the index finger into the larynx, ca 1927. (From Kirschner M, A Schubert (Hrsg.) *Allgemeine und spezielle chirurgische Operationslehre*. Springer-Verlag. Berlin-Wien, 1927, p 130, with permission.)

“the act of anaesthesia (from) comprising painful sensations” and to “avoid events... that appear to be repulsive to a human being” [88]. Schneiderlin advised performing a trial injection of about 0.3 mg scopolamine and 10 mg morphine, and to repeat the dosage after an interval of up to two hours. As he recommended repeating the injection up to four times to achieve the desired effects, it is not surprising that side effects were also observed.

The Freiburg surgeon Bertholt Korff (1859–1918) appreciated the advantages of preoperatively administered scopolamine-morphine [89]. Unfortunately, the doses recommended by Schneiderlin were excessive, leading critics to question the advantages of the medication. Revised instructions for dosage, and the use of new agents such as Pantopon (a mixture of all the alkaloids in opium), reduced adverse events, and increased acceptance among surgeons

in Germany. Patients now came to the operating theatre in a state of greater mental and physical tranquillity than before.

In addition to the purported sedative and anxiolytic effects of scopolamine-opioid medication, surgeons believed there was an antiemetic effect. Given the antiemetic effect of scopolamine on motion sickness, this had some basis. Moreover, they noticed a decreased incidence of post-operative pneumonia, attributed by Hermann Kümmell (1852–1937) of Hamburg, to decreased salivary secretions. Additionally, the course of anaesthesia became smoother with preoperative medication, and the amount of anaesthetic required could be reduced [90]. Leading pharmacologists suggested that morphine and scopolamine were mutually antagonistic in their effects on the human body, perhaps convincing physicians that side effects of each drug were lowered [91]. It became common practice to concurrently administer both drugs subcutaneously.

Schneiderlin’s enthusiastic reports stimulated the Austrian obstetrician Richard von Steinbüchel (1862–1952) of Graz, to use morphine-scopolamine in his practice. The medication allowed the conduct of obstetric procedures such as perineal suture, dilatation of the cervix, or a delivery with forceps. He found that scopolamine-morphine premedication markedly decreased the requirement for inhalation anaesthesia [92, 93].

From Bottle Droppers to Complex Anaesthesia Machines

Resisting innovations in the design of inhalers and gas apparatus, most German surgeons continued to use the simple open drop method of anaesthesia administration in the first decade of the twentieth century. Special bottle droppers allowed the continuous application of controllable amounts of ether and chloroform [94].

The surgeon Oskar Witzel (1856–1925) reported this open-drop method of anaesthesia for the first time in 1895. His several publications made the technique popular in Germany and abroad. Continuously dripping ether or chloroform on a loosely fitting face mask, the concentration of the agent was progressively increased, thus minimizing side effects such as apnoea due to the sudden imposition of high concentrations of vapour. Moreover, Witzel was convinced that the use of his technique lowered the incidence of cardiovascular side effects and, in combination with the positioning of the patient’s head in extension, minimized obstruction of the upper airway [95]. The broader use and acceptance of anaesthetic apparatus resulted from sequential advancements, including the production of pure oxygen, probably in the mid 1880s and the introduction of steel cylinders for storage of oxygen under high pressure in 1887.

Munich engineer Carl von Linde (1842–1934) liquefied oxygen in 1895. The storage and delivery of oxygen, and the manufacture of anaesthetic apparatus is closely connected with the name of the brothers Heinrich Dräger (1847–1917) and Bernhard Dräger (1870–1928), the founders of the Dräger-Company in Lübeck [96, 97].

In 1902, Lübeck surgeon Otto Roth (1863–1944) presented the first model of an anaesthetic apparatus, during the 31st Annual German Congress of Surgeons in Berlin. It was a sturdy oxygen-chloroform apparatus. Oxygen stored under high pressure was reduced in pressure and dispensed by a pressure reducing valve. Concurrently an injector drew liquid chloroform from a storage flask at a controlled rate that was allowed to vaporize in the oxygen stream. Roth detailed the improvements in anaesthetic control provided by the device:

“...We have now succeeded in making the falling drops of chloroform visible by using the suction effect of the oxygen stream and an especially made vessel; by virtue of this new construction the drops are always the same size so that about 50 drops always make one gram. An adjustable valve controls the number of drops and thus allows small or large amounts of chloroform on demand to fall into the oxygen stream, which is flowing at a known rate below the drip device, where they are able to evaporate. An indicator positioned above a scale of the valve gives details about the number of drops at any given time—and thus the chloroform dose in grams, which is evaporated per minute. In this way a true and accurate drip procedure is guaranteed which cannot be affected by the impatience of the operator.” [98]

This new anaesthetic apparatus was a milestone in anaesthesia—the modern beginning of delivery of precisely controlled dosages of anaesthetic vapours [99].

Following the suggestion of the gynaecologist Bernhard Krönig (1863–1917) of Jena, in 1911, a second drip for ether was added. A later addition to the anaesthetic apparatus made artificial ventilation possible. An oxygen operated injector, independent of the anaesthetic components, alternately imposed positive and negative pressures to the tightly-fitting breathing mask. By virtue of their manufacture and development of such devices, Dräger became and continues as a leading manufacturer of anaesthetic apparatus in the world [100].

Another milestone was the incorporation of the Pulmotor into an anaesthetic apparatus to allow automatic ventilation of the lungs. Dräger built the first Pulmotor for rescue purposes in 1907. A clockwork motor controlled the flow of oxygen to positive and negative pressure Venturi tubes. A later model was oxygen powered. The apparatus continued in use to the beginning of the 1960s [100].

Concurrent with Witzel’s open drop experiences at the end of the nineteenth century, Roth invented a completely metal, anaesthetic mask, which became the prototype for new models of anaesthetic masks. In contrast to the popular Schimmelbusch mask [96], Roth’s model could be employed

with an anaesthetic apparatus and anticipated the face-mask used in modern anaesthesia apparatus [101]. Some models provided for carbon dioxide absorption. Kuhn tested the technique clinically in 1906, but did not pursue it beyond initial trials [102].

After World War I, Würzburg obstetrician Carl Gauss recommended administration of the strange smelling acetylene with the newly invented anaesthetic machines [103]. However, several explosions occurred, leading clinicians to abandon acetylene [104]. The Dräger Company developed a comparable machine for delivery of ether-nitrous-oxide-oxygen. Two Hamburg surgeons Helmut Schmidt (1895–1979) and Paul Sudeck (1866–1945) had initiated this development, and accordingly, the model was often called the “Sudeck-Schmidt” apparatus. A positive pressure attachment could be added to the model which might then be used for thoracotomies [105]. The apparatus helped popularize nitrous-oxide-oxygen anaesthesia in Germany. Obstetricians, in particular, applied it for pain relief during labour. In the mid 1940s, Gauss initiated the development of a device for the self-administration of nitrous oxide oxygen mixtures. The apparatus was introduced in 1949 as the “Dräger Spezial-Lachgas-Analgesie- und Narkoseapparat nach Prof. Dr. C. J. Gauss”. A labouring parturient would inhale nitrous-oxide-oxygen via a tightly fitting mask as soon she felt contractions. The device could also deliver ether, allowing minor surgical procedures like suturing of the perineum or curettage to be done. This popular apparatus was also used in dentistry [100].

Monitoring and Documentation During Anaesthesia

At the turn of the twentieth century, heart rate, blood pressure and the amount of anaesthetic was sometimes noted in so-called “ether charts” [106]. This development was prompted by the American surgeon Harvey Cushing (1869–1930), and expanded despite rejection in the official statement of the Massachusetts General Hospital in 1903: “The adoption of blood-pressure measurement in surgical patients does not at present appear to be necessary as a routine measure” [107]. After Schmidt learned of the advantages of intraoperative documentation of vital parameters during a trip to the US at the end of the 1920s, he introduced the “anaesthesia protocol” into the Department of Surgery at the Eppendorf Hospital in Hamburg in 1929 where it continued to be used for decades [108].

Automated Measurement of Blood Pressure in Anaesthetized Patients

In 1932 the Siemens Company reported on the development of the “Autonograph”, a sophisticated device for continu-

Fig. 29.11 Heinz Oehmig's anaesthesia "workstation" of the late 1950s with integrated sophisticated monitoring devices, comparable to those that we use today. (From Oehmig H: *Sichere Narkose. Die Umschau in Wissenschaft und Technik* 1962; 23:730–4, with permission.)

ous measurement of blood pressure. It provided a printout of its recordings and was recommended for safer anaesthesia: "The blood pressure data can be consulted at any time as evidence for 'flawless' monitoring of the anaesthesia should any lawsuits arise" [109]. A few years later, in 1937, another device, the "Kardiotron" was developed for the same purpose [110]. It allowed the surveillance of additional hemodynamic parameters. Facilitated by the invention of piezoelectric crystals, even weak signals of heart rate or blood pressure could be transformed into acoustic and optical signals to alert the anaesthesiologist [111].

Monitoring and Recording Data from Patients after World War II

The importance of sophisticated monitoring was not appreciated immediately after World War II in Germany. The development of heart surgery in the mid 1950s changed this attitude. The anaesthetist Karl Oehmig (1919–2006) of Heidelberg, and later Cologne, was the most prominent Ger-

man advocate of comprehensive monitoring systems for use in the operating theatre. In the mid 1950s, he introduced a monitoring system similar to that which we use today. His sophisticated apparatus could continuously record blood pressure, heart rate, ECG, EEG, temperature, respiratory minute volume, exhaled carbon dioxide and the concentration of inspired air-oxygen mixture (Fig. 29.11). Later models also recorded the inspired and exhaled anaesthetic vapour concentrations [112].

Over decades, Oehmig sought to popularize such systems, but most anaesthetists felt little need for their use [113]. Problems associated with the new apparatus may explain part of their reluctance. For example, initially the ECG oscilloscopes provided a poor quality display subject to artifacts and interference, especially from diathermy. The use of needle electrodes or spiral-shaped stylus electrodes inserted into the skin also made the device less attractive [114].

On the Way to Inhaled Gas Control and Monitoring

The need to control the anaesthetic state stimulated the development of measurements of inhaled agents in anaesthetic circuits and in blood. Crucial to control was the measurement of the gas flow delivered from the anaesthetic machine. The engineer Karl Küppers (1874–1933) invented the rotameter to precisely measure the flow of gases, and his development was soon applied in anaesthetic apparatus. In 1908, Küppers obtained a patent for his invention, and in 1910, Heidelberg obstetrician Maximilian Neu (1877–1940) used rotameter flow meters to precisely control the delivery of different anaesthetic gas mixtures from a newly developed anaesthesia machine of the Rotameter Company, Aachen [115].

Cost initially limited the use of nitrous-oxide-oxygen anaesthesia in Germany. The anaesthetic had to be imported, making it expensive. Methods to minimize nitrous oxide consumption were sought, possibly leading to the reintroduction of rebreathing, a technology previously developed in an apparatus built by the Dräger Company in 1906. In 1925, rebreathing was revived in two models, the Gauss-Wieland apparatus for acetylene and the Dräger apparatus "Model A" for nitrous oxide [100]. These models also featured separate tubes for inhalation and exhalation, low-resistance micro foil valves, a carbon-dioxide absorber (as a single use cartridge, which could be shut off wholly or partly), and a breathing bag which allowed manual ventilation. A venting valve and an overpressure limiting valve were available extras [116].

The appeal of both rebreathing anaesthetic devices prompted new efforts to analyse the concentration of inhaled agents and carbon dioxide. Introduction of acetylene

as a potent, expensive, and explosive inhaled anaesthetic was instrumental in the development of such a monitoring device in German speaking countries. In the early 1920s, the Dräger Company constructed a new anaesthetic apparatus that incorporated rebreathing to decrease the cost of this expensive anaesthetic, and limit exposure of operating room personnel to the strange smelling agent [100].

Despite these precautions, deaths from explosions limited the use of acetylene. Convinced that elevated concentrations of the anaesthetic gas inside the operating rooms caused this hazard, Hamburg physiologist and internist Wilhelm Knipping (1895–1982) recommended the use of a device to continuously monitor the exhaled concentration of acetylene [116]. By so doing, the anaesthetist could use closed-circuit anaesthesia, decreasing the concentrations in the operating room. Moreover, Knipping proposed that by using his device, the anaesthetist would know the concentration of gases within the circle system, thus minimizing the risk of administration of hypoxic mixtures, or awakening of the patient due to inadequate anaesthetic concentrations, anticipating in the mid-1920s modern concerns regarding the “awake” patient [117].

Monitors of Inhaled Gas Concentrations Become Available

As indicated above, the use of gas analysis during nitrous oxide anaesthesia would allow the anaesthetist to identify possible hypoxic mixtures [118]. But use of such an analytical device, manufactured by the Siemens Company, did not spread in the 1920s and 1930s despite being repeatedly mentioned in reports and in Hesse, Lendle and Schoen’s textbook of anaesthesiology [74]. The device made use of the different thermal conductivity of different gases, measuring the effect of the gas on the rate of cooling of an electrically heated wire. The greater the thermal conductivity of the gas, the greater the cooling that resulted, measured quantitatively by the loss of resistance in the cooled wire [119].

After World War II, the Heidelberg anaesthetist Rudolf Frey reported his design of an electronic device that allowed continuous analysis of volatile agents. The apparatus, which became available in 1953, was similar to that which Knipping had constructed 20 years earlier. Frey repeated the arguments Knipping had advanced earlier [120]. Although Morris’ Copper Kettle and the British variable bypass vaporizers appeared in the 1950s, many vaporizers (e.g., Boyles’ vaporizer) provided uncalibrated concentrations of potent volatile agents like halothane or enflurane. The profound depression of circulation and respiration that these new anaesthetics could produce imposed a greater need for control over the anaesthetic state. Several new devices to measure

gas concentrations, like those developed by Helmut Vonderschmidt (1914–1998) or the already mentioned Karl Oehmig (Fig. 29.11), became available [121]. Since that time, such monitoring devices have become an integral part of all anaesthesia delivery systems. The Dräger company supplies the majority of anaesthesia equipment in Germany except for monitoring devices, where the influence of Anglo-American and Scandinavian companies has increased during recent times.

Anaesthetic Pollution—A Problem in the Operating Theatre?

Health risks to doctors and nurses by chronic occupational exposure to anaesthetic vapours, were repeatedly discussed in German journals of surgery. In the early 1920s, the Dresden surgeon Georg Kelling (1866–1945), called for decreases in such trace concentrations of inhaled agent [122]. His articles stimulated surgeons like Perthes (1869–1927) from Tübingen, and the Cologne obstetrician Josef Wieloch (1890–1944), to design devices for scavenging waste anaesthetic gases, designs similar to those used today [123].

Middle Twentieth Century Status of Physician and Nurse Anaesthetists

Major deficiencies in the quality of anaesthesia in Germany were evident through the 1920s. Nevertheless, leading German surgeons opposed the development of an independent specialty of anaesthesiology. For decades all authors of German surgical textbooks stated that only experienced doctors, mostly attending surgeons in training, should administer anaesthetics in close cooperation with the operating and responsible surgeon. The trainee was part of the surgical team and this arrangement ensured that the surgeon controlled the doctors administering anaesthetics. The Ministry of Health played a passive role, and supporters of the development of an independent specialty of anaesthesiology were again rebuffed at the 43th Meeting of the Aerztetag in Bremen, in 1924 [124]. In 1937, another attempt was made to establish anaesthesiology as the 16th area of expertise among recognized medical specialities. Again, the attempt failed. After World War II, surgeons recognized the importance of the advances in modern anaesthesia that had occurred in the US and UK. Nevertheless the majority hesitated to support the idea of a speciality of anaesthesia, instead discussing legal issues concerning the training of nurses to become anaesthetists qualified for German operating rooms. “According to German law, the surgeon is still responsible for the whole surgical procedure and the anaesthesiologist is

only an aide.” [125] In the following years, surgeons realized that they had to accept that anaesthesia had become the responsibility of the anaesthesiologist instead of the surgeon or nurses.

Another consensus was achieved after World War II. Nurses were officially not allowed to perform any kind of anaesthesia in Germany, a position which is still current [126]. Nevertheless it must be conceded that even today the reality is different in daily anaesthetic practice, although in 1959, nursing authorities officially refused to perform “intravenous anaesthesia methods, intubation procedures, controlled ventilation or use of curare” [127]. In contrast to these “modern anaesthetic procedures”, they did not object to performing traditional inhalational ether anaesthesia. By the 2000s, this limit was applied to Austria and Germany only [128] whereas in Switzerland, specialized trained nurses were officially still allowed to perform anaesthesia under the anaesthesiologist’s surveillance [129].

Postgraduate Training in Anaesthesiology

When the German Society of Anaesthesia (DGA) became the 16th area of expertise among recognized medical specialties in 1953, the training time was set at 5 years. It was typical that the regulations for specialist physicians required only a minimum training period for individual specialties, without a formal curriculum. In 1953, for example, specialist physician training in anaesthesia required a postgraduate training period of 4 years, made up of:

- 1 year of surgery
- 2 years of anaesthesia
- 6 months of pharmacology or physiology
- 6 months of internal diseases

Agreement had to be reached on transitional regulations for those colleagues who had practiced as anaesthesiologists for a long time. For unclear reasons, in 1967 the professional training time was reduced to 4 years. New regulations governing accreditation of the specialty soon followed, demanding a revision of the professional training curriculum. It was designed to be employed in surgery, but since the knowledge of an anaesthesiologist had to cover all areas of surgery, it was initially established only in anaesthesia related subjects.

The growing complexity of daily anaesthetic practice, especially during the 1960s and 1970s, increased the demand for qualified and well-trained anaesthesiologists. Specific training in thoracic, abdominal and obstetric anaesthesiology resulted in the neglect of other surgical disciplines, and led to the realisation that specific specialist education was required in anaesthesia itself. A new curriculum for the broader certification in anaesthesiology had to be established. In

1992, after several years of discussion, a 5 year education programme in anaesthesiology was restored. Finally, German anaesthesiology was on equal footing with other major European countries [130].

Training with the Anaesthesia Simulator

In the past 15 years, training on simulators has become widely accepted in Germany. Equipped with software allowing the display of a variety of physiological, pharmacological, respiratory and hemodynamic circumstances, these patient simulators allow an individualized sophisticated training commensurate with the participant’s individual educational level. The various State Chambers of Physicians in Germany are now considering how to use simulators to validate certification. Such an application will encourage all university departments to purchase anaesthesia simulators for teaching [131].

Further Professional Training in Anaesthesiology

Reflecting the increasing sophistication and knowledge base in medicine and anaesthesiology, the Deutsche Akademie für Anästhesiologische Forschung (DAAD, German Academy of continuous Education in Anaesthesiology) was established by the DGAI and BDA (German Society of Anaesthesiology and Intensive Care Medicine and Professional Association of German Anaesthetists) in 1977. This institution oversees continuing medical education in the specialty. Since 2003, a uniform certificate, valid nationwide, has been established in Germany, but this may be replaced by the European diploma in the future [132].

A Reprise and Conclusion

German scientists have contributed to major aspects of the history of anaesthesia. In 1804, Sertürner isolated morphine from opium. And months after Morton’s momentous 1846 demonstration, Heyfelder administered ether as an anaesthetic in Germany. Many advances followed, including the use of ethyl chloride anaesthesia (1848) in humans, the isolation (1853) and purification (1860) of cocaine, and the delivery of anaesthesia via a tracheotomy (1869). In 1884, Koller reported that cocaine had topical anaesthetic effects, opening the door to its application by numerous German-speaking physicians for infiltration and nerve blockade, and by Bier in 1898 for spinal anaesthesia. In 1890, Schimmelbusch invented his mask, used by Witzel in 1895 for continuous open drop anaesthesia.

In the early 1900s, the Dräger Company developed various anaesthetic machines, and new anaesthetic compounds were synthesized, including barbitone, the first useful sedative barbiturate (1903) and procaine (1904). In 1905, Kuhn invented an oro-pharyngeal airway, equipped with an inflatable cuff, the result anticipating by 80 years the development of laryngeal mask airways. By 1910, rotameters were invented and used in anaesthetic machines, and a decade later carbon dioxide absorbers were added. In 1912, Perthes described the localization of peripheral nerves by electrical stimulation. In 1925, Knipping developed a device to continuously monitor the exhaled concentration of respiratory and anaesthetic gases. Books and monographs were written, and in 1928, two anaesthesia related journals were published “Der Schmerz” and “Narkose und Anaesthetie”. The 1930s saw the synthesis of hexobarbital (1932, and meperidine/pethidine (1939). Blood volume expanders were developed in the 1940s.

In 1950, Henley's German textbook “Introduction to the Practice of Modern Inhalation Anaesthesia” was published, followed by numerous texts written by German speaking anaesthesiologists. Several subsequent developments supported the advancement of anaesthesiology in German speaking countries, including publication of the journal “Der Anaesthetist” (1952), founding of the Austrian and Swiss Society of Anaesthesiology (1952) and the German Society of Anaesthesia (1953), and the establishment of increasing numbers of chairs in anaesthesiology (e.g., Innsbruck, Austria, 1959; Basle, Switzerland, 1963; Hamburg-Eppendorf, Germany, 1963). The “Berufsverband Deutscher Anästhesisten” (BDA; German Association of Anaesthetists) was founded in 1961. In 1971, Doenicke published the first report on the clinical use of etomidate.

In summary, German speaking scientists and physicians added to the development of anaesthesiology. Perhaps more than in other countries, surgeons and obstetricians led the way, doing so for a century. Only in the last half century has anaesthesiology developed as a specialty in its own right.

The Evolution of Anaesthesia in the British Isles

30

Cedric Prys-Roberts

Summary

In 1800, Davy suggested that nitrous oxide might be used to relieve pain during surgery, but no one acted on his suggestion. Morton's 16 Oct 1846 discovery led to ether anaesthesia in Scotland and London on 19 Dec 1846. Liston proclaimed "*This Yankee dodge beats mesmerism hollow*". Simpson discovered and popularized chloroform anaesthesia in 1847. In the late 1840s, Snow developed an anaesthetic vaporiser and correlated anaesthetic dose and effect. In 1904, the General Medical Council (GMC), added anaesthetics as the 16th subject that every medical course and examination should contain.

The *British Journal of Anaesthesia*, and *Anaesthesia* began publishing in 1923 and 1946, respectively. Magill helped found the Association of Anaesthetists of Great Britain and Ireland (AAGBI) in 1932, and in 1935, the Anaesthetic Section of the Royal Society of Medicine awarded the Diploma in Anaesthesia. Lord Nuffield underwrote the Nuffield Department of Anaesthetics (NDA) at Oxford in 1937. Universities at Bristol (1946), Newcastle-upon-Tyne (1949), Cardiff (Welsh National School of Medicine; 1952) and Liverpool (1959) created Departments of Anaesthesia. In 1948, the Royal College of Surgeons established a Faculty of Anaesthetists, soon to introduce a Fellowship by examination (FFARCS). Parallel developments led to the Irish Faculty of Anaesthetists in 1959. Between 1960 and 1971, 15 new university departments headed by chairs of anaesthesia emerged in the UK.

In the early 1950s, ICI's Suckling and Raventós developed halothane which quickly became the world's anaesthetic, aided by the new calibrated vaporizer, the Fluotec. In 1967, Baird and Reid described the clinical use of pancuronium. JB Glen and colleagues at ICI discovered propofol in 1973, but formulation troubles delayed its release until the 1980s. In 1981, Wellcome Research Laboratories released atracurium, and in 1983, Brain introduced the laryngeal mask airway (LMA).

Established in 1988, the independent College of Anaesthetists (to gain Royal charter in 1992) participated in creating the Inter-Collegiate Faculty of Intensive Care Medicine in the late 2000s, and developed an independent Faculty of Pain Medicine. Similarly, in Ireland, a College of Anaesthetists (CAI) was created within the RCSI, becoming independent in 1998, and later creating an inter-Collegiate Faculty of Intensive Care Medicine, and its own Faculty of Pain Medicine.

In 2010, Pandit reported that only 6 of 23 UK universities sustained a departmental or divisional structure for anaesthesia. Will "anaesthesia" as "perioperative medicine"—encompassing anaesthesia, intensive care medicine, and pain medicine be a more attractive and effective format for the advancement of our specialties into the future?

Early British Medicine

In Britain and other European countries monks and priests, working as hospitallers, developed the science and art of healing. Two London hospitals, St Bartholomew's and St Thomas's, date from the 12th century. By the 15th century, many British physicians studied at Italian schools in Padua, Bologna, Pisa and Ferrara, and Protestant schools in Switzerland and Holland. These were the centres of the medi-

cal universe at the time [1]. Following a petition from the universities of Oxford and Cambridge in 1421, the English Parliament decreed that graduates of foreign universities should be granted the degree of Doctor of Medicine (DM Oxon, or MD Cambridge) to allow them, as well as graduates of Oxford or Cambridge, to practice medicine. Now, in the United Kingdom and in the Republic of Ireland, 'doctors' qualify with Bachelor's degrees in medicine and surgery (eg, MB, BS), whereas DM or MD are higher degrees based on research presented as theses or dissertations.

Thomas Linacre (1460–1524), a physician, scholar and humanist, studied at Padua for 12 years. With a group of distinguished physicians, he recognised the need for licensing physicians and apothecaries. Under charter from King Henry VIII, he founded the College of Physicians of London

C. Prys-Roberts (✉)

in 1518 [1, 2]. The College licensed those qualified to practice, and identified and allowed the law to punish unqualified practitioners and those engaged in malpractice. The College acquired the “Royal” prefix in 1674. Linacre also established lectureships at Oxford and Cambridge that later became the Regius Professorships of Medicine. Robert Sibbald and colleagues founded a College of Physicians in Edinburgh and obtained a “Royal” charter from Charles II in 1681. Similar colleges had been established in Glasgow (1599), and in Ireland (1654), both later acquiring the “Royal” prefix.

Surgery developed at a slower pace. In the 14th century, the Guild of Surgeons in London was in dispute with the Worshipful Company of Barbers, and in 1542, Henry VIII united the two groups to form the Company of Barber-Surgeons. Unlike the physicians, they had no qualifications, let alone a medical degree. In 1745, the surgeons separated from the barbers to form the Company of Surgeons, and gained a royal charter in 1800 to become the Royal College of Surgeons in London. In 1845, Queen Victoria granted them a further charter to become the Royal College of Surgeons of England [3], and the Royal College of Physicians concurrently insisted that surgeons should acquire a medical degree before they could practise. Until then, surgeons could not prescribe medicines.

Surgeons in Glasgow functioned as a joint Faculty with physicians, becoming a Royal Faculty in 1909, and a Royal College of Physicians and Surgeons in 1962. Barber-surgeons in Edinburgh incorporated as a Craft Guild in 1505 and were granted a charter by George III to become the Royal College of Surgeons of the City of Edinburgh (1778) and finally the Royal College of Surgeons of Edinburgh (1851) [4].

The progress of surgery in Ireland was much more interesting. The Barber-Surgeons Guild of St Magdalene was incorporated in 1446 by King Henry VI, becoming the first such corporation in the British Isles. Limerick surgeon, Sylvester O’Halloran, proposed a College of Surgeons modelled on the College de St Cosme in Paris, which had trained and regulated French surgeons since its receipt of a charter from Louis IX in 1255! However, this did not materialise and in 1785, George III chartered the Dublin Society of Surgeons as the Royal College of Surgeons in Ireland [5]. This college is one of the five constituent Colleges of the National University of Ireland and, unlike all other Royal Colleges, has its own undergraduate medical school. Although Ireland became a republic in 1922, the Royal Colleges maintained their chartered names as they include both Northern Ireland and the Republic.

Until 1999, all British (and Irish) Royal Colleges, in addition to their specialist training and regulatory functions, held examinations in medicine and surgery allowing them to license graduates to practise medicine. In 1993, the Society of Apothecaries, together with the five English and Scottish Colleges of Physicians and Surgeons, formed the United

Examining Board (UEB) to conduct the non-university examination for a registrable medical qualification. The UEB was dissolved in 2007, to conform to European Commission rules that allow only universities to grant qualifications in medicine. Other medical specialties, including anaesthesia, became chartered Royal Colleges after World War II.

Anaesthesia Develops as a Specialty in Great Britain

Humphry Davy (1778–1829) was neither an anaesthetist nor an academic, neither attending nor teaching at a university. At the age of 17, he was apprenticed to JP Borlase, a surgeon in Cornwall, and in that occupation he prepared and inhaled nitrous oxide, a gas discovered by Joseph Priestley (1733–1804). Priestley received the Copley medal of the Royal Society for a paper entitled “*The Different Kinds of Air*”. This paper stimulated Thomas Beddoes (1760–1808), an Oxford physician, to establish the Pneumatic Institution in Dowry Square, Bristol, ostensibly to treat pulmonary tuberculosis by the inhalation of these new airs. Beddoes met Humphry Davy during a holiday in Cornwall, and invited the 19 year old to become Superintendent of the Institution. There, Davy prepared nitrous oxide by heating ammonium nitrate as described by Berthollet in 1785, and studied the effects of breathing the gas, on himself and others. Some of Davy’s experiments were conducted at a time when he suffered from inflammation of the gums. In 1800 he described his experiences: “*On the day when the inflammation was most troublesome, I breathed three large doses of nitrous oxide. The pain always diminished after the first four or five respirations*”. Based on this simple observation [6, 7], Davy concluded that as (nitrous oxide) “*appears capable of destroying physical pain, it may probably be used with advantage during surgical operations in which no great effusion of blood takes place*”.

No power analysis, no randomised double-blind investigation but, nevertheless, a powerful prophesy. Davy went on to other great scientific discoveries, but missed his chance to provide the greatest advance in all of medicine. The discovery of anaesthesia was still 45 years away.

In 1823–4, Henry Hill Hickman (1800–1830), in Birmingham, experimented with inhaled carbon dioxide to create a state that he described as suspended animation, but his findings aroused little general or medical interest [8, 9].

News of the new paradigm called anaesthesia crossed the Atlantic Ocean on Samuel Cunard’s ship the *Acadia*, in December 1846. William Fraser (1819–1863) was medical officer on board the *Acadia* and travelled on to Dumfries in Scotland. His personal report of Morton’s public demonstration of ether anaesthesia in Boston, resulted in the successful administration of ether at the Dumfries and Galloway Hospital on 19 Dec 1846 [10].

A letter from Jacob Bigelow (the father of Henry Bigelow) to his friend Henry Boott in London, also travelled on the *Acadia*. Boott persuaded his neighbour in Gower Street, James Robinson, a dentist, to administer ether to a Miss Lonsdale for extraction of a molar tooth, also on 19 Dec 1846 [11], reported in the *Illustrated London News* on 9 January 1847. This early success led to the use of diethyl ether as an anaesthetic, when Robert Liston amputated the leg of Frederick Churchill on 21 December 1846, only four days after the news arrived in London. Liston proclaimed, “*This Yankee dodge beats mesmerism hollow*”.

Three physicians, James Young Simpson (1811–1870), John Snow (1813–1858), and Joseph Thomas Clover (1825–1882) dominated the clinical and academic development of anaesthesia in Britain from 1847 to 1876.

Simpson, Professor of Midwifery at the University of Edinburgh and Doctor of Medicine, was primarily an obstetrician. He was persuaded by David Waldie, the chemist of the Apothecaries’ Company of Liverpool, to test several volatile compounds, including chloroform, as potential anaesthetics to relieve the pain of labour (p24) [12]. Having inhaled these compounds, Simpson chose chloroform because it was effective, pleasant to breathe, and induced anaesthesia rapidly. In November 1847, Simpson presented a paper to the Edinburgh Medical and Chirurgical Society entitled “*Notice of a New Anaesthetic Agent as a Substitute for Sulphuric Ether in Surgery and Midwifery*”.

John Snow was a remarkable man [13]. At age 14, he commenced studies as one of eight students attending the Medical School of Newcastle-upon-Tyne, at its inception in 1832. He left Newcastle in 1836 and walked 285 miles to London, where he attended lectures at the Westminster Hospital, and at the School of Anatomy founded by William Hunter, the elder brother of John Hunter. He qualified in medicine in 1838, as a Member of the Royal College of Surgeons. To prescribe medicines (which “Barber-Surgeons” were not allowed to do), he also passed the examinations at the Apothecaries Hall. In 1844 he became an MD in London University, and was appointed Lecturer in Forensic Medicine at the Aldersgate School of Medicine for 5 years.

Early in 1847, Snow attended an administration of ether by Robinson, who wrote “I again operated this morning with the most perfect success, in the presence of my friends—Mr Stocks, Mr Snow and Mr Fenney (p16) [12]. Anaesthesia caught Snow’s imagination. He applied his mind to improving the administration of ether, soon developing an ether inhaler allowing production of constant saturated concentrations of ether vapour, thus increasing the safety of the procedure. Within the year, he had published “*On the Inhalation of the Vapour of Ether in Surgical Operations*” in which he described five degrees (today we might call them stages) of ether anaesthesia [14]. The anaesthetist might control the level—and safety—of anaesthesia by observing these de-

grees. Snow was appointed as anaesthetist to St George’s Hospital. He also worked with Robert Liston at University College Hospital, and William Fergusson at King’s College Hospital. He was the leading anaesthetist of his time, and probably of all time. He performed one of the earliest outcomes studies through a review of reports of deaths arising during anaesthesia, determining that chloroform might cause death by producing “cardiac syncope”. He investigated the effects of several vapours, including bromoform, ethyl bromide and amylene on himself and animals.

Snow developed a rebreathing system containing caustic potash (potassium hydroxide) for carbon dioxide absorption. Experimenting on himself, he showed that rebreathing chloroform present in the expired air prolonged anaesthesia. He found that the production of carbon dioxide during chloroform anaesthesia was decreased, suggesting that chloroform depressed metabolism [15].

By the time of his death in 1858, Snow had administered chloroform to more than 4000 patients with only one death potentially attributable to the agent. Snow administered chloroform to Queen Victoria during the births of Prince Leopold (1853) and Princess Beatrice (1857), deviating from his normal practice by dropping 15 minims (approximately 0.9 ml) of chloroform intermittently onto a handkerchief! Published posthumously in 1858, his book “*On Chloroform and other Anaesthetics*” was an extraordinary scientific treatise for that time [15]. He originated academic anaesthesia in Britain, perchance the world.

Snow had eclectic interests. He is considered the father of epidemiology, largely for his studies on cholera, his suppression of a cholera epidemic in London, and his 1849 book “*On the Mode of Communication of Cholera*” [16].

Clover succeeded Snow as the leading scientific and practical anaesthetist. Like Snow, Clover was primarily concerned with safety, and developed methods and apparatus for the delivery of precise concentrations of both chloroform and ether. In 1871, he claimed to have given 11,000 anaesthetics without a death, 7000 of them with chloroform. In the same year he showed that nitrous oxide’s anaesthetic effect was not the result of asphyxia. In 1876, he introduced the nitrous oxide/ether sequence that evolved as the most widely used approach to anaesthesia for the next half-century [12].

By the last quarter of the century, formal appointments of anaesthetists were made in many teaching hospitals, but anaesthetics were largely administered by general medical practitioners. There were no official training programmes or specialised qualifications. Two more British anaesthetists emerged as successors to Snow and Clover. Sir Frederic Hewitt (1857–1916) was appointed Lecturer on anaesthetics at the London Hospital in 1886. He advocated instruction in anaesthesia to medical students, and persuaded the Government of the day to draft a Bill to prevent anaesthetic administration by unqualified people. In 1892, JFW Silk published

a plea for anaesthesia to be an essential part of the medical curriculum [17].

We remember Dudley Buxton (1855–1931), anaesthetist at University College Hospital, for the first British textbook (1888) on “*Anaesthetics: their uses and administration*” [18], and for popularising the use of premedication with opiates, atropine or hyoscine, alone or in combination. However, his major academic contribution was to advocate for compulsory inclusion of the study of anaesthetics in the medical curriculum (1901) [19]. He argued that there should be a course of lectures during the final clinical year, and that every student should witness anaesthesia on at least 50 occasions, and have administered at least 12 anaesthetics before qualifying. Following representations to the Medico-Legal Society and the General Medical Council (GMC), *The Anaesthetics Bill* was proposed to the House of Commons. The first clause read that: “no person should be registered under the Medical Acts... unless he shall have produced evidence that he has received theoretical and practical instruction in the administration of anaesthetics” [20]. The *Anaesthetics Bill* never became law, but after another 3 years, the GMC added anaesthetics as the 16th subject that every medical course and examination should contain; not only for every university-based medical school, but also for the joint qualifications of the Royal Colleges of Physicians and Surgeons, and for that of the Society of Apothecaries. Up to 1922, the whole of Ireland was part of the United Kingdom, and thus these criteria also applied to Irish medical schools. At that time, almost every doctor might be required, as a house officer (intern), to administer anaesthetics.

The Twentieth Century

Surgeons and anaesthetists made innovations during the first thirty years of the twentieth century. Arthur Barker (1850–1916), Professor of the Principles and Practice of Surgery at University College Hospital, London, used beta-eucaine for infiltration analgesia in 1899; and pioneered spinal anaesthesia in Britain, controlling the level of blockade by using glucose to alter baricity. He used Stovaine (amylocaine), a synthetic local anaesthetic developed to avoid the toxic effects of cocaine, for spinal anaesthesia [21].

The introduction of continuous flow anaesthetic machines by Henry Boyle in the 1930s, popularized the co-administration of nitrous oxide and oxygen with ether or chloroform. Sir Ivan Magill (1888–1986; Fig. 30.1) and Stanley Rowbotham (1890–1979) worked with plastic surgeon Sir Harold Gillies, at Sidcup Hospital, treating servicemen injured during World War I. They developed tracheal insufflation of warm ether from a Shipway apparatus through one of two gum-elastic tubes (gas entering via one tube and exiting via the other) passed with the aid of laryngoscopy. Subsequently

Fig. 30.1 Sir Ivan “Paddy” Magill (1888–1986) holding an equine version of his tracheal tube

Magill developed mineralised rubber tracheal tubes, and later endobronchial tubes and bronchus blockers to advance the feasibility and safety of thoracic surgery. Rowbotham developed the art of blind nasal-tracheal intubation.

Magill contributed to academic anaesthesia and the recognition of anaesthesia as a specialty through the founding of the Association of Anaesthetists of Great Britain and Ireland (AAGBI) in 1932, and through the inauguration of the Diploma in Anaesthesia (DA) in 1935, under the auspices of the Anaesthetic Section of the Royal Society of Medicine [12]. Other hospitals appointed specialist anaesthetists, but, even so, only 50 existed in the whole of the UK. Numerous hospitals employed general practitioners, many with limited training, as anaesthetists for general surgical procedures and for the administration of ethyl chloride or nitrous oxide for dental extractions.

Between 1901 and 1925, many universities established honorary or part-time anaesthetic appointments, mostly within surgical departments, to enable the teaching of undergraduates.

The Chair of Anaesthetics at the University of Oxford [22]

Oxford had no clinical medical school in the early 1930s. The then Minister of Health, Neville Chamberlain, (yes the same Neville Chamberlain who in September 1938 and as

Fig. 30.2 Lord Nuffield (William Morris) (1877–1963), philanthropist and benefactor of anaesthesia, in academic regalia

Prime Minister returned from Munich stating “I believe it is peace for our time”) consulted with the Regius Professor of Medicine, Farquhar Buzzard, about the desirability of setting up a postgraduate medical school. Douglas Veale, who had been Chamberlain’s private secretary, moved to Oxford to become the University Registrar. Hugh Cairns, an Australian neurosurgeon who had trained with Harvey Cushing in Boston, was interested in this concept and wrote two extensive memoranda proposing a research-orientated medical school at Oxford. Buzzard, Veale and Cairns targeted Lord Nuffield for support. Nuffield, as William Morris, had developed a major automobile industry in Oxford and became one of Britain’s great philanthropists. (Fig. 30.2) Nuffield initially offered the University £ 1.25 million to establish “a school where professors and their assistants may pursue their research in clinical medicine unhampered by the claims of private practice or the routine teaching of students [22]. In a presidential address to the 104th Annual Meeting of the British Medical Association at Oxford in 1936, Buzzard stated that “The task of the heads of medical research departments, who must all be recognized leaders in their field, would be to link observations at the bedside with those made in laboratories” (translational research is not new!) [23].

Buzzard and Veale proposed that the grant be used to fund professors and departments of medicine, surgery, and obstetrics (and gynaecology). However, as a young man Nuffield had experienced problems following general anaesthesia for dental extractions, and was adamant that he wanted a Chair

Fig. 30.3 Sir Robert Macintosh (1897–1989), the first Nuffield Department of Anaesthetics chair

of Anaesthetics as part of his endowment. In August 1936, Cairns wrote to Howard Florey (Professor of Pathology, representing pre-clinical disciplines) that a Department of Anaesthetics would be: “quite feasible—to serve primarily as a training ground which could turn out all the young anaesthetists of the country at large, and probably many from the Dominions”. Meeting with Nuffield’s secretary, Veale “...wondered whether Nuffield really meant a Professorship, not a Readership, suggesting that anaesthetics might not be a subject of professorial status” [22]. Veale also proposed allocating a lower salary for this position, £ 1500 compared with £ 2000 for the other professors. Nuffield increased his gift to £ 2 million provided that a Chair of Anaesthetics was included, and that Robert (later Sir Robert) Macintosh, a New Zealander, would be appointed to the chair (Fig. 30.3). The University reluctantly agreed to Nuffield’s proposal, in doing so establishing anaesthesia as an academic subject, and creating the first Chair of Anaesthetics in Britain, the British Commonwealth, and Europe [22].

The Oxford hospitals created three major problems for the four new Nuffield professors, especially Macintosh. Who controlled a hospital service; who controlled fees from paying patients, and who controlled secondary costs to the hospital? After many discussions Macintosh won dominion in that “... the Honorary Anaesthetists had no

objection to Professor Macintosh being in general charge over the Department ..." (p35) [22]. The Oxford hospitals insisted that the newly appointed Nuffield professors, and their medical assistants, would not undertake private practice, and the University introduced a £ 500 per annum bonus to a Nuffield Professor who did not accept fees from private patients. The third issue concerned the building of new departmental accommodations for the Nuffield professors. The Departments of Surgery (Hugh Cairns) and Obstetrics (Chassar Moir) controlled new wards and operating facilities, but Macintosh endured a prolonged battle for suitable accommodation. From the outset, and throughout the war years, Macintosh's department, now named the *Nuffield Department of Anaesthetics* (NDA) was housed in a temporary structure on the roof of another hospital building. The final purpose-built department came into being after Macintosh's retirement in 1965!

During the war years (1939–1945), the NDA had a heavy teaching commitment, training postgraduate specialists to achieve the new Diploma in Anaesthesia, and thereby supply the burgeoning demand for anaesthetists in the armed forces. Macintosh was an Air Commodore in the Royal Air Force and travelled widely to ensure that equipment for that service was up to standard. During the war years, the NDA developed a submarine escape apparatus using CO₂ absorption, and studied the physiological effects of flying at high altitude (up to 40,000 feet). A novel, but unsuccessful, study designed a system that would allow Winston Churchill to breathe oxygen at altitudes greater than 8000 feet while smoking the cigars to which he was habituated [22]. Edgar Pask (1912–1966) allowed himself to be anaesthetized and subject to ventilatory arrest by forced hyperventilation with 15% ether in order to test the efficacy of various methods of resuscitation. To test the efficacy of 17 types of life-jackets, Pask allowed himself to be anaesthetized, have his trachea intubated, and then to be submerged under water on four separate occasions [22].

Macintosh's main contribution to research in anaesthesia was to develop, in co-operation with Hans Epstein, and Morris Motors (Nuffield's factory), an accurate portable draw-over vaporizer for ether (the Oxford vaporizer). The vaporizer allowed delivery of controllable ether vapour concentrations and thus safer anaesthesia, to be administered under field (armed forces) conditions, with or without added oxygen [24]. The principles of the Oxford vaporiser were later applied to the design, in 1956, of the EMO (Epstein, Macintosh, Oxford) vaporiser, and a subsequent miniature vaporizer, both robust and reliable devices. They formed the basis of future vaporizer designs. Macintosh also designed a laryngoscope blade that quickly gained worldwide acceptance.

Was Anaesthesia Safe?

In 1943, George Godber, Chief Medical Officer of Health (CMO), surveyed hospital services, finding that "virtually all the anaesthetists were also in general practice [25]. Unstated was the conclusion that the resulting occasional anaesthetist must compromise safety.

Immediately After World War II

Soon after World War II, four more universities created Departments of Anaesthesia. In 1946, the University of Bristol created a department headed by Ronald Woolmer (as a Senior Lecturer, later upgraded to Reader). In 1957, Woolmer was appointed Professor in the Research Department of Anaesthesia at the Royal College of Surgeons in London. Edgar Pask, became a Reader in the University of Newcastle-upon-Tyne in 1947, and full Professor in 1949. William Mushin (1910–1993), previously First Assistant in the NDA, was appointed Director of Anaesthesia to the Cardiff group of hospitals. In 1952 he was elected to a Chair of Anaesthesia in the Welsh National School of Medicine. T Cecil Gray (1913–2008) gained an MD in 1947, and was appointed Head of Department (Reader) in the University of Liverpool (Fig. 30.4). He was subsequently granted a Personal Chair in 1959. Gray and his Liverpool colleagues (Halton, G Jackson Rees, Utting, and Robinson) popularized the use of curare (d-tubocurarine) in British anaesthesia, and created the 'Liverpool technique' based on nitrous oxide anaesthesia, muscle relaxation induced by curare, and manually controlled ventilation [26]. Shafer, who argues that Gray's real innovation was that of balanced anaesthesia with a combination of drugs rather than a single inhalational agent, recently reviewed Gray's enormous contribution to modern anaesthetic practice [27].

Open cardiac surgery, mostly in adults, was made possible in 1952–1953 by pump-oxygenators (either the Melrose design developed at the Hammersmith Hospital, or the American Mayo-Gibbon machine), or profound hypothermia as pioneered at the Westminster Hospital. Induced hypotension techniques were developed to facilitate neurosurgery and plastic surgery. In the late 1940s, John Gillies (1895–1976) in Edinburgh, pioneered total spinal anaesthesia for the surgical treatment of hypertension by thoraco-lumbar sympathectomy, achieving drastic decreases in blood pressure (to less than 50 mm Hg) [28]. Subsequently, ganglion-blocking and adrenoceptor-blocking drugs combined with head-up tilt made the process potentially much safer [29].

1948–1988

The Faculty of Anaesthetists of the Royal College of Surgeons of England

After World War II, academic aspects of anaesthesia progressed on several fronts. The Goodenough Committee proposed that medical schools should create clinical academic departments, and that universities should support whole-time staff [30]. Representations by the Association of Anaesthetists to the Spens Committee led to the recognition that anaesthetists should be accorded equal status (and thus pay) with other hospital-based specialists [31]. The inauguration of the National Health Service (NHS) in 1948, led to the recognition that the number of suitably qualified consultant (specialist) anaesthetists was too small to staff the major hospitals of the country. The specialty moved rapidly to upgrade the Diploma of Anaesthesia (DA), then organised jointly by the Royal Colleges of Physicians and Surgeons, to a two-part examination: Primary (basic sciences) and Final (clinical anaesthesia). The Association of Anaesthetists requested the Royal College of Surgeons to establish a Faculty

of Anaesthetists. The Board of the resulting new Faculty met on 23 March 1948 under its first Dean, Archibald Marston. It was considered that a proposed Fellowship (1952) of the new Faculty (FFARCS) “would greatly enhance the academic status of the Faculty as well as being a means to encourage anaesthetists to attain the highest distinction in their speciality”. The GMC now considered anaesthesia to be a postgraduate subject, and consequently omitted the teaching of anaesthetics from the undergraduate curriculum in 1947, a regressive step that was corrected in the 1980s.

The training of specialist anaesthetists, which increasingly included intensive care, followed the pattern taken by other medical and surgical specialties. After internship, trainees occupied training posts in NHS hospitals, at senior house officer and then registrar status. The NHS assumed responsibility for trainee employment, while the Faculty (of Anaesthetists) controlled the setting and supervision of standards of training, and of examinations. After passing the final examination, trainees progressed to Senior Registrar posts for 3 to 5 years advanced training, after which they could apply for NHS consultant posts. Senior Registrars were encouraged to spend time abroad, expanding their research and clinical training, mostly in North America, Europe, Australia or New Zealand.

In the UK and the Republic of Ireland, unlike other countries in Europe, universities were not responsible for medical specialist training. The relevance of this statement will become evident later in this essay.

During its first forty years, the Faculty of Anaesthetists was accommodated in the Royal College of Surgeons, and the organization of its parent, the Royal College of Surgeons, largely determined the organization of the Faculty. Although the Faculty became financially independent, it enjoyed close support and good relations with its parent College. The Faculty had three major responsibilities: postgraduate (specialist) education, examination for the primary and final fellowship, and the setting of professional standards in anaesthesia, intensive care and, increasingly, treatment of severe and chronic pain.

The Faculty of Anaesthetists of the Royal College of Surgeons in Ireland, established in 1959, developed along almost identical lines, and until 1995 there was a reciprocal recognition of training standards and examinations between the two Faculties.

So, as the sixties began, academic anaesthesia was advancing well. Between 1960 and 1971, 15 new university departments headed by chairs of anaesthesia emerged. Britain differed from Germany and many other European countries, where a higher degree (doctorate, Habilitation) was an absolute requirement for advancement to an academic chair. John Nunn at Leeds (Fig. 30.5), and Alex Crampton Smith (Fig. 30.6) (as Macintosh’s successor) at Oxford were the

Fig. 30.5 John Nunn in his robes as Dean of the Royal College of Anaesthetists

great facilitators of scientific research, and sought to raise the calibre of the specialty by promoting research doctorates (PhD and MD). NHS hospitals increasingly supported Intensive Care, and a few university anaesthesia departments (Leeds, Oxford, Glasgow, Royal Postgraduate Medical School—Hammersmith) concentrated research efforts on this new sub-specialty.

Anaesthetic Research Society and Publication of Research

The Anaesthetic Research Group began in 1958 as a discussion forum for research in progress, rather than completed work [32]. Initially some established professors (Macintosh, Gray, Mushin, and Pask) were not supportive, but by 1967, the group meetings attracted substantial pre-publication presentations of research from both university and NHS departments. The group was reformed as the Anaesthetic Research Society in 1968. Two anaesthesia journals, the *British Journal of Anaesthesia* (founded in 1923), and *Anaesthesia* (founded in 1946), contributed enormously to the development of clinical and research aspects of anaesthesia and in-

Fig. 30.6 Alex Crampton Smith (1917–2010) on the high seas

tensive care during this period, by supplying a distinguished print forum for the work of investigators in anaesthesia. The *Lancet* and *BMJ* only accepted articles of general interest to medical practitioners, and specialist journals such as the *Journal of Physiology*, *Journal of Applied Physiology*, and *Cardiovascular Research* were relevant to only a handful of researchers.

Drug Development

The success of the pharmaceutical industry in developing new drugs, greatly influenced four categories of progress in clinical anaesthesia: inhalational agents, opioid analgesics, intravenous anaesthetics, and muscle relaxants. Working at Imperial Chemical Industries (ICI), near Manchester, in the early 1950s, Suckling [33] and Raventós [34] developed halothane. Introduced into clinical practice in the late 1950s [35, 36], and delivered with a calibrated vaporizer, the Fluotec, halothane rapidly replaced the flammable anaesthetics, diethyl ether and cyclopropane. Although halothane caused hypotension, and indeed was used specifically for induced hypotension [29], this was widely considered to be safe because it had been described as a vasodilator [36]. However, studies in animals [37] and humans [38] showed that halothane produced a concentration-dependent depression of the myocardium.

In 1961, Tunstall [39] described the first use of a pre-mixed gas, nitrous oxide (50%) and oxygen (50%), for analgesia during childbirth. This development was to be of considerable benefit in obstetrics, and also in accident and emergency medicine.

Paul Janssen, in Belgium, developed a new series of synthetic opioids modelled on pethidine (meperidine). They were initially introduced in the UK in 1964, to add to the technique of neuroleptanalgesia [40], a technique combining an opioid (phenoperidine) with a neuroleptic drug (haloperidol) to produce a ‘vegetative’ state that could be augmented with nitrous oxide anaesthesia. Subsequently, fentanyl (1965), alfentanil (1976), sufentanil (1976) and remifentanyl (1993) became widely used as the analgesic components to supplement ‘balanced’ inhalation anaesthesia and, from the mid-sixties onwards, of total intravenous anaesthesia.

Although thiopentone had been the standard induction agent, methohexitone and Althesin became popular in the UK and Ireland. Althesin, a combination of the steroids alphaxolone (the main effective anaesthetic) and alphadolone, solubilized in Cremophor EL, was developed by Glaxo Ltd (Uxbridge, Middlesex) in 1972. It was widely used as an induction agent and later as a continuous infusion [41, 42]. The rapid recovery from single or multiple doses of Althesin was a great advantage over thiopentone. The latter rapidly declined in popularity in the UK, whereas in the US it remained the main agent for induction of anaesthesia. Althesin was withdrawn from human use following reports of complement-mediated anaphylactoid reactions to Cremophor EL [43]. Glaxo Ltd subsequently developed a water soluble steroid anaesthetic, Minaxolone [44], but teratogenicity issues in animals caused it to be withdrawn. Finally, in 1980, Glen and colleagues at ICI Pharmaceuticals, near Manchester, developed a new intravenous anaesthetic: di-isopropyl phenol [45]. This lipid-soluble anaesthetic was also initially solubilized in Cremophor EL, but concerns that anaphylactic reactions might occur [46] led to its reformulation in a lipid emulsion [47]. Released in 1986, propofol, became the most popular agent world-wide for intravenous induction of anaesthesia, for the sedative component of total intravenous anaesthesia, and for continuous sedation in intensive care.

In 1967, Baird and Reid reported on the clinical use of pancuronium, a new muscle relaxant developed by Organon Laboratories, of Cambridge [48]. Pancuronium became widely used as a medium duration neuromuscular blocking agent (NMB), that had mild vagolytic effects on the cardiovascular system. In 1981, atracurium was released by the Wellcome Research Laboratories, of Beckenham, Kent, as a novel NMB that underwent spontaneous degradation by the Hofmann reaction [49, 50]. Cis-atracurium, a stereoisomer of atracurium, has largely superseded the parent drug.

The Eighties

Archie Brain designed, and in 1983 introduced, a remarkable advance in airway management, the laryngeal mask airway (LMA) [51]. This simple device evolved into the most widely used new airway since the introduction of the oral airway and tracheal tube. Although the main use of the mask has been in anaesthesia, it has also been applied in emergency medicine, in situations where manipulation of the head or neck is difficult because of potential cervical spine injury, or during rescue in confined spaces. Modifications include channels for gastric suction (LMA ProSeal™, LMA Supreme™), and for guiding endotracheal tubes into the larynx (ILMA—Intubating Laryngeal Mask Airway) and LMA-Fastrach™ [52].

A pilot study by Lunn and Mushin of mortality associated with anaesthesia [53] led to the initiation of a joint venture between anaesthetists and surgeons and the publication in 1987 of the first report of the Confidential Enquiry into Perioperative Deaths (CEPOD) [54]. This initial report quoted a mortality, within 30 days of surgery, of 0.7% in a cohort of half a million patients, with more than half the deaths in patients over 75 years old. The authors recommended that all anaesthetists and surgeons should audit their personal and departmental clinical practices, to enhance quality assurance for patient care; and that they should review consultants’ supervision of trainees. NCEPOD (N for National) continued on an annual review basis, evaluating perioperative deaths in a range of patient age groups or surgical interventions. During the first 11 years, the number of deaths reported was fairly consistent (range: 18,132 to 20,442 deaths per annum), but the number of deaths attributed to anaesthesia decreased progressively and is now considered to be between 1 and 2 deaths per million anaesthetics. In 2004 the same acronym, NCEPOD, changed to mean National Confidential Enquiry into Patient Outcome and Death, thus expanding the objectives. A similar system had been established in 1952, as the Confidential Enquiry into Maternal Deaths (CEMD) and the Confidential Enquiries into Stillbirths and deaths in Infancy (CESDI) [55].

The most recent (2011) NCEPOD report [56] compared data on mortality for patients undergoing major non-cardiac surgery in the UK and US in comparable hospitals over the same time period. Applying the P-POSSUM (Portsmouth modified Physiological and Operative Severity Score for the enUmeration of Mortality and morbidity) index, the authors concluded that patients in the UK with a predicted 0–5% mortality risk had an actual mortality (2.5%) that was eight times higher than their counterparts in the US (0.3%). A critique of this report [57] pointed out that the US spends significantly more (15.3%) of its GDP on health care than does the UK (8.2%), and has nearly 6 times the number of intensive care beds than does the UK. Their conclusion

that "...the NHS needs to invest in more critical care beds to improve outcomes in high risk surgical patients." was tempered in an accompanying editorial [58] which identified several strategies that could, with economy, improve outcomes.

Changes in Governance and Funding of Academia

From 1981 to 1985, Margaret Thatcher's Conservative government, driven by Keith Joseph, the Secretary of State for Education, greatly decreased funding of UK universities, a process previously regulated by the University Grants Committee (UGC) based on quinquennial estimates of financial needs from each university. Concurrently, Alex Jarratt, then chairman of the Committee of Vice-Chancellors and Principals, produced a report [59], responding to the growing demand from Thatcher for universities (and the NHS) to demonstrate efficiency, and accountability for public funds. Jarratt shocked many academics by his perception that universities should be seen as business enterprises in which students were customers. Academics were viewed as shop-floor deliverers of education, subject to performance indicators, rather than as a self-governing collegial group seeking to expand knowledge [60, 61]. The organizational functions of universities were viewed as requiring dedicated business managers, with a transfer of these roles from academics to such managers. The report thus laid the ground for the increase of "managerialism in the academy" [62] and it has become explicit government policy that university staff are paid to help their employers compete against sister institutions, rather than to serve the more traditional roles of university teachers. The adoption of the report led to the abolition of academic tenure.

In 1986, the government redistributed funding previously paid directly to universities. Funds were now directed to research councils, such as the Medical Research Council (MRC) and the Science Research Council (SRC), and University staff could then bid for grants from the research councils. Thus a substantial proportion of the funding of their university would depend on the quality of their grant applications. Another important consequence was the introduction in 1986, by the UGC, of the Research Assessment Exercise (RAE). Submissions from each subject area (or unit of assessment) were ranked by a subject specialist peer review panel. The rankings were used to inform the allocation of quality-weighted research funding that each higher education institution received from their national funding council. A decrease of one rank point (on a five point scale), by one or more small clinical academic departments, could decrease university funding by £ 1.5 million over a 4 year period. Most universities could only absorb such a loss by not reappointing academic staff.

For small clinical academic departments such as anaesthesia, these changes imposed major disadvantages. Firstly,

compared with their non-clinical colleagues, most clinical academics contracted to work 50% of their time in the National Health Service (NHS), limiting the time assignable to research and the writing of grant applications. Secondly, for seemingly equivalent quality applications from academic anaesthetists versus those from other specialties, anaesthetists fared poorly in their applications to MRC or SRC, or the Wellcome Trust. In 1988 Professor Rosen, as the first President of the College of Anaesthetists, invited the MRC secretary, D Davies to explain why the MRC was so parsimonious in their support of anaesthesia research. To paraphrase his reply: heart disease, cancer, asthma, tuberculosis, malaria and AIDs kill millions of patients—anaesthesia may kill one in a million! Eight years later, the new Chief Executive of the MRC, George Radda, gave the Royal College of Anaesthetists much the same answer.

The Faculty of Anaesthetists Finds a New Home

During this period of academic upheaval, most anaesthetists believed that, despite excellent working relationships between the Faculty of Anaesthetists and their parent Royal College of Surgeons (RCS), the specialty needed independence and equal status with other specialties that had become, or were becoming, Royal Colleges. With the consent and support of the RCS, officers of the Faculty engaged with the Privy Council to seek a constitutional pathway to achieve their aims. The solution, of a College (of Anaesthetists) within a College (RCS), seemed to be a satisfactory arrangement that would allow the former to maintain its functional and geographical links with the surgeons. Thus the College of Anaesthetists came into being in 1988. However, further discussions with the Privy Council revealed that the concept of a 'Royal College within a Royal College' was not compatible with the charter of the RCS. It was therefore decided to petition the Privy Council to create a charter for an independent Royal College of Anaesthetists (RCoA).

The Nineties and Noughties (1990–2010)

The Royal College of Anaesthetists (RCoA) was granted its charter (Fig. 30.7) in 1992 and occupied premises in Russell Square, London until 2002 when the College acquired larger premises in Red Lion Square (Fig. 30.8). In 1996, the RCoA sought to create a Faculty of Intensive Care Medicine but found little support from the various Colleges of Physicians and Surgeons, and settled eventually for an Inter-Collegiate Board. Continuing discussions over the ensuing fourteen years led to creation of the Inter-Collegiate Faculty of Intensive Care Medicine [63]. The RCoA also established an independent Faculty of Pain Medicine.

Similarly, in Ireland, a College of Anaesthetists was initially created within the RCSI, but in 1998 the College

Fig. 30.7 Charter of the Royal College of Anaesthetists (1992)

(CAI) became independent, and later also created an inter-Collegiate Faculty of Intensive Care Medicine, and its own Faculty of Pain Medicine.

Like other Colleges, during the 1990s, the RCoA had to respond to the directives of the Council of Europe. Firstly, changes were required in the way that anaesthesia in the UK recognised ‘specialists’ so as to conform to Council Directive 93/16/EEC ‘to facilitate the free movement of doctors and the mutual recognition of their diplomas, certificates and other evidence of formal qualifications’ [64]. In the UK and the Republic of Ireland, trainees had acquired the status of ‘Consultant’ as the final point of training, whereas in most other European countries, a doctor became a ‘Specialist’ after a shorter period of training. The European Specialist Medical Qualifications Order 1995; No 3208 [65] created a new system in which, at the end of a structured training programme overseen by the relevant Royal College, the Specialist Training Authority (STA) granted a Certificate of Completion of Specialist Training (CCST). The STA was a new regulatory body set up by, and responsible to, the government; as an expedient alternative to empowering the GMC for this purpose.

Secondly, the European Working Time Directive 93/104/EEC [64] required that by 2003, trainees should not work for more than 56 hours per week, and that by 2009, they should not work for more than 48 hours per week. This directive, initially promulgated in 1998, paralleled a general directive aimed at workers in many industries. It was perceived by the BMA and by the Royal Colleges to be incompatible with the traditional programme of training in which trainees spent a substantial number of hours each week ‘on call’, and profited from the experience. The Temple report [66] concluded that “... high quality training can be delivered in 48 hours per week, but not where trainees: have a major role in out-of-hours services; are poorly supervised; (and) have limited access to learning opportunities”. In order to comply with these requirements, consultants in specialties such as surgery, obstetrics and anaesthesia, have had to take on night call duties in place of trainees. Consequently trainees have had their exposure to emergency anaesthesia substantially decreased. Nevertheless, a recent study [67] in a London teaching hospital concluded that “High quality anaesthetic training is still possible in the UK despite reductions in junior doctors’ hours”.

Fig. 30.8 Present home to the Royal College of Anaesthetists, London

The Evolution of Specialist Training and Academia in Anaesthesia

As noted earlier, unlike the US, Canada and most of Europe, universities in the UK and Ireland have no direct responsibility for training specialist doctors; they exist primarily to teach undergraduates (including students preparing for first degrees in medicine, dentistry and veterinary medicine), and to prosecute research (including postgraduate research-orientated degrees such as MSc, PhD, and MD). University teachers in medical and dental subjects are appointed according to the importance of their specialist subject in the undergraduate curriculum, and their research profile. During the 1950s to 1970s, universities usually paid all grades of academic anaesthetists from UGC funds. However, with the growing importance of specialist training, some Regional Health Authorities, seeking to improve the quality of basic science education in certain specialties, funded university lectureships and chairs. In 1997, in preparing the inaugural Macintosh Lecture in Oxford, I consulted my British academic colleagues and found that 50% of professors and readers, and 75% of senior lecturers (all at NHS consultant equivalence) were paid by the NHS! Nunn produced similar data in his 1999 review

[68]. Fig. 30.9 shows the expansion of academic departments of anaesthesia headed by professors, from 1937 to 2000. These foregoing changes prompted many universities to distance themselves from their responsibilities for small clinical departments, using the savings to enhance non-medical subjects. All the while, the NHS demanded a greater role of clinical academics in the education of specialist trainees.

During the 1970s and onwards, the provision of specialist training was the responsibility of the NHS; co-ordinated for the Government by Postgraduate Deans, appointed by the Regional Health Authorities that were responsible for health-care on a geographical basis. Universities initially played host to the Postgraduate Deans (often granting them personal professorships) and their Deanery offices, although the deans drew their salaries from the NHS (Department of Health) and not from the universities (Department for Education and Science). During the past ten years, there has been a functional and geographical detachment of most Postgraduate Deans and Deaneries from Universities, further undermining the health:education sector partnership. Medical Schools have played a decreasing role in postgraduate training, reflecting their emphasis on undergraduate education and research, the latter driven by the three-yearly RAE.

One problem bedevilling the relationships between successive governments (tasked with staffing the NHS) and the Royal Colleges (tasked with maintaining standards of training and clinical practice), has been the disparity between the number of doctors in training and the number required to provide clinical services on a 24-hour basis. In 2004, following national devolution (transfer of certain powers from the UK parliament to regional governments), the four UK Health Ministers (for England, Wales, Scotland and Northern Ireland) responded to a paper by the CMO, Liam Donaldson, entitled “*Unfinished business: Proposal for reform of the SHO grade*”, by establishing a new system for specialist training [69]. The future shape of foundation, specialist and general training programmes was enshrined in the document “*Modernising Medical Careers (MMC)—The Next Steps*” [70]. The essence of MMC would be a two-year foundation training common to all specialties, followed by 5 to 7 year fixed-term specialist training appointments (FTSTAs) that were competency-based and ‘run-through’, (Fig. 30.10). The RCoA welcomed the changes and rapidly adapted their training programmes to the new outline.

Unfortunately, MMC was linked to MTAS (Medical Training Application Service), a computerised centralised admission system set up to enable recruitment into the first year of the new First Specialist Training year (ST1 in Fig. 30.10). This scheme was intended to be similar to the National Resident Matching Program in the USA. However, from early 2007 there were reports of technical problems with MTAS and evidence of unacceptable variation in the individuals selected for interview, together with evidence that doctors who previously would have been regarded

Fig. 30.9 Schematic of the expansion of departments of anaesthesia headed by professors in UK universities in decades from 1937 to 2000. Each small rectangle represents a professorial department. In the list of departments only the name of the initial professor is given, except where more than one professor was appointed (mainly for subjects, such as physics, related to anaesthesia). One academic department was merged with another within the University of Glasgow. Individual professors were funded either by HEFCE (Higher Education Funding Council for England and Wales)—open rectangles, or by the NHS through Regional Health Authorities

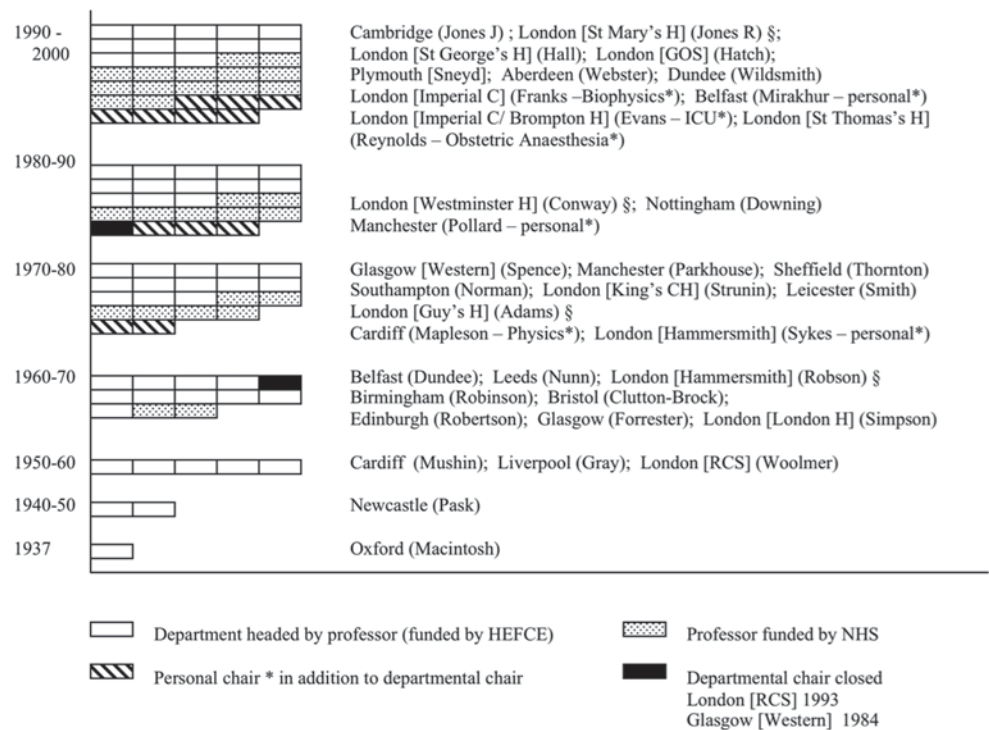

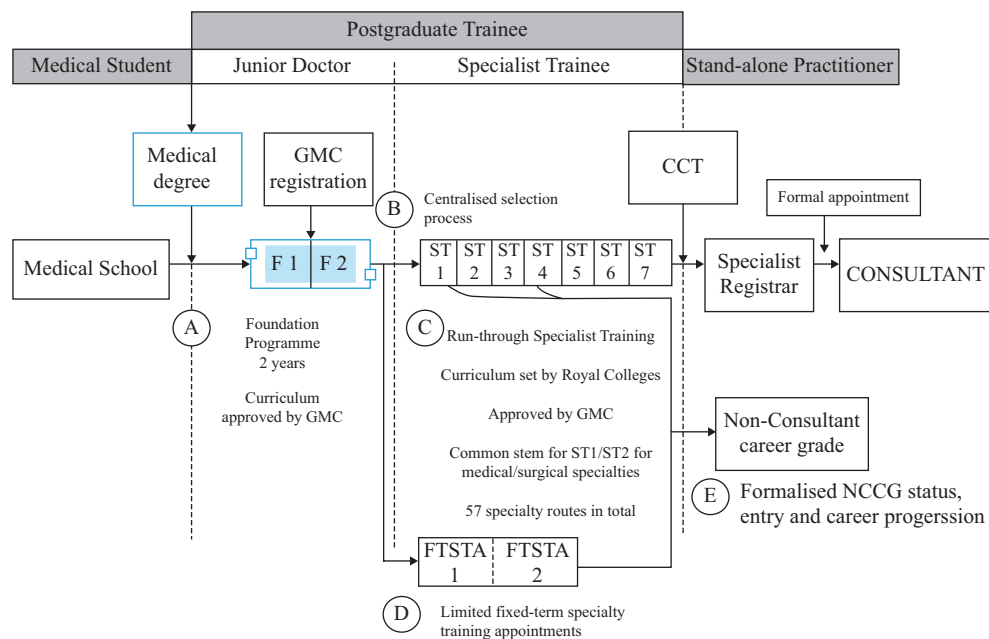

Fig. 30.10 Schematic of the process of specialist medical training since the introduction of “Modernising Medical Careers” in 2007. Letters A to E in circles represent the 5 policy instruments of MMC. The scheme differs from the previous process in that (1) F1 and F2 replace the single year of medical/surgical internship with a 2 year foundation programme for all doctors; and (2) Specialist Training (ST1 to ST 7) is now a run-through appointment that does not require periodic re-appointment in intermittent grades. The number of trainees in each specialty will be based on predicted manpower requirements for the relevant specialty as agreed between the Royal Colleges and the Department of Health.

as first-class candidates were not being short-listed. That MTAS was a disaster became evident later in 2007, provoking the government to establish yet another inquiry led by John Tooke. The report—“Aspiring to Excellence” was scathing and recommended corrective action on eight major issues in MMC [71].

A sub-committee of MMC, chaired by Mark Walport, Chairman of the Wellcome Trust was tasked with reviewing what was described as “... the perilous state of acad-

ic medicine and dentistry in the UK.”, and recommending processes for training clinical academics in line with the main MMC recommendations. The report [72] started by identifying three barriers for potential clinical academic trainees:

1. Lack of both a clear route of entry and a transparent career structure
2. Lack of flexibility in the balance of clinical and academic training
3. Shortage of properly structured and supported posts on completion of training.

The core proposal of the report was to ensure that:

“dedicated academic training programmes are developed in strong host environments, in partnerships between universities and local NHS Trusts and Deaneries”, and that “substantial efforts are made to develop academic training programmes in those specialties that have been subject to decline in their academic activity”. Additionally, a National Institute of Health Research (NIHR) was created, *“in which the NHS supports outstanding individuals, working in world class facilities, conducting leading edge research focused on the needs of patients and the public. The NHS reputation for international excellence is growing as it gains recognition for being the preferred host for collaborative and multi-centred research in the public interest in partnership with and for industry.”*[73]

In addition to increasing problems on the training front, the Academy of Medical Sciences perceived an impending crisis in academic medicine in general, especially in anaesthesia [74]. The RCoA commissioned a review by a strategist (J Pandit) who was appointed to work with the College’s Academic & Research Committee chaired by JAW Wildsmith. A central tenet of Pandit’s Strategy Report [75] was that *“... academic anaesthesia is an important and necessary activity: it includes not just research but also teaching, the development of new techniques for patient care, and professional leadership. As such, academic anaesthesia is essential for the future of the specialty as a scientific (and consultant-based) discipline”.* The report identified as the main cause of the crisis, the Research Assessment Exercise (RAE) and its effect on the policies of various universities on the staffing and structure of their medical schools. The report also pointed to the slow adaptation by the Royal Colleges to the changes imposed by government from 1986 onwards. A multidisciplinary campaign by the British Medical Association, the Academy of Medical Sciences, and others, sought to redress the harm done to clinical academic medicine. The Department for Education and Science responded with a consultation document *Reform of Higher Education Research Assessment and Funding* [76] in which they proposed to replace the RAE by 2010, with a simpler metrics-based system derived from various forms of research income other than QR (rather than the existing peer-review system). It is too early to assess the effects on academic anaesthesia of any proposed changes.

Seeking to redress potential damage to academic anaesthesia, and following the recommendations of the Pandit Report, the RCoA, together with the Association of Anaesthetists and the British Journal of Anaesthesia, established a National Institute of Academic Anaesthesia (NIAA). The College envisaged that the NIAA would engage with NIHR and other funding bodies to press the cause of academic anaesthesia. (However, it appears that the NIAA relates to individual researchers, in training or in career positions, rather than with universities or other employing agencies.) In its first report on the years 2008–11 the NIAA reported

that over £ 2million had been sourced and distributed as research grants, a very significant success story. Data in the Pandit report suggested that only six out of 23 UK universities sustained an independent departmental or divisional structure for anaesthesia. Between 2000 and 2012, twelve London medical schools have been merged within a new Collegiate structure (University College, King’s College, Imperial College, and Queen Mary College), and there has been a consequent decrease in the number of chairs of anaesthesia compared with the number shown in Fig. 30.9. Despite the restructuring within universities, most Divisions of Anaesthesia have been able to sustain their identity and their clinical links. It is worthy of note that the NDA (now Nuffield Division of Anaesthetics) has been subsumed into a new Nuffield Department of Clinical Neurosciences, and that the current Nuffield Professor of Anaesthetic Science (Irene Tracey) is Director of the Oxford Centre for Magnetic Resonance Imaging of the Brain.

The quantity and quality of research publications can give an estimate of the productivity of academic departments. Feneck and colleagues surveyed the output of original research from British university departments from 1997 to 2006, concluding that there had been a severe progressive decline in research publications from the UK, compared with other parts of the world [77]. A parallel assessment used bibliometric data and indices, to conclude that from 2004 to 2008, UK anaesthetists published research on a par with their European and Canadian peers [78]. Of the 23 UK academic units assessed, four (Oxford, Cambridge, University College and Imperial College, London) contributed 51 % of all publications. A similar preponderance of research output in the US comes from a small fraction of the academic institutions there.

The Future

As the oarsman steers by his wake, we also rely on the history of our specialty to guide our progress into an uncertain future. The RCoA, the CAI and the AAGBI have collaborated to develop “perioperative medicine” as the focus of their activities, encompassing intensive care medicine and pain medicine. The training programmes and curricula developed by RCoA and CAI are now an integral component of the MMT process, and will undoubtedly ensure for the future, a steady supply of fully-trained anaesthetists, intensivists and pain specialists. The specialty of clinical anaesthesia is thriving in the UK and Ireland, and remains attractive to medical students as a springboard to specialist training.

The future of academic anaesthesia in the UK is less certain. Whereas academics, at all grades, were previously primarily anaesthetists, universities are now tending to appoint professors (and related staff) within groups of allied

clinical and non-clinical scientists to form university departments with common purposes (for instance neurosciences, cardiovascular sciences and pharmacology). Thus there are greater opportunities to expand the other aspects of perioperative medicine, such as pain management, and intensive care medicine, linking these activities with research in allied areas such as immunology and sepsis. However, there is a danger that such developments may sequester the academicians both geographically and functionally from their clinical counterparts, making it more difficult to maintain a holistic environment for the academic and clinical education of trainees, and thus the future integrity of the specialty.

Kunio Suwa

Summary

In 1804, Seishu Hanaoka performed breast surgery in women anesthetized with herbs producing unconsciousness for 8–24 hours. News of Morton's discovery arrived in Japan in 1850 with Seikei Sugita's translation of Schlesinger's German monograph. In 1855, Sugita gave the first ether anesthetic, and Genboku Ito gave chloroform in 1861. Nagayoshi Nagai discovered ephedrine in 1887. In what may have been the first use of intrathecal opioids, Otoziro Kitagawa injected two patients with 10 mg of morphine in 1901, relieving pain in both.

In 1934, the Nippon Dental Junior College established the first anesthesia department, but anesthesia remained relatively undeveloped until after World War II. Anesthesia usually consisted of open drop ether and spinal anesthesia, administered by the youngest member of the surgical team. In 1950, American Meyer Saklad lectured in Tokyo, attracting the interest of Japanese surgeons in tracheal intubation and artificial ventilation. Surgeon Kentaro Shimuzi, convinced a young surgeon, Hideo Yamamura, to concentrate on anesthesia. Following study in the US, in 1956 Yamamura became the Professor and Chief of the Department of Anesthesia at the University of Tokyo. The Japanese Society of Anesthesiologists initiated board examinations in 1963.

In 1972, Takuo Aoyagi of Nihon-Kohden invented and patented the basic principles of pulse oximetry. The Maruishi Drug Co obtained the rights for sevoflurane in 1983, and sevoflurane was approved for clinical use in Japan in 1990—and the rest of the world soon thereafter.

The Japanese Journal of Anesthesia, *Masui*, began publication in 1954. An English language journal, The Journal of Anesthesia began publication in 1987. Perhaps the event most increasing recognition of the specialty was Emperor Showa's (Hirohito) surgery in 1987. It increased the public appreciation of epidural anesthesia, the scope of the specialty, and the capabilities of anesthesiologists. As of 2009, more than 20,000 Japanese physicians were qualified to practice anesthesia.

History of Anesthesia in Japan During the Edo Era (1600–1867)

Between 1637 and 1853, Japan was closed to all Western countries except Holland. Contact was maintained with China and Korea. Medical concepts were principally governed by Chinese principles, adjusted and modified to Japanese needs, and supplemented by information from the few Dutch people residing in the Western part of Japan.

One record relates that in 1689, Tokumei Takamine (1653–1738) successfully repaired a cleft lip in Ryukyu while using mafutsu-san, which was considered at the time to be some form of general anesthesia. Ryukyu, now called Okinawa and located at the western end of Japan, was a semi-independent country at that time, ruled loosely by both Japan and China. Akitomo Matsuki, a medical historian and one

of Japan's leading anesthesiologists, has studied the original record and concluded however, that mafutsu-san was not an anesthetic but rather was an ointment applied to dress the incision and surgical wound [1].

In 1804, Seishu Hanaoka (1760–1835; Fig. 31.1) performed the first successful surgical treatment of breast cancer under general anesthesia. Many claim that it was the first ever general anesthetic administered for a surgical procedure. Hanaoka performed surgery for many other kinds of surgical procedures in a total of 156 cases prior to his death in 1835 [2]. The “anesthetics” consisted of mixtures of various ingredients obtained from herbs and were given per mouth. The medication kept the patients unconscious for 8 to 24 hours. Detailed information is given in Matsuki's article [2]. Although Hanaoka taught this technique to his students, it was not widely publicized beyond his school, thereby limiting its application to a relatively small group of physicians and patients.

In 1850, Seikei Sugita (1817–1859) translated the Dutch version of J. Schlesinger's monograph on ether anesthesia (in German) into Japanese. He also coined the word “Masui”,

literally meaning “paralysis” plus “unconsciousness”. In 1855, Sugita himself gave ether anesthesia, probably the first inhalational anesthetic given in Japan. The record indicates that he performed a mastectomy under ether anesthesia, but no additional details are available. There are also records describing Genboku Ito administering chloroform anesthesia for limb amputation in 1861, as taught by Franz von Siebold (1796–1866), who was a German physician and scientist. Chloroform was imported from Holland by a Dutch Navy doctor.

1868 to 1950

In 1853, Commodore Perry, a US naval officer commanding four battle-ships, forced Japan to open herself to various Western countries. In 1868, the Shogun officially resigned, starting the Meiji Era, and initiating aggressive efforts to obtain information from Western civilizations.

In 1878, cocaine was imported, but its use was not recorded until 1885, when it was administered for pain relief during tooth extraction. The route of administration is not known. In 1887, a pharmacist Nagayoshi Nagai discovered ephedrine, extracting it from a Chinese herb. This was reported

to a German journal, [3, 4] and mentioned by KK Chen and Carl Schmidt who rediscovered this agent in 1924 [5]. Before 1900, a few sporadic records described importation of nitrous oxide and the equipment required for its use.

In 1901, Otoziro Kitagawa performed spinal anesthesia for the first time in Japan using the local anesthetic “eucaine” ($C_{15}H_{21}NO_2$), an agent supplied as either alpha or beta eucaine (the latter known also as betacaine). This anesthesia was given to patients with intractable pain. It was used for some time around the turn of twentieth century because it was less toxic than cocaine, yet later abandoned because of its side-effects.

In two patients, Kitagawa injected 10 mg of morphine intrathecally. One patient was a 33-year-old man who was relieved of severe pain for several days, and the other was a 43-year-old woman who was relieved of pain in the lower back for two days. This may be the earliest description of narcotic use in the subarachnoid space [6]. Recognizing that this intrathecal dose of morphine might have been associated with profound respiratory depression, Matsuki comments that Kitagawa used a large needle, possibly enabling a leakage of CSF and preventing (of course, fortuitously) respiratory depression [6].

In 1912, surgeon Hakaru Hashimoto of Kyushu University reported four cases of an unusual type of thyroid disease, later known as “Hashimoto disease” or “Hashimoto’ thyroiditis” [7]. In this report, he performed surgery in all four cases under “chloroform anesthesia”.

1900 to 1930 saw the use of various techniques and instruments, including epidural anesthesia, intravenous alcohol administration, and tracheal tubes. In 1934, a Department of Dental Anesthesia was established at Nippon Dental Junior College (now the Nippon Dental College). This is believed to be the first Japanese academic department specializing in anesthesia, more than 20 years before any department in a Japanese medical school.

Beginning in 1936, Daisuke Nagae, an Army surgeon, spent two years at the Mayo Clinic in Rochester, Minnesota, observing the practice of medicine. Upon returning in 1938, he published a report entitled “Trends in Surgical Anesthesia at Mayo Clinic [8].” In retrospect, although this superb report clearly described various aspects of general anesthesia including tracheal intubation, it had little impact upon Japanese medicine because it was published in the *Journal of Army Medicine*, and access was not only difficult but was more or less deliberately kept secret. This period immediately preceded hostilities between Japan and the US, and Nagae, an Army Surgeon, could not officially report the superiority of American techniques, although he did publish the article.

In 1941, Japan attacked Pearl Harbor, and following the war, was occupied by the US until 1952. Despite his contributions to medicine and his sympathies towards the US,

Nagae was excluded from official or governmental positions because he was a high ranking official in the Army when the war ended, and was considered to have contributed to the war effort. He died in 1957 and his contributions to Japanese medicine became known only after his death, mainly due to the efforts of Matsuki [9].

There is little published information describing how anesthesia was practiced during this period. Anecdotal evidence suggests that the youngest member of the surgical team administered open drop ether and spinal anesthesia. There were no known formally trained anesthetists, although there might have been a few individuals who gave anesthesia routinely. There are records showing that Japan manufactured a small amount of anesthesia equipment. Tracheal tubes, if used at all, were probably inserted by dentists rather than by physicians, and even most thoracic surgery was done under local anesthesia. Clearly, Nagae's revolutionary report made little impact.

1950 to the Present: Various Academic Anesthesia Departments

The Impact of Meyer Saklad's Lecture on Japanese Medicine/Anesthesia

In August 1950, Meyer Saklad of Rhode Island Hospital attended the Japanese-American Joint Conference of Medical Educators, held in Tokyo. This meeting was a part of Unitarian Service Committee (USC) activities, American efforts aimed at the exchange of medical information and the establishment of close relationships between the American medical profession and members of the profession in post-war foreign countries.

This Conference had a major impact on Japanese surgeons (there were no anesthetists at that time) attending the meeting. They were particularly interested in tracheal intubation and maintenance of artificial respiration. Saklad's lecture was translated into Japanese by Kentaro Shimizu (Fig. 31.2), a leading surgeon of the University of Tokyo who had just returned from a visit to the US. Hideo Yamamura (Fig. 31.3), a 30 year old surgeon in Shimizu's department, attended the meeting only reluctantly to satisfy the request of Shimizu, but was soon attracted to anesthesia. (This story was told to me by Yamamura himself.) Recognizing Yamamura's interest, Shimizu suggested that Yamamura abandon surgery and concentrate on anesthesia. Yamamura agreed and in 1952, Shimizu established a small section of anesthesia in the department of surgery at the University Hospital, and then sent Yamamura to the US for further study.

Saklad's lecture attracted many other surgeons to this new field, particularly because of the delivery of anesthesia via tracheal tubes, resulting in an enormous increase in the

Fig. 31.2 Kentaro Shimizu. (From the author's collection.)

Fig. 31.3 Hideo Yamamura. (From the author's collection.)

number of anesthesia-related reports at surgical meetings. In 1954, Shimizu organized the first meeting of the Japanese Society of Anesthesiology (JSA). In the same year, publication of the Journal, *Masui* (The Japanese Journal of Anesthesiology) began. This journal was, and still is, published only in Japanese, yet it achieved semi-official status as the journal of JSA. On return from the US in 1956, Yamamura

* Deceased

became the Professor and Chief of the Department of Anesthesia at the University of Tokyo, the first such department in a Japanese Medical School. Yamamura retired from academic medicine in 1980 at age 60, and in 2010 at the age of 90, still practices medicine in his clinic. He does not smoke, drink, or take coffee. He ate little even when he was young. He is not active in any sport, but does play the piano, his only hobby besides studying, of which I am aware.

At this time, many young physicians went to the US for anesthesia training, adding to those already in the US who were training in other fields but switched to anesthesia. The information describing who studied in which institutions and when they were there, was mostly lost, but fortunately the “The Aqualumni Tree” by Lucien Morris, appearing in the September 2001 ASA Newsletter, prompted discussion and interest among Japanese anesthesiologists about this matter. The following list of those who were trained in 1950 resulted from that discussion (Table 31.1) [10]. Alas, I am certain that I must be missing many other names due to the difficulty in tracing them.

In the meantime, several companies began producing carbon-dioxide absorbents (Soda-lime: Wako Junyaku Co.),

thiopental (Tanabe Co., Now Tanabe-Mitsubishi Drug Co.) and nitrous oxide (Showa Denko Co.). Ether and chloroform were already available for inhalational anesthetic use. Anesthesia machines and equipment were originally imported, but were soon manufactured locally (Senkosha Co., Acoma Co, and AIKA Co.).

Establishment of the Specialty

Until recently, once qualified (holds a permanent medical license) a Japanese physician could practice any specialty. The names of these specialties were legally recognized, but as late as the middle of the 1950s, anesthesia was not included in the list of recognized specialties, because at the time the law was written, anesthesia as a specialty was unknown in Japan. As it became widely known, pressure increased, to include anesthesia as a legally recognized specialty. Subsequent discussion resulted in making anesthesia a “special” specialty which meant that unlike all other specialties, anesthesia could not be chosen (as could other specialties), without fulfilling one of two requirements: completion of two years of training, or experience administering general anesthesia to 300 patients using anesthesia equipment. In addition, a category for those not satisfying the above requirements that allowed the “choice” of anesthesia was extended to the “pioneers” trained in overseas programs.

This system was established in 1961 and still exists. It consists of a permanent qualification (i.e., medical license) that once obtained, remains in force indefinitely. According to the law, therefore, any physician of any specialty may practice anesthesia as long as he or she is qualified once, as described above.

Currently a debate exists as to whether this system should be maintained. In some respects, it is a stronger and more legitimate qualification than that required to practice any other specialty because the training requirements are written into law, and thus established officially. Qualification in other specialties is weaker because it is determined by individual private societies.

Recognizing that this system provided only a limited test of the quality of training in anesthesia, ten leading anesthesiologists decided to establish a specialty board using an American model—the first formal certification of and by a medical specialty in Japan. The Japanese Society of Anesthesiology conducted the first examination in 1963, and although the exact number of candidates is no longer known, 44 anesthesiologists qualified by passing the examination consisting of oral and written examinations, and the testing of skills. The JSA initiated certification of “Instructing Hospitals” (i.e., residency programs) in 1973, dictating minimum standards for the instructing staff and residency experience. In 1991, Renewal of Instructor and Instructing Hospi-

tal Certification became necessary every 5 years. In 2004, guidelines for certification and accreditation common to all specialties were established. To comply, the JSA certification mandated a three stage system: Certified Anesthesiologist, Certified Anesthesia Specialist, and Certified Anesthesia Instructor. Certification had to be renewed every 5 years, and was judged by document review.

The present specifics are as follows. Hospitals may post clinical services that they provide, including anesthesiology, when they have staff anesthesiologists who have been trained by JSA Certified Instructors for 2 years or more, or have been instructed by such Instructors in 300 cases or more at a Certified Instructing Hospital. Such staff anesthesiologists have been recognized by the Ministry of Health, Labor and Welfare (MHLW) with posting permits since 1960 and now total more than 20,000. The posting permit does not have to be renewed and the MHLW does not keep track of permits once issued. The number of postings does not define the number of anesthesiologists presently in practice. Today's physicians trained in anesthesiology might include four groups.

1. Some are non-anesthesiologists who had trained in anesthesiology (see previous paragraph) but who principally practice a discipline other than anesthesia.
2. As of 2012, approximately 2,500 physicians are Certified Anesthesiologists. These are senior residents or junior faculty who have had at least 2 years of training (not simply those who have given 300 cases or more under supervision), have gained a MHLW permit, and have joined the JSA. They would usually have had more than 3 years of postgraduate training. Through a review of documents, a JSA committee adjudges that they have reached this stage (no test is given).
3. Approximately an additional 3,000 physicians are Certified Anesthesia Specialists. These usually have faculty status at an academic hospital and have taken 4 or more years of training in anesthesia and 6 or more years of postgraduate training. They must pass a written, an oral, and, if deemed necessary, a skill test.
4. Approximately an additional 3,300 physicians are Certified Anesthesia Instructors. They have held the position of Certified Anesthesia Specialist for more than 4 years. A committee for adjudging instructor certification in the JSA has found them capable of training Anesthesia Specialists. During their fifth year as a Specialist they will apply for the title of Certified Anesthesia Instructor.

My Experience Taking the American Board of Anesthesiology Examination

Among Japanese physicians, anesthesiologists as a group are particularly fond of America. There are several reasons for this: anesthesiology was born and developed in America; most of us learned from American textbooks and journals;

and many, including me, received part or all of their training in America.

Between the 1950 and the 1970, America was considered so wealthy that, coming from Japan, a country still recovering from the devastation of World War II, it seemed like a paradise. In addition, I was impressed that such an affluent society was at the same time a "fair society", far fairer than I had expected.

I began residency training at the Massachusetts General Hospital in Boston in July 1963. At the end of the second year of training, I passed the written examination of the American Board of Anesthesiology. In my third year, I studied pulmonary gas exchange while also working in the OR (partly to earn my keep). Coincidentally at that time, the ABA changed the requirements for entrance into the Oral Exam from two years of clinical training and two years of practice time to three years of clinical training or two years of clinical training and one year of research. Taking into account the time required for completion of the application process, I was eligible to take the Oral Exam in the Spring of 1967.

I was a Fulbright scholar, and the scholarship covered travel expenses and allowed me to stay in the country for three years. However, even with extensions, the maximum was 3 years, 3 months and 2 weeks. It was before the era of the jumbo-jet, and international airfares were astronomical, especially for Japanese, because Japan had just begun her economic redevelopment and the currency exchange rate was 360 yen to a dollar (ah, how times have changed!) Had I been forced to return to Japan in 1966 upon completion of residency training, the cost of a return trip to America in 1967 to take the examination would have consumed my annual income.

However, the examination in October 1966 would be held just within the time-limit allowed by the Fulbright committee. In desperation, I wrote to the Board explaining the situation and pleading that I be allowed to sit for the examination for which I was, strictly speaking, not eligible. I thought that my chances were minimal because, after all, I was asking the ABA to break its own rule, but to my delight, the ABA allowed me to sit for the exam in October, cautioning me that I would know the result—success or failure—only after April 1967. I was jubilant. Not only could I take the exam, but the ABA had flexibly applied its rule without breaking its basic position. I learned later that the ABA ruling in my case was not only an expression of fairness, but resulted partly from the amusement of the ABA staff. I think they enjoyed both my letter, and giving me this opportunity. The oral exam held in the Broadmoor Hotel in beautiful Colorado Springs was an anticlimax. Overcoming the hurdles preceding the test gave me confidence that I would pass. In May 1967, I learned the good news. (Coincidentally, Lawrence J. Saidman, one of the editors of this book and later a Director of the ABA also took his Oral Exam in Colorado Springs at the same time and Ted

Eger, also an editor of this book was an examiner at that exam. It is a small world.)

For a few years, I was one of only a few Japanese certified by the ABA. Japanese members were Fellows of the American College of Anesthesiology (FACA). We held regular meetings. I remember attending one where I felt envied because I was both FACA and ABA accredited.

The History of Pulse Oximeters in Japan

Takuo Aoyagi of Nihon-Kohden invented and patented the basic principles of pulse oximetry in 1972. Only a month later, Akio Yamanishi of Minolta and others applied for similar patents but were rejected, because of the prior submission by Aoyagi. Although the latter request from Yamanishi of Minolta was rejected, Minolta did succeed in obtaining the patent internationally, including in the US and Britain, because Aoyagi or Nihon-Kohden failed to apply for international patent protection. Furthermore, while Nihon-Kohden produced only a few test models, Minolta produced a commercially viable version and began selling it. This Minolta model reached both William New at Stanford and the Biox Company in Colorado, and sparked the development of a more practical unit, both in the use of photodiodes and digital technology, including microprocessors. It was the Biox Company (now a part of Ohmeda) that incorporated most of the technical improvements. William New was trained as an anesthesiologist, but after spending a year in the Stanford Business School's Sloan Program, and realizing the usefulness of pulse oximeters in the OR, ICU and other hospital environments, he decided to leave academia and establish Nellcor.

As an aside, there is no evidence that Minolta imitated the Nihon-Kohden device. It appears that they simply pursued a similar idea by a different route. Minolta's initial model used a finger probe rather than the Nihon-Kohden earlobe probe, fixing the subsequent path of development of this instrument.

The Contribution of John Severinghaus

In addition to his great contributions to various fields in anesthesia and medicine, Severinghaus also clarified the history of pulse oximeters. While studying pulse oximeters and the history of blood gas measurement, Severinghaus became interested in who actually invented the pulse oximeter. Realizing that the pulse oximeter was invented in Japan, he consulted Yoshiyuki Honda, Professor of Physiology at Chiba University with whom he had been cooperating in research. Honda traced the discovery back to Aoyagi and supplied this information to Severinghaus. Severinghaus subsequently described the circumstances surrounding the discovery, in the *Journal of Clinical Monitoring*, giving Aoyagi priority as the discoverer of the principle of pulse

oximetry and the inventor of the instrument, a fact not known widely, even inside Japan. Severinghaus subsequently wrote a book on the History of blood gas measurement, further securing Aoyagi's seminal role in this discovery [11–13].

My Regrets and a Little Pride

In 1974 I attended the meeting in Osaka at which Aoyagi made the first public presentation of his work. It was a large meeting with many simultaneous sessions, and I did not attend the particular session at which Aoyagi presented his findings. The abstract had been sitting on my bookshelf, and I only found it many years later.

Sometime in 1976, I first came across the Minolta model of the pulse oximeter, immediately realizing its potential as well as its drawbacks. I then had young Masayuki Suzukawa with me, and asked him to study it. His resulting paper was published in Japanese in 1978 [14]. Mr. Nakamura (first name lost), a professional science writer, translated it into high quality English, but this English version was never submitted to an English language journal, probably because I thought it was after all, only a description of our experiences, and not an original paper. Suzukawa's paper, of which only the abstract was in English, has been quoted many times. Suzukawa was quite young at that time, and it was entirely my responsibility to decide whether and when to submit the paper. I greatly regret that I failed to make a little more effort to submit the English version.

Minolta's pulse oximeter was supplied to us for clinical trials and was the device Suzukawa studied. After successfully applying for funds from the Ministry of Education and Culture of the Japanese Government the following year, I bought a Minolta unit. I was later told that although the Minolta Company successfully patented the pulse oximeter outside Japan, they sold only 100 units or so before making major revisions using a combination of digital technology and optical diodes similar to Nellcor and Biox. I am glad that I had the sense to write about this Minolta instrument in one of my books on blood gases. So I take quiet pride in my early recognition of the instrument's potential [15].

In 1985, the chairman of a major anesthesiology department complained to me that during his sick-leave, his vice-chairman bought and installed pulse oximeter units in every OR in the hospital. This chairman then mentioned that we should not rely on such devices for knowing patient's oxygen levels. I responded, saying, "By taking sick-leave, you have done a great service to your patients and to the department. With the help of pulse oximeters, your patients will be much safer and do much better under anesthesia. Also, your residents will learn more quickly about the dynamics of oxygen during anesthesia." He might have taken this statement of mine as a joke, but I was serious. Indeed, we used a pulse oximeter when we anesthetized the Emperor (see below).

Introduction of Sevoflurane into Clinical Use (See also Chapter 46)

Sevoflurane was independently developed in the US by Ross Terrell at the Ohio Chemical Co, and by Richard Wallen at Baxter-Travenol Laboratories. After studies in the early 1970, both companies stopped further development because of sevoflurane's modest rate of metabolic degradation and its breakdown by soda-lime. The breakdown issue seemed especially important because isoflurane was being studied at about the same time and showed an extremely low degree of metabolism, more than an order of magnitude less than that of sevoflurane.

In 1983, the Maruishi Drug Co. obtained the rights for this agent from Travenol. Because Maruishi did not have an extensive knowledge of any inhalational agent, Kazuyuki Ikeda, Chairman of the Anesthesiology Department of Hamamatsu Medical School was consulted. Ikeda was chosen because he had worked closely with Maruishi on some sterilizing agents to be used in the OR. They concluded that while metabolism of sevoflurane is high, it was not enough to preclude sevoflurane's clinical use. Later Ikeda stated that he was impressed with both the reported low value of the blood-gas partition coefficient and with the ease of anesthetizing animals. He said that the ease of anesthetizing animals was so impressive that he thought, even if it failed as a clinical agent, it would be a superb agent in the laboratory.

Sevoflurane was approved for clinical use in 1990 in Japan, and its acceptance was immediate because of its low blood:gas partition coefficient and its minimal or absent pungency. Both induction and emergence proved to be fast and smooth. Currently, sevoflurane is used for more than 90% of cases of inhalational anesthesia in Japan. It is the only inhalational anesthetic in which Japanese anesthesiologists played a major role in its clinical introduction. Ikeda recently retired and lives happily with his family. Tomiei Kazama, who played an active role during the development of sevoflurane, is now the Professor and Chairman of Anesthesiology of National Defense Medical College.

An English Language Japanese Journal: Journal of Anesthesia

As described above, the first Japanese academic departments were formed around 1952. A Specialty Journal originated at this time. *Masui* or the "Japanese Journal of Anesthesiology" was and is published in Japanese. Although it is indexed, many Japanese anesthesiologists wanted a journal published in English. Towards the end of the 1950s and into the early 1960s, several issues of the *Far-East Journal of Anesthesia* were published in cooperation with American anesthesiologists stationed in Japan. The journal failed to thrive, however.

The Japanese Society of Anesthesiologists prepared for, and finally published an English language journal, the *Journal of Anesthesia*, in 1987. It was published by Koku-seido originally, the same company publishing *Masui*, but its publication was transferred later to Springer. It too, is now included in Medline.

The Emperor's Surgery and its Effect on Anesthesia

Emperor Showa (HIROHITO) headed the Royal family from 1926 to 1989. In the Fall of 1987, at the age of 86 he developed signs of duodenal obstruction and surgery was performed on a semi-emergency basis in a small hospital inside the palace. The hospital was poorly staffed and poorly equipped, and major surgery was performed only a few times a year. Personnel from the University of Tokyo, including surgeons, two anesthesiologists (including me), and nurses were asked to participate.

Although we were not given the opportunity to see the patient before the planned surgery, we were allowed to check the OR and its equipment. An old anesthesia machine was available. It could only deliver nitrous oxide, oxygen, and halothane but appeared to function satisfactorily. The monitoring equipment consisted of a few manual blood pressure instruments. We asked the hospital personnel to obtain at least one EKG monitor. Originally they asked if it might be possible to use a regular paper-recording EKG instrument instead. We said "No" and they said "OK, we will get one. The Ministry of Finance won't be happy if we simply ask for a new instrument, but they would be willing to get one for the Emperor." We thought they were kidding, but they were serious.

The Word "Epidural" Becomes Famous

The emperor was in poor health, suffering from cardiac and kidney disease. Nevertheless, he tolerated 2 hours of surgery fairly well, including a gastro-jejunostomy. Anesthesia consisted of a combined epidural and general (halothane and nitrous oxide) anesthetic. We used a pulse oximeter and monitored CVP postoperatively.

One newspaper ran a headline "The Emperor had surgery done under general anesthesia". We immediately informed the journalists that it was not simply general anesthesia but was combined with epidural anesthesia. However the term "epidural" was not familiar and we had to explain it in detail—first to them, then to the public. Interestingly, this resulted in a fee increase in health insurance. Before this surgery, the fee was the same whether general anesthesia was given alone, or combined with an epidural. After the event, insurance regulators agreed that the reimbursement for combined general-epidural should be increased.

Although we had not intended it, this event turned out to be a great advertisement to the general public, about anesthesia and the role of the anesthesiologist. Few knew that specialists gave anesthesia, and the Emperor's surgery changed things dramatically. Patients now knew the word "epidural", and we anesthesiologists had no difficulty explaining its usefulness to our patients during the routine preoperative visit. In fact, our patients often asked to receive the anesthesia given to the Emperor. Several anesthesiologists, including me, wrote books for the general public explaining what anesthesia was, and the Japanese public now is far more aware of anesthesia and anesthesiologists than they had been prior to the "Emperor's anesthetic".

Similar transformations occurred in surgery. Previously, surgeons had difficulty persuading elderly patients to undergo surgery, simply because they thought they were too old. The fact that the old Emperor benefited from surgery done at 86, made elderly patients considerably less hesitant to have surgery.

The transfer of a pulse oximeter from the hospital to the palace provided an additional unintended consequence of "the surgery". At that time, we had only four units for our 14 operating theaters. After the surgery, the journalists wanted to know everything we had done to this patient. I mentioned the pulse oximeter after which I was asked to write an article describing the device for the newspaper's readers. This was probably the first time a pulse oximeter became known to the general public beyond the medical environment. I was quite aware of the possibility that such an article would help practicing anesthesiologists when asking their hospital administration to buy pulse oximeters for their operating rooms. Though not immediately, we obtained a good number of pulse oximeters for the entire OR suite. We also explained the use of pH and blood gases (the samples were taken to the University hospital and analyzed there), and the incentive spirometer for resolving atelectasis, each of which received considerable newspaper coverage. In the early 1990, JSA set the standards for monitoring in anesthesia, which included the use of pulse oximeters, but this was probably related to the standards already established in other countries, rather than the use of a pulse oximeter in caring for the Emperor.

In retrospect however, we made one mistake that fortunately did not cause any adverse outcome. The surgery was performed in a small, little-used hospital. Although these circumstances were for the most part out of our control, we were fortunate that nothing untoward resulted. Some fifteen years later, when the current Emperor (succeeding Showa Emperor) suffered from prostate disease, surgery was done in a University Hospital, a more logical and sensible solution.

The PC and the Software Contest Impacts Japanese Anesthesiology

Computer programming appeals to many Japanese including anesthesiologists. Indeed, Japanese found programming attractive before the PC appeared. The number of Japanese engaged in programming increased considerably when the PC was introduced. At the time of the introduction of the PC, commercially available software applications were expensive and of poor quality.

A group of anesthesiologists in JSA set up what we called a Software Contest within the JSA. Contestants presented their products to compete for the prize. If they won the prize, they were asked to make their product free to all. Usually, some 15 to 20 software applications were submitted annually, including some from foreign countries. This contest continued annually for fifteen years before being absorbed into the general session of the JSA [16].

One example coming from the contest was Hiroshi Hagihira's BSA (bispectral analyzer). When the BIS monitor appeared on the market, we wanted to know what and how it analyzed the EEG. Understandably, the Aspect Company (recently bought by Covidian) did not disclose the details of this proprietary analysis. But someone with knowledge and capacity should be able to write similar software, and that was what Hagihira did. Before it was reported to a highly cited journal like *Anesthesiology*, it was presented and discussed extensively among local anesthesiologists. Unlike the BIS, Hagihira's BSA was open and the source-code was freely available. Hagihira's software has not totally replaced the BIS, but it has been used in many ways in analyzing the EEG [17].

A Shortage of Anesthesiologists and the Lack of Group Practice

An important problem related to anesthetic practice in Japan, is that except for those anesthesiologists associated with academic institutions, (and who are interested in research and teaching) there are relatively few Japanese physicians practicing only anesthesiology. These academic physicians are paid a more or less fixed salary, and never create a group practice.

Institutions (e.g., medical schools) or hospitals employ nearly all anesthesiologists. Until recently, private practice in anesthesia—whether solo or as a group—was rare. The law does not prohibit private practice, but the insurance system and many other hurdles discourage it. I believe that this situation provides a major explanation for the limited supply of anesthesiologists.

An additional reason for the shortage of anesthesiologists is that the daily surgical schedule is unusually long. Whereas other specialties may manage their workload by controlling activity, anesthesiologists have little control over their workload and the ratio of surgeons to anesthesiologists often exceeds 10 to 1. Surgical patients come to the OR one after another, with too few anesthesiologists trying to cope with the load. As a consequence, anesthesiologists sense that they have failed and resign.

There are exceptions of course. A few anesthesia chiefs negotiate a reasonable ratio of procedures to anesthesiologists, or a hospital administrator wisely realizes the advantage of such a ratio. Then the size of the anesthesiology department may be expanded substantially, and incidentally, the status of the staff may increase. Unfortunately, these more favorable situations are the exception rather than the rule.

Since 2000, there have been several examples in which anesthesiologists, especially those from government institutions, and usually because the work load increased, have resigned as a group. This increased the workload of those remaining, resulting in both longer working hours and occasional “parallel anesthesia”, or one anesthesiologist caring simultaneously for more than one patient at a time. Because these incidents occurred in leading institutions, such as the National Cancer Center Hospital in Tokyo and in the National Cerebral and Cardiovascular Center Hospital in Osaka, forcing a decrease in the number of surgeries, they were widely publicized on television and in the newspapers. However, it is unclear whether society really understood the problem and whether the journalists accurately portrayed the difficulties.

Some institutions solved the problem by increasing the number of positions. In others, group practices finally appeared. Groups successfully negotiated working conditions, including their income, with the hospital. Whether such group practice continues and thrives is difficult to predict.

Concluding Remarks

Japanese medicine has a long and honorable history, but anesthesiology began only after World War II and was largely influenced by those physicians studying in America. Academically, the specialty has been modestly successful,

and its research and training systems are running smoothly. A major problem is the shortage of anesthesiologists resulting from the relatively low prestige of the specialty and the high workload. Group practice is increasing, but whether this will solve the problem is difficult to predict.

Summary

News of anesthesia's discovery came via Great Britain and France, and ether was given by February 1847. Chloroform quickly followed, but its lethality caused a reversion to ether by 1900. During the last half of the nineteenth Century, surgeons directed delivery of anesthesia by nurses and non-medical persons. Operations were few in number, and infections remained the dominant surgical risk. Surgeons introduced local and regional anesthesia after Koller's 1884 demonstration of the anesthetic effects of cocaine.

Until the 1930s, nurse anesthetists, directed by surgeons, continued to provide most anesthesia. Surgeons persuaded a few colleagues like Gordh (Sweden) to pursue a career in anesthesia. Gordh returned home in 1940 after 2 years training in the US. World War II delayed the training of other Nordic pioneers. Swedish scientists synthesized lidocaine, and Gordh clinically tested it in 1943. In 1950, Thesleff, and von Dardel in Sweden studied succinylcholine in patients.

In 1949, the World Health Organization established a one-year anesthetics course in Copenhagen for European and third world countries physicians. The course was repeated 23 times. After 1950, Nordic doctors needed 3 years of anesthesia training to become specialists in anesthesia. Besides the course in Copenhagen, each country developed its own annual postgraduate course.

In 1950–1952, polio epidemics struck Denmark and Sweden, and Ibsen applied long-term ventilation to decrease mortality, leading to the development of intensive care units (ICUs). In December 1952, Bauer opened the first ICU in Sweden, and in 1953 Ibsen did the same in Denmark. In the 1950s, Norwegian toy manufacturer Laerdal developed "Resusci-Anne". He supported Safar's 1961 first-ever meeting on closed chest cardiac massage.

Nordic anesthesia associations were founded in the mid-twentieth century. The first congress took place in Oslo in 1950. In 1957, the Association launched *Acta Anaesthesiologica Scandinavica*, with Eric Nilsson as the first editor.

From the 1960s onwards, Nordic anesthetic practice paralleled that in other developed countries. For example, the Swedish Society of Anesthesiologists increased from 180 members in 1966, to 400 in 1974, and 1400 in 2011. Within a department of anesthesia, teams of anesthesiologists and nurse anesthetists delivered anesthesia. Nordic anesthetists also provided prehospital acute care, intensive and postoperative care, and support for interhospital transportation.

Introduction

Anesthesia is a young Nordic specialty. The first position for an anesthesiologist in Scandinavia and mainland Europe was established in 1940, at the Karolinska Hospital in Stockholm, Sweden. Why did anesthesiology take longer to develop in Nordic countries than in Great Britain (GB) and the United States (US)? Until the 1930s, Nordic medical practice followed that on the European mainland. Nordic students and young doctors traveled to Germany and France to further their education, and anesthesiology in these countries lagged behind that in GB and the US. While European surgeons needed modern anesthesia as much as did their British and American counterparts, they regarded this new 'technology' as another "surgical method" for nurses or technicians. Every young physician wanted to be THE surgeon. Besides, there were no paid hospital jobs for anesthesiologists.

The Early Days

The political geography of Scandinavian countries in 1846 differed from today. Finland was a part of the Russian Empire, albeit with considerable independence. Its cultural bonds were to Sweden of which it had been part for 400 years. Sweden and Norway were united in an unpopular union, created in 1814 after the Napoleonic wars. Norway had its own constitution (created in 1814) and longed for independence. Norway was also the Scandinavian country most closely connected with GB. As part of the large European peninsula, Denmark had always been more influenced by the south. Denmark also ruled Iceland until World War II, and shaped its development.

Health care provided to Nordic inhabitants before 1850 was limited to urban areas. Operative reports indicate that all surgeries were performed without anesthesia or systematic use of analgesics [1]. Operations included treatment of skull fractures, removal of the mandible, gastrotomy, and repair of inguinal hernias and cleft lips.

The Start in Scandinavia

News of ether anesthesia reached Scandinavia in February 1847. Swedish chemist Jöns Jacob Berzelius wrote a letter from France, describing the discovery, a letter read to the Swedish Society of Medicine on 2 February. One month later, Carl Ekströmer, head surgeon at the Karolinska Institute reported satisfactory anesthesia in young healthy colleagues who volunteered to receive ether [2].

The Finn, Carl von Haartman, had a son studying in Paris who heard of ether's effects. He wrote of these to his father who read the letter to the Finnish Medical Association on 13 February [3], leading to the first anesthetics in Finland at the beginning of March.

On 18 February, in Norway, a letter from the young physician Petter Winge describing anesthesia, was read to the Norwegian Medical Society. The first trials of ether anesthesia took place at the national hospital (Rikshospitalet) at the beginning of March [4].

How the news reached Denmark is uncertain, but the first anesthetic was given on 20 February, 1847 [5]. Medical practice in Iceland lagged behind that in Europe, the first hospital opening in 1866. A general practitioner, Jon Finsen, working in the small town of Akureyri on Iceland's north coast, gave the first anesthetic in 1855 [6].

1847–1900; Ether, Chloroform and Complications

As in mainland Europe, Nordic anesthetic practice developed slowly after 1847. Many surgeons, other doctors, and even

lay members of society maintained a continuing skepticism concerning anesthesia. Eventually, the use of ether became accepted throughout Europe, but these European anesthetic experiences were seldom documented and no "champion anesthesiologist" (like John Snow in England) advanced the specialty. Different methods for the administration of ether were 'imported' or invented. A Swedish surgeon, EG Palmgren, designed an apparatus for ether vaporization within one month of the news of the discovery reaching Sweden [7].

Chloroform became popular in Scandinavia, soon after Simpson described its anesthetic properties. In Finland, Carl von Hartmann (the man who reported Morton's discovery), visited Simpson and became an enthusiastic chloroform champion, persuading Finns to use chloroform instead of ether for 4 decades [8]. For a time, chloroform was the most common anesthetic in all Nordic countries, but it gradually decreased in popularity as complications with its use became obvious. After 1880, ether again became the primary anesthetic with chloroform's use eliminated by the beginning of the twentieth century.

Although the incidence of complications related to anesthetics indicated that the work demanded significant professional skill, nurses or technicians provided part-time anesthesia care throughout continental Europe. As noted, part of physician disinterest in anesthesia lay in low pay and status. In addition, there was a shortage of doctors and especially surgeons in all Nordic countries. Denmark, with 1.9 million inhabitants, had only 80 doctors in 1857, and surgery had become a medical specialty only 15 years earlier [9]. The total number of operations remained small for nearly two decades after the introduction of anesthesia. Concern about the risk of postoperative infections and associated morbidity and mortality may have limited surgery. Only when antiseptic, and then, aseptic surgery were introduced, could the surgeon's world expand.

The relationships between anesthetic depth, inadequate ventilation, hypoxia and hypercarbia were poorly appreciated during the first decades after the discovery of anesthesia. Few anesthetists considered the implications of carbon dioxide accumulation, inadequate oxygen transport and cyanosis. Patients might breathe (and even re-breathe) hypoxic mixtures of air and ether or chloroform gas, in inadequate volumes, with partly obstructed airways, without assistance.

Few reports described Nordic anesthesia during the nineteenth century. In Denmark, Berthelsen found 24 anesthesia-related papers published in the decade after 1847 [9]. Most articles discussed techniques, complications, and comparisons distinguishing ether and chloroform. Few dealt with pharmacology and physiology. None considered the question of who should administer anesthetics.

At its first meeting (in Gothenburg), the Scandinavian Society of Surgeons (Nordisk kirurgisk forening) launched

an inter-Nordic anesthetic survey for 1894–1895. In 11,047 open drop chloroform anesthetics, 5 patients died (one death per 2,209 cases), while no deaths occurred in 1,279 ether anesthetics. When chloroform was used only as the induction agent, preceding 2,122 ether anesthetics, no deaths occurred. The greater “chloroform mortality” was consistent with results from Germany, France and Great Britain [10].

Anesthetic Delivery

Technical improvements focused on anesthetic administration. Though open drop anesthesia was preferred, many physicians constructed versions of Morton’s original ‘inhaler’. In Europe, the most common ‘ether inhaler’ became the French Charrière model.

In Denmark, around 1880, surgeon Oskar Wancher introduced a curious and potentially dangerous method for the administration of ether. Wancher’s bag was a rubber bag of unknown volume connected to a breathing mask. The anesthesiologist placed 50 ml of ether into the bag, forming a pool in the bottom of the bag which was then filled with the patient’s exhaled air. The ether evaporated into this air. The decreased oxygen and increased carbon dioxide in the rebreathed gases stimulated ventilation and thereby accelerated induction of anesthesia. “Fresh air” was added by letting the patient occasionally breathe room air [11]. The influential Danish surgeon, Professor Thorkild Rovsing strongly recommended this method in 1901, and it remained in frequent use for 30–40 years! The associated mortality remains unknown.

The use of nitrous oxide is mentioned around 1860. The slow development of nitrous oxide anesthesia is not surprising given the absence of a good method of storage, difficulty in manufacture, absence of an ability to easily add oxygen, and the limited potency of nitrous oxide. In 1894, the Gothenburg dentist Hjalmar Carlsson rediscovered ethyl chloride as a general anesthetic, reporting his accidental observation that ethyl chloride acted as a general anesthetic if used for local anesthesia in the mouth [12]. It became popular for rapidly inducing anesthesia before maintenance of anesthesia with ether.

Norwegian surgeon Jacob Heiberg (1843–1888) became an expert on treating anesthetic-associated complications in the 1870s. When respiration and circulation deteriorated, he taught: “*Throw away your surgical instruments. Stop the operation and open all windows and bathe the patient in masses of cold water* [13].” Heiberg soon realized that airway obstruction (and not warm rooms) was the major cause of complications stemming from inhalational anesthesia. He invented the “jaw thrust” to open the airway, and published this in 1873 [13]. The jaw thrust saved thousands of lives. Five years later, Johan von Esmarch (1823–1908) a German (who introduced the tourniquet), described a similar tech-

nique, for a time known as the Esmarch-Heiberg technique, but later attributed only to von Esmarch [14].

In 1898, Ingjald Reichborn-Kjennerud (1865–1949) published the first comprehensive description of anesthesia practice in Norway: “Anesthesia and local anesthesia” (Narkose og local anesthesi) [15]. In the introduction, he wrote: “The number of general anesthetics is so few that one can’t get much experience with its use. Hence one is at a disadvantage compared to larger towns in Europe, with hundreds of patients to evaluate one’s technique.”

The development of anesthesia as a clinical and scientific specialty, in Sweden before 1900, was similar to that in Norway. Fritjof Lennmalm (a neurologist) described that history in a review presented to the Swedish Society of Medicine in 1908 [16]. Except for mention of the 1847 demonstration of ether anesthesia, Lennmalm found no additional references describing progress in anesthesia before 1908 [16]. He stated that from 1838–1858 “*the great time for the surgeons had not yet come*” and when he summarized the years 1879–1904 he described surgical progress with scarcely a mention of anesthesia. He did note that chloroform was the most commonly used anesthetic.

In the second half of the nineteenth century, Swedish physiologists immobilized experimental animals with curare and gave them artificial ventilation. In Stockholm where only a narrow street separated laboratories and operating theatres, the famous Finnish/Swedish physiologist Robert Tigerstedt (who discovered and named renin in 1898) used this technique [17]. In Uppsala, his colleague Frithjof Holmgren, proposed the use of curare and intermittent positive pressure ventilation (IPPV) in a patient with tetanus, intending to evaluate whether curare had any analgesic effects [18].

The Nordic Medical Society recognized the importance of anesthesia at the end of the nineteenth century. At the 1898 meeting of the Swedish Society of Medicine, John Berg, professor of surgery, gave an honorary lecture entitled “*the start, development and current status of surgical anesthesia*”. His presentation seems to have produced no effect on anesthesia research or clinical development.

Specialization in Anesthesia
