**ABSTRACT:** In this paper, we made an analog computational analysis of the piezometer tube in the sections 0 + 225 of a dam. The results demonstrate that the cause of the abnormality lies in the seepage failure of the core wall, during which time the fluctuation of the water level in the tube reflects the development of seepage failure. Therefore, this research achievement may be used for reference in other projects.

**Keywords:** piezometer tube; abnormality; simulation; cause analysis

## 1 INTRODUCTION

The height of the earth-rock dam with clay core is 324.50 m. The concrete wave wall of the dam is 1.2 m high, 406 m long and 8 m wide, setting up the dam crest. The maximum height of the dam is 49.9 m. In 2013, the piezometer tube in the sections 0 + 225 of a dam raised the water levels abnormally. In this paper, through value simulated computation and abnormality analysis, we provide a theoretical basis for reference in other projects [1–3].

## 2 THE ABNORMAL PROCESS OF THE PIEZOMETER TUBE

On September 25, 2013, the water level of the tube PT2-1 in sections 0 + 225, which was 295.21 m recorded by the auto-measurement, increased to 7.88 m compared with the height of 287.33 m measured artificially on September 5. At this time, the reservoir level basically remained unchanged. After that, the water level of the tube fluctuated around 295.00 m. On October 6, the water level rose to 312.25 m suddenly, i.e., 17.04 m higher than the level on September 25. On October 8, it rose to 313.71 m and then gradually fluctuated in a down-trend. On October 30, it dropped from 306.21 m to 293.70 m suddenly, decreasing by 12.51 m. After October 31, it continued to rise slowly, and it had increased to 303.95 m with fluctuations until January 25, 2014.

Figure 1 shows the stage hydrograph of the tube from September 5, 2013 to January 25, 2014. As shown in the figure, the change in the water level in the tube PT2-1 was extremely abnormal.

Table 1 presents the change in the potential energy of the tube PT2-1's position in some

Figure 1. The stage hydrograph of the tube, from September 5, 2013 to January 25, 2014.

Table 1. Potential energy changes in the position of the tube PT2-1 in some important periods of time.

Date	Upper level (m)	Water level in the tube PT2-1 (m)
September 5, 2013	317.64	287.33
October 9, 2013	317.99	313.31
October 30, 2013	317.90	293.95
December 12, 2013	317.13	300.07
January 24, 2014	316.53	303.79
February 24, 2014	313.60	304.21

important periods of time from September 5, 2013 to February 24, 2014.

From Table 1, it can be seen that the potential energy of the tube's position accounted for only 10.1% in September 2013, which means that the core wall accounted for 89.1% of the head due to the great anti-seepage capability of the core wall. However, early in October, the potential energy of the tube's position at this point rose from 10.1% to 86.3%, indicating that the heart wall accounted for merely 13.7% of the head. In other words, the anti-seepage capability of the core wall upstream was almost lost. In late October, the anti-seepage capability of the core wall was recovered abruptly, undertaking 70.5% of the head, and then gradually declined. In late January 2014, the core wall accounted for 39.1% of the head only. In general, these data suggest that the anti-seepage capability of the core wall becomes increasingly weak with the development of seepage failure as well as the formation of the seepage flow channel.

### 3 ANALOG COMPUTATION OF THE ABNORMAL PIEZOMETER TUBE

Because of the limitation of the calculation theory and method, it is difficult to simulate holes, penetrating cracks upstream and downstream. Considering only the constant destruction of the core wall and the increasing permeability coefficient, back analysis can be carried out based on the coefficient of permeability in every zoned part, which can be compared with geological prospecting achievement for further analysis. Owing to the local failure of the core wall, we should adjust the permeability coefficient of the core wall to ensure that both the first piezometer tube of the dam and the foundation reach the observed value.

In the two cases mentioned above, water head dissipation of the core wall is limited in the upstream side of the piezometer tube, and the head is mainly bore by the core wall behind, the tube together with the inverted filter. If the width of the core wall behind the tube is 4.5 m, the average hydraulic slope would be 6.67 and 4.44. The permissible hydraulic slope for soil destruction of the core wall is 1.28. When the filter protection is taken into account, the permissible hydraulic slope can be increased 2 to 3 times. However, due to the poorly graded soil in the downstream dam shell, the filter material in the second layer or the transition layer cannot be protected. Worse still, once the downstream dam shell cannot protect the fine particles in the second reversed filter, the fine particles will be lost, resulting in weakened protection or even the situation when the second layer cannot protect the first layer of the filter material

Figure 2. The water head of the piezometer tube around the sections 0 + 225 1 (after seepage failure).

Figure 3. The water head of the piezometer tube around the sections 0 + 225 2 (after seepage failure).

effectively. Moreover, it led to the decrease or loss of protection to fine particles in the core wall by the first reversed filter. The fine particles, which should be in the core wall, will pass through the first and second reversed filters to the dam shell. Finally, the function of the filter fails and seepage failure takes place in the core wall [4].

### 4 ANALYSIS OF THE ABNORMAL PIEZOMETER TUBE

Level swelling of the tube in the sections 0 + 225 shows that the anti-seepage function of the core wall had weakened largely in the upstream side of the tube from early September to early October. The sudden drop in the water level in late October may be caused by the situation when the seepage-proofing function of the core wall was partially restored owing to the original seepage channels that were clogged by the collapsing soil. Afterwards, the water level in the tube increased slowly, which demonstrates that the seepage-proofing function of the core wall was impaired gradually. During this time, the fluctuation of the water level shows the process of seepage failure development [5].

According to a comprehensive analysis of the construction and geological exploration material, the existing construction quality of the core wall is too inferior to meet the design requirements; the water filling test in the field proved that the

permeability of the core wall did not fulfill the design requirements; the core material was poorly graded, which lacked intermediate particle size and it was easy to make seepage failure with low construction quality. Since congenital defects of the core wall led to its seepage failure easily, it is crucial to protect the filter in the downstream dam crest. The material of the first and second reversed filters satisfied the requirements of the design as well as the standards, but the sand gravel in the dam shell downstream was poorly graded, which could not prevent the washing away of fine particles from the second reversed filter material (transition layer). Furthermore, it led to the loss of fine particles in the first layer, which resulted in the inefficiency of the filter downstream. Also, under the construction of a local dam shell, size segregation may occur, which will cause the disability of protecting the second reversed filter due to the block concentrating and even the first filter. Finite element simulation analysis also confirmed that seepage failure did take place in the core wall.

## 5 CONCLUSION

In brief, this paper provides an analog computational analysis of the piezometer tube in the sections 0 + 225 of a dam, the results of which show that the occurrence of the permeability channel in the core wall upstream is the cause of the sudden rise in the tube. The reason for a sudden drop in the water level may be attributed to the clogging of the original seepage channels by the collapsing soil, and to the partial restoration of the seepage-proofing function of the core wall.

After that, the water level in the tube rose slowly, indicating that the seepage-proofing function of the core wall decreased gradually. In this process, the fluctuation of the water level shows the development process of seepage failure. Therefore, this achievement may play a referential role in other projects.

**ABSTRACT:** Due to the influence of overexploitation of groundwater, from 1972 to 2003, Baotu spring was dried up. The reason for the failure to successfully protect the spring for about 40 years is that the function of karst water system was not clearly grasped. The evolution trend of the Jinan spring zone resource amount is calculated by the equilibrium method, revealing the inferior degeneration of the function of the karst water system. Recharge locations are determined according to formation, structure, permeability, and water quality. A proper recharge amount (290,000 m<sup>3</sup>/d) is attained by regression analysis. Based on the analysis, a three-dimensional groundwater flow numerical model of the Jinan spring area is established. Optimizing the layout of exploitation wells and the exploitation amount of the Jinan spring area are inverted through the model, including the exploitation of Jixi (in the west of the Jinan spring area) increasing by 110,000 m<sup>3</sup>/d, that of Xijiao (the western suburbs) by 30,000 m<sup>3</sup>/d and that of Dongjiao (the eastern suburbs) by 20,000 m<sup>3</sup>/d. Conjunctive regulation of surface water and groundwater is adopted to restore the function of the groundwater system, being able to achieve flowing constantly of Jinan spring all over the year.

**Keywords:** recharge; optimizing exploitation; numerical simulation; function of resources; karst water; protecting spring

### 1 INTRODUCTION

Groundwater is the main water source of agriculture, industry and urban living, which has an important influence on economical development. The software of numerical simulation (e.g. Visual modflow, GMS, Feflow) plays a significant role in groundwater management. As for research on groundwater numerical simulation, a lot of work such as water flow transport model and solute transport model has been done worldwide, attaining great achievements (Qu, W.J., 2014; Liu, Y.P., 2014; Careghini, A., 2015; Zhao, C.Y., 2005; Xing, L.T., 2007). Research and tests on the study field of groundwater management show that artificial recharge of groundwater is an effective engineering measure to adjust and utilize groundwater resources (Wang, X.J., 2005). Artificial recharge of groundwater can not only lift the groundwater level and reduce land subsidence caused by over-exploitation, but also lift storage water resources to achieve optimized use of groundwater (Zhang, Y., 2014). However, there still exist some disadvantages such as recharge amount and determination of recharge locations.

Groundwater exploitation in Jinan City from 1958 to 2014 experienced three stages, namely the stage of low exploitation (1958–1969), the stage of over-exploitation (1970–2002) and the stage of restrictive exploitation (2003–2014) (Wang, M.M., 2008). During the stage of over exploitation, the spring water level rapidly decreased while spring flux decayed, resulting in the stoppage of Baotu spring flow. In order to realize spring perennial gushing, negative measures of restrictive exploitation of groundwater are taken. The negative measures are that groundwater only accounts for 30% of urban citizen water supply, and the inferior Yellow River water accounts for 70% of urban water supply, while a lot of superior groundwater is not utilized rationally. In order to ensure that the spring flows normally and citizens are able to use superior groundwater, it is very necessary to study optimizing the exploitation of groundwater in Jinan City.

Jinan karst water system not only functions as a resource supply, but also involves in maintaining the ecological environment. Spring cutoff means destruction of the function of keeping the ecological environment, while artificial recharge combining

increasing exploitation is to restore the function of resource supply of the groundwater system.

Therefore, this article attempts to carry out developed and utilized research of superior groundwater based on artificial recharge. Applying the numerical model of visual modflow, the groundwater system of the Jinan spring area is simulated to optimize the layout of exploitation wells and recharge sites.

## 2 GEOLOGICAL BACKGROUND

Jinan City is located in the northern edge of the central Shandong mountainous region. The terrain of south is higher than that of north (Xu, J.X., 2012). From south to north, the main exposed formations are Archean Taishan Group (Art), Cambrian system of Palaeozoic era, Ordovician, Carboniferous and Quaternary strata in the Jinan spring area. The south that the limestone exposes is the main rainfall recharge zone of the spring area. The groundwater flowing to the north is blocked by the northern rock of Yanshanian, forming the karst large spring (Fig. 1) (Xu, J.X., 2012).

## 3 ESTIMATION OF THE NUMERICAL MODEL

### 3.1 Conceptualization of the aquifer

Boundary delineation of the model is based on hydrogeological conditions and structure, as shown in Figure 1. The boundary of the west is the Mashan fracture, and that of the east is the Dongwu fracture. The boundaries of the north are Jinan rock and formation of Carboniferous-Permian system, the south is the surface dividing line of Zhangxia and Xuzhuang group of middle Cambrian.

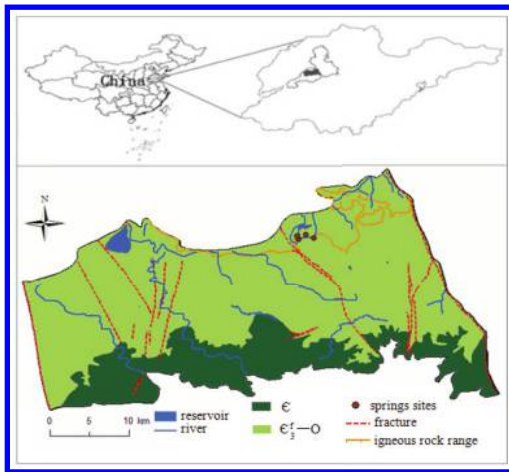

Figure 1. Geological scheme of the Jinan spring area.

Simulation area is conceptualized for three layers. The first layer that is unconfined water aquifer is mainly the formation of Holocene series and the upper Pleistocene series of the Quaternary system. Lithology of the aquifer is the formation containing medium-coarse sand and sand gravel rock. The second layer that is leaky formation is the clay layer beneath the bottom floor of the unconfined water aquifer. The third layer that is confined aquifer is the formation of the Zhangxia and Fengshan group of Cambrian and Quaternary strata. According to drill data, limestone is buried deeply. The depth of the model is about 600 m according to developed and utilized depth of karst water as well as development depth of karst.

According to the hydrogeological prospecting data of Jinan spring area, limestone layer mainly develops eroding fissure of network. Thus, fissure-karst aquifer medium is conceptualized for an anisotropic heterogeneous unsteady flow. In a word, fissure-karst aquifer system can be conceptualized for a confined three-dimensional unsteady flow of inhomogeneity and anisotropy.

### 3.2 Mathematical model building and discretization

The groundwater flow system is described by partial differential equations as follows on the condition that the elastic yield of aquitard is not considered (Xing, L.T., 2007).

$$\begin{cases} S \frac{\partial h}{\partial t} = \frac{\partial}{\partial x} \left( K_x \frac{\partial h}{\partial x} \right) + \frac{\partial}{\partial y} \left( K_y \frac{\partial h}{\partial y} \right) \\ \quad + \frac{\partial}{\partial z} \left( K_z \frac{\partial h}{\partial z} \right) + \varepsilon & x, y, z \in \Omega, t \geq 0 \quad (1) \\ h(x, y, z, t)|_{t=0} = h_0 & x, y, z \in \Omega, t \geq 0 \quad (2) \\ K_n \frac{\partial h}{\partial n} \Big|_{\Gamma_1} = q(x, y, t) & x, y, z \in \Gamma_1, t \geq 0 \quad (3) \\ K_n \frac{\partial h}{\partial n} - \frac{h - h_s}{\sigma} \Big|_{\Gamma_2} = 0 & x, y, z \in \Gamma_2, t \geq 0 \quad (4) \end{cases}$$

In the formula, the symbol is omitted.

Jinan spring area is subdivided into 6,800 cells, with each cell being square of 500 m × 500 m. Moreover, the number of cells of the simulation area is 3382, with the total area being 845.5 km<sup>2</sup> (Fig. 2).

### 3.3 Identification and calibration of the model

Identification period of model designation is from October 1, 2010 to September 30, 2011. The model

Figure 2. The graph of the grid subdivision.

Figure 3. The distribution of observation points.

Figure 4. The simulating flow field of the identification period.

Figure 5. Simulating curves of the water level of the identification period.

conditions of flow field at the end of the simulating identification period. The total flow directions of the simulating flow field and the actual flow field are equivalent. The calculation of the hydraulic gradient is close to the real hydraulic gradient, and the simulating effect is great.

The matching flow yield (Fig. 6) and the duration curve (Fig. 7) of the calibration period are shown as follows.

The simulating flow field and the actual flow field are basically fit, with the total flow direction being equivalent (Fig. 6). The simulating model is fundamentally up to the precision requirement, meeting hydrogeological conditions, and basically reflects the hydraulic features of groundwater.

### 3.4 Reliability analysis of the model

#### 1. Analysis of matching error

Node error statistical table during the stage of model calibration is attained by comparing relative error of the actual and simulating water levels (Table 1).

Actual flow field and calculated flow field during the stage of identification and calibration are rather similar, with error being within the allowable range.

Figure 6. Matching flow field of the calibration period.

Figure 7. Matching curves of the water level of the calibration period.

calibration period is from October 1, 2011 to September 30, 2014. Figure 3 shows the locations of simulating observation holes.

The simulating flow yield (Fig. 4) and the duration curve (Fig. 5) of the identification period are shown as follows.

Simulating flow field basically reflects the trend and regulation of groundwater flowing from

Table 1. Statistical table of node error during the testing stage.

Error range	<2.0 m	2.0~5.0 m	>5.0 m
Node number	79	28	13
Ratio	65.83%	23.33%	10.83%

Furthermore, the trend of simulation water level and measured water table is relatively close. Therefore, it is regarded that the identification model and the actual hydrogeological model are basically fit.

## 2. Parameter evaluation

The model parameter value of the total calculation area is basically fit for data of single well pumping test. According to regional hydrogeological conditions and water abundance of aquifer, the simulation area is subdivided and the parameter is inverted by the calculation of the model. The inverted result is close to the result of the pumping test, the difference being about an order of magnitude. The hydrogeological parameter and subarea gained by the model inversion meet the actual hydrogeological conditions. The estimated model that the reliability is great can be used for prediction.

## 4 FEASIBILITY ANALYSIS OF RECHARGE

### 4.1 Necessity of recharge

The area of building region in Jinan City increased constantly from 1978 to 2012. The utilization of land makes roads harden, directly resulting in the decrease of the rainfall seepage recharge amount, the sedimentation of river, the recession of permeability of the riverbed as well as the reduction of the seepage amount of the river. Expansion of the city and hardness of the land surface is one of the factors that cause the decrease in the spring recharge amount.

According to the comparison and analysis of the calculation result (Table 2), the recharge resource amount decreased by 250,000 m<sup>3</sup>/d from 1960s to current year.

### 4.2 Groundwater transport conditions

According to the tracer test (Fig. 8), groundwater flow field and drilling data, it is concluded that groundwater hydrodynamic field characteristics of the Jinan karst water system mainly have four points. (1) The apparent groundwater velocity is different because fractured karst development is heterogeneity, the degree of karst development differs from different lithologies and different tectonic positions. (2) Groundwater storage space is very large because the location of high karst

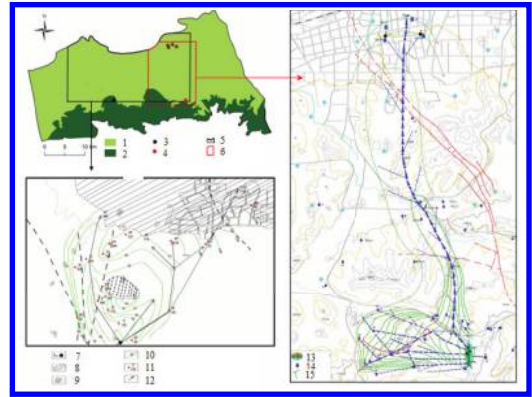

Figure 8. Time contour of the tracer spread to the peak and tracer migration path 1. C; 2. C<sub>3</sub>-O; 3&7. tracer release site (Cuima); 4&13. tracer release site (Quanlu); 5. tracer test range of Cuima; 6. tracer test range of Quanlu; 8. igneous rock range; 9. stagnant water area; 11&14. observation wells; 10&15. time contour of tracer spread to the peak; 12. the main direction of groundwater transport.

development is mainly the confluence discharge area, and karst development shape is given priority to honeycomb, reticular and holes. (3) Along the tectonic fracture zone and influence zone of fracture fissure, a good migration pathway of groundwater is formed, in which the apparent groundwater velocity is fast and the structural belt is the ideal source location. (4) Tectonic fracture zone is with good hydraulic conductivity, resulting in a good hydraulic connection between the Zhangxia group and Ordovician limestone, and recharging groundwater in Zhangxia limestone has an effect on spring protection.

### 4.3 Determination of recharge amount

The monthly variation of the water level was selected to be studied from 2008 to 2012. Monthly rainfall ( $x$ ) is represented as the horizontal coordinate and monthly variation of water level ( $y$ ) as the vertical coordinate. A scatter diagram is shown in Figure 9. It is not difficult to find a linear relation between them. The trend line is matched to show their relations. The corresponding equation is given as follows:

$$y = 0.0038x - 0.1411 \quad (5)$$

The multiple correlation coefficient ( $R^2$ ) is 0.6865.

Linear relation shows that a certain amount of rainfall can cause a certain amount of increase in the groundwater level. There is a rainfall threshold value causing the rise in the groundwater level.

Table 2. Chart of the recharge resource amount unit: 10,000 m<sup>3</sup>/d.

Stage	1960s	1970s	1980s	Current year
Resource amount	69.49	66.77	55.88	44.24

Figure 9. The correlation between variation of spring water level and rainfall in the monthly scale.

The intersection point of the linear equation and the x axis is 37.13 mm, which is the rainfall threshold value under the monthly scale. If monthly rainfall in the dry season is less than 37.13 mm, recharge needs to be done to keep the spring water steady. The 37.13 mm rainfall is converted into the recharge amount of groundwater, which is 290,000 m<sup>3</sup>/d. In other words, it is necessary to carry out groundwater recharge in order to keep the spring water table steady, and the recharge amount is 290,000 m<sup>3</sup>/d.

The 37.13 mm rainfall, which is a threshold value under the monthly scale, is different from the threshold value of the water level increase caused by single rainfall.

There are Yellow River water, Yangtze River water and local storm water in Jinan. The available water sources of recharge are relatively abundant.

#### 4.4 Determination of recharge location

Integration of strata, structure, permeability and recharge sources, main recharge locations are shown in Figure 11. Making full use of natural conditions, groundwater can be recharged by infiltration ditch and seepage of river.

### 5 RESTORATION OF THE KARST WATER SYSTEM

According to the case concerning groundwater being restrictively exploited in the spring region, adopting the condition of present artificial recharge (100,000 m<sup>3</sup>/d), acting measured rainfall as natural recharge, the predicting result shows that the water level in the annual low water season is less than the yellow warning water level of Baotu spring, which is 28.15 m. Furthermore, the water level in the dry season will be less than the orange warning water table, which is 27.6 m in the dry year when the frequency of rainfall is rather low (Fig. 10).

The principle reason is attributed to the decrease in the recharge area of rainfall infiltration, resulting in the reduction of rainfall recharge of groundwater. Thus, it is tough for the spring water level to be recovered at the historical level. If groundwater

⑧Zhongjing	0.8
⑨Mengjia	1

Figure 11. The graph of location of multiple recharge and exploitation.

exploitation is increased, it is inevitable for the spring to stop flowing in the dry season.

Given that the recharge amount is 290,000 m<sup>3</sup>/d that is attained by combining the above research, the permeability of recharge location, the recharge amount of designation (Table 3) and recharge locations (Fig. 11) are added to the model. Besides, the exploitation is increased in the spring area through the model to adjust, and the yellow warning water

Table 4. The optimizing exploitation amount ( $10^4$  m<sup>3</sup>/d).

Location	ⒶJixi	ⓔXijiao	ⓒDongjiao
Exploitation amount	12	3	2

level that is 28.15 m of urban spring serves as the controlling variable (warning water level is set by the department of protecting spring based on the elevation of spring vent by 26.9 m). Through repeated adjustment, the forecasting graph (Fig. 10) of the spring water level is gained finally, being able to ensure that the spring flows throughout the year, and the optimized schemes of exploitation is obtained, as shown in Figure 11 and Table 4.

## 6 SUMMARY

1. The fundamental reason for the stoppage of Jinan spring flow is the degradation of resource supply function of the karst water system under the anthropogenic influence. It is necessary to carry out artificial recharge in order to recover the spring's water level.
2. Spring water dynamic is the real-time appearance of profit and loss of the karst water system in the Jinan spring region. Regression analysis shows that keeping spring flowing under current conditions needs to increase the recharge amount to 290,000 m<sup>3</sup>/d.
3. Optimizing the calculation of the numerical simulation implies that by carrying out scientific artificial recharge, the exploitation amount in the spring area can be increased by 170,000 m<sup>3</sup>/d, which can protect the spring and water supply, and recover the natural functions of the karst water system.

# Stability analysis of the cracks of the concrete gravity dam due to the explosion damage

C.D. Liu

*Nanjing Hydraulic Research Institute, Nanjing, China*

Z.J. Wang

*Changjiang Institute of Survey, Planning, Design, and Research, Wuhan, China*

Y. Xiang

*Nanjing Hydraulic Research Institute, Nanjing, China*

**ABSTRACT:** Many cracks appeared on the upstream face of Huangwo concrete gravity dam built in 1939 due to bomb explosion during the War in 1945. The cracks are not only harmful to the suitability and durability of the dam body, but also cause damage to the dam because of the unstable extension of the cracks. To determine the stability of the cracks on the upstream face of the dam, the theory of liner elastic fracture mechanics is applied to analyze the cracks. The result shows that the stress intensity factors of the crack tips are smaller than the fracture toughness of the concrete, indicating that the cracks remain stable. However, the monitoring of the cracks should be strengthened, and the treatment should be taken if the propagation of cracks is observed.

**Keywords:** concrete gravity dam; crack; explosion; stability; analysis

## 1 INTRODUCTION

Huangwo Reservoir was designed and constructed in China in 1939. This reservoir project consists of main dam, auxiliary dam, spillway and water duct. The main dam of the reservoir is gravel concrete

gravity dam. Dam upstream face is vertical above the elevation of 198.70 m, and it has a slope of 1:0.06 below that elevation. The downstream main dam slope is designed as step type with a slope of 1:0.7, and the main dam crest width is 5.0 m. The auxiliary dam is also designed as gravel concrete

Figure 1. Typical cross-sectional view of the main dam.

Figure 2. Typical cross-sectional view of the auxiliary dam.

gravity dam with a vertical upstream face and a slope of 1:0.75 for downstream face. The capacity of the reservoir is  $33.6 \times 10^4 \text{ m}^3$  and the dam crest elevation is 206.80 m. The maximum reservoir dam height is 28.21 m, and the cross-sectional views of the main dam and the auxiliary dam are shown in Figure 1 and Figure 2.

## 2 ONSITE OBSERVATION OF DAM CRACKS

The onsite checking was conducted on April 20, 2013, and it was found that cracks appeared on the upstream face of the dam. The cracks were mainly generated between concrete blocks and on the surface of concrete. In addition, the pitch part in the dam joints was aging. The locations of the cracks are presented in Table 1, and their distribution is shown in Figure 3. According to the introduction of administration staff of the reservoir, the dam cracks on the right bank was caused by the bomb blast in the reservoir area in 1945. The existing cracks not only are harmful to the safety, applicability and durability of the structure, but also induce structure destruction due to the unstable propagation of cracks. The computation and analysis are applied to the dam cracks based on the linear elastic fracture mechanics theory in this study, in order to understand the stability of cracks on the upstream face of the dam.

Table 1. Locations of the cracks on the upstream face of the dam.

Locations	Characteristics of cracks
Joint between the main dam and the auxiliary dam	1 crack at dam crest, with a length of about 1 m and a width of 2–5 mm 1 crack from dam crest downwards 2.2 m, inclined, with a length of 4 m and a width of 2–10 mm
Right of main dam	2 cracks on dam body, vertical, 2.3 m and 6.4 m away from the right of the main dam, with a width of 2–3 mm
Auxiliary dam	1 crack on dam body, vertical, 11 m away from the left of the auxiliary dam, with a width of 2–3 mm

Figure 3. Distribution of cracks on the upstream face of the dam.

## 3 THEORY OF COMPUTATION

The purpose of control and determination of crack stability of the structure is to attain the Stress Intensity Factor (SIF) at crack tip under different external factors or influences. The fracture finite element method (Jiang, J.J. & Lu, X.Z. 2005; Jiang, H.D. 1992) adopted in this study is an efficient numerical method to solve the crack stability problem (Motsonelidze, A. et al. 2010; Jin, C. 2005; Das, R. & Cleary, P.W. 2013; Chen, Z.H., et al. 2006; Secchi, S. & Schrefler, B.A. 2012; Chahrour, A.H. & Ohtsu, M. 1994). The computation has two parts: one is to construct the singular element model that reflects the singularity, and to compute the SIF, i.e. stress intensity factor. The other part is to determine the fracture criterion based on the material fracture property, and to determine the stability and develop the pattern of cracks based on the criterion.

Three different basic combinations of fracture mode can be classified: Type I is the opening, Type II is the shearing and Type III is the tearing. The stress and displacement at crack tip can be expressed as follows:

$$\sigma_{ij} = \frac{K}{\sqrt{r}} f_{ij}(\theta), \quad u_i = K \sqrt{r} f_i(\theta) \quad (1)$$

where  $(r, \theta)$  is the polar coordinates with the crack vertex as the origin and  $f_{ij}(\theta)$  and  $f_i(\theta)$  are the decided functions for every type of crack.

The cracks on the upstream face of the reservoir dam can be decided as Type I, the opening crack, based on the onsite observation, and this type of crack is also the most common and dangerous crack.

The accuracy of displacement is usually higher than the stress in the finite element computation. Thus, the analysis was conducted using the stress intensity factor, which was computed from the displacement component in the fracture mechanics theory (Das, R. & Cleary, P.W. 2013). The equations of three-dimensional stress intensity factor derived from Williams' displacement expansion (Jiang, J.J. & Lu, X.Z. 2005) can be expressed as follows:

$$\left. \begin{aligned} K_I &= \lim_{r \rightarrow 0} \left[ \frac{\sqrt{2\pi E}}{4(1-\mu^2)} \cdot \frac{U'_i}{\sqrt{r_i}} \right] \\ K_{II} &= \lim_{r \rightarrow 0} \left[ \frac{\sqrt{2\pi E}}{4(1-\mu^2)} \cdot \frac{V'_i}{\sqrt{r_i}} \right] \\ K_{III} &= \lim_{r \rightarrow 0} \left[ \frac{\sqrt{2\pi E}}{4(1-\mu)} \cdot \frac{W'_i}{\sqrt{r_i}} \right] \end{aligned} \right\} \quad (2)$$

where  $E$  is the modulus of elasticity of the material;  $\mu$  is Poisson's ratio; and  $U'_i, V'_i, W'_i$  are displacements at node  $i$  perpendicular to the crack extended direction,

along the crack shearing direction and along the crack tearing direction respectively.  $r_i$  is defined as the distance between the node  $i$  and the crack tip.

Normally, the above displacements  $\{U', V', W'\}_i^T$  at node  $i$  on crack sides are not the displacements  $\{U, V, W\}_i^T$  in the global coordinates. The local coordinates  $x', y', z'$  at the crack tip can be built up to derive their relationships. The transforming relationships between global coordinates and local coordinates are shown in Figure 4.

$$\begin{Bmatrix} x' \\ y' \\ z' \end{Bmatrix} = \begin{bmatrix} l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \\ l_3 & m_3 & n_3 \end{bmatrix} \begin{Bmatrix} x \\ y \\ z \end{Bmatrix} \quad (3)$$

$$\begin{Bmatrix} U' \\ V' \\ W' \end{Bmatrix} = \begin{bmatrix} l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \\ l_3 & m_3 & n_3 \end{bmatrix} \begin{Bmatrix} U \\ V \\ W \end{Bmatrix} \quad (4)$$

where  $l_j, m_j, n_j$  ( $j = 1, 2, 3$ ) are the angle cosine between  $x, y, z$  and  $x', y', z'$ , respectively.

The extrapolation method (Jiang, H.D. 1992) is adopted to calculate the stress intensity factor based on the complexity of the project. The values at tips  $K_I, K_{II}, K_{III}$  are determined by extrapolating stress intensity at  $n$  nodes, which are not singularity elements on crack sides, and the equations are given in detail as follows:

$$K_I = \frac{\sqrt{2\pi E}}{4n(1-\mu^2)} \left[ \begin{aligned} & \sum_{j=1}^n \frac{U'_j - U'_0}{\sqrt{r_j}} \\ & - \frac{n \sum_{j=1}^n (U'_j - U'_0) \sqrt{r_j} - \sum_{j=1}^n r_j \cdot \sum_{j=1}^n \frac{(U'_j - U'_0)}{\sqrt{r_j}}}{n \sum_{j=1}^n r_j^2 - \left( \sum_{j=1}^n r_j \right)^2} \cdot \sum_{j=1}^n r_j \end{aligned} \right] \quad (5)$$

Figure 4. Transforming relationships between global coordinates and local coordinates.

$$K_{II} = \frac{\sqrt{2\pi E}}{4n(1-\mu^2)} \left[ \begin{aligned} & \sum_{j=1}^n \frac{(V'_j - V'_0)}{\sqrt{r_j}} \\ & - \frac{n \sum_{j=1}^n (V'_j - V'_0) \sqrt{r_j} - \sum_{j=1}^n r_j \cdot \sum_{j=1}^n \frac{(V'_j - V'_0)}{\sqrt{r_j}}}{n \sum_{j=1}^n r_j^2 - \left( \sum_{j=1}^n r_j \right)^2} \cdot \sum_{j=1}^n r_j \end{aligned} \right] \quad (6)$$

$$K_{III} = \frac{\sqrt{2\pi E}}{4n(1+\mu)} \left[ \begin{aligned} & \sum_{j=1}^n \frac{W'_j - W'_0}{\sqrt{r_j}} \\ & - \frac{n \sum_{j=1}^n (W'_j - W'_0) \sqrt{r_j} - \sum_{j=1}^n r_j \cdot \sum_{j=1}^n \frac{(W'_j - W'_0)}{\sqrt{r_j}}}{n \sum_{j=1}^n r_j^2 - \left( \sum_{j=1}^n r_j \right)^2} \cdot \sum_{j=1}^n r_j \end{aligned} \right] \quad (7)$$

where  $U'_0, V'_0, W'_0$  are the displacement components at crack tip in local coordinates, and  $n$  is the chosen extrapolated points.

## 4 STABILITY ANALYSIS OF CRACKS

### 4.1 Finite element model

In order to better understand the causation and stability of crack, the Finite Element Method (FEM) model was established based on the properties and cracks distribution of the reservoir dam. The model satisfies the accuracy requirement of the project. Figure 5 shows the finite element

Figure 5. The FEM model for the joint part of the main dam and the auxiliary dam.

model and Figure 6 shows the local refined finite element model.

The three-dimensional finite element model was constructed for the joint part of the reservoir main dam and auxiliary dam, where many cracks appeared. The computation domain extended to a distance 1.5 times of the dam height from the dam body to both upstream and downstream, and 1 time of dam height towards the dam base. The meshes are generated using isoparametric elements with hexahedral eight nodes, and a serious crack on the joint part of the reservoir main dam and auxiliary dam and a typical crack on the main dam itself were considered in the mesh generation. There are 13,957 elements and 16,616 nodes in total in the finite element model. The nodes in crack were set with 1/4 of crack side interval in order to compute the stress intensity factor at crack tip, and then to determine the crack stability.

#### 4.2 Parameters

The model parameters are listed in Table 2.

Figure 6. Local FEM model.

Table 2. The model parameters.

Material	Specific gravity, $\gamma/\text{kN/m}^3$	Modulus of elasticity, $E/\times 10^{10} \text{ Pa}$	Poisson's ratio, $\nu$
Mass concrete of the dam	24.00	2.00	0.167
Rocks of foundation	22.00	1.00	0.220

#### 4.3 Loadings of operating condition

The normal water level in the reservoir is adopted as the operating condition for computation, which includes the loadings of self-weight of the dam body, the reservoir water pressure and the uplift pressure.

#### 4.4 Crack stability criterion

The stress intensity factor of type  $K_I$  is analyzed because the cracks on the upstream face of the reservoir dam are the opening type cracks. According to the relationships between  $K_I$  and fracture toughness  $K_{IC}$ , the stability criterion of crack can be determined as follows:

$$\begin{aligned} K_I < K_{IC} & \quad \text{No propagating crack} \\ K_I = K_{IC} & \quad \text{Critical crack} \\ K_I > K_{IC} & \quad \text{Propagating crack} \end{aligned} \quad (8)$$

where  $K_{IC}$  is the fracture toughness of crack type I.

$K_{IC}$  is determined through the experiment. However, the equation from the literature (Jiang, H.D. 1992) is adopted in this study due to the lack of fracture experimental data of this dam. The equation is expressed as follows:

$$K_c = 0.28 k f_c \quad (9)$$

where  $f_c$  is the strength of the concrete cube; 0.28 is the coefficient; and  $k$  is adopted as 1.9 for mass concrete based on the influence of concrete dimension.

The fracture toughness  $K_c = 1.33 \text{ MPa} \cdot \text{m}^{1/2}$  can be obtained using Equation (9) for those typical cracks on the main dam and the upstream face of the joint part of the reservoir main dam and auxiliary dam.

#### 4.5 Results and discussion

The normal water level in the reservoir is chosen as the operating condition and the depth of crack is used by the estimated value. Since the cracks on the upstream face of the reservoir dam are opening type, the stress intensity factors of two typical cracks (one at the joint part of the main dam and the auxiliary dam and the other one on the main dam) were calculated under the operating condition. The stress intensity factor of crack at the joint part of the main dam and the auxiliary dam is  $0.467 \text{ MPa} \cdot \text{m}^{1/2}$  and a value of  $0.762 \text{ MPa} \cdot \text{m}^{1/2}$  is for the crack stress intensity factor on the main dam.

Therefore, the stress intensity factors of the two typical crack tips chosen are both smaller than the fracture toughness of mass concrete, with large values of safety coefficient. The cracks on the dam are at a stable state.

## 5 CONCLUSIONS

Cracks on the upstream face of the reservoir concrete gravity dam were caused by the bomb blast when Japanese troops retreated. The cracks were generated due to damage caused by humans, and their unstable propagation would affect the integrated dam safety system. The computation results based on the linear elastic fracture mechanics theory in this study show that the stress intensity factors at typical crack tips are smaller than the concrete fracture toughness with large values of safety coefficient, which indicates that those cracks on the dam are at a stable state. However, monitoring for the cracks is still suggested and the treatment must be done quickly if there is an observed propagation of cracks.

**ABSTRACT:** The rational development of shallow underground brackish water for agricultural irrigation can not only solve the problem of water shortage, but also descend the underground water level to reduce the soil secondary salinization hazards. In this paper, we select the Yellow River Delta as the study area, where freshwater is in short supply, groundwater is shallow, and the soil water and salt movement are active. In order to investigate the most applicable irrigation schedule with saline water (2–5g/L) for winter wheat in the area, a validated Finite Element Subsurface FLOW System (FEFLOW) model was used to evaluate the effect of various brackish water irrigation modes on soil moisture, salt balance, crop growth and groundwater table. The simulated results indicated that the optimal irrigation schedule of winter wheat was that: 1) the key time of irrigation was needed with enough saline water; 2) two times of irrigation were needed with saline water mixed with freshwater; 3) three or four times of irrigation were needed with alternate of saline water and freshwater. This paper can provide a scientific basis for reasonable exploitation and sustainable utilization for agricultural water and soil resources in the Yellow River Delta.

**Keywords:** FEFLOW; brackish water; irrigation system; soil salinity; Yellow River Delta

## 1 INTRODUCTION

The development of poor quality water (brackish water and alkaline water) for irrigation has become an important method to solve the shortage of agricultural water resources. In the Yellow River Delta, which belongs to the warm temperate semi-humid continental monsoon climate zone, the Yellow River water is the main water resources in the area, accounting for more than 90%, and the agriculture mainly depends on irrigation from the Yellow River. In recent years, the Yellow River water has decreased, and the agricultural irrigation water is facing severe challenges. According to statistics, the brackish groundwater resources are rich in the area, and the groundwater is shallow, and also easily exploited<sup>[1]</sup>. Therefore, the development of poor quality water for irrigation has become an important method to solve the shortage of agricultural water resources in this area.

In the late 1970s, the FEFLOW (Finite element subsurface FLOW system) software based on the finite element method was exploited by WASY water resources planning and Research Institute in Germany. The software can be used to simulate in a porous medium saturated and unsaturated

groundwater flow and contaminant transport, which is also widely used in groundwater environment numerical simulation, groundwater evaluation and management<sup>[2–6]</sup>. However, the FEFLOW model was used to simulate the dynamics of the groundwater table and soil salinity migration under different irrigation modes, and the simulation of irrigation management was less. In this paper, we select the Yellow River Delta as the study area, where freshwater is in short supply, groundwater is shallow, and the soil water and salt movement are active. Based on the FEFLOW software, the simulation model of water flow and solute transport numerical of Wuqi irrigation district was established. Moreover, the model was applied to simulate the brackish water irrigation scheme of winter wheat, which is helpful to establish the appropriate brackish water irrigation mode for winter wheat in the Yellow River Delta.

## 2 MATERIALS AND METHODS

### 2.1 Overview of the study area

The Wuqi irrigation district is located in the north-east of Kenli, Dongying city, Shandong province, east longitude 118°38'–118°57', north latitude

37°40′~37°43′, the Yellow River as the boundary in west, north, south, and the east to the moisture-proof dam. Climate change of the seasons is obvious, and rainfall mainly concentrated in July and August, accounting for 70% of the year. The average annual evaporation precipitation ratio is as high as 3.22. The coastal saline fluvo aquic soil is the main type of soil type in this area. The groundwater is shallow, mostly between 1.4 and 2.4m, and the average salinity is up to 32.4 g/L, thus the seasonal change in the groundwater depth and salinity is significant.

## 2.2 Field sample collection and analysis

The continuous block of a relatively flat terrain (about 4.1km long, 1.1 to 1.6 km width, about 520 hm<sup>2</sup>) was selected as the study area, and we selected three samples from the center of the study area, and each point was stratified sampling of 0~20 cm, 20~40 cm, and 40~60 cm, 60~80 cm. The time is mid-July, late October in 2011, and mid-January, mid-May, late September in 2013, when the soil moisture and salt movement are active, also the variation of the groundwater table is obvious.

Soil samples were sieved through a 2mm sieve after air-drying, and mixed with water at a 1:5 ratio, followed by sucking filtration and leaching extraction of soil solution. The measurement of the soil samples including the cation Ca<sup>2+</sup>, Mg<sup>2+</sup>, Na<sup>+</sup>, K<sup>+</sup>, the anion HCO<sub>3</sub><sup>-</sup>, CO<sub>3</sub><sup>2-</sup>, SO<sub>4</sub><sup>2-</sup>, Cl<sup>-</sup>, total salt content, conductivity and pH was made. Among them, the pH value was measured by PHSJ-5, conductivity by the conductivity meter DDS-307, CO<sub>3</sub><sup>2-</sup> and HCO<sub>3</sub><sup>-</sup> by double indicator titration, Cl<sup>-</sup> by AgNO<sub>3</sub> titrimetry, SO<sub>4</sub><sup>2-</sup> by EDTA Indirect Titration, Ca<sup>2+</sup> and Mg<sup>2+</sup> by EDTA complexometric titration, and K<sup>+</sup> and Na<sup>+</sup> by the subtraction method.

## 3 ESTABLISHMENT AND VERIFICATION OF THE MODEL

### 3.1 Model establishment

According to the hydrological geological conditions of Wuqi irrigation district, non-confined aquifer can be divided into two layers: one layer of soil for planting; the other layer is saline aquifer. Saline aquifer is set to weak aquifer, and the bottom is waterproof floor. The free water surface of phreatic aquifer was set as the upper boundary, which can accept infiltration recharge, river supplement, and evaporation discharge. Meanwhile, the interception of 5m depth was set as the lower boundary, which is an impermeable boundary. The study area can be generalized as the groundwater flow system of non-steady homogeneous, isotropic horizontal direction. Therefore, FEFLOW

software was applied to the Wuqi irrigation district to conduct the unsaturated and saturated flow numerical simulation in the paper.

### 1. Area partition

The study area was divided into 107052 grids by the automatic triangulation principle of FEFLOW software, also into 73564 grid nodes (Fig. 1). Owing to the study area and land use types being single, besides the observation hole on the network nodes, there were no local features encrypted.

### 2. Stress period

The simulation period of the numerical model from January to December in 2010, a full calendar year, was divided into 12 stress periods, with each stress period corresponding to a month. At each stress period, the balance items, including recharge and discharge input conditions, do not change, with January as the initial flow field of the model, and December as the terminal flow field.

### 3. The model parameters and input items

① Rainfall infiltration replenishment, calculated by the infiltration replenishment coefficient method.

$$R_p = \alpha P_e; P_e = \beta P \quad (1)$$

where  $R_p$  is the quantity of rainfall infiltration replenishment, mm;  $P_e$  is the effective rainfall, mm;  $\alpha$  is the coefficient of rainfall infiltration replenishment, taken as 0.2;  $\beta$  is the effective utilization coefficient, when the rainfall is less than 5mm,  $\beta$  is 0, when the rainfall is larger than 5mm,  $\beta$  is 0.8; and  $P$  is the rainfall.

② The irrigation infiltration replenishment. Irrigation mainly depends on the Yellow River, and flooding irrigation is the traditional irrigation method. The irrigation time is from March to April when winter wheat is at the reviving stage and jointing stage. Furthermore, autumn irrigation is carried out

Figure 1. Grid partition graph of Wuqi irrigation district.

during harvest to freezing for salt leaching and moisture conservation of soil, usually in mid to late November. Referring to previous research results, the irrigation replenishment coefficient is 0.5.

- ③ Groundwater evapotranspiration is calculated by the groundwater evapotranspiration coefficient method as follows:

$$E = CE_0 \quad (2)$$

where  $E$  is the groundwater evapotranspiration of the quaternary pore aquifer;  $C$  is the groundwater evapotranspiration coefficient and  $E_0$  is the water surface evaporation.

The soil layer of the area is single, so we take the average of various depths as the groundwater evapotranspiration coefficient. It is ignored when the groundwater depth is more than 2.5m. Calculation of the groundwater evapotranspiration coefficient with different groundwater depths and crops cover conditions are presented in Table 1.

- ④ Solute transport parameters

Selecting the total salinity as a typical pollution ion, all inflow boundaries are given concentration values. At the same time, due to low salinity of surface water and groundwater for irrigation, we deal with the net recharge solute concentration in the model. Solute transport parameters include the retardation factor  $R_p$ , the decay coefficient  $\lambda$  and the hydrodynamic dispersion coefficient  $D$ . The simulation object is salt, which is composed of chemical group that can easily migrate and has no porous medium solid phase adsorption, so  $R_p$  is 1 in the model, and there is no attenuation in the salt migration process, so

$\lambda$  is 0, and the mechanical dispersion is much smaller than the mechanical dispersion, so  $D$  can be ignored.

- ⑤ Aquifer characteristic parameters

In the model, the aquifer characteristic parameters include the permeability coefficient and the specific yield, which referred to the existed pumping test parameters in the Yellow River irrigation district.

### 3.2 Model verification

- 1. The simulation of groundwater table

In order to identify the hydrogeological conditions, adjustment is made for the hydrogeological parameters, supply and drainage items, and fitting the groundwater dynamic process. The supplements of the model are rainfall and irrigation infiltration replenishment, while groundwater evapotranspiration and drainage are the major discharge parameters. We select the groundwater table dynamic process from January to December 2010 as the simulation object for the validation of the model (Fig. 2). According to the significance testing of the groundwater table between the simulated value and the observed value, the model has a significant correlation at the level of  $P = 0.05$ ; therefore, the simulation model can fit the hydrogeological conditions of the study area.

Table 1. The statistics of the groundwater evapotranspiration coefficient.

Month	Depth/m					Average
	0.5	1	1.5	2	2.5	
September	0.75	0.59	0.56	0.38	0.21	0.5
October	1.1	0.77	0.53	0.17	0.06	0.53
November	0.66	0.56	0.53	0.42	0.29	0.49
December	0.78	0.59	0.42	0.25	0.2	0.45
January	0.78	0.59	0.42	0.25	0.2	0.45
February	0.78	0.59	0.42	0.25	0.2	0.45
March	0.52	0.42	0.31	0.16	0.11	0.3
April	1.74	1.6	1.07	0.51	0.43	1.07
May	1.86	1.98	1.71	1.1	1.08	1.55
June	0.45	0.45	0.44	0.24	0.3	0.38
July	1.28	1.04	1.02	1.09	0.35	0.96
August	1.28	1.04	1.02	1.09	0.35	0.96

Figure 3. Simulation of soil moisture and soil salt content.

Table 2. Proposed irrigation scheme for winter wheat.

Irrigation scheme	Seeding to wintering	Reviving stage	Jointing to booting	Heading to filling
Scheme 1	Freshwater		Brackish water	
Scheme 2.1	Freshwater		Freshwater	Brackish water
Scheme 2.2	Freshwater		Brackish water	Brackish water
Scheme 3.1	Freshwater	Brackish water	Freshwater	Brackish water
Scheme 3.2	Freshwater	Freshwater	Brackish water	Brackish water

## 2. The simulation of solute transport

In the solute model, dynamic terms included irrigation infiltration, rainfall infiltration, salt exclusion, and groundwater evapotranspiration. Owing to the different concentrations of dynamic terms in each period in the area, we took the initial leaching concentration of soil moisture and salt content of 0–80cm measured in July 15, 2011 as the initial term, and the simulation and identification of the solute model in October 30, 2011 (Fig. 3). From the overall perspective, the soil moisture and salt content values of the simulation are consistent with the measured value, and the significance testing shows that the simulated and measured values are significantly correlated at the  $P = 0.01$  level, which suggest that the model is reliable and the parameters are reasonable. So, the model can be used to simulate the water and salt dynamic of long sequence.

## 4 SIMULATION OF BRACKISH WATER IRRIGATION MODE FOR WINTER WHEAT

### 4.1 Proposed irrigation scheme

Generally, there are five technical indices in the formulation of the brackish water irrigation system, respectively: ① the irrigation water salinity is less than 5g/L; ② perfect field drainage engineering; ③ each net irrigation is more than 750m<sup>3</sup>/hm<sup>2</sup>; ④ irrigation frequency is 2 to 3 times; ⑤ irrigation for wheat after the jointing stage. The investigation showed that the existing irrigation mode in Wuqi irrigation district can meet the five technical indices.

According to the existing irrigation system for winter wheat, combined with the freshwater from the Yellow River (salinity is less than 1g/L) and local brackish groundwater (salinity is 2 to 5g/L), three kinds of irrigation scheme were designed (Table 2). Scheme 1 includes seeding to overwintering irrigation water from the Yellow River, turning green to jointing irrigation of local brackish water; scheme 2 includes “two freshwater and one saline water” (seeding to wintering, jointing to heading

Figure 4. Soil salinity simulation under saline water irrigation.

stage irrigation water from the Yellow River, reviving to jointing stage irrigation of local brackish water), “one freshwater and two saline water” (only in seeding to wintering irrigation water of the Yellow River); scheme 3 include “alternative irrigation of freshwater and saline water” and “irrigation of freshwater and saline water, respectively”. In addition to scheme 1, jointing stage irrigation quota is 1200m<sup>3</sup>/hm<sup>2</sup>; the other irrigation quota is 750 m<sup>3</sup>/hm<sup>2</sup>. The solute transport model can simulate and forecast the soil salinity of the brackish water irrigation system, which can help to determine the optimal brackish water irrigation mode in the research area.

### 4.2 Analysis of the simulation results

We took the suitable soil salt content (seedling stage was 0.2%, from the jointing to filling stage was 0.6%) as the reference standard, and the average soil salt content of 0–80cm layer was simulated under different brackish water irrigation modes. As shown in Figure 4, the green line (late May) is the mature period of winter wheat, and the black line (salt content 0.6%) represented the limited soil salt content in the winter wheat growth period. As can be seen, the soil salt content can maintain a suitable growth level in the growth period under the irrigation mode of Scheme 1, Scheme 2.1 and Scheme 3.1. However, in the brackish water irrigation from the wheat jointing to heading stage, as carried out in Scheme 2.2 and Scheme 3.2, the soil salt content exceeded the crop salt tolerance,

which will lead to winter wheat reduction or death. Therefore, it is determined by the winter wheat soil salt tolerance that the three irrigation modes are conducive to winter wheat growth, including one-time irrigation filled with brackish water in the key stage, irrigation of brackish water mixed with freshwater, and alternative irrigation of brackish water and freshwater.

## 5 DISCUSSION AND CONCLUSION

1. Based on the FEFLOW software, the model of water flow and solute transport numerical of Wuqi irrigation district was established, and the model parameters were calibrated and verified by the experimental data of winter wheat in this area. The significance testing showed that the simulated and measured values are significantly correlated, which suggest that the model is reliable and the parameters are reasonable; therefore, the model can be used to simulate the water and salt dynamic of long sequence in the Yellow River Delta.
2. We applied the model to simulate the groundwater table and soil salt content under different brackish water irrigation modes. Three irrigation modes are conducive to winter wheat growth in this area, including one-time irrigation filled with brackish water in key time, irrigation of brackish water mixed with freshwater, and alternative irrigation of brackish water and freshwater.
3. Freshwater can be saved when brackish water is used; however, the soil cannot receive sufficient leaching, and the salt will accumulate in the root layer after several years, which will cause irreversible soil secondary salinization. Therefore, in order to maintain soil fertility, when the brackish water irrigation mode is used after 3 to

5 years, it is necessary to flush the soil by freshwater from the Yellow River.

# Seepage analysis of human earth-rock dam during a flood

C.D. Liu & J.Z. He

Nanjing Hydraulic Research Institute, Nanjing, China

Z.J. Wang

Changjiang Institute of Survey, Planning, Design, and Research, Wuhan, China

**ABSTRACT:** Human Reservoir encountered the design flood of 100 years return period after operating five years on the basis of the dam reinforcement. As a result, the dam operates safely. The seepage field evolution of the dam core wall is investigated through analyzing the observational data of seepage behavior for the earth-rock dam during the flood. The anti-seepage effect of the core wall encountering the flood is evaluated according to the water level of several typical cross sections of the dam. And the seepage behavior for the dam under different loads is analyzed by using finite element numerical computation. The results indicate the seepage behavior of the dam is safe. However, several weak links in the seepage safety control of the dam are pointed out. The research provides guidance for the safety operation and management of such type of reservoir dams during a flood.

**Keywords:** earth-rock dam; flood; seepage; observational data; finite element analysis

## 1 INTRODUCTION

Human Reservoir (Xiang, Y. & Liu, C.D. 2012) locates in the east of Wenling City, China, which is a medium reservoir with multiple utilizations: mainly for water supply, but also for irrigation, hydropower and aquaculture. The design flood of the reservoir is a hundred year return period and the check flood is a thousand year return period. The total reservoir capacity is  $3.453 \times 10^7 \text{ m}^3$ . The reservoir project is consisting of the dam, spillway, drainage culvert, tunnel and power plant. The dam is a loess core dam with a dam crest length of 206.0 m and the maximum height of 20.60 m. The clay core wall crest has an elevation of 23.50 m and the width of 3 m. The width is 5 m at the elevation of 17.50 m and below that elevation, the upstream face of core wall has a slope of 1:2 and the downstream face has a slope of 1:1.5. The rest outside the core wall of the dam is sandy loam.

## 2 THE FLOOD

The reservoir dam after the reinforcement in 2005 has served for many years and met a flood in July, 2010. The water level in reservoir on 15 May, 2010 was 20.66 m and the rain started in reservoir area from 21 July, 2010. The water level reached 19.97 m on 24 July, 2010 while the normal water level was 20.47 m. Heavy rainfall happened on 26 July, 2010

with a precipitation of 255.3 mm on that day. The water level of the reservoir increased dramatically. The water level was 20.90 m at 14:30 on 26 July, 2010 and was 21.30 m at 00:30 on 27 July, 2010. Then the water level was only 0.67 m away from the design flood level (21.97 m). At 02:30 on 27 July, 2010, the water level of the reservoir reached the maximum value 21.41 m and later returned to the normal. At 05:10 on 27 July, 2010 the water level was 21.37 m and then came back to 20.26 m on 28 July, 2010.

## 3 THE OBSERVATIONAL DATA OF SEEPAGE

### 3.1 Dam seepage behavior before the flood

The time series of seepage pressure information before the flood can be seen in [Figure 1](#) and [Figure 2](#).

1. The reservoir water level is the main factor to influence the dam seepage pressure. The seepage pressure increases with a higher reservoir water level and vice versa.
2. From the arrangement of the piezometers, those piezometers set up before the core wall have better correlation with reservoir water level, and they almost change synchronously. For instance, the measured piezometer values in U1-1A, U1-2A and U1-3A, which set at elevation 15.00 m with a spacing of 9.5 m, have high correlation

Figure 1. Time-series of measured pressure at U1-1A, U1-2A and U1-3A in front of diaphragm wall.

Figure 2. Time-series of measured pressure at U3-1B, U3-2B and U3-3B behind diaphragm wall.

Table 1. Variation of reservoir water level during the flood in July 2010.

Item	Time and date	Reservoir water level (m)	Comment
1	14:30, 26 July, 2010	20.90 m	Normal water level: 20.47 m.
2	00:30, 27 July, 2010	21.30 m (0.67 m below the design flood level)	Design flood level with a hundred year return period: 21.97 m.
3	02:30, 27 July, 2010	21.41 m (0.56 m below the design flood level)	Check flood level with a thousand year return period: 22.67 m.
4	05:10, 27 July, 2010	21.37 m (0.60 m below the design flood level)	
5	08:10, 28 July, 2010	20.26 m	

coefficients about 0.90 with the reservoir water level (measurements of pressure in three points can be seen in Fig. 1). However, the values have little variation of those piezometers which set close to the dam downstream, indicates a low correlation with the water level in reservoir. For instance, the measure point U3 has a rough constant value of 8.00 m and U4 has a unchanged value of 5.00 m, they are not related to the reservoir water level, which shows the anti-seepage system works well for the entire dam.

### 3.2 Dam seepage behavior during the flood

The precipitation was 255.3 mm on 26 July 2010, and at 2:30 on 27 July 2010, the reservoir water level reached 21.41 m, which was the highest water level in the history. This changing of water level can be seen in Table 1.

#### 3.2.1 Reservoir water level

#### 3.2.2 Cross section of 0+070.00 m

The variation of measured piezometer values at dam cross section of 0+070.00 m can be read in Table 2.

#### 3.2.3 Cross section of 0+110.00 m

The variation of measured seepage behavior at the cross section of 0+110.00 m can be seen from Table 3.

#### 3.2.4 Cross section of 0+150.00 m

The variation of measured seepage behavior at 0+150.00 m cross section is shown in Table 4.

As can be seen from the variations of seepage behavior inside the core wall (Table 2–Table 4), the reservoir water level increased 0.51 m within two days (26 July 2010 to 27 July 2010) and reached the maximum water level of 21.41 m, which

6	15:50, 27 July 2010	20.44	15.72	8.25	4.54	19.46	6.69
7	16:15, 28 July 2010	19.93	15.71	8.03	4.43	19.01	6.10

was only 0.41 m below the design flood level (21.97 m). The water levels inside the core walls of 0+070.00 m, 0+110.00 m and 0+150.00 m cross sections increased by 0.61 m, 0.04 m and 0.01 m respectively. There was little variation of water level behind the core wall, with a difference smaller

than 0.10 m usually. Under the influence of diaphragm wall in dam (Fig. 3 to Fig. 5), the three piezometer values at U1-1A, U1-2A and U1-3A, which in front of the diaphragm wall, have high values and the values are close to reservoir water level. However, the piezometer readings reduce

Figure 3. The 0+070.00 m cross sectional saturation line during the flood on 27 July, 2010.

Figure 4. The 0+110.00 m cross sectional saturation line during the flood on 27 July, 2010.

Figure 5. The 0+150.00 m cross sectional saturation line during the flood on 27 July, 2010.

a lot after the diaphragm wall. For instance, the remain water heads after diaphragm wall are about 27.49%, 17.46% and 21.45% at dam cross sections of 0+070.00 m, 0+110.00 m and 0+150.00 m. The anti-seepage effect from the diaphragm wall is significant and it works even better in 0+110.00 m cross section than any other cross sections.

#### 4 STABILITY ANALYSIS ON SEEPAGE

##### 4.1 Computation domain and permeability coefficients

The computation domain is chosen at dam cross section 0+110.00 m. The assignments of materials and finite element mesh for the computational domain can be seen in Figure 6.

The inversion algorithm (Xu, H. et al. 2013; Zhang, H.H. 2014;) is used to calculate parameters based on the observed seepage information of Human Reservoir dam. The high values of piezometers at cross section of 0+136.00 m on 27 July 2010 are selected for computation, with the corresponding reservoir water level is 21.41 m. The observed data of osmometers from 0+110.00 m cross section on that day is used as a reference. The measured values of dam piezometers and osmometers are listed in Table 5. The initial permeability coefficients for the dam computational domain are obtained from the geological survey information

and the values of coefficient are listed in Table 6. The computational results and field measurements are compared in Table 5 and the permeability coefficients after the adjustment using inverse calculation are shown in Table 6.

##### 4.2 Numerical simulation for seepage behavior during the flood

The simulated operating condition for the dam seepage behavior during flood is shown as follow. The steady seepage under the design flood level 21.97 m with the corresponding downstream water level.

The finite element model is adopted and shown in Figure 6 and the permeability coefficients obtained using the inverse calculation (shown in Table 6) are applied to the model. Some calculated dam seepage parameters during a flood are listed in Table 7.

As can be seen from the calculated results in Figure 6 and Table 7, the maximum seepage gradients in the different sections of reservoir dam during a flood are all smaller than their allowed values in gradient. The dam will remain safety running without any seepage damage. However, due to the limitation of width in dam core wall with a minimum value of 3.0 m, the anti-seepage effect is limited in high water level and the core wall will not be able to reduce the

Figure 6. Finite element meshes in the computational domain.

Figure 7. The dam seepage equipotential lines from numerical simulation during the flood.

seepage pressure significantly. Furthermore, the permeability coefficient is small in the dam downstream sandy loam, which is not good for draining the seepage water and thus leads to a high value of saturation line in the downstream slope of dam. Last but not least, the bottom

elevation of wave wall constructed using mortar rubbles is higher than the crest elevation of core wall in dam, which means the wave wall have no close contact with the dam anti-seepage system, and this introduces one more potential risk in seepage control.

	0.755	<i>Vertical</i>		

## 5 CONCLUSIONS

The seepage field evolution of Human reservoir dam is investigated through analyzing the observational data of seepage behavior for the earth-rock dam during a flood. And the anti-seepage effect of the core wall encountering the flood is evaluated according to the water level of several typical cross sections of the dam by using finite element numerical computation. The results indicate the seepage behavior of the dam is safe. However, several weak links in the seepage safety control of the dam are pointed out.

**ABSTRACT:** Urban flood disaster in China is becoming a serious problem caused by the rapid urbanization and global climate change. It has aroused widespread attention from all sectors of society. Urban storm water simulation is an important technical support for urban storm water management. In this paper, features, applicability and limitations of calculation methods for runoff generation and flow concentration, and main urban storm water simulation models are introduced and reviewed. Finally, the shortcomings and future challenges in urban storm water simulation research in China are pointed out.

**Keywords:** urban flood disaster; storm water simulation; GIS

## 1 INTRODUCTION

Urbanization is an important sign of development of human society. With the change of global climate and the rapid development of urbanization, a series of significant changes happened in the natural environment, ecosystems and hydrological characteristics of the city area and the nearby area. Thus, there are a series of urban hydrological problems, which are different from natural river basin. These problems can be mainly expressed as follows.

1. The increase of impervious area reduced the regional storage capacity and the precipitation loss resulted by infiltration. All of above let runoff generation happen ahead of time, reduce flow concentration detention storage time, increased the total amount of runoff and heightened the peak flow runoff. Runoff generation was uneven and behaved scary ups and downs along with time. Meanwhile, the speed of flow increased so that the content of suspended matter and pollutant increased.
2. Urban landscape features are complex, all kinds of buildings, streets and squares spread all over the place. The constant changes of urban landscape made the runoff generation and flow concentration mechanism extremely complex. Therefore, the calculation of runoff generation and flow concentration in urban area is more difficult than that in natural river basin.

Urban storm water simulation is an important technical support for urban storm water management. Its stability, accuracy, and efficiency is directly related to the effectiveness of urban flood control and disaster mitigation. In allusion to urban storm flood simulation technology, the paper reviewed the research achievement in recent years and commented on it. The paper set forth the main features, applicability and limitations of various simulation technology and different simulation models. Finally, the paper pointed out the difficulties and challenges China faced in the urban storm water simulation research and looked forward to the development direction of urban storm water simulation.

## 2 CALCULATION OF RUNOFF GENERATION AND FLOW CONCENTRATION

According to long-term observation and research, scholars at home and abroad usually conclude urban runoff generation and flow concentration in three aspects, which include urban storm water runoff generation calculation, land surface flow concentration calculation and drainage system flow concentration calculation. [Table 1](#) shows different aspects of urban storm water calculation.

It is relatively simple to calculate the runoff generation in impervious area. It is about equal to the precipitation minus the preliminary loss of depressions fill hollow, interception by plants

Table 1. Urban storm water runoff generation and concentration calculation methods.

Calculation Methods		Main Characteristics	
Runoff generation calculation	Runoff coefficient method	Calculate runoff generation according to different ground rainfall runoff coefficients.	
	Infiltration formula method	Confirm runoff generation according to infiltration amount calculated by infiltration formula.	
	SCS method	Calculate rainfall-runoff relationship by the coefficient CN which reflect comprehensive feature of basin. Applicable when lack of data.	
	Conceptual rainfall-runoff model	Using conceptual rainfall-runoff relationship to calculate land storm runoff generation and the calculation is complex.	
Surface flow concentration calculation	Rational formula method	Presuming rainfall runoff area increases linearly, runoff coefficient remains constant, only concerns peak flow but not flow duration curve.	
	Area-time method	Calculate regional flow concentration area according to same flow concentration time. Difficult when divide land flow concentration calculation.	
	Hydrological method	Instantaneous unit-line method	Complex calculation which relies on information and has normal result.
		Linear reservoir method	Simple calculation which has low accuracy and can't simulate non-linear process.
		Non-linear reservoir method	Relatively simple method which can simulate non-linear process and has high accuracy.
	Hydrodynamic method	Simulate land flow concentration based on kinematic wave equations. Physical process is clear but calculation is time-consuming.	
Drainage system flow calculation	Hydrological method	Muskingum method	Simple calculation which is applicable when the slope of pipelines and canals is steep or the downstream backwater effect is small.
		Instantaneous unit-line method	Simple calculation but has low accuracy.
		Reservoir adjustment algorithm	Simple calculation and has normal accuracy.
	Hydrodynamic method	Kinematic wave method	Ignore inertia and diffusion item of momentum equation. It is applicable when the slope of pipelines and canals is steep or the downstream backwater effect is small.
		Diffusion wave method	Ignore inertia item of momentum equation.
		Dynamic wave method	High accuracy with large applicable range.

and surface evaporation. Depending on different starting points, there are a lot of methods to calculate runoff generation in flooded area, such as runoff coefficient method, infiltration formula method, SCS method, etc.

Land runoff confluence calculation includes two aspects, hydrological models and hydrodynamic models. Hydrological method is easy to calculate, but the physical mechanism is not clear yet, so that it has great limitation. For instance, the traditional reasoning only concerns on peak flow which can't reflect the process of storm water flow; area-time method is more difficult when we divide the land runoff confluence calculation; unit line method teaches a large dependence of the measured data and is not easy to calculate flow duration curve; linear reservoir method does not consider non-linear characteristics and the result is not reliability;

nonlinear reservoir method has relatively high computational accuracy. Compared with hydrological method, hydrodynamic method can provide more detailed urban storm water surface unsteady flow process. However, hydrodynamics models need more accurate boundary, parameters (roughness, slope, etc.), initial conditions and boundary conditions. Therefore, hydrodynamic method has greater difficulty in practical applications.

Drainage system Runoff convergence calculation includes hydrological method and hydrodynamic method. Hydrological method has many types, such as Muskingum method, unit-line method, reservoir adjustment algorithm, etc. But these methods are simplified methods so that the applicable ranges are limited. Hydrodynamic method includes complete dynamic wave method, diffusion wave method and kinematic wave method. Among these methods,

diffusion wave method and kinematic wave method are simplifications of the Saint-Venant equations on the basis of certain assumptions. We can use corresponding methods according to the specific circumstances in a practical application. For example, we can use kinematic wave method when the slope of pipelines and canals is steep or the downstream backwater effect is small. When it is required to consider a variety of flow patterns coexist, pressure flow, backflow and so on, complete dynamic wave equation can be used.

### 3 URBAN STORM WATER SIMULATION

Study on urban storm water models started earlier overseas. American and European developed

countries began to develop urban storm water model since the sixties of the last century. The purpose is to meet the requirement of urban flood control and drainage, environmental governance and storm water management. There are hundreds of urban storm water models so far. Table 2 shows some wide-used and typical models.

These models are mainly concentrated in urban areas, including both simple conceptual models and complex physical models. They also include statistical analysis models and deterministic models. With the expansion of urban area and significant changes in global climate, urban hydrologic study should not be limited to urban areas. We should consider the interaction and interconnection between urban area and natural area. Therefore, there is still great limitations in the range of the application.

Table 2. Main urban storm water models.

Model	Developer	Calculation method			Main characteristics
		runoff generation	Surface flow concentration	Drainage system flow calculation	
TRRL	TRRL	Rainfall buckle loss method	Area-time method, linear reservoir method	Kinematic wave method	Only concern runoff generation in impervious and the result is lower than normal.
ILLUDAS	Illinois	Rainfall buckle loss method	Area-time method	Kinematic wave method	Modified version of TRRL which is able to concern land runoff in flooded area.
STORM	USACE	Rainfall buckle loss method, SCS	Unit-line method	Hydrological method	Using the aggregative indicator CN relied on some information which is relatively easy to determine to calculate rainfall process.
Wallingford	Wallingford hydraulic Institute	Correct reasoning formula method	Nonlinear reservoir method	Muskingum method, Hydrodynamic method	Divide each hydrological cell into roof, paving and pervious area.
Info Works CS	Wallingford software Ltd	Constant proportion runoff model, Infiltration formula method, SCS	Linear and nonlinear reservoir method, SWMM runoff module calculation	Hydrodynamic method	Various modules and complete functions.
SWMM	EPA	Infiltration formula method, SCS	Nonlinear reservoir method	Hydrodynamic method	Generalize each hydrological cell into flooded area, stagnant impervious area and fluent impervious area.
MIKE-SWMM	DHI	Infiltration formula method, SCS	Nonlinear reservoir method	Hydrodynamic method	Using MIKE 11 to replace EXTRAN in SWMM

#### 4 CONCLUSION AND OUTLOOK

In recent years, it has made considerable progress in the theory and practice of urban storm water models and built a relatively complete model framework and technical solutions. Compared with foreign mature technology, Chinese urban storm water simulation still faces many challenges and difficulties and needs to strengthen the research work in the following areas.

1. Strengthen the research on urban runoff generation and flow concentration mechanism. Through experiments and model simulation, analyzing the rule of urban runoff generation and flow concentration and responding mechanism, especially analyze the influence impervious surface distribution made on runoff generation and flow concentration.
2. Strengthen the research on urban hydrology and hydrodynamic coupling model. Consider the ease and speed of hydrological method with the accuracy of hydrologic method. Through theoretical research, experimental analysis and numerical simulation, establishing a fully functional urban storm water mode to achieve a whole process simulation of two-dimensional coupling, surface groundwater coupling and quantity and quality coupling.

3. Build a distributed database of time and space for storm water information. Establish and perfect urban storm flood monitoring system to achieve all-round, multi-angle monitor.
4. Carry out research on multi-source information coupling technology, approaching quantitative precipitation forecast and data assimilation techniques. Get the integration of GIS spatial analysis and visualization function. Gradually build urban rain flood real-time simulation and forecasting warning scientific decision support system.

# Analysis on the right abutment stability of Gomal Zam Dam against sliding

X.E. Xu & H.Y. Fang

*China Water Resources Beifang Investigation, Design and Research Co. Ltd., Tianjin, China*

**ABSTRACT:** The stability of the right abutment against sliding is one of the critical issues for the Gomal Zam Dam Project due to the existence of Faults F2 and F3. A FEM-LEM approach, which combines the Finite Element Method (FEM) and the traditional Limit Equilibrium Method (LEM), is adopted to assess the abutment stability. First, the deformations and stresses of the dam and its foundation/abutments are calculated using 3-D FE models. Then, the overall stability of the right abutment is assessed using the LEM based on the results of FEM stress computations. Since the FE model may or may not include the concrete replacement works for the faults, the effects of the proposed treatment measures are evaluated.

**Keywords:** curved gravity dam; stability against sliding; FEM-LEM approach; Gomal Zam Dam Project

## 1 INTRODUCTION

The Limit Equilibrium Method (LEM) is still one of the main methods for assessing the sliding stability of dam abutments, and has gained wide popularity in practice. Much experience has been accumulated, and applicable safety assessment criteria have been established. Although LEM is simple, it provides no direct information regarding deformations of the abutments, and the effects of other contributing factors and interaction of the dam and the foundation/abutments could hardly be realistically considered, which can be adequately considered and modeled in FE. Thus, the FEM-LEM approach can make the analysis more applicable to the reality, and the result can be easily understood and adopted.

In the present study, the basic steps for assessing the sliding stability of the right abutment by using the FEM-LEM approach are as follows. ① Define a sliding block/wedge based on the geological conditions in the right abutment. ② Compute stresses in the dam and its abutments by using the FE program ANSYS. It may also include or not include the concrete replacement works in the right abutment depending on the purpose of the analysis. ③ Calculate the factor of safety for sliding of an assumed sliding wedge. ④ Compare the calculated value of the factor of safety for sliding with the required values specified in the relevant code to assess the stability of the assumed sliding wedge and the right abutment.

## 2 GENERAL GEOLOGY

The Gomal Zam Dam was designed to be a curved RCC gravity dam, having a maximum dam height of 133 m. The dam site is located at the west-wing of the short-sleeved fold, where it is carbonatite, sandy and clayey shale of the Jurassic System, showing a monoclinical structure with localized small folds. The general striking of the rock stratum is NW320~350°, and dips southwesterly at an angle of 30~70°. The main geological structures include faults, joints/fissures, beddings and bedding shear zones, among which Faults F2, F3 and F13 on the right bank are of significance to the project.

As shown in [Figure 1](#), Fault F2 generally trends NE55°~70° dipping northwesterly at an angle of 87°, 0.01~1.1 m wide, being filled with mylonite, breccia and clastic rock, brown colored, argillaceous cemented. Fault F3 strikes NE45° dipping northwesterly at an angle of 80°, 0.01~0.6 m wide, being filled with breccia and clastic rock, with horizontal slickenside. Fault F13 generally trends NW320°~345° dipping northeasterly at an angle of 68°, 0.60 m wide, being filled with mylonite, breccia, and clayey material, clayey calcium cemented, with slickenside.

As shown in [Figure 2](#), joints/fissures are well developed in the right abutment, mostly in the pattern of 5 joint sets: ① NW313°/NE∠54°; ② NW285°/NE∠76°; ③ NE42°/SE∠82°; ④ NE40°/NW∠75°; and ⑤ NE66°/SE∠81°. The openness of joints is typically less than 3 mm, mostly filled with rock fragments and calcite coating, some with

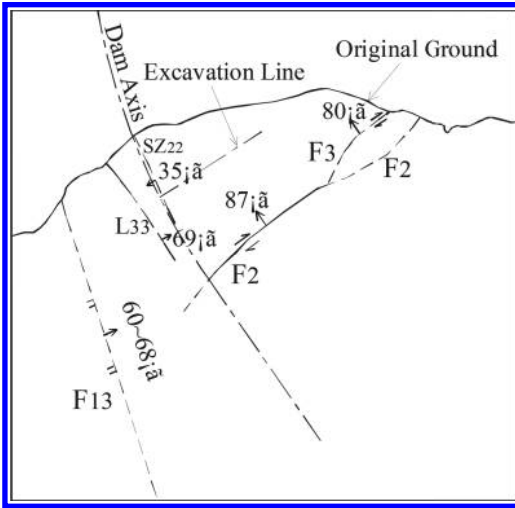

Figure 1. Horizontal section at El.690 m.

Figure 2. Pole diagram of joints.

argillaceous film. A certain number of the joints/fissures dip at an angle of 10–30°, but generally occur in random form and stretch over a short distance as observed in adits and excavation pit.

### 3 FEM MODEL

The Gomal Zam Dam is a curved gravity dam, with a downstream slope of 1:0.6 and a base thickness of 78 m. The dam along the thickness direction is divided into 8 layers of element.

The volume of the foundation included in the FE model to account for the flexibility effects of the foundation rock was selected based on the experience, the geological conditions at the dam site, and the purpose of the analysis. As shown in Figure 3, the foundation range included in the FE model is 195 m wide for the left bank, about 1.5 times of the dam height, and 271 m wide for the right bank, about 2.0 times of dam height. As the sliding stability of the right abutment in the upstream-downstream direction is to be checked, and Fault F13 is located near the dam heel and therefore weakens the restraint of upstream rocks to the right abutment, the model extends for 183 m upstream and 300 m downstream. In the vertical direction, 133 m, 1 time of the dam height, thickness of the rock beneath the dam foundation is included in the FE model.

In the FE model for the computation (Figs. 3 and 4), the geometry of the dam and its foundation/abutments, major zoning of rocks, major faults in the right abutment, such as F2, F3 and F13, and treatment works for the faults are taken into consideration. The origin of the FE grid is located at the bottom center of the central cantilever, its X axis is parallel to the dam axis with the positive direction pointed from the right bank to the left bank, its Y axis is perpendicular to the dam axis with the positive direction pointed from the downstream to the upstream, and its Z axis is vertical with the positive direction pointed upwards. The model is composed of 476828-node solid elements for the dam body and the rocks, 58324-node surface to surface contact elements for the major faults, slip surfaces and the joints between the arch and the concrete thrust blocks.

The bottom face of the model, as shown in Figure 3, is considered to be fixed in the x, y,

Figure 3. FE grid for dam and foundation.

Figure 4. View of the dam and main faults.

and z directions. And all other ends (left/right ends and upstream/downstream ends) are considered to be pinned.

#### 4 SELECTION OF FAILURE WEDGE

##### 4.1 Bottom slip surfaces

As disclosed by geological mapping, the major joint sets and shear zones at the right abutment are of steep angles, and the gentle joints/fissures (dipping at an angle of not larger than 30°) only occur in random form and stretch over a short distance. They are less likely to form potential bottom slip surfaces. Meanwhile, based on the results of the FEM stress computations, the results of the point safety factor method show that the minimum values of the safety factor against sliding at El.690 m and 660 m are less than the specified value. Thus, the horizontal plane cut at El.690 m and 660 m is, respectively, assumed as the bottom slip surface, along which the shear strength is that of the rock mass.

##### 4.2 Lateral slip surfaces

It is found that two steep faults (labeled F2 and F3) and three steep joint sets run sub-parallel to the river flow in the right abutment. As the statistics show, the continuity rate of joints is only about 20%, while the extension of Faults F2 and F3 can intersect downstream river banks to form the exposed or free face. Given the compositions and thickness of faulted zones, indicating that the shear strength of the jointed rock mass is much higher than that of the faults, the potential sliding failure can only occur along the weaker Faults F2 and F3.

#### 5 PHYSICAL AND MECHANICAL PARAMETERS

Physical and mechanical parameters of the concrete, rock masses and faults are listed in Table 1 and Table 2.

#### 6 STABILITY ANALYSIS OF THE RIGHT ABUTMENT

The basic loads are mainly composed of thermal load, dead weight, upstream water pressure, downstream water pressure, wave pressure, sediment pressure, uplift pressure as well as seismic effect. The detailed load combinations are presented in Table 3.

The dam structure is simulated as the elastic structure, while the foundation rock is simulated as the elastic-plastic structure. The ideal elastic-plastic *in situ* structural property is applied for the analysis of the foundation rock. The augmented Lagrangian method is applied as the criteria for the nonlinear stress yield analysis of the major faults in the abutments and joints in the dam.

The finite element program ANSYS is used to compute the deformations and stresses in the dam and its foundation/abutments, and analyze the stability of the right abutment. Based on the results of the FEM stress computations, the Factors of Safety (FS) against sliding for potential failure wedges at natural conditions (i.e. without any replacement works, and the shear strength of the lateral slip surface is selected to be equal to that of the fault) are calculated using the following equation:

$$K = R/S = \frac{\sum N_i f_i + \sum C_i A_i}{\sum T_i} \quad (1)$$

where  $K$  is the factor of safety for sliding of the assumed sliding wedge;  $R$  is the total resistance force acting on the assumed sliding wedge;  $S$  is the total shear force acting on the assumed sliding wedge;  $N_i$  is the force acting normal to a sliding failure surface of a sliding wedge;  $f_i$  is the coefficient of internal friction of the material on a sliding failure surface;  $C_i$  is the cohesive strength of the material on a sliding failure surface;  $A_i$  is the area of a sliding failure surface;  $T_i$  is the shear force acting parallel to the assumed sliding direction.

For the calculation of  $N_i$  and  $T_i$  on a slip surface of an assumed sliding wedge, the computation results at the last step are used.

The results are summarized in Table 4.

It can be seen that in the static usual load cases (Case 1 and Case 2), the factors of safety against sliding for failure wedge with El.690 slip surface

Silt pressure	✓	✓	✓	✓	✓	✓	✓
Temperature drop	✓		✓			✓	
Temperature rise		✓		✓			✓
0.1 g (OBE)			✓	✓	✓		
0.25 g (MCE)						✓	✓

Table 4. Factor of safety against sliding at natural conditions.

Bottom slip surface	El.660	El.690
Case 1	4.41	1.72
Case 2	4.52	1.69
Case 3	3.10	1.44
Case 4	3.19	1.52
Case 5	5.13	2.64
Case 6	3.39	1.73
Case 7	5.19	3.11

are less than 2.0 (criteria value in EM1110-2-2201), which indicates that the stability of the right abutment at its natural conditions, namely no treatment measures for F2 and F3 (situation S-2), would not meet the code requirement.

## 7 TREATMENT OF FAULTS F2 AND F3

To strengthen the rock mass integrity at the right bank abutment and to enhance the overall stability of the right abutment, the concrete replacement method is applied for treatment of Faults F2 and F3.

Treatment works consist of replacement adit 1 for Fault F3 and replacement adit 2 for Fault F3 at EL660 m, replacement adit 3 for F2 at EL690 m, and replacement adit 4 for F2 at EL720 m, replacement shafts 3 and 4 connecting replacement adits 3 and 4, and force-transfer adits along Fault F2 at EL660 m, EL690 m and EL720. The lengths of the replacement adits at EL660 m, EL690 m, and EL720 m are about 84 m, 50 m and 35 m, respectively, and the length of each of the two replacement shafts is about 30 m. The cross-sections of the replacement adits and shafts are dimensioned in the range of 3 m–5 m, which is about the same as the size of the elements for their surrounding rocks.

In the FE model for the computation, 2442-node beam elements are included for concrete replacement adits, replacement shafts and force-transfer adits. An area-weighted equivalent method is used to reflect the effect of fault treatment works on the increase of shear strength of the faults.

In addition to the concrete replacement works, consolidation grouting with a depth of 5 m was proposed to be conducted around the replacement adits. Deep hole consolidation grouting along Fault F2 was also proposed to be performed from replacement adits at EL660 m and EL690 m in order to enhance the shear strength and deformation modulus of the fault fractured zone.

Table 5. Factor of safety against sliding with fault-strengthening works.

Bottom slip surface	El.660
Case 1	2.60
Case 2	2.68
Case 3	2.57
Case 4	2.67
Case 5	4.42
Case 6	3.01
Case 7	2.20

The maximum grouting pressure was selected at 3.0 MPa. Contact grouting was proposed for all concrete replacement works to ensure the bond and hence increase the shear strength between the concrete and the surrounding rock.

The FS calculation follows the same [Equation \(1\)](#), and the results are summarized in [Table 5](#), which

suggest that the stability against sliding of the right abutment with the current fault-strengthening works can meet the code requirement, indicating the treatment measures are effective and feasible.

## 8 SUMMARY

Steep Faults F2 and F3 run sub-parallel to the river flow in the right abutment of the Gomal Zam Dam in such a way that it may form a lateral slip surface. A FEM-LEM approach is used to assess the right abutment stability against sliding, in which the result shows that the safety factor against sliding of the wedge combining the bottom slip surface at El.690 m and lateral slip surface of Fault F2 cannot meet the code requirement at natural conditions and can meet the code requirement with the current fault-strengthening works, indicating that the effects of concrete replacement works for Faults F2 and F3 are desired.

# Study on optimum band combination of multi spectral vegetation information extraction in Taihu Basin

T.T. Cui, Y.Q. Long, Y.T. Wang, Q.F. Hu & Y. Liu

*State Key Laboratory of Water Resources and Hydraulic Engineering and Science, Nanjing Hydraulic Research Institute, Nanjing, China*

**ABSTRACT:** Based on the Landsat ETM+/TM remote sensing data, ENVI software is employed to calculate statistical characteristics of remote sensing image. The Taihu basin is taken as the typical case. The statistical characteristics of each band, the band correlation and OIF index are analyzed. According to the data analysis and image comparison, the band combination of TM2, TM4 and TM7 is the optimum band combination for extracting vegetation information, and respectively given a red band, the green band and blue band. This band combination has achieved good results in the Taihu Basin vegetation information extraction.

**Keywords:** landsat ETM+/TM data; vegetation information extraction; optimal band combination; OIF index

## 1 INTRODUCTION

The urbanization could greatly change the vegetation which is one of the most important environmental components and one of the best marks of eco-environment. Analysis of the vegetation information could be used in urbanization management, flood protection, environment protection. Efficiency and accuracy of the extracting the vegetation information from the Remote Sensing (RS) data is the key and hot point in the field of image processing and RS image interpretation (Mei et al. 2001, Guo & Liu 2012). Artificial Visual Interpretation (AVI) is one of the major methods for vegetation information extraction. The efficacy of the AVI is depended on the image quality which is affected by the image data redundancy caused by the admixture of different bands of the multi-spectrum image (Ma et al. 2010). So extracting the clear image with plenty useful information from the RS image is the hard and important point for AVI. In this paper, the Taihu Basin in China is taken as the typical case for applying AVI in a fast urbanization area. By evaluating the different combination of bands of the multi-spectrum image, the best combination of bands of vegetation information is extracted. The method could enhance the separability of terrain and reduce image data redundancy.

## 2 BACKGROUND OF THE TAIHU BASIN

The Taihu Basin locates in the south of the Yangzi delta. The north of the Taihu Basin is the Yangzi

River, the south is the Qiantang River, the east is the East China Sea, and the west is the Tianmu Mountain. The Taihu Basin belongs to subtropics monsoon climate region with plenty rainfall and frequently typhoon. Because of the moderate climate and pleasant geographical condition, the Taihu Basin contains most of the wealthy metropolis in the north China. The rapid urbanization in the Taihu Basin greatly changes the vegetation which is one of the decisive factors of runoff, precipitation infiltration, flood and transpiration. Finding the best combination of bands for extracting vegetation information could be useful for urbanization management, flood control, groundwater protection and water resource management.

## 3 DATA

Five Landsat ETM+/TM RS scenes are spliced together to generating the whole RS image of the Taihu Basin. These Landsat ETM+/TM RS scenes are obtained from <http://www.gscloud.cn>. Their WRS path and starting row numbers are 118/038, 118/039, 119/038, 119/039 and 120/038, the acquisition dates are 2009/9/19, 2009/7/17, 2010/5/24, 2010/5/24 and 2009/5/4. All the images are acquired in sunny day without cloud, and have been applied geometric correction. So these images could be used to interpretation directly. The 6th band of these images is infrared band which is sensitive to the thermal object. The 8th band of these images is panchromatic band, and it cannot show the color

of the terrain. In this paper, we don't use the 6th and 8th bands to identify the best combination of bands for extracting vegetation information.

## 4 METHOD

The RS image spectrum characteristic analysis and the Optimum Index Factor (OIF) are used to identify the optimum band combination for extracting the vegetation information in the Taihu Basin.

There are many bands in the multi-spectrum RS image, and each band could contain information of different types of vegetation. So a good band combination is the basis to extract the vegetation information. Usually, three rules should be followed to choose proper band combination (Jiang et al. 2002, Wu & Liu 2007). Firstly, band should contain more information. Then the relativity between different bands should be as small as possible. Finally, the objective terrain should be identified easily in the band combination.

Optimum Index Factor method (OIF) proposed by Chavez et al. (1982) uses standard deviation of three band and coefficient between different band to calculate the optimum index factor. The OIF could be calculated as the followed equation.

$$OIF = \frac{\sum_{i=1}^3 S_i}{\sum_{i=1}^3 |R_{ij}|} \quad (1)$$

where the  $S_i$  is the Standard Deviation (SD) of the  $i$ th band. The  $R_{ij}$  is the Correlation Coefficient (CC) between band  $i$  and band  $j$ . The standard deviation is bigger, the more information the band has. The coefficient between two bands is smaller, the more independent these bands are, and the less data redundancy is. If an image contains many bands, the correlation matrix should be calculated and then each of the OIF combinations of three bands should be calculated. The OIF is bigger, the more information the band combination could have.

## 5 ANALYSIS OF BAND COMBINATION

### 5.1 Information of band

The statistical characteristics could be used to evaluate the plenty of band information. We calculate the statistical characteristics of the RS images of the Taihu Basin by ENVI. The statistical characteristics of the six bands are shown in Table 1.

The standard deviations of band TM4, TM7, and TM5 are bigger than the standard deviations of other bands. So the band TM4, TM7, and TM5 have more information than other band.

Table 1. Statistical characteristic of bands.

Band	Min	Max	Mean	SD
TM1	0.071	0.341	0.119	0.018
TM2	0.010	0.767	0.111	0.020
TM3	0.001	0.742	0.093	0.026
TM4	0.025	1.265	0.225	0.060
TM5	0.000	0.548	0.141	0.045
TM7	0.000	0.801	0.094	0.048

Table 2. Correlation matrix of different bands.

Coefficient	TM1	TM2	TM3	TM4	TM5	TM7
TM1	1.000	0.943	0.921	-0.201	0.249	0.553
TM2		1.000	0.970	-0.155	0.215	0.475
TM3			1.000	-0.180	0.272	0.539
TM4				1.000	0.666	0.304
TM5					1.000	0.870
TM7						1.000

Table 3. The combinations of chosen bands.

Type I	Type II	Type III	Band combination
TM1		TM5	TM1+TM4+TM5, TM1+TM4+TM7
TM2	TM4		TM2+TM4+TM5, TM2+TM4+TM7
TM3		TM7	TM3+TM4+TM5, TM3+TM4+TM7

### 5.2 Band correlation

We calculate the correlation matrix of TM1, TM2, TM3, TM4, TM5, TM6 and TM7 by ENVI.

The correlation coefficients of TM1, TM2 and TM3 are bigger than 0.92. That means the three bands have great data redundancy, and cannot be used as a combination. We take the three bands as type I. The correlation coefficients of band TM4 and other bands are smaller than 0.67. That means the TM4 is independent of the other bands, and it can assemble a combination with any band. The TM4 is taken as type II. The correlation coefficients of TM5 and TM7 is bigger than 0.87, so the two bands cannot assemble a combination. TM5 and TM7 are taken as type III. We choose a band from each type; the chosen bands can assemble six combinations (Table 3).

### 5.3 Optimum index factor

The OIF of each band combination are shown in Table 4.

### 5.4 The optimum band combination

Table 4 shows that the first three band combinations have the biggest OIF than other combinations. So the optimum band combination could be one of the three combinations. The statistical characteristics of band combination show that the first band combination in Table 4 has the smallest correlation and standard deviation. Though the data analysis show the first band combination could be the optimum combination, we still need use the AVI to confirm the judgment. Comparing the colorful images generated from the first three band combinations, we find the image corresponding to the first combination can clearly exhibit the terrain, vegetation, and the urban area. The second combination could exhibit large vegetation area, but cannot exhibit the tiny vegetation and differentiation between terrain objectives clearly. The image corresponding to the third combination is darker than the first two images. It is difficult for people to interpret information from a dark image. Finally, the first band combination is chosen as the

Table 4. The OIF of different band combination.

No.	Band combination	Sum of SD	Sum of CC	OIF
1	TM2+TM4+TM7	0.129	0.934	0.138
2	TM3+TM4+TM7	0.135	1.023	0.132
3	TM2+TM4+TM5	0.125	1.036	0.121
4	TM1+TM4+TM7	0.126	1.058	0.119
5	TM3+TM4+TM5	0.131	1.118	0.117
6	TM1+TM4+TM5	0.123	1.115	0.110

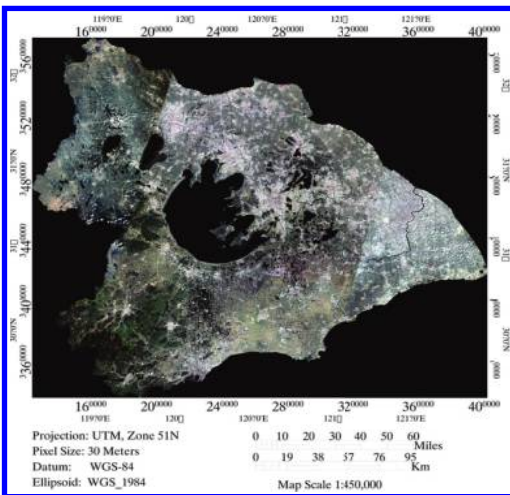

Figure 1. TM3 TM2 TM1 combined imaging.

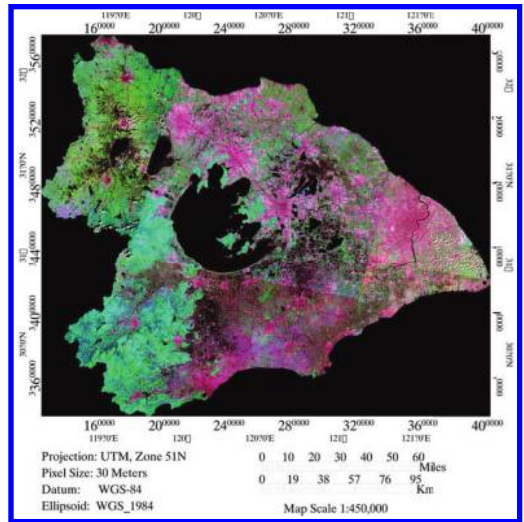

Figure 2. TM1 TM4 TM5 combined imaging.

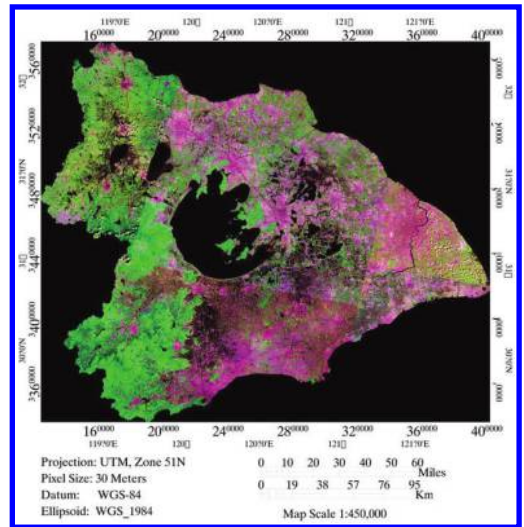

Figure 3. TM2 TM4 TM7 combined imaging.

optimum combination to interpret the vegetation information of the Taihu Basin.

## 6 CONCLUSION

The optimum band combination is very important for RS image interpretation. A reliable optimum band combination is the basis of correct and accurate artificial visual interpretation. We take the Taihu Basin as the typical case. Considering the information plenty and data redundancy, we use

the standard deviation, correlation coefficient, and OIF to identify that the optimum band combination is TM2+TM4+TM7. The combination can clearly exhibit the terrain, vegetation, and the urban area. The method in this paper could be very useful for interpreting multi-spectrum image, but further study is needed to find out whether the method is useful for interpreting high spectrum image.

# Agricultural water-saving zoning and suitable water-saving measures in the Yellow River Delta

G.B. Pang

*School of Resources and Environment, University of Jinan, China*

S. Zhang

*Handun Irrigation Management Bureau of Binzhou City, China*

**ABSTRACT:** Agricultural water-saving zoning is not only the foundation work of water-saving agricultural development, but also an important basis for the planning and implementation of regional agricultural water-saving program. Dongying city located in the hinterland of the Yellow River Delta was studied, and index systems about agricultural water-saving zoning were built in this paper, including administrative division, soil types, groundwater mineralization and distribution of river systems. In addition, the method of Geographical Information System (GIS) spatial analysis combined with geostatistics was applied to the water-saving zoning. Dongying city was divided into 5 major types; meanwhile, reasonable agricultural water-saving measures of different regions were proposed to direct the agricultural irrigation and production. This can provide a guideline for high efficiency use of water resources and healthy development of regional economy.

**Keywords:** Yellow River Delta; water-saving agriculture; zoning indicators; GIS

## 1 INTRODUCTION

In recent years, the economic development of the Yellow River Delta has increased rapidly. Due to the scheduling of the Yellow River Basin, the Yellow River water level has decreased. On the one hand, the contradiction between agricultural water and industrial water has become more acute. On the other hand, the agricultural irrigation water efficiency is only 0.45<sup>[1]</sup>. Thus, the development of water-saving agriculture and water-saving technology is critical, while the agricultural water-saving zoning as a foundation work for water-saving agriculture is to be carried out urgently<sup>[2]</sup>. Therefore, the study on the agricultural water-saving irrigation of the Yellow River Delta zoning, proposing agricultural water-saving measures and development direction, can provide a guideline for agricultural water-saving irrigation planning and implementation.

## 2 DIVISION PRINCIPLE

The formulation of agricultural water-saving zoning can reveal the diversity and consistency in the area around the range of agricultural development, and provide evidence for agricultural water conservation planning. The total principle<sup>[3]</sup> is based

on the following aspects: “generalizing similarity, distinguishing difference, considering administrative boundaries”, and following four principles in detail<sup>[4]</sup>. The first is the consistency of natural elements. It means that climate, topography, geomorphology, soil and other natural geographical conditions have a certain similarity, and water resources conditions are similar. Second, the targets of water-saving irrigation are consistent. It means that the main irrigated crops and water-saving irrigation measures should be uniform in the same area. The third one is the integrity of the administrative division. It means that the agricultural water-saving zoning should consider the existed administrative boundary. The fourth is the relative independence. It means that the division results should reflect the characteristics of water-saving irrigation districts. As part of agricultural water conservancy zoning, water-saving irrigation zoning has significantly different characteristics to other water conservancy measures, which is helpful for guiding the development of water-saving irrigation to maintain its relative independence.

## 3 ZONING INDICATOR

The indicators of agricultural water-saving zoning should meet the requirements such as

comprehensiveness, generality and obtaining easily<sup>[5]</sup>. Generally speaking, zoning indicators include 4 to 6 indicators, which are selected from landform, climate, soil, agricultural structure, type of irrigation district and degree of water shortage.

The climate of the Yellow River Delta is similar. It is a typical warm temperate zone monsoon climate area. The irrigation district are mainly the Yellow River irrigation district, where the exploitation of groundwater is rare. It belongs to the northwest plain area of Shandong, and is mainly microtopography in the region. Therefore, climate characteristics, the types of irrigation district and landform are not considered, while the soil structure and water resources distribution have an obvious influence on agricultural water-saving measures. As a result, the administrative divisions, soil type, groundwater salinity, and distribution of river system are selected as agricultural water-saving zoning indicators of Dongying city. They can exactly reflect the agricultural water-saving types and characteristics on this basis of agricultural water-saving zoning.

### 3.1 Administrative division

There are 5 counties and districts, 40 townships and streets in Dongying city. As summarized in Table 1, the Hekou district and Kenli county area are larger, accounting for 27% and 27.82% of Dongying city, while the largest agricultural land is Guangrao county, which is located in the south coast of the Yellow River, accounting for 69.05% of the county. From the overview of the city, agricultural land area accounts for only 39.78% of

Dongying city, which is mainly due to soil salinization, irrigation water shortage, and aging hydraulic project in the area.

### 3.2 Soil type

There are five soil types in Dongying city (Table 2). Cinnamon soil, accounting for about 4%, is mainly distributed in the south of the Xiaoqinghe River, where is the grain, cotton and vegetable high yield area of the city. Lime concretion black soil is mainly distributed in the low-lying place of south brown soil area of the Xiaoqinghe River, accounting for 0.6%, which is suitable for wheat, maize, sorghum and shallow root crops, where is a potential soil type of agriculture. Alluvial soil accounts for 59%, and it is suitable for wheat, maize, and cotton improved by using the tillage method. Saline soil is distributed in the zonal coast, accounting for 36%. There are natural vegetations including reeds, thatch, and wormwood, which mainly rely on aquatic and pasture products. Paddy soil is distributed in Lijin, Kenli county, and accounts for only 0.2%, which has the characteristics of paddy soil in infancy after more than 20 years of water tillage aging.

### 3.3 Groundwater mineralization

Dongying city is formed in the saline basement, in addition to sections of the south of the Xiaoqinghe River, groundwater mineralization is lower than 2 g/L, and nearly 70% of the groundwater depth is 1 to 3 meter and mineralization is 5 to 30 g/L. Moreover, nearly 20% of the

Table 1. The administrative division and agricultural land of Dongying city.

Region	Total area/km <sup>2</sup>	Proportion/%	Agricultural land/km <sup>2</sup>	Proportion/%
Dongying	1155.62	14.59	538.58	46.60
Hekou	2138.97	27.00	569.93	26.65
Kenli	2204.07	27.82	663.29	30.09
Lijin	1286.91	16.24	594.26	46.18
Guangrao	1137.87	14.36	785.75	69.05
Sum	7923.26	100.00	3151.81	39.78

Table 2. The soil types of Dongying city.

Soil types	Area/km <sup>2</sup>	Proportion/%	Distributed district
Cinnamon soil	316.92	4	South of Xiaoqinghe River
Lime concretion black soil	47.54	0.6	Low-lying place of brown soil area
Alluvial soil	4674.57	59	Middle and west of Dongying city
Saline soil	2852.28	36	Zonal coast
Paddy soil	15.85	0.2	Old paddy land of Lijin, Kenli county

groundwater mineralization is more than 30 g/L, with some areas being as high as 100 g/L. As summarized in Table 3, the mineralization of 2 to 10 g/L of groundwater accounts for 56.71%, the mineralization of 10 to 50 g/L accounts for 30.15%, and less than 2 g/L of groundwater only accounts for less than 6%. Brackish water resources should have further development and utilization.

### 3.4 River system

According to the river basin, the current river systems of Dongying city are divided into Huaihe River Basin and Haihe River Basin (Table 4). The south of the Yellow River belongs to the Huaihe River Basin, mostly from east to west, including Xiaoqinghe, Zhimaihe, Guanglihe, Yongfenghe, and its tributaries amount to 20 rivers. The north of the Yellow River belongs to the Haihe River Basin, mostly from south to north, including Chaohe and its tributaries Chuguanhe, Taipinghe, Maxinhe, Zhanlihe, Tiaohe, Shenxiangou and its tributary Xinweidonghe amount to 10 rivers.

Table 3. The groundwater mineralization of Dongying city.

Degree of mineralization/g·L <sup>-1</sup>	Area/km <sup>2</sup>	Proportion/%
<1	284.32	4.18
1~2	118.28	1.74
2~10	3859.29	56.71
10~50	2051.76	30.15
>50	491.92	7.23

## 4 DIVISION METHOD

There are many division methods, for example, empirical method, index method, type method, overlapping method, cluster method, and fuzzy cluster method<sup>[6]</sup>. The method of GIS spatial analysis combined with geostatistics has a strong spatial analysis function, and a good quantitative and spatial interpolation. It has not only the basis of significant but also characteristics of quantification, and it is superior to the traditional mapping methods, which can provide a more accurate method for regional agricultural water-saving zoning.

As shown in Figure 1, first, ArcGIS10.2 was applied to implement geometric correction, vectorization of division element base map and construct division element database. Second, the spatial analysis function of GIS was applied to draw the river system distribution density map based on the administrative divisions; at the same time, the space distribution features of groundwater mineralization, soil texture, river system distribution density were analyzed. Third, a multi-factor comprehensive analysis based on the correlation analysis of each factor and agricultural water saving was carried out; thus, the space analysis function of GIS was applied to complete the space layout of agricultural water-saving zoning. Finally, fuzzy evaluation based on the results of the multi-index spatial overlay analysis, and the thematic mapping function of GIS were used to draw the mapping of agricultural water-saving zoning.

## 5 DIVISION RESULT

As shown in Figure 2, agricultural water-saving zoning of Dongying city can be divided into

Table 4. The river system of Dongying city.

River basin	Channel	Area/km <sup>2</sup>		Length/km	
		Total	Dongying	Total	Dongying
Huaihe river basin	Xiaoqinghe	10337	585	237	34
	Zhimaihe	3382	1508	135	68.2
	Guanglihe	510	510	47.3	47.3

	Shenxian	350	350	30	30

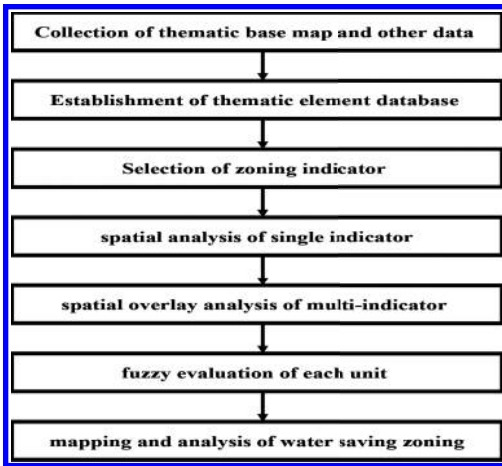

Figure 1. The flow chart of division.

Figure 2. The agricultural water-saving zoning of Dongying city.

five types. The location, area, and proportion of each division are listed in Table 5. The suitable agricultural water-saving measures and development direction are established according to the characteristics of each division, especially water resources condition, agricultural planting structure and soil type.

I. area is 669.49 km<sup>2</sup>, it accounts for 8.45% of Dongying city, located in the south of Xiaoqing River, Guangrao county. The average annual rainfall is 602 mm, the soil and water

conditions are better, which contains high-yield grain, cotton, vegetable production areas of Dongying city. In this area, grain crops (wheat, corn) are suitable for surface irrigation and pipeline irrigation, and economic crops (cotton, vegetables) are suitable for sprinkler irrigation and drip irrigation. The strategy is priority exploitation of surface water and moderate exploitation of groundwater, maintaining the existed grain area, improving the yield, and establishing grain and vegetable production base of the city.

II. area is 3567.73 km<sup>2</sup>, which accounts for 45.03% of Dongying city, located in the middle and west of the city and distribution along the Yellow River. It is the biggest division, and the average annual rainfall is 560 mm. There is little amount of fresh groundwater in Lijin and Kenli county along the Yellow River, and the rest of the groundwater salinity is 2 to 10 g/L, which is not suitable for irrigation, so it relies mainly on Yellow River water and surface water. Major soil type is alluvial soil, and it is mainly cultivated soil of the city, which is suitable for wheat, corn, rice and other food crops after cultivation improvement. In this area, food crops (wheat, corn, rice) are suitable for surface irrigation, pipeline irrigation and controlled irrigation, and crops' brackish water irrigation technology (2–5 g/L) should be explored. The strategy is priority exploitation of surface water and Yellow River water, speeding up the engineering construction, lining the channels, expanding the existed grain area, improving the yield, and establishing the food production base of the city.

III. area is 684.55 km<sup>2</sup>, and it accounts for 8.64% of Dongying city, located in the west of the Tiaohe River, and in the east of the Zhanli River. The average annual rainfall is 530 mm, and the groundwater salinity is more than 10 g/L, so it relies mainly on the Yellow River water, and the soil types are moderate and severe salinization alluvial soil, which is suitable for wheat, cotton, and fruit trees after cultivation improvement. In this area, food crops (wheat) are suitable for surface irrigation and pipeline irrigation, and economic crops (cotton, fruit trees) are suitable for sprinkler irrigation and drip irrigation, and the area of high soil salinization can develop an agriculture-fishery mode. It mainly adopts irrigation way by plain reservoir and conveyance channel, building a new plain reservoir, speeding up the engineering construction, lining the channels, maintaining the existed grain areas, exploring the agriculture-fishery development mode actively, and establishing

Table 5. The agricultural water-saving zoning of Dongying city.

Division	Denomination	Area/km <sup>2</sup>	Proportion/%
I	South piedmont alluvial plain region	669.49	8.45
II	Middle and west Yellow River flood plain region	3567.73	45.03
III	North coastal plain region	684.55	8.64
IV	Modern Yellow River Delta region	1731.18	21.85
V	Coastal beach region	1267.68	16

an efficient planting and raising the ecological agriculture mode.

IV. area is 1731.18 km<sup>2</sup>, and it accounts for 21.85% of Dongying city, located in the east of Kenli county along the Yellow River, which includes mostly east of the Hekou district and Kenli county. The average annual rainfall is 550 mm, and the groundwater salinity is more than 2 to 10 g/L, which is not suitable for irrigation, so it relies mainly on the Yellow River water, and the soil type are moderate and severe salinization alluvial soil in the area, which is suitable for wheat, cotton, fruit trees, vegetables and other crops after cultivation improvement. In this area, food crops (wheat) are suitable for surface irrigation and pipeline irrigation, and economic crops (cotton, fruit trees) are suitable for sprinkler irrigation and drip irrigation, and crops' brackish water irrigation technology (2–5 g/L) should be explored. It mainly adopts irrigation way by plain reservoir and conveyance channel, building a new plain reservoir, speeding up the engineering construction, laying pipes, and developing facility agriculture, tourism agriculture and other modern ecological agriculture mode.

V. area is 1267.68 km<sup>2</sup>, and it accounts for 16% of Dongying city, located in the zonal coastal beach. The average annual rainfall is 560 mm, and the groundwater salinity is more than 10 to 50 g/L, and the surface water is also saline water and the fresh water relies mainly on the Yellow River. In this area, salt-tolerant economic forest is planted by using saline-alkali land afforestation technology, developing animal husbandry by rich forage grass resources, exploiting the mariculture, improving the ability of fishing, and building modern fishery production base gradually.

## 6 CONCLUSION

Index systems about agricultural water-saving zoning were established, including administrative

division, soil types, groundwater mineralization and distribution of river systems. In addition, the method of GIS spatial analysis combined with geostatistics was applied to the agricultural water-saving zoning. Dongying city was divided into 5 major types. At the same time, reasonable agricultural water-saving measures were proposed to direct the agricultural irrigation and production, which can provide a guideline for regional agricultural water-saving irrigation planning and implementation.

**ABSTRACT:** This paper uses two kinds of conventional methods to calculate the internal force of the lock head side pier and the lock head floor. The first calculation method is recommended in the *Code for design of hydraulic structures of ship locks*, calculating the internal force of the lock head structure when considering the supporting wall as an independent structure to bear the gate thrust individually. Another analytical method is to distribute the miter gate thrust to the front and rear sections of the gate before calculating the internal force of the lock head. Moreover, ANSYS software is also used to analyze the lock head structure in this article. The comparative analysis of the results shows that defects exist in the code of the first conventional method. However, the results of the second conventional method are consistent with those of the calculation of ANSYS software.

**Keywords:** miter gate thrust; lock head structure; internal force; finite element method

## 1 INTRODUCTION

The ship lock is a hydraulic structure, which ensures that the ship can sail across the channel where there is concentrated water drop. The ship lock is composed of the upper lock head, lower lock head, gate lock, water retaining structure and water conveyance system, which can ensure the rise and fall of the water level<sup>[1]</sup>.

Lock head structure can be divided into front door segment, niche segment and supporting segment in the longitudinal direction. The supporting segment of the gate refers to the section that can bear the gate thrust, and should meet the requirements of structural strength and stability. In the engineering design, the length of the supporting segment could be determined by checking the supporting segment's strength and stability under the independent working condition. Therefore, the supporting segment needs to have enough length.

## 2 ENGINEERING EXAMPLE

The lower head of a ship lock from Anhui Province is a monolithic, concrete and symmetric structure.

The lower head is composed of the miter gate, flat bottom floor, side pier with an empty container and a water transmission way. The width of the lock head is 42 m. The length of the lock head is 24 m. The length of the emergency gate is 2.4 m. The lock head structure details are shown in Figure 1.

Figure 1. Planar graph of the lock head.

### 3 THE INTERNAL FORCE CALCULATION OF THE LOCK HEAD STRUCTURE

#### 3.1 The selection of the calculation conditions

The completion period is selected for the calculation conditions. During the completion period, the side pier is completed, no water in the lock head and backfill soil is backfilled temporarily to the top of the floor. So, the side pier only bears self-gravity and the earth's pressure. Then, by using the conventional methods and the finite element method, the internal force of the side pier of the lock head and that of the lock head floor can be obtained.

Because this paper is mainly focused on the influence of the miter gate thrust on the side pier and the floor, the maximum water level difference period is selected. The miter gate thrust reaches the maximum and the side pier reaches the most disadvantageous state in this period.

According to the literature data and reasonable analysis<sup>[2]</sup>, the overhaul period is often the control load for the maximum negative moment of the lock floor, because the lock head is under a high uplift pressure because there is no water in the lock head and there is a high underground water level behind the lock head wall. So, the overhaul period should be selected.

As shown in Figure 1, the lock head structure can be divided into three sections: the first section is the niche segment; the second section is the supporting segment; the third section is the front door segment. This paper focuses on the effect of the influence of the miter gate thrust on the lock head structure, so the first segment and the second segment are selected and analyzed, which are affected by the miter gate thrust.

#### 3.2 The conventional calculation methods

##### 3.2.1 The calculation method of the supporting wall

Bidirectional bending compression formula is used to calculate the strength of the supporting wall. The stress of the four corner points (A, B, C, D) is calculated by the following formula:

$$\sigma_{min}^{max} = \frac{\Sigma V}{F} \pm \frac{\Sigma M_x}{W_x} \pm \frac{\Sigma M_y}{W_y} \quad (1)$$

where  $\sigma_{max}$  = maximum stress of the bottom of the supporting wall;  $\sigma_{max} < [\sigma]$ ,  $[\sigma]$  = allowable compressive strength;  $\sigma_{min}$  = minimum stress of the bottom of the supporting wall,  $\sigma_{min} > 0$ ;  $F$  = area of the bottom of the supporting wall;  $W_x$  and  $W_y$  are the section modulus of the bottom of the supporting wall in the X and Y axis;  $M_x$  = the sum of the X axis's moment that is dependent on the

longitudinal horizontal force; and  $M_y$  = sum of the Y axis's moment that is dependent on the transverse horizontal force and vertical force.

##### 3.2.2 The calculation method of the lock head floor

When the miter gate thrust acts on the supporting segment, the cross component of the miter gate thrust can be assigned along the lock head's axial direction, which is according to the following methods: the cross component of the miter gate thrust, which is transferred along the side pier's height, can be divided into several concentrated forces ( $S_{yi}$ ). Each concentrated force is diffused into a certain range according to the diffusion angle of 45 degrees along the side pier from top to bottom (see Fig. 2). The lateral force ( $T$ ), which is transmitted to the unit length of the floor, and the moment ( $M$ ) are given in the following formulas:

$$\left. \begin{aligned} T &= \sum_{i=1}^n \frac{S_{yi}}{l_i} \\ M &= \sum_{i=1}^n \frac{S_{yi}h_i}{l_i} \end{aligned} \right\} \quad (2)$$

where  $h_i$  = distance from  $S_{yi}$  to the central axis of the floor and  $l_i$  = the distribution length of  $S_{yi}$  transferring to the lock head floor.

##### 3.2.3 The calculation methods

The conventional methods can be calculated by using the following two methods.

Method 1: using the method recommended by the Code for design of hydraulic structures of ship locks<sup>[2]</sup>. The lateral component of miter gate thrust is average supported by the supporting segment.

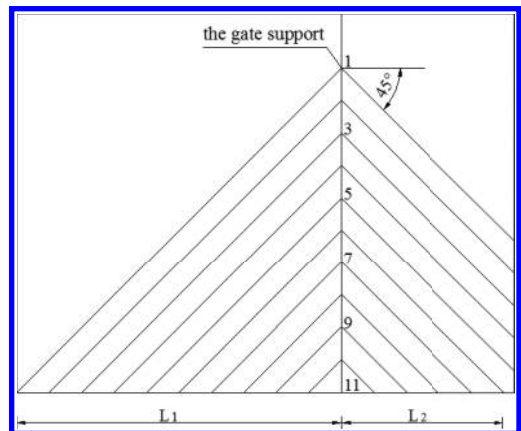

Figure 2. The lateral thrust distribution along height of the miter gate.

Then, the four corners stress can be calculated by formula (1). The internal force of the floor can be calculated by Guoshi Charts and can be adjusted by the weighted average method.

Method 2: using the method recommended by the *Canalization project*<sup>[3]</sup>. First, the cross component of the miter gate thrust is assigned to the two segments, which are calculated according to formula (2). Second, the four corners stress can be calculated by formula (1). Third, the internal force of the floor can be calculated by Guoshi Charts and need not be adjusted.

### 3.3 Comparative analysis and calculation of ANSYS

First, the internal force of the structure is analyzed by using ANSYS. Then, SOLD45 is selected, which is the three-dimensional 8-node isoparametric unit, to form the head lock. Because the lock head structure is symmetrical, it can be set up only half of the model for calculation and analysis<sup>[4-5]</sup>. Figure 3 shows the finite element model of the lower lock head. Figure 4 shows the finite element model of the lock head floor.

Figure 3. Finite element model of the lower lock head.

Figure 4. Finite element model of the lock head floor.

## 4 COMPARISON BETWEEN THE CALCULATION RESULTS USING THE CONVENTIONAL METHOD AND THE CALCULATION RESULTS USING THE ANSYS METHOD

Three represented conditions are selected to calculate the lock head. The four corners of the supporting wall and the lock head floor can be calculated by using the two kinds of methods.

### 4.1 The analysis of calculated results in the completion period

#### 4.1.1 The analysis of stress of the supporting wall in the completion period

The stress pattern of the Z direction, which is on the bottom of the supporting wall in the completion period, is abstracted from the ANSYS model. The stress pattern is shown in Figure 5.

As shown in Figure 5, the maximum tensile stress is 3.22 Mpa and the maximum compressive stress is 1.04 Mpa. Due to the uneven settlement of the lock head structure, the tensile stress zone appears on the bottom of the supporting wall. The area of the tensile stress zone is 2.34 m<sup>2</sup>.

The stress, which is on the bottom of the supporting wall in the completion period, is abstracted from Figure 5, which is given in Table 1.

Figure 5. The stress pattern of the Z direction on the bottom of the supporting wall in the completion period.

Table 1. The stress of the bottom of the supporting wall in the completion period (kPa).

Location	A	B	C	D
ANSYS	296.8	341.4	336.2	221.4
Method 1	339.3	339.3	339.3	339.3
Method 2	339.3	339.3	339.3	339.3

Because there is no miter gate thrust in the completion period, it results in the same results according to method 1 and method 2. Through comparing the results of two conventional methods with those of one ANSYS method, the conventional method and ANSYS method calculation results are approximately the same. However, the two kinds of methods have a large difference in the results of location D. This is because ANSYS considers the overall working characteristics of the side pier. The settlement of the lock head under self-weight is not uneven, which leads to the local tensile stress zone on the bottom of the supporting wall.

#### 4.1.2 The analysis of stress of the lock head floor in the completion period

The first and the second moment values, which are on the bottom of the supporting wall in the completion period, are abstracted from the ANSYS model. The moment pattern figures are shown in Figure 6 and Figure 7.

It can be seen from Figure 6 and Figure 7 that in the absence of the miter gate thrust, the conventional methods and the ANSYS method lead to approximately the same results for the floor moment of the first section and the second section. However, the moment distribution curves of

Figure 6. The first section of the moment of the lock head floor in the completion period.

Figure 7. The second section of the moment of the lock head floor in the completion period.

the lock head floor of ANSYS calculation results are smoother than the results of the conventional method calculation.

#### 4.2 The analysis of calculated results in the maximum water level difference period

##### 4.2.1 The analysis of stress of the supporting wall in the maximum water level difference period

The stress pattern of the Z direction, which is on the bottom of the supporting wall in the maximum water level difference period, is abstracted from the ANSYS model. The stress pattern is shown in Figure 8.

As shown in Figure 8, the force of the supporting wall is in the most unfavorable circumstance under the miter gate thrust. The maximum tensile stress reaches up to 5.27 Mpa. The maximum compressive stress is 1.38 Mpa. On the bottom of the supporting wall, the distribution range of the tensile stress increases. The area of the tensile stress zone increases to 2.62 m<sup>2</sup>.

The stress, which is on the bottom of the supporting wall in the maximum water level difference period, is abstracted from Figure 8, as presented in Table 2.

Compared with the results of ANSYS, the results of method 1 in both the maximum stress

Figure 8. The stress pattern of the Z direction on the bottom of the supporting wall in the maximum water level difference period.

Table 2. The stress of the bottom of the supporting wall in the maximum water level difference period (kPa).

Location	A	B	C	D
ANSYS	320.6	497.9	280.1	160.6
Method 1	634.4	457.5	180.0	3.2
Method 2	314.9	478.9	158.6	322.7

and minimum stress are over-conservative, as it can be seen from Table 2. The results of method 2 are approximately in agreement with those of the ANSYS model. The central zone of tensile stress (Fig. 8) calculated from the ANASYS model leads to the stress result of location D, and is less than that of model 2. Therefore, a sufficient cognition about the tensile stress zone should be taken into consideration in the engineering design.

#### 4.2.2 The analysis of stress of the lock head floor in the maximum water level difference period

The values of the first and the second moment, which are on the bottom of the supporting wall in the maximum water level difference period, are abstracted from the ANSYS model. The moment pattern figures are shown in Figure 9 and Figure 10.

Figure 9 and Figure 10 reflect the moment results of the lock head floor according to the different calculation methods. As shown in the figures, the floor moment values are relatively small by using method 1, especially the gap between the results of the floor in the first section by using method 1 and the results by using the ANSYS model is very large. The reason for the gap is that

Figure 9. The first section of the moment of the lock head floor in the maximum water level difference period.

Figure 10. The second section of the moment of the lock head floor in the maximum water level difference period.

the cross component of the miter gate thrust is averagely borne by the supporting wall. Compared with method 1, the results of method 2 agree well with those of the ANSYS model and can reflect the actual working state of the floor better. The reason is that the miter gate thrust that acts on the floor is distributed by formula (2) and the middle section of the floor bears the maximum external force.

#### 4.3 The analysis of calculated results in the overhaul period

##### 4.3.1 The analysis of stress of the supporting wall in the overhaul period

The stress pattern of the Z direction, which is on the bottom of the supporting wall in the overhaul period, is abstracted from the ANSYS model. The stress pattern is shown in Figure 11.

As shown in Figure 11, the maximum tensile stress is 1.79 Mpa and the maximum compressive stress is 0.93 Mpa. There is no miter gate thrust during the overhaul period. The effect of the earth's pressure behind the wall leads to the decrease in tensile stress zone on the bottom of the supporting wall. The area of the tensile stress zone decreases to 1.1 m<sup>2</sup>.

The stress, which is on the bottom of the supporting wall in the overhaul period, is abstracted from Figure 11, which is given in Table 3.

It can be analyzed from Table 3 that the calculation results of the conventional methods agree well

Figure 11. The stress pattern of the Z direction on the bottom of the supporting wall in the overhaul period.

Table 3. The stress of the bottom of the supporting wall in the overhaul period (kPa).

Location	A	B	C	D
ANSYS	122.9	501.2	267.2	257.4
Method 1	112.3	491.5	272.4	651.6
Method 2	112.3	491.5	272.4	651.6

Figure 12. The first section of the moment of the lock head floor in the overhaul period.

Figure 13. The second section of the moment of the lock head floor in the overhaul period.

with those of the finite element method, because there is no miter gate thrust and the supporting wall just bears water pressure and earth's pressure behind the wall.

#### 4.3.2 The analysis of stress of the lock head floor in the overhaul period

The first and the second moment values, which are on the bottom of the supporting wall in the overhaul period, are abstracted from the ANSYS model. The moment pattern figures are shown in Figure 12 and Figure 13.

It can be analyzed from Figure 12 and Figure 13 that in the absence of the miter gate thrust, the conventional methods and the ANSYS method lead to almost the same floor moment values.

## 5 CONCLUSIONS

In this paper, a lock head of a ship lock project is analyzed by using the three-dimensional nonlinear finite element method and two conventional methods. By comparing the ANSYS method with the

two conventional methods, the main conclusions can be drawn as follows:

1. In the absence of the miter gate thrust, the stress on the bottom of the supporting wall and the moment of the lock head floor, calculated by conventional methods, can reflect the lock head's overall working condition well. The results of conventional methods are approximately in agreement with the calculation results of ANSYS.
2. When the side pier of the lock head bears the miter gate thrust, the view that the supporting wall is a unique structure is too conservative when compared with the results of ANSYS. The supporting wall stress is reasonable by assigning the cross component of the miter gate thrust. There exist defects in the two conventional methods when the miter gate thrust exists. This is because the two methods cannot consider the tensile stress zone on the bottom of the supporting wall.
3. When there is no miter gate thrust that acts on the side pier, the conventional methods agree well with the ANSYS method with respect to the results of the lock head floor. But when the miter gate thrust exists, the moment results of the floor by using method 1 are relatively small, in which case, the results by using method 2 agree well with those by using ANSYS.

Therefore, in order to ensure the rationality of the engineering structure design, the two conventional methods should be calculated, respectively, and the more disadvantageous values by using the two conventional methods should be used as the design basis.

# Study on the prediction of flood disaster in Nanning City based on the gray neural network

R.Y. Ma, M. Lu & S.Y. Wang  
Guangxi University, Nanning, China

**ABSTRACT:** First, the feasibility of forecasting flood is studied, which is based on the combination model of neural network and the gray system theory. Then, taking the flood disaster of the Yu River in Guangxi Nanning City as the research object, the disastrous flood level is defined as 73 m and 75 m sequences of 2 cases for forecasting research by comparing according to the annual flood disaster data of Nanning City. By establishing the gray GM (1, 1) model of two series, respectively, and the 2 cases of the above flood series in the most recent disastrous flood year are forecasted based on the gray neural network. The results show that the predictive accuracy of the gray neural network model is very high and has high reliability. Finally, the 2 flood sequences are extrapolated to forecast, respectively, by using the trained network weights and threshold. The results show that the next disastrous flood in Nanning City will occur in 2018, which can be used as a reference for decision-making of disaster prevention and mitigation in Nanning City.

**Keywords:** combination model; gray neural network; flood disaster; flood forecasting

## 1 INTRODUCTION

Flood disaster is a common kind of disaster, which is one of the natural disasters that brings most serious losses to human life and property, and almost 40% of the loss that natural disaster brings to the modern society is caused by it. Therefore, disastrous flood forecasting is vital for preventing a city from being attacked by flood. There are different models for disastrous flood forecasting. However, due to the complication of the causes and influence factors on the formation of flood disaster, the study conducted in the field for forecasting flood disaster still needs constant exploration and improvement at home and abroad. In recent years, with the continuous progress of science and technology, new mathematical models have emerged endlessly, which provides a lot of new ways for flood forecasting, such as gray system theory method, artificial neural network method and combination model method.

The theory of combination model was proposed in the 1960s. In 1969, J.M. Bates and C.W.J. Granger explained the forecasting method of combination model systematically, and their study has been widely recognized by other experts and scholars in this relevant field. Since 1980, the combination model has been paid more attention. More scholars have put their effort into studying it, and more relevant essays have been published. In recent years, scholars in China have also made great

achievements in the study of combination model. Geng Yuemin proposed a forecasting method of combination model based on optimal weighting, which is used to solve the existing problems of various single traditional forecasting methods. The Tianhe hydrological station in Pearl River Delta was taken as an example. Under the forecasting requirements of water level, a combination model was constructed, which is composed of the multiple linear regression, GM (1, 1) and BP neural network, by using the optimal weighting method. The results show that the predictive accuracy of the combination model has a larger increase than the single model.

This paper establishes a gray neural network combination model of flood forecasting of the Yu River in Nanning City, and then extrapolates the occurrence time of the next disastrous flood in Nanning City.

## 2 GRAY NEURAL NETWORK MODEL

### 2.1 Principle theory of combination model

In practical engineering, we usually choose various different kinds of prediction model to forecast a set of time sequence variables. In the prediction process, due to the different structures and characteristics of the model, different prediction models can provide different available information. If a class of prediction errors of a model is simply

rejected, a lot of available information will be lost as well.

The comprehensive utilization of different forecasting models can reduce the randomness and make effective use of information, to avoid losing important information of a single model. Forecasting model of multiple characteristics is combined together with suitable ideas and forms through scientific analysis, and then establishes the corresponding combination model to forecast. It is the development direction for future forecasting in this field.

### 2.2 *The feasibility of the gray neural network model*

In the prediction process, how to establish a suitable prediction model is of great importance. When modeling the gray system theory, it does not fully adhere to the original data. It not only respects the rationality of the original data, but also allows for scientific treatment, adjustment and amendment to the original data of the forecasting object, which makes the gray system model combine more properly than other models, and can be used as an appropriate model to do combination forecasting with other models.

The GM model has many great advantages. For example, it weakens the randomness of the original data, needs a small amount of calculation and sample data, and has a relatively high predictive accuracy in a short period of time. But there are also some specific limitations, such as lack of self-organized adaptability and feedback corrected ability. And it is difficult to adjust by the error's feedback. However, artificial neural network has a good nonlinear learning ability and adaptive ability, and it can control the predicted error. It also has advantages such as good robustness, fault tolerance and generalization ability, which can make up the inherent limitations of the gray system models to a certain extent.

Under the condition of giving full play to the advantages of the gray system model, with the help of the advantage of the artificial neural network to modify the poor prediction residual sequence, satisfactory results can be obtained. Therefore, the establishment of the gray system combined with the neural network forecasting model will greatly improve the predictive accuracy of the models.

### 2.3 *The forecasting model structure of the gray neural network*

The basic structure of the gray neural network prediction model is essentially a kind of combination forecasting model with residual error correction. First, the original data is normalized and one-time cumulated to establish the gray neural network model.

1. Forecast with the original data sequence  $x^{(0)}(i)$ , according to the principle of the least square method and GM (1, 1). The simulated data  $\hat{x}^{(0)}(i)$  is the prediction sequence, and the residual sequence of GM (1, 1) is obtained after fitting.
2. Establish the BP neural network model, and calculate the residual sequence  $e^{(0)}(i) = x^{(0)}(i) - \hat{x}^{(0)}(i)$ ,  $i = 1, 2, \dots, n$ . If the predictive order is S, then some sequences such as  $e^{(0)}(i - 1)$ ,  $e^{(0)}(i - 2)$ , ...  $e^{(0)}(i - S)$  form. The input vectors are  $e^{(0)}(i - 1)$ ,  $e^{(0)}(i - 2)$ , ...  $e^{(0)}(i - S)$ , and the output vector is  $e^{(0)}(i)$ . The network is trained through the residual sequence based on the BP neural network algorithm, and different input vectors will get corresponding output vectors. The parameters such as weights and threshold are the trained values, which are obtained through the neural network's self-adaptive learning. After achieving the satisfactory accuracy of error, the trained BP neural network can be used as the effective means of residual sequence prediction to get better results.
3. Data combination. sequence  $e^{(0)}(i)$  is fitted and forecasted using the trained network, and then the residual sequence  $\hat{e}^{(0)}(i)$  is obtained after correction. The final model is  $\hat{X}^{(0)}(i) = \hat{x}^{(0)}(i) + \hat{e}^{(0)}(i)$ .

## 3 THE PREDICTION MODEL OF DISASTROUS FLOOD OF THE YU RIVER IN NANNING CITY BASED ON THE GRAY NEURAL NETWORK

### 3.1 *Determination of the disastrous flood level of the Yu river in Nanning City*

The warning level of flood control of the Yu River in Nanning City is 73 m. When the flood level exceeds it, Nanning will suffer different degrees of floods. A total of 131 years of historical data, from 1881 to 2012, in Nanning hydrological station II demonstrate that there are a total of 32 flood levels that exceed the warning level, as shown in [Table 1](#).

### 3.2 *The establishment and inspection of the prediction model of disastrous flood of the Yu River in Nanning City*

**3.2.1 *The establishment of the prediction model***  
 Before forecasting, the forecasting accuracy of the gray neural network should be analyzed. First, we select the first 31 sequences above 73 m and the first 31 sequences above 75 m as learning samples to forecast, while the occurrence time of the 32nd flood and the 14th flood are used as the testing dataset to know the accuracy of the gray neural network forecasting model.

Table 1. Above the warning level of the Yu River in Nanning hydrological station II.

Year	Level (m)	Flow (m <sup>3</sup> /s)
1881	79.89	19486
1908	76.13	13360
1913	79.1	18167
1914	75.15	12021
1915	77.4	15348
1936	76.37	13730
1937	77.58	15640
1947	74.06	10673
1950	73.3	9844
1954	73.03	9552
1955	74.48	11186
1958	73.73	10308
1958	74.71	11446
1960	73.07	9596
1968	75.16	12034
1968	76.39	13761
1971	75.37	12316
1973	73.64	10211
1978	73.37	9920
1978	73.12	9860
1980	73.55	10114
1985	75.42	12383
1985	73.64	10211
1986	73.44	9995
1986	75.74	12812
1992	74.18	10820
1994	75.42	12383
1994	74.36	11039
2001	77.18	14912
2008	75.18	11300
2008	74.34	11010
2012	73.06	9620

Generating matrices of the original sequence, respectively, we obtain

$$x^{(0)}(i) = (x^{(0)}(1), x^{(0)}(2), \dots, x^{(0)}(31));$$

$$y^{(0)}(i) = (y^{(0)}(1), y^{(0)}(2), \dots, y^{(0)}(13)).$$

We then normalize the model. Before establishing the model, all the original data are divided by 1000 and minus 0.881 to make the initial value as 1.

According to the gray system theory, the original data are one-time cumulated in order to improve the regularity of the original data. Establishing the corresponding albinism differential equation of GM (1, 1) model, we obtain

$$dx^{(1)}/dt + ax^{(1)} = u.$$

where  $a, u$  are parameters.

$$\text{Suppose } \hat{a} = \begin{pmatrix} a \\ u \end{pmatrix}.$$

Table 2. Parameters  $a$  and  $u$ .

Parameters	Sequence $x^{(0)}(i)$	Sequence $y^{(0)}(i)$
$a$	-0.0029	-0.0089
$u$	1.0352	1.0058

The values of the parameters can be estimated by the least-squares error method.

The solution of the differential equation is the fitting calculation value  $\hat{x}^{(1)}(i)$  of the time response function  $\hat{x}^{(1)}(k+1) = \left[ x^{(0)}(1) - \frac{u}{a} \right] e^{-ak} + \frac{u}{a}, (k=1, 2, \dots, n-1)$ . Using IAGO on the original data sequence, the predicted value can be estimated as follows:

$$\begin{aligned} \hat{x}^{(0)}(k+1) &= \hat{x}^{(1)}(k+1) - \hat{x}^{(1)}(k) \\ &= (1 - e^a) \left[ x^{(0)}(1) - \frac{u}{a} \right] e^{-ak} \end{aligned}$$

According to the formulas and the above data, values of  $a$  and  $u$  in 2 different sequences are solved by using MATLAB. The results are presented in Table 2.

Suppose that  $x^{(1)}(1) = x^{(0)}(1) = y^{(1)}(1) = y^{(0)}(1) = 1$ , then

$$\begin{aligned} \hat{x}^{(1)}(k+1) &= \left[ x^{(0)}(1) - \frac{u}{a} \right] e^{-ak} + \frac{u}{a} \\ &= 356.9655e^{0.0029k} - 355.9655 \end{aligned}$$

$$\hat{y}^{(1)}(k+1) = \left[ y^{(0)}(1) - \frac{u}{a} \right] e^{-ak} + \frac{u}{a} = 114e^{0.0089k} - 113$$

Substituting  $k = 1, 2, \dots, n - 1$  into the above formulas, we can get the simulation data and predicted value of the GM (1, 1) model.

Among these, the predicted value of sequence  $x^{(0)}(i)$  is 1.1335, and that of  $y^{(0)}(i)$  is 1.1345. It can be suggested that the next disastrous flood will occur in 2014.5 according to the sequence  $x^{(0)}(i)$ . This has a difference of 2.5 year by comparison of actual time. In addition, it has a difference of 7.5 year by comparison of actual time according to the  $y^{(0)}(i)$  sequence. The results show that the predictive one is similar to the actual one.

### 3.2.2 The inspection of the forecasting model

From the reduction of the original value and reducing value, the residuals sequence  $e^{(0)}$  of each model can be obtained. Subsequently, we test the precision of the model. The calculation process of the testing parameters is omitted, and the results are summarized in Table 3.

It can be seen from Table 3 that the testing precision of 2 gray GM (1, 1) models is satisfactory, and it demonstrates that the extrapolating predictive

Table 3. Testing parameters of the GM (1,1) model of disastrous flood of the Yu River in Nanning City.

	S1	S2	C	P	$\xi$
$x^{(0)}(i)$	0.0317	0.006575	0.2074	1	0.645775
$y^{(0)}(i)$	0.0395	0.006849	0.1734	1	0.612898

Table 4. Forecasting results of disastrous flood of the Yu River in Nanning City based on the gray neural network.

Model	$x^{(0)}(i)'$	$y^{(0)}(i)$
Forecasting values of residual error	0.000623	-0.00472
Inverse normalized value (year)	0.62325	-4.72
Occurrence time (year)	2018.12325	2018.48

results of the GM (1,1) model have certain credibility. So we can use the BP neural network to train and correct the next step.

### 3.3 The training and amendment of the predicted residual sequence made by the BP neural network

We take the sequence  $y^{(0)}(i)$  as an example. The residual errors between the simulation and historical actual value from  $e^{(0)}(1)$  to  $e^{(0)}(13)$  were trained by the BP neural network, and forecast the value of  $\hat{e}^{(0)}(14)$  again, and thus the value of  $\hat{Y}^{(0)}(14)$  can be obtained by using the following formula:  $\hat{Y}^{(0)}(i) = \hat{y}^{(0)}(i) + \hat{e}^{(0)}(i)$ .

First, the residual errors between the simulation value and the historical actual value are used as the basic data. The first 13 residual data are used as the training samples and the 14th data are used as the test samples. Each of the 3 data recurs as a cycle. That is to say, the first 3 data are the input vectors, and the latter data is the output vector.

After setting the parameters, we can initialize the neural network, and train and fit forecast based on the neural network. After 3 steps of iterative training, the BP neural network can meet the requirements of former setting accuracy, so that the predictive value -0.00755 will be obtained. After using the inverse normalization, the 14th residual predictive value is -7.55 based on the BP neural network. Therefore, we can get the predictive value of 2007.95, which coincides with the actual value of 2008.

Similarly, the residual errors of sequence  $x^{(0)}(i)$  of the flood level above 73 m are trained and fitted forecast based on the BP neural network. The predictive value is 2011.966, which coincides with the actual situation of above 73 m of disastrous flood in 2012 in Nanning City. The predictive results show that the BP neural network for the residual error of the GM (1,1) model is of great effect, and

it improves the forecasting accuracy greatly even for small samples.

## 4 THE PREDICTION OF DISASTROUS FLOOD OF THE YU RIVER IN NANNING CITY

By fitting and testing the above forecasting accuracy, the satisfactory results of the gray neural network model can be obtained, which shows that it has certain reliability. Therefore, we can use the gray neural network model to forecast the flood disaster occurring the next time in Nanning City.

All the data of Table 1 are used as learning data. Substituting the flood data in 2012 into the sequence  $x^{(0)}(i)$ , the new sequences  $x^{(0)}(i)' = (x^{(0)}(1)', x^{(0)}(2)', \dots, x^{(0)}(32)')$  can be obtained.

Similarly, substituting the flood data in 2008 into the sequence  $y^{(0)}(i)$ , the new sequences  $y^{(0)}(i)' = (y^{(0)}(1)', y^{(0)}(2)', \dots, y^{(0)}(14)')$  can be obtained.

With the above steps of prediction and methods, the forecasting results are summarized in Table 4. The extrapolating results show that there will be a disastrous flood of the Yu River in Nanning City that exceeds 75 m in 2018 or 2019. The forecasting results can be used for reference in Nanning City for flood control and disaster mitigation decision.

## 5 CONCLUSION

1. The forecasting model of the gray neural network is substantially a combined predictive model used to modify the residual error. The predicted data are derived from time series prediction through the GM (1, 1) model. By subtracting the primary data and the predicted data, a residual sequence forms. The autonomous learning ability of the BP neural network can be used to revise the residual sequence. Thus, the final predictions of the gray neural network model can be obtained though adding up the predicted data and revised residual sequence.
2. Based on the practical situations of disastrous flood of the Yu River in Nanning City, the stability of the forecasting model can be tested by comparing the two sequences of disastrous flood (above 73 m and above 75 m).
3. Since the neural network training and study has the characteristics of randomness and volatility to some extent, the data and information of the most recent disastrous flood should be used as the test sample to make predictions for examining the precision of the gray neural network model through previous data. The predictive accuracy can be greatly improved through the extrapolated forecasting of the trained gray neural network model, which is based on a good precision.

## Study on the hydraulic model test of diversion-type hydropower station

Chun Qiu & Chenglan Liu

Sichuan College of Architecture Technology, Deyang, China

**ABSTRACT:** Diversion-type hydropower station is widely used in west China. Sediment deposition often appears near the water intake for the larger angle between diversion pipe and flow direction. The discharge capacity, sediment control and other hydraulic problems are studied. Shape optimization is conducted on water intake and other hydraulic facilities. Flow velocity, water surface and scour depth are measured. Some suggestions are mentioned to ensure the safety of the project. The results obtained in this paper can provide reference to the similar hydraulic engineering.

**Keywords:** hydraulic model test; discharge capacity; sand trap; water intake; sediment control

### 1 INTRODUCTION

The hydropower project, with the total installed capacity of 96 MW and the normal water level of 3004 m, is located on the Bachu River in Cichuan Province, China. The project including three release sluices, namely 6 m wide and 3 m high, one scouring sluice, 3 m wide and 3 m high, is mainly for power generation and flood control. There are more studies on similar projects [1–5]. Under the opening conditions of 2994.58 m

(checking flood level) and 2991.6 m (designing water level), the corresponding discharge is 521 m<sup>3</sup>/s, 330 m<sup>3</sup>/s, respectively. The details of the two operating conditions are provided in Table 1.

Model experiment with a scale of 1:40, based on the gravity similarity, is conducted to study the hydraulic performance of the project. The length of the prototype simulated in the experiment is 1100 m. The panorama of the model experiment is shown in Figure 1.

Table 1. Details of the two conditions.

Operating condition	Flood frequency	Return period (year)	Flow rate (m <sup>3</sup> /s)	Water level before gate (m)	Operating mode
1	0.2	500	521	2994.58	No power generation + full opening
2	2	50	330	2991.60	No power generation + full opening

Figure 1. The panorama of the model experiment.

Figure 2. Deposit of the sediment after 12-hour scours at the check discharge.

## 2 ANALYSIS OF PRELIMINARY RESULTS

Figure 2 shows the deposit of the sediment of reservoir after a 12-hour open discharge. Though the floor elevation of water intake is 2990 m, 3 meters higher than that of the river bed, some sediment is still involved in the water intake. To ensure the safety of the hydropower station, the form of water intake must be optimized.

It can be seen from Figure 3 (a) that preventing water is apparent at the anterior part of the gate piers, which influences the flood discharge. Water-wing after gate piers is shown in Figure 3 (b), which shows the pier should be optimized to eliminate the water-wing.

The main optimization work is as follows. An arc-shaped weir is placed before the water intake with the elevation 2992 m. The height of the breast wall increases 1.5 m in order to enhance the conveyance capacity. The head parts of gate piers are replaced by ellipse one for reducing the preventing water and improving the flow rate. The straight upper reach guide wall is changed into arc one. A new device is placed to the tail of the gate piers to alleviate the water-wing.

Figure 3. Flow pattern at the check discharge.

## 3 HYDRAULIC PERFORMANCE ANALYSIS AFTER OPTIMIZATION

It can be seen from Figure 4 that the water surface keeps calm at the normal water level and dead water level, without the formation of vertical-axis vortex, which meets the requirement of the water intake. Figure 5 shows the flow property before the gate piers, while the flow discharge is  $521 \text{ m}^3/\text{s}$  and  $330 \text{ m}^3/\text{s}$ . The flow pattern is stable for the constraint of the arc-shaped guide wall.

Figure 6 shows the sediment deposition of reservoir after the 12-hour open discharge at the

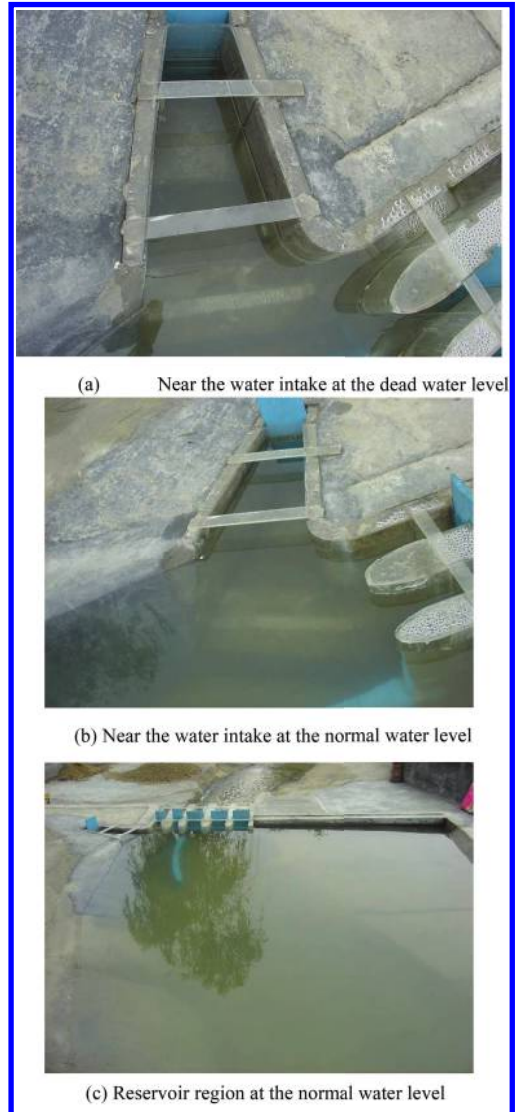

Figure 4. Water surface of the reservoir.

Figure 5. Flow pattern of the reservoir.

Figure 6. Deposit graph after 12-hour scour at the check flood.

discharge of  $521 \text{ m}^3/\text{s}$  during the full opening conditions of scouring sluice and release sluice. Most of the sediment near the foundation of the arch-shaped guide wall is scoured to downstream and not into the water intake, which meets the need of power generation.

Figure 7 shows the relationship between the discharge  $Q$  and the water head  $H$  before the middle-pier of the hydropower project. The water level has a little decrease by comparison with the original case. And the flow becomes free flow under every operating condition.

Figure 7. Variation of  $Q$  with  $H$  before the middle-pier.

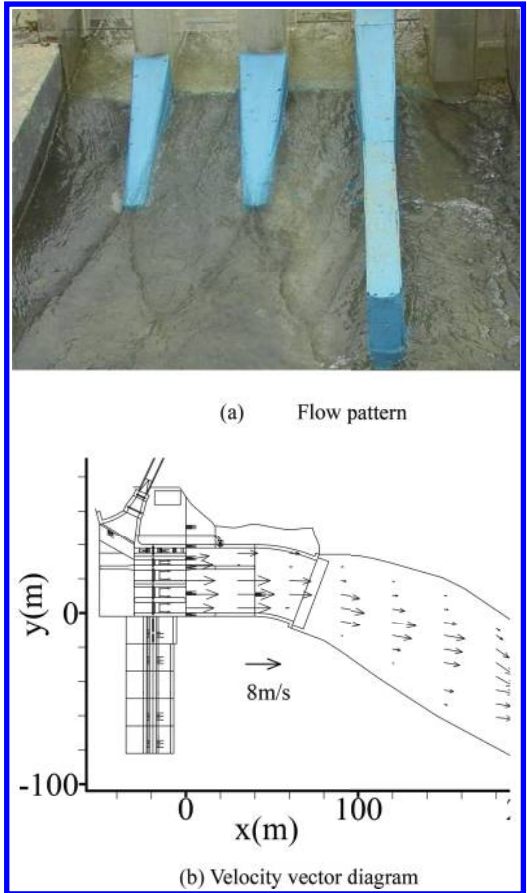

Figure 8. Flow condition at the design flood.

It can be seen from Figure 8 that the water wing after the gate piers is reduced greatly, which expressed that the device to eliminate the water wing is effective. The attention should be given while opening the gate at the normal water level of 3004 m; the flow velocity downstream reaches to 15.8 m/s near the middle release gate for the large drop height of the upper and down water levels. From Figure 8 and Figure 9, we can see that the average flow velocity on the apron is about 12.7–14.9 m/s, while the flow discharge is 521 m<sup>3</sup>/s and 330 m<sup>3</sup>/s, which is the situation that needs to be considered.

It is concluded from the model experiment that the scour depth is about 3–7 m, and the deepest point is located near the anti-scour trench. For security reasons, the corresponding foundation should be excavated to 2977 m; lead cage and riprap protection should also be added to ensure the safety. Figure 10 shows the distribution of scour and silting at design flood when all gates are opened. The similar distribution at the check flood

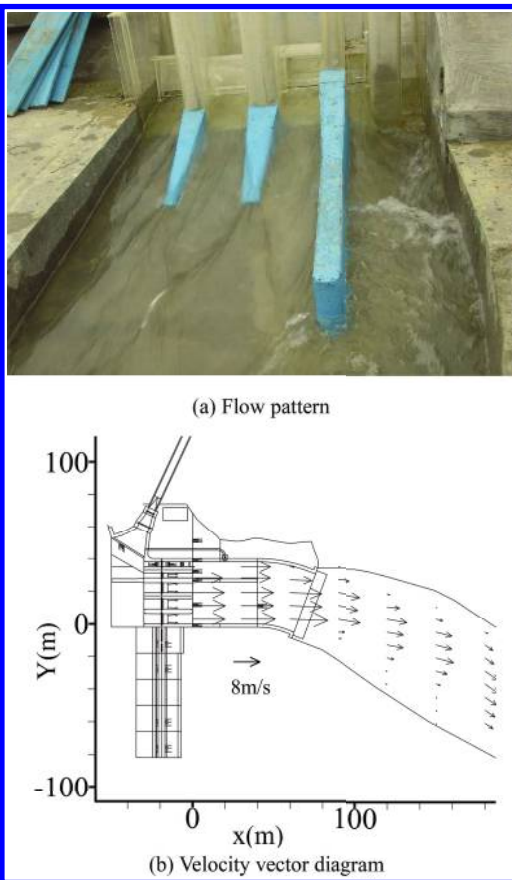

Figure 9. Flow condition at the check flood.

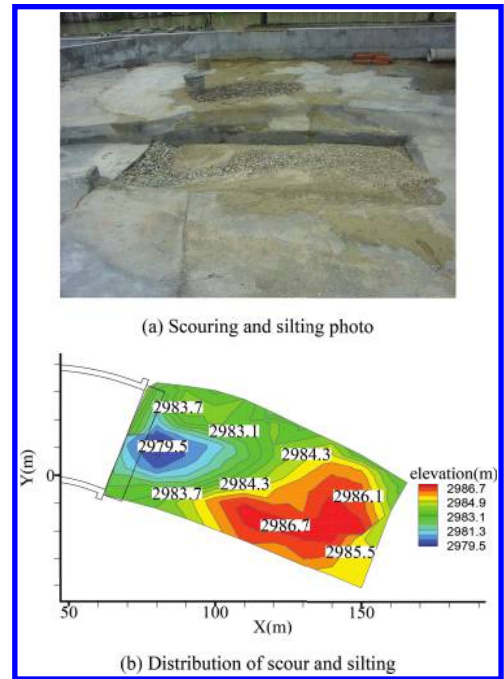

Figure 10. Scour and silting condition at the design flood.

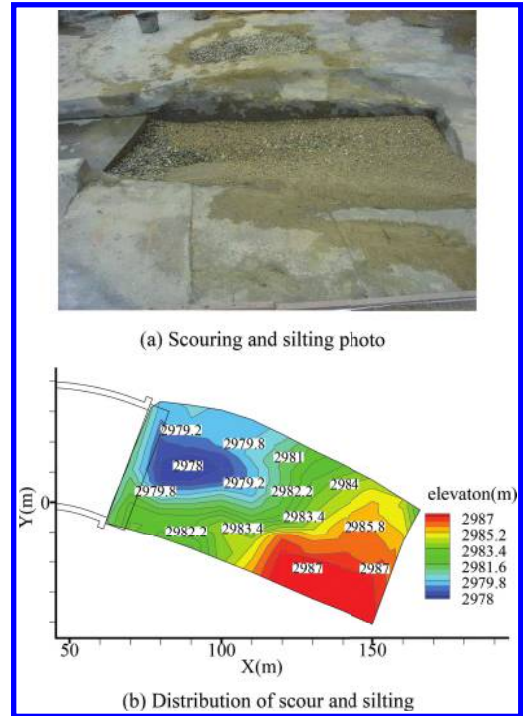

Figure 11. Scour and silting condition at the check flood.

is shown in Figure 11, where the maximal depth of the scour pool is about 7 m near the anti-scour trench.

#### 4 CONCLUSION

There are no vertical vortex and other disadvantages near the water intake after shape optimization. The sediment will not enter the water intake under different working conditions, which shows that the shape modification is effective. The magnitude of the scouring sluice and release sluices can satisfy the requirement of the draining flood. The arc-shaped guide wall makes the flow pattern smoother. The scouring sluice operating together with the release sluice will achieve better results for the sediment transport capacity. Protective measures should be made to ensure the safety of the downstream bed. The results obtained in this paper are also suitable for the similar project, which can provide an important reference for the hydraulic engineering.

# Discussion on the development of remediation technology in Chinese metropolitan large mountainous river bank protection

Wei Guo, Juan Dai, Yinjun Zhou & Yue Zeng  
*Changjiang River Scientific Research Institute, Wuhan, China*

**ABSTRACT:** Taking the developing process of flood prevention and bank protection projects of the Yangtze River and Jialing River in Chongqing City for example, this paper conducts a summary and evaluation on the flood prevention comprehensive treatment technology of city stream segment part of Chinese large-scale mountainous river. A conclusion could be made that the concept of building a harmonious relationship between humans and water as well as the ecological bank protection treatment technology have become an inevitable tendency of present dike project technology development. The treatment concept oriented to the flood prevention treatment of city stream segment part of Chinese large-scale mountainous river has gradually changed from a single flood prevention project into a multi-objective one. Moreover, the treatment technology has also changed from the traditional project technology to ecological and natural bank protection technologies. However, the pure natural bank protection is usually applied to the recent middle and small river treatment at present, and for large rivers, the engineering natural bank protection technology is often adopted.

**Keywords:** mountainous river; flood prevention and bank protection; the harmonious relationship between human and water; natural ecology

## 1 INTRODUCTION

Just as its name implies, metropolitan large-scale mountainous river has three characteristics, namely, mountainous river has a high water level difference, the flood rises and drops very rapidly, the water contains a large number of sand and could have a big impact on the river band, so it has a high disaster-causing capacity, so the river has a high requirement on the reliability of flood control project. Second, it refers to the large-scale river: large rivers usually play a strategic role in the national flood prevention system, as its flood control is closely related to national economy and social influences, so it has a higher flood control standard. Third, these rivers belong to metropolitan rivers, so they play important roles in water supply, green land maintenance, environmental protection, resource protection, entertainment, transportation and cultural education. Moreover, its comprehensive function is also needed for the flood control project.

It can be seen that the metropolitan large-scale mountainous river revetment shall taken strong reliability, high flood control standard and comprehensive functions into consideration. Especially for some ecological problems about the rivers, advanced countries, such as Switzerland and

Germany, have subsequently proposed some ecological technologies in slope protection. In the late 1980s, a “natural bank protection” technology<sup>[1]</sup> was proposed. In the early 1990s, Japan proposed a vegetation-growing eco-concrete technology<sup>[2]</sup>; the watercourses nearby the cities along the Rhine River adopted movable embankment, which increased the hydrophilia of people<sup>[3]</sup>. For a long time, the metropolitan large-scale mountainous river bank protection project has been mainly developed based on the above-mentioned multiple objective mission. Now, taking Chongqing City as an example, we analyzed this issue from two aspects, namely, design idea and flood control technology.

## 2 CHANGES OF MANAGEMENT IDEA

The central downtown river in Chongqing locates in the junction of the Yangtze River and Jialing River, which is a mountainous river on the upstream of the Yangtze River. The gradient between the riverbed and the river is large, the river runs fasts, and under the influences of flooding water on both rivers, the flood control project has become very necessary in recent years. The management idea has gone through four stages, which are as follows:

1. Negative treatment: because of the special topographic condition and geographical conditions in the central downtown of Chongqing, and the limitation of economic conditions at that time, the central downtown of Chongqing has been lacking dike for a long time after the foundation of China. It keeps a negative attitude towards the flood control, that is, "retreat while the flooding comes, and moves forward while the flooding shrinks." But with the economic development and urban expansion increasing, the number of buildings and industries are set up along the river, so the damage and losses that flood disaster has on the nearby areas increases. For example, the worst flood in 50 years that occurred in July 1981 flooded wide areas, cities and villages along the Yangtze River and Jialing River, 130,000 people were affected by the disaster; as a result, houses collapsed, traffic stopped, water supply and power supply was interrupted, which brought a huge loss to the life and property of China and its citizens.
2. Basically meeting the demands for flood control and support transportation: in 1988, Yuzhong, Chongqing carried out the project that combined waterfront protection with the embankment project (Changbing road; full length 5.1 km), which symbolizes that the embankment project in the central downtown areas starts, but the flood control standard is still unclear. The construction of the project aimed to connect the transportation and control flood disaster. Afterwards, the flood control project from the right bank of Jialing River in Yuzhong District to Qiansimen Reach (full length 4.5 km) was started; in Nanan District, it was from the Shibampo bridge on the right bank of the Yangtze River to Shuibingying (the full length is 7.5 km) and the project from the Yudong Yangtze River bridge on Banan district to the estuary of the Jiantan River (full length 5.0 km). In 1997, Chongqing government released a report about the urban flood control project, and in 1998, Regulations on Flood Control of Rivers in Chongqing were passed, which offered basic references for the planning, implementation and management of the urban flood control project.
3. The specific flood control standard, transportation and urban environment are considered in the project construction. With the rapid development of urban construction, the effect of water conservancy project that was constructed on the upstream of the Yangtze River and that of the three gorges project on the central zone on the flood level of central downtown were considered. In 2007, Chongqing water conservancy bureau adapted the urban flood control plan, which was approved by Chongqing government. This program confirmed the flood control standard and designed the flood control level in a specific manner. However, at that time, Chongqing was in a rapid development period, so it had high requirement on land and transportation. As the flood prevention and bank protection reached the flood control standard, it occupied a large area of watercourse and capacity of reservoir, for instance, the fifth phase of the project on the Nanbing Road of Nanan District (3.96 km, occupying 1.234 million m<sup>3</sup> capacity of reservoir) and the comprehensive regulation project (5.3 km, occupying 1.13 million m<sup>3</sup>) from the Huanghuayuan Bridge to the Dafosi Bridge. It is worth pointing out that according to the confirmed flood control standard and designed flood level after confirmation, there is a 12 km substandard engineering section in the constructed embankment, including 7 km of the first phase project in Nanan District and the section from the Caiyuan Dam, Changbin Road to 5 K of the Yangtze River Bridge.
4. Comprehensive improvement on bank-protection projects for multiple objectives: with the development of urban cities, relevant departments have come up with new requirements on the bank protection project<sup>[4]</sup>, which not only has to meet the demand for flood control and transportation, but also needs to reflect the project functions as landscape greening and its hydrophilic nature. Meanwhile, the reservoir management of the three gorges project shall be strengthened, so as to avoid the occurrence of occupying the reservoir capacity. Therefore, in the project design, factors such as flood control, transportation, bank protection, urban construction, riverside greening and hydrophilic nature are considered. Moreover, the flow pattern of stored water in the three gorges reservoir, the reduction of excavation and filling in project have also been taken into consideration, so as to make the construction easier. Levee alignment has been combined with the water regime of the Yangtze River in the project and the demand of municipal construction, so the project stresses on the flood discharge and the smooth of flow line. For instance, the 3.12 km distance between Foeryan on Banan District and Yudongche Wharf and the 10.2 km comprehensive improvement project for flood prevention of Nanping Dike, Maliuzui Town of Banan district; all these projects have not occupied the reservoir capacity of the three gorges reservoir, and have created a leisure area with a strong hydrophilic nature.

### 3 ADVANCEMENT IN THE FLOOD CONTROL TECHNOLOGY

#### 3.1 Traditional river bank regulation

China has a long history in river regulation. According to the historical records, in early 28 BC, baskets weaved by willow branch and baboons were used to reinforce the river bank and channels with stones in it. To sum up, the traditional bank protection technology can be divided into slope revetment and wall revetment, where slope revetment can be further classified into loose-stone revetment, cement rubble revetment, precast concrete plank bank revetment and cast-in-situ concrete protection. Generally, these are paved on the bank slope and levee foot and formed subsequent overlay protection, which have a little effect on the riverbed boundary condition and near-shore currents and have good adaptability to the soil foundation. There are three types of retaining walls in wall revetment, namely, gravity retaining wall, anchored retaining wall and thin-wall retaining wall. These retaining walls are usually set up in important river reaches with narrow water area and no bunds. They have the advantages of little section and small land occupation. The traditional river bank regulation technologies have achieved certain outcomes until now, and also are important forms in the large-scale river flood control projects in Chongqing, but the traditional river regulation projects have cut off the interactive channels between water and soil, broken the connection between water and soil, and brought many negative effects on the ecological environment. Therefore, to develop a new river protection project with new theories, materials and technologies have become the main tasks for hydraulic engineers.

#### 3.2 New methods for revetment projects

Ecological riverbank is the latest river bank protection method. It can be divided into three types, namely, nature bank protection, natural bank protection and engineering natural bank protection<sup>[5]</sup>.

Figure 1. Nature bank protection.

The former one uses building materials and soil vegetation in bank protection. The natural bank protection usually applies building materials to river bottom protection and uses soil vegetation for slope protection. Engineering natural protection uses soil vegetation for both river bottom

Figure 2. Natural bank protection.

Figure 3. Engineering natural bank protection.

Figure 4. Cylinder mold bank protection.

Figure 5. Conceptual graphs for ecological concrete.

protection and slope protection, and it prevents the flood shock with the soil fixation of certain plants. Obviously, the ecological management of three ecological riverbanks is being strengthened in sequence, while the structural intensity is basically becoming weaker in sequence. Therefore, pure natural bank protection is used for middle and small rivers in the plain terrain, and natural bank protection is used for large rivers in the plain terrain, while the new type of bank protection applied for large mountainous rivers is usually the engineering natural bank protection.

The studies and practices of bank protection projects of large rivers shall be started from two aspects: first, fix the stone or rubble with reseau or mesh cage to strengthen the bank and resist the flood impact, which has good air and moisture permeability and does not affect the water exchange and its ecological function. Second, new materials such as ecological concrete or cement planting material are used. These new materials have not only the intensity of traditional building materials, but also a similar ecological function of natural soil. Here, the former one refers to gabion box, gabion mesh, reno mattress, sack gabion and geotechnical net, which have integrality and flexibility, and natural vegetation can be planted on it, and the ecological environment and landscape can be improved. At present, these types of cylinder mold heel block have been put into standardized commercial production, and currently they have been widely used in all places of China, including western provinces such as Chongqing and Sichuan<sup>[6]</sup>; the latter one mainly includes cement ecological planting material, vegetation type eco-concrete<sup>[7]</sup> and soil stabilizer<sup>[8]</sup>. Most of them are introduced from foreign countries, which has strong intensity, and could meet the requirement for ecological bank protection. At present, this method has been used in many typical embankment segments and urban rivers.

Besides, there are three new technologies in bank protection, namely, concrete permeable frame of

tetrahedron with six sides, planting grass seed with waterpower and net mold water draining engineering for bank protection. The technology of concrete permeable frame of tetrahedron with six sides was developed and improved by Northwest A&F University and Hehai University, because of its good performance and impact resistance, so it has been widely applied to the regulation of large rivers. As for planting grass seed with waterpower technology, grass seed, pulp, adhesive, fertilizer and water are added into the grass spraying water tank, and then they are spread on the slope segment for grass protection. Under proper conditions, those grass seeds will sprout and result in greening and prevention of water and soil loss<sup>[9]</sup>. It is mainly used to improve the appearance of water conservancy project, so it has been used in the reconstruction and beautification of traditional water conservancy project, including the early embankment and dam project. Geotextile and grait has been used in the net mold water draining engineering for bank protection, and this technology is one of the geotextile mattresses, which belongs to the eco-type bank protection and can be used in the slope protection of river regulation. It has been applied to the river regulation of the Jinjiang River that has large river-bed deformation, and has been selected into the advanced practical technologies.

#### 4 RIVER REGULATION IDEA AND TENDENCY OF ITS TECHNOLOGICAL DEVELOPMENT

The urban river reaches of large urban rivers not only have their natural functions, but also undertake some social functions, such as urban flood control, municipal transportation, landscape, water culture and water recreation<sup>[10]</sup>, so the idea of river regulation gradually presented its comprehensiveness, and the river regulation has multiple objectives, the river regulation project must meet the demands of

Table 1. Idea development of large river improvement in Chongqing.

Idea	Requirements	Finished time	Typical projects
Negative coping	—	Before 1988	—
Flood control-centered and also involved with transportation factors	Certain flood control function and structural strength	1988–1997	Changbin Road, Yuzhong District
Meet the standard of flood control, protect the transportation and urban environment	Meet flood control and hydrophilia requirements	1997–2007	The fifth phase project of Nanbing Road, Nanan District
Comprehensive improvement for multiple objectives	Flood control, transportation, urban environment, hydrophilia, nature, meet the management requirement in the Three Gorges Reservoir Region	Recent years	Foeryan, Banan District to Yudongchedu Wharf

Table 2. Basic types of bank protection technologies.

Types	Traditional bank protections	New kind of bank protections
Types	Slope protection	Engineering natural bank protection
Typical types	Loose-stone, grouted rubble, precast concrete plank	Cylinder mold structure and new materials such as heel block and eco-concrete
	Wall revetment	Natural bank protection
	Gravity type, anchored type, Thin-walled type	Common building materials in river bottom protection + soil vegetation in slope protection
Analysis of characteristics and adaptability	No special requirement to foundation, and have strong adaptability; large space occupation; interrupted the soil and land connection between the river and the bank slope	Retain the soil and water connection along the riverbank; strong flexibility and anti-resistance; can be applied to large river regulation
	Have high requirement to foundation; small space occupation, adaptable to narrow river; interrupted the soil and water connection between the river and the bank slope, and poor hydrophilicity	Retain the soil and water connection along the riverbank; the anti-impact mainly depends on the soil reinforcement of plants; applied to small and middle river regulation
		Nature river bank, adaptable to the river regulation in the plain terrain

multiple departments of national economy and try to realize the eco-regulation, remain or optimize the natural function of river itself. Meanwhile, the flood control project of big urban rivers usually requires larger investment, so its construction also requires achieving certain economic benefits, to bring forward the rapid development of surrounding economy by reaching the flood control standard, stabilizing bank slope, improving transportation function, greening and beautifying the areas along the river, so as to solve the flood control problem with less national investment, change the environment of the construction area, improve the image of urban cities, and create considerable economic benefits, which is an important index for the feasibility assessment on a large embankment project.

At present, there are some basic problems that exist. In most large mountainous rivers, the road-embankment integrated method has been used in the construction of flood control and bank protection project. Based on the current standards, it shall be designed with a high flood control standard, while the natural development of urban cities exists nearby water, so embankment shall be constructed along the outside waterside area, so these are the protective objectives. In these places, embankments and roads are obviously higher than the land elevation in the rear area, so waterlogging occurs very frequently in the rainy season. Meanwhile, most embankment projects in the metropolis have been constructed for many years, so the standard and construction technology are different; as a result, the early embankment is a substandard, and a wooden barrel effect occurs in the entire flood control project.

For the idea of man-water harmony, eco-bank protection technology is an inevitable tendency for the development of embankment engineering project, and new materials and technologies will be more widely used in the regulation of middle and small rivers, but are not used in large river regulations, so the application and promotion of new technologies and materials shall be quickened, but problems related to cost and reliability shall be considered. In terms of the flood control and bank protection projects in the Yangtze River and Jialing River in Chongqing, engineering natural bank protection technology has been used very frequently, but pure natural bank protection is hardly adopted, so it is necessary to introduce both ideas and technologies to realize river regulations naturally with multiple objectives.

## 5 CONCLUSIONS

Development situations: for the flood control project of large-scale mountainous river nearby cities, the flood control concept gradually developed

from a singular flood control project into a multi-objective project, including transportation, landscape, ecology and cultural construction. The flood control technology already changed from the traditional engineering technology to ecotype and natural-type bank protection technologies.

Existing deficiencies and differences: there are conflicts between multi-objective projects and economic benefits. The multiple-objective task usually requires higher costs, so its implementation usually is restricted by the evaluation of economic benefits; and the nature-type bank protection is mainly used in the management of medium or small rivers, while large rivers have higher requirements to ensure the reliability of projects, but nature-type bank protection technology has been widely applied in the river regulation in China.

Development tendency: human-water harmony theory and ecotype revetment regulation technologies are the inevitable tendency for the development of embankment engineering, so a human-water harmonious relationship is a must tendency in river regulation in the future. As the ecotype revetment technology becomes more mature, the cost will reduce, while its reliability and adaptability may increase. The flood control project of large mountainous rivers in urban areas will be applied more widely.

## In-situ measurement study on stress of frozen inclined shaft lining crossing water-rich sand stratum

Jianxi Ren & Jielong Sun

*Xi'an University of Science and Technology, Xi'an, China*

**ABSTRACT:** There is no nature theory or method to design and construct the frozen inclined shaft lining in water-rich sand stratum. In order to solve this problem, the paper used in-situ measurement to study the stress of frozen inclined shaft lining crossing water-rich sand stratum. The results show that the force of frozen inclined shaft lining can be divided into three stages of change: Slow increase stage, rapid increase stage, and stable stage, the vertical steel bars of inner shaft lining mainly bearing tensile stress and the maximum tensile stress is 13.8 MPa, the circular steel bars bearing tensile stress fist and then turn to compression and the maximum compressive stress is 35.06 MPa, which is far less than the limit of eastern alluvium, the frozen inclined shaft lining is too thick which can increase the construction cost; therefore, the design and construction of frozen inclined shaft lining crossing water-rich sand stratum needs to be optimized.

**Keywords:** water-rich sand stratum; frozen inclined shaft; shaft lining stress; temperature; in-situ measurement

### 1 INTRODUCTION

The study on frozen shaft has already achieved significant achievement in eastern alluvium (e.g., Yang et al, 2010, review and prospects of research on freezing design theory of coal mine shaft; Wang et al, 2007, in-situ measurement on the stress of reinforcing steel bar of outer freezing shaft wall in deep alluvium; Xi et al, 2014, in-situ measurement study on stress and temperature of frozen outer Shaft lining in western cretaceous strata). But there are few studies in western water-rich sand stratum especially for the frozen inclined shaft. The theory and method for frozen inclined shaft lining is not mature and most design and construction were based on the experience of frozen shaft. And the different regions and shaft arrangement will lead to a thick shaft, high temperature stress, and so on (Fan et al, 2013, construction technology of freeze sinking method in inclined shaft soil layer; Liu et al, 2012, study on temperature field distribution law of freezing wall for inclined shaft). The paper will use in-situ measurement to study the stress mechanism of frozen inclined shaft, analysis of the stress of vertical and circular steel bars of inner shaft lining and provide the basis for frozen inclined shaft in western.

### 2 ENGINEERING SITUATION FAVOR

The coal mine is located at 20 km of Yulin City, Shaanxi Province. The design production of coal mine is 8 million tons a year. The length of main

inclined shaft is 1303.3 m, the inclination is  $14^\circ$ , the section area is  $16.3 \text{ m}^2$ , the width is 5.0 m, the vertical wall is 1.25 m, and the arch is 2.5 m. The horizontal distance from frozen position to the wellhead is 80.215 m, the inclined length of frozen shaft is 377 m, the horizontal length of frozen shaft is 365.8 m, and the vertical depth is range from 20 m to 111.208 m.

The pumping test results show that the inflow of water is  $1250 \text{ m}^3/\text{h}$ . Use multi-row freeze-tubes method to sinking shaft. The number of freeze-tubes is five and the distance is 2.35 m. The design thickness of shafts roof is 6.0 m, the roadway is 3.0, and the floor is 5.0 m. Figure 1 is the profile of freezing hole.

Figure 1. Profile of freezing hole.

Figure 2. Schematic diagram of test point arrangement.

### 3 MEASURE SCHEME OF SHAFT LINING FORCE

The monitoring contents are freezing pressure, the stress of vertical and circular steel bars of inner shaft lining, and the temperature of shaft. The VWL Load-meter is used to monitor the freezing pressure, which can monitor the temperature of frozen shaft. The VWR Stress-meter is used to monitor the stress of steel bars. Fixed the load meter and stress meter when the shaft tunneling to the monitoring section.

The distance from monitoring section to well-head is 259 m and the vertical depth is 62.7 m. Install one load meter at shaft roof, arching, and floor. Install one stress meter at the inner steel bars of shaft roof and the outer steel bars of arching and shaft floor. Figure 2 is the schematic diagram of test point arrangement.

### 4 CHARACTERISTICS OF SHAFT LINING FORCE

#### 4.1 Analysis of freezing pressure

Figure 3 is the measured curve of freezing pressure, from the curve we can see that the range of freezing pressure is 30.69–696.87 KPa.

The Figure 3 shows that the frozen inclined shaft lining can be divided into three stages of change: Slow increase stage, rapid increase stage, and stable stage. Slow increase stage: in this stage the freeze wall can be regarded as  $t$ , which can bear the water and earth pressures with shaft. The increased shaft is caused by the frozen wall refrozen. Rapid stage: the frozen wall begin melt after monitoring 52 days, which lead to the force acting on the shaft rapid increase. At this time, the force of the frozen wall beard is reduced. Stable stage: when the monitoring carried out to 200 days, the frozen wall melted completely and the force acting on the shaft became stable.

Figure 3. Measured curve of freezing pressure.

In addition, the force acting on the right shaft is lower than the left and roof before thawing, but the force acting on the right shaft rapid increases after thawing and transcendence the left and roof, which is due to the rock and soil anisotropic, freezing temperatures and frozen brine pipe deflection, and so on.

#### 4.2 Force analysis of the vertical steel bars

Figure 4 is the measured curve of the vertical steel bars and the maximum tensile stress is 13.8 MPa, which is far less than the limit of eastern alluvium 300 MPa, and the results shows the shaft is safe.

The Figure 4 shows that the mainly bearing tensile stress and the tensile experienced four stages. First, rapid increase stage: because concrete hydration heat the temperature of inner shaft increased rapidly, the compressive stress of vertical steel bars of inner shaft lining is  $-0.8$ – $3.4$  MPa and turn to tensile stress in 1–8 days then increased rapidly. Second, slow reduce stage: force acting on the shaft is reduced but the force acting on the frozen wall is increased, which has been caused by the refreezing of frozen wall. Third, stable stage: in this stage the refreezing of the frozen wall is complete; the pressure acting on the wall remains stable (the stress of a certain range). Last, slow increase stage: in conjunction with Figure 3 we can see that the frozen wall begins to melt; the force acting on the shaft increases gradually, which leads to the vertical steel bars stress increase.

#### 4.3 Force analysis of the circular steel bars

Figure 5 is the measured curve of the circular steel bars and the maximum tensile stress is 35.06 MPa, which is also less than the limit of eastern alluvium.

The Figure 5 shows that the circular steel bars bear tensile stress at the beginning of monitoring, which is caused by the concrete hydration heat and with the gradual reduction of temperature turn to compressive stress. The changes above all are

Figure 4. Measured curve of the vertical steel bars.

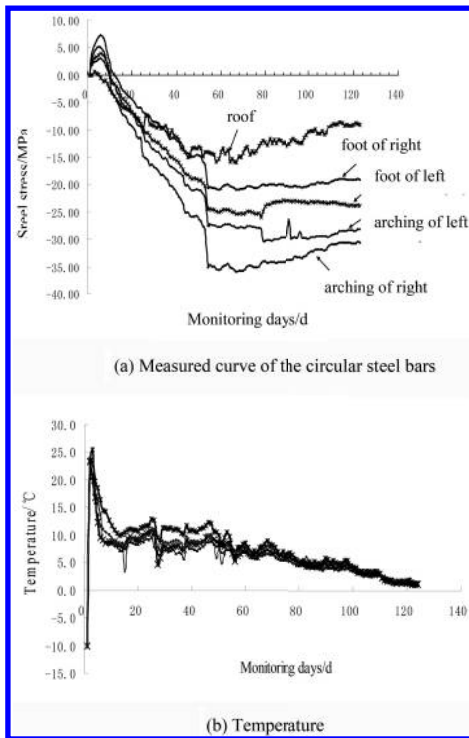

Figure 5. Measured curve of the circular steel bars.

caused by the force acting on the shaft and frozen wall refrozen. When the monitoring carried out to 52 days, the stress suddenly increases. In conjunction with Figure 3, the frozen wall began melting while it was being monitored to 52 days, which lead to the force increase that acting at shaft, also cause the mutations of circular stress. With the melt of frozen wall, the force acting on the shaft and the stress of circular steel became stable.

## 5 CONCLUSIONS

1. The maximum pressure of frozen inclined shaft lining is 696.87 KPa, which is far less than the limit of eastern alluvium; the force frozen inclined shaft lining can be divided into three stages of change: Slow increase stage, rapid increase stage, and stable stage; the pressure acting on the shaft lining is closely related to the melting of the frozen wall; the greater rate of the frozen wall, the greater rate of the pressure increase; when the frozen wall melt completely the pressure tends to be stable.
2. The vertical steel bars of inner shaft lining mainly bearing tensile stress and the maximum tensile stress is 13.8 MPa; the tensile stress can be divided into four stages of change: rapid increase stage, slow reduce stage, stable stage, and slow increase stage. The circular steel bars tensile stress first and then turn to compression and the maximum compressive stress is 35.06 MPa, which is far less than the limit of eastern alluvium.
3. The stress of steel bars and frozen pressure are less, the frozen inclined shaft lining is too thick which can increase the construction cost; therefore, the design and construction of frozen inclined shaft lining crossing water-rich sand stratum needs to be optimized.

# Numerical study on effect of opening ratio for flow field of artificial reefs based on VOF model

RuiJin Zhang, Man Tao, JinMei Zhou, XueZhi Huang & Peng Lian

College of Marine Technology and Environment, Dalian Ocean University, Dalian, China

**ABSTRACT:** Six artificial reefs in which opening ratio differs from 0 to 0.5 have been numerically simulated to study the effect of the opening ratio for flow field of artificial reefs through the establishment of VOF model. Results show that the maximum velocity of the upwelling current decreases with the increasing opening ratio, and the reefs with larger opening ratio (0.5) produce two vortexes and reefs back at the bottom of the eddy current level (span increases with openings than a declining trend).

**Keywords:** VOF; opening ratio; flow field effect of artificial reefs

## 1 INTRODUCTION

Artificial reefs mainly aim to prolife rate fishery resources through its surrounding ecological flow field effect. Therefore, the study of flow field effect of artificial reefs is of great significance. Flume experiments and numerical simulation are the main research methods that people study the flow field effect of artificial reefs. Comparing with physical model experiments, numerical simulation study of complex single-phase or multiphase flow is more convenient. It also saves the experimental consumption expenditure. It is the major development trend of the future.

Jun et al. (2010)<sup>[1]</sup> applied numerical simulation to flow field of m-shaped artificial reefs and compared with the result of the flume experiment. Yanxuan et al. (2014)<sup>[2]</sup> used three stacking kinds of artificial reefs pipe to do flume experiments and the simulation results were compared. Hyunkyounq et al. (2003)<sup>[3]</sup> contrasted the model results and numerical simulation results in three different sizes of reefs surrounding the flow field. In the process of numerical simulation, both the upper boundary and lateral boundary adopted the symmetrical boundary condition. At present, there is no related literature of establishing a VOF model for numerical simulation of artificial reefs flow field effect. We have to make numerical simulation experiment situation more real. This paper used the VOF model to define water flow field boundary of free surface, numerically simulated the flow field surrounding different opening size cube of artificial reefs and discussed the effects of opening ratio. It also considered the effect of tank wall friction at the same time, making the numerical simulation closer to the actual working condition.

## 2 NUMERICAL SIMULATION

### 2.1 Governing equations<sup>[4]</sup>

The governing equations include the continuous equation and the momentum equations in which the fluid is assumed to be incompressible:

1. continuous equation:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0 \quad (1)$$

2. momentum conservation equation:

$$\begin{aligned} \frac{\partial(\rho u)}{\partial t} + \text{div}(\rho u \vec{u}) &= \text{div}(\mu \text{grad} u) - \frac{\partial p}{\partial x} + S_u \\ \frac{\partial(\rho v)}{\partial t} + \text{div}(\rho v \vec{u}) &= \text{div}(\mu \text{grad} v) - \frac{\partial p}{\partial y} + S_v \\ \frac{\partial(\rho w)}{\partial t} + \text{div}(\rho w \vec{u}) &= \text{div}(\mu \text{grad} w) - \frac{\partial p}{\partial z} + S_w \end{aligned} \quad (2)$$

In the equations,  $u$ ,  $v$  and  $w$  are the velocity in the  $X$ ,  $Y$ , and  $Z$  direction, respectively. Also,  $t$  is the time,  $\rho$  is the density of fluid,  $\vec{u}$  is the vector of velocity,  $\mu$  is the dynamic viscosity,  $p$  is the pressure,  $S_u$ ,  $S_v$  and  $S_w$  are the generalized source terms of the equation to the momentum conservation.

### 2.2 The calculation region

Numerical calculation has been performed by simulating the actual experiment flume. The size of calculation area was set according to the circumstance of flume experiment. A tank with 160 cm long, 60 cm and 45 cm wide was simulated with 40 cm water depth. Cubes of artificial reefs with different

Figure 1. Model of six artificial reefs.

openings which size is  $10\text{ cm} \times 10\text{ cm} \times 10\text{ cm}$  were put in the bank. And the inlet of velocity is  $18\text{ cm/s}$ .

In order to study the influence of opening of the artificial reefs, a parameter: opening ratio ( $r$ ) is set to be the ratio of opening size and reefs' length. Six cubes whose opening ratio differs from 0 to 0.5 have been numerically simulated. If  $r$  is 0, the reef turns to be a cube.

### 2.3 The VOF model

Choose the steady-state solver in this experiment, set up two-phase flow model of air and water, and open the channel flow. Select RING  $k$ -epsilon turbulence model, call up the physical parameters of water, and set the air for the primary-phase, water for the second phase. Reference point of pressure set in the area of the air and gravity is along the  $z$ -axis direction. Water inlet boundary is defined as the velocity-inlet, with water velocity of  $18\text{ cm/s}$ , air inlet is defined as pressure-inlet, water's volume fraction in the multiphase is 0 from the air-inlet, water's volume fraction in the multiphase is 1 from the water-inlet. The out of the water and air are all pressure-outlet, need to set the out-of-water condition, open the channel from the multiphase of the water-out, and calibrate the level of the free surface. Suppose the reefs body model and the bottom and side of sink as wall. The friction coefficient is 0.5. Set flow field boundary to free surface and suppose above the sink as pressure outlet boundary conditions.

## 3 ANALYSIS AND DISCUSSION OF THE RESULTS OF NUMERICAL SIMULATION

The main flow field effects caused by artificial reefs are the upwelling current in front of the reefs and the reverse vortex flow backward. The upwelling

Figure 2(a). Contour map of upward velocity ( $r = 0$ ).

Figure 2(b). Contour map of upward velocity ( $r = 0.1$ ).

Figure 2(c). Contour map of upward velocity ( $r = 0.2$ ).

Figure 2(d). Contour map of upward velocity ( $r = 0.3$ ).

Figure 2(e). Contour map of upward velocity ( $r = 0.4$ ).

Figure 2(f). Contour map of upward velocity ( $r = 0.5$ ).

current could promote the nutrients to flow from the up and low and the reverse vortex could create a lower speed area for fish to inhabit. Opening of the artificial reefs would change the flow around the artificial reefs, resulting in changing the region of the upward and reverse vortex around the artificial reefs. Therefore, the opening ratio is an important impact factor for the flow of the artificial reefs. Here, the upward flow is defined when the Z direction velocity component ahead and above the reefs is greater than 10% of flow velocity<sup>[5]</sup>.

The distribution of upwelling current differs with the changes in opening ratios. When the opening ratio reaches a certain degree, two obvious vortexes appear in the back of the artificial reef. The upwelling current horizontally increases with the increase in opening ratios, but the reverse vortex flow gradually disappears. The distribution of upwelling current and reverse vortex are shown in Figure 2.

The paper mainly focuses on the changing trend of the maximum velocity of the upwelling current in the front part of the reefs and the width of reverse vortex current with the changing of the opening ratios. The maximum velocity of the upwelling current turns to be the maximum speed among the vertical direction in the area. There appear two vortexes right behind the reefs body while the reefs are open. And fish are more likely to gather in the lower part of vortexes, which explains the value of reverse vortex current to be the level of the largest span of the back of reefs in this paper. Figure 3 shows the maximum velocity of the upwelling current for different opening ratios. The maximum velocity of the upwelling current reduces with the increasing opening ratios.

Figure 3. Change of maximum velocity of the upwelling current for different opening ratios.

Figure 4. Change of width of the reverse vortex for different opening ratios.

When  $r$  is 0, the maximum upwelling current is the biggest, i.e. 16.47 cm/s, which is 91.5% of the inlet velocity. Figure 4 shows the width of the reverse vortex for different opening ratios. When  $r$  is 0, vortices are obvious behind the reefs, the level of the largest span of the reverse vortex current takes 18.96 cm. The width of the reverse vortex current reduces with the increasing opening ratios, but a turning point occurred when  $r$  is 0.2. The results of the experiment are consistent with the results of Dongwei et al. (2012)<sup>[6]</sup>, which turns out to be that the upwelling maximum speed and the width of reverse vortex current reduce with the increasing opening ratios.

#### 4 CONCLUSION

Six artificial reefs whose opening ratio differs from 0 to 0.5 have been numerically simulated to study the effect of the opening ratio for flow field of artificial reefs through the establishment of VOF model. It could be concluded that: (1) When the opening ratio increases from 0 to 0.5, the maximum velocity of the upwelling current decreases. When the opening ratio is 0, the maximum velocity of the upwelling current can be 91.5% of the inlet velocity. (2) When the reefs are opening, there will be two vortices right behind the reefs' body.

Through the increasing process of the opening size, the width of the reverse vortex current tends to decrease, but there is a small turning point when  $r$  is 0.2. When the opening ratio is 0, the upwelling current and reverse vortex are better than the others, but it has less area for fish to inhabit. The maximum velocity of the upwelling current and the width of the reverse vortex are not the only two factors to be concerned in designing artificial reefs; therefore, in the further work, more factors should be considered to looking for a best opening ratio of the artificial reefs.

# Quantities calculation of truncated cone-shaped metal structural steel funnel

Nan-ming Mo

Infrastructure Construction Department of Kunming University, Kunming, Yunnan, China

Li-ya Wang

Yunnan Provincial Water Conservancy and Hydropower School, Kunming, Yunnan, China

**ABSTRACT:** Regarding it as rectangular, according to the quantities calculation principle of truncated cone-shaped steel structural steel funnel, it derives the universal theoretical calculation formula for steel plate quantities with different central angles with mathematical theory. In this way, it is not only convenient for cost members to calculate steel plate quantities and complement for theoretical knowledge about construction cost, but also provides theoretical basis for metalers to calculate the steel (copper) plate area of transition joint fittings with different sizes like air duct, exhaust hood and chimneys; and creates conditions for construction cost digitalization and quantities calculation with informational software.

## 1 INTRODUCTION

Truncated cone-shaped metal structural steel funnel is widely used in industrial and agricultural production and mankind's daily life, for example, in the joints of steel plate steel funnel, exhaust hood, cylindrical pipeline (water supply, gas supply, drainage pipeline, etc.), metal silo, metal water (oil) tank as well as other equipments and appliances, funnels have forms like circular truncated cone and quadrangular frustum pyramid. In practical construction cost, there is no research literature of quantities calculation formula for the steel plate area of steel funnel for people's full and complete use.

## 2 CALCULATION RULES FOR STEEL FUNNEL QUANTITIES

### 2.1 *The calculation principle for steel funnel quantities as the construction engineering cost valuation basis<sup>[1]</sup> for a province*

First, the quantities calculation principle of "steel structural engineering": the quantities of steel structure manufacturing shall be calculated in tons according to the steel geometry size in the design drawing (including steel plate, profile steel, excluding bolts), the weight of eyelets, cut limbs, and side cuts. The steel plate area shall be calculated as a rectangle, when calculating the area of an irregular or polygonal steel plate, it shall be calculated as the

smallest circumscribed rectangle as shown in the figure.

Second, the steel funnel manufacturing quantities shall be calculated as composed dimensions shown in the figure without deducting the areas of manhole, access hole, and cleaning hole. The profile steel attached to the funnel shall be calculated together with the funnel.

Third, the quantities calculation principle of "component transportation and installation engineering": the steel member shall be calculated in tons according to component figure. The welding structure shall be calculated as quantities plus 1.5% welding line weight, the riveted structure shall be calculated as quantities plus 2% rivet weight.

### 2.2 *The calculation principle of steel funnel quantities for Code of Valuation with Bill Quantity of Construction Works<sup>[2]</sup>*

First, the calculation principle for bill of quantities of "A.6 steel structural engineering" steel funnel (No. 010606010): calculate according to design figure in weight, including the weight of eyelets, side cuts and cut limbs but excluding the weight of welding rods, rivets and bolts, the irregular or polygonal steel plates shall be calculated as external rectangle area  $\times$  thickness  $\times$  theoretical unit mass, the funnel attached to shape steel shall be calculated together with the funnel quantities.

Second, metal faced paint (No. 020505001): shall be calculated by mass according to the dimensions in the design figure.

### 3 CALCULATION OF STEEL PLATE QUANTITIES

It can be known from the above national specification and the price foundation of construction cost of some province that the divisional work item including production, installation, transportation, and paint of metal construction need to use the area or mass of metal face as the measurement unit and quantity of quantities.

The calculation of steel plate area of pyramid-shaped funnel has been researched and described in cost member series textbook of Yunnan construction work including *Constructional Engineering Metering And Ration Application*<sup>[3]</sup>. For quantities calculation of the truncated cone-shaped funnel, there is no discussion or research in textbooks. Even if some materials may include a bit of research, it is only to calculate the volume of truncated cone-shaped funnel from aspect of math or from view of superficial area.

To calculate the metal funnel quantities is to calculate the area or mass of steel plate. Even if it is to calculate the mass, it is that the steel plate area multiplies by the steel plate mass per square meter. And the steel plate mass per square meter is a given datum (which may be got from relevant data) or calculated with the theoretical formula. Therefore, the key to quantities calculation of steel plate funnel is to calculate the steel plate area.

And the area for calculation of the steel funnel quantities is the area of external rectangle rather than the superficial area of metal construction. Therefore, the formula that is to be derived again is to calculate the truncated cone-shaped funnel of different shape, size and height. Different unfolded plane shapes can cause different calculation formulas of rectangle area. These situations have not been researched and described in the present literatures.

The basic condition of truncated area is as follows: truncated cone-shaped funnel is shown in Figure 1, and its unfolded shape is a sector shape shown in Figure 2. The central angle is  $\beta$ .

#### 3.1 Calculation of area of steel plate quantities in case of central angle $\beta$ within $180^\circ$

The central angle of wafer is  $\beta$ , and the bisected angle of wafer is  $\theta$ . In case of  $\beta < 180^\circ$  or  $\theta < 90^\circ$ , the steel funnel of metal structure is as shown in Figure 3. The radius of upper and lower bases is given or calculated according to the given outer arc length and inner arc length.

The upper base radius  $R = \text{outer arc length} / 2\pi$ , lower base radius  $r = \text{inner arc length} / 2\pi$

$$\tan \alpha = \frac{R-r}{H} \text{ is } \alpha = \arctan\left(\frac{R-r}{H}\right)$$

Figure 1.

Figure 2.

Figure 3.

$$l = \sqrt{(R-r)^2 + H^2}$$

$$l' = \frac{r}{\sin \alpha}$$

$$\text{Or } l' = r \times \csc \alpha = \frac{r}{R-r} l$$

$$L = l + l' = \sqrt{(R-r)^2 + H^2} + \frac{r}{\sin \alpha}$$

$$\text{Or } L = \frac{R}{R-r} \sqrt{(R-r)^2 + H^2} = \frac{R}{R-r} l$$

$$\beta = \frac{2\pi R}{L} \times \frac{180^\circ}{\pi} = \frac{360^\circ \times R}{L}$$

$$\text{or } \beta = \frac{360^\circ \times r}{l'} = 360^\circ \sin \alpha$$

$$a = 2(a' + a'') = 2 \left( l \sin \frac{\beta}{2} + l' \sin \frac{\beta}{2} \right) = 2L \sin \frac{\beta}{2}$$

$$b = l + l' - l' \cos \frac{\beta}{2} = L - l' \cos \frac{\beta}{2}$$

The area of steel plate quantities =  $a \times b$

$$= 2L \left( L - l' \cos \frac{\beta}{2} \right) \times \sin \frac{\beta}{2}$$

Example 1: The steel funnel designed by some project is as shown in Figure 4. In case of  $R = 64/2 = 32$  mm,  $r = 30/2 = 15$  mm and  $H = 46$  mm,

$$l = \sqrt{(R-r)^2 + H^2} = \sqrt{(32-15)^2 + 46^2} = 49.0408 \approx 49 \text{ mm}$$

$$l' = \frac{r}{R-r} l = \frac{15}{32-15} \times 49.0408 = 43.2713 \approx 43 \text{ mm}$$

$$L = \frac{R}{R-r} \sqrt{(R-r)^2 + H^2} = \frac{32}{32-15} \sqrt{(32-15)^2 + 46^2} = 92.3121 \approx 92 \text{ mm}$$

$$\begin{aligned} \beta &= \frac{360^\circ \times R}{L} = \frac{360^\circ \times R}{\frac{R}{R-r} \sqrt{(R-r)^2 + H^2}} \\ &= \frac{360^\circ \times (R-r)}{\sqrt{(R-r)^2 + H^2}} = \frac{360^\circ \times (32-15)}{\sqrt{(32-15)^2 + 46^2}} \\ &\approx 124^\circ 47' 39'' \end{aligned}$$

The area of steel plate quantities =

$$\begin{aligned} &2L \left( L - l' \cos \frac{\beta}{2} \right) \sin \frac{\beta}{2} \\ &= 2 \times 0.092 \times \left( 0.092 - 0.043 \times \cos \frac{124^\circ 47' 39''}{2} \right) \\ &\quad \times \sin \frac{124^\circ 47' 39''}{2} \approx 0.0118 \text{ m}^2. \end{aligned}$$

### 3.2 Calculation of area of steel plate quantities in case of central angle $\beta$ beyond $180^\circ$

These are steel funnel of metal structure in case of central angle  $\beta$  of wafer between  $180^\circ \leq \beta < 360^\circ$ .  $180^\circ \leq \beta < 270^\circ$  is shown in Figure 5,  $\beta = 270^\circ$  is

shown in Figure 6, and  $270^\circ \leq \beta < 360^\circ$  is shown in Figure 7. The derived formula is as follows:

$$l' = \frac{r}{\sin \alpha}, \quad l = \sqrt{(R-r)^2 + H^2}$$

By means of the principle of similar triangles, you can get  $H = \frac{l}{l'} \sqrt{l'^2 - r^2}$

$$\theta = \frac{\beta}{2} = \frac{180^\circ}{L} \times R \text{ or } \theta = \frac{\beta}{2} = \frac{180^\circ}{l'} \times r$$

Therefore, length =  $2 \times L$

Width =  $L - L \cos \theta$

The area of steel plate quantities = length  $\times$  width =  $2L^2(1 - \cos \theta)$ .

Figure 4.

Figure 5.

Figure 6.

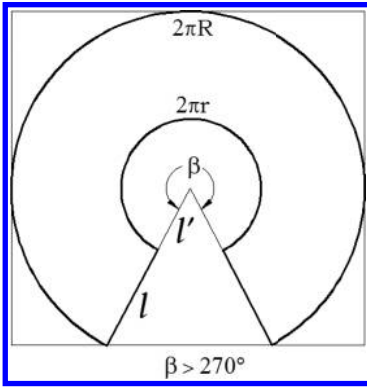

Figure 7.

Example 2: There is a steel funnel:  $l = 50$  mm,  $l' = 40$  mm,  $r = 25$  mm, and  $R = 63$  mm. Please calculate the area of steel plate quantities.

Answer:

$$\theta = \frac{180^\circ}{L} \times R = \frac{180^\circ}{90} \times 63 = 126^\circ$$

$$H = \frac{l}{l'} \sqrt{l'^2 - r^2} = \frac{50}{40} \sqrt{40^2 - 25^2} \\ = 39.03124 \approx 39 \text{ mm}$$

$$\text{Length} = 2 \times L = 2 \times (l + l') = 180 \text{ mm}$$

$$\text{Width} = L - L \cos \theta = 90 - 90 \cos 126^\circ = 142.90067 \approx 143 \text{ mm}$$

$$\text{The area of steel plate quantities} = 0.180 \times 0.143 = 0.0257 \text{ m}^2.$$

### 3.3 Calculate the area of steel plate quantities according to the diameters of upper and lower bases of steel funnel

If the diameters of upper and lower bases of steel funnel are given, the calculation method of area of steel plate quantities are as follows:

$$\tan \alpha = \left( \frac{D-d}{2} \right) / H$$

$$\alpha = \arctan \frac{D-d}{2H}$$

$$\frac{\beta \times 2\pi L}{360^\circ} = \pi D$$

$$\frac{\beta \times 2\pi l'}{360^\circ} = \pi d$$

$$(1)-(2): \frac{\beta \times 2\pi(L-l')}{360^\circ} = \pi(D-d)$$

$$\text{Namely } \beta = \frac{180^\circ \times (D-d)}{L-l'}$$

$$\text{And } L-l' = \sqrt{\left( \frac{D-d}{2} \right)^2 + H^2}$$

$$\text{Therefore, } \beta = \frac{180^\circ \times (D-d) \times 2}{\sqrt{(D-d)^2 + 4H^2}} \\ = \frac{D-d}{\sqrt{(D-d)^2 + 4H^2}} \times 360^\circ$$

According to this  $\beta$  value, the calculation types of steel plate quantities can be determined in case of  $\beta < 180^\circ$  and  $\beta > 180^\circ$ , as described above.

Then it is calculated from Formula (1) that  $L = \frac{180^\circ D}{\beta}$

Then it is calculated from Formula (2) that  $l' = \frac{180^\circ d}{\beta}$

Therefore, the length, width and area of steel plate quantities shall be calculated from  $\beta$ ,  $L$  and  $l'$ , which is not described here.

## 4 CONCLUSION

The following conclusions can be resulted from the analysis and discussion on quantities area calculation of the truncated cone-shaped funnel:

Conclusion 1: For the truncated cone-shaped funnel, a kind of method shall be chosen to calculate the quantities area of steel plate, namely the steel plate quantities, if the physical dimensions of shape are given.

Conclusion 2: In case of wafer central angle  $\beta < 180^\circ$ , the rectangle length of steel plate quantities =  $2L \sin \frac{\beta}{2}$ , width =  $L - l' \cos \frac{\beta}{2}$ , area =  $2L^2 \sin \frac{\beta}{2} - L \cdot l' \sin \beta$ ;

$$\text{or the area} = L^2 \left( 2 \sin \frac{\beta}{2} - \frac{d}{D} \sin \beta \right)$$

Conclusion 3: In case of wafer central angle  $\beta \geq 180^\circ$ , the rectangle length of steel plate quantities =  $2L$ , width =  $L - L \cos \frac{\beta}{2}$ , area =

$$(1) = 2L^2 - 2L^2 \cos \frac{\beta}{2}$$

$$(2) = 2L^2 \left( 1 - \cos \frac{\beta}{2} \right);$$

$$\text{or the area} = 2L^2 \sin \frac{\beta}{2} \times \left( 1 - \frac{d}{D} \cos \frac{\beta}{2} \right)$$

Conclusion 4: A mathematical model formula is derived for the quantities calculation in the costing area and for the digitization and information of construction cost.

# Numerical research on the effect of the water level on the urban drainage network in Huinan, Pudong district

J. Huang, S.Z. Wang, S.Z. Deng & X.B. Yang

Shanghai Pudong New Area Hydrology and Water Resources Administration, Shanghai, China

**ABSTRACT:** A numerical model by MIKE FLOOD software has been set up to simulate the storm waterlogging in Huinan, Pudong District. The validated urban waterlogging model with the reports in Huinan on October 8, 2013 was adopted to simulate the local storm waterlogging. Based on that, the significant effect of the water level on the urban drainage network in the local region was studied with 8.8% larger total flooded area and 50% deeper overland flow water depth, so it cost 3 more hours for the overland flood water to subside.

**Keywords:** storm waterlogging; numerical simulation; coupled; water level; urban drainage network

## 1 INTRODUCTION

The torrential rain has the characteristic of the high intensity and large amount of rainfall for the higher water level. When the rainfall exceeds the capacity of the urban drainage system, it is easy for the local ground to be waterlogged due to all the rainwater which is not drained quickly and efficiently, and then the urban flooding will occur with the low-lying houses that got drowned, the local traffic is crippled, which strongly affects the people's life and work.

The urban waterlogging is the disaster that has attracted many researchers' attentions, and a few mathematical models have been established to simulate the urban flooding (Werner, 2001); (Mark, et al. 2004); (Schmitt, et al. 2004), e.g. InfoWorks CS (Tan, 2007); Storm Water Management Model (SWMM) (Barco, et al. 2008); GIS-based urban flood inundation model (Chen, et al. 2009); 2D hydrodynamic model capable of simulating flash floods (Xia, et al. 2011); MOUSE model (Huang, et al. 2014).

Huinan, located in the south to central of Pudong District in Shanghai, has a tropical East Asian monsoon, and the oceanic climate with plenty of rains. Pudong canal, Zhonggang river, Yaogou river, and Sanzaolu river flow around it (Fig. 1), with the normal water level of 2.50 ~ 2.80 m. At present, Huinan has the drainage system depending on the gravity flow of rainfall itself, and during the heavy rain falls, the waterlogging disaster often occurs with many houses, factories and croplands suffering, especially, the region east to Yaogou river, south to Zhonggang river, west to Pudong canal, and north to Sanzaolu river (Fig. 1).

Figure 1. Diagram of the river network in Huinan, Pudong District.

To solve the urban waterlogging disaster in Huinan, Pudong District, the urban waterlogging model coupled with the rainfall runoff sub-model by MIKE URBAN, the underground network sub-model by MIKE URBAN, the river sub-model by MIKE 11 and the overland flow sub-model by MIKE 21 are established in MIKE FLOOD platform to simulate the storm waterlogging in this research, and the effect of the water level to the urban drainage network in the local region is studied.

## 2 MODEL SET-UP

### 2.1 Control equations

The runoff in the rain inlet can be calculated by Huang, et al. (2014)

$$Q = q\psi F \quad (1)$$

where  $Q$  represents the runoff in the rain inlet and  $q$  is the designed rainfall intensity; the formula of  $q = 5544 (P^{0.3} - 0.42)/(t + 10 + 7lgP)^{0.82+0.07lgP}$  is available to Shanghai (Sun, et al., 2013), where  $P$  is the designed reoccurrence period,  $t$  is the rainfall duration,  $\psi$  is the coefficient of the rainfall runoff,  $F$  is the catchment area.

The surface runoff can be calculated by Huang, et al. (2014)

$$\begin{aligned} W &= W_1 + W_2 + W_3 = HS_1 + HS_2 - Q_x + HS_3 - Q_i \\ &= qtS_1 + qtS_2 - \sum_{i=1}^m Q_i + qtS_2 - 60fS_3t \end{aligned} \quad (2)$$

where  $W$  is the surface runoff,  $W_1$  is the runoff of the impervious zone without the depression storage,  $W_2$  is the runoff of the impervious zone with the depression storage,  $W_3$  is the runoff of the pervious zone,  $S_1$  is the area of the impervious zone without the depression storage,  $S_2$  is the area of the impervious zone with the depression storage,  $S_3$  is the area of the pervious zone,  $H$  is the total rainfall,  $Q_x$  is the infiltration of the impervious zone with the depression storage,  $Q_i$  is the depression storage capacity of the  $i$ th hollow,  $Q_t$  is the infiltration of the pervious zone, and  $f$  is the infiltration rate.

The discharge of the ///pipeline can be calculated by (Huang, et al. 2014)

$$\begin{cases} \frac{\partial A}{\partial t} + \frac{\partial Q}{\partial x} = 0 \\ \frac{\partial Q}{\partial t} + \frac{\partial}{\partial x} \left( \frac{Q^2}{A} \right) + gA \frac{\partial H}{\partial x} + gAS_f + gAh_L = 0 \end{cases} \quad (3)$$

where  $A$  is the cross-sectional area of the pipeline,  $Q$  is the discharge of the pipeline,  $H$  is the water head, and  $S_f$  is the frictional resistance of the slope.

When the hollow has the storage function, its discharge can be calculated by (Huang, et al. 2014)

$$\frac{\partial h}{\partial t} = \frac{\sum Q_i}{S_i} \quad (4)$$

where  $h$  is the water head of the hollow,  $Q_i$  is the discharge of the hollow, and  $S_i$  is the water area of the hollow. But when the hollow has the only connect function, its discharge is calculated by  $\sum Q_i = 0$ .

Saint-Tenant Equation is adopted for 1D hydrodynamic model, which is

$$\begin{cases} \frac{\partial A}{\partial t} + \frac{\partial Q}{\partial x} = q \\ \frac{\partial Q}{\partial t} + \frac{\partial}{\partial x} \left( \frac{Q^2}{A} \right) + gA \frac{\partial h}{\partial x} + g \frac{Q|Q|}{C^2 AR} = 0 \end{cases} \quad (5)$$

where  $A$  is the area of the river cross-section,  $Q$  is the discharge,  $h$  is the water level,  $q$  is the lateral inflow,  $n$  is the bed roughness coefficient,  $R$  is the hydraulic radius, and  $g$  is the gravity acceleration.

## 2.2 Computational grids

The drainage system in the local region depends on the gravity flow by itself with 642 hollows, 619 pipe lines, and 22 outlets. The 23.4 km total pipe lengths, has to be divided to be  $579 \times 656$  square grids with the uniform interval of 4 m (Fig. 2). The 614 catchments in the study area has been generated with Thiessen method with one water collection hollow in each catchment to make the rainfall runoff flow into the drainage pipes.

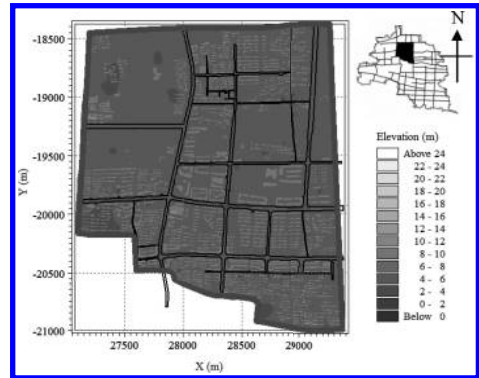

Figure 2. Layout of the computational grids of the research region with the terrain elevation in 2013.

Figure 3. Graph of the observed rainfalls and water levels at Huinan Station from October 8 to October 11 in 2013.

### 2.3 Boundary conditions

In this study, the river open boundaries are setup with the field observed time-series and water levels at Huinan Station (Fig. 1). So is the rainfall condition. Considering the subsiding of overland flood, the observed time-series water levels and rainfalls at Huinan Station from 0:00 Oct 8th to 0:00 Oct 11th in 2013 have been adopted to set up the open boundary condition and rainfall condition respectively with the time interval of 5 minutes (Fig. 3). It was raining during 3:45 and 21:20 on Oct 8th in 2013, the maximum rainfall reached 40.0 mm from 8:10 to 9:10 in that day and the total rainfall in 24 hours was 127.0 mm (Fig. 3).

The simulated region is mainly composed of buildings, roads, green fields, and water. The different impervious rates have been used, e.g. 90% for buildings, 85% for roads, 25% for green fields, zero for water, 50% for the rest.

### 3 MODEL VALIDATION

The simulated results have been compared with the report of the storm waterlogging happened in Huinan on October 8 in 2013 to validate this model. After the validation, it shows that the

Table 1. Comparisons of the simulated results with the observed situation in Huinan, Pudong District.

Location	Actual situation	Simulated results
Gongji Road	≈ 0.10 m	About 0.10 m on average, and the maximum water depth of 0.25 m in the intersection of Gongji Road and Jinhai Road, and Gongji Road and Meihua Road
East Renmin Road (Nanzhu Road ~ Jinhai Road)	≈ 0.15 m	About 0.15 m on average, and the maximum water depth of 0.25 m
Jinhai Road (Gongbei Road ~ East Renmin Road)	≈ 0.20 m	≈ 0.20 m
Jinhai Road (north of Gongle Road)	≈ 0.10 m	≈ 0.10 m
Dongchenghuayuan II Neighborhood	≈ 0.05 m	About 0.05 m, and the maximum water depth of 0.20 m
Jindicheng Neighborhood	≈ 0.10 m	About 0.10 m, and the maximum depth of 0.20 m

modeled distribution range and depth of the waterlogging agree with the actual situation (Table 1). So this model could be adopted to simulate the storm waterlogging in Huinan, Pudong District.

### 4 SIMULATION RESULTS

Huinan has been suffered by the urban waterlogging disasters for years. In this research, the validated rainstorm waterlogging model has been adopted to study the effect of the water level to the urban drainage network in Huinan, Pudong District on October in 2013.

Under the condition of the pipe outlets beneath the water level, the maximum drowned area is about 0.62 km<sup>2</sup> at 10:00 on October 8 in 2013 and then it reduces until 1:25 on October 9 in 2013 with the total ponding area of 0.25 km<sup>2</sup>, while it will decrease to 0.57 km<sup>2</sup> at 9:10 on October 8 in 2013 without the interaction between the surrounding river and the pipes, under which condition the total ponding area will be stable by 0.22 km<sup>2</sup> after 22:30 on October 8 in 2013 (Fig. 4).

In fact, the river often impedes the pipe output flow and the impact depends on the water level. When the river water level exceeds the elevation of the outlets, the overland flood water depths in the roads are in the range of 0.10 ~ 0.20 m, and the waterlogged depths in the residential areas are below 0.10 m. However, if the outlets are above the water, the water depth of the overland flood will reduce to 0.05 m (Fig. 5).

In this research, the local drainage system depends on the gravity flow by itself. With the interaction effect of the river on the pipes, it is often easier to generate the surface runoff when the rainfall exceeds the full capacity of the drain lines or the rain arrives more quickly than the local pipe networks that can absorb it (Fig. 6). But if there is not the interaction, it will be hard for the overland flow (Fig. 6).

Figure 4. Changes of the total ponding areas whether the water level is considered or not.

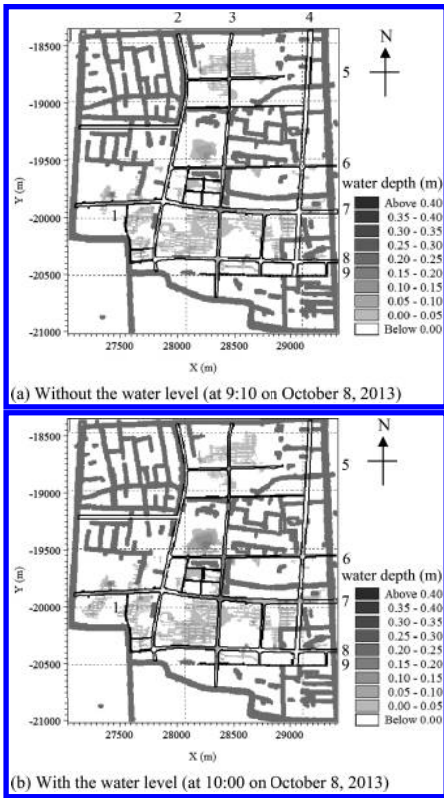

Figure 5. Comparisons of the simulated over flood depths whether the water level is considered or not (Numbers “1” ~ “9” show Meihua Road, Nanzhu Road, Jinhai Road, Chuannanfeng Road, Tanghong Road, Gongbei Road, Gongji Road, East Renmin Road and Huayuan Road).

Figure 6. Profiles of the pipes at Gongji Road (Jinghai Road ~ Yaogou River) whether the water level is considered or not (the water flow is filled in dark grey).

## 5 CONCLUSIONS

In this research, a numerical model by MIKE FLOOD software has been set up with rainfall runoff coupled with the sub-model and underground network sub-model by MIKE URBAN, the river sub-model by MIKE 11 and the overland flow

model by MIKE 21 to simulate the storm waterlogging in Huinan, Pudong District. After the validation of the report of the storm waterlogging happened in Huinan on October 8, in 2013 and the simulated results, it was shown that the range and depth of the waterlogging and the time to subside water were agreed with the actual situation so that this model could be adopted to simulate the storm waterlogging in Huinan.

Based on that, the effect of the water level to the urban drainage network in Huinan has been simulated. When the river water level exceeds the elevation of the outlets, it is often easier to generate the surface runoff when the rainfall exceeds the full capacity of the drain lines or the rain arrives more quickly than the local pipe networks can absorb it, so that the total flooded area and overland flow water depth will increase by 8.8% and 50%, meanwhile, it should cost more 3 hours for the overland flood water to finish subsiding. It is indicated that the river water level has the significant effect on the urban drainage network in Huinan, Pudong District. So the measures to control the sluices for the lower water level should be taken to alleviate the storm waterlogging in Huinan, Pudong District.

## On inverse problems for a beam with added spring

Xia Tian

College of Science, Qilu University of Technology, Jinan, China

Chuan-xiao Li

Institute 53 of China Weapon Industry Group, Jinan, China

**ABSTRACT:** The effects of adding spring to a beam on its frequencies are investigated for cantilever beam. Consider two systems: cantilever beam and the same cantilever beam added additional spring. By using two natural frequencies of each system, we identify the structural parameter of the original system. The method is nondestructive. The stiffness of the additional springs is known. Given the natural frequencies of each system, the stiffness of the additional springs and the total mass of the beam, the bending rigidity and density of cantilever beam are reconstructed. The solution of the problem is given and the conditions for the construction of the beam are derived. It is not iterative and therefore demands a modest computational effort.

**Keywords:** inverse problem; eigen value; cantilever beam

### 1 INTRODUCTION

Consider a transversely vibrating uniform Bernoulli–Euler beam as shown in Figure 1. Physical properties of beam are modulus of elasticity  $E$ , density  $\rho$ , cross sectional area  $A$ , and moment of inertia  $I$ . The equation of motion for a transversely vibrating uniform beam is given by

$$\frac{\partial^2}{\partial x^2} \left( EI \frac{\partial^2 y}{\partial x^2} \right) + \rho A \frac{\partial^2 y}{\partial t^2} = 0 \quad (1)$$

Assuming the solution to be a following harmonic motion of the form

$$y(x, t) = Y(x) \sin(\omega t + \phi) \quad (2)$$

Substituting (2) to (1), the following eigen value problem of beam can be derived:

$$Y^4(x) - \frac{\omega^2 m}{EI} Y(x) = 0 \quad (3)$$

where  $m = \rho A$ ,  $\beta^4 = \omega^2 m / EI$ . The boundary conditions of cantilever beam are

Figure 1. Uniform cantilever beam.

$$Y(0) = 0, Y'(0) = 0, Y''(l) = 0, Y'''(l) = 0 \quad (4)$$

The solution of (3) can be written as

$$Y(x) = A \sin \beta x + B \cos \beta x + C \sinh \beta x + D \cosh \beta x \quad (5)$$

where  $\beta$  must satisfy the transcendental equation  $\cos \beta l \cosh \beta l = -1$ . Now consider the cantilever beam with spring as shown in Figure 2.

In the following section, the inverse problem of beam with added spring will be discussed.

**Problem:** Suppose that the following data are given natural frequency of cantilever beam  $\omega$ , frequency of modified beam  $\mu$ , the total mass of beam  $l$ , the position of spring  $l_1$ , stiffness of translational spring  $k$ , stiffness of rotational spring  $k_\theta$ , reconstruct the physical parameters of cantilever beam  $EI, m$ .

Figure 2. Modified beam (cantilever beam with translational spring and rotational spring).

## 2 SOLUTION OF PROBLEM

Consider uniform cantilever beam as shown in the [Figure 1](#). By using  $\omega_n = \frac{\chi_n \pi^2}{l^2} \sqrt{\frac{EI}{m}}$ , the following relationships can be obtained

$$m/EI = \chi_n^2 \pi^4 / \omega_n^2 l^4, \quad (6)$$

where  $\chi_n = (n - 1/2)$ .

Let  $\beta_1^4 = \mu^2 m/EI$ . The mode shape of modified beam is

$$Y_1(x) = A_1 \sin \beta_1 x + B_1 \cos \beta_1 x + C_1 sh \beta_1 x + D_1 ch \beta_1 x, \quad (7)$$

When  $0 \leq x \leq l_1$ . The mode shape of modified beam is

$$Y_2(x) = A_2 \sin \beta_1 x + B_2 \cos \beta_1 x + C_2 sh \beta_1 x + D_2 ch \beta_1 x \quad (8)$$

When  $l_1 \leq x \leq l$  is hold. The boundary conditions corresponding modified beam are written as following:

$$Y_1(0) = 0, Y_1'(0) = 0, Y_2''(l) = 0, Y_2'''(l) = 0 \quad (9)$$

$$Y_1(x) \Big|_{x=l_1} - Y_2(x) \Big|_{x=l_1} = 0, Y_1'(x) \Big|_{x=l_1} - Y_2'(x) \Big|_{x=l_1} = 0 \quad (10)$$

$$\left( (EIY_1'(x))' - (EIY_2''(x))' \right) \Big|_{x=l_1} + kY_1(x) \Big|_{x=l_1} = 0 \quad (11)$$

$$(EIY_1''(x) - EIY_2''(x)) \Big|_{x=l_1} - k_\theta Y_1'(x) \Big|_{x=l_1} = 0 \quad (12)$$

Letsin  $\beta_1 l_1 = s_1$ ,  $\cos \beta_1 l_1 = c_1$ ,  $sh \beta_1 l_1 = sh_1$ ,  $ch \beta_1 l_1 = ch_1$ ,  $\sin \beta_1 l = s$ ,  $\cos \beta_1 l = c$ ,  $sh \beta_1 l = sh$ ,  $ch \beta_1 l = ch$ . Applying the boundary conditions(9) to [equation \(7\)](#), we have

$$A_1 + C_1 = 0, B_1 + D_1 = 0, C_1 = -A_1, D_1 = -B_1$$

Similarly, applying other boundary conditions (9–11) to [equation \(7\) \(8\)](#) and expressing them to the matrix, we have  $Ax = 0$ , where,  $x = (A_1, B_1, A_2, B_2, C_2, D_2)^T$ ,

In order to obtain the non-trivial solution of equation  $Ax = 0$ , that is  $|A| = 0$ , the following equation must hold

$$\beta_1^6 a (EI)^2 + (k_\theta \beta_1^4 b + k \beta_1^2 d) EI + k k_\theta \beta_1 e = 0, \quad (13)$$

where

$$a = \begin{bmatrix} 0 & 0 & -s & -c & sh & ch \\ 0 & 0 & -c & s & ch & sh \\ s_1 - sh_1 & c_1 - ch_1 & -s_1 & -c_1 & -sh_1 & -ch_1 \\ c_1 - ch_1 & -s_1 - sh_1 & -c_1 & s_1 & -ch_1 & -sh_1 \\ -s_1 - sh_1 & -c_1 - ch_1 & s_1 & c_1 & -sh_1 & -ch_1 \\ -c_1 - ch_1 & s_1 - sh_1 & c_1 & -s_1 & -ch_1 & -sh_1 \end{bmatrix},$$

$$b = \begin{bmatrix} 0 & 0 & -s & -c & sh & ch \\ 0 & 0 & -c & s & ch & sh \\ s_1 - sh_1 & c_1 - ch_1 & -s_1 & -c_1 & -sh_1 & -ch_1 \\ c_1 - ch_1 & -s_1 - sh_1 & -c_1 & s_1 & -ch_1 & -sh_1 \\ -c_1 + ch_1 & s_1 + sh_1 & 0 & 0 & 0 & 0 \\ -c_1 - ch_1 & s_1 - sh_1 & c_1 & s_1 & ch_1 & sh_1 \end{bmatrix},$$

$$d = \begin{bmatrix} 0 & 0 & -s & -c & sh & ch \\ 0 & 0 & -c & s & ch & sh \\ s_1 - sh_1 & c_1 - ch_1 & -s_1 & -c_1 & -sh_1 & -ch_1 \\ c_1 - ch_1 & -s_1 - sh_1 & -c_1 & s_1 & -ch_1 & -sh_1 \\ -s_1 - sh_1 & -c_1 - ch_1 & s_1 & c_1 & -sh_1 & -ch_1 \\ s_1 - sh_1 & s_1 - sh_1 & 0 & 0 & 0 & 0 \end{bmatrix},$$

$$e = \begin{bmatrix} 0 & 0 & -s & -c & sh & ch \\ 0 & 0 & -c & s & ch & sh \\ s_1 - sh_1 & c_1 - ch_1 & -s_1 & -c_1 & -sh_1 & -ch_1 \\ c_1 - ch_1 & -s_1 - sh_1 & -c_1 & s_1 & -ch_1 & -sh_1 \\ -c_1 + ch_1 & s_1 + sh_1 & 0 & 0 & 0 & 0 \\ s_1 - sh_1 & c_1 - ch_1 & 0 & 0 & 0 & 0 \end{bmatrix},$$

If  $\Delta = (k_\theta \beta_1^2 b + kd)^2 - 4k k_\theta \beta_1^2 ea \geq 0$ , then  $EI = \frac{-(k_\theta \beta_1^2 b + kd) \pm \sqrt{\Delta}}{2\beta_1^3 a}$ . We can determine  $m = \chi_n^2 \pi^4 EI / \omega_n^2 l^4$  from (6).

$$A = \begin{bmatrix} 0 & 0 & -s & -c & sh & ch \\ 0 & 0 & -c & s & ch & sh \\ s_1 - sh_1 & c_1 - ch_1 & -s_1 & -c_1 & -sh_1 & -ch_1 \\ c_1 - ch_1 & -s_1 - sh_1 & -c_1 & s_1 & -ch_1 & -sh_1 \\ EI \beta_1^2 (-s_1 - sh_1) - k_\theta \beta_1 (c_1 - ch_1) & EI \beta_1^2 (-c_1 - ch_1) + k_\theta \beta_1 (s_1 + sh_1) & EI \beta_1^2 s_1 & EI \beta_1^2 c_1 & -EI \beta_1^2 sh_1 & -EI \beta_1^2 ch_1 \\ EI \beta_1^3 (-c_1 - ch_1) + k (s_1 - sh_1) & EI \beta_1^3 (s_1 - sh_1) + k (c_1 - ch_1) & EI \beta_1^3 c_1 & -EI \beta_1^3 s_1 & -EI \beta_1^3 ch_1 & -EI \beta_1^3 sh_1 \end{bmatrix}$$

### 3 NUMERICAL METHOD AND EXAMPLES

From the above discussion, give the numerical algorithm for solving problem 1.

**Example** Consider an cantilever beam with  $l = 1m$ . The spring is placed at  $l_1 = 0.5m$ , suppose that lowest natural frequencies of cantilever beam and modified cantilever beam are  $\omega_1 = \pi^2/8$  and  $\mu = 1/2$  respectively. The stiffness of translational spring and rotational spring are  $k = 0.5$  and  $k_\theta = 0.5$ .

We obtain the following data from the given data

$$\chi_1 = 1/4, m/EI = \chi_1^2 \pi^4 \omega_1^2 l^4 = 4,$$

$$\beta_1^4 = \mu^2 m/EI = 1, s_1 = 0.4794, c_1 = 0.8776,$$

$$sh_1 = 0.5211$$

$$ch_1 = 1.1276, s = 0.8415, c = 0.5403, sh = 1.1752,$$

$$ch = 1.5431,$$

Therefore, we have  $a = -14.6698, b = 8.4827, d = 0.6595, e = 0.4717, \Delta = 26.9783 \geq 0$ . Substitute these to [equation \(3\)](#), the following equation is obtained

$$-29.3397(EI)^2 + 4.5711EI + 0.1037 = 0$$

The solution of the above equation is

$$EI_1 = 0.3328, EI_2 = -0.0212 \text{ (we delete it because } EI > 0, m > 0), m = 1.3312.$$

**ABSTRACT:** Groynes are the hydraulic structures that have functions of protecting bank erosion and maintaining water level by deflecting flow direction. In this paper, the research for reappraising groynes as a nature-friendly river training structure and for making full use of groynes to improve ecosystem have been introduced. By projection and experiment study, flow pattern and formation of source and sink have been studied. The form and size of eddy according to conditions of groynes are main factors causing in particularly wake vortexes in a front edge of groyne. The impermeable groyne was remarkably larger than the permeable one and the permeable groyne showed little change against varying permeability, showing overall decrease whereas permeability increased. The scour area was found to be the biggest in the impermeable groyne.

**Keywords:** hydraulic structures; groynes; flow pattern

## 1 INTRODUCTION

Groynes are the hydraulic structures that have functions of protecting bank erosion and maintaining water level by deflecting flow direction. In Europe, Japan, USA, and others, the groynes have long been used as a measure of water training. Although the usage of groynes is reduced as the development of direct methods for bank erosion protection like as concrete revetment, the groynes are continuously installed to control the flow for navigation and improve the channel alignment. Recently, groynes attract attention again because the natural bank form made by groynes is very beneficial to river ecosystem. The case of China is similar to that. In developing ages the social needs for river environment is insufficient. And groynes did not attract the attention because of the convenience of concrete revetment. However, the value of groynes as a bank protection technique with the consideration of river environment have been reevaluating recently. And various types of groynes have been installed as a pilot project. In this paper, we will introduce the research for reappraising groynes as a nature-friendly river training structure and for making full use of groynes to improve of ecosystem.

## 2 PROJECTION STUDY

In China, usually groyne is applied to the river regulation, and groynes considering river environment are established in NanSi River in Shandong Province. Si River is one of the main rivers managed by Shandong province. NanSi River originating from Mount. It has about 1,700 m<sup>2</sup> basin and it is close-to-nature comparatively. In the course of nature, concave and convex bankline was created by establishing the series of groynes at almost

Figure 1. Sand bar in downstream of NanSi River.

straightened channel and created bar in groynes downstream created habitats for protected birds, where are restored nature-friendly conditions, as in Figure 1. Previous model experiments were not practiced, but a groyne was established as an experiment in field. Design engineers were not sure because it was very venturous to construct, but at this moment the stability and effect of a groyne are verified from three-time floods in the past.

### 3 EXPERIMENT STUDY

Both thalweg and recirculation zone are important factors for the installation of groynes (Fig. 2). According to the installation of groynes thalweg would change and the velocity of main flow increases more than before the installation groynes. This increased scale of velocity is a very important variable of design relating bed erosion. Also, the recirculation zone, decreasing the velocity scale compare to the main flow, is a main factor of design to create a refuge for life in rivers. As a groyne is designed to create habitats, input conditions are the velocity scale during a flood in relevant river and ecological characteristics of life required protection (in case of fishes, the limit velocity for swimming in which relevant fish can stand). Design engineers should consider the velocity scale, which relevant life need during a flood, to construct groynes.

According to interval of groynes the change of thalweg and recirculation zone are shown in Figure 4 and 5. The position of thalweg from the installed side (TCL/B) decreases until an interval of groynes in about 3l, but it goes up as an interval is 6l. And the width of recirculation zone (Sh/B) decrease until an interval is 4l, and then it increases gradually. In the case of 1–3l, the second groyne obstructs flowing backward that occurred in recirculation zone. But in the case of more 4l, the flowing backward is fully developed. This results verifies that the scale of thalweg and recirculation zone are caused by not only a deflecting flow in a front edge of upstream groynes, but also the obstructing effect of second groyne within recirculation zone made by the first groyne.

Figure 2. Outline and definition.

Figure 3. Equipment for experiment and measurement point.

Figure 4. Variation of Sh/B and TCL/B.

Figure 5. Variation of SL/l.

The length of recirculation zone shown in Figure 5 is measured that it increases linearly as intervals of groynes increase. In experiment conditions, the length of recirculation zone is 18l as the maximum interval of groynes is 12l. This result shows that a deflection flow in downstream groynes is smaller than in upstream groynes as considering

the recirculation of single groyne is about twelve times. According to these results, it is identified that the recirculation zone scale of groynes has close relations with a deflecting flow caused by upstream groynes and a flow of recirculation zone transformed by downstream.

The change of velocity in thalweg shown in Figure 6 is corresponding to the interval change of groynes. The velocity of thalweg has the same tendency with the velocity change in an origin spot of the maximum width of recirculation zone. The velocity change has the same tendency with the analysis of the width of thalweg and recirculation zone, and it has the minimum value as an interval of groynes is 3, 4l. It is discovered the more an interval increases, the more the velocity increases. The velocity of thalweg has the maximum value at 1.5 times compare to the approach velocity as an interval is 12. Figures 7–9 show the velocity of groyne area considering intervals. The maximum velocity of groyne area following intervals of groynes is about 1.7–1.8 times to the approach velocity without any connection with intervals. The maximum velocity of groyne area does not occur in a point in where thalweg has the maximum width, and it occurs in a downstream point to identify the difference of origin spots relating to intervals of groynes.

In designs for general structures occurrence of scour is a defensive, and it is required to identify the scale of scour for the stability of structures. However, holes created by scours can function as ecological habitats. An experiment was performed in Clear Water Scour conditions to identify scour affects caused by groynes only. Figure 10 show results of experiments according to permeability. And Figure 11 shows scour sections by groynes.

In measuring the scale of the scour area, the impermeable groyne was remarkably larger than the permeable one and the permeable groyne showed

Figure 6. Variation of  $UCL/U_a$  and  $USH/U_a$ .

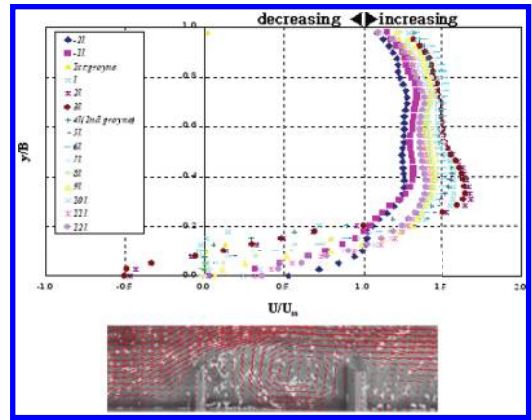

Figure 7. Distribution of velocity  $S = 41$ .

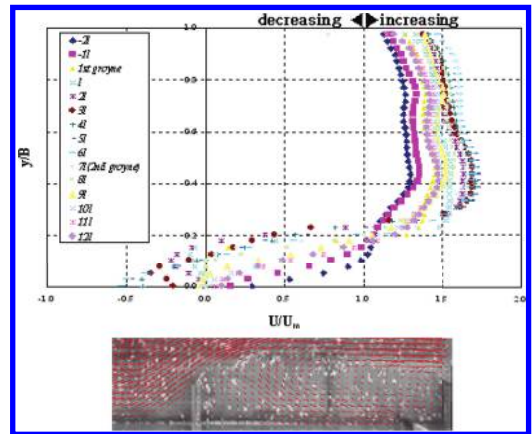

Figure 8. Distribution of velocity  $S = 81$ .

Figure 9. Distribution of velocity  $S = 121$ .

Figure 10. Outline of scour by groyne.

Figure 11. Scour according to permeability.

Figure 12. Comparison of scour area according to permeability.

little change against varying permeability, showing overall decrease whereas permeability increased. The scour area was found to be the biggest in the impermeable groyne. Figure 12 compares the scour area by varying permeability.

The form and size of eddy according to conditions of groynes are main factors causing in particularly wake vortexes in a front edge of groyne. The area of groyne is a main variable to generate wake vortexes, and they are different as permeability. The maximum size of eddy is occurred at the impermeable groyne having the maximum area of obstructing flow.

The location where the maximum scour depth occurs is the front edge of groyne, which is the same in case of both impermeable and permeable groynes. However, in case of impermeable groynes local scours are concentrated in front edges of groyne and the other side in cases of permeable groynes local scours with similar values are occurred around groynes.

#### 4 CONCLUSION

In China, because recently the issue considering such as “How to make a river nature-friendly?” and “How to restore river ecosystem?” is rising, groynes which provide various ecological environment and improve scenery around a riverbank including water use and flood control get lots of attention.

Few verified design guideline of groynes causes to hesitate about the application of groynes for a channel plan. Moreover, groynes depend on river conditions particularly considering structure characteristics of groynes. The result of the experience will give practical and reasonable guideline for fundamental designs of groynes.

**ABSTRACT:** Nansi Lake is a famous shallow lake in China. It is very important to know the water level and runoff of different sections at different times for engineer. A new calculating method has been proposed, which is called three lakes and two rivers model. Because Nansi Lake is divided into three parts, western part, lake surface, and eastern part. There are two narrow rivers to connect the three parts. In the model, water balance equations are used to instead of continuity equations. The auxiliary curve is used to instead of momentum equation to reflect the river channel storage volume and the approximate relationship between outflow and inflow. Iteration formula is provided in the paper. The numerical calculation methods were used to verify that two rivers and three lakes model is of high precision and the calculation is simple and practical.

**Keywords:** in order to; MS word

### 1 INTRODUCTION

The research approach can be divided into hydrology method and hydraulic method. The hydrology method is based on the water balance and storage-discharge equation and the hydraulic method is based on Saint-Venant Equations. The hydrology methods mainly include the Muskingum method, reservoir flood routing method, etc. The hydrology method considers the main influence factors and their interactions, which can simplify the calculation and guarantee calculation precision; the structure is simple and the hydrology method can well simulate the flood movement in the river and gives the main characteristic of flood in a river section. But the hydrology method is not strict to basic information. The hydrology method is difficult to analyze the complex flow in river channel and main characteristics. And it is difficult to provide the spatial and time distribution of water. Hydraulics methods include characteristic line method, finite difference method, finite element method, finite analysis method and finite volume method. The hydraulic method can build the spatial distribution structure in details, so it can reflect the interaction among various factors comprehensively. The hydraulic method can be suitable for various initial boundary conditions. But the disadvantages of

hydraulic method are the cost of building model, which is high. The hydraulic method has high demands for water regime information in practical application and it is difficult in operation.

### 2 PROJECTION

Nansi Lake is located in the southwest of Shandong province; it is China's famous shallow lake. Located in east longitude  $116^{\circ}34' - 117^{\circ}21'$ , north latitude  $34^{\circ}27' - 35^{\circ}20'$ , Nansi Lake is general name for it including four tandem lakes (Nanyang Lake, Dushan Lake, Zhaoyang Lake, and Weishan Lake). Nansi lake basin precipitation is mainly influenced by monsoon circulation, changing with the seasons. The precipitation increases significantly in summer from July to September. The maximum precipitation is 1191 mm (in 1964), the minimum precipitation is 356 mm (in 1988). The variations of rainfall in a year are big. And rainfall of flood season 6–9 month accounts for 72% of the annual rainfall.

Nansi lake, which is lower in the south than in the north, and belongs to the Huaihe River basin in Yishu water river. There are 53 rivers into Nansi Lake. Nansi Lake is divided into upper and lower two parts by a dam which built in 1960, the part of

north is called upper lake whose catchment area is 27500 km<sup>2</sup>, accounting for 87% of the total drainage area and the part of south is called lower lake.

There are two ways for flood calculation, that is water balance method and flow synthesis method.

### 2.1 Water balance method

Water balance formula is as follows:

$$Q_{idea} = Q_{inflow} + \sum W_{impoundment} / \Delta t - \sum Q_{outflow} \quad (1)$$

$Q_{idea}$ : ideal flow into the lake (m<sup>3</sup>/s);  
 $Q_{inflow}$ : measured flow out of the lake (m<sup>3</sup>/s);  
 $W_{impoundment}$ : the sum of storage volume including Nansi Lake, (m<sup>3</sup>); and  
 $Q_{outflow}$ : irrigation recession water from Yellow River (m<sup>3</sup>/s).

### 2.2 Flow synthesis method

Nansi Lake is divided into three parts, western part, lake surface and eastern part to calculate the flood process respectively, the sum of the three parts as Nansi Lake natural flood process. The main flow channels in eastern lake area have the all flow observation data, but the stations fail to control the entire area of the corresponding rivers, by the survey station ideal flow process and through modifying the area and rainfall ratio to calculate the flow into the lake. The western part is divided into the Liang-Ji Canal, Mo-zhao-xin River, Wan-fu River, Dongyu River, Fuxing River, and Fengpei area, using rainfall data, calculating flood volume by rainfall-runoff relationship. The lake surface adopt rainfall and deduction evaporation to calculate flood volume, negative value as zero.

Using 24 years of measured flood volume (1951–1974) and 1703, 1730, 1921, 1926, 1931, and 1937 a total of 6 years historical max floods, which focus to consider the flood data after 1921, and using P-III curve empirical fitting to analyze different frequency flood on 7 days, 15 days, and

Table 1. Nansi Lake flood calculation results.

30 days. The calculation results of Nansi Lake flood volume frequency is shown in Table 1.

## 3 MATHEMATICAL MODEL OF FLOOD

### 3.1 “Three lakes and two rivers” Model

Nansi Lake is long and narrow, different from other deep water areas and mostly shallow water area. Considering the natural geographic features, Nansi Lake is divided into Nanyang Lake (A), Dushan Lake and Zhaoyang Lake (B), and Weishan Lake (C), three tandem lakes in which Nanyang Lake is from 12 K mile stone to 34 K mile stone. The narrow and shallow section is from 42 K mile stone to 94 K mile stone, which connects A lake and B lake. Wang Yan station is on behalf of the average water level of Nanyang lake, Shikou station is on behalf of the Duzhao Lake average level, the Weishan station is on behalf of the average level of Weishan Lake. The water exchange among the three lakes through steady flow calculation, regardless of river channel storage function, gets relationship simulation of  $H_{up} \sim H_{down}$ , but the volume is incorporated into the calculation of adjacent lakes. Using the flood travel time reflects the river channel storage volume, assuming the flood travel time from Nanyang Lake to Du Zhao Lake for 1 days and the flood travel time from Zhao lake to Weishan Lake for 2 days. According to the flood dispatching method of Nansi Lake, during the flood regulation once every 50 years, only Hanzhuang canal participates in operation. Nansi Lake outlet, Hanzhuang sluice gate and Yijia River sluice, are not affected by the downstream water, which have a fixed relation curve of water level and discharge.

The Saint-Venant equations are simplified and only continuity equations as a mathematical model of unsteady open-channel flows, which right there gets the water balance differential equation.

$$Q - q = \frac{dS}{dt} \quad (2)$$

$Q$  is flow into the river reach;  
 $q$  is flow out the river reach; and  
 $S$  is water storage volume in the river reach.

The finite difference form of water balance equation is:

$$\frac{Q_1 + Q_2}{2} \Delta t - \frac{q_1 + q_2}{2} \Delta t = S_2 - S_1 \quad (3)$$

$Q_1, q_1$ : inflow, outflow at the begin of the time period (m<sup>3</sup>/s);  
 $Q_2, q_2$ : inflow, outflow at the end of the time period (m<sup>3</sup>/s); and

$S_1, S_2$ : reservoir water storage at the begin and end of the time period.

Water balance equation shows the difference between the inflow and outflow as reservoir water storage changes on the time period.

According to the characteristics of the Nansi Lake, flood formula of Nansi Lake, which is as 3 tandem lakes, is as follows:

$$\frac{Q_{a_1} + Q_{a_2}}{2} \times t - \frac{q_{a_1} + q_{a_2}}{2} \times t = S_{a_2} - S_{a_1} \quad (4)$$

$$\frac{Q_{b_1} + Q_{b_2}}{2} \times t + \frac{q_{a_1} + q_{a_2}}{2} \times t - \frac{q_{b_1} + q_{b_2}}{2} \times t = S_{b_2} - S_{b_1} \quad (5)$$

$$\frac{Q_{c_1} + Q_{c_2}}{2} \times t + \frac{q_{b_1} + q_{b_2}}{2} \times t - \frac{q_{c_1} + q_{c_2}}{2} \times t = S_{c_2} - S_{c_1} \quad (6)$$

Moving the known items to the right end, then the formula becomes:

$$\frac{2S_{a_2}}{t} + q_{a_2} = Q_{a_1} + Q_{a_2} + \left( \frac{2S_{a_1}}{t} + q_{a_1} \right) - 2q_{a_1} \quad (7)$$

$$\frac{2S_{b_2}}{t} + q_{b_2} = q_{a_1} + q_{a_2} + Q_{b_1} + Q_{b_2} + \left( \frac{2S_{b_1}}{t} + q_{b_1} \right) - 2q_{b_1} \quad (8)$$

$$\frac{2S_{c_2}}{t} + q_{c_2} = q_{b_1} + q_{b_2} + Q_{c_1} + Q_{c_2} + \left( \frac{2S_{c_1}}{t} + q_{c_1} \right) - 2q_{c_1} \quad (9)$$

The water balance equations are used to instead of continuity equations. The continuity equation can be for flood regulating calculation of three tandem lakes, but the two river ways are connected the lakes. So it need to use the auxiliary curve instead of momentum equation to reflect the river channel storage volume and the approximate relationship between outflow and inflow and then flood routing from the upper lake to the lower lake, the final completion of flood routing work of the “three lakes two rivers”.

### 3.2 Numerical model

The flood travels in the river (or reservoir, lake), along the water level, flow, flow velocity with the time change. The flow regime belongs to unsteady open-channel flows and the law of motion can be described by the Saint—Venot equations:

$$B_T \frac{\partial Z}{\partial t} + \frac{\partial Q}{\partial x} = q \quad (10)$$

$$\frac{\partial Q}{\partial t} + \frac{\partial}{\partial t} \left( \frac{Q^2}{A} \right) + gA \frac{\partial Z}{\partial x} + gA \frac{|Q|Q}{K^2} = 0 \quad (11)$$

where  $q$  is the flank inflow of the channel ( $m^3/s$ );  $B_r$  is the equivalent river width (m);  $A$  is water-crossing section area ( $m^2$ );  $Z$  is section water lever (m);  $Q$  is cross section flow ( $m^3/s$ );  $K$  is the flow modulus ( $m^3/s$ );  $t$  is the time (s);  $X$  is the distance along the direction of flow (m); and  $G$  is the gravitational acceleration. Numerical model grid is as shown in Figure 1.

## 4 CALCULATION RESULTS

The two methods above were used to calculate water level process of Nansi Lake, respectively.

Figure 1. Numerical model.

Figure 2. Two model result comparison of Nanyang Lake.

Figure 3. Two model result comparison of Duzhao.

Figure 4. Two model result comparison of weishan.

The results of calculation is shown in Figures 2–4. It can be seen from the figures that the two methods are basically the same and the water level of the ‘three lakes two rivers’ model is higher than the water level of the numerical model only in the peak part.

## 5 CONCLUSION

According to the characteristics of the Nansi Lake, two rivers and three lakes model has

been proposed. In the model, water balance equations are used to instead of continuity equations. The auxiliary curve is used to instead of momentum equation to reflect the river channel storage volume and the approximate relationship between outflow and inflow. It is simple for engineer to calculate by hand. The numerical calculation methods were used to verify that two rivers and three lakes model is high precision and the calculation is simple and practical.

## Study on the comprehensive response to drought in China

B.S. Weng, D.H. Yan & S.J. Bao

*State Key Laboratory of Simulation and Regulation of Water Cycle in River Basin, China Institute of Water Resources and Hydropower Research, Beijing, China*

**ABSTRACT:** Against the backdrop of global change with a higher and higher frequency of drought, the aim of this study is to analyze the trend and character of the drought, and to set up a series of the integrated coping technologies to cope with droughts in China. China is in urgent need of making three major shifts in terms of its drought relief patterns. First, emergency-based management pattern should be shifted to a combination of risk-based management and normal management. Second, instead of only focusing on short-term emergency-based management, the pattern should also pay due attention to mid-term and long-term management results. Third, finite objective-oriented management should be shifted to a combination of whole process-oriented management and integrated management. Proceedings from several pertinent links associated with a comprehensive drought response plan which includes drought relief planning, monitoring, evaluation, early warning/forecasting, dispatch and management, and impact assessment. We should aim at improving drought relief planning technologies of risk-based management patterns, drought monitoring technologies based on hydrological cycle process and all-dimensional pattern, drought evaluation technologies based on water resources supply and demand situations, drought early-warning and forecasting technologies based on remote sensing and land-atmosphere coupling model, comprehensive multi-water source emergency operation and management technologies geared to drought relief and integrated real-time assessment technologies on drought impact catering to coordinated regional development with the ultimate goal of developing three kinds of capabilities on risk-based drought management, monitoring and evaluation as well as early warning and forecasting, and emergency dispatch and management.

**Keywords:** drought; comprehensive response; drought assessment; drought risk management

### 1 INTRODUCTION

With the increasing impact of climate change and human activities, drought occurs in areas with higher frequency. Since 1990, drought disasters have caused more than 11 million deaths, and affected more than 2 billion people globally (United Nations International Strategy for Disaster Reduction Secretariat, 2009). The losses of drought disaster accounted for 55% of the losses of meteorological disaster which accounted for 61% of all losses from natural disasters in the last 50 years in China (Li et al., 2003). The annual average affected areas (the areas that crop yields decreased by over 10% than normal annual yields) and damaged areas (the areas that crop yields decreased by over 30% than normal annual yields) of drought disasters were nearly 21 million square km and 10 million square km from 1950 to 2010, which were 2.19 times and 1.77 times than the impacts of flood disasters, respectively (State Flood Control and Drought Relief Headquarters, 2010). Since 1990, the average annual direct economic losses above 1% of GDP over the same period in China

were caused by drought, and over 2% in case of severe drought (State Flood Control and Drought Relief Headquarters, 2010), taking the drought that happened in Southwest China in 2009 for example. Since the autumn of 2009, an unprecedented drought spell had wrought havoc in Southwest China and had extended rapidly to North China, exerting a grievous influence on regional economic and social development and threatening its ecological and environmental security. In addition to inadequate regional water projects and emergency-based drought response management pattern, both a long period of low rainfall and a record of high temperatures and the flood season, which ended much earlier last year, were mainly responsible for this disastrous drought.

Drought impacts not only on industrial and agricultural production, but also on water safety in urban and rural residents. Serious cases will bring great harm to ecosystem and impact on social and economic sustainable development. Drought response is the major question in achieving sound and fast economic and social development in China.

## 2 NEW FEATURES OF DROUGHT IN CHINA

China lies in the Asian monsoon climate zone and combines with three ladder-like pattern of the landscape, which fundamentally determines the background of the frequency of drought in China (Yu, 2003). Space does not match the soil and water resources, which is difficult to eliminate fundamentally the drought. Global warming speeds up the rate of hydrological cycle. It reduces the stability of the hydrological cycle system and improves the frequency of severe weather such as drought. Drought occurs not only in northern China with shortage of water resources, but also in southern China with relatively abundant water resources frequently, such as Xingjian River Basin, PoYang Lake Plain, Sichuan Basin, and Yunnan-Guizhou Plateau.

In the past, it was noted that drought occurs in the arid and semi-arid regions. However, the characteristics of drought have changed with a new trend of group occurrence, extensiveness and continuity. According to the analysis in temporal order, drought occurred mainly in spring and autumn in the past. But now, it takes place throughout the year and usually happens all over the country.

Climate and landscape character determine the background of the frequency of drought, while climate change and human activities exacerbate the occurrence of drought. Therefore, to adapt to the regional climate, eliminate the irrational human activities, and mitigate the losses due to drought, is an overall goal of comprehensive drought response in China.

## 3 GENERAL IDEA OF THE COMPREHENSIVE RESPONSE TO DROUGHT IN CHINA

Against the backdrop of global change with a higher and higher frequency of droughts, China is in an urgent need of making three major shifts in terms of its drought relief patterns. First, emergency-based management pattern should be shifted to a combination of risk-based management and normal management, incorporating drought response to daily IWRM routines and formulating risk-based management patterns so as to prevent drought-induced risks (ISDR, 2007; Knutson et al., 1998). Second, instead of only focusing on short-term emergency-based management, the pattern should also pay due attention to mid-term and long-term management results. On the basis of water resources carrying capacity, drought-related elements should also be taken into consideration for overall regional planning and integrated water resources planning

by means of defining drought risk areas, and accordingly the industrial layout and water conservancy project distribution will be optimized and contingency plan developed. Third, finite objective-oriented management should be shifted to a combination of whole process-oriented management and integrated management. An all-dimensional integrated monitoring and assessment system should be established to integrate drought early warning and forecasting, real-time drought relief decision making and drought impact evaluation.

Proceeding from several pertinent links associated with a comprehensive drought response plan which include drought relief planning, monitoring, evaluation, early warning/forecasting, dispatch and management, impact assessment, we should aim at improving drought relief planning technologies of risk-based management pattern, drought monitoring technologies based on hydrological cycle process and all-dimensional pattern, drought evaluation technologies based on water resources supply and demand situations, drought early-warning and forecasting technologies based on remote sensing and land-atmosphere coupling model, comprehensive multi-water source emergency operation and management technologies geared to drought relief and integrated real-time assessment technologies on drought impact catering to coordinated regional development with the ultimate goal of developing three kinds of capabilities on risk-based drought management, monitoring and evaluation as well as early warning and forecasting, and emergency dispatch and management.

## 4 OVERALL TECHNICAL FRAMEWORK OF THE COMPREHENSIVE RESPONSE TO DROUGHT IN CHINA

The overall technical framework of the comprehensive response to drought in China consists of six parts (Fig. 1). There are planning techniques, monitoring techniques, evaluation technologies, forecasting and early-warning technologies, jointing emergency dispatching and management techniques, as well as timely and comprehensive assessment techniques.

Planning techniques on drought would be based on risk management mode. Rational allocation of water resources for drought is a new approach to shift emergency management level into water resources allocation planning and carrying out water supply and demand analysis under situation of possible extreme drought in future (Wang et al., 2004). Comparing with the traditional water allocation that is just accounting for normal water resources, the new approach takes full account of the hydrological extreme events, and that of climate change (Wilhite, 2005). It could apply to

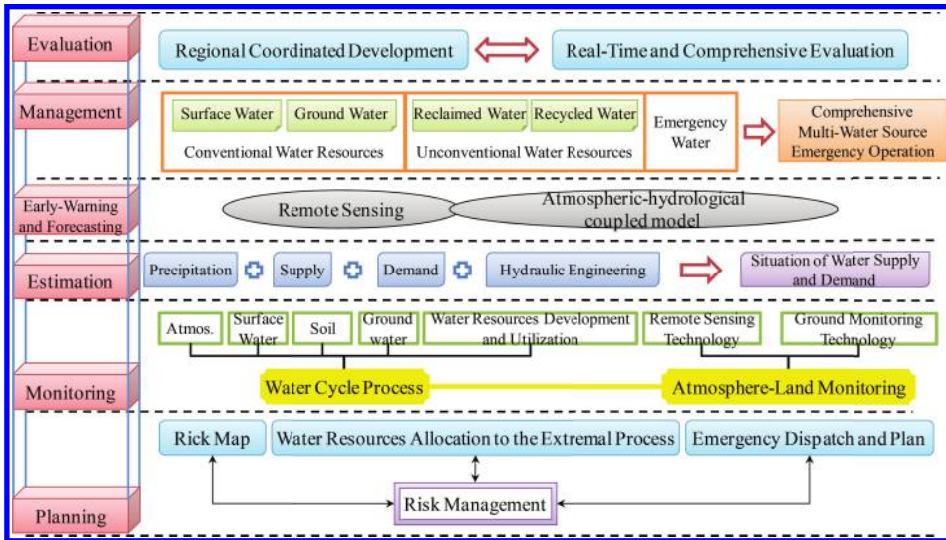

Figure 1. The overall technical framework of the comprehensive response to drought in China.

the region's water resources carrying capacity under extreme drought situation, optimize the layout of regional industry structure, and enrich the connotation of water resources management.

Monitoring techniques on drought would be based on sky–earth integration mode and water cycle process. In order to monitor the water cycle of the atmosphere, surface, soil, and groundwater and improve the utilization of water resources, a comprehensive monitoring technique system for drought should be constructed, which combines remote sensing technique (satellite remote sensing, air sounding etc.) and the ground detection technique (Dente et al., 2008).

Drought evaluation technologies would be based on supply and demand situation of water resources. According to the impacts of the evolution of elements and processes of water cycle, droughts are classified into meteorological drought, hydrological drought, agricultural drought, socio-economic drought, ecological drought, and so on (American Meteorological Society, 1997). Drought indices, such as Palmer Drought Severity Index (Palmer, 1965; Garen, 1991), Standardized Precipitation Index (McKee et al., 1993), Surface Water Supply Index (Shafer & Dezman, 1982), etc., were proposed. Dynamic evaluation of drought is required to be combined with regional precipitation, water demand, water supply, and the features of the hydro-project.

Forecasting and early-warning technologies of drought would be based on remote sensing and land–atmosphere coupling model. In combination with the unified physical model, techniques such as RS, atmospheric prediction, hydrological

prediction, ecological simulation, and crop mode are integrated into drought warning and forecasting, with the purpose of improving the accuracy of prediction. Besides, dynamic amendment and aggregation techniques should also be utilized during the whole process.

Jointing emergency dispatching and management techniques of multi-source water to drought combines the warning and forecasting of drought and its effects. It includes information gathering, assessment, prediction, strategic decision, implementation, and post-evaluation. The integrated reallocation of conventional water resources (surface water, groundwater, etc.), unconventional water resources (reclaimed water, etc.), and emergency water resources has been proposed. At the same time, comprehensive security measures are also pointed out (Weng & Yan, 2010).

Timely and comprehensive assessment techniques of drought impacts to regional development would be researched. To provide the basis for the dynamic amendment of drought prevention strategies, real time evaluation of the effects that results from drought should be implemented. At the same time, to provide the basis for post-construction planning and management, overall evaluation should be also carried out for the impacts of drought. Real-time integrated evaluation techniques are composed of three parts. The first part is the forecasting technology before the occurrence of drought. To establishing overall response scheme, activating contingency plans would be required. The second one is the evaluation technology when the drought occurs, which needs to amend the response scheme

dynamically. The last one is the impact assessment technology after the drought. To reconstruct after the drought disaster and amend the emergency plan would be required.

## 5 CONCLUSION

Drought is the extreme event in water cycle. The occurrences of drought events usually contain dual characteristics: determinacy and randomness. With the increasing impact of climate change and human activities, drought happens in more area with a higher frequency, and now it endangers the water and ecological security in the river basin. Drought has changed from its event, which is shortage of water resources to disaster. Therefore, China is in urgent need of making three major shifts in terms of its drought relief patterns. By analyzing the data of drought and flood, the general features of drought in the changing environment of China were summarized. This paper put forward and experienced a new method based on basic hydrological process for researching extreme weather issues. Finally, the integrated coping strategies have been discussed in this study, such as RS and land-atmospheric coupling mode, integrated contingency reallocation and management techniques, Real time integrated evaluation techniques. However, there are also some shortages and challenges in resist drought, such as the ability to resist drought is not balance. And the accuracy of drought monitoring and prediction should be improved so that the integrated coping strategies would be coped with drought effectively.

# Distributed hydrological and silty model in Chabagou basin of Yellow River based on DEM

H.J. Zhao & Y.D. Jin

Beijing Engineering Corporation Limited, Beijing, China

F.X. Chai

China Institute of Water Resources and Hydropower Research, Beijing, China

**ABSTRACT:** The digital stream network and spatial information were extracted from raster-based DEM data. The grid-based distributed hydrological and silty model was developed on the basis of excess infiltration mechanism in the areas with high and coarse sediment yield, considering the impact of structural measures for soil conservation on runoff routing. The model was implemented in the Chabagou basin of the Wuding River that is a tributary of the Yellow River from the year 1970 to 1989. The results show that the developed distributed model is suitable for the small watershed in the loess area.

**Keywords:** distributed model; hydrological and silty; digital elevation model; Chabagou basin

## 1 INTRODUCTION

Soil erosion in the Yellow River basin especially the areas with high and coarse sediment yield is very serious, so the study on distributed hydrological & silty model and its application in the areas is not only helpful to understand the hydrological and sediment processes in the semi-arid regions but also in favor of quantitative analysis of soil erosion and Quantitative assessment of soil erosion control measures, which can provide scientific basis for the water and soil conservation planning and treatment in the small watershed (Zhonggen Wang, Hongxing Zheng & Changming Liu, *et al.* 2004).

## 2 MODEL PRINCIPLE AND STRUCTURE

### 2.1 Spatial analysis of watershed characteristics

The grid flow is set by D8 method and the fill algorithm to determine the direction of depression. The flow velocity and soil erosion rate of constant current were calculated by the flow path length and gradient of the grid, and the flow velocity is approximate as the confluence velocity to carry out grid convergence of water and sediment routing.

### 2.2 Runoff generation model of grid unit

Considering the underlying surface condition, precipitation characteristics and short time step

factors of the study area, the infiltration excess runoff pattern of grid unit runoff production model was used to calculate the runoff yield. Philip formula (Maidment David R., Jianyun Zhang & Jisheng Li 2002) was adopted to calculate runoff depth of each grid in different periods, followed by computing their inflow into the river network.

$$f = B^2 \left( 1 + \sqrt{1 + A\theta/B^2} \right) / \theta + A \quad (1)$$

where  $f$  is infiltration rate, mm/h; both  $A$  and  $B$  are the undetermined coefficients, which are related to soil characteristics;  $\theta$  is cumulative infiltration quantity, mm.

### 2.3 Confluence model of grid unit

1. Calculation of collection time. The confluence time is the flow translation time from the central point of the runoff grid to the river outlet, and the formula is as follows (Li Li 2003).

$$t_c = \frac{L}{V} = \frac{L}{K_v S^{1/2}} \quad (2)$$

where  $L$  is length of flow path of channel segment, m;  $S$  is slope of reach;  $V$  is flow velocity, m/s;  $K_v$  is velocity constant, containing influence of roughness, hydraulic radius and other factors to water flow.

2. Storage calculation of the pond. The pond storage coefficient  $\zeta$  was used to simulate, and the formula is as follows.

$$R' = R \cdot \zeta \quad (3)$$

where  $R$  is runoff depth of the mesh before storage, mm;  $R'$  is runoff depth of the mesh after storage, mm;  $\zeta$  is the pond storage coefficient (values 0–1).

#### 2.4 Sediment yield model of grid unit

1. Splash erosion. The magnitude of the splash erosion rate depends on the erosion force of raindrops, while the erosion force is related to the impact force of the raindrops running into the soil particles (Wenyi Yao & Liqun Tang 2001).

The splash erosion rate of a rainfall can be expressed as follows.

$$d_R = K_d \rho d_{50}^2 V_{m50}^2 \cos^2 \alpha f(y) \quad (4)$$

where  $K_d$  is the coefficient related to soil characteristics;  $d_{50}$  is median particle size of raindrop, mm;  $V_{m50}$  is raindrop terminal velocity, m/s;  $\theta$  is the slope gradient,  $f(y)$  is the function related to slope runoff depth. When there is no runoff on slope surface,  $f(y)$  is the maximum (1.0), with the increase of slope runoff depth,  $f(y)$  reduces gradually, while runoff depth is more than three times of raindrop diameter. Raindrop erosion effect becomes very small and  $f(y)$  is calculated by the formula below.

$$f(y) = \begin{cases} 1 & y = 0 \\ \frac{d_{50}^2}{y^2} e^{-\frac{3d_{50}}{8y^2}} & 0 < y < 3d_{50} \\ 0 & y \geq 3d_{50} \end{cases} \quad (5)$$

The median particle size of raindrops was calculated by the following formula.

$$d_{50} = \begin{cases} 2.77I^{0.27} & TT > 60 \text{ min} \\ 3.32I^{0.25} & TT \leq 60 \text{ min} \end{cases} \quad (6)$$

where  $I$  is rainfall intensity and  $TT$  is the duration. Terminal speed. The rain drop was calculated by the followed formula.

$$V_{m50} = \begin{cases} \sqrt{\left(\frac{38.9\nu}{d_{50}}\right)^2 + 2400gd_{50}} - \frac{38.9\nu}{d_{50}} & d_{50} \leq 3 \text{ mm} \\ \frac{d_{50}}{0.113 + 0.0845d_{50}} & 3 \text{ mm} < d_{50} \leq 6 \text{ mm} \end{cases} \quad (7)$$

where  $g$  is gravity acceleration, m/s<sup>2</sup>;  $\nu$  is air movement viscosity coefficient, m<sup>2</sup>/s.

2. Runoff erosion. According to its slopes, the grids were divided into three kinds of slope surfaces: hill slope, gully slope, and trench. Using the runoff and sediment dynamics model in small watershed, the sediment yields of three slopes were carried out separately (Wenyi Yao & Liqun Tang 2001).

Soil erosion rate calculation formulas of three kinds of grids: hilly slope, gully slope, and trench are shown as formula (8) ~ formula (10).

$$E_r = e_r \cdot b_r \quad (8)$$

$$E_g = e_g \cdot b_g \quad (9)$$

$$E_c = B_c \frac{\sqrt{\gamma_m g}}{\gamma_s - \gamma_m} \tau_0^{3/2} V \quad (10)$$

Among them:

$$E_r = A_r \frac{\gamma_m}{\gamma_s - \gamma_m} (\tau_0 - \tau_c') V \quad (11)$$

$$E_g = A_g \frac{\gamma_m}{\gamma_s - \gamma_m} (\tau_0 - \tau_c') V \quad (12)$$

$$\tau_0 - \tau_c' = \gamma_m R J + (\gamma_s - \gamma_m) d \sin \alpha - \mu (\gamma_s - \gamma_m) d \cos \alpha \quad (13)$$

$$\tau_0 = \gamma_m R J \quad (14)$$

where  $e_r$  and  $e_g$  are single width soil erosion rates of hill slope and gully slope respectively;  $b_r$  and  $b_g$  are hill slope width and gully slope width respectively. Here is grid width, m;  $\gamma_s$  and  $\gamma_m$  is sediment compacting dry density and bulk density of muddy water, respectively. N/m<sup>3</sup>;  $\tau_0$ ,  $\tau_c'$  and  $(\tau_0 - \tau_c')$  is flow shear stress, starting shear stress of sediment on the slope and effective shear stress of sediment particles on the slope, respectively. N/m<sup>2</sup>;  $V$  is flow velocity, m/s;  $h$  is runoff depth, m;  $J$  is gradient;  $d$  is sediment particle size, mm;  $\alpha$  is grid slope;  $f$  is the friction coefficient;  $A_r$ ,  $A_g$  and  $B_c$  are dimensionless synthetic coefficients, set by the measured data.

3. The overland flow sediment carrying capacity. The followed formula fitted the overland flow sediment carrying capacity better.

$$T_c = \frac{1}{22284} \left( \frac{\tau_0 - \tau_c'}{d^{0.33}} \right)^{2.457} \quad (15)$$

4. Calculation of sediment amount intercepted by the projects. The typical calculation formula of

sediment amount intercepted by the silt storage dam is as follows.

$$\Delta W_{sg} = M_s k (1 - \alpha_1) (1 - \alpha_2) \quad (16)$$

where  $\Delta W_{sg}$  is mud quantity intercepted by the silt storage dam in the watershed,  $m^3$ ;  $M_s$  is intercepted mud amount per square meter,  $m^3/m^2$ ;  $k$  is area of the dam within the grid,  $m^2$ ;  $\alpha_1$  is the scale coefficient artificial filling dam area in total dam area;  $\alpha_2$  is the proportion coefficient of bed load quantity in sediment amount intercepted by the dam.

### 2.5 Sediment converge model of grid unit

Slope and gully erosion material must be transported to the exit section to become a watershed sediment yield while the transport of erosion materials is restricted by such factors as hydraulic condition, sediment conditions and channel boundary conditions. Research in the reference (Jinren Ni, Xiaoyong Liu & Tianhong Li, *et al.* 2004) considers that most parts of the Loess Plateau Gully or river course have exposed bedrocks, that although have no bedrock, the deposits belonging to them have gravels or sands that are thicker and the sediment transport ratio is close to 1.0. So sediment yields of the watershed outlet section can be calculated by superposing soil erosion of each unit in staggered several propagation period.

## 3 SURVEY AND DATA OF THE RESEARCH AREA

### 3.1 Survey of the research area

Chabagou watershed located in the first sub region of the Loess hilly region, the northern Zizhou County of Shaanxi province, belongs to semi-arid and semi-humid area. The watershed area is  $205 \text{ km}^2$ , of which the control area of the Cao Ping hydrological station is  $187 \text{ km}^2$ . Chabagou is a branch of Dali River. Its shape is basically symmetrical, the average width is  $7.8 \text{ km}$ , the channel length is  $26.3 \text{ km}$ , and the channel density is  $1.07 \text{ km/km}^2$  (Fig. 1). The average erosion modulus of the watershed is  $22,200 \text{ t}/(\text{km}^2 \cdot \text{year})$ , the largest is  $71,100 \text{ t}/(\text{km}^2 \cdot \text{year})$ , still the smallest is  $2110 \text{ t}/(\text{km}^2 \cdot \text{year})$ .

### 3.2 Date and processing

Hydrological data include 11 sessions precipitation data extract in total and corresponding flood discharge and sediment concentration data extract of Cao Ping Station during the same period.

Figure 1. Drainage map of Chabagou watershed.

Because there is no evaporation data of the study area, the evaporation data of the latest Suide station on Dali River, Wuding River system was used. The topographic data was obtained from the 1:10,000 contour line map drawn by Shaanxi Province Bureau of Surveying and Mapping Bureau, resulting in the formation of  $50 \text{ m} \times 50 \text{ m}$  grid DEM, which divided the basin into 446 rows and 633 columns, i.e. a total of 282,318 grids. The extracts of the flow and precipitation process were interpolated into the time series of equal interval (30 min), while the inverse distance squared method is used to spatial interpolation of the hydrological data.

## 4 CALCULATION RESULTS AND ANALYSIS

### 4.1 Model setting

1. Floods selection. In the principles of large or middle water and unimodal or bimodal flood, 7 floods were selected from the 11 floods data of 700,718, 700,731, 710,705, 720,719, 740,731, 780,807, 790,723, 800,718, 830,726, 880,715, and 890,716 floods.
2. The determination of the initial value of the model state variables. Initial soil moisture  $W_r$ , initial linear reservoir surface water  $SS0$ , and underground water storage capacity  $SG0$  were determined by the calculation results of the daily model (here is no longer detailed); while the initial value of the pond storage coefficient  $\zeta$  was confirmed in GIS based on such composite factors as the size and shape of the ponds.
3. Parameter setting. The artificial trial calculation method was adopted to determine the parameters. It was found after debugging that the values of such parameters as  $n$ ,  $A$ ,  $B$  and

$W_i$  influenced the flood peak, flood volume and peak time greatly.  $n$  affected the peak time and peak shape mainly: the smaller the value of  $n$ , the earlier the time of the flood peak, also the peak shape was impacted;  $A$  and  $B$  mainly affected flood volume changes: the smaller the  $A$  and  $B$ , the larger flood volume; the influence of  $A_r$ ,  $A_g$ , and  $B_c$  on sediment amount is large: the greater the  $A_r$ ,  $A_g$ , and  $B_c$ , the more sediment amount.

The debugging steps were as follows: first to adjust the flow production parameters  $A$  and  $B$  to make the simulated flood volume be close to the actual process; then to adjust roughness coefficient  $n$  according to the underlying surface information to regulate the peak shape of the simulation results to improve the deterministic coefficient of flow process simulation. Adjusting 3 parameters  $A_r$ ,  $A_g$ , and  $B_c$  were adjusted to make the simulate sediment amount proves to be close to the actual sand content; the staggered transporting time was

changed to improve the deterministic coefficient of sediment amount process simulation. The average value of the seven water and sediment parameters after adjustment was adopted by the model. Table 1 shows the calculation results of the hydrological and silty model of the calibration and verification floods in Chabagou watershed.

#### 4.2 Model verification

The other 4 floods were selected, and the hydrological and silty model was tested. From the results of calculation, it can be seen that the computed quantity of flow and sediment is in line with the measured process line of discharge and sediment quantity, what verified the model is reasonable and feasible. Figure 2 and Figure 3 show the discharge and sediment transport rate comparison of the actual and the simulated, respectively. Each grid precipitation obtained from the measured rainfall data interpolation of the rainfall stations within the study area, so the discrepancy of calculated spatial

Table 1. Results of modeling calculation.

Figure 3. Silty hydrographs of observation and simulation data of No. 700702 flood.

and temporal rainfall distribution and the actual was caused, which gave rise to the error of the runoff and sediment yield calculation. In addition, due to the time step being valued by half an hour, original records of rainfall, discharge and sediment concentration data had a certain degree of homogenization, and the peak value of the rainfall, runoff and sediment concentration may be missed.

## 5 CONCLUSIONS

Based on the extraction of spatial information of watershed based on DEM data, the distributed hydrological and silty model of Chabagou watershed in the Loess Hilly Region was constructed according to the geographical and climatic features of the watershed. Calibration and verification results show that the model is basically applicable for the high and coarse sediment area of the Yellow River Basin. Due to climate change and human activities, the pad surface of the basin is undergoing profound changes, so the distributed hydrological model in the following aspects is to be further explored and researched: (1) Spatio-temporal homogenization of precipitation data; (2) the integration of the watershed underlying surface change information; (3) sediment transport computations; and (4) the confluence time of water and sediment.

## ACKNOWLEDGMENTS

This work was financially supported by Science and Technology Innovation Foundation of Water Resources Ministry of China (SCX2002-08): Study on Distributed Water and Sedimentation Model in the areas with high and coarse sediment yield of the Loess Plateau.

# Numerical simulation on the impact of oil spills on a fishing port

RuiJin Zhang, JinMei Zhou & XueZhi Huang

*College of Marine Technology and Environment, Dalian Ocean University, Dalian, China*

**ABSTRACT:** In this paper, the water dynamic model of a fishing port in the east China sea is established by using MIKE 21 which is one of a relatively mature international DHI software series, then a fishing harbour oil spill model which is based on the Lagrangian particle tracking theory was set up to research oil spill pollution problem near an island in the east China sea. Simulating spilled oil under the northeast wind, southerly wind a tide weeks within 12 h diffusion trajectory and the distribution of the different situation are analyzed. Research shows that the direction of the wind and hydrodynamic conditions are the key factors which affect the sea oil spill and the biggest factor is the south wind of this sea area. The research results can be reference for the decision of potential oil spill emergency response.

**Keywords:** hydrodynamic; oil spill; simulation

## 1 INTRODUCTION

As the country's increasing demand for oil and the continuous development of transportation industry, oil spill accidents on ships at sea is also increasing. After the oil flow into the ocean, it can lead to serious pollution to the Marine ecological environment, not only destroys the ecological balance, the impact of tourism development of Marine aquaculture, but also threatens human's health. Recently, the sea oil spill has gradually aroused the concern of the society and people, many marine oil spill event is a sudden one, so after the accident whether we can made a timely and effective manner to emergency response and take corresponding measures to control pollution loss reduction plays a key role. The completion of fishing port engineering of a certain island makes the vessel traffic density increasing, the potential of oil spill risk is also increasing, so it is necessary to conduce the oil spill simulation research of the area for prediction.

In order to improve the forecast accuracy of water spilled oil, extensive research at home and abroad have been carried out. Since the early 1980 s China has carried out oil spill forecasting model research under different conditions, such as ice-free sea, ice sea, shallow sea waters, and so on. Huang Liwen etc use ECOM—si for open boundary islands waters to built sea flow field prediction model for oil spill simulation of the Zhoushan islands; Lou Angang in the tide of harmonic analysis and observation of wind as a force, for plastic chau bay constructs a three-dimensional oil spill at sea transport and the end-result of model; De-qi xiong, such as using HAMSOM three-dimensional ocean model for tidal harmonic

analysis for flow field forecast, to simulate oil spill huhu pearl river mouth waters on the features of the tidal river road extension, drifting of oil spill test; Zhong Deyu on contaminant transport carrying water full transformation rule is simulated. But for the moment for east island fishing port to carry out the oil spill simulation work is relatively lacking.

## 2 THE NUMERICAL SIMULATION OF THE MARINE HYDRODYNAMIC ENVIRONMENT

For the offshore oil spill, the biggest factor is water. So is the hydrodynamic simulation of offshore oil spill simulation work carried out one of the most basic. An island near the water level changes in the East China Sea fishing especially after the completion of the complex hydrological conditions undergone significant changes in recent years in this regard since the technology has been widely studied. Combined with the needs of the project, the project will use water flow field data dimensional hydrodynamic modeling techniques to simulate resolved.

### 2.1 Flow calculation results analysis

Large sea calculate the flow field flow field in front of representatives of the project, where the tide of the field to take the trend analysis. The results show that simulated tidal waters, including two fluctuation process. Observing the trend of changes in tidal C01 as a reference time point, [Figure 1](#) and [Figure 2](#) shows the trend of process on behalf of the two moments of the flow field, respectively, and the ebb

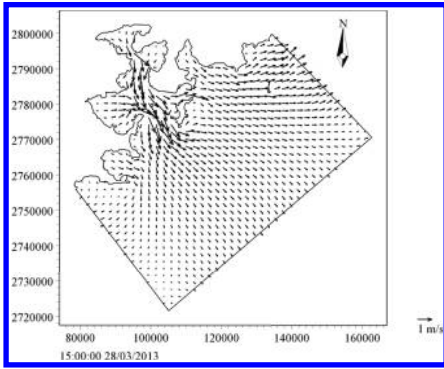

Figure 1. The flow field of ebb middle.

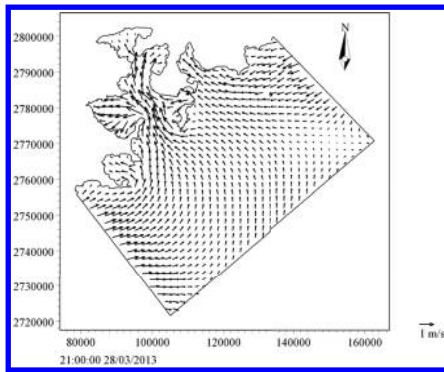

Figure 2. The flow field tide middle.

tide when the middle of the middle. Figure 1 is the first time the ebb tide in the middle field, off the coast of the computational domain tide flowing from the SW to NE, near the project area, the water flowing out from the bay through the island, with the outer flow convergence Sea to the NE flow. Flow field at low tide, and this was the moment bypass, flow decreases. Figure 2 is the first time the tide high tide in the middle field, the basic trend is calculated from the sea outside NE to SW flow, part of the water flowing into the bay through the island, the height of the flow field, and this was the moment bypass flow rate was reduced. From the above chart the flow field can also be seen, mathematical models simulate the flow field of engineering nearby waters to meet the project needs, you can follow the hydrodynamic and oil spill modeling work.

### 3 THE NUMERICAL SIMULATION OF OIL SPILL IN WATERS

#### 3.1 Prediction model

This evaluation uses the oil particle model, and it can correctly predict the spread of the oil spill.

The model of oil particle is based on the tidal current of the wind-driven currents. It use the way of Lagrange particle track method to track the trail of particle. At the same time, it uses the random walk method to simulate the turbulence diffusion of oil particles. This method is based on the behavior selection of the motion object, and use the deterministic model to simulate the conditions of environment dynamic (mainly flow field). It uses the random model to simulate the turbulent diffusion field of the oil spill particle, and Improves the effect of the forecast of oil spill. Regardless of the turbulence diffusion and based on the mathematical simulation of flow field (euler field), it uses the Lagrange to track the drift process of particles. We get the trail of particles which are under the action of tide (including wind current).

#### 3.2 The system of computational condition

The main model simulation NE (7.6 m/s) and S (4.7 m/s) winds ebb tide and high tide period of 100 kg and 10 kg spill occurred when an oil slick drift tide weeks, expansion and scope of pollution caused by the random diffusion and pollution levels. Click on the apron oil spill starting point, shown in Figure 1. Calculation program is divided into eight kinds, detailed in Table 1.

##### 3.2.1 The analysis of spill model simulation results on winds NE

After the data statistical analysis, it is concluded that the direction of prevailing wind of this island is NE in the oil spill waters. The highest frequency of the wind is direction of prevailing wind. So this wind direction is the most likely wind direction of the oil spill accident, and is the most likely to impact on the marine and terrestrial environment. To simulate the direction of prevailing wind in the oil spill sea area, and can produce a positive guiding significance to oil spill emergency action. The following Figure 3 and Figure 4 are respectively oil spill in the early and late diffusion area chart in the direction of prevailing wind (NE).

As can be seen from the above chart, in the initial stages of oil spills, when the tide began to ebb,

Table 1. The calculation scheme.

Condition	Tide	Oil spillage	Climate
1	Spring tide	10 kg	Northeast (7.6 m/s)
2	Spring tide	10 kg	Southerly (4.7 m/s)
3	Spring tide	100 kg	Northeast (7.6 m/s)
4	Spring tide	100 kg	Southerly (4.7 m/s)
5	Neap tide	10 kg	Northeast (7.6 m/s)
6	Neap tide	10 kg	Southerly (4.7 m/s)
7	Neap tide	100 kg	Northeast (7.6 m/s)
8	Neap tide	100 kg	Southerly (4.7 m/s)

sea tide flowing from the SW to NE. After the oil spill from the oil spill point of overflow, the oil spill will drift and diffusion along the direction of the trend. But also by the role of wind direction, facing east and west of the oil spill oil spill points accordingly extended. Its shape to the east is wider, while the west is narrow. When the oil spill occurred about six hours, the trend at low tide, when the bypass time, the film will be in contact with the coast in the joint action of wind and tide. After that, the tide began to rise, the sea tide is dominated by NE to SW flow, then, the trend is consistent with the wind direction, with the accumulation of oil spill on the shore, and by the flow of both the role of coastal waters, the film will spread westward, then, the trend is consistent with the wind direction, will reduce the impact of the oil spill point on the east coast, while the west side continues to spread, thereby increasing the impact area, forming a connection point of a wide strip spill east and west sides of the bay and harbor at other waters less affected by oil spills.

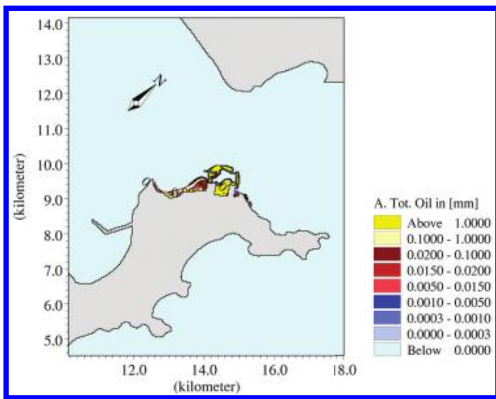

Figure 3. The oil spill area chart of early diffusion on NE.

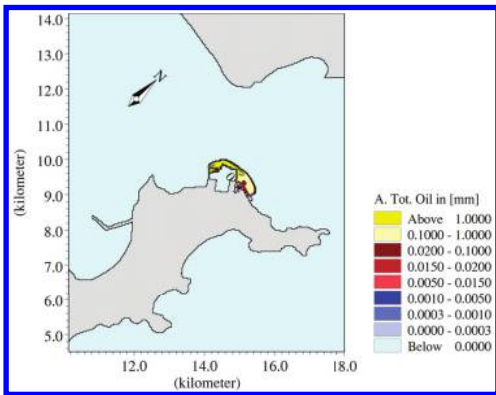

Figure 4. The oil spill area chart of late diffusion on NE.

Area when the spill occurred about 12 hours, the tide was at its height, the joint action of the tide and wind, the point on the eastern side of the oil spill all the basic drift to the west, and with evaporation and emulsification of oil spills, oil spill spread of significantly reduced.

Under constant wind effect, the oil spill will have a serious impact on the marine and terrestrial environments. Due to a wide range of oil pollution in the area, drift-diffusion speed, and a higher likelihood of occurring, oil spill relevant departments need to do this to the appropriate emergency response strategies.

### 3.2.2 The analysis of spill model simulation results on winds S

With the statistical analysis of wind data, the second often wind direction of this island in a sea of oil spills is south, Wind is an important factor affecting the behavior of the oil spill, the simulation results can be seen, the impact of the oil spill behavior is more significant at south, and may cause more severe effects on the marine and terrestrial environments. The oil spill simulation to the greatest impact of the oil spill waters wind, will provide a more clear, effective, and fast guide oil spill response action. The following Figure 5 and Figure 6, respectively, is the initial and late diffusion spill area chart for the wind direction of south.

Early oil spill occurred, the diffusion behavior of the oil spill are mainly affected by the wind and the east China sea tide of two factors. At this time, as can be seen from the initial spill map, the early oil spill drift diffusion direction along the direction of the trend, mainly from SW to NE. Due to southerly wind to function at the same time, the oil spill area has a certain extend in the direction of the gulf. After the oil spill occurred about six hours, the oil film forward continued eastward to, under the action of tide and wind, oil spill things two to spread and form

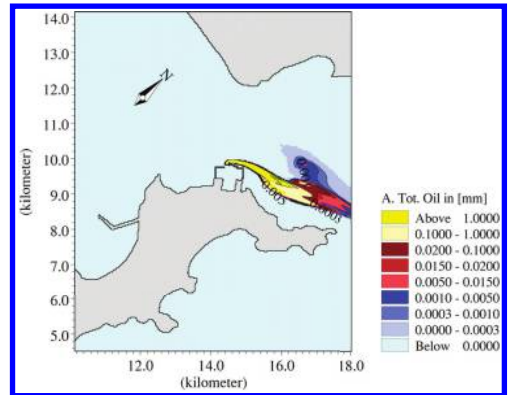

Figure 5. The oil spill area chart of early diffusion on S.

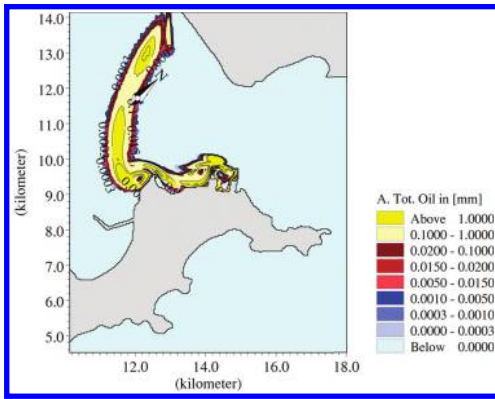

Figure 6. The oil spill area chart of late diffusion on S.

Table 2. List of different tide sweeping Sea area after spill ( $>0.3 \mu\text{m}$ , unit:  $\text{km}^2$ ).

Condition	3 hours	6 hours	9 hours	12 hours
1	0.48	1.37	2.62	2.62
2	4.11	4.73	8.42	14.59
3	0.57	1.75	3.31	3.31
4	4.42	5.51	8.86	16.26
5	0.15	0.24	0.49	1.55
6	1.04	5.20	8.02	1.04
7	0.15	0.29	0.76	1.62
8	1.29	2.35	4.53	12.92

thin strip along the coast. After nine hours, by the terrain and trends together, the amount of spilled oil spill westward drift more. In the latter part of the oil spill, oil spills with the trend to more and more to the west, and southerly winds disturbed the role of the accumulation of oil spill on the coast near the harbor was taken, along with the trend of the movement to drift near the bay the impact of shipping and ports around people's normal life.

In the action of secondary often wind, oil spill will produce a great impact on the marine and terrestrial environment. As a result of oil spill pollution area is wide, the oil spill drift diffusion speed, so need to related department to make emergency countermeasures quickly and accurately.

### 3.3 Calculate result

Different computational scheme and scanning area of spilled oil film at different time of tide is shown in Table 2. We can conclude that the wind direction has a great influence on spilled oil. In case of the south wind, the spring, and the oil spillage of 100 kg, the scanning area reach the maximum of  $16.26 \text{ km}^2$  after a tidal cycle. The current velocity

also affect the scanning area. After a tidal cycle, the area is  $16.26 \text{ km}^2$  during the springs while  $12.92 \text{ km}^2$  during the neaps.

## 4 SUMMARY

1. Using DHI MIKE to build a hydrodynamic model based on an unstructured grid, 2-D's current near a island in the East China Sea. We can find the stimulation results reflect the hydrodynamic character around the Island.
2. Based on the Lagrange and random walk theory, we build a oil spill model near a island on the hydrodynamics basis. Further more, we stimulate the oil spill of the north island during the northeast wind and southerly wind. At last, we analyze the drifting routine and the change of the oil spillage.
3. According the influence on oil spill accident, we can conclude that the wind direction and hydrodynamic condition are the key factors affecting the oil spill at the sea zone, which the south wind has the biggest impact. Futhermore, the scanning area of oil spill during the springs is larger than that during the neaps. At the worst, the scanning area reach  $16.26 \text{ km}^2$  after a tidal cycle.
4. In this paper, we only consider the process of the oil particles' drifting, diffusion, and evaporation under the action of external environment, while we must take the processes of physical, chemical, and biological effects into account during the longer time scale. Thus, we need improve the problem in the future.

**ABSTRACT:** In order to study more practical ice force of the Yellow River-related buildings, it is necessary to study practical mode. This study is of great significance to the design of river-related buildings and the standardized management of Yellow River. At present, there are many research results into ice force of the practical model of Yellow River-related buildings and the theory is mature. But there are few research results related to the practical ice force model of Yellow River-related buildings. The research results of many domestic colleges and related units are analyzed in the paper. Their research results all have certain limitations and don't apply to the practical ice force model of Yellow River-related buildings completely. Therefore, it is necessary to do further research into it.

**Keywords:** Yellow River; river-related buildings; ice force; practical model; further research

## 1 INTRODUCTION

Ningxia-Inner Mongolia reach of Yellow River lies at the northernmost tip of Yellow River Valley. Its winter is as long as four to five months. The maximum ice thickness is usually 0.8~1.1 m. It has a serious ice regime. This reach breaks up in early or middle December or at the beginning of next March. The river section is blocked by drift ice, which forms large impact force on river-related buildings. Large areas of ice floes can produce pressure and friction at the same time, which will do great harm to the river-related buildings such as dams and bridges. For example, 11 bridge piers of Guisuihe River Bridge on Beijing-Baotou Railway were broken by the huge ice pressure in the winter of 1957.

With the rapid development of economy, there are more and more Yellow River-related buildings. The river-related buildings are often struck violently by drift ice when Yellow River freezes up or breaks up. At present, the research into the fore against the river-related buildings is not deep enough due to the complexity of the problem. For security's sake, the design department usually adopts large safety coefficients when designing river-related buildings such as bridges, so that the size of piers

is increased and they occupy the valid flooding section and affect the flood safety of river channel. Therefore, it is necessary to conduct physical model tests of ice force on river-related buildings and propose the ice force that is more practical, which will be of great guiding significance to the design of river-related buildings such as bridges and of great reference value to the standard management of Yellow River channel.

## 2 RESEARCH STATUS OF ICE FORCE MODEL TEST

Ice force model test started with the research into ice breakers. The first low temperature ice pool laboratory was set up in the Soviet Union in 1955. At present, most of the existing low temperature ice pool laboratories in the world were founded in the 1980s.

Ice force model test has a long history. Most of the past tests were aimed at static ice force. With the increase of development activities in freezing waters, the requirement for solving the problems caused by the dynamic ice force resulting from ice-structure interaction is more and more urgent. In recent years, dynamic ice force model test has been carried out in some ice force laboratories at home and abroad.

### 2.1 Research status of sea ice force model

1. Low temperature laboratories were founded in Tian Jing University in 198, in which ice force

---

Project supported by Special Fund of Basic research operating expense of Central Public-interest Scientific Institution (No: HKY-JBYW-2013-20).

Project supported by National Natural Science Foundation of China (No: 51409115).

model test on ice-resistant platform in Liaodong Bay of Bohai Sea was carried out for the first time. It was a static ice force model experiment, made in No. 2 low-temperature marine lab of Tianjin University. This lab consists of low temperature chamber, ice pool, trailer, refrigerating machine, buffer chamber and test chamber, and so on. The lowest temperature is up to  $-22^{\circ}\text{C}$  during work. Nanjing University built large ice engineering labs in the Ninth Five-Year Plan period and formed the only ice mechanics and ice engineering experimental base, where many ice mechanics tests have been carried out for years. The material for model ice used in the lab is urea ice that is made up of fresh water and a certain percentage of urea, which can increase the strength and the modulus of elasticity of the ice to make sure the mechanical properties of ice can meet the requirement of the test. Before freezing, spray the mixed urea ice which is the same as the one in the ice pool with the pressure with 20 standard pressure through micropore to the sky above the ice pool. The urea ice freezes in the air and then falls into the pool and forms ice-crystal nuclei so as to avoid too higher ice strength. Stop refrigerating before ice thickness reaches the required value. Make thickness increase naturally to the required value and then make the temperature increase naturally and slowly. The strength and the modulus of elasticity of the ice decrease slowly during temperature returning. Monitor the strength and the modulus of elasticity of the ice when taking these steps and start to conduct the test as soon as the scheduled targets are realized.

In recent years, Song An, Huang Yan, Shi Qingzeng et al. have made related research into dynamic ice model, especially in similarity law. They learned about some similarity criteria applied in dynamic ice model experiment, such as Froude Similarity Criterion, Cauchy Criterion, and ice nuclei equivalence, on the basis of which, they conducted experiments and discussed the applicability of the these laws in static ice model experiment and studied the similarity law of dynamic ice force model by dynamic ice force model experiment. They presented parameter-interaction coefficient resulted from the combined action of elastic control, rate control, and geometric dimensioning. The similarity system based on this coefficient completely adapts to model test of ice-induced vibration on vertical structure.

2. An ice force-related lab, State Key Laboratory of Coastal and Offshore Engineering, was founded in Dalian University of Technology. The first ice force physical model test was conducted at this lab. The monitoring technology

of the area, concentration and movement speed of ice block was developed and the experimental relationship between the impact ice of drift ice on single piles and wharf piles and physical and mechanical parameters of the same models was found. The problem of similarity recovery of the impact force of drift ice from physical simulated results to ice force of the prototype design ice was solved.

The material for model ice was studied in this lab and DUT-1, a kind of non refrigerated model ice, was developed by Wang Xueyong, Li Zhijun and Li Guangwei. It expands range of choice. This kind of model ice was made from the mixture of polypropylene powder, white cement, plastic bead, water and others, which were mixed, stirred, and molded. It needn't be made in a large low temperature lab. Its physical and mechanical properties can keep it stable during a long period of experiment. Li Zhijun et al made systematic experimental research into its physical and mechanical properties and physical simulation and experimental study on the interaction between model ice and wave and the interaction between model and circular pile, conical, and semicircular levee structure. The results of many physical model tests show that this model ice can be used in the 1:10 to 1:30 scale model experiment. All indicators meet the requirement. This model ice is the ideal material for physical simulated experiment on ice and inclined structure and ice and wave, ice accumulation, ice ridge, and ice jam.

## 2.2 *Research status of the impact force of river ice*

River ice research was first made in the former Soviet Union. The calculating formula of ice effect on bridge piers was proposed in bridge and culvert design. Inland river construction standard of USSR was issued in 1959. The research results on ice of the scholar from former Soviet Union were cited in the ice protection and ice resistance design of many cold countries. In addition, much research into river ice was made in Canada and the US and some related rules that were suitable for their situation were made.

According to the domestic research results, the research subject is mostly sea ice and river ice research focuses on a few rivers in Heilongjiang Province. Yu Tianlai et al from Northeast Forestry University made deep research into the physical properties and river ice and the impact force of drift ice on piers. They collected samples of river ice on the spot, carried to the lab in Harbin, machined it in detail, and determined modulus of elasticity by compression test. Then they installed pressure

sensors where drift ice impact piers and vibration pick-ups on the top of piers to measure the value of the impact force of drift ice and the vibration property of the piers under impact, analyzed the collected data, simulated the impact force of drift ice on piers by means of some soft wares, such as ANSYS, and discussed the mechanism of the action of drift ice on structure. Yuan Zhenguo set up a computer simulation analysis model of the impact force of drift ice on piers by explicit dynamical analysis software package LS-DYNA. Through further study, we found research into river ice focuses on mechanical properties of river ice, measured impact force of river ice on piers and numerical simulation analysis of the impact force of river ice on piers and that no research into physical model of the impact force of river ice on piers has been carried out.

According to the analysis, the research into the mechanical properties of river ice is not further enough in our country. In addition, because there are many difference in the nature of river ice in different rivers in different areas, the existing experiment data are not typical. There are some problems in the standard strength value required in the specification. The calculating method of the impact force of drift ice on piers is not on sound experimental basis.

### 2.3 Conclusion

At present, there are few research results on the impact force of ice in Yellow River during ice run. The research results are mostly on field measurement and numerical simulation. No laboratory physical model experiment research has been made. Archetype observation is costly and complicated field conditions add human factors to analysis results. Numerical simulation is less intuitive than physical model research. There are more and more river-related buildings on Yellow River and the problem of the impact force of drift ice on river-related buildings is increasingly prominent. As a result, there is increasing urgent need of physical mode research.

## 3 THE SIMULATION RESEARCH THOUGHTS AND PROSPECT OF THE IMPACT FORCE OF ICE ON RIVER-RELATED BUILDINGS ON YELLOW RIVER

At present, the domestic research into the similarity laws of ice force physical model is mature. By summarizing the existing similarity laws, we can propose model similarity laws that are more suitable for physical model tests of the impact force of ice on Yellow River-related buildings.

Another more important factor in physical model tests is selection of the material for model ice.

At present, refrigerated model ice is usually used for tests in our country. The texture of refrigerated model ice makes great difference to test results. It is hard to control the indicators during the course of the test, which leads to poor comparison of test results. In spite of continuous study at home and abroad, there is no widely accepted material for refrigerated model. In addition, refrigerated model ice must be used in large low temperature laboratories which need huge investment. From all sides, non-refrigerated model ice is more practical during the preliminary stage of physical model research into the impact force of ice on Yellow River-related buildings.

DUT-1, non-refrigerated model ice developed by Dalian University of Technology is only used for sea ice model test at present. Whether it is suitable for the research into the impact force of ice on Yellow River-related buildings is open to question. We look forward to select a material for model ice that is more suitable for Yellow River through continuous study and further research.

The design span of Yellow River-related buildings, especially bridges, is larger and larger. The flexibility of the structure of bridges is higher and higher. The impact of all kinds of ice on structure during ice run is greater and greater. If we can conduct physical model tests on the impact force of ice on Yellow River-related buildings soon, we can provide basis for anti-ice design of river-related buildings and ensure the safety of the structure of buildings. The research will be of great significance to flood control safety of Yellow River.

## Characterization of urban rainwater quality for the reuse purpose

Zheng Li, Weipeng Chen, Jun Li & Siyang Yue

*Suzhou Industrial Park Design and Research Institute Co. Ltd., Suzhou, China*

**ABSTRACT:** In order to provide basic data for the reuse of rainwater to supplement the water resources to alleviate the water stress, rainwater quality was assessed in a typical metropolis in the east of China. Rainwater from seven districts was collected, and chemical oxidation demand, suspended solid,  $\text{SO}_4^{2-}$ ,  $\text{Cl}^-$ ,  $\text{NO}_3^-$ ,  $\text{NO}_2^-$ ,  $\text{NH}_4^+$ , and Fe in rainwater were determined. Possibly because of the release from chemical industry and electronics manufacturer, aromatic compounds such as phenols and toxic heavy metal Hg were also detected. Based on the rainwater quality, several treatment methods and suggestions were thus proposed to guarantee the safety of reusing rainwater for different purposes.

**Keywords:** rainwater; quality; characterization; inorganic ions; organic pollutants

### 1 INTRODUCTION

Most of the surface water distributing on our planet is salt sea water, and can't be used directly currently, or a very high cost is inevitably required (Zimmerman et al. 2008). Various areas on the earth have different geophysics, geochemistry, and climate conditions, leading to the uneven distribution of transpiration and the resulting precipitation (Fischer & Knutti 2015). Arising from the rapid development of agriculture and industry, etc., much more clean water is badly demanded, which has never been seen before on the history, for example, the large usage of water by the agriculture irrigation, livestock products, energy generation (e.g. electric infrastructure) (Bonsch et al. 2015). As a consequence, the world is meeting the problem of water crisis, but this problem is especially further amplified by the increasing water pollution mainly caused by the anthropogenic activity by releasing contaminants from agriculture, industrial, etc. into the environment (Zimmerman et al. 2008, Van Beek et al. 2011, Wada et al. 2011, Schwarzenbach et al. 2010).

In essence, almost all the fresh water on the land, including surface water in rivers and lakes and underground water, is originated from precipitation, with rainwater as the most important source (Jung et al. 2010). Thus, the rainwater harvesting is one of the feasible approach to satisfy the water demand, and has been under intense worldwide study (Vieira et al. 2014, Cheng et al. 2014). More and more technologies including urban planning, infrastructure reconstruction, rainwater harvesting methods, new and optimum building design (green building), and new farming and wetland systems,

have been proposed and developed (Vieira et al. 2014, Cheng et al. 2014, García-Montoya et al. 2015). Actually, rainwater can be used in many fields, such as farm irrigation, toilets, and even for drinking (Naddeo et al. 2013).

However, the anthropogenic activity has caused the global pollution, resulting in various contaminants, e.g. particles, ammonia, aromatic organics, and metals, in the rainwater (Schwarzenbach et al. 2010, Cheng et al. 2014, Kabir et al. 2014). Before reusing, the harvested rainwater should be treated by many methods, for instance, coagulation, precipitation, membrane filtration, and UV or chlorine disinfection. As for the organics, adsorption or even advanced oxidation is usually necessitated. Nonetheless, the treatment methods used depend on the rainwater quality and reuse purpose.

Water stress in China usually occurs, especially in the dry parts and also rapidly developed areas, and thus water use efficiency should be improved, and new sources are indeed required (Zhao et al. 2015). This study dealt with the assessment of urban rainwater quality for the different reuse purposes, and aimed to clarify the district-specific difference in rainwater quality. A typical metropolis, one of the economic and education center located in the east of China, is undergoing rapid development with heavy traffic and extensive infrastructure construction and is also notorious for its lots of chemical industry and bad air quality. The city is facing serious shortage of clean freshwater, so it was selected as the target city. Rainwater quality was assessed in seven different districts having different population and economy style, and the area-specific characteristics were analyzed.

## 2 MATERIALS AND METHODS

### 2.1 Rainwater sampling

Rainwater samples were collected in a rainfall event in June 2013 from seven districts, named XW, QH, GL, JY, PK, JN, and QX, respectively. The rainfall sampling event was defined as the samples collected from the onset until the end of a rainfall period, which lasted for about 70 min. The amount of this rainfall was estimated to be about 54 mm. Rainwater samplers were placed on the rooftop (~1.5 m from the floor of the roof) away from the soil and any specific pollutant sources, and three samples were collected individually at every site. The samples were kept in dark at 4 °C prior to analysis. Precautions were taken in both collection and analysis procedures to minimize the contamination. Average values of three samples with one standard are represent.

### 2.2 Chemical analysis

Solution pH was determined by a pH meter (PB-10, Satorious). The cations ( $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{NH}_4^+$ ,  $\text{Ca}^{2+}$ , and  $\text{Mg}^{2+}$ ) and anions ( $\text{NO}_3^-$ ,  $\text{NO}_2^-$ ,  $\text{SO}_4^{2-}$ , and  $\text{Cl}^-$ ) were analyzed on a Dionex ICS-3000 ion chromatograph, equipped with a SP gradient pump, an anion self-regenerating suppressor (ASRS 300, 4 mm), a conductive detector, and an AS40 autosampler. For anions, a Dionex AS11-HC column (4 × 250 mm) and a Dionex AG11-HC guard column (4 × 250 mm) were selected for separation using 20 mM KOH as isocratic eluent at 1.5 mL min<sup>-1</sup> with a suppressor current of 75 mA, while an IonPac CS12 A Column (4 × 250 mm), methanesulfonic acid (30 mM at 1.0 mL min<sup>-1</sup>) and suppressor current of 50 mA were used for the analysis of cations. Total Organic Carbon (TOC) and Total Nitrogen (TN) were analyzed using a TOC analyzer (TOCL, Shimadzu). UV absorption at 254 nm was determined on a UV-vis spectrophotometer (Cary 300, Varian). Irons and other metals were analyzed by inductively coupled plasma atomic emission spectrometry (ICP-AES, PerkinElmer). Phenols were determined on LC-MS (Waters). Other analysis was performed according to the EPA standard methods.

## 3 RESULTS AND DISCUSSION

### 3.1 Meteorological data

The city studied is constituted of more than ten districts, of which seven were selected to assess the rainwater quality, and has resident population of more than 8 million. The meteorological and population data are shown in Figure 1. The air was polluted, and the average concentrations of PM<sub>2.5</sub>, SO<sub>2</sub>, and NO<sub>2</sub> were about 105.6 μg/m<sup>3</sup>, 36.3 μg/m<sup>3</sup>,

Figure 1. Meteorological and population of the seven districts.

and 92.1 μg/m<sup>3</sup>, respectively. It seems that PM 2.5 partially positively depends on the population. The traffic in QH and JN districts were heavy, and there was an airport in JN district. NO<sub>2</sub> shows a certain relationship with traffic density. It is noted that the data was recorded 7 days after the last rainfall but one day before this one studied here.

### 3.2 COD, SS, and pH

The rainwater was collected and determined as soon as possible. Figure 2 shows the Chemical Oxidation Demand (COD), Suspend Solid (SS) and pH of rainwater. The rainwater in the city had average COD of about 77.6 mg/L and SS of about 11.2 mg/L, suggesting certain pollution. The rainwater pH was all lower than 7.0, indicating some acidity. Especially in QH, JN, and PK districts, pHs were even lower than the threshold of 5.6 for acid rain, indicating the pollution by NO<sub>2</sub> and SO<sub>2</sub>. The results are consistent with that in Figure 1. This can be interpreted by the heavy traffic in QH and JN districts, and many chemical industries in PK district.

### 3.3 Inorganic ions

Typical inorganic ions such as SO<sub>4</sub><sup>2-</sup>, Cl<sup>-</sup>, NO<sub>3</sub><sup>-</sup>, NO<sub>2</sub><sup>-</sup> and F<sup>-</sup> were usually detected in the rainwater (Kabir et al. 2014). Figure 3 shows the SO<sub>4</sub><sup>2-</sup> and Cl<sup>-</sup> in the rainwater in seven districts, with the average concentrations of about 226.3 μM and 25.4 μM, respectively. The rainwater had a similar range of sulfate and chloride with that from many other sites of the world (Kabir et al. 2014). Furthermore, it seems that the two kinds of anions showed no significant dependence on the areas.

### 3.4 Nitrate, nitrite and ammonia

Nitrogen species undergoes complex reactions and transformation in the atmosphere with the assistance of light irradiation (Gruber &

Figure 2. COD, SS and pH of rainwater.

Figure 4. Nitrate, nitrite, ammonia, total organic nitrogen and total phosphorus in the rainwater.

Figure 3. Sulfate and chloride in rainwater.

Figure 5. Typical cations and metals in the rainwater.

Galloway 2008). The nitrogen species usually enter the rainwater in terms of  $\text{NO}_3^-$ ,  $\text{NO}_2^-$  and  $\text{NH}_4^+$ . Figure 4 shows the concentrations of  $\text{NO}_3^-$ ,  $\text{NO}_2^-$  and  $\text{NH}_4^+$ , Total Organic Nitrogen (TON) and Total Phosphorus (TP) in the rainwater, with the average concentration of about 210.1  $\mu\text{M}$ , 6.4  $\mu\text{M}$ , 106.5  $\mu\text{M}$ , 360.9  $\mu\text{M}$ , and 0.12 mg/L, respectively. Thus, the rainwater was indeed polluted by the nitrogen species, agreeing with the  $\text{NO}_2^-$  concentration in Figure 1. It seems that the chemical industry in PK district contributed to the nitrogen pollution (e.g. nitrate and TON) in air and rainwater.

### 3.5 Cations and metals

There are usually metal pollutants, such as irons and copper, in the rainwater, depending on the release of ions, metal compounds, etc. (Kabir et al. 2014). Figure 5 shows the typical cations and metals in the rainwater.  $\text{Ca}^{2+}$  showed the highest level among the cations and metals, averaged at about 152.5  $\mu\text{M}$ . Iron in the form of  $\text{Fe}^{2+}/\text{Fe}^{3+}$  was also determined, and had the average concentration of about 1.3  $\mu\text{M}$ .

Note that toxic metal Hg was also detected in the rainwater, with an average concentration of about 6.1 nM. While cations show no significant dependence on districts, Iron and Hg were much higher in rainwater from GL and PK districts. It may be caused by the electronics industry manufacturing screen, electronics board, television, phone, and computer.

### 3.6 Organic pollutants

Arising from the release of volatile organic pollutants, especially aromatic organics such as phenol and benzene, to the air, these organics will be present in the rainwater by participation in the formation of nuclei of rain droplet, adsorption to the interface of droplet, mass transfer to and subsequent dissolution in the rainwater. Figure 6 shows the total volatile phenols in the rainwater and the corresponding UV absorption at 254 nm. An average concentration of about 0.014  $\mu\text{M}$  of phenols were detected, suggesting the pollution of the rainwater. Actually, some aromatics including benzene and derivatives were also detected (data not given). The level of phenols was the highest in PK district, which had many chemical industries as mentioned above. This may

Figure 6. Total volatile phenol in the rainwater and the corresponding UV absorption at 254 nm.

be caused by the industry and the related release of aromatics into air or their volatilization from wastewater or solid wastes from the chemical industry, petrochemical industry, electronics manufacturers, agricultural chemical producers, and traffic exhaust gas (Harrison et al. 2005). The absorbance of UV<sub>254</sub> indicates the presence of unsaturated organics, most of which are aromatics. The result about TON in Figure 4 also supports the organic pollution of rainwater. The results agree with the detection of phenols, both having the similar trend related to different districts. The microbial analysis results were not reported due to the big variance among the three sample (bigger than 30%).

Obviously, the rainwater collected was polluted by the nitrogen species, heavy metals and organics. The quality does not comply with the guidelines of water reuse, especially for the drinking purpose. The nitrogen species are factors that stimulate reproduction and growth of microbe and algae, so biological or chemical denitrification pretreatment is required. Heavy metal like Hg are toxic, and their efficient removal by adsorption or filtration is necessary. Because organic pollutants are volatile and toxic, the rainwater have to be treated to remove them prior to their reuse in irrigation and home use (e.g. toilet). When it is for the purpose of drinking, advanced treatment, such as adsorption, membrane filtration, oxidation and disinfection, is required.

#### 4 CONCLUSIONS

COD, SS, SO<sub>4</sub><sup>2-</sup>, Cl<sup>-</sup>, NO<sub>3</sub><sup>-</sup>, NO<sub>2</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, and Fe in rainwater were about 77.6 mg/L, 11.2 mg/L, 226.3 µM, 25.4 µM, 210.1 µM, 6.4 µM, 106.5 µM, and 1.3 µM, respectively. About 0.014 µM of phenols and 6.1 nM Hg were also determined. The rainwater was mostly acidic, indicating the pollution by SO<sub>2</sub> and NO<sub>2</sub>. The distribution and level of nitrate, ammonia, heavy metals, and aromatic organics in rainwater was possibly partially dependent on the heavy traffic, petrochemical industries, electronics

manufacturers, and agricultural chemical producers, climate conditions in the districts. For various purposes, rainwater should be treated by different methods, to guarantee the safety of water reuse, but also by taking into account the costs.

**ABSTRACT:** The river valley of the Xiao Lang Di Reservoir basin is wide upstream and narrow downstream. The width of the upper side of the river valley (above 67 km) is 200 m to 400 m, and the lower sect 800 m to 1400 m. There is a 4-km sect named “Ba li bystreet” 26 km–30 km from the dam whose width is 200 m to 300 m. They are all concentrated in the lower reservoir area which has a rugged topography. This article has researched the modes of density current converse intruding tributary through the prototype and physical model data of Xiao Lang Di Reservoir. Also, the change of the sediment transport character and the silt configuration of tributary density current has been resolved. Formula Han Qiwei and Formula Qin Wenkai on the converse intruding tributary length both have been calculated and validated as an example.

**Keywords:** converse intruding; vertical velocity distribution; Xiao Lang Di Reservoir; sedimentation

## 1 INTRODUCTION

The river valley of the Xiao Lang Di Reservoir basin is wide upstream and narrow downstream. The width of the upper side of the river valley (above 67 km) is 200 m to 400 m, and lower sect is 800 m to 1400 m. There is a 4-km sect named “Ba li bystreet” 30 km near the dam, whose width is 200 m to 300 m. There are more than 10 big branches like Da Yu River, Mei Yao River, Zhen Shui River, Shi Jing River, Dong Yang River, Da Jiao River, Xi Yang River, Yu Li River, Yan Xi River, Bo Qing River and so on, which converge in the reservoir. They are all concentrated in the lower reservoir area which has a rugged topography. Among the inflow and silt load of branches, Dong Yang River has a max annual average inflow of 0.091B m<sup>3</sup> and accounts for 0.22% of the dam; Zhen Shui River has a max annual average silt load of 0.000897B tons and accounts for 0.07% of the dam. So the inflow and silt load of branches could be left out of account when branches’ deposition shape would have been studied.

Since the beginning of water storage in September 1999, with the reservoir water level rising, the inflow and silt load of the stem river have been influencing the deposition of branches greatly. So it is notable to observe the change of branches’

capacity, which account for 35.7% of whole. Since Xiao Lang Di Reservoir has been operated as a higher operating water level, the physical model results and prototype data show [1] that during the early stages, which are demarcated in the sediment retention period, the main deposition mode is deposition induced by the density current converse intruding tributaries.

The branches’ storage capacity of the Xiao Lang Di Reservoir influences the operating mode heavily. Studying typical tributaries can improve understanding of the characteristics of the tributaries flow backward, and clear the changes in the characteristics of tributary storage capacity. It is good for extending the service life of the reservoir and playing a vital role to reservoir sedimentation reserved and reduction effectiveness.

## 2 SEDIMENT TRANSPORT CHARACTER IN RESERVOIR TRIBUTARY

The velocity change process of density current converse intruding tributary varies from the mouth to the climax and from big to small, and it decreases rapidly. Silt concentration decreases along the way. For the coarse particles deposit at the mouth, the fine come into the tributary and its groups settling

velocity is bigger. So the vertical profile of silt concentration is uniformity. But some branches at the mouth have a different convergence regional scale, this cause the vertical profile of velocity and silt concentration being constrained by the main stream. The extent has relations with the mouth width and the convergence angle.

The convergence angle of stem and branches is less than  $90^\circ$  or  $90^\circ$  in the Xiao Lang Di Reservoir. When density current goes through the mouth, it submerged intrudes the tributaries conversely. Its velocity is very small. The muddy interface elevation of the stem near the mouth is close to the mouth. The entrainment sediment have all deposited in branches. The capacity of branches becomes little. Figure 1 and Figure 2 is vertical velocity and silt concentration distribution of individual branch mouth during the Xiao Lang Di Reservoir physical model validated test [1]. Figure 3 is the change process of mainstream average velocity and silt concentration with time during the period of density current converse intruding Yun Xi River mouth, which is one of Xiao Lang Di Reservoir braches [2].

Figure 1. Vertical velocity distribution of branch mouth.

Figure 2. Vertical silt concentration distribution of branch mouth.

Figure 3. Change process of mainstream average velocity and silt concentration with time during the period of density current converse intruding Yun Xi River mouth, which is one of Xiao Lang Di Reservoir braches in year 2003.

Figure 4.  $L_{han}$  results and measured.

Figure 5.  $L_{Qin}$  results and measured.

Otherwise, when density current moves to the tributary end, along with the processes of silt deposition, the mixing of interface and water coming out of the muddy flow, discharge decreases and its kinetic energy does correspondingly.

### 3 CALCULATION

#### 3.1 Deposition

The river valley of the Xiao Lang Di Reservoir basin is wide upstream and narrow downstream. The width of upper side of the river valley (above 67 km) is 200 m to 400 m, and lower sect is 800 m to 1400 m. There is a 4-km sect named “Ba li bystreet” 30 km near the dam, whose width is 200 m to 300 m. There are more than 10 big branches like Da Yu River, Mei Yao River, Zhen Shui River, Shi Jing River, Dong Yang River, Da Jiao River, Xi Yang River, Yu Li River, Yan Xi River, Bo Qing River and so on, which converge the reservoir. They are all concentrated in the lower reservoir area, which has a rugged topography. Among the inflow and silt load of branches, Dong Yang River has a max annual average inflow of 0.091B m<sup>3</sup>, and accounts for 0.22% of the dam; Zhen Shui River has a max annual average silt load of 0.000897B tons, and accounts for 0.07% of the dam. So the inflow and silt load of branches could be left out of account when branches deposition shape would have been studied.

Since the beginning of water storage in September 1999, with the reservoir water level rising, the inflow and silt load of the stem river have been influencing the deposition of branches greatly. So it is notable to observe the change of branches capacity which account for 35.7% of whole. Since Xiao Lang Di Reservoir has been operated as a higher operating water level. The physical model results and prototype data show: that during the early stages which are demarcated in the sediment retention period, main deposition mode is deposition induced by the density current converse intruding tributaries.

#### 3.2 Formulars

In order to understand the converse intruding tributary length, taking use of the preceding harvest of that for reference, the converse intruding Zhen Shui River lengths have been calculated.

Zhen Shui River is the largest tributary of Xiao Lang Di Reservoir and enters the Yellow River directly. It comes from the second valley in Xin An and into the Yellow River at Xi Wo of Xin An County. Its total length is 51 km, drainage area 84.5 km<sup>2</sup>, and convergence angle of stem and branches 90°. Zhen Shui River has a lot of branches attributed to Luo He Drainage. But Zhen Shui River enters the Yellow River directly.

Han Qiwei [3] has taken use of flow-tube method to build Bernoulli equation for ascertaining the length. He assumes the slope small, flow-tube border and superstratum born shear stress whose

distribution is linear. After a series of derived equations, then:

$$L = \frac{1 + \frac{1}{2} Fr^2}{J_0 + \frac{\lambda_0}{8} Fr^2} h_1 \quad (1)$$

Above:  $Fr^2 = \frac{U^2}{\eta_{eg} h_1}$  is amendments Froude number after intruding.

When  $Fr^2 = 0.247$  and  $\lambda = 0.03$ , then

$$L = \frac{1.13h_1}{J_0 + 0.000926} \quad (2)$$

Qin Wenkai, etc<sup>[4]</sup> has taken use of flow-tube method to build momentum equation for ascertaining the length. After the same thought and different assumption conditions, with they have the length when  $q = 0$  under considerations of the interface resistance.

$$L = \frac{1 + 2Fr^2}{J_0 + \left( \frac{\lambda_0}{4} + \frac{K_1 \lambda_i}{12(1 - K_1)^2} \right) Fr^2} h_1 \quad (3)$$

When  $\zeta = 0.6$ , then  $K_1 = 0.6$ ,  $Fr^2 = \frac{U^2}{\eta_{eg} h_1} = 0.297$ .

When  $\lambda_0 = 0.025$ , then  $\lambda_i = 0.005$ , Formula (3) is briefed for

$$L = \frac{1.594h_1}{J_0 + 0.002135} \quad (4)$$

Formula (1) to Formula (4) have the same form and explain the length decided by amendments Froude number, resistance coefficient and especially muddy flow height and slope. This could be explained from its physical meanings. For muddy flow height represents the discharge of intrusion which functions as the energy magnitude. On the contrary, slope represents resistance along the way which functions as reaction.

#### 3.3 Case study

In the process of calculation, slope takes the data measured before flood, computed separately among the sects and averaged at the end. Muddy flow height is before the mouth. For convenience, Muddy flow height of upstream and downstream sections near braches mouth is borrowed. Distance from the stem to mouth is neglected. So calculation results are smaller than measured.

The results is listed in the [Table 1](#).

Table 1. Results of Zhen Shui River from year 2000 to year 2009 length.

Year	Sect for calculation	Muddy flow height (m)	Length (m)		
			Measured	$L_{Han}$	$L_{Qin}$
2000	–	10.00	1.653	1.640	1.968
2001	HH11	18.40	3.488	3.344	3.949
2002	HH9	11.90	2.728	2.851	3.201
2005	HH9	5.10	1.653	1.570	1.666
2006	HH9	6.2	4.465	4.965	3.772
2007	HH9	10.7	5.600	5.607	5.068
2008	HH9	8.6	4.465	5.046	4.373
2009	HH9	10.7	6.035	6.278	5.440

## 4 DISCUSSION

The deposition process of Zhen Shui is closely related to natural topographic conditions, deposition morphology of confluence areas of mainstream and tributary, process of incoming water and sediment and so on. Field observation data show that there is little incoming water and sediment in Zhen Shui and basically there is no sediment. Therefore, nearly all the deposition comes from flowing backward from mainstream. The sand bar is mainly caused by terrain condition. The Zhen Shui estuary is very narrow and the width is only about 600 m. That is, the width of water and sediment laterally flowing into Zhen Shui from mainstream is narrow, and it means that only a little sediment can flow into Zhen Shui. The Zhen Shui is open internally, for example, the valley width of cross section 3 km apart from estuary is more than 2500 m. It means that the flowing backward width increases suddenly, the flow velocity decreases rapidly, correspondingly, the carrying capacity decreases greatly, and there is a lot of sediment deposition. With the evolution of flow, the distance apart from estuary becomes longer and longer, the sediment carried by the flow becomes less; however, the deposition width becomes large. Therefore, the deposition thickness becomes thinner. In a word, all these are the main causes of less deposition thickness in internal Zhen Shui internal. With the quick uplift of mainstream riverbed, the deposition surface in Zhen Shui internal uplifts slowly, and the height difference of mainstream and tributary internal will increase year by year.

### 4.1 Conclusions

By October 2012, the amount of sediment in Zhen Shui reached 0.224 billion  $m^3$ , and the sand bar was 7.1 m. Until 2010, the converse intruding tributary length by density currents could be predicted

by formula (1). This could be predicted in other lengths in the same condition.

The researches of operational mode of Xiao Lang Di Reservoir for flood control and sedimentation reduction during later sediment retaining periods show that, regardless of the test, the height of Zhen Shui sand bar is more than 25 m. The sand bar can prevent water and sediment exchange between mainstream and tributary, and the internal storage capacity of tributary is not effectively used. The analyses show that because of the particularities of terrain, the formation of sand bar at Zhen Shui estuary has certain inevitabilities.

## PHOTOGRAPHS AND FIGURES

Calculation results of the two formulas and measures are compared in the same figure, respectively pointed in Figure 3 and Figure 4. From the figures, calculation results seems to be practical basically, but results of Han's are less than Qin's, and more in line with the measured. For there is no measured data during the flood period. But the flood would have plunged and density current would have come into practice, muddy flow converse intruded tributaries. This makes an excuse for the difference between the results and measured.

**ABSTRACT:** According to the drainage system of the tailing pond in Hebei province, the discharge flux of the drainage system is measured by the normality hydraulic model test. The flow pattern in the drainage system is observed in the condition of the normal water level and flood level. And then the location of instable flow and the possible damage is found. Based on the model test, the three-dimensional numeric model of the drainage system in tailing pond is set up, and then the flow pattern is simulated. Compared with the numeric results and the test result, the numeric results agree well with the test result, and then CFD methods used in the drainage system of the tailing pond is discussed in the paper.

**Keywords:** tailing pond; drainage system; model test; numeric simulation

## 1 INTRODUCTION

Drainage system of the tailing pond is of a special hydraulic structure. Compared with the municipal pipe network and water conveyance pipeline in the hydrographic engineering, its characteristics reflect the difference between the lateral size and axial length. Because of the arrangement along the mountainous terrain, it has a slope gradient. Generally, drainage system of the tailing pond is made from the shaft, drainage pipe, drainage tunnel, and so on. In conditions, such as negative pressure, mixed free-surface-pressure flow, the flow in the drainage system is tangled. For this reason, in the “*Code for design of tailings facilities*” [1], the design of drainage system must abide by the results of the hydrodynamic calculation and flood regulating calculation; in particular, according to the first degree, second degree, and complex drainage system, the hydraulic model test must be used to verify the design.

Hydraulic model test is an important research method in hydraulic structure engineering. The complex flow patterns are observed and predicted by the hydraulic model test designed by the gravity similar theory, through which we can examine the reliability and accuracy of the designing scheme, and then optimize the design of the hydraulic structure engineering.

Wang Shi-xia [2] study the flood carrying capacity of the tower-type inlet silo of the tailing pond by normality hydraulic model test, and the flow

patterns is described. Ma Lin-yuan [3] study the stability of the drainage system of Wai-tou-shan tailing pond by normality hydraulic model test, and verify its discharged capability. Dang Ning [4] studied the flow characteristics of the frame-type drainage well in the Da-xi-gou [5] tailing pond, and analyzed the its discharged capability and flow state. At present, lots of hydraulic model tests have been used in the drainage systems of the tailing ponds, improved the related theory and test technique of the hydraulic model test. However, the numerical simulation, with the development of compute technique, the numerical simulation will be widely used in the design of the drainage system.

In the paper, the drainage system of the tailing pond in Hebei province is selected, and some research works is carried out as the following:

1. The hydraulic model test is designed based on the similarity criterion, which need to abide by gravity similarity criterion strictly.
2. Through the hydraulic model test, the discharge flux of the drainage system is surveyed to judge if the maximum discharge flux meets the design requirements. Meanwhile, the flow pattern in the drainage system is observed, and then determines if the instable flow exists in the drainage system to verify the reasonableness of the design.
3. A three-dimensional numeric model of the drainage system in tailing pond is set up, and then the flow pattern is simulated. By the

numeric simulation, the flow flux, flow velocity, flow pressure, and so on are determined. Then the analysis with the test model is carried out, and some meaningful conclusions are drawn.

## 2 ENGINEERING SITUATION

The drainage system of tailing dam in Hebei province must meet a requirement of the return flow flux 2.01 m<sup>3</sup>/s under the normal condition, and maximum discharge flux 5.69 m<sup>3</sup>/s under the flood condition. The design uses drain well, drain pipe, tunnel, and open channel, which are made from the whole reinforced concrete lining with 300 mm thickness, with the smooth inside edge of the wall, and controlling surface irregularities of height less than 20 mm. Through the drainage calculation the flood drainage structures form and size are determined: the drainage wells are all of frame structure, with the inner diameter 4.0 m, the height 2.0 m, and ring beam height 0.3 m between each layer. Each layer of the frame well has 10 hole-inlets. All the circular pipes' inner diameter is 1.2 m: drainage tunnel are arch-wall type with the width 1.5 m; the clear height of 1.8 m, the straight wall is 1.05 m high, and the arch is 0.75 m. The shafts are connected with the drainage tunnel and drain pipe, and the shaft diameter is 1.5 m.

Through hydraulic model experiment combined with numerical simulation, this paper studies the late drainage system in the accumulation of elevation of 610.0 m (range from the 4th well to the tunnel exit, namely T4-P2-P1-P0 section, the section model total length of 42.71 m, height of 1.85 m). Through the hydraulic model test, the discharge flux of the drainage system is surveyed to judge if the maximum discharge flux meets the design requirements. Meanwhile, the flow pattern in the drainage system is observed, and then determines if the instable flow exists in the drainage system to verify the reasonableness of the design.

## 3 MODEL DESIGN AND CONSTRUCTION

Based on the similarity theory of hydraulic model test, according to the gravity similarity criterion, the hydraulic model is designed. The selected model of geometric scale  $\lambda_L = 24$ . The physical quantities of similar relations are shown in Table 1.

Model materials select organic glass. Roughness of prototypical concrete is  $n_p \approx 0.014$  and the requirements of model roughness is  $n_m \approx n_p / \lambda_n \approx 0.0082$ . The roughness of organic glass is about 0.008~0.010. After testing verification, the selected organic glass meets the similar requirements of resistance.

Table 1. The quantities of the model scale relationship and model scale ratio.

Physical quantity	Scale relations	Physical quantity scale
Velocity	$\lambda_v = \lambda_L^{0.5}$	4.90
Flow	$\lambda_Q = \lambda_L^{2.5}$	2 821.81
Roughness	$\lambda_n = \lambda_L^{1/6}$	1.70
Time	$\lambda_t = \lambda_L^{0.5}$	4.90
Pressure	$\lambda_p = \lambda_L$	24.00

Figure 1. Production, installation and completion of the model.

In order to maintain the water flow similar to the prototype, “Hydraulic (conventional) model testing procedure” (155-2012 SL) regulates that the model Reynolds number should reach the area of resistance. If sometimes there is difficulty reaching the area, at least it should be guaranteed in the turbulent zone. The results show that the Reynolds number of the model and the prototype is far greater than the critical Reynolds number and the flow is in turbulent state.

The model shown in Figure 1 is produced and installed.

## 4 TEST RESULT ANALYSIS

### 4.1 Discharge flow

The discharge of the tailings dam in the accumulation elevation of 610 m under normal condition and flood condition by the model test are shown in Table 2.

Table 2 shows that when tailings pool stacking elevation is 610 m, the discharge flux of the drainage system is 2.57 m<sup>3</sup>/s in normal condition and meet requirement of the return flow flux of

Table 2. Drain system discharge flow at 610 m accumulation height of dam.

Working conditions	Weir head		Discharge flow	
	Model values/m	Prototype values/m	Model values/(L · s <sup>-1</sup> )	Prototype values/(m <sup>3</sup> · s <sup>-1</sup> )
Normal condition	0.013	0.30	0.91	2.57
Flood condition	0.042	1.01	0.60	16.93

2.01 m<sup>3</sup>/s; Under the condition of flood, discharge flux of drainage system is 16.93 m<sup>3</sup>/s, it is greater than the required maximum discharge flux of 5.69 m<sup>3</sup>/s and meets requirement of the design discharge flux.

#### 4.2 Typical flow pattern

Under normal operating condition, the inflow of the 4th drainage well is the overflow of the weir, the flow around the inlet hole of the drainage well is smooth and there is no poor hydraulic phenomenon. The flow at the bottom of the drainage well is rolling violently, the aeration phenomenon in the upper water column is obviously, and it looks cystose. The turbulence is small in the lower water body, without the aeration phenomenon, which is transparent. The free flow is observed in the tunnel from the inlet to the outlet. Under normal condition, the bottom flow pattern of No. 4 drainage well is shown in Figure 2(a). Under flood condition, the inflow flux of the drainage well is larger, the backwater phenomenon occurs in the drainage well. Aeration of drainage wells is obvious and the bubbles enter the downstream tunnel with the water flow. Because the water in the well is very deep, the pressure flow is observed in the tunnel from the inlet to the outlet. The flow pattern at the bottom of No. 4 drainage well under flood condition is shown in Figure 2(b).

Under normal operating conditions, the P1~P2 section of the tunnel is free flow and the depth of the water is about 0.59 m. As with the No. 1 tunnel junction P2 flow steering slightly larger, refracted phenomenon appears in the P1~P2 section of tunnel in the range of 45.60 m, Then the flow pattern is smooth and without aeration phenomenon. Under the condition of flood, because of the large flow rate of the 4 drainage wells, the P1~P2 section tunnel is pressure flow and the maximum pressure head is about 14.5 m. Flow pattern of two operating conditions are shown in Figure 3(a) and Figure 3(b).

Under normal operating conditions, the water flow of No. 1 branch tunnel is free flow and the depth of the water is about 0.59 m in the junction of No. 1 tunnel and main tunnel at P2, because

Figure 2. Model test under the normal condition.

Figure 3. Model test under the flood condition.

flow takes a sudden turn, here the flow pattern is complex and the backwater phenomenon occurs. Far away from the junction of the P2, the flow become stable and water depth grows large, and the maximum hamed water depth is 1.03 m. Under normal operating condition, the flow pattern is shown in Figure 3(a). Under flood condition, because of the large inflow, the 1st tunnel is full of pressure flow and the maximum pressure head is about 19.95 m. Under flood condition, the flow pattern is shown in Figure 3(b).

#### 4.3 Flow velocity

The experimental results show that the flow is approximately uniform flow along the tunnel except the bend section. Under normal operating condition, the velocity of the uniform flow in the drainage system is small, and the flow velocity is 2.90 m/s. Under the condition of flood, the flow velocity of the drainage system is larger, and the flow velocity is 6.81 m/s. Under the two operating

conditions, the flow Reynolds number of each part of the drainage system is much higher than the critical Reynolds number, and the flow is in the turbulent zone.

## 5 NUMERICAL SIMULATION

A numerical simulation is conducted at point P2 where the branch tunnel crosses the main tunnel meeting with the angle of 107 degree. The upstream of main tunnel is blocked, and the water flow direction is changed violently, which flow pattern is complex.

The water pressure distribution and velocity distribution under the two conditions are calculated as shown in Figure 4 and Figure 5.

Figure 4(a) shows normal conditions of the pressure cloud picture, Figure 4(b) is the flow velocity diagram, and Figure 4(c) is the velocity vector diagram. Under normal conditions, from Figure 4(a) we can see that tunnel not only is full of free flow but also has less pressure. Maximum pressure appears at the junction where the branch tunnel crosses the main tunnel, and the maximum pressure is about 9.2 kPa. The pressure cannot

cause damage of the concrete side wall of tunnel. Through Figure 4(b) and Figure 4(c), it is shown that the upstream water flow of branch tunnel is stable; the average velocity of the cross section is 3.16 m/s, which as obtained from tests is 2.90%, the error within 9.0%. As hindering effect by main tunnel side wall, water flow produces backwater area in the branch tunnel. With the flow-cross section increased, flow velocity decreases to 1.48 m/s. The changing flow direction leads to backwater area where velocity is reduced gradually from the outside to the inside. The outside maximum flow velocity is 3.32 m/s and the inner minimum flow velocity is 1.53 m/s.

Figure 5 shows the pressure cloud picture, flow velocity, and velocity vector diagram under the condition of flood. From Figure 5(a), it can be seen that the pressure flow change is larger because discharge flux is greater, and the pressure of the tunnel keeps above 400 kPa. The maximum pressure acted on the tunnel surface caused by the flow of the main tunnel is 502.5 kPa, which will not cause damage of concrete side wall of tunnel. As Figure 5(b) and Figure 5(c) show, branch tunnel velocity distribution is homogeneous, mean velocity in section is 7.11 m/s, which obtained from tests is 6.81 m/s, and comparing error is 4.4%. At the bend location of the tunnel, the flow velocity of the vortex flow is gradually reduced from the outside to the inside of the vortex, and the outside maximum flow velocity is 9.98 m/s, and the inner flow velocity is 0.96 m/s.

Figure 4. Numerical simulation under the normal condition.

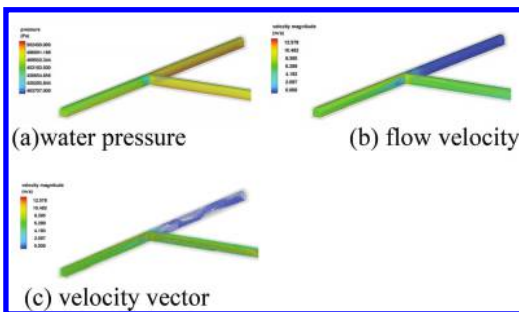

Figure 5. Numerical simulation under the flood condition.

## 6 CONCLUSION

According to the drainage system of a tailing reservoir in Hebei Province, the gravity similarity criterion is used to establish test model, and the following work is accomplished:

1. Through the model test, the discharge flux of the drainage system is obtained. The discharge flux under normal condition is 2.57 m<sup>3</sup>/s, and meets the requirement of the return flow flux 2.01 m<sup>3</sup>/s. The discharge flux under normal condition is 16.93 m<sup>3</sup>/s, and greater than the required maximum flow discharge flux 5.69 m<sup>3</sup>/s, which meet the design discharge flow requirement.
2. A detailed analysis of the flow pattern is carried out, which can supply for next the optimization of the design.
3. The flow velocity of the drainage system is smaller under the normal condition; however, the flow velocity is larger under the flood condition, in which maximum flow velocity is 6.81 m/s. Those will not cause erosion of the drainage system.

4. The three-dimensional numerical model of drainage system is established to analyze the discharge flow characteristic, and the numerical results are in accordance with the model test results, which show Computational Fluid Dynamics (CFD) method can be used in design, optimization and research of drainage system of tailings pond.

# Analysis on optimizing preloading water head of water distribution ring pipe in hydropower station

Bo Liu

*Changjiang Institute of Survey, Planning, Design and Research, Wuhan, China*

J.T. Lai

*Yalong River Hydropower Development Company, Ltd., Chengdu, China*

**ABSTRACT:** A three-dimensional finite element model of the water distribution ring pipe in hydropower station has been carried out, using the finite element program ANSYS and nonlinear contact theory. With different preloading water head (0.7, 0.8 and 0.9 times of minimum hydrostatic pressure), the stress of surrounding concrete of the water distributing ring pipe has been analyzed, which provide reference for the optimal selection of the preloading water head. The result shows that the surrounding concrete will not crack in the three schemes, because the design tensile strength of the surrounding concrete of the water distributing ring pipe is high (3.27 MPa). Considering the stress of surrounding concrete and the requirements of unit's long-term stable operation comprehensively, the water distribution ring pipe's preloading water head of this project is suggested to be 4.8 MPa, 80% of the minimum head (598.5 m).

**Keywords:** water distribution ring pipe; preloading water head; finite element analysis

## 1 INTRODUCTION

Water distributing ring pipe is an important part of the hydropower station. With the surrounding concrete, it undertakes the water pressure during the operation of the hydropower station<sup>[1]</sup>. Water distributing ring pipe is buried in the concrete and its structure is more complex than the common spiral case structure. It belongs to a part of the joint load-bearing structures, can effectively control and regulate the load-bearing proportion of steel and surrounding concrete, give full play to the advantages of steel to reduce cracking of the surrounding concrete, meet the plant substructure overall stiffness requirement<sup>[2, 3]</sup>. Furthermore, due to gravity of water bodies can effectively prevent water distribution ring pipe floating, eliminating some of the pull anchor when the surrounding concrete pouring, water distribution ring pipe conducive to the stability of unit operation. For large-scale unit and pumped storage unit, water distributing ring pipe has been widely adopted at home and abroad<sup>[4]</sup>.

In this paper, using the software ANSYS and taking into account of the friction of the steel liner with the surrounding concrete<sup>[5]</sup>, a 3-D model is established to calculate the stresses of steel liner and surrounding concrete. Based on one unit of a hydropower station, surrounding concrete stress of

the water distributing ring pipe has been studied, by using a simplified algorithm. The reasonable preloading water head has been proposed. Finally, conclusions were summarized.

## 2 FEM MODEL

In this paper, an actual water distribution ring pipe structure in hydropower station was modeled. The model is built up according to the middle standards unit. The distance in the direction along the longitudinal axis is totally 14.10 m, and the width along the direction from upstream to downstream is 25.26 m, and the vertical distance is 17.5 m. The inlet diameter of cross section of the hydropower station's distributor is 1 meter. The distributor utilizes WDB620 steel plate and the thickness of the section is 25 mm to 50 mm. The distributor is complicated in structure and bears very high internal water pressure, as a result, the design for it is not only a matter of significant techno-economy, but also has a concern in that the power station is or is not able to generate electricity on schedule and realize a long-term safe operation.

Cartesian coordinate system is adopted in the numerical analysis, in which X-axis is assumed as the horizontal direction along the longitudinal axis at the extreme left to plant (facing downstream),

Y-axis is set along the vertical direction and upward is positive. And Z-axis is set along the horizontal direction, whose positive direction is from upstream to downstream. Coordinates origin is set at the intersection of installation elevation and unit axis.

Distributor and its surrounding concrete are all simulated according to their actual size in calculation range. Normal constraints are applied on the sides and bottom of the foundation. Earth pressure is applied on the upstream, downstream and left regions of powerhouse contacted with earth, water pressure is applied on the region contacted with water. The region of right contacted with water is applied water pressure. The else are considered as free surfaces.

The model includes four groups of element, i.e. concrete, distributor, steel liner of motor-pumped well and foundation. Concrete and foundation adopt eight-node hexahedral element, distributor and liner of motor-pumped well adopt four-node plane shell element. The calculation model is of 83821 nodes and 77204 elements among which concrete is 54234 elements, distributor 1690 elements, lining of motor-pumped well 280 elements, and foundation 21000 elements. Parts of the grid are shown in Figure 1~Figure 3.

Figure 1. Grids of the whole model.

Figure 2. Grids of the powerhouse structure.

Figure 3. Grids of the distributor.

### 3 CALCULATION SCHEMES

The preloading water head directly determines the value of internal water pressure beared by both distributor and its surrounding concrete under the running operation of a power station, and it has large influence on reinforcement design of the surrounding concrete. Meanwhile the value should ensure no disengaging between distributor and its surrounding concrete in order to guarantee stable operation of units. Based on that, we select 0.7, 0.8 and 0.9 times of minimum hydrostatic pressure (5.985 MPa) as the preloading water head to analyze and compare, in order to choose the preloading water head which is appropriate to the distributor of the hydropower station. Calculation schemes and load combinations are shown as Table 1.

### 4 STRESS OF THE SURROUNDING CONCRETE OF DISTRIBUTOR

According to the above three calculation schemes, circumferential stress of some keypoints are list in Table 2. The numerical value in Table 2 are normal stress of corresponding sections, which is positive for tensile stress and negative for compressive stress. The unit of stress is MPa. The location of sections is shown in Figure 4, and location of keypoints in Figure 5.

1. In the scheme of LC-1, the jointly bearing value shared by both distributor and concrete is larger in this scheme than the other two, so the stress level of concrete is the highest relatively.

From the Table 2, it can be seen that with the interaction of internal water pressure and loads

Table 1. Calculation schemes and load combinations.

Calculation schemes	LC-1	LC-2	LC-3
Preloading water head (MPa)	4.2	4.8	5.4
Structure weight	√	√	√
<i>Stator base plate per each (MN)</i>			
Radial	0.089	0.089	0.089
Tangential	0.145	0.145	0.145
Axial	0.393	0.393	0.393
<i>Under-rack base plate per each (MN)</i>			
Radial	0.066	0.066	0.066
Tangential	0.033	0.033	0.033
Axial	0.025	0.025	0.025
<i>Upper bracket base plate per each (MN)</i>			
Radial	0.031	0.031	0.031
Tangential	0	0	0
Axial	0	0	0
<i>Uniform Live Load on floor (MN/m<sup>2</sup>)</i>			
Generator floor	0.025	0.025	0.025
Turbine floor	0.025	0.025	0.025
Ball valve floor	0.015	0.015	0.015
<i>Vertical load on each upstream and downstream pillar located on generator floor (MN)</i>			
Upstream	0.663	0.663	0.663
Downstream	0.681	0.681	0.681
Tailrace level (m)	1612	1612	1612
Jointly bearing pressure (MPa)	2.62	2.02	1.42

coming from superstructure, the circumferential tensile stress of each section is large and the maximum value is 1.94 MPa. The difference of circumferential tensile stress between top and bottom of the inner edge is a little small. While the medial stress level is higher than the lateral, it is because the thickness of medial concrete is thinner than lateral. The circumferential stress of each keypoint is less than the design tensile strength (3.27 MPa) of the concrete, the concrete will not crack.

2. In the scheme of LC-2, under the jointly bearing internal water pressure of 2.02 MPa, the maximum circumferential stress value of each keypoint is 1.49 MPa. The stress distributions are similar to scheme LC-1. Because of the decrease of the jointly bearing value, the stress level of concrete is less than scheme LC-1, so the surrounding concrete will not crack either.
3. In the scheme of LC-3, under the jointly bearing internal water pressure of 1.42 MPa, the maximum circumferential stress value of each keypoint also appears at the bottom of 2# section and the maximum value is 1.03 MPa.

Overall, since the design tensile strength of the surrounding concrete of distributor is high, the concrete will not crack in above three schemes.

## 5 DETERMINATION OF THE PRELOADING WATER HEAD OF DISTRIBUTOR

From the analysis of previous section, it can be seen that the preloading water head has a significant impact on the stress level of the surrounding concrete. Obviously the higher of the preloading water head, the better to the stress of concrete structure, and the distributor can play a full role when jointly bearing. The preloading filling measurement is essentially making a initial gap between distributor and its surrounding concrete before operation. The gap is not only related to the size of the preloading water head, but also related to the temperature differences between the construction and operation of distributor.

As the impact of hydration heat of concrete, even if the cooling measurement is taken, the temperature of the distributor during construction is generally higher than the minimum temperature during operation, so it will form a gap between distributor and surrounding concrete when the power station is operating. Assuming that the diameter of the distributor inlet is 1 m and maximum thickness is 50 mm, then every 1°C temperature difference will cause a gap of about 0.0078 mm which is equal to increasing the preloading water head of 0.32 MPa.

Table 2. Circumferential stresses of keypoints.

Section	Keypoints	LC-1	LC-2	LC-3
1#	a	1.19	0.94	0.68
	b	1.17	0.91	0.64
	c	0.96	0.7	0.43
	d	0.98	0.72	0.46
	e	—	—	—
2#	a	1.31	1.01	0.7
	b	1.75	1.35	0.96
	c	1.94	1.49	1.03
	d	1.42	1.09	0.76
	e	0.2	0.15	0.1
3#	a	0.75	0.6	0.4
	b	0.74	0.58	0.4
	c	1.18	0.85	0.32
	d	0.86	0.59	0.28
	e	0.43	0.3	0.11
4#	a	1.34	1.03	0.73
	b	1.37	1.06	0.76
	c	1.35	0.98	0.61
	d	0.94	0.68	0.43
	e	0.39	0.27	0.14
5#	a	0.85	0.65	0.46
	b	1.36	1.05	0.73
	c	1.29	0.92	0.54
	d	0.89	0.62	0.36
	e	0.23	0.12	-0.02
6#	a	1.27	0.95	0.65
	b	1.25	0.96	0.67
	c	1.07	0.76	0.45
	d	0.97	0.7	0.43
	e	-0.11	-0.16	-0.2

Figure 4. Location of typical sections.

To ensure the stable operation of the units, it needs to guarantee the sum of the actual preloading water head and the increased water head caused by cold gap is less than the minimum hydrostatic pressure, so it will not appear disengaging of distributor at any running water head. Preliminary estimated according to this standard, the allowable maximum temperature differences of scheme LC-1, LC-2, and LC-3 are 5.6°C, 3.7°C and 1.8°C respectively, so the higher of the preloading water pressure, the

Figure 5. Location of keypoints.

smaller of the allowable temperature difference, and the higher demand of keeping temperature measurements. From this point, the preloading water head can not be too high.

In a word, the determination of the preloading water head of distributor is not only to consider about the impact of the surrounding concrete stress, but also need to take the requirements of stable operation of units into account. Comprehensively considered of the two factors, the preloading water head can be determined as 80% of the minimum hydrostatic pressure, which is 4.83 MPa.

## 6 CONCLUSIONS

As to the preloading water head of water distribution ring pipe, it is necessary to consider the impact of stress of surrounding concrete and also take account of the requirements of unit's long-term stable operation. Considering these two factors comprehensively, the distributor's preloading water head of this project is suggested to be 4.8 MPa, 80% of the minimum head (598.5 m).

# Based on the grey GM (1,1) model to predict the total water consumption of Liaoning Province

Jinliang Chen

Liaoning Water Conservancy Vocational College, Shenyang, China

**ABSTRACT:** Based on the theory of grey system, this paper established a GM (1, 1) model for forecasting the amount of water consumed in Liaoning province. The precision of the model was sufficiently high to be used to predict the water demand in Liaoning Province. The results showed that the total water consumption in Liaoning province would grow continuously. The increasing water consumption may eventually lead to a situation where water supply could not keep up with the demand, adversely affecting people's lives and productions. Recommendations were presented for the protection and reasonable use of water resources in Liaoning province.

**Keywords:** GM model; grey system; water consumption; use of water resources

## 1 INTRODUCTION

The grey system is an analysis method proposed by Chinese scholar Deng Julong in the early 80s. The grey nature of a system is the result of its complexity. Grey Model (GM) establishes differential equations from the generating operation of the original data sequence, thus GM is actually generating sequence model. Since the inception of the grey system theory and method in 1982, the breadth and depth of its theoretical research have been constantly expanding. Its application is also popular among engineers and technicians. Because of its less stringent requirements of the quantity and distribution of data, as well as the simplicity of this theory and method, the forecasting method has been widely applied in oil, energy, water conservancy, transport, industrial control and other fields.

## 2 GREY FORECASTING MODEL

### 2.1 Steps of GM (1, 1) model

1. Accumulated generating operation of raw data  
 Perform the first accumulated generation on the measured raw data  $x^{(0)}$  to obtain  $x^{(1)}$ :

$$x^{(0)} = \{x^{(0)}(k) \quad k = 1, 2, \dots, n\} \quad (1)$$

$$x^{(1)} = \{x^{(1)}(k) \quad k = 1, 2, \dots, n\} \quad (2)$$

where  $x^{(1)}(k) = \sum_{i=1}^k x^{(0)}(i) \quad (i = 1, 2, \dots, n)$ .

2. Quasi-smooth test on  $x^{(0)}$

$$\rho(k) = \frac{x^{(0)}(k)}{x^{(1)}(k-1)} \quad (3)$$

If  $\rho(k) < 0.5$ , ( $k = 4, 5, \dots, n$ ) is valid when  $k > 3$ ,  $x^{(0)}$  satisfies the smooth condition.

3. Regularity in index variation test on  $x^{(1)}$

$$\sigma^{(1)}(k) = \frac{x^{(1)}(k)}{x^{(1)}(k-1)} \quad (4)$$

If  $\sigma^{(1)}(k) \in [1, 1.5]$ , ( $k = 4, 5, \dots, n$ ) is valid when  $k > 3$ ,  $x^{(1)}$  has regularity in index variation. Thus, GM (1, 1) can be established for  $x^{(1)}$ .

4. Close to the mean generation on  $x^{(1)}$

$$Z^{(1)}(k) = 0.5(X^{(1)}(k) + X^{(1)}(k-1)) \quad (5)$$

5. Least square estimation of  $\hat{a} = [a, u]^T$  to obtain  $a$  and  $u$

$$\hat{a} = \begin{bmatrix} a \\ u \end{bmatrix} = (B^T B)^{-1} B^T Y_N \quad (6)$$

$$B = \begin{bmatrix} -0.5(X^{(1)}(2) + X^{(1)}(1)) & 1 \\ -0.5(X^{(1)}(3) + X^{(1)}(2)) & 1 \\ \vdots & \vdots \\ -0.5(X^{(1)}(n) + X^{(1)}(n-1)) & 1 \end{bmatrix} \quad (7)$$

$$Y_N = [X^{(0)}(2) \ X^{(0)}(3) \ X^{(0)}(3) \ X^{(0)}(n)]^T \quad (8)$$

6. Establishing model  
 GM (1, 1) model is

$$\frac{dx^{(1)}(t)}{dt} + ax^{(1)}(t) = u \quad (9)$$

whose time response function is

$$x^{(1)}(t+1) = e^{-a}x^{(1)}(t) + \frac{u}{a}(1 - e^{-a}) \quad (10)$$

which gives the differential equation

$$x^{(1)}(t+1) = \left[ x^{(0)}(1) - \frac{u}{a} \right] e^{-at} + \frac{u}{a} \quad (11)$$

### 7. Inverse accumulated generating operation

$$\hat{x}^{(0)}(i) = x^{(1)}(i) - x^{(1)}(i-1), \quad i \geq 2 \quad (12)$$

where  $\hat{x}^{(0)}(1) = x^{(1)}(1) = x^{(0)}(1)$ .

### 2.2 Evaluation of grey system model

Test values are the main criteria to evaluate a model. GM (1, 1) model generally has the following four test values: average relative error, correlation, variance of error to variance of raw data ratio, and small error probability. These four test values together determine the model accuracy grade, that is, the four test values of each grade must be within the required ranges simultaneously. There are four grades of model accuracy, listed in Table 1. The first three grades imply that GM (1, 1) model is a suitable modeling tool. On the other hand, the

Table 1. Reference table of model accuracy grade.

Prediction accuracy grade	<i>P</i>	<i>c</i>
First (Good)	>0.95	<0.35
Second (Pass)	>0.8	<0.5
Third (Barely pass)	>0.7	<0.65
Fourth (Failed)	≤0.7	≥0.65

Table 2. The total water consumption in Liaoning province during 2002–2013.

Year	Total water consumption (× 10 <sup>8</sup> m <sup>3</sup> )	Proportions of different types of water consumption			
		Agricultural	Industrial	Domestic	Ecological
2002	127.1	0.654	0.181	0.165	0.000
2003	128.3	0.651	0.171	0.179	0.000
2004	130.2	0.658	0.153	0.183	0.007
2005	133.3	0.654	0.158	0.179	0.008
2006	141.2	0.648	0.166	0.172	0.014
2007	142.9	0.642	0.171	0.170	0.018
2008	142.8	0.637	0.173	0.172	0.019
2009	142.8	0.638	0.167	0.171	0.023
2010	143.67	0.625	0.174	0.177	0.024
2011	144.56	0.650	0.166	0.154	0.034
2012	142.19	0.644	0.162	0.165	0.031
2013	142.13	0.639	0.160	0.165	0.036

fourth grade means that the raw data cannot be characterized by GM (1, 1) model accurately.

## 3 BASED ON GREY THEORY TO PREDICT WATER AMOUNT IN LIAONING PROVINCE

### 3.1 Raw data

Based on the proportions of water resource usage in Liaoning Province from 2002 to 2013 shown in Table 2, agricultural water was on the decline, industrial water and domestic water remained stable, while ecological water increased year by year. The base value was chosen to be the total water consumption in Liaoning Province from 2002 to 2013. The trend in water demand in Liaoning Province was then predicted by GM (1, 1) model based on the three-year average data.

### 3.2 GM (1,1) model

#### 1. Model parameters

$$a = -0.013447, b = 137.156805$$

#### 2. Time response type

$$\hat{x}^{(1)}(k+1) = 10328.36299 \exp(0.013447k) - 10199.83299$$

### 3.3 The forecasting results

Table 3. The predicted total water demand in Liaoning Province.

Year	2014–2016	2017–2019
Predicted water demand (× 10 <sup>8</sup> m <sup>3</sup> )	145.60	147.55

Table 4. Precision of the model-predicted results.

Index number (k)	Year	Actual value ( $\times 10^8 \text{ m}^3$ )	Predicted value ( $\times 10^8 \text{ m}^3$ )	Absolute error	Relative error (%)
1	2002–2004	128.53			
2	2005–2007	139.13	139.83	0.69	0.50
3	2008–2010	143.09	141.92	-1.37	-0.96
4	2011–2013	142.96	143.63	0.67	0.47
Average					0.3

#### 4 CONCLUSION

In this paper, the grey theory was applied to establish a forecasting model for the total water consumption in Liaoning Province, which was used to predict the water demand of the next 6 years in Liaoning Province. Results showed that this model had a very high precision, suitable for prediction of water demand in Liaoning Province. Predicted results showed that during 2014–2016 and 2017–2019, the total volume of water would reach 14.56 billion  $\text{m}^3$  and 14.755 billion  $\text{m}^3$  respectively. With the continuous growth of water consumption in Liaoning province, demand will definitely exceed supply. Currently, it is crucial to develop and use water resources, so as to achieve the efficient use of water resources. Adopting water conservation measures and enhanced effluent treatment, increasing water recycling and raising residents' awareness of water saving measures are recommended. This paper can provide a reference for optimal and rational allocation of water resources in Liaoning province.

# Analysis of research status of the effect of pollutant adsorption on the motion characteristics of sediment

Yanfen Ren, Chao Zhu & Lianjun Zhao

*Yellow River Institute of Hydraulic Research and Yellow River Institute of Hydraulic Research, MWR Yellow River Sediment Laboratory, Zhengzhou, China*

**ABSTRACT:** The inaction between pollutants and sediment is very complicated. On the one hand, sediment has effect on the absorption and desorption of pollutants. On the other hand, the appearance of the sediment changes after absorbing pollutants and the mechanical motion characteristics of sediment also changes. Research trends, such as surface characteristics of the polluted sediment and the effect of pollutants on the behaviors of sediment, are summarized. The direction of further study of environment sediment is proposed: ① research into absorption of organic pollutant on the surface of particles at the micro-scale; ② research into scouring and silting deformation of environmental sediment; ③ the effect of new organic pollutants on the mechanical properties of sediment.

**Keywords:** pollutant; sediment; absorption; motion characteristics

## 1 INTRODUCTION

In recent years, with the geometric growth of the population in China, water discharge from modern industry, municipal waste, pesticide application and so on have led to serious river pollution. The rivers in China have high sediment concentration, so there is a strong interaction between pollutants in the polluted water and sediment. On one hand, sediment has important effect on water quality of rivers, that is to say, sediment has effect on the absorption and desorption of pollutant. And on the other hand, after sediment absorbs pollutants, its physical characteristics (appearance, structure and density and so on) change, which will have effect on its motion characteristics such as start, suspension, transport, and sedimentation.

The research into the law of the start, suspension, transport and sedimentation of the sediment in the river under the action of fluid is the basis of that into the motion characteristics of sediment-laden flow. Many famous scholars at home and abroad have devoted their lives to this research and laid a theoretical foundation for mechanics of sediment transport, which has formed a complete theoretical system. The subject of the traditional sediment research is clean sediment. But water has

been seriously polluted in the past ten years. So the pollutants that act on sediment must be taken into consideration in the study of the characteristics of sediment in water environment system. The study of the effect of pollutant on the physical and chemical characteristics is a necessary part of that of the mechanism of the interaction between pollutants and the sediment in rivers.

## 2 RESEARCH INTO THE EFFECT OF POLLUTANT ABSORPTION ON SURFACE CHARACTERISTICS OF SEDIMENT PARTICLES

### 2.1 *Research into the surface feature of natural sediment*

Sediment surface is the interface of the interaction between sediment and all kinds of pollutants. Correct understanding of the appearance and structure of sediment surface is the basis of the research into the interaction between sediment and pollutants. Surface features are very complicated. Among them, specific surface, pore size distribution, and surface charge are the most basic physical and chemical parameters.

Tang Hongxiao et al. measured the value of specific surface and analyzed the differences between northern and southern distribution. They think the greater the specific surface of sedimentary particles is, the more adsorption sites they have and the stronger their absorbability. As for the research into pore size distribution of particles, the

---

Project supported by National Natural Science Foundation of China (Grant No 51309109), Special Fund of Basic research operating expense of Central Public-interest Scientific Institution (No: HKY-JBYW-2013-08).

scholars at home and abroad discussed the porosity character of different particles, such as modified montmorillonoid, activated carbon, clay. Fang Hongwei et al. studied the pore distribution characteristics of the surface of Guangting bottom sediment through Nitrogen absorption-desorption test and found the fractal dimension of Guangting bottom sediment is 2.6~2.85. The pore volume of the polluted sediment particles whose pore diameter is less than 10 nm changes a lot and their fractal dimension becomes smaller because the surface pore is filled with pollutants.

Aquatic particulates carry a certain amount of charge due to lattice defect, isomorphous replacement and surface chemical reaction. Complex double electrode layer forms on particulates and has strong effect on the stability and interaction in different aspects. Huang Lei et al. made initial research into the distribution of surface charge of sediment particulates and measured the morphology and charge distribution of the surface of particles of silica sand by means of the measuring technical of the Electrostatic Field Microscope (EFM) for Scanning Probe Microscope (SPM) under the mode of phase imaging. They found charge distribution on the surface of sediment particles is uneven. Charge mostly concentrates on the saddle, uplifted parts and sunk parts and few charges distribute at groove, ridge and flat parts.

## 2.2 *Research into the effect on the surface features of environmental sediment particles*

The pollutants in water environment are generally divided into inorganic pollutants and organic pollutants. More attention is paid to heavy metal, nutrients and organics in environmental chemistry. Absorbing different pollutants leads to different changes in the surface features of sediment particles. This part mainly introduces the effect of absorption of heavy metal, nitrogen, and phosphorus nutrients and microbes on the surface features of sediment particles.

### 1. Research into the effect of heavy metal pollutants on the surface characteristics of sediment particles

Heavy metal pollutants mainly results from such human factors, as mining, waste gas discharge, sewage irrigation and use of products with too much heavy metal. Human activities results in the increase of the content of heavy metal in water environment. If the content of heavy metal exceeds the normal range, it will do harm to people's health and leads to water-environmental qualitative deterioration. Heavy metal pollutants exist in water in the form of ions. After sediment absorbs ion pollutants, the

surface characteristics of sediment particles will change. The research into this aspect mainly focuses on copper ions.

Chen Zhihe et al. analyzed pore size distribution and changes in the characteristics of pores through the experiment sand that has absorbed copper ions by means of physical and chemical adsorption instrument. Surface pores of sediment particles are mainly micropores and mesopores. Surface pores of sediment particles have strong copper ion absorption. Copper ions tend to be absorbed in  $r < 5$  nm pores when sediment particles absorb copper ions.  $r > 5$  nm mesopores and macropores are the passage by which copper ions are transported and diffused. The pore volume changes slightly. Specific surface area, total pore volume and average pore size tend to remain constant when copper ions fill the inner space of the pores gradually.

In order to study the morphology change after sediment absorbs pollutants, Chen Zhihe et al. summarized the distribution regularity of copper ions in heavy ions on the surface of sediment particles through copper nitrate absorption experiment and performed a statistical analysis on the micro-morphological characteristics of the particles with copper ions. Copper ions are mainly absorbed on the sides and at the depression of the surface of sediment particles, accounting more than 90% of the absorption number. Curvature reflects the copper ion absorption of complex morphology to a certain extent. The number of absorbed ions is the largest at the areas where Cu is equal to 1.1.

### 2. Research into the effect of nitrogen and phosphorus nutrients on the surface features of sediment particles

Nitrogen and phosphorus nutrients have numerous sources and are large in quantity, including sanitary sewage (organic matter and emergent), agricultural (chemical fertilizer and farmyard manure) and industrial waste water, waste and son on. Nitrogen and phosphorus are important influencing factors in aquatic system and one of the main limiting factors of eutrophication. When phosphorous pollutants come into water, they will spread and transport with water and some of them will be absorbed by the sediment particles in water. The study of the effect of phosphorous pollutants absorption on the surface features of sediment particles mainly focuses on the distribution regularity of phosphorous pollutants on sediment particles.

Chen Minghong et al. studied phosphorous pollutants absorption on the surface of sediment

particles at the micro-scale by means of Scanning Electron Microscope (SEM), and analyzed the distribution regularity of phosphorous on the surface of sediment by picture processing and with differential geometry approaches and expanded the traditional sediment research methods to multidimensional space. The research results show that there are more active chemisorbed sites at the saddle, depression and bulge of sediment particles and they are likely to absorb phosphorous.

Xiao Yang et al. made quantitative research into the surface features of sediment particles and the effect on phosphorous absorption by removing oxide and organic materials. They found that surface feature is one of the important factors that influence pollutant absorption of sediment. The median grain size of sediment has exponent relation to specific surface area. When grain size decreases to cosmid or fine silt, specific surface area increases remarkably. Langmuir isotherm can give a better description of the between liquid phase phosphorus equilibrium concentration and phosphorus equilibrium adsorption quantity in a phosphorus absorption test than Freundlich isotherm. With different initial concentrations of the water phase phosphorus, the phosphorus equilibrium adsorption quantity of sediment decreases with the increase of the grain size of sediment and the equilibrium adsorption quantity in low concentration region increases more quickly than that in high concentration region. When the initial concentration of phosphorus increases to a certain content, equilibrium adsorption quantity doesn't change gradually and increases to the maximum absorption quantity.

### 3. Research into the effect of microorganism adsorption on the surface characteristics of sediment

Microorganism is a kind of living organic matter and beings with the largest number, the widest distribution and the smallest individual. In nature, they live in the growing environment in attached state instead of free state. Sediment can absorb different kinds of nutrient due its unique surface absorption. Therefore, they attract much organic matters to the surface. Fang Hongwei et al. observed the morphology change of sediment particles after biological film grows on them with by means of Scanning Electron Microscopy (SEM). They found that sediment particles with biological film change a lot. The sediment particles in group are connected with each other and form netted texture or flocculent structure, while the surface of single sediment particle

with film is smooth and thus there are fewer changes in morphology.

## 3 RESEARCH INTO THE MOTION CHARACTERISTICS OF ENVIRONMENTAL SEDIMENT

### 3.1 *Research into the effect of ion pollutant absorption on the motion characteristics of sediment*

The effect of ion pollutants on sediment mainly manifest as the effect of positive ions in water on sediment flocculation. Under natural water condition, the surface of sediment usually is negatively charged. The charge on the surface of sediment and ions in water form structure of diffused electric double layer. When reverse ions in water increase, they will neutralize the electric doublet layer on the surface of compressed sediment and make the electrostatic repulsion among particles smaller, which leads to the increase of flocculation degree.

Cation ions in the water mainly refer to  $\text{Na}^+$ ,  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$  and  $\text{Fe}^{2+}$ . Chen Hongsong et al. studied the effect of  $\text{NaCl}$ ,  $\text{CaCl}_2$  and  $\text{AlCl}_3$  on flocculation and sedimentation in static water of fine grained sediment. The results show that during flocculation and sedimentation, the higher the concentration of  $\text{NaCl}$  and  $\text{CaCl}_2$  is, the faster flocculation and settling are. Liu Lin et al from Wuhan University studied the concentration of sediment with different  $\text{Ca}^{2+}$  ion concentrations on the course of flocculation and sedimentation. They found that the flocculating and settling speed increases with the concentration of sediment. It increases at the beginning and decreases gradually when it reaches the maximum. Under different ion conditions, the maximum flocculating and settling speeds and the maximum concentrations are different. The concentration of sediment that has reached the maximum will decrease with the increase of concentration of ion. The maximum speed increases with the concentration of ion.

Jin Ying and Jiang Guojun et al. studied the effect of the number of cation ions and valences on flocculating and settling of fine grained sediment. The sediment with larger number of valences has the larger amount of flocculation. They obtained the relation between flocculation and the number of cation ions in sea water. Wang Jiasheng et al. studied the effect of the common cation ions in the water on the settling of fine grained sediment in river water. The results show that the settling speed of sediment increases with the increase of the concentration of cation ions.

We can see ion pollutants mainly have effect on the flocculating and settling of fine sediment. This phenomenon is remarkable in estuaries. It mainly

influences the deposit of fine grained sediment in estuaries and the evolution of the riverbed in estuaries.

### 3.2 *Research into the effect of microbiological contaminants on the motion characteristics of sediment*

Microbiological contaminants mainly have effect on the biological film of sediment particles. In the polluted water, due to excess nutrients, the biological film resulted from the microbial activity on the surface of sediment has effect on and can change the motion characteristics of sediment.

Fang Hongwei et al. studied the changes in the motion characteristics of the sediment particles with biological film, including start, settling and so on. In the test of analyzing the settling of the sediment particles with biological film, they measured the size of the particles and the changes in settling speed through image analysis and deduced calculation formula of the settling speed of the sediment with biological film. The study shows that biological film has changed the surface characteristics of particles a lot. It increases the resistance to settling of particles. Compared with the sediment particles with the same size without biological film, its settling speed decreases remarkably.

Anderson et al. think the structure and composition of the community in water may have effect on the nature of sediment particles and have an important effect on settling of sediment particles through measured data and studied the effect of microbes' waste on the settling speed of erosion substance on the intertidal riverbed. Stal explored the effect of microbes and their waste on intertidal sediment.

In conclusion, the existing results show that the effect of pollutants on the behavior of sediment in natural water environment, especially in the polluted water isn't allowed to neglect. There is little research into other aspects.

## 4 FUTURE PROSPECT

At present, the research into the effect of pollutants on sediment is still not sufficient and further study need to be made.

1. The research into pollutant absorption on the surface of sediment particles at the micro-scale mainly focuses on heavy metal copper and nutrients such as phosphorus. There is little research into other heavy metal, organic pollutants, especially refractory organics. In the future, we should make more research into the

effect of different kinds of pollutants on the surface characteristics of sediment and set up more perfect interactive mechanism between sediment and pollutants.

2. The research into the effect of pollutants on the motion characteristic of sediment mainly focuses on the effect of pollutants on flocculating, settling, start and flowing speed of sediment. There is no research into scouring and silting deformation of sediment and we should strengthen the research into this aspect.
3. The previous research objects are limited to some common pollutants. But there are various pollutants in water, such as some new organic pollutants, plasticizers, surfactants, antibiotics, spices, cosmetics and so on. These new organic pollutants have complicated compositions, which have complicated effect on the motion characteristics of sediment. For example, different organic pollutants carry different charges. After they are absorbed by sediment, they can increase the flocculating speed of sediment and also may promote the dispersion of sediment, leading to more complicated effect on the motion of sediment.

**ABSTRACT:** The secondary water delivery is the important part of the urban water supply and the problem becomes more and more prominent. In this paper, with the factual example of national secondary water supply, the pollution reasons of secondary water supply are analyzed, and the measures for preventing the pollution of secondary water supply are proposed to satisfy the safety of residents drinking water, including improving the pipe network capacity, and regulating the design, construction and management.

**Keywords:** secondary water delivery; water quality pollution; prevention measures

## 1 INTRODUCTION

With the rapid development of China's economy and urbanization, more and more high-rise buildings have appeared, and the level of building water supply, drainage systems and construction equipment will be achieved a higher degree<sup>[1]</sup>. However, many weaknesses in security and stability exposed of the secondary water quality, it attracts more and more public attention. The definition of secondary water supply is that the water from urban public water supply facilities and self-built water facilities is provided for residents by special pipes after storage, compression, advanced treatment and disinfection. Water supply system must ensure adequate water supply to the users and adequate water pressure and also make sure that water meets state drinking water health standards. Now the construction and management of secondary water supply facilities attract more and more attention, and branch end of water distribution system is the truly reflection of the water quality. Therefore the quality assurance system establishment of the secondary water supply is the key mission for the safety of drinking water<sup>[2,3]</sup>.

## 2 EXAMPLE OF THE NATIONAL URBAN SECONDARY WATER SUPPLY AND THE WATER QUALITY EFFECTS

Until the end of 2010, in order to ensure water quality, Shanghai had renovated the secondary water

supply pipe network of residential area before 1997, and the water quality remains improving. However, the quality indexes of water in the secondary, such as sensory color and iron had increased, but the amplitude of residual chlorine tanks was reduced. The water quality deteriorates if it is kept in the tank for a long time. Meanwhile more study and discussion on secondary water supply facilities, capital and property measurement issues needs to be conducted, as well as secondary water supply facilities and management duties.

There were 386 residential areas requiring secondary water supply, 1472 tanks and 344 pools, and the number of users who need secondary water supply was 40% of the total residential users in zhuhai. First, the design of secondary water supply facilities was not rational, with a larger water reservoir, easily to increase the water retention time; second, the pools and water tanks used concrete structure, without appropriate treatment for the inner wall; Finally, operational management was not well, for example pools and water tanks were not cleaned regularly and disinfected, and the inlet holes of pool was damaged or none.

Since 2003, the Wenzhou water company investigated and transformed the secondary water supply facilities, tank construction materials, and the health conditions of water tanks in the urban areas. On the basis of ensuring the water quality, the secondary water disinfection team was established to disinfect the secondary water supply facilities by free. Meanwhile, the secondary water

supply company was also established to manage the received secondary water supply facilities, and combined the reform of “a water meter for one family”. Through these measures, the passing rate of secondary water quality in Wenzhou had become more than 98% by 2006.

### 3 REASONS OF THE SECONDARY WATER POLLUTION

The main problem of secondary water supply is the low pass percent of water quality, and the pass rate without secondary disinfection is only 60% to 70%<sup>[4,5]</sup>. The main pollution sources are ponds and water tanks, and the main pollutants are visible substances, bloodworms, turbidity, microorganisms, organic matter, chlorine and chlorine byproducts<sup>[6,7]</sup>.

The main reasons of pollution are design, construction, pipe materials and management.

#### 3.1 *Design and construction reasons*

##### 3.1.1 *Unreasonable technological design*

Because of improper tank design, the water will be easily “dead”. For example, part of the high water tank volume is too large, which makes water demand greater than domestic consumption. Therefore, the time of the water in the tank is over the theory time. The level of some pool tank is higher than the outlet, as a result that the water cannot be drained. In addition, the inlet pipe and pump suction tube pool are located in the same position, which make the water in the other end of stagnant water fostering a lot of plankton.

##### 3.1.2 *Unreasonable construction and structure*

Now the construction is not standardized, the current urban secondary water supply facilities needn't be required the license of the technical standards, the engineering drawings lack, the health awareness is weak, construction is not satisfied with hygiene requirements, construction are multi-contracting, and engineering quality is difficult to guarantee. According to specification for design of indoor water supply and drainage, life impounding reservoir should be far away from septic tanks of water storage tank, such as kitchen, toilet hygiene (>10 m), to prevent contamination of the drinking water. And the water pump room decorate also have certain requirements. But in the process of construction, real estate developers who want to save costs, are not according to the standard construction, leading to underground cisterns improper site selection, septic tanks and cisterns, mutual penetration, or pump room space is too small, the distance between the equipment

and pipeline cannot meet the specification requirements, and brings to the maintenance of equipment and system are difficult.

#### 3.2 *Unreasonable selection of pipe materials*

Some pipes in water supply system are using eliminated by national compulsory galvanized steel pipe which is easy to oxidizing reaction with water, corrosion fouling, leading the water quality pollution. But there is still a construction unit or develop commercial using cold galvanized steel pipe instead of hot dip galvanized steel pipe, and the leakage of the this tube is easy to burst, making the tap water polluted. Most of the roof water tank uses cement pavement with rough surfaces, providing the survival opportunity for algae and other biological, and lead-based ceramics lining would be harmful to human body.

#### 3.3 *Unreasonable management*

The reasons are as follows: lack of perfect health management system, no personnel management for the maintenance of the facilities, retired worker assumed for this task, a low professional quality, a big liquidity, and poor responsibility binding. Health and safety measures should be taken to ensure if the water tanks are cleaned and disinfected regularly.

According to the basic requirements of drinking water, cleaning the roof of the water tank is necessary atleast once in six months, but most of the water supply facilities are not provided to the secondary water disinfection facilities and equipment<sup>[7]</sup>.

## 4 PREVENTION MEASURES FOR SECONDARY WATER SUPPLY POLLUTION

#### 4.1 *Improve the pipe network and the carrying capacity*

It is needed to make a proper plan for water supply system, innovating the aging pipeline network, increasing the pump station and improving the network carrying capacity to make the pipe network pressure balanced, reducing the secondary water supply facilities. By these measures the problem of secondary water supply, water quality pollution will be solved at the source. Different water supply ways are adopted in building plot or high-rise buildings, and the different water supply pipeline is not with a direct connection to prevent the drinking water pollution by the non-drinking water<sup>[8]</sup>.

#### 4.2 *Regulate the design, construction and management*

Use separate life and fire-fighting pool construction, reasonable pool volume, reduce the stay time in the pool, and the location of the pool and the location of the in and out of the water pipe should be specific in strict accordance with the requirements of design. Use new type of feed water pipe, such as plastic pipe with good corrosion resistance and not easy to scale, keeping good health and long-term water performance. Construction unit must have the corresponding qualifications in strict accordance with the design requirements for construction, and reinforce the management of the construction process. Reform the original unqualified secondary water supply facilities, increasing the necessary disinfection equipment<sup>[9,10]</sup>.

#### 4.3 *Strengthen the facilities maintenance and management of secondary water supply*

Government departments should attach great importance to the management of secondary water supply, and formulate some corresponding regulations and institutions to strengthen the supervision of water supply facilities, regularly cleaning pool, and spottily check water quality. Reinforce the training for the management personnel to help them master the basic knowledge of water supply, preventing water quality pollution again because of improper management.

### 5 CONCLUSIONS

Secondary water supply is an essential part of the urban water supply. Therefore, to solve problems in secondary water supply is related to social stability, peace and contentment for people to live and work. Water quality of secondary water supply problems, whether the construction unit, design, construction and management departments, should be focused seriously, and comply with the relevant state laws and regulations. By these measures, the prevention of the water secondary water supply pollution will be ordering, scientific and legalization.

#### ACKNOWLEDGMENT

This research got the support from industry-university-research cooperation demonstration

base in colleges and universities of human province—the key technology integration for the safety of urban water supply.

**ABSTRACT:** In order to quickly locate the leakage in urban water distribution network, a model of pressure-dependent leakage detection is developed based on the principle that the leakage is positively correlated with the pressure. Particle Swarm Optimisation (PSO) is applied to solve the model, and the feasibility of pressure-dependent leakage detecting method is verified by using a test function. Finally, the model is applied in the water distribution network of City A to locate leakage. As a result, simulating leakage nodes are located within the range of 125 m to 467 m from actual leakage nodes, which indicates that the developed model can significantly improve the efficiency of leakage detection.

**Keywords:** water distribution network; pressure-dependent leakage location; particle swarm optimisation; leakage node; location deviation

## 1 INTRODUCTION

Water is the life line of cities. Water distribution network is the imperative bridge for connecting the waterworks and end users. However, Leakage occurs frequently along the water pipelines because of inappropriate constructions, pipeline aging and corrosion etc. The 2009 Annual Report of Urban Water Distribution (2010) from the Ministry of Housing and Urban-Rural Development of the People's Republic of China indicated the average leakage rate could be as high as 21.5% in most cities in China, and the leaked water could be as high as 6 billion m<sup>3</sup> every year. Pipe leakage leads to not only treated water resources loss but also the waste of electricity for water treatment, which causes direct economic losses to the water companies. Moreover, the security of drinking water can be threatened by

contaminations on the leak points, and soil losses caused by leakage can make negative impacts on the safety of buildings and traffic and further the related personnel security. Therefore, it is necessary to quickly locate and control the leakage in the complex and belowground water distribution networks.

The core work is to detect the invisible leakage. The conventional leakage detection methods mainly include voice-listening method and district metering method. Both the two methods have considerable disadvantages. The voice-listening method needs plenty of manpower and material resources, which is not efficient. Whilst the district metering method requires the reconstruction of the present water distribution networks to deploy more flowmeters, which is time-consuming and not economically efficient. Wu and Sage (2006) invented a new leakage detection method based

on hydraulic model check in water distribution networks, and applied it to one city in the UK. However, this method requires high accuracy of the input data of the hydraulic model, such as the network topology, pipe property and the real time monitoring data. Dong et al. (2013) built a leakage location inverse problem optimised model for water distribution system, and give a solution based on genetic algorithm. However, this method relies on the accuracy of the real time monitoring data such as water pressure, flow etc. They only used lab simulating platform to verify their model but no further practical verification was made. This paper uses the positive correlation between the leakage and the water pressure to build the leakage location model. PSO is applied to solve the model. After the leakage region is quickly confirmed, traditional leakage detection instruments can be used for further detection around the nodes in the region. This method can significantly reduce the range of detection and enhance the efficiency.

## 2 PRESSURE-DEPENDENT LEAKAGE LOCATION MODEL

The leakage is positively correlated with the pressure. Zhang (2013) indicated leakage can be regarded as a model related to the pressure-dependent water demand. The model can be built by injection flow. The relation between injection flow and pressure is given in Equation (1).

$$Q_i(t) = K_i [P_i(t)]^n \quad (1)$$

where

$Q_i(t)$  is the total leakage of node  $i$  until the time  $t$ ;  
 $P_i(t)$  is the node pressure of node  $i$  at the time  $t$ ;  
 $K_i$  is the injection coefficient at the node  $i$ ;  
 $n$  is the leakage flow index.

The leakage flow index is in a range of 0.5~2.5 based on the different pipe materials. The detectable leakage of the metal pipes refers to the leakage flow index 0.5.

According to Equation (1), every node in the water distribution network has its own injection coefficient. When the injection coefficient at one node is a positive number, there is leakage at this node. When the injection coefficient at one node is zero, no leakage happens at this node. Therefore, it is essential to optimise the injection coefficient to justify whether the leakage happens. When the optimised injection coefficient is above zero at one node, this node is regarded as a leak node (leakage may exist at the pipeline connected with this node).

## 3 APPLICATION OF PSO

In 1995, Kennedy and Barnhart invented the PSO. It suits to solve some problems that cannot be solved by traditional optimisation algorithms.

### 3.1 The fundamental principles of PSO

PSO is introduced by simulating foraging behaviour of the bird flock. Wang et al. (2001) indicated that this process is facilitated by the environmental adaptation of the particles. Wang and Liu (2008) indicated that all the particles in the searching space could be the potential solution of the problem in the entire optimising process. Particles can use their location memorability and share their information to obtain the best location they experienced themselves and the best location they experienced in the flock. Then they can adjust their speed and go to the best solution. PSO is the process that the particles continuously learn from themselves and the neighbours.

### 3.2 The parameter settings of PSO

PSO has relatively fewer parameters and simpler process compared to traditional optimising algorithms. The parameters of standard PSO include the flock scale  $n$ , inertia weight  $w$ , study factors  $c_1$  &  $c_2$ , the maximum speed of the particles  $V_{max}$  and algorithm terminating conditions.

It is important to assign the value of the inertia weight in PSO because the inertia weight can decide the size of the impact of the last speed on the current one and affect the current moving direction of the particle. Chatterjee and Siarry (2006) indicated the introduction of the inertia weight is to balance the local searching capability and the overall searching capability in the algorithm. When  $w = 1$ , the algorithm is the fundamental PSO.

The flock scale is the number of particles in the searching space. There is no unified settings on the flock scale. The empirical flock scale is 20~40 in most situations.

Under normal circumstances, the values of study factors have the relation  $c_1 = c_2$ , and they are in the range 0~4.

The maximum speed of the particles decides the maximum moving distance of the particles at every step of iteration. In the beginning  $V_{max}$  is large, and the overall searching capability is high. Then in the process of iteration, the region of the best solution can be initially confirmed. Finally  $V_{max}$  decreases, and the local searching capability enhances, which lead to the fast converging to the best solution (Fan, 2002).

### 3.3 Test of PSO

#### 3.3.1 Ackley function

Ackley function is used to compare the calculation ability of PSO and Genetic Algorithm (GA) on it. Goldberg (1989) indicated that the most widely used evolutionary algorithm is the GA which is based on the rules of evolution and natural selection.

Ackley function is given in Equation (2).

$$f(x) = -20 \cdot e^{-0.20 \sqrt{\frac{1}{n} \sum_{j=1}^n X_j^2}} - e^{\frac{1}{n} \sum_{j=1}^n \cos(2 \cdot \pi \cdot X_j)} + 20 + e |X_i| \leq 32 \quad (2)$$

The least value of this function is zero at the point of zero.

$$\min(f(x_*)) = f(0, 0, \dots, 0) = 0 \quad (3)$$

There are many local minima on the chamber of Ackley function. If the searching space of traditional algorithms is too small, it is easy to sink into the local minima. However, if the searching space is too large, it is easy to jump over the valley and search the suboptimal solution. Therefore, Ackley function is the problem which is hard to overcome by using traditional optimising algorithms.

#### 3.3.2 Test result

The initial particle number is set to 50, and the study factors are 1.4 and 1.2 respectively for the PSO. Whilst for the GA, the initial population is set to 50, and the mutation probability is 0.2, and selection probability is 0.5, and terminating condition is that the row difference of the best solution is 1e-10, and the maximum iteration times are set 100 and 200 respectively.

Figure 1 and Figure 2 show that the adaptability function value changes with the iteration times by using PSO and GA to solve the Ackley function when the maximum iteration time is 100 and

Figure 1. Maximum iteration times: 100.

Figure 2. Maximum iteration times: 200.

200 respectively. When the maximum iteration time is set to 100 by using PSO, the best solution converges to 0.00352367. Whilst when the maximum iteration time is set to 100 by using GA, the best solution only converges to 0.10863. When the maximum iteration time is set to 200 by using PSO, the best solution converges to 4.82083e-6. Whilst when the maximum iteration time is set to 200 by using GA, the best solution only converges to 0.0032612.

Set to the same iteration times, the converging speed of PSO is faster than GA, and the optimal solution by using PSO is also nearer to the actual value than by using GA. Therefore, this paper selects PSO to solve the leakage model.

## 4 THE DEVELOPMENT OF PRESSURE-DEPENDENT LEAKAGE LOCATION MODEL

The solution of leakage location model is evaluated by objective function. Objective function is defined by the difference of the actual value and simulating value of node pressure and pipe flow. The smaller value of objective function is, the nearer between the simulating pipe operating condition and the actual pipe operating condition. During the operation of the water distribution network, flow and pressure are the most direct reflection of the pipe operating condition. In order to equally consider the pressure and flow, by using two self-defined transform parameter the pressure and flow can be transformed to no-dimensional values. Then optimisation can be implemented. The objective function is given by Equation (4).

$$F(\bar{X}) = \sum_{t=1}^T \left[ \sum_{nh=1}^{NH} W_{nh} \left[ \frac{H_{S_{nh}}(t) - H_{0_{nh}}(t)}{H_{pnt}} \right]^2 + \sum_{nf=1}^{NF} W_{nf} \left[ \frac{Q_{S_{nf}}(t) - Q_{0_{nf}}(t)}{Q_{pnt}} \right]^2 \right] \quad (4)$$

× NH + NQ

where

$H_{shh}$  is the simulating pressure of node  $nh$  at the time  $t$ ;

$H_{0nh}$  is the actual pressure of node  $nh$  at the time  $t$ ;

$Q_{snf}$  is the simulating flow of pipe  $nf$  at the time  $t$ ;

$Q_{0nf}$  is the actual flow of pipe  $nf$  at the time  $t$ ;

$H_{pnt}$  is the pressure transform factor;

$Q_{pnt}$  is the flow transform factor;

$NH$  is the number of pressure monitoring points;

$NQ$  is the number of flow monitoring points.

Therefore, leakage detection model can be concluded as

$$Mnimize : F(\vec{X})$$

where

$$\vec{X} = (LN_i, K_i), LN_i \in J, i = 1, 2, \dots, N \text{ Leak};$$

The constraint conditions are

$$0 \leq K_i \leq \bar{K}, 1 \leq i \leq n$$

$$P_i > 0, 1 \leq i \leq n$$

$$\sum \pm q_{ij} + Q_i = 0$$

$$\sum h_{ij} - \Delta H_k = 0$$

where

$K_i$  is the injection coefficient of node  $i$ ;

$n$  is the number of nodes;

$\bar{K}$  is the maximum injection coefficient of node  $i$ ;

$P_i$  is the pressure of node  $i$ ;

$Q_i$  is the flow of node  $i$ ;

$q_{ij}$  is the flow of the pipelines connected with node  $i$ , and  $i, j$  are the start and end number of pipelines;

$h_{ij}$  is the head loss of the pipeline in basic ring  $k$ ;

$\Delta H_k$  is the loop closure or the pressure difference caused by pressurizing and decompressing devices in basic ring  $k$ .

## 5 APPLICATION OF PRESSURE-DEPENDENT LEAKAGE LOCATION MODEL IN CITY A

### 5.1 Engineering background of City A

There are one raw water plant, seven waterworks in City A. The capability of daily water distribution is 1.05 million  $m^3$  and the actual output of supplying water is 0.7 million  $m^3$ . The waterworks mainly serve the main city zone, east and west area of the city. The total length of the water distribution network in City A is 3294 km. The maximum height difference of the city is over 100 metres because of the large height difference between north and

south areas. There are 30 pressure stations in the water distribution network, and approximately 500  $km^2$  area and 3.2 million people are served. This paper is proposed to focus on the leakage location model of one certain district in City A.

The sub-model of this district is showed in Figure 3. One water plant in this district includes 1,431 nodes, 2,079 pipelines, 6 pressure monitoring points and 5 flow monitoring points. All the monitoring points are remote communication meters, which can provide real time data. The pressure and flow monitoring points are showed in Figure 4.

### 5.2 Pressure-dependent leakage location

According to the record of pipeline maintenance in City A, leakage occurred on 2nd March 2013 and the leak point is showed Figure 5. Leakage detecting area can be initially confirmed based on the direct pressure and flow data. The whole water

Figure 3. The sub-model of one certain district in City A.

Figure 5. Leakage detecting area in the sub-model.

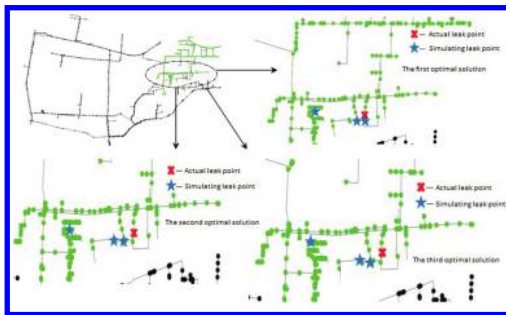

Figure 6. The first, second and third optimal solution.

distribution network can be influenced if leaking water quantity is high, so that it is easy to detect the leakage. This paper uses the monitoring data from the midnight to 4 a.m. for calculation because water consumption is low, pressure and leakage is high during this period. In the process of calculation, optimisation is implemented when the maximum leak points are 4, 2 and 1 respectively. Then the obtained optimal solutions are compared and analysed to accurately locate the leak points. In this area there are 6 pressure monitoring points and 5 flow monitoring points. 44 groups of data were obtained during this period, based on which PSO is implemented. The maximum iteration times are set to 100 and 200 respectively, and the number of particles are 100, and the study factors are set to 1.2 and 1.4 respectively, and the maximum moving speed is set to the 20% of the parameter changing range (that is 0.2).

### 5.2.1 The maximum leak points are 4

Initially the maximum leak points are set to 4, which is the number of the maximum leak points in the optimisation area are 4. The result keeps three optimal solutions showed in Figure 6 and Table 1, 2 and 3.

Table 1. The first optimal solution.

Node	Optimal injection coefficient	Distance to the actual leak point (m)	Value of objective function
Node 17015	0.288	125.299	0.086
Node 17750	0.254	200.96	
Node 13391	0.229	46.606	

Table 2. The second optimal solution.

Node	Optimal injection coefficient	Distance to the actual leak point (m)	Value of objective function
Node 17015	0.290	125.299	0.091
Node 15533	0.239	197.206	
Node 16541	0.238	217.046	

Table 3. The third optimal solution.

Node	Optimal injection coefficient	Distance to the actual leak point (m)	Value of objective function
Node 17015	0.290	125.299	0.103
Node 15533	0.238	197.206	
Node 17057	0.236	467.181	

Figure 7. The first, second and third optimal solution.

Table 4. The first optimal solution.

Node	Optimal injection coefficient	Distance to the actual leak point (m)	Value of objective function
Node 12370	0.336	165.06	0.072
Node 12354	0.333	201.851	

### 5.2.2 The maximum leak points are 2

The maximum leak points are set to 2. The result keeps three optimal solutions showed in Figure 7 and Table 4, 5 and 6.

Through the analysis, when the maximum leak points are set to 2, the result of optimisation shows

Table 5. The second optimal solution.

Node	Optimal injection coefficient	Distance to the actual leak point (m)	Value of objective function
Node 12370	0.349	165.06	0.075
Node 12354	0.320	201.851	

Table 6. The third optimal solution.

Node	Optimal injection coefficient	Distance to the actual leak point (m)	Value of objective function
Node 12370	0.349	165.06	0.099
Node 12354	0.324	201.851	

Table 7. The first optimal solution.

Node	Optimal injection coefficient	Distance to the actual leak point (m)	Value of objective function
Node 4744	0.796	323.268	0.007

Table 8. The second optimal solution.

Node	Optimal injection coefficient	Distance to the actual leak point (m)	Value of objective function
Node 4744	0.792	323.268	0.011

Table 9. The third optimal solution.

Node	Optimal injection coefficient	Distance to the actual leak point (m)	Value of objective function
Node 12462	0.790	223.581	0.047

that Node 12370 and Node 12354 are always suspicious leak points.

### 5.2.3 The maximum leak point is 1

The maximum leak points are set to 1. The result keeps three optimal solutions showed in Table 7, 8 and 9 and Figure 8.

Pressure-dependent leakage location cannot exactly accurately locate the leak points, but it can find the district where leakage occurs. The actual leak points need to be confirmed by workers

Figure 8. The first, second and third optimal solution.

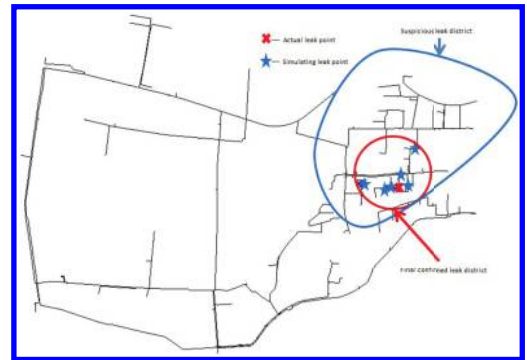

Figure 9. Comparison between the actual and simulating leak district.

using leakage detection devices. According to the result of optimisation, comparing the values of objective function when the maximum leak points are set to 4, 2 and 1 respectively, leak points can be confirmed in the area near Node 17015, 15533, 17750, 16541, 13391, 12462 and 4774. The distance of the nearest simulating leak point to the actual leak point is 125 m, and the farthest is 467 m. Therefore, the leak district can be confirmed as the circle area which the centre is the actual leak point and radius is 467 m, showed in Figure 9.

Shown in Figure 9, the blue district is the detecting area when traditional leakage detection methods are used. All the pipelines in this large area need to be detected if traditional leakage detection methods are used, so that both work and economic efficiency is low and it is a waste of manpower and material resources. The red circle district is the final confirmed leak district by using pressure-dependent leakage location method. Compared to

the blue district it is much smaller. Only the circle area which the centre is the actual leak point and radius is 467 m needs to be detected. Therefore, both detection and repairing efficiency is largely enhanced, and leakage is significantly reduced.

## 6 CONCLUSION

This paper builds pressure-dependent leakage location model based on the sub-model of City A, and PSO is applied to calculate the model. Calculation is based on the actual situation on 2nd March 2013. The maximum leak points are set to 4, 2 and 1 respectively and three optimal solutions are considered. Through analysis, the farthest distance from the actual leak point is 467 m, and the nearest is only 125 m. The leak district can be confirmed in the circle area which the centre is the actual leak point and radius is 467 m. Traditional leakage detection methods need workers to investigate in a large area. However, this method indicated in this paper significantly reduces the suspicious leak district, so that repairing time is reduced and efficiency is enhanced. Pressure-dependent leakage location method is relatively new compared to the conventional methods and the located leak district is relatively accurate. But the exact leak points still needed to be confirmed by using additional detecting devices.

*Hydrology Bureau of Linyi, China*

**ABSTRACT:** Based on the basic situation of Lanling, water resources, water supply and use, and water utilization level were analyzed. Some engineering and management measures for promoting rational development and utilization of water resources were proposed for water resources development problems. These measures have certain significance for the rational water resources allocation.

**Keywords:** water resources; exploitation and utilization; the most strict water management system; water utilization level; measures

## 1 THE GENERAL SITUATION OF LANLING

Lanling is located in the south of Shandong province, southwest of Linyi. The total area is 1724 km<sup>2</sup>, accounting for 1.1 percent of the province's total area. It is located in the southern edge of the hilly area of Lunan, the north is hilly area, the south is plain area, and the terrain decreases from the northwest to southeast. Northern hilly areas are composed of the Cambrian, middle and lower Ordovician Limestone, shale formations. The formation of southern plain areas is friable rock of quaternary system. The sandstone thickness of quaternary groundwater is thickened from north to south, especially a large sand thickness in the southeastern.

It is warm temperate semi-humid monsoon climate zone in Lanling. It demonstrate typical characteristic of significant continental climate, discernible season, rain in hot season. The rivers belong to middle canal water system of Huaihe Valley. The main rivers are Taoye River, Yunnv River, Xijia River, and other twelve from west to east. The total length is 321.12 km. These rivers are shallow and swift. Most of rivers are seasonal. They import middle canal in Pizhou of Jiangsu Province flowing from north to south.

There are 17 towns (streets), 1024 administrative villages in Lanling. It has favorable natural conditions. The industrial and agricultural production is developing rapidly. It has formed the

industrial system currently. The leading industry is mining, building materials, food, machinery, chemicals, light industry etc. The total population is 127.54 million, county urbanization rate is 7.94%, the GDP is 27.156 billion yuan; industrial added value is 9.652 billion yuan; three industrial structure adjustment is 18:36:46; the per capita GDP is 23,133 yuan, and net income per capita is 10,323 yuan at the end of 2013.

## 2 THE SITUATION OF WATER RESOURCES

### 2.1 *Temporal and spatial distribution of water resources*

According to 55 years (1956–2010) of runoff, annual mean surface water resources is 557.43 million m<sup>3</sup>, and annual mean groundwater resources is 242.83 million m<sup>3</sup>. Apart from overlap counting, the annual total capacity of Lanling is 705.67 million m<sup>3</sup>.

The water resources of Lanling have several important features.

The distribution of precipitation is uneven throughout the year, 72.9% of which is concentrated in June to September, and monthly precipitation has larger difference. The change of precipitation among different years is large, and wet year and dry year are consecutive. Maximum annual precipitation is 40% larger than annual mean, and minimum annual precipitation is 55% of annual mean.

Modulus of surface water resources is 323300 m<sup>3</sup>/km<sup>2</sup>, modulus of groundwater resources is 140900 m<sup>3</sup>/km<sup>2</sup>, and surface water resources are relatively rich in Shandong province. The average person possession of water is only 541 m<sup>3</sup>, slightly higher than the average of Shandong province, just as 25% of our nation's. It belongs to water shortage area.

The time and spatial distribution of water resources is very uneven, which impacted by rainfall, geological structure, topography and geomorphology, and hydrogeology condition. In terms of surface runoff, relatively large difference between water resources formed by wet year and dry year. Shallow groundwater resources are mainly comprise the rain, river and irrigation seepage etc. It has a regulation in the year, annual distribution with small changes.

### 2.2 Water quality of water function area

According to "water function zoning of Shandong province," there are eight first-degree water functional areas and four second-degree water function areas. Water quality regular rate of water function area reach 100%, according to the water quality monitoring data of water function area in 2013.

## 3 PRESENT SITUATION OF EXPLOITATION AND UTILIZATION OF WATER RESOURCES

### 3.1 Water supply project and quantity

It has 135 water storage projects, including a large reservoir, 4 medium-sized reservoirs, 41 small reservoirs, 92 embankments in Lanling. The current supply capacity of water storage project is 53.39 million m<sup>3</sup>. The county has four water diversion projects, diversion size is 1.2 m<sup>3</sup>/s, and the current supply capacity is 12.3 million m<sup>3</sup>. The total amount of surface water development and utilization was 73.04 million m<sup>3</sup>, the utilization ratio was 13.1% in 2013.

There are 2828 shallow groundwater matching electromechanical wells with 59.2 million m<sup>3</sup>/a supply capacity in Lanling, mainly used for industrial production, agricultural irrigation and domestic water supply for urban residents. The total amount of groundwater development and utilization was 59.2 million m<sup>3</sup>, the utilization ratio was 24.4% in 2013.

A sewage treatment plant was built in 2006, with a capacity of treat municipal sewage up to 13.02 million tons, load operation rate of 88%.

The annual average water supply quantity of 5 years (2009~2013) is 136.57 million m<sup>3</sup>. The surface water is 73.87 million m<sup>3</sup>, and groundwater is 62.7 million m<sup>3</sup>. The supply quantity of water storage project

is 52.14 million m<sup>3</sup>, water diversion is 20.21 million m<sup>3</sup>, and mention water is 6.77 million m<sup>3</sup>. The supply quantity of shallow groundwater is 59.91 million m<sup>3</sup>, and deep groundwater is 2.61 million m<sup>3</sup>. The surface water supply is 54.09% of the total water supply, and groundwater is 45.91%.

### 3.2 Water consumption and utilization structure

Water consumption of Lanling includes farmland irrigation, farming, forestry, animal husbandry, and fishery, industry, town public, resident living and ecological environment, etc.

The average water consumption of Lanling from 2009 to 2013 is 135.7 million m<sup>3</sup>. Among them, farmland irrigation is 82.09 million m<sup>3</sup>, farming, forestry, animal husbandry and fishery is 50.6 million m<sup>3</sup>, industry 8.35 million m<sup>3</sup>, town public 5.46 million m<sup>3</sup>, resident living 28.1 million m<sup>3</sup>, ecological environment 9.28 million m<sup>3</sup>, account for total water consumption 60.49%, 3.73%, 6.15%, 4.02%, 20.71%, 6.84%, respectively.

### 3.3 Control targets of the most strict water management system

#### 3.3.1 Control targets of the total water use quantity

The surface water, groundwater index allocated to Linyi by Shandong Province were 1.546 and 0.492 billion m<sup>3</sup> respectively, and the total was 2.605 billion m<sup>3</sup>. The surface water, groundwater index allocated to Lanlin were 0.094 and 0.063 billion m<sup>3</sup> respectively, and the total was 0.157 billion m<sup>3</sup>. (see Table 1).

The total amount of water use is not exceed control targets of the total water use quantity in Lanling in 2013. But groundwater water utilization is 59.2 million m<sup>3</sup>, and it is close to the upper limit of control targets. The local surface water supply is 73.04 million m<sup>3</sup>. There is a certain margin in the total amount control targets of surface water.

#### 3.3.2 Control targets of the water use efficiency

In 2015, the control targets of water consumption of 10,000 Yuan industrial added value decreases 14% compared to 2010. It drops to 14.19 m<sup>3</sup>. The water consumption of 10,000 Yuan industrial added value is 9.14 m<sup>3</sup>, less than control targets.

Table 1. Control targets of the total water use quantity in Lanling in 2013. (billion m<sup>3</sup>).

Administrative area	Surface water	Groundwater	Total
Linyi	1.546	0.492	2.038
Lanling	0.094	0.063	0.157

### 3.3.3 Limit pollutant control targets of water function area

Limit pollutant control targets of water function area COD is 1216.91t/a, and NH<sub>3</sub>-N is 60.38t/a in Lanling. The measured value of COD and NH<sub>3</sub>-N are 230.97t/a and 7.89 t/a respectively in 2013. They meet the limit pollutant control targets of water function area.

## 3.4 Analysis of supply and demand balance

### 3.4.1 National economic indicators

In recent years, economy has developed rapidly in Lanling. The economic development indicators are shown in Table 2.

Table 2. Economic development indicators in Lanling.

Level years	2013
<i>Population (people)</i>	
Urban population	9.85
Rural population	117.69
Total population	127.54
Industrial added value (Yuan)	96.50
<i>Irrigation area (Mu)</i>	
Paddy field	1.60
Irrigated land	16.68
Vegetable fields	23.30
Subtotal	41.58
Fruit irrigated area (Mu)	2.18
<i>Livestock (Ten thousand head)</i>	
Big livestock	2.05
Small livestock	56.05

Table 3. Water requirement in Lanling.

Level years	2013
City Life water requirement (million m <sup>3</sup> )	10.95
Rural life water requirement (million m <sup>3</sup> )	23.80
<i>Livestock (Ten thousand head)</i>	
Big livestock	0.30
Small livestock	4.09
Industrial water requirement (million m <sup>3</sup> )	8.82
<i>Agricultural water requirement (million m<sup>3</sup>)</i>	
50%	109.58
75%	130.37
95%	130.37
Ecological environment water requirement (million m <sup>3</sup> )	14.03
<i>Total water requirement (million m<sup>3</sup>)</i>	
50%	171.57
75%	192.36
95%	192.36

### 3.4.2 Water requirement

Water requirement by various sectors of the national economy is obtained by economic development indicators and water quota in 2013. Agricultural water requirement of 95% guaranteed rate is consistent with guarantee 75%. The total water requirement is the sum of water requirement in various sectors of the national economy and water requirement of ecological environment.

### 3.4.3 Calculation of supply and demand balance

Table 4. Water supply and demand balance analysis and calculation in Lanling in 2013.

Level years	Guaranteed rate	Available water supply (million m <sup>3</sup> )	Water demand (million m <sup>3</sup> )	Deficiency (million m <sup>3</sup> )	Water shortage degree
2013	50%	157.33	17.157	-14.24	-8.30%
	75%	151.76	192.36	-40.60	-21.11%
	95%	142.91	192.36	-49.45	-25.71%

50%, 75%, 95% guaranteed rate, there is a water shortage, mainly for agricultural water.

## 3.5 Water utilization level and efficiency

The total water use quantity is 132.24 million m<sup>3</sup>, water consumption of 10,000 Yuan GDP is 48.7 m<sup>3</sup>, water consumption of 10,000 Yuan industrial added value is 9.14 m<sup>3</sup>, repeated use rate of industrial water is 60%, utilization efficiency of irrigated water is 0.55, water saving irrigation rate is 23%, irrigation consumption of water per mu of farmland is 96.42 m<sup>3</sup>, leakage rate of city's water supply systems is 10%, urban life comprehensive water quota is 150 L per person day, centralized sewage treatment rate is 75%, and water quality double-index regular rate of water function area reach 100%. The total water use quantity, water use efficiency (water consumption of 10,000 Yuan value added, utilization efficiency of irrigated water), limit pollutant indicators of water function area meet the most strict water management system. There is a gap between some indicators and water-saving society control target demands of Shandong province.

## 4 THE MAIN PROBLEMS EXISTING IN THE DEVELOPMENT AND UTILIZATION OF WATER RESOURCES

### 4.1 Water project are not fully unrealized

The supporting construction of water conservancy project has lagged behind in the body and affected

the overall effectiveness for a long time. Most water supply projects built in the 1950s and 1960s is still in disrepair. Much of them are in extended use or ill run. The engineering maintenance costs are inadequate because of the low water price for a long time. Further sedimentation and water pollution are affecting the water supply project benefits seriously.

It should increase investment in water supply project to achieve the desired results.

#### 4.2 *Water utilization is not high*

People's awareness of the water is not clear and water-saving awareness is weak because water resource fee and water fee are persistently low. The utilization efficiency of irrigated water and repeated use rate of industrial water are low. Many residents have not used water-saving appliances. Industry, agriculture and life have a greater life saving potential.

Industrial water save is strengthened by optimizing the industrial structure and layout and speeding up the elimination of backward high-water technology, equipment and product to promote water-saving technology and equipment and other measures. Agricultural water-saving engineering is promoted by speeding up the adjustment of agricultural structure and developing characteristic agriculture. Domestic water is saved by the renewal and transformation of water supply network, reducing the leakage rate, implementing "one family, one table, measuring out the door" reform, trying out ladder water prices, strengthening life water-saving appliances certification, establishing market access system for water-saving products, and enhancing the people's awareness of water saving to achieve the purpose of water saving.

#### 4.3 *There are different levels of water contamination*

With the continuous development of social economy, waste water which is unable to handle and directly into waters is increasing each year. It causes a lot of water pollution and water environment deterioration.

Most rivers are polluted to different degrees currently. Water pollution has infiltrated from the surface to the underground. Control and management of the sewage outfall into the river are strengthened in view of existing situation, in order to reach the standard of water function area, protect, and improve surface water environment.

## 5 MEASURE OF EXPLOITATION AND UTILIZATION OF WATER RESOURCES

### 5.1 *Engineering measures*

On the basis of the existing water conservancy project, as much as possible surface water resources

are remained by strengthening the management of water conservancy projects, optimizing water supply dispatching, carrying out the use of rain floods, improving the utilization of surface water under the premise of meet downstream ecological, strengthening soil and eater conservation in the upper basin, carrying out small watershed management, increasing vegetation and water conservation, constructing reservoirs, ponds, and sluice and dam, in order to store runoff and increase infiltration.

Groundwater supply quantity assumes 45.9 percent of total water supply in Lanling in 2013. It has abundant multi-year regulating characteristic, and plays an important role in the supply pattern. Groundwater is actively protected and rationally explored, accordance with the "overall balance, control overexploitation, regional adjustment, wet season recharge" principle. Groundwater exploitation should be strictly controlled in the range of allowable exploitation by reasonably adjusting groundwater extraction layout and constructing recharge project, in order to gradually achieve rational development, control mining, leave room, and virtuous circle.

Unconventional sources include wastewater reuse, mine water use and rainwater storage and utilization. The sewage treatment and reuse should be increased further, and effluent from sewage treatment plant should be treated profoundly. It is widely used in the less quality demand water such as industrial cooling water, dust, miscellaneous municipal water, irrigation, and other water. The mine is widely distributed in Lanling, with large displacement and use potential. The main pollutants are SS. It can be directly used for industrial production and agricultural irrigation by simple process. Moreover, the construction of rain collection should be carried out according to local conditions, on the base of full using terrain and geological conditions. Rainwater is stored as much as possible by combining small watershed comprehensive management project in the mountainous areas. Rainwater through the housing, space, roads, and other venues are collected in other regions.

### 5.2 *Management measures*

Water resources development or inter-basin water transfer cannot solve fundamentally the increasingly outstanding water shortage problem, in the case of limited total water resources and growing demand for water.

Therefore, we must implement the most stringent water management system, establish, and implement three red lines of water resources management around water resources allocation, conservation and protection, strictly implement

total water control, curb unreasonable demand for water, strengthen water resources unified deployment capability, build a water-saving society, strengthen water demand management, take the content development, strengthen supervision and management of water function area, control the total amount of sewage into the river, promote the protection and restoration of aquatic ecosystems, improve water resources management system, lead the transformation of water resources management approach, and perfect policies and regulations and social supervision mechanism.

The contradiction between water supply and water demand will be effectively alleviated through engineering and management measures in Lanling, with the sustainable use of water resources to support and ensure sustainable economic and social development.

# Stochastic optimal operation and improved multi-objective particle swarm algorithm for water supply and environment

J. He, S.P. Gu & W.X. Tan  
Hohai University, Nanjing, China

**ABSTRACT:** To alleviate the threat of water shortage and water pollution with economic development, we need to enhance the capacity of the water supply guarantee and environmental protection. Multi-objective optimal operation of Projects is an effective approach. This paper defines indicators and multi-objective functions to coordinate water supply and environment. With stochastic runoff, the method in this paper is to pre-define operation rules of power function and find out optimal parameters. On this basis, the stochastic optimal operation model is established. And the improved multi-objective particle swarm optimization is given. Example of verification gives the satisfactory results. It is proved that the method is reasonable and efficient.

**Keywords:** stochastic optimal operation; multi-objective particle swarm optimization; water supply; environment

## 1 INTRODUCTION

### 1.1 Background

With the acceleration of urbanization, Chinese water resource problems include water shortage and water pollution, etc. In addition to natural conditions and social reasons, reservoirs have not played potential to make the water supply and environment objectives optimal.

### 1.2 Solutions

The first solution in this paper is formulating reasonable water supply indicators and water environment indicators. It is useful to build multi-objective functions. The second difficulty is that hydrological factors are stochastic; it is hard to forecast for a long time. To solve it, optimal rules of power function are designed in this paper. It is more scientific to make stochastic optimal rules instead of assuming that the runoff is certain. At last the improved multi-objective particle swarm optimization algorithm is established. It is more adaptable and effective to solve the model than the traditional dynamic programming.

## 2 DEFINITION OF OPERATION RULES WITH STOCHASTIC RUNOFF

### 2.1 Progress in the field

The long-term optimal operation of reservoirs can be categorized into two: the explicit stochastic

optimization and the implicit stochastic optimization. The former takes Markov Decision Plan as the basic model. There is obstacle for a large number of reservoirs. The implicit stochastic optimization method was proposed by Young first in 1967<sup>[1]</sup>, including two steps<sup>[2]</sup>: a) based on the runoff series measured or generated by Monte Carlo method, apply deterministic operating optimization technology obtain a long-term strategy; b) in the results, using regression analysis to design operating rules.

With development of optimization technology, it also can be pre-defined scope of the rules, and then use simulation and optimization to find the optimal rule. It is consistent with the essence of stochastic optimization operations. In this paper, we are using this method.

### 2.2 Rules pre-defined

Stochastic optimal operation is the optimal rule<sup>[3]</sup> of reservoirs with stochastic runoff. Generally, the decision variables described as a function of the state vector, Assuming, the period is one month, one year is divided into 12 periods. At the beginning of each month, the state variable is the amount of water in the reservoir. Decision variable is the amount of water retained in the reservoir of the end of the month. Now, the monthly runoff is random. So the decision is not definitive, but a rule. Rule is described as a power function defined in [Equation 1](#).

$$X_i = \alpha_i (S_i + Q_i)^{\beta_i} + \varepsilon \quad (1)$$

where  $X_i$  = the amount of water retained in the reservoir at the end of the period  $i$ ;  $S_i$  = the amount of water in the reservoir at the beginning of the period  $i$ ;  $Q_i$  = the inflow to the reservoir in the period  $i$ ;  $\alpha_i$ ,  $\beta_i$  = undetermined parameters;  $\varepsilon$  = random error.

In the long series, the initial water level of the reservoir is uncertain, which can cause errors in the first year benefit assessment. The first solution is to calculate the different strategies under different initial water level, but the solution is not unique. The second is, the first year is not involved in the assessment, but the data is wasted. The third is, the initial water level is optimized, when constraint is that the water level at the end of December last year must equal to the initial level. It can be achieved by penalty function method. See Equation 2.

$$S_0^{(1)} = S_n^{(N)} \quad (2)$$

where  $S_0^{(1)}$  = the initial water level in the first year;  $S_n^{(N)}$  = water level at the end of December last year.

### 3 DEFINE WATER QUALITY INDICATORS AND WATER QUALITY MODEL

#### 3.1 Water quality reaching standard degree

Water quality reaching standard degree is defined as the closeness to the standard (such as Class III water) in this paper. Water quality indicators are too many to be controlled. Key indicators must be controlled. It is better to choose  $COD_{Mn}$  as the representative of the pollution indicator for river water quality. See Equation 3.

$$\varphi = \begin{cases} \frac{\mu_a^*}{x} & x > \mu^* \\ 1 & x \leq \mu^* \end{cases} \quad (3)$$

where  $\varphi$  = the degree of water quality reaching standard;  $x$  =  $COD_{Mn}$  concentration,  $mg/l$ ;  $\mu^*$  =  $COD_{Mn}$  concentration of class III water standard,  $mg/l$ .

This approach allows the flexibility to choose the target water quality standards in accordance with local current situation or water functional area requirements, so as to effectively guide the behavior of water resources management.

#### 3.2 Water quality model

Since the model is designed to optimize strategies statistically to control the average concentration

of pollution, so one-dimension stable river water quality model are adaptable. See Equation 4.

$$C = C_0 e^{-k_1 \frac{x}{u}} \quad (4)$$

where  $C$  = concentration of pollutants downstream section,  $mg/l$ ;  $C_0$  = concentration of pollutants upstream mixing section,  $mg/l$ ;  $u$  = flow rate of the river,  $m/s$ ;  $x$  = distance from the downstream section to the upstream section,  $m$ ;  $k_1$  = pollutant degradation rate constant.

## 4 MULTI-OBJECTIVE OPTIMIZATION OPERATION MODEL

### 4.1 Definitions of water supply objective function

Water supply guarantee degree is defined as indicator. Water supply guarantee degree equals to ratio of water supply and water demand, and equals to 1—water shortage rate. Few if dry months, take the minimum value of the year as an indicator of the year, because the monthly balance is important. Then the objective function is established as the average of the series of water supply guarantee. See Equation 5.

$$\max G = \frac{1}{Y} \sum_{y=1}^Y \min_{t \in 1-T}^{(y)} \frac{\sum_k (u_k^{(t)} + g_k^{(t)})}{R^{(t)}} \quad (5)$$

where  $G$  = multi-year average degree of water supply guarantee;  $Y$  = years of long series runoff;  $y$  = number of year;  $T$  = months of a year;  $t$  = number of month;  $k$  = number of reservoirs;  $R^{(t)}$  = water demand in month  $t$ ,  $10^6 m^3$ ;  $u_k^{(t)}$  = water supply of reservoir  $k$ ,  $10^6 m^3$ ;  $g_k^{(t)}$  = water supply of the others, such as underground water,  $10^6 m^3$ .

### 4.2 Definitions of water environment objective function

The water environment objective function is used as controlling indicators of each river section and each period. See Equation 6. Take the geometric mean to raise the low end value.

$$\max \Phi = \frac{1}{Y} \sum_{y=1}^Y \frac{1}{T} \sum_{t=1}^T \frac{1}{L} \sum_{l=1}^L \varphi_{ytl} \quad (6)$$

where,  $\Phi$  = multi-year average of water quality reaching standard degree.  $\varphi_{ytl}$  = the degree of water quality reaching standard at section  $l$  in month  $t$  of year  $y$ .

### 4.3 Constrains

The main constraints include the water balance of each reservoir, the limit of capacity, the limit of the river flow, the water yield of each sub-basin, groundwater resources, water demand in each district, outfall location and emissions of pollutants, and so on.

## 5 IMPROVED MULTI-OBJECTIVE PARTICLE SWARM ALGORITHM

### 5.1 Improved iteration format

Particle swarm optimization algorithm, PSO, is a computational technique based on swarm intelligence evolution. According to Equation 7, 8, each particle determine itself speed and position of the search space.

$$v_{t+1} = wv_t + c_1 \text{rand}() (p_t - x_t) + c_2 \text{rand}() (g_t - x_t) \quad (7)$$

$$x_{t+1} = x_t + v_{t+1} \quad (8)$$

where  $w$  = the inertia constant;  $c_1$  = learning constant;  $\text{rand}()$  = random numbers on  $[0,1]$  uniformly distributed;  $P_t$  = time  $t$  their own the best position, fitness is  $p_{best}$ ;  $g_t$  = time  $t$  global optimum location, fitness is  $g_{best}$ .

It is found that these parameters need to be debugged. This is because the constraint of operation of reservoir is more complex. After debugging and summary, we found an improved format, more suitable for reservoir optimal (see Equations 9 and 10).

$$v_{t+1} = w[v_t + c_1 \text{rand}() (p_t - x_t) + c_2 \text{rand}() (g_t - x_t)] \quad (9)$$

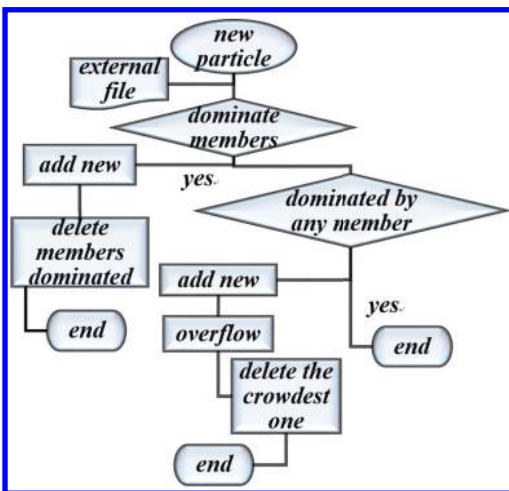

Figure 1. Algorithm for external file manage.

$$w = \begin{cases} 1 & K\%10 < 5 \\ 0.618 & K\%10 \geq 5 \end{cases} \quad (10)$$

where  $K$  = the number of iterations completed; % denotes a remainder operation.

### 5.2 Design of multi-objective particle swarm algorithm for external file

In the multi-objective iteration, the best position is not always with each other without domination. MOPSO of elite strategy is more advanced algorithms. External file update algorithm shown in Figure 1.

## 6 EXAMPLES

### 6.1 Introduce

Shimantan Reservoir and Tiangang Reservoir are located in the Huaihe River basin, upstream of Xiaohonghe River, Huaihe River tributaries. Shimantan reservoir catchment area is  $230 \text{ km}^3$ , total capacity is  $120 \times 10^6 \text{ m}^3$ , and normal capacity is  $63 \times 10^6 \text{ m}^3$ . Tiangang Reservoir at a distance of 5 km from Shimantan Reservoir. The normal capacity is  $8.9 \times 10^6 \text{ m}^3$ . Two reservoirs are connected in series.

Based on hydrology data from 1997 to 2006, upstream basin of Shimantan Reservoir annual average precipitation is 1049 mm. The reservoir annual average inflow is  $84.57 \times 10^6 \text{ m}^3$ . The reservoir's water supply coverage is shown in Figure 2. Reservoirs provide living water, industrial water, agricultural water, and ecological water.

Some companies and factories discharged a large number of untreated wastewater directly. According to the monitoring data, environmental monitoring stations show that in March 1996 at the monitoring section water quality indicators of Chemical Oxygen Demand (COD), permanganate index ( $\text{COD}_{Mn}$ ) exceeded rate is 100%. Main tributaries

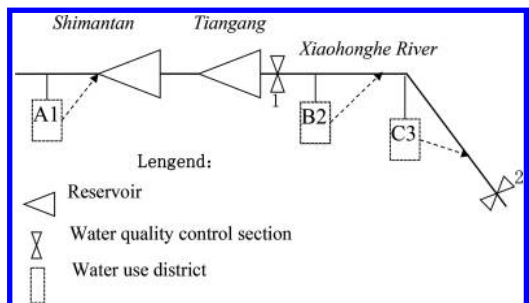

Figure 2. Reservoirs, water use districts, and water quality control sections.

of Huaihe River upstream, the Xiaohonghe water pollution is most serious.

### 6.2 Calculation results analysis

According to MOPSO, improved program was developed with c/c++ language. Data input included monthly runoff, water demand, and emissions information. The Pareto frontier was gained successfully. See Figure 3.

From Pareto front obtained and uniformly select a few typical scenarios, with the base scenario compared in Table 1. From Table 1, optimal scheduling efficiency goals in water supply is not, mainly because the region does not substantially dry, most of the year is a guarantee of 100%. Increased potential is very limited. In terms of water quality improving more obvious, COD<sub>mn</sub> concentration decreased from 25 mg/l to 15 mg/l nearby, and III water standard is close to 10%. This suggests that environmental objectives optimal operation of water is effective. Stochastic optimization rules determined scheduling is credible. On the whole, the solution 3 significantly improved the water quality, but also to ensure water supply guarantee degree, the solution is worth to be recommended. Evaluate

Figure 3. MOPSO Pareto frontier. Where WQRSD is water quality reaching standard; WGD is water guarantee degree.

Table 1. Optimization solutions comparison.

Solutions	Water supply (10 <sup>6</sup> m <sup>3</sup> )	Ave.* GD*	Min GD*	COD <sub>Mn</sub> (mg/l)	RSD*
Basic solution	373	98.6%	83%	25.0	45.4%
Opt. solution 1	363	97.2%	88.9%	19.1	52.8%
Opt. solution 2	362	96.0%	89.4%	17.4	55.6%
Opt. solution 3	362	95.6%	88.6%	14.7	58.4%
Opt. solution 4	360	95.1%	84%	15.2	60%
Opt. solution 5	355	93.7%	82.1%	14.6	60%

\*Ave. = Average; GD = Water Guarantee Degree; RSD = Water Quality Reaching Standard Degree.

## 7 CONCLUSION

This paper established a water supply and environmental objectives stochastic optimal operation model, and improved iteration format and effectiveness of multi-objective particle swarm algorithm. The advantage is that water supply and environmental indicators easy to coordinate, both of which are relative indicators. Flexibility is enough in the choice of Water quality standards according to the actual situation. Second, stochastic optimization operation model concluded realistic, direct search optimization rules, more simple than regression analysis to determine the rules, but also more logical. Third, the improved multi-objective particle swarm algorithm is suitable for solving the problem of reservoir operation. It is proved that good results are achieved in the Examples.

# Influence of moisture gradient to concrete strength based on Weibull statistical model

D. Zheng & Q. Chen

*Department of Hydraulic Engineering, Chongqing Jiaotong University, Chongqing, P.R. China*

S.W. Chen

*Guangdong Jindonghai Group Co. Ltd., Shantou, P.R. China*

**ABSTRACT:** The Influence of moisture gradient to concrete strength are investigated in this paper based on Weibull statistical model. The mechanism of how concrete strength is by influence moisture is discussed and the surface energy need to form new microcracks decrease are adopted in this paper. The moisture distribution in concrete is calculated by solving partial different equation. The global elastic modulus and strength reduction of concrete strength element are determined. The relationship between wet concrete strength and the time concrete immersed time is obtained. The comparison between the results by the model proposed in this paper and those by experiments in some available references indicates a good agreement.

**Keywords:** concrete; moisture gradient; strength; Weibull

## 1 INTRODUCTION

Concrete structures such as dams, bridges piers and ship locks, are often working in water environments. Researches have shown that the mechanic properties of concrete were influenced by moisture content. Saturated concrete has higher elastic modulus and lower strength compared with dry concrete. However, the influence of moisture to concrete strength has not been taken into account in structures design nowadays. Hence, it is quite important to make researches on wet concrete and provide more precise parameters for concrete structures design and safety evaluation.

Since the elastic microscopic theory of anisotropic composite material are well developed, elastic modulus of concrete with different porosity and moisture content can be analyzed. However, the mechanism of moisture influence to concrete strength is not very clear and no consensus has yet been reached. There are mainly 2 representative explanation of moisture dependency of concrete strength: (1) incompressible pore water pressure wedged into the cracks, which helps to microcracks propagation, (2) moisture decreases the surface energy need to form new microcracks.

Most research are focused on concrete strength without moisture gradient, i.e. fully dry or fully saturated concrete. However, the moisture gradient will influence concrete strength too. Experiments

of Li have shown that concrete strength when changed with immersed time. Guo attribute the influence of moisture content to different deformation between inner and outer concrete.

In this paper, the moisture distribution in concrete is calculated by solving partial different equation and the global elastic modulus and strength reduction of concrete strength element are determined. The relationship between wet concrete strength and the time concrete immersed time is obtained. The influence of moisture gradient to wet concrete strength is researched in this paper based on Weibull statistical model.

## 2 MECHANISM OF MOISTURE CONTENT INFLUENCE TO CONCRETE STRENGTH

At the base of aforementioned theoretical and experimental research, The mechanism of how concrete strength is influenced by moisture is assumed to be lower surface energy need to form new microcracks.

Firstly, experiments showed that tensile strength of concrete will be influence by moisture content. However, pore water pressure is in proportion to concrete volumetric deformation, which means water content will reduce concrete strength even when pore water pressure cannot be generated.

It also should be mentioned that volume of concrete will increase when the external compressive loading approaching its strength, which is called dilation material. At that moment, pore water pressure cannot be generated either. Therefore, pore water pressure theory cannot explain existed experiments and cannot represent physical mechanism of water influence to concrete strength. Secondly, experiments of cement-based material liquids with different surface tensions showed that strength of mortar decreases linearly with increases in the surface tension of immersion liquid.

Basically, the fracture process of concrete at the macro scale is the generation and propagation of internal microcracks. Strain energy will be stored in concrete when loaded, and parts of strain energy will be released as surface energy in the form of microcracks when the value of the strain energy reaches the limit. According to Griffith (1920), when the value of the released strain energy becomes equal to the surface energy on the new microcracks, the microcracks stop growing. However, further increases in loading result in further accumulation of strain energy. When the value of the strain energy reaches the limit again, microcracks are formed and released again. Through a repetition of these processes, the microcracks accumulated and resulted in the damage in the concrete till final failure. Thus, concrete strength is highly related to microcracks evolution and directly influenced by surface energy of microcracks.

$$\sigma_c = \sqrt{\frac{2E\gamma}{\pi c}} \quad (1)$$

where  $c$  is crack half length,  $E$  is elastic modulus of cracked material and  $\gamma$  is the surface energy of material.

It should be mentioned that Griffith's theory deals with a situation in which tensile force works on an ideal crack. On the other hand, it is thought that the fracture process of concrete under uniaxial compression is the generation and propagation of many microcracks and that several fracture modes are mixed. Thus, the theory cannot be applied directly to the compressive fracture process of concrete. However, it can be applied to research concrete strength variation with different moisture content.

On the other hand, according to Young's equation, solid-liquid interface energy is equal to the difference between solid and liquid surface energies as given by

$$\gamma_{sl} = \gamma_s - \gamma_l \cos \theta \quad (2)$$

where  $\gamma_{sl}$ ,  $\gamma_s$  and  $\gamma_l$  are energy of solid-liquid interface, solid surface and liquid surface respectively,

Figure 1. Surface energy of solid-liquid surface schematic diagram.

$\theta$  is contact angle of solid-liquid surface, as shown in Figure 1.

It showed that immersed time will influence wet concrete strength too. For concrete are anisotropic material, it can be assumed that in microscopic level, the element strength are different. Under external loading, concrete failure will happen at the lowest strength. Since the moisture distribution are not uniform in concrete, which makes the surface energy decrease are different too. When concrete are shrinked in water, the outside contact with water and will be saturate very fast, however, the diffusion process will last for a long time, which makes internal keeps dry and the origin strength. Hence, the strength reduction due to water is different in non-saturated concrete, which makes the failure mode differ too.

In this paper, a probability model is establish to analyze the moisture dependent of concrete strength considering the heterogeneity and moisture gradient of concrete.

### 3 MOISTURE DISTRIBUTION IN CONCRETE

#### 3.1 Moisture distribution in concrete

The sorption of pore material like concrete can be theoretically described by Darcy's law. The govern equation of the moisture distribution in concrete can be expressed as:

$$\frac{\partial \theta}{\partial t} = \Delta [D(\theta)\Delta \theta] \quad (3)$$

where  $\theta$  is relative moisture content,  $D$  is diffusion coefficient, which is function of relative moisture content  $\theta$ . For simplification, the problem is ideal as axial symmetries. Then equation can be expressed as:

$$\frac{\partial \theta}{\partial t} = \frac{1}{r} \frac{\partial}{\partial r} \left[ r D(\theta) \frac{\partial \theta}{\partial r} \right] \quad (4)$$

Table 1. Surface energy of cement paste under different humidity.

Moisture content	0	20%	50%	70%	85%	100%
surface energy/ mJ · m <sup>-2</sup>	72.17	41.89	31.35	32.49	29.80	28.2

Since concrete has been completely dried before immersed in liquid, it can be regarded that the initial moisture content is 0 and concrete outer surface are completely contacted with water. Hence, the initial and boundary condition can be showed as:

$$\begin{cases} \theta = 0 & t = 0 \\ \theta = 1 & r = R \end{cases} \quad (5)$$

Researches by Leech showed that can be expressed as exponential function or power function, it can represents water sorption in concrete.

$$D(\theta) = D_0 e^{n\theta} \quad D(\theta) = D_0 \theta^r \quad (6)$$

where  $D_0$  and  $\theta$  are parameters calibrated from experiments. The power function are adopted in this paper. Because the sorption coefficient are not constant, the govern equation are nonlinear partial difference equation, and it is almost impossible to achieve the theoretical solution. Normally, a numerical method in needed to solve the equation.

### 3.2 Influence of moisture to surface energy

The surface energy of concrete is difficult to measure. However, Adolphs (2005) measured the surface energy of cement paste at different moisture content with inverse gas chromatography method, which is shown as Table 1.

Hence, experiments of Adolphs can be utilized to analyze the relationship between moisture content of strength of cement-based material.

## 4 INFLUENCE OF MOISTURE CONTENT TO CONCRETE STRENGTH

### 4.1 Introduction of weibull strength model

As is well known, the Weibull distribution has been found to successfully describe a large body of brittle materials failure process. It is often supposed that a small volume in a brittle material is like a chain of many links, and if any link breaks, then the whole material will fail. Based on this weakest-link principle and an empirical function, the cumulative probability of failure of a brittle material

subjected to a load  $s$ , i.e., the Weibull strength distribution can be represented as:

$$F(u) = 1 - \exp\left[-\left(\frac{u}{\mu_0}\right)^m\right] \quad (7)$$

where  $\mu_0$  and  $m$  are Weibull parameters. Without loss of generality, it is supposed that  $\mu_0 = 1$  and eqa. (7) can be transformed as:

$$F(u) = 1 - \exp(-u^m) \quad (8)$$

Under the acting of stress, the failure probability of a chain with  $N$  links can be expressed as

$$\Phi(y) = 1 - [1 - F(u)]^N \quad (9)$$

The strength expectation is:

$$\sigma_N = \int_{-\infty}^{+\infty} u \, d\Phi(u) = Nm \int_{-\infty}^{+\infty} u^m e^{-Nu^m} \, du \quad (10)$$

Introduce  $Nu^m = x$ , Eqa. (10) can be simplified as:

$$\sigma_N = N^{-1/m} \Gamma\left(1 + \frac{1}{m}\right) \quad (11)$$

where  $\Gamma$  is Gamma Function. When the water gradually diffused into internal concrete, it decrease the surface energy of crack and micro element strength in concrete.

### 4.2 Concrete strength with moisture gradient

During the process of moisture diffusion, the moisture content varied with its location. For simplification, it is assumed a cylindrosymmetry model. Therefore, during the diffusion process, the relative moisture concrete at the same distance to the cylinder centre is the same. The element strength reduction coefficient at radius  $r$  can be expressed as  $0 < f(r) \leq 1$ ,  $0 \leq r \leq R$ , the Weibull strength distribution at radius  $r$  can be represented as:

$$F'(u) = 1 - \exp\left[-\left(\frac{u}{f}\right)^m\right] \quad (12)$$

the failure probability of a chain with  $N$  links can be expressed as:

$$\Phi'(u) = 1 - \prod_{i=1}^N \left[ \exp\left[-\left(\frac{u}{f_i}\right)^m\right] \right] \quad (13)$$

Eq. (13) can be simplified as:

$$\Phi'(u) = 1 - \left[ \exp(-u^m) \right]^{\sum_{i=1}^N f_i^m} \quad (14)$$

Eq. (14) can be transform as when  $N$  is big enough:

$$\Phi'(u) = 1 - \left[ \exp(-u^m) \right]^{N'} \quad (15)$$

where

$$N' = \frac{N}{R} \int_0^R f^{-m}(r) dr \quad (16)$$

Suppose  $r = Rdt$ ,  $g(t) = f(r/R)$ :

$$\frac{\sigma'_N}{\sigma_N} = \left[ \frac{1}{R} \int_0^R f^{-m}(r) dr \right]^{-1/m} = \left[ \int_0^1 g^{-m}(t) dt \right]^{-1/m} \quad (17)$$

Therefore, if the element strength reduction  $f(r)$  is known, the non-saturated concrete strength reduction can be achieved with Eq. (17). For saturated concrete, the relative moisture content is 1,  $g(t) = k$  from Eq. (17),  $\sigma'_N/\sigma_N = k$ .

## 5 NUMERICAL RESULTS AND DISCUSSION

To verify the accurate of difference equation and, the water diffusion in cement pasted is solved and the results are compared with existing experiments. The parameters used are as following:  $n = 4$ ,  $D_0 = 4.5 \text{ mm}^2/\text{s}$ ,  $x = 225 \text{ mm}$ ,  $m = 3$ .

The moisture distribution in cement pasted is showed in Figure 1 along with experiments. The moisture content in the experiments is achieved by NMR test. It can be seen from Figure 2 that the model proposed in this paper can describe moisture content distribution in concrete well.

Figure 3 shows relative moisture distribution in concrete at different time. It can be seen from Figure 3 that, the relative moisture near concrete surface reach saturate rapidly, however, inner concrete still dry, and increasing gradually with moisture diffusion process until it became saturate. If concrete immersed in water for more than 14 days, concrete will be saturated for inner side to outer side.

Figure 4 shows the relation between immersed time and concrete strength reduction along with experiments in reference in Li (2004). It can be seen from Figure 4 that the results correlate well with experiments. The strength of wet concrete

Figure 2. Moisture distribution in concrete.

Figure 3. Water content in concrete with different immersed days.

Figure 4. Strength reduction of concrete with different immersed days.

decreased with water diffusion. At the beginning of water contact with concrete, only surface concrete and with water diffused into concrete inner, its moisture content increased and saturated at 8~10 day, concrete strength became stable.

## 6 CONCLUSIONS

Water immersed into concrete can result in decrease of material surface energy, which will decrease concrete strength according to Griffith fracture mechanics.

By analyzing the mechanism of various influence factors to concrete strength, it is considered that immersion liquid reducing concrete surface energy is the main factor causing the wet concrete strength decrease. Based on solid diffusion, fracture mechanics and statistics strength theory, the moisture distribution and compressive strength of concrete under different moisture gradient are analyzed. The influence parameters on concrete strength are also discussed.

**ABSTRACT:** In order to master the positioning performance of the Beidou-2 second stage, the “5GEO+3IGSO+27MEO” BeiDou global constellation using STK software is simulated. Based on this simulation, the satellite visibility and GDOP (Geometric Dilution of Precision) value in some typical regions such as Beijing, Wuhan, Sanya, Guam, New York and Victoria Island are systematically analyzed. The analysis results are compared with that of GPS, which shows that the numbers of visible satellites and the GDOP values of BeiDou-2 second stage are better than that of GPS in these regions, and the positioning performance of BeiDou-2 second stage needs to be increased in the high latitude and west hemisphere regions.

**Keywords:** BeiDou satellite navigation; typical foreign regions; STK; visibility; GDOP

## 1 INTRODUCTION

The development of Chinese navigation satellite system follows the “three step” strategy, that is, “the demonstration system, the regional system, and the global system” (Yang et al. 2014). The demonstration system is also called BeiDou-1 Satellite Navigation System. The stages of the BeiDou-2 Satellite Navigation System construction are divided into two stages, namely, the BeiDou-2 first stage (the regional navigation system) and the BeiDou-2 second stage (the global navigation system). With the launch of the last GEO satellite on October 25, 2012, BeiDou-2 first stage had been successfully established, which consists of 14 satellites, including 5 GEO (Geostationary Orbit) satellites, 5 IGSO (Inclined Geosynchronous Orbit) satellites, 4 MEO (Medium Orbit) satellites. It is quite important to master the characteristic and positioning performance of the BeiDou-2. Some researchers have done a lot of work about the satellite visibility and GDOP (Geometric Dilution of Precision) of BeiDou-2 first stage, which shows that the performance of BeiDou-2 first stage in Positioning, Navigation, and Timing (PNT) has reached or even exceed the design specification (Yang, 2010; Montenbruck et al. 2013; Li, 2013). But little work has been done about BeiDou-2 second stage. Here we mainly describe the

positioning performance of BeiDou-2 second stage, and give detailed analysis about the comparison of BeiDou-2 second stage and GPS in some typical regions at home and abroad.

## 2 THE SIMULATION OF BEIDOU-2 SECOND STAGE AND GPS CONSTELLATIONS

The BeiDou-2 second stage consists of 30 satellites, including 5 GEO (Geostationary Orbit) satellites, 3 IGSO (Inclined Geosynchronous Orbit) satellites, 27 MEO (Medium Orbit) satellites. GPS

Figure 1. The three-dimensional scene of Beidou-2 second stage constellation.

Figure 2. The three-dimensional scene of GPS constellation.

consists of 24 MEO satellites. The Beidou-2 second stage and GPS constellations are constructed with the help of STK (Satellite Tool Kit) software. Their space three-dimensional scenes are shown in Figure 1 and Figure 2 respectively.

### 3 THE POSITIONING PERFORMANCE COMPARISON OF BEIDOU-2 SECOND STAGE AND GPS IN SOME TYPICAL REGIONS AT HOM

Parameters used to indicate the positioning performance mainly include the satellite visibility and GDOP, which could help us master the positioning effect and provide reference for the practical application. These can be obtained using “Coverage Definition” and “Figure of Merit” modules in STK. Assuming the simulation time is from 12 o’clock 1 May 2014 to 12 o’clock 2 May 2014, Beijing (39.55°N, 116.24°E), Wuhan (30.35°N, 114.17°E) and Sanya (18.14°N, 109.31°E) are chosen as the typical regions at home. Taking Beijing as example, the total numbers of visible Beidou-2 second stage and GPS satellites are shown in Figure 3 and Figure 4, while the GDOP values are shown in Figure 5 and Figure 6 respectively. The statistics of visible satellites and GDOP values of Beidou-2 second stage and GPS are listed in Table 1 and Table 2 respectively.

From Table 1 and Figure 2, one could find that the visible satellites of Beidou-2 second stage are much more than that of GPS, while the GDOP value of Beidou-2 second stage is less than that of GPS at home.

### 4 THE POSITIONING PERFORMANCE COMPARISON OF BEIDOU-2 SECOND STAGE AND GPS IN SOME TYPICAL REGIONS AT ABROAD

Assuming the simulation time is from 12 o’clock 1 May 2014 to 12 o’clock 2 May 2014, Guam (14°N,

Facilities	Beidou-2 second stage/GPS		
	Min	Max	Mean
Guam	1.06/1.31	1.39/2.17	1.21/1.59
New York	1.32/1.33	2.41/2.90	1.66/1.75
Victoria Island	1.35/1.36	2.72/4.70	1.59/2.06

much more than that of GPS at Guam and Victoria Island and the GDOP value of Beidou-2 second stage is a little bigger than that at home.

## 5 SUMMARY

The visibility and GDOP of BeiDou-2 second stage and GPS are analyzed in some important regions, such as Wuhan, Beijing, Sanya, Guam, New York and Victoria Island using STK. The analysis results show that the numbers of visible satellites and the GDOP values of BeiDou-2 second stage are better than that of GPS in these regions, and the positioning performance of BeiDou-2 second stage needs to be increased in the high latitude and west hemisphere regions.

# Analysis of roof water inrush risk and forecast of the outflow rate of 3229 working face in Tianzhu Coal Mine

H. Wang

*Institute of Mine Construction, Tiandi Science and Technology Co. Ltd., Beijing, China*

*Beijing China Coal Mine Engineering Co. Ltd., Beijing, China*

*National Engineering Laboratory for Deep Shaft Construction Technology in Coal Mine, Beijing, China*

**ABSTRACT:** Analyzing water inrush risk and forecasting outflow rate of each workface is one of the important tasks of mine water prevention. 3229 working face in Tianzhu Coal Mine is partial below the Jinsha River. There are four aquifers above the 3229 working face, which are strong pore free aquifer of Quaternary (Q) alluvium, weak pore free aquifer of Early Cretaceous Hekou Group, weak pore-fissured confined aquifer of Late Jurassic Kushuixia Group, and pore-fissured confined aquifer of Middle Jurassic Yaojie Group. Therefore, it will be likely that water inrush will take place during the mining process. On the basis of fully analyzing the geological and hydrogeological data of mine field, adopting “Up Three Zone” Theory of coal seam roof (the caving zone, water flowing fractured zone and bending sinking zone), principles of hydrogeology and theory of ground surface strata movement law, and combining the research results of ground fissure, roof water inrush risk of 3229 working face was analyzed, and outflow rate was forecasted. The results show as follows: (1) Mining 3229 working face will probably lead to the extension of surface subsidence area to Jinsha River valley; (2) The maximum height of water flowing fractured zone is 107.48 m, so the water of Yaojie Formation aquifer will inrush the mined-out area of the working face; (3) The surface crack depth is less than 70 m, so the water of Jinsha River will not rush in the mined-out area of the working face; (4) The ordinary outflow rate of the working face is 13.60 m<sup>3</sup>/h, and the maximum outflow rate is 27.20 m<sup>3</sup>/h. It is proposed that the necessary water prevention and control measures be taken to ensure the safety in mining the working face.

**Keywords:** water inrush risk; outflow rate; water flowing fractured zone; ground fissure; open well calculation method

## 1 INTRODUCTION

Water damage accident, as one of the major coal mine disasters, is prone to cause mass casualty accidents. In extraordinarily serious coal-mine accidents, water damage is second only to the gas outburst/explosion hazard. According to statistics, from 2009 to 2013, 5603 accidents have occurred at the national coal mines in China, causing 9488 deaths, among which 174 water damage accidents occurred, causing 793 deaths, accounting for 3.1% of the total accidents and 8.4% of the total deaths, respectively. 64 large water damage accidents have occurred, causing 313 deaths, accounting for 15.3% of the total large accidents and 15.8% of the total deaths, respectively; 23 serious or extremely serious water damage accidents have occurred, causing 361 deaths, accounting for 24.2% of the total serious or extremely serious accidents and 18.9% of the total deaths respectively; 12 water damage accidents have taken place in working faces, accounting for 18.8% of the total. When the water

damage accident has occurred it will take a long time and is very difficult to rescue, and it is very difficult to carry out the rescue work, causing huge economic losses and extensively negative impact on society, and simultaneously bringing about serious damage to water and environment resources of the mining area [1, 2]. Therefore, before mining working face, accurate and comprehensive analysis of the hydrogeological conditions of the working face, analysis of water inrush risk and forecast of outflow rate, and taking the necessary prevention and measures of controlling water, are of great significance to ensure the safety of mining working face.

## 2 GENERAL OVERVIEW OF TIANZHU COAL MINE AND 3229 WORKING FACE

### 2.1 General overview of tianzhu coal mine

Tianzhu Coal Mine is located in Tanshanling Town, Tianzhu Tibetan Autonomous County,

Gansu Province in Northwest China, about 74 km southwest to the county seat (Huazangsi Town). Its geographical position is 102°41'E, latitude is 36°54'N.

According to the data of drilling engineering and tunnel engineering outcropping, in the coal-field, from old to new the formations are thus distributed: Proterozoic Lower Sinian Maxianshan Group (AnZ<sub>mx</sub>), Proterozoic Middle Sinian (Z<sub>2</sub>), Mesozoic Lower Jurassic Daxigou Group (J<sub>1dx</sub>), Mesozoic Middle Jurassic Yaojie Group (J<sub>2y</sub>) and Xinhe Group (J<sub>2x</sub>), Mesozoic Upper Jurassic Kushuixia Group (J<sub>3k</sub>), Mesozoic Cretaceous (K), Cenozoic Quaternary (Q). Among them, Mesozoic Middle Jurassic Yaojie Group (J<sub>2y</sub>) is main coal-bearing strata (Table 1). Strikes of coal measures strata are generally N10–40°W, of which inclinations are NE, with angles of 9–18; There are four coal seams in coal measures strata, of which the average total thickness is 9.94 m, including two mineable coal seams (Upper and Middle coal seams) and one locally-mineable coal seam (Top coal seam).

It belongs to continental alpine climate in Tanshanling area, with an average annual precipitation of 476.6 mm, annual evaporation of 1548.5 mm. The rainy season is from June to September, and the snowy season is from October to next April. The atmospheric precipitation is main source of water supply for the mining area. Jinsha River and Shajin River are two live streams in the mining area. Jinsha River flows into the area from north, extending in the north-south direction almost threading the entire the mining area.

The strata in mining field is from the top to the bottom divided into six aquifers: strong pore free

aquifer of Quaternary (Q) alluvium, weak pore free aquifer of Early Cretaceous Hekou Group, weak pore-fissured confined aquifer of Late Jurassic Kushuixia Group, pore-fissured confined aquifer of Middle Jurassic Yaojie Group, pore-fissured confined aquifer of Early Jurassic Daxigou Group Lower Member, weak fissured confined aquifer of Early Sinian metamorphic rock. There are two aquifuges, aquifuge of Middle Jurassic Xinhe Group and aquifuge of Early Jurassic Daxigou Group Upper Member.

## 2.2 General overview of 3229 working face

3229 working face is located in No.3 Mining Area, starting from the south spot at the 2060 m general return airway, and extending northward to the 87500 m latitude line. In its west part the 9 m coal pillar is set between it and 3227 working face. In its east part the minimum horizontal projection distance between it and the west boundary Jinsha River is approximately 180 m (Fig. 1). The length of its return airway is 1378 m, transport roadway is 1342 m, with declination width of 140 m, mineable strike length is 1340 m. Upper and middle coal seams will be mined in the working face. In the mining area, the total thickness of upper and middle coal seams is 5.34–8.80 m, the average is 6.42 m; the dip angle is 11–17°, with the average is 14°; between two coal seams there is a rock parting, of which the thickness is 0.19–0.33 m, with the average of 0.26 m. The elevation of middle coal seam floor is 2218.75–2284.92 m, of which the buried depth is 355.89–384.84 m (Fig. 2). The thickness of mantle soil over the working face is 6.00–12.00 m, with the average of 6.21 m. The direct roof of upper coal

Figure 1. The geological profile of the 16th exploratory line in Tianzhu Coal Mine.

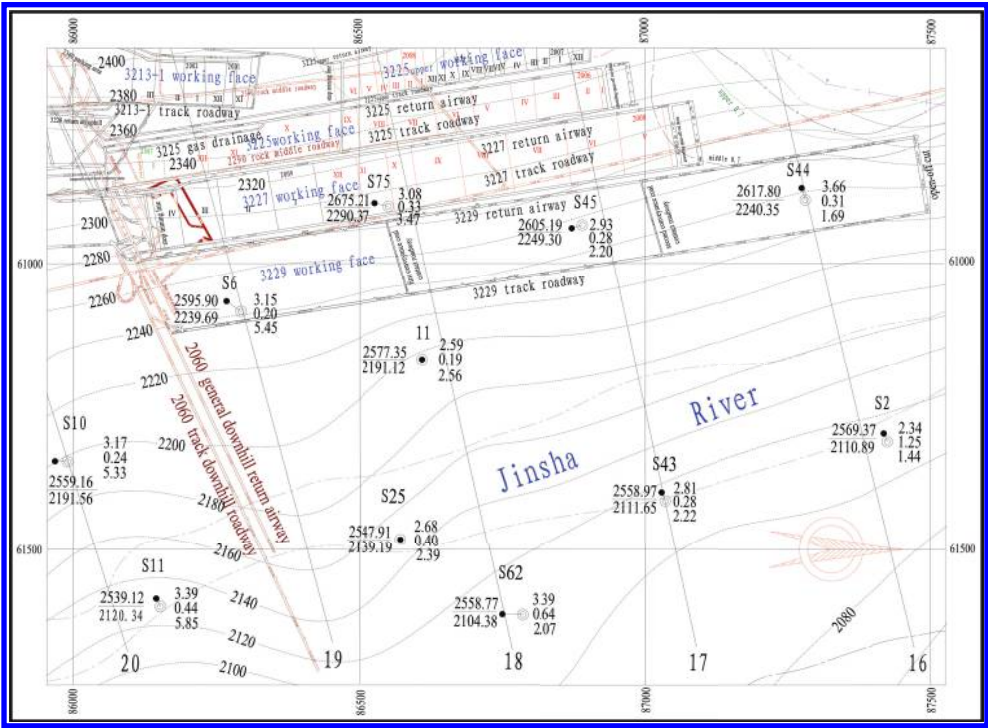

Figure 2. The local excavation engineering chart in Tianzhu Coal Mine.

seam is oil shale, gray-black, with plant fossils fragments and black coal strip, of which the thickness is 5.40–8.54 m, the average is 7.57 m. Direct coal floor is siltstone, partial mudstone, its thickness is 1.07–7.06 m, with the average of 4.34 m. The working face intends to use fully-mechanized top coal caving method. There is no obvious fracture in 3229 working face and its surrounding.

### 3 ANALYSIS OF WATER INRUSH RISK FROM ROOF DURING MINING THE COAL SEAM OF 3229 WORKING FACE

#### 3.1 Forecast of surface subsidence area on the side of transporting roadway

After mining the underground coal seam, overburden and floor rocks of mined-out area will move because the stress balance is destroyed. With the expansion of mined-out area, the scope of rock movement will correspondingly increase. When the mined-out area expands to a certain range, strata movement extends towards ground surface, causing the movement of the strata of ground surface, resulting in the subsidence area. The range of surface subsidence area can be worked out through

some parameters, such as buried depth of working face, dip angle of strata, displacement angles of bedrock and surface soil, shape and dimensions of working face, and etc (Fig. 3). Near the 16th exploratory line, the horizontal distance is the shortest between transport roadway of 3229 working face and Jinsha River (Fig. 2), where the overburden strata are mainly Jurassic strata, of which the coal seams are gently inclined (dip angle  $\theta \leq 35^\circ$ ). According to empirical formula in Fuxin, Jiao River, Jixi and Shuangyashan mining areas of the reference [3], we selected the minimum value as the downhill draw angle of overburden strata of 3229 working face (Table 2).

Therefore, the horizontal distance of geographical coverage positions between the east boundary of ground subsidence area and transport roadway of 3229 working face in 16th exploratory line is calculated as follows:

$$l = h_{jy} \cot \beta + h_{bi} \cot \varphi \quad (1)$$

where,

$l$ —the horizontal distance between mining boundary of working face and boundary of ground subsidence area on the same side, m;

Figure 3. The diagram of surface subsidence area range after mining gently dipping coal seam.

Table 2. Downhill draw angle calculation results of overlying strata of 3229 working face.

Mining area	Downhill draw angle $\beta$ (°)	
	Empirical formula	While dip angle of strata $\theta = 14^\circ$
Fuxin	$\beta = 83 - 0.9\theta$	70.4
Jiaohe	$\beta = 75 - 0.8\theta$	63.8
Jixi	$\beta = 78 - 0.7\theta$	68.2
Shuangyashan	$\beta = 75 - 0.3\theta$	73.8

$h_{jy}$ —the thickness of overburden bedrock of working face, m;

$h_{bt}$ —the thickness of overburden surface soil of working face, m;

$\beta$ —the downhill draw angle of overburden bedrock of working face, (°);

$\varphi$ —the draw angle of overburden surface soil of working face, (°).

On cross section of 16th exploratory line (Fig. 1), we looked on the outside floor of transport roadway of 3229 working face as punch mark, and drew a ray as  $63.8^\circ$  downhill draw angle, the node of the ray and bedrock surface is just below the valley of Jinsha River. On this basis, we could more accurately calculate the east boundary position of ground subsidence area of 3229 working face in the 16th exploratory line. From Figure 1, we could know that the east boundary of ground subsidence area in the 16th exploratory line is close to Jinsha River, and thickness of Quaternary mantle soil near the ground subsidence area boundary is about 6.0 m, where the bedrock surface elevation is about 2590 m, and the bottom elevation of middle coal seam at transport roadway of 3229 working face in the 16th exploratory line is about 2220 m. In addition, according to the reference [3], taking the draw angle of overburden surface soil  $\varphi = 40$ , we calculated as follow:

$$\begin{aligned}
 l &= h_{jy} \cot \beta + h_{bt} \cot \varphi \\
 &= (2590 - 2220) \times \cot 63.8^\circ + 6 \times \cot 40^\circ \\
 &= 189.21 \text{ (m)} \\
 189.21 - 180 &= 9.21 \text{ (m)}
 \end{aligned}$$

This means that the ground subsidence area of 3229 working face entered the Jinsha River valley about 9 m, therefore, we must analyze the risk that Jinsha River water rushes in the 3229 working face.

### 3.2 Calculating the height of water flowing fractured zone

Lithology of overburden strata of 3229 working face is mainly sandstone, secondly marl, on the whole, belongs to hard stratum. According to the reference [4], the height of water flowing fractured zone could be calculated as follow:

$$H_{ii} = \frac{100 \sum M}{1.2 \sum M + 2.0} \pm 8.9 \quad (2)$$

Or

$$H_{ii} = 30 \sqrt{\sum M} + 10 \quad (3)$$

where,

$H_{ii}$ —the height of water flowing fractured zone, m;

$\sum M$ —cumulative mining thickness, m.

The  $\sum M = 8.80$  and  $n = 1$  are substituted into formula (2),(3) respectively, results are as follow:

$$\begin{aligned}
 H_{ii} &= \frac{100 \sum M}{1.2 \sum M + 2.0} + 8.9 \\
 &= \frac{100 \times 8.80}{1.2 \times 8.80 + 2.0} + 8.9 = 78.06 \text{ (m)}
 \end{aligned}$$

(Note: Given safety, the “+” value was selected from formula (2).)

Or

$$H_{ii} = 30 \sqrt{\sum M} + 10 = 30 \sqrt{8.80} + 10 = 98.99 \text{ (m)}$$

In addition, Wu Qiang, a professor of China University of Mining and Technology (Beijing) [1] (2013) combined the measured results of recent scientific research projects and documents, collecting the measured data over 40 working faces by fully-mechanized top coal caving mining technology in “two zones” (caving zone height measured values, water flowing fractured zone), and using the methods of mathematical statistics and regression

analysis, to have obtained the calculation formula for the height of water flowing fractured zone under medium hard overburden strata by fully-mechanized top coal caving mining technology (mining and caving height is 3.5~12.0 m), namely:

$$H_{li} = \frac{100M}{0.26M + 6.88} \pm 11.49 \quad (4)$$

where,  $M$ —thickness of coal seam, m.

The  $M = 8.80$  is substituted into formula (4), and the result is as follows:

$$\begin{aligned} H_{li} &= \frac{100M}{0.26M + 6.88} + 11.49 \\ &= \frac{100 \times 8.80}{0.26 \times 8.80 + 6.88} + 11.49 = 107.48 \text{ (m)} \end{aligned}$$

(Note: Given safety, the “+” value was selected from formula (4).)

Compared with above-mentioned three  $H_{li}$  values, we took the maximum  $H_{li} = 107.48$  m.

In addition, according to the design method of safety waterproof coal rock pillar of mining coal seam around water, the aim of setting safety waterproof coal rock pillar is to keep the water flowing fractured zone from spreading to water body; therefore, its vertical height should be greater than or equal to the sum of the maximum height of water flowing fractured zone( $H_{li}$ ) and the thickness of the protective layer( $H_b$ ) (Fig. 4), namely:

$$H_{sh} \geq H_{li} + H_b \quad (5)$$

where,

$H_{sh}$ —vertical height of safety waterproof coal rock pillar, m;

Figure 4. The sketch of setting waterproof coal (rock) pillar while outcrop of gently dipping coal seam contacting with strong watery stratum in loose stratum.

$H_{li}$ —the maximum height of water flowing fractured zone, m;

$H_b$ —the thickness of the protective layer, m.

Currently, there is rarely the study on setting protective layer thickness of the roof bedrock aquifer. Therefore, we referred to the Table 6–4 of reference [4], and selected the maximum value of protective layer under hard overburden rocks, namely:

$$H_b = 7A \quad (6)$$

Thus, we could get:

$$H_{sh} \geq H_{li} + H_b = 107.48 + 7 \times 8.80 = 169.08 \text{ (m)}$$

By the above calculation and referring to Table 1, we could see that after mining the 3229 working face, its water flowing fractured zone will penetrate the roof oil shale stratum, oil shale and marl interbedded strata (the total thickness is 14.19 m), and penetrate the roof Yaojie group aquifer (the thickness between its roof and upper coal seam roof is 80.5 m),  $H_{sh}$  is less than the thickness between the floor of Kushuixia group aquifer and the roof of upper coal seam (196.04 m). Therefore, during mining the 3229 working face, the water of Yaojie group aquifers will flow into the working face, of which the outflow rate should be forecast, and the necessary measures for prevention and control of roof water should be taken; it is very unlikely for the water of Kushuixia group aquifer to flow into the working face.

### 3.3 Forecast of the depth of ground fissure

Mining subsidence causes nonuniform settlement and horizontal movement of the ground surface, leading to ground fissures in part area of the subsidence basin [5]. As one of geological hazards, ground fissure is widespread in many countries all over the world. Its occurrence frequency and disaster scale are aggregating year by year, graduating into a major regional geological hazard. It not only causes direct catastrophic damage to all types of construction engineering, transportation facilities, urban lifeline engineering and land resources, but also may lead to a series of serious eco-environmental problems [6]. In China, ground fissures are also quite serious, especially in Shanxi, Shaanxi, Inner Mongolia, Jilin, Liaoning, Henan, Shandong, Anhui and other coal-producing provinces. In coal mines, the ground fissures even have led to collapse of surface water into the underground mine, causing water inrush accidents, e.g., at 18:00 on August 16 and 23:00 on August 31, 1995, two water inrush accidents took place in No.2 Mining District of Wangjiashan Coal Mine in half a month, the causes of both incidents were attributed to heavy

rainfalls. The rain water affluxed from Shigou Ditch formed debris flow, which flowed into the underground mine through the ground fissures of mined-out area and submerged about 2400 m-long roadway of three levels (i.e. 1600 m level, 1650 m level, 1700 m level) in No.2 Mining District, causing a disastrous accident that claimed eight lives [7]. Based on considering the serious harm of the ground fissure, many experts in China respectively have carried out in-depth studies on the ground fissure disasters in coal mines by the methods of theoretical analysis, numerical simulation, similarity simulation, field measurement, and etc [5, 7–13]. The results showed that: the widths of ground fissures are generally 0.01–2.0 m; depths of ground fissures are generally 1.0–5.0 m, and even up to 30 ~ 70 m in small number of mines.

Quaternary loosen stratum covers the ground surface of 3229 working face, of which the thickness 6.0–12.0 m. Considering 3229 working face belongs to thin loosen stratum and thick bedrock covered working face, the depth of its ground fissure was selected from the maximum value of the above research results (i.e. 70 m). Referring to Table 1, we knew that after mining 3229 working face, ground fissure would only penetrate Cretaceous aquifer, and extend 18 m deeper into the large-grained sandstone stratum of the upper part of Kushuixia group aquifer (thickness 92.97 m), it would not join water flowing fractured zone, in other words, the surface water (including stream water of Jinsha River), and Cretaceous aquifer water will unlikely flow into the 3229 working face.

#### 4 FORECAST OUTFLOW RATE OF 3229 WORKING FACE

There are many methods in forecasting the outflow rate of mine pit, including the analogue method (water content coefficient method, mine specific capacity analogue method, correlation analysis method, etc.),  $Q=f(s)$  curve extrapolation method, analytical method (open well calculation method, horizontal gallery method), water resource balance method, numerical method, and etc [14]. Comprehensively considering the control degree of hydrology geological conditions and the applicable conditions of each forecasting method in reference [14], we used open well (confined water converting unconfined water complete well) calculation method to forecast the outflow rate of 3229 working face.

Under the condition of confined water converting unconfined water complete well:

$$Q = 1.366K \frac{(2H - M)M - h^2}{\lg R_0 - \lg r_0} \quad (7)$$

where,

$Q$ —outflow of water,  $m^3/d$ ;  
 $K$ —coefficient of permeability,  $m/d$ ;  
 $H$ —height of water column,  $m$ ;  
 $h$ —water column height between dynamic level and negative confining bed,  $m$ ;  
 $M$ —height of aquifer,  $m$ ;  
 $r_0$ —radius of the “open well” ( $r_0 = \sqrt{F/\pi}$ ),  $m$ ;  
 $R_0$ —influence radius of the “open well” ( $R_0 = r_0 + 100$ ),  $m$ .

During the course of mining the 3229 working face, the threat of water damage will be mainly from the overlying Yaojie group aquifer ( $J_{2y}$ ). According to the Yaojie Group aquifer ( $J_{2y}$ ) pumping test results of S13 borehole in reference [15], permeability coefficient of Yaojie Group aquifer is  $9.29 \times 10^{-4} m/d$ , confined water level is 322.07 m higher than middle coal seam roof, therefore, normal outflow rate of 3229 working face ( $Q_{nor}$ ) could be calculated as follows:

$$\begin{aligned} Q_{nor} &= 1.366K \frac{(2H - M)M - h^2}{\lg R_0 - \lg r_0} \\ &= 1.366 \times 9.29 \times 10^{-4} \\ &\quad \times \frac{(2 \times 322.07 - 66.31) \times 66.31}{\lg \left( \sqrt{\frac{1340 \times 140}{3.14}} + 100 \right) - \lg \sqrt{\frac{1340 \times 140}{3.14}}} \\ &= 326.43 (m^3/d) = 13.60 (m^3/h) \end{aligned}$$

According to the experience in mining working face of production level (2240 m level), we could calculate the maximum outflow rate of 3229 working face as follows:

$$Q_{max} = \mu Q_{nor}$$

where,  $\mu$  is the spare coefficient maximum outflow rate, generally it is 2.

Thus, there is:

$$Q_{max} = 2Q_{nor} = 2 \times 13.60 = 27.20 (m^3/h)$$

#### 5 CONCLUSIONS

1. The ground subsidence area will extend eastward, to the stream valley of Jinsha River after mining the 3229 working face.
2. The maximum development height of water flowing fractured zone will be 107.48 m; the depth of ground fissure will be less than 70 m. In mining the working face, the threat of water damage will be mainly from the overlying Yaojie group aquifer ( $J_{2y}$ ), while the water of other overlying aquifers and Jinsha River will unlikely flow into the 3229 working face.

3. It is forecasted that the normal outflow rate of 3229 working face is 13.60 m<sup>3</sup>/h in mining process; and the maximum is 27.20 m<sup>3</sup>/h.

# Prediction research on the hazardous extent of volcano secondary debris flow in Changbai Mountains based on simulation of FLOW3D

Xiao Tong, Peihua Xu, Guang Li, Mo Zhang, Pengfei Li & Zhanling Chen  
*College of Construction Engineering, Jilin University, Changchun, Jilin, China*

**ABSTRACT:** The Tianchi Volcano in Changbai Mountains is one of the few extant active volcanoes of our country. Researching on the hazardous extent of volcano secondary debris flow aims at offering scientific references to the prediction and prevention of geologic hazards in Changbai Mountain. Based on the parameters obtained from field geological investigation and indoor simulation experiment, this paper applied FLOW3D, a numerical stimulation software of fluid dynamics, to simulate the developing process of 0.5 trillion cubic meters debris flow of volcanoes in Changbai Mountains. The predicted results show that the maximum packing length of the debris flow is approximately 42 km, with the distance of 8 km from Erdao-baihe town during the 1800s simulated time; however, after the end of the simulation, part of the debris flow still has the velocity, only with the lower velocity and smaller scope, which will not produce much influence on the living and production of the Erdao-baihe area.

**Keywords:** Tianchi volcano in Changbai Mountain; secondary volcano debris flow; FLOW3D; the maximum hazardous extent; numerical simulation

## 1 INTRODUCTION

Locating in the northeastern part of Ji Lin Province of China, and being the frontier between China and North Korea, Changbai Mountains is a renowned active volcano which is likely to erupt<sup>[1]</sup>. As a nature reserve and tourist resort, Changbai Mountains is famous in home and abroad for its unique volcanic landform and entire ecosystem as well as magnificent natural landscape<sup>[2]</sup>. However, debris flow disaster happens frequently in this area because of the special geological environment and weather condition. Among different types of debris flow in this area, secondary debris flow induced by volcanic disaster receives much concern for its prompt destructiveness. Volcano erupts again and produces water in the volcanic lakes spewing or the high temperature, and this melts the ice and snow in the summit of volcano into a large amount of water which mixes the loose deposits previously erupted, then under the effect of gravity they flow fast downward along the ravine or hillside forming a special kind of debris flow, which causes a fatal harm to the buildings and residents in the area of coverage<sup>[3]</sup>.

Foreign scholars gain the understanding and conduct research concerning the secondary debris flow much earlier, such as Yokoyam, Blong who studied and defined the secondary volcano debris flow as a kind of volcano geological hazards as early as in the middle and late periods of the 20th century<sup>[4]</sup>.

During the following 30 years, geologists from different countries made a further research and study towards the material composition, formation, accumulation pattern, scope of influence as well as prevention measures of secondary volcano debris flow<sup>[5]</sup>. Although the domestic research had a late start toward the secondary volcano debris flow, a large number of scholars make joint efforts and made much achievement. For nearly 20 years from the late 20th century, geologists such as Liu Xiang, Wei Haiquan, Sun Ping, and Nie Baofeng made research to the composition characteristics, source reserve, topographic condition, and distribution regularity of volcano debris flow in the Changbai Mountain area<sup>[6-7]</sup>.

It designs and simulates the developing process of secondary volcano debris flow in Tianchi volcano of Changbai Mountain so as to acquire the velocity in the motion process of debris flow and the distribution of section height as well as the influence scope, which could be the scientific references for disaster prevention and reduction.

## 2 MODEL BUILDING BASED ON FLOW3D

### 2.1 Grid partitioning of model area

The model building data derives from topographic map of scale 1:100,000 and imports to FLOW-3D software through Gocad software. After the consideration of computer memory and operational

capability, simulation area is finally confirmed to be integrated with the previous research result (as shown in Fig. 1).

The scope in this model is roughly to the south of 55,000 m and about 34,000 wide of waterfall in the Tianchi Lake area of Changbai Mountains. The simulated area is divided into 13 subregions to make network processing. There are 4,984,048 cells whose scale is 80 m \* 80 m \* 25 m, and the number of the active cells is 2,739,392. We can get the three-dimensional model in Figure 2 after the calculation has been done by FAVOR and VOF numerical method in FLOW3D, and the approximate location of Baishilazi natural reserve and Erdaobaihetown can be seen in the figure. Direction of the X-axis is east, the Y-axis positive direction is north, and the Z-axis is the vertical upward direction.

## 2.2 Setting of boundary condition

There are 10 species of boundary conditions in FLOW3D; the boundary assignment in this simulation will be shown in Table 1.

## 2.3 Debris flow viscous coefficient value

Based on the consulting literature, we learnt that when the proportion of the solid particles in the

Figure 1. Mesh subdivision of the calculation model.

Figure 2. Three-dimensional model based on FAVOR.

Table 1. Boundary conditions at different small zones.

Zone	$X_{\min}$	$X_{\max}$	$Y_{\min}$	$Y_{\max}$	$Z_{\min}$	$Z_{\max}$
1	O	C	S	C	W	S
2	C	O	S	C	W	S
3	O	C	S	C	W	S
4	C	O	S	C	W	S
5	O	O	C	C	W	S
6	O	O	C	C	W	S
7	O	O	C	C	W	S
8	O	O	C	C	W	S
9	O	O	C	C	W	S
10	O	C	C	C	W	S
11	O	O	C	C	W	S
12	O	O	C	O	W	S
13	C	C	P	C	W	S

Notice: C is the continuative boundary, O is the outflow boundary, P is the pressure boundary, S is the symmetry boundary, W is the wall boundary.  $X_{\min}$  is the minimum value in the X direction,  $X_{\max}$  is the maximum value in the X direction.  $Y_{\min}$  is the minimum value in the Y direction,  $Y_{\max}$  is the maximum value in the Y direction.  $Z_{\min}$  is the minimum value in the Z direction,  $Z_{\max}$  is the maximum value in the Z direction.

debris flow is small, the viscous increase in the mixture is not large<sup>[8]</sup>. Assuming that solid particles in debris flow is non-viscous spherical particles, the distance between the particles is large enough and there is no interaction between the particles, the relative viscosity coefficient can be calculated according to equation (1). When there is interaction between the particles, we need to amend equation (1). Based on analyzing and summarizing a lot of literature, Thomas proposed the amendments to the formula, which is now known as equation (2).

$$\mu_r = 1 + 2.5S_v \quad (1)$$

The  $\mu_r$  in equation (1) is the ratio of the viscosity coefficient of viscosity and fluid at the same temperature,  $S_v$  is the volume concentration of solid particles.

$$\mu_r = 1 + 2.5S_v + 10.05S_v^2 + A \exp YBS_v Y \quad (2)$$

Lian Banghui provides that  $A=0.00237$ ,  $B=16.6$ . So, we set the viscous coefficient as 0.00274.

## 2.4 Some assumptions in the simulation

Due to the lack of detailed records of overflow location caused by volcanic eruption, the water head height and the duration of the water spill of Changbai Mountain. So, this article can only combine with the existing domestic and international research and experience and assume that:

1. All water in crater lake comes from the waterfall mouth of Tianchi.
2. The total volume of the water flow from Tianchi and loose accumulational materials on the slope is 5 hundred millions cubic meter.
3. The debris flow is relatively and evenly fluid and it ignores the movement of loose rock.

### 3 SIMULATION RESULTS AND ANALYSIS

#### 3.1 Simulation results

After building the model, analog computation began, producing volume of fluid variable curve, which is shown as following Figure 3.

It can be revealed from the figure that the model total water has increased significantly in the period from 0 to 190 seconds resulting from volcanic eruption, while water level has a dramatic fall and total water decreases after 190 seconds, and the water volume after the curve tending to be steady is water outflow (roughly 0.5 billion  $m^3$ ), which accords with experiment research. After analog computation, 3-dimensional images of section height distribution and velocity of debris flow in 1800 seconds have been acquired, and the author selects the typical timing to analyze.

It can be seen from Figure 4 that debris flow has a down-slope movement within 50 seconds of volcano eruption from waterfall mouth of Tianchi northern slope. Affected by the landform and topography in the vicinity of waterfall mouth, debris flow is not confined to due north, but it is divided into two flow channels: the mainstream flows along the north by east with depth 200 m and flow velocity increasing from 30 m per second to 100 m per second, whereas the tributary volume is smaller with only around ten meter in the first 50 seconds. Due to steep slopes, the early velocity amounts to 50 m per second, increasing rapidly to 100 m per second, and flows along downward north by west.

It can be seen from Figure 5 above, the mainstream flushes downslope in the form of a thin strip within the period from 50 seconds to 300 seconds combined with slower deposit velocity and decreased flow velocity followed by increasing one, which illustrates that this section of slop has experienced some fluctuation. The leading edge of

Figure 3. Alternation curve of flow total volume.

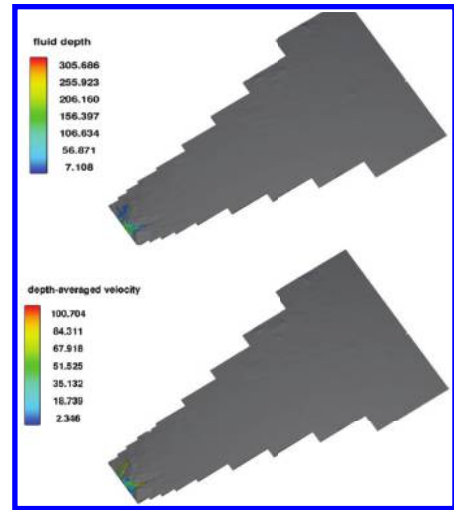

Figure 4. Section depths and section velocity of debris flow at the 50 seconds.

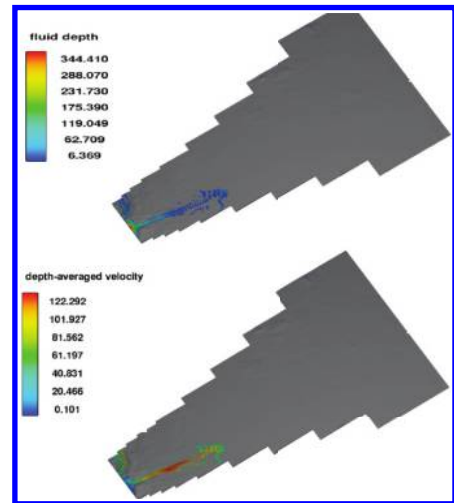

Figure 5. Section depths and section velocity of debris flow at the 300 seconds.

debris flow presents an obvious fan shaped spread, and the flow velocity of debris flow in sections 6 and 7 keep at around 100 m per second accompanied by the relatively small pile thickness of this section, which illustrates that this section is the steepest. After the 100 seconds of the tributary, the fluid runs out of the model with about 10 meters per second deposit velocity. Considering the slower flow velocity compared with the mainstream, the estimated amount of loss is small.

After the time of 1800 seconds, which is shown as Figure 6, the debris flow remains certain flow velocity and continues to run only with pretty

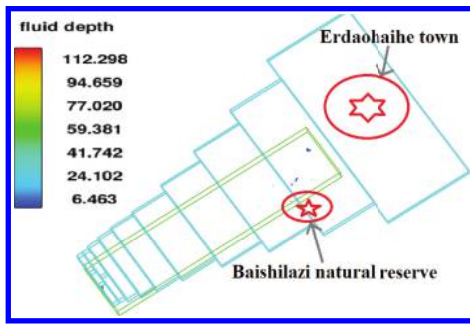

Figure 6. The maximum scope of influence at the end of simulation.

shallow depth and slow flow velocity. Considering the restrictions of computer memory and other objective factors, the simulation has ended. Within the period of 1800 seconds simulation, the maximum deposit length of debris flow is around 42 km with an approximately 8 km to Erdaobaihe town. At the end of simulation, part of debris flow still has certain velocity to flow, which will not exert significant impact on producing and living condition of the Erdaobaihe residents considering the slow velocity and small scale compared with original debris flow condition. The simulation analysis results have guiding influence on the prevention and control as well as study of flow debris.

### 3.2 Result analysis

Throughout the entire process of debris flow in the model from happening to basic static condition, water depth is the deepest in the Tianchi mouth and gradually decreases downward while rebounds when arriving at grid 9, which illustrates that this section is low-lying area with the capacity to store part of the fluid. In terms of the flow velocity, the tributary is generally faster than the mainstream, which demonstrates the steeper terrain of the tributary. The mainstream mean velocity reaches its peak at over 100 m per second at grids 6 and 7, which illustrates big altitude difference and steep slope, and the debris flow velocity increases considerably under the effect of gravity. However, due to the restrictions of computer configuration, memory and computational capabilities, the elaborate model has not been built and current model featured by larger unit size and coarse could not manifest the flow in detail, so there may be some errors.

The purpose of this simulation is to quantitatively estimate the maximum scope of debris flow influence downward Tianchi As is shown in Figure 7, the leading edge of debris flow could reach as far as 4.2 km in the simulation time 1800 seconds with 0.5 billion debris flow. However, at the end

of simulation, the debris flow has still developed to a certain degree. The population of the region is mainly inhabited in Erdaobaihe town, which is 5 km to Tianchi mouth. According to the experience, the scope of debris flow influence under such situation would not reach Erdaobaihe town nor has it any significant influence on it.

## 4 CONCLUSION

According to the conclusion above, we can see that the secondary debris flow in Changbai Mountains has certain threat even in a small volume of fluid; moreover, when the debris flow occurs, the danger is greater than the simulation in this paper. So, we should adopt a comprehensive method to the prevention and treatment of secondary debris flow in Changbai Mountains<sup>[9]</sup>. As long as we all work together, act according to circumstances, make effective defense plans and adopt scientific measures to prevent the debris flow disasters, we will overcome this disaster by all means and protect our lives and property and the ecological environment from more serious violations.

# Research trend on the prediction of coal and gas outburst

Xin Wu

*Institute of Technology, Sichuan Normal University, Chengdu, Sichuan, China*

**ABSTRACT:** This thesis analyzed the development trend of the coal and gas outburst. It introduces some new methods, such as acoustic emission, electromagnetic radiation, microseism technique, dynamic indicators of gas emission, and so on, which predict coal and gas outburst, and meanwhile, this thesis analyzes both the advantages and disadvantages of these methods. Also it sums up the widely used non-linear theories at present in the prediction of the coal and gas outburst, such as, computer simulation, fuzzy mathematics, gray system, neural network technique, expert system, and fractal analysis. Finally based on the analyses above, this thesis foresees the research trend of the field of prediction of coal and gas outburst.

**Keywords:** coal and gas outburst; prediction; acoustic emission

## 1 INTRODUCTION

Coal and gas outburst is one of the most serious natural disasters in mine. It is a complex dynamics phenomenon and badly threatens to the safety of production of coal. The purpose and significance of coal and gas outburst forecast is to provide a scientific basis for taking reasonable and effective measures to reduce outburst, to reduce the anti-outburst engineering and time, to ensure the normal process of mining and production, and to protect underground life and property from danger. For a long time, many scholars both from the domestic and the foreign make a lot of work and achieved in some extent on coal and gas outburst principle and the fatalness of outburst. With the rising of the modern mathematics, physical theory and high technology in other fields, coal and gas outburst forecast also gets its new advancement.

## 2 NEW PREDICTION TECHNIQUES OF COAL AND GAS OUTBURST

### 2.1 *Acoustic emission*

There are a lot of defects such as cracks in internal coal and rock. Coal and rock deformation and damage result in fracture, expansion, and transfixion. Research shows that the production and expansion of cracks will generate energy radiation in the form of elastic waves, which is AE. AE technology can locate the source of rupture. In the early 1940s, the United States was on the use of acoustic emission technology for monitoring the metal mine rock burst. With the application of computer technology, AE technology gets a more extensive

use in the coal mine and it has made some achievements in the rock burst monitoring. In the early 1980s, Australia exploited a dual-channel AE outburst forecasting system; AE outburst forecasting system was tested from 1983 to 1987 in the Cynheidre South Wales Coal Mine in British; however, there were no outburst in the course of the trial. Other countries like the United States, Germany, Japan, and Poland have some study in this area. The former Soviet Union predicts the outburst of coal and gas by recording the number of pulse noise and extends it to Donbas coal field. China's studies begin lately and apply less. Pingdingshan Mining Bureau introduced an AE monitoring system from Russia, and made an application to the study of coal and gas outburst. Chongqing Institute of China Coal Research Institute (CQCCRI) produced acoustic emission monitoring systems and applied it to Pingdingshan mining area during 9th Five-Year Plan. Xi'an Institute of China Coal Research Institute (XACCRI) also developed MJY-1-AE real-time monitoring system, and initiated a local experiment in the 10th Mine of Pingdingshan coal mine<sup>[1]</sup>.

Although the AE technique can assess effectively and continuously the outburst fatalness of coal edge, but there are many shortcomings, mainly because both equipment structure and receive and switch of the signals are complicated, what is more, it requires that piezoelectric sensors and coal wall can be a good coupling, in fact, which is very difficult. However, with the introduction of large capacity, high-speed computer systems and the development of the acoustic receive technological, maybe by using AE technique, outburst forecast will get some breakthrough.

## 2.2 Electromagnetic radiation

Like other materials, coal rock is made of tens of thousands of elementary particles such as atoms of electron. When coal rock suffers from deformation and fracture load, electron and other electronic particles change velocity and release electromagnetic radiation, which is called Electromagnetic radiation. The study of rock electromagnetic radiation starts when chun-worker discovers the electromagnetic anomaly before the earthquake. China and the former Soviet Union launched earlier in this field than other countries, then Japan, Greece, the United States, Sweden, Germany, and other countries also did research in this area. After more than 10-year deep research on electromagnetic radiation, which happens under the circumstances of loaded coal rock and desorption flow of gas, China University of Mining discovers that basically the electromagnetic radiation signal displays the trend of gradually strengthening during the deformation of loaded coal rock (that the coal and rock containing the deformation and fracture process, for a gradual strengthening of trend). The fundamental purpose of electromagnetic radiation technology study is to forecast the earthquakes and other disasters, which satisfactorily succeed in earthquake prediction. The current use of electromagnetic radiation, to forecast Dynamic disaster in coal rock, set off the study upsurge.

Electromagnetic radiation prediction technology is a complete non-contact monitoring method. This method is feasible and will not be influenced by artificial work and the asymmetry and instability of working face, do not drill, and works simply but it requires high level of the testing equipment performance.

## 2.3 Seismic technology

Research shows that there is rupture and shock in the process of destruction of the coal and rock, and shake waves or acoustic waves are emitted from the shake source. Maybe coal will be destructed suddenly, and outburst, when the intensity and frequency of the shock waves or sound waves reach certain values. The shock waves inside coal and rock can be received by the detection equipment (for example, underground sound receiver and shock wave receiver) installed in coal, and can be recorded after enlarging. And then we can predict fatalness of outburst through the analysis on the data.

Research shows that outburst is caused by a series of fracture, and abnormal Seismic radiation produced before fracture 5–45 min, so the Seismic radiation has luciferous prospects as a kind of forecasting methods, but the data monitoring and filtering need to be improved. Since the beginning of the 1970s, the U.S. mining bureau has studied

coal seam structure damage through the standard Seismic technology. At the same time, they adopt ultrasonic monitoring technology to monitor the energy of noise in rock.

## 2.4 Dynamic gas emission targets

V30 is the ratio of gas release quantity and coal drop quantity in 30 minutes after blasting of the excavate working face. The critical value in Germany is 40 percent of the gas content that can be desorption. Fushun Institute of China Coal Research Institute's study on Beipiao bureau shows that the critical value of outburst is  $9 \text{ m}^3/\text{t}$ . Chongqing Institute of China Coal Research Institute's study on Beijiao coal mine of Furong mining Bureau shows that there is outburst risk in front of working face about 2–5 m when the  $V_{30} \geq 9 \text{ m}^3/\text{t}$  or the change coefficient of Gas Emission  $K_V \geq 0.7$ . At present, for casting outburst by  $V_{30}$  or  $\Delta_Q$  has not been promoted to a large area.

In fact, the real forecast technology of gas emission is a kind of technology based on the relation between gas emission situation detected by Environment Monitoring System's continuous monitor and coal and gas outburst, so the real monitoring system is the key to exact forecast.

## 3 NEW METHOD OF COAL AND GAS OUTBURST FORECAST

### 3.1 Computer simulation

Mine is a complex engineering project. Many problems of mining work is very difficult to answer, and it will produce a greater engineering error according to contrast. The application of computer simulation technology in the works of mine gives a new start in mine engineering technology. Computer simulation in the progress of mining, simulation of the roadway stress distribution, simulation of the stability of tailings dam, and other examples show that numerical simulation technology has become an important tool for mining projects. As an advanced productive force to promote the mining engineering technology, computer simulation technology is rising.

### 3.2 Fuzzy math

Fuzzy math theory, first proposed by the U.S. cybernetics expert LAZadeh, is the important means to express and deal with imprecise data and ambiguous information. Many scholars domestic and abroad quantitatively evaluate the mine geological changes, the occurrence of gas and the danger of the gas disaster by using fuzzy evaluation theory combined with statistical methods.

Through analyzing the complexity of the inherent mechanism of coal and gas outburst, and the inaccurate relationship between the outburst factors and the outburst itself, we can give the right express and treatment to the inaccurate information and relation under the help of the fuzzy theory and technique. The treatment means turns from the traditional ones based on the experience and analogy to the practice of mathematics and science<sup>[2-3]</sup>.

### 3.3 Gray system theory

Gray System Theory is a new theory proposed by Professor Deng Julong<sup>[4]</sup>. Coal and gas outburst forecast parameters are fuzzy, randomness, which are the factors of the gray system theory. We can apply gray correlation analysis to quantitatively deal with coal and gas outburst factors in the design of the gray factors. Through the gray correlation analysis, we can analyze the main factors by putting aside the complicated ones, which has some significance to promote the accuracy of the outburst forecast.

Gray cluster method has some advantages, such as dynamic forecasts. This method will consider a number of factors by the numbers, which affect the outburst heavily, it jumps out of the conventional forecasting methods which only rely on a single indicator to predict, so it can improve the forecast accuracy. The result shows that it is a new method to accurately reflect the laws of the coal and gas outburst in the mine.

### 3.4 Neural networks

Neural Networks is another important branch of the science of artificial intelligence, which develops fast in late 1980s of the 20th century. Besides its strong vitality in pattern recognition, treatment and control of nonlinear dynamics, and other areas, it shows a good applicable effect in the forecast, the evaluation and so on. In recent years, fuzzy neural network technology, which is represented by the BP neural network model that is auto-adaptive to outburst intensity forecast gets notable achievements in the coal and gas outburst forecast field.

Coal and gas outburst is a complex phenomenon of nonlinear dynamics, and has a complex non-linear relationship with the factors causing the outburst. The current prediction methods are not effective, because it cannot accurately reflect objective mathematics relationship between the dependent variable and independent variable. To accurately reflect this relationship, we must adopt a more suitable way. Artificial neural network technology can achieve this better: what has been proven is that artificial neural network can

in any precision approach any arbitrary complex functions, if there is a hidden layer. It is a approximation model of common function<sup>[5]</sup>. Therefore, artificial neural network can more accurately reflect the mathematical relations between the coal and gas outburst and its factors, so as to predict the risk of outburst more accurately.

### 3.5 Expert system forecasts the outburst

Expert System is a computer program which simulates a human expert to solve the problem by using knowledge and experience of a human. UPEL expert system in British Coal Company can be used to forecast the danger of coal and gas outburst during the course of underground mining<sup>[6]</sup>. The Chinese Academy of Sciences Institute of Geology is also developing an expert system GASBURST to forecast the outburst. According to its users' information about the mine geological structure, underground water, gas, drilling dust, stress and the information providing the outburst events, this system can mark the the danger area and the danger zone of the outburst, predict the trend of the development of the criticality according to the mining depth. It can also forecast the the location of the outburst, display the location of the danger area of the outburst and the underground location of the outburst, and meanwhile show the relationship among the different outburst on the computer screen.

### 3.6 Fractal theory

Fractal geometry, as a theoretical tool and method for studying the nonlinear problems, has been widely used in the coal industry in recent years. Dr Fu Boxue carried out some fractal research in coal reservoir pores and cracks system, and analyzes the relationship among the fractal dimension, the coal pores, cracks, coal development, and the degree of degeneration, which provides a more precise way to evaluate the coalbed methane adsorption and desorption, the proliferation of seepage, coal and gas outburst prediction and the effective penetration rate estimate. Shao-Lin Lu and other researchers do some research in the outburst coal on the size of fractal, and the result shows that: outburst coal fractal characteristics cannot only give a quantitative description on outburst coal's ability to resist outside devastating forces and recognize the differences between the outburst coal and non-outburst coal from the aspect of media's mechanical behavior, but also comprehensively evaluate coal's ability to absorb and give out the gas. In addition, the fractal geometry is widely applied in analyzing the complexity of the network faults and the distribution characteristics in the region of the coal and gas outburst.

## 4 CONCLUSION

With the development of high technology in various fields, such as acoustic emission technology, electromagnetic radiation monitoring technology, Seismic technology, gas emission dynamic indicators, which all depend on the advanced monitoring technology, develops fast; although these technologies in practice need to be further improved, yet it is promising.

Inherent mechanism of coal and gas outburst is extremely complicated. The relevant laws between the influence factors of outburst and the outburst itself are not accurate and clear. The application of the traditional forecasting technique, which is based on the experience and the statistical forecasting methods based on mathematical modeling, is restrained badly. Presently, some advanced theoretical methods, such as computer simulation, fuzzy math theory, gray system theory, neural network, expert systems, fractal theory, and the theory of nonlinear<sup>[7-10]</sup>, have been applied in the quantitative evaluation and analysis of coal and gas outburst, and get some achievements.

# The research significance of the steel reinforced recycled aggregate concrete's fire resistance

Bing Wang & Xiao Liu

*School of Architectural and Civil Engineering, Shenyang University, Shenyang, China*

Lu Gao

*School of Civil Engineering, Lanzhou University of Technology, Lanzhou, China*

**ABSTRACT:** This paper analyzes the features and significance of steel reinforced recycled aggregate concrete based on reading lots of documents. The analysis shows that steel reinforced recycled aggregate concrete is a new type of structure form can meet the requirements of bearing capacity, but also has significant environmental, economic, and social benefits. Research on the fire resistance of steel reinforced recycled aggregate concrete is the precondition of its wide application. It has important research significance.

**Keywords:** steel reinforced recycled aggregate concrete; recycled aggregate; fire resistance

## 1 INTRODUCTION

In recent years, domestic and foreign scholars on steel have systematically researched the structural performance of recycled concrete composite and made a lot of achievements [1–3]. Along with the research and engineering application, studying the fire resistance performance of concrete structure of recycled steel is becoming more and more urgent. In this paper, on the basis of the reading of vast amount of literature, we deeply analyzed the characteristics and research significance of the steel reinforced recycled aggregate concrete.

## 2 THE CHARACTERISTICS OF STEEL REINFORCED RECYCLED AGGREGATE CONCRETE

### 2.1 *The characteristics of reinforced recycled concrete*

Recycled aggregate is aggregate of the waste concrete after crushing, washing, grading, and resulting from the interaction of aggregate by certain proportion. And the use of recycled aggregates as part or all of the concrete aggregate is known as recycled aggregate concrete, recycled concrete for short. According to the size, the recycled aggregate can be divided into recycled coarse aggregate and recycled fine aggregate; according to the source it can be divided into road construction and recycled aggregate; according to the use, it

can be divided into recycled aggregate concrete, recycled aggregate, and recycled aggregate mortar block. The recycled concrete technology can realize the re-processing of waste concrete, to restore the original performance, and form the new building materials products. Thus, it not only can make the limited resources be reused, but also to solve some environmental problems, and achieve the sustainable development of the construction industry.

Because of the differences between the physical properties of recycled aggregate and natural aggregate, there is a certain difference in mechanical properties between the recycled concrete and normal concrete. The cube, prism compressive strength, and elastic modulus of recycled concrete is lower than that of ordinary concrete. The peak strain is higher than that of ordinary concrete, the ultimate strain lower than that of ordinary concrete [4].

In addition, studies have shown that after heated to 300°C, the residual compressive strength of recycled concrete has increased, and the recycled concrete replacement rate is high, the more obvious upward trend. It has obvious decline to 500°C. The reason for this phenomenon may be that the surface of recycled coarse aggregate is rough, and it makes the interface between recycled coarse aggregate and cement strengthen when they are in contact, so that the high-temperature low-impact compressive strength of recycled aggregate concrete [5].

## 2.2 *The characteristics of steel reinforced recycled aggregate concrete*

Steel reinforced recycled aggregate concrete is an independent structure of steel combined with recycled concrete. Its core part is steel, and its external for recycled concrete and with the right amount of longitudinal are bounded by pushing for reinforcement and the stirrup. The internal steel parts and outsourcing of reinforced concrete formed a whole, namely steel reinforced recycled aggregate concrete. Steel can not only take more load, provide large deformation ability, at the same time it constrains the formation of concrete at the core. The compression of concrete in a three-way state greatly improves the strength and deformation properties of recycled concrete. Steel reinforced recycled aggregate concrete is also used as recycled concrete to reduce construction waste, improve the urban environment, save the characteristics of the economy. So the steel reinforced recycled aggregate concrete structure has become a kind of structure system with ecological significance.

## 3 THE SIGNIFICANCE OF THE RESEARCH

### 3.1 *The significance of the research of recycled concrete*

A large number of construction waste increased due to the increased rate of urban construction and frequent earthquakes and other natural disasters, as shown in Figure 1. According to statistics, the number of building demolition waste and construction waste of most countries in the world accounts for about 30%–40% of the total municipal waste. And the waste concrete containing large aggregates. If they could be reasonably recycling, production of recycled concrete used in the new building, not only can reduce the cost, save natural resources, alleviate the contradiction between supply and demand of aggregate, but also reduce the environmental pollution of waste concrete. And it is an important part of the sustainable development strategy. Therefore, how to make full, efficient, economical utilization of construction waste, especially the waste concrete in many countries has become a topic of common research.

At the same time, China's construction industry is developing vigorously, the thickness of aggregate demand is very big, but will increase along with the development in the future. For such a big consumption, the earth's natural aggregate native thickness will be exhausted, so, seeking to substitute for natural aggregate is very important from the perspective of resources reasonable development use and sustainable development.

Figure 1. A large number of abandoned concrete demolition and earthquake disaster.

The application of recycled concrete, solves the problems of construction waste pollution problem and the lack of natural aggregate, has significant economic benefits, social benefits, and environmental benefits.

### 3.2 *The research significance of the fire*

The fire is the loss of control in time and space the disaster caused by burning. Fire can be divided into building fires, forest fires, traffic fire, and so on. The building fires occur frequently, causing casualties and major property damage because of the number of people and valuables at the scene of the fire; combustible variety; ignition source high frequency; limited space; and prone to secondary disasters. Not only that, but also building fire cause air pollution, destruct the ecological environment, and after fire waste has caused environmental pollution.

In recent years, with the increasing scale and the growing number of buildings, fire frequency increased. Shanghai Yuyao road Jiaozhou road teacher's apartment fire, Hongkong Garden Street in Mong Kok fire, Tianjin Jixian County building fire, Jilin Baoyuanfeng poultry company major fire accident, and Yunnan Shangri-La County dukezong fire, causing casualties and significant property damage.

Recently, our country has undergone several major fire accidents. In January 5, 2015, in Changzhou City, the building of Changzhou Mingtai textile printing and dyeing Co. Ltd. Caught fire killing 3 construction workers; in January 3, 2015, the national key cultural relics protection units Dali Gongcheng saw building fires, Gongcheng floor basically burned; in January 2, 2015, Hal Hama Kuraku fire caused collapse, causing 5 fire fighters' lives to be sacrificed along with 14 people. More than 2000 people were injured, 549 households, and part of the street merchants were affected.

Through the research on fire resistance of structures, we can effectively prevent fire by a local collapse and the overall collapse caused by the fire and personnel evacuation difficult and serious casualties. And it can provide important technical guidance for the repair and reinforcement of structure after fire, reduce the cost of repairing structure after fire, shorten the functional recovery after a disaster, and indirectly reduce economic losses caused by the fire. Therefore, the structure fire resistance design is very necessary.

#### 4 CONCLUSION

In summary, steel reinforced recycled aggregate concrete can not only meet the requirements of bearing capacity, but also has significant environmental, economic, and social benefits. Research on the fire resistance of steel reinforced recycled aggregate concrete is the precondition of its wide application. It has important research significance.

# Constitutive model derivation and numerical simulation of iron based Shape Memory Alloy pipe joint

Wei Wang, Bo Wang, JiYuan Liu & Hong Hai

School of Civil Engineering, Shenyang Jianzhu University, Shenyang, China

**ABSTRACT:** Based on the Brinson's constitutive model of Shape Memory Alloys (SMA), and combined with the lame formula of thick wall cylinder, we deduced a simplified constitutive model for SMA pipe coupling. Using MATLAB software to compile executable program, we used this program to carry on the numerical simulation for the SMA coupling structure. The results show that under the condition of the other factors are fixed, firstly, the radial compressive stress between the SMA pipe joint and the connected pipe increases with the increase of wall thickness of SMA pipe joint; secondly, the radial compressive stress decreases with the increase of hole enlargement rate of SMA pipe coupling; lastly, the radial compressive stress decrease with the increase of diameter of connected pipe.

**Keywords:** Shape Memory Alloys; constitutive model; radial compressive stress; pipe joint; wall thickness

## 1 INTRODUCTION

Serious corrosion problems existed in oil and gas pipelines, which lead to huge economic losses. The great part of corrosion existed in the joints of pipeline, which is because the original pipe connected by welding, this method needs high technical requirements, and the welding itself has many defects. NiTi Shape Memory Alloys (NiTi SMA) have excellent shape memory properties, so it was applied earliest in military aircraft hydraulic pipeline connection. Now it has been widely used in aerospace and other fields of pipe connection. Iron base Shape Memory Alloys (Fe SMA) has many advantages, such as high strength, high restored deformation, and good property of corrosion resistance. Its phase transition temperature  $M_s$  is near the room temperature. In addition to the above advantages, the alloy of Fe SMA is easy to process and its price is cheaper than NiTi SMA. Due to the above advantages, this alloy is widely used in pipeline connection in the field of petroleum, chemical industry, and so on.

The Fe SMA pipeline joints are easy to keep at room temperature, due to its inverse phase transition temperature is above room temperature. Because the inner diameter of pipe joint is smaller than the outer diameter of connected pipe, the joint diameter expands in room temperature, then the joint can be set on the outside of the connected pipe. And then to heat the pipe joint, the SMA joint is induced the shape memory effect because

of the increasing temperature, the radius of the joint becomes narrow. At last the joint and pipeline connected together tightly.

This paper, using the Brinson's constitutive model derived previously, and combined with the lame formula of thick wall cylinder, we deduced simplified constitutive model for SMA pipe coupling to simulate the structure of SMA fittings, to study the effect of different factors to the fastening force (radial compressive stress) between SMA joint and pipeline.

## 2 BRINSON'S MODEL FOR SMAS

Brinson [1] divided the martensite fraction into two parts  $\xi_T$  and  $\xi_S$ , where  $\xi_T$  represents the fraction of material that is purely temperature-induced martensite with multiple variants and  $\xi_S$  denotes the fraction of the material that has been transformed, or oriented, by stress into a single martensite variant, the constitutive relation of SMA can be expressed as:

$$\sigma - \sigma_0 = D(\xi)\bar{\epsilon} - D(\xi_0)\bar{\epsilon}_0 + \Omega(\xi)\xi_S - \Omega(\xi_0)\xi_{S0} + \Theta(T - T_0) \quad (1)$$

### 2.1 Conversion to detwinned martensite

For  $T > M_s$  and  $\sigma_s^{er} + C_M(T - M_s) < S < \sigma_f^{er} + C_M(T - M_s)$

$$\xi_s = \frac{1 - \xi_{s0}}{2} \cos \left\{ \frac{\pi}{\sigma_s^{cr} - \sigma_f^{cr}} (S - \sigma_f^{cr} - C_M (T - M_s)) \right\} + \frac{1 + \xi_{s0}}{2} \quad (2)$$

$$\xi_T = \xi_{T0} - \frac{\xi_{T0}}{1 - \xi_{s0}} (\xi_s - \xi_{s0}) \quad (3)$$

For  $T < M_s$  and  $\sigma_s^{cr} < \sigma < \sigma_f^{cr}$

$$\xi_s = \frac{1 - \xi_{s0}}{2} \cos \left\{ \frac{\pi}{\sigma_s^{cr} - \sigma_f^{cr}} (S - \sigma_f^{cr}) \right\} + \frac{1 + \xi_{s0}}{2} \quad (4)$$

$$\xi_T = \xi_{T0} - \frac{\xi_{T0}}{1 - \xi_{s0}} (\xi_s - \xi_{s0}) + \Delta_{T\xi} \quad (5)$$

where, if  $M_f < T < M_s$  and  $T < T_0$

$$\Delta_{T\xi} = \frac{1 - \xi_{T0}}{2} \left[ \cos(a_M (T - M_f)) + 1 \right]$$

else

## 2.2 Conversion to autenite

$$C_A(T - A_f) < \sigma < C_A(T - A_s)$$

For and  $\Delta_{T\xi} = 0$

$$\xi = \frac{\xi_0}{2} \left\{ \cos \left[ a_A \left( T - A_s - \frac{S}{C_A} \right) \right] + 1 \right\} \quad (6)$$

$$\xi_s = \xi_{s0} - \frac{\xi_{s0}}{\xi_0} (\xi_0 - \xi) \quad (7)$$

$$\xi_T = \xi_{T0} - \frac{\xi_{T0}}{\xi_0} (\xi_0 - \xi) \quad (8)$$

$T > A_s$

## 3 STRESS STATE BETWEEN PIPELINE AND SMA PIPE JOINT

By the elastic-plastic theory, the stress state between pipeline and SMA joint meet the thick wall cylinder problem of plane axisymmetric problem [2]. Because of the austenitic phase transformation, the connected pipe limits the shape recovery of SMA joint, so the SMA joint can produce restore stress. The recovery stress provides the hoop stress  $\sigma_\theta$  in the pipe joint system. And then the radial compressive stress  $\sigma_r$  produced in the pipeline and SMA joint P2, the connected pipes thus produced fastening

force P2, and the connected pipelines and SMA joint connected together tightly. The stress analysis of pipe coupling structure is shown in Figure 1.

According to the lame formula, we can get the relationship of hoop stress, radial stress, and fastening force in the connected pipelines just as follows [3]:

$$\sigma_{sr} = -\frac{R_b^2 P_2}{R_b^2 - R_a^2} \left( 1 - \frac{R_a^2}{r^2} \right) \quad (9)$$

$$\sigma_{s\theta} = -\frac{R_b^2 P_2}{R_b^2 - R_a^2} \left( 1 + \frac{R_a^2}{r^2} \right) \quad (10)$$

Can also get the relationship of hoop stress, radial stress, and fastening force in the connected pipelines just as follows:

$$\sigma_r = \frac{R_c^2 P_1}{R_d^2 - R_c^2} \left( 1 - \frac{R_d^2}{r^2} \right) \quad (11)$$

$$\sigma_\theta = \frac{R_c^2 P_1}{R_d^2 - R_c^2} \left( 1 + \frac{R_d^2}{r^2} \right) \quad (12)$$

By above formula can deduce the expressions of radial stress and fastening force using hoop stress:

$$P_1 = \frac{\left( \frac{R_d^2}{R_c^2} - 1 \right)}{1 + \frac{R_d^2}{r^2}} \sigma_\theta \quad (13)$$

$$\sigma_r = \frac{\left( 1 - \frac{R_d^2}{r^2} \right)}{1 + \frac{R_d^2}{r^2}} \sigma_\theta \quad (14)$$

$$p_1 = -p_2 \quad (15)$$

Figure 1. Stress analysis of pipe coupling system.

#### 4 NUMERICAL SIMULATION AND CALCULATION ANALYSIS

The radius of SMA joint in parent phase is smaller than the radius of connected pipes, expanding the diameter under low temperature, in this process, the twin martensite transformation to detwined martensite by the external force, then heating the SMA joint, the joint wants to restore the radius before expanded. But the recovery is limited by the connected pipes, so the SMA joint produce large recovery force. Write the MATLAB program according to the relevant transformation formulas in the reference (1) and formula (13)–(14), to simulate the structure of SMA pipe coupling, analysis the relationships of fastening force and hole enlargement ratio, wall thickness of pipe, and the radius of connected pipe.

The parameter of SMA joint as follows: moduli  $D_a = 67000\text{Mpa}$ ,  $D_m = 26300\text{Mpa}$ , transformation temperature  $M_f = -9\text{ }^\circ\text{C}$ ,  $M_s = 0\text{ }^\circ\text{C}$ ,  $A_s = 80\text{ }^\circ\text{C}$ ,  $A_f = 250\text{ }^\circ\text{C}$ , transformation constants  $C_M = 8\text{ MPa}/^\circ\text{C}$ ,  $C_A = 13.8\text{ MPa}/^\circ\text{C}$ ,  $\sigma_s^{cr} = 100\text{Mpa}$ ,  $\sigma_f^{cr} = 170\text{Mpa}$ . The sizes of connected pipe are  $R_a = 34\text{ mm}$ ,  $R_b = 42\text{ mm}$  respectively. Here assume that the connected pipe is rigid, and the radius is fixed.

Example 1: chose the expanding rate of SMA joint from 0.022 to 0.13, the thickness of SMA joint is 12 mm, and the outer radius of connected pipe is 42 mm. The results are shown in Figure 2, know from the curve that the radial pressure decreases from 108.7 Mpa to 41.3 Mpa. This is mainly because the deformation of SMA joint increases with the increase of hole enlargement ratio, which lowered the recovery stress of SMA pipe joint. So in practical application, while increase the rate of hole enlargement can convenience construction, it will also reduce the recovery stress of SMA pipe joint, and affect the values of fastening force.

Figure 2. Relationship between radial pressure and expanding rate.

Figure 3. The relationship between radial pressure and wall thickness.

Figure 4. Relationship between radial pressure and outer radius of connected pipe.

Example 2: If the wall thickness of SMA joint is from 2 mm to 20 mm, the expanding rate of SMA joint is 3%, and the outer radius of connected pipe is 42 mm. The results are shown in Figure 3, know from the curve that the radial pressure increases from 17.1 Mpa to 136.7 Mpa. According to the formula (11), when the tangential stress is fixed, the radial compressive stress changed as the change of wall thickness of SMA pipe joint.

Example 3: chose outer radius of connected pipe from 42 mm to 62 mm, the expanding rate is 3%, and wall thickness of SMA joint is 12 mm. The results are shown in Figure 4, know from the curve that the radial pressure decreases from 94.0 Mpa to 66.9 Mpa.

#### 5 CONCLUSIONS

Based on the Brinson's constitutive model of Shape Memory Alloys (SMA), combined with the state of stress distribution between the pipe and pipe joint, get a simplified constitutive model, which fit the SMA pipe coupling structure. Use this constitutive model to simulate the stress distribution during the process of heating up, system discuss the relationship between the radial compressive stress

and various influencing factors. The simulation results show the radial compressive stress increase with the increase of wall thickness of SMA pipe joint, and the radial compressive stress decrease with the increase of hole enlargement ratio of SMA pipe joint and outer radius of connected pipe. Therefore, according to the practical engineering, selecting suitable thickness of SMA pipe wall, hole enlargement ratio, and outer radius of connected pipe, to achieve optimal results.

# Evaluation on thermal stress distribution of a cable-stayed footbridge under temperature loading

X.F. Fan, B. Chen & Y.J. Jiang

*School of Civil Engineering and Architecture, Wuhan University of Technology, Wuhan, China*

Y.Q. Xu

*Key Laboratory of Roadway Bridge and Structural Engineering, Wuhan University of Technology, Wuhan, China*

**ABSTRACT:** The thermal stress distribution of a cable-stayed footbridge is investigated in this study through numerical computation. With appropriate assumption, the temperature field of the footbridge is simplified and divided into several components. Fine finite element models are constructed for the deck plate, bridge section, and bridge tower to calculate the structural thermal stress distribution. The made observations demonstrate that the temperature induced stresses of the footbridge is substantially large, which should be taken in consideration in the maintenance process.

**Keywords:** thermal effect; footbridge; numerical simulation; thermal stress

## 1 INTRODUCTION

To be a kind of important traffic infrastructures, footbridges are widely-constructed and applied across the world for the last hundreds years. Footbridges are in the open air and inevitably subjected to daily, seasonal and yearly environmental thermal effects. Variations of temperature in footbridge components will cause movements due to indeterminacy and non-uniform distribution of temperature, which may induce the non-uniform thermal stress distribution. It is frequently reported that many footbridges across the world are damaged due to the thermal stress effects. The thermal behaviour of bridges has been investigated more than two decades. Zuk investigated the thermal behaviour of several highway bridges and found that the temperature distribution was affected by air temperature, wind, humidity, intensity of solar radiation and material type. Capps measured temperature and longitudinal movements of a steel box bridge in the UK. Early studies in the field include Priesley, and Churchward and Sokai among others.

The thermal stress distribution of a cable-stayed footbridge is investigated in this study through numerical computation. With appropriate assumption, the temperature field of the footbridge is simplified and divided into several components. Fine finite element models are constructed for the deck plate, bridge section, and bridge tower to calculate the structural thermal stress distribution. The made observations demonstrate that the temperature induced stresses of the footbridge is substantially

large, which should be taken in consideration in the maintenance process.

## 2 DESCRIPTION OF THE CABLE-STAYED FOOTBRIDGE

A cable-stayed footbridge constructed in China is taken as the example to examine the thermal stress

Figure 1. Plan view of the footbridge.

Figure 2. Elevation view of the footbridge.

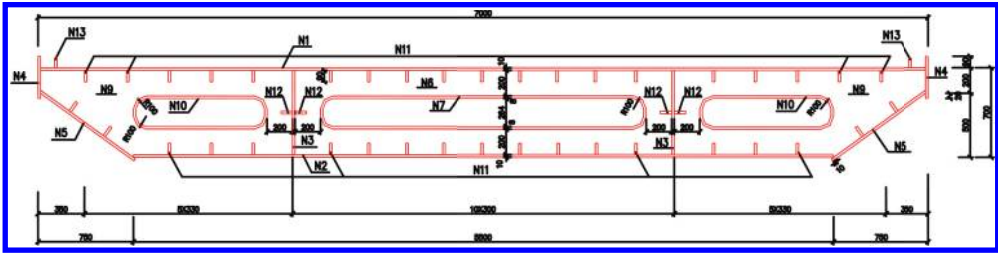

Figure 3. Cross section of the box beam in the main span.

Figure 4. Longitudinal section of the box beam in the main span.

distribution through numerical computation. The elevation view and plane view of the footbridge are displayed in Figures 1 and 2, respectively. It is seen that the footbridge has a single tower and eight stayed cables. The main span is constructed by using steel box girder while the south part of the footbridges is fabricated using concrete piers. The main span is 45 m and the total length of the footbridge is 88.25 m. The height of the tower is 24.5 m above from the ground. Displayed in Figure 3 is the cross section of the box beam in the main span. The width and thickness of the bridge deck are 7.0 m and 0.7 m, respectively.

### 3 THERMAL EFFECT ANALYSIS

#### 3.1 Solar radiation

The flow of heat in a solid is governed by the well-known Fourier partial differential equation. For the footbridge under the solar radiation, it can be assumed that thermal variation in the direction of the longitudinal axis is normally not significant. Consequently, the temperature field  $T$  of a bridge cross section at any time  $t$  can be expressed by a two-dimensional heat flow equation as

$$k \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) = \rho c \frac{\partial T}{\partial t} \quad (1)$$

in which  $x$  and  $y$  are Cartesian coordinates,  $k$  is the isotropic thermal conductivity coefficient,  $\rho$  is the density of material, and  $c$  is the specific heat of the material.

For a bridge subjected to solar radiation, the thermal energy transferred between the bridge surface and environment consists of convection  $q_c$ , thermal irradiation  $q_r$ , and solar radiation  $q_s$ . The rate of heat transfer by convection  $q_c$  is associated with the movement of the air particles. It depends on the convection heat transfer coefficient  $h_c$  and difference between the air temperature  $T_a$  and the bridge surface temperature  $T_s$  as

$$q_c = h_c(T_a - T_s) \quad (2)$$

The heat transfer between the bridge surface and the surrounding environment due to thermal irradiation can be expressed in a quasi-linear form as

$$q_r = h_r(T_a - T_s) \quad (3)$$

where  $h_r$  is radiation heat transfer coefficient. The rate of heat absorbed by the bridge surface due to solar radiation  $q_s$  is

$$q_s = \alpha I \quad (4)$$

where  $\alpha$  ( $0 < \alpha < 1$ ) is absorptivity coefficient of the surface material;  $I$  is solar radiation including direct solar radiation, diffuse solar radiation, and reflected solar radiation on a surface, respectively. Then, the temperature variations of the footbridge can be computed with the aids of the finite element method. After that, the temperature variations of the footbridge can be taken as the thermal loading acting on the footbridge to compute the structural thermal effects, such as displacement and stress distribution.

### 3.2 Thermal stress

The displacement of the footbridge can be expressed as

$$\mathbf{u} = \mathbf{N}\mathbf{a} \quad (5)$$

where  $\mathbf{u}$  is the displacement of a certain place;  $\mathbf{a}$  is the displacement vector,  $\mathbf{N}$  is the matrix of the shape function.

The stress vector  $\boldsymbol{\sigma}$  can be expressed as

$$\begin{aligned} \boldsymbol{\sigma} &= [\sigma_x, \sigma_y, \sigma_z, \tau_{xy}, \tau_{yz}, \tau_{zx}]^T \\ &= \mathbf{D}(\boldsymbol{\epsilon} - \boldsymbol{\epsilon}_T) = \mathbf{D}(\mathbf{B}\mathbf{a} - \boldsymbol{\epsilon}_T) \end{aligned} \quad (6)$$

$$\boldsymbol{\epsilon} = [\epsilon_x, \epsilon_y, \epsilon_z, \gamma_{xy}, \gamma_{yz}, \gamma_{zx}]^T \quad (7)$$

$$\boldsymbol{\epsilon}_T = [\alpha_T T, \alpha_T T, \alpha_T T, 0, 0, 0]^T \quad (8)$$

where  $\boldsymbol{\epsilon}$  is the stress vector;  $\boldsymbol{\epsilon}_T$  is the strain induced by temperature variation;  $\mathbf{D}$  is the elastic matrix.  $\nu$  is the passion ratio;  $\alpha_T$  is the thermal expansion coefficient;  $T$  is the temperature change;  $E$  is the Young's modulus.

The force equivalent equation of footbridge under thermal loading can be expressed as

$$\mathbf{K}\mathbf{a} = \mathbf{f}_T \quad (9)$$

where  $\mathbf{K}$  is the entire stiffness matrix of the footbridge;  $\mathbf{f}_T$  is the thermal loading of the footbridge which can be expressed as the sum of thermal loading of each element

$$\mathbf{f}_T = \sum_{i=1}^{ne} \mathbf{f}_T^i \quad (10)$$

$$\mathbf{f}_T^i = \int_v \mathbf{B}_i^T \mathbf{D} \boldsymbol{\epsilon}_T dv \quad (11)$$

where  $\mathbf{B}_i$  is the strain-displacement matrix of the  $i$ th element.

## 4 FINITE ELEMENT MODEL

The finite element model of the cable-stayed footbridge is established by using the commercial package ANSYS as shown in Figure 5. The cables of the footbridge are simulated by using the link elements while the steel box girder is simulated by using shell elements. The two concrete piers are modeled by using three dimensional beam elements. The tower is fabricated using steel plate and is also simulated by using shell63 elements. The deck, tower and cable are constructed by using steel and the

Figure 5. Finite element model of the cable-stayed footbridge.

Table 1. Material properties of the cable-stayed bridge.

	Young's modulus (GPa)	Density (kg/m <sup>3</sup> )
Deck and tower	210	7900
Cable	210	7900
Pier	25	2500

pier is constructed by using concrete. The Young's moduli of the steel and concrete material are 210 and 25 GPa, respectively. The densities of the steel and concrete material are 7900 and 2500 kg/m<sup>3</sup>, respectively. The basic material parameters are listed in Table 1. In the thermal effects analysis, the reference temperature of the footbridge is supposed as the 10°C. Two loading scenarios are taken into consideration, namely the temperature of the bridge increased by 10°C (case No. 1) and 20°C (case No. 2) in the summer, respectively.

It is well-known that there exists some sag for the fixed cable subjected to self-weight. The axial stiffness of the cable may be affected by the sag, which can be modified based on Ernst expression:

$$E_{eq} = \frac{E}{1 + \frac{(wl)^2 AE}{12T^2}} \quad (12)$$

In which:  $E$  is the Young's modulus of the material,  $A$  is the cross-section area of the cable,  $T$  is the tension force of the cable,  $w$  is the weight of the cable per meter;  $l$  is the projected length of the cable on horizontal plane.

## 5 STRESS DISTRIBUTION

Displayed in Figures 6 and 7 are the contours of the footbridge for the 10°C and 20°C temperature increase, respectively. Listed in Table 1 are the stresses of some typical nodes.

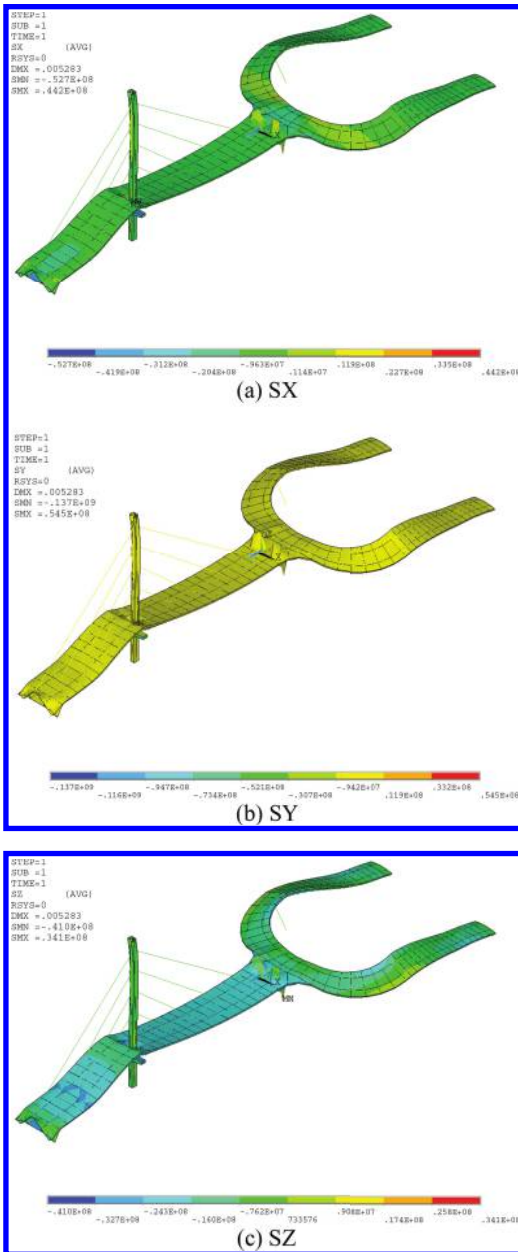

Figure 6. Nodal stress contour of the footbridge (case No. 1).

The made observations demonstrate that the peak tensile stress and pressure stress of the bridge in the  $x$  direction SX are 44.2 MPa and  $-52.7$  MPa, respectively. The made observations demonstrate that the peak tensile stress and pressure stress of the bridge in the  $y$  direction SY are 54.5 MPa

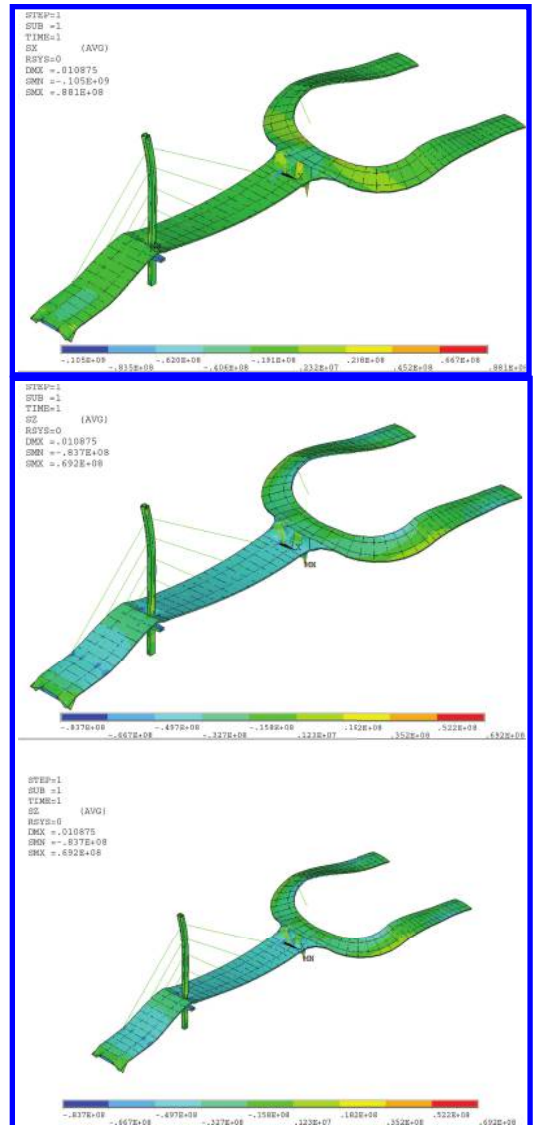

Figure 7. Nodal stress contour of the footbridge (case No. 2).

and  $-137$  MPa, respectively. The made observations demonstrate that the peak tensile stress and pressure stress of the bridge in the  $z$  direction SZ are 34.1 MPa and  $-41.0$  MPa, respectively. It is well know that the  $10^{\circ}\text{C}$  temperature increase in the summer for a single day is very common and even larger. Therefore, it is expected that the thermal stress of the footbridge in a whole day can reach more than 100 MPa and even more. These observations should be taken in consideration in the maintenance process.

Table 2. Nodal stress for scenario No. 1 (case No. 1).

	Node	SX (MPa)	SY (MPa)	SZ (MPa)
Tower	13411	-31.5	-31.4	0.0
	13362	-31.7	-31.3	0.0
	13410	-32.5	-28.2	0.0
	13389	-32.3	-25.9	0.0
Deck	2449	-39.3	-0.033	-28.2
	12569	-40.1	-0.037	-28.7
	12484	-38.5	-0.061	-37.9
	2503	43.9	0.00	-18.9

## 6 CONCLUSIONS

The thermal stress distribution of a cable-stayed footbridge is examined in this study through numerical simulation. The finite element model of the cable-stayed footbridge is established with the aiding of the commercial package. The reference temperature of the footbridge is supposed as the 10°C and the temperature of the bridge is assumed to increase by 10°C to simulate the solar radiation effects in the summer. The made observations demonstrate that the temperature induced stresses of the footbridge is substantially large, which should be taken in consideration in the maintenance process.

# Investigation on dynamic properties of a steel-concrete composite cable-stayed footbridge

Xia Fei

CCCC Second Highway Consultants Co. Ltd. (CCSHCC), Wuhan, China

**ABSTRACT:** Footbridges are inevitably subjected to environmental effects, such as wind, traffic induced vibration, human activities and temperature variations. The investigation on the dynamic characteristics of the footbridges is of much importance and is a direct and crucial approach to reflect the structural dynamics responses and assess the structural performance. To this end, a cable-stayed footbridge is taken as a real example to investigate properties of the natural frequency and the mode shapes through finite element analysis in this study. The deck, tower and cable are simulated by using the shell element, beam element and cable element, respectively. The mass matrix of the cable is the lumped mass matrix. The axial stiffness of the cable affected by the sag is modified based on the Ernst expression. The made observation indicate that the dynamic properties of the steel-concrete composite cable-stayed footbridge are different to those of the common long span cable-stayed bridge.

**Keywords:** natural frequency; mode shape; footbridge; dynamic property

## 1 INTRODUCTION

Footbridges are inevitably subjected to environmental effects, such as wind, traffic induced vibration, human activities and temperature variations. The environmental effects may induce the excessive vibration of the footbridges. Vibration of footbridges induced by human activities has been frequently observed across the world. It is well-known that if the lower natural frequencies are close to the frequency of the human activities, resonance of the footbridge can be expected. Therefore, the investigation on the dynamic characteristics of the footbridges is of much importance and is a direct and crucial approach to reflect the structural dynamics responses and assess the structural performance.

To this end, a cable-stayed footbridge is taken as a real example to investigate properties of the natural frequency and the mode shapes through finite element analysis in this study. The deck, tower and cable are simulated by using the shell element, beam element and cable element, respectively. The stiffness and mass matrices of the deck and tower are constructed by using the finite element method. The stiffness matrix of the cable is the combination of the linear stiffness matrix and nonlinear stiffness matrix. The mass matrix of the cable is the lumped mass matrix. The axial stiffness of the cable affected by the sag is modified based on the Ernst expression. The made observation indicate that the first mode shape is the lateral vibration of tower. The second mode shape is the

vertical vibration of the deck. The third one is the first order torsional rotation of the deck. These observations are different to those of the common long span cable-stayed bridge.

## 2 DESCRIPTION OF THE CABLE-STAYED FOOTBRIDGE

A cable-stayed footbridge constructed in China is taken as the example to examine the structural

Figure 1. Plan view of the footbridge.

Figure 2. Elevation view of the footbridge.

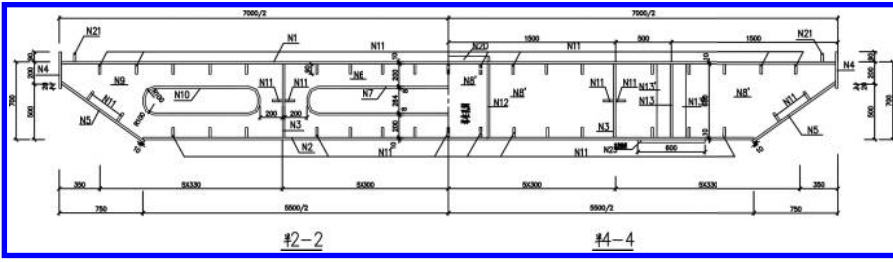

Figure 3. Cross section of the box beam in the main span.

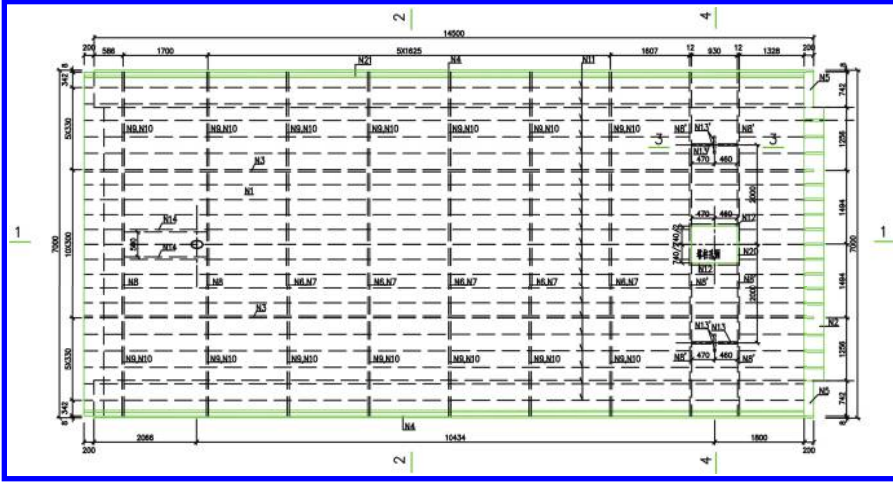

Figure 4. Plane view of the bridge deck in the main span.

dynamic characteristics through the finite element analysis.

The elevation view and plane view of the footbridge are displayed in Figures 1 and 2, respectively. The cross section of the box beam and the plane view of the bridge deck in the main span are displayed in Figures 3 and 4, respectively. It is seen that this is a cable-stayed footbridge with single tower and eight stayed cables. The main span is constructed by using steel box girder while the south part of the footbridges is fabricated using two concrete piers. The main span of the footbridge is 45 m and the total length of the footbridge is 88.25 m. The height of the tower is 24.5 m above from the ground. Displayed in Figure 3 is the cross section of the box beam in the main span, respectively. The width and thickness of the bridge deck are 7.0 m and 0.7 m, respectively.

### 3 FINITE ELEMENT MODEL

As a typical traffic structure, a footbridge can be analyzed based on finite element method by

adopting shell elements, beam elements and cable elements. The element stiffness and mass matrices in the global coordinate system (GCS) are expressed as

$$\bar{\mathbf{K}}_e^{(m)} = \mathbf{T}_a^{(m)T} \mathbf{K}_e^{(m)} \mathbf{T}_a^{(m)} \quad (1)$$

$$\bar{\mathbf{M}}_e^{(m)} = \mathbf{T}_a^{(m)T} \mathbf{M}_e^{(m)} \mathbf{T}_a^{(m)} \quad (2)$$

where  $\mathbf{K}_e^{(m)}$  is the element stiffness matrix in the local coordinate system (LCS);  $\bar{\mathbf{K}}_e^{(m)}$  is the element stiffness matrix in the GCS;  $\mathbf{M}_e^{(m)}$  is the element mass matrix in the LCS;  $\bar{\mathbf{M}}_e^{(m)}$  is the element stiffness matrix in the GCS;  $\mathbf{T}_a^{(m)}$  is the transform matrix.

After determining the element stiffness and mass matrices in the global coordinate system, one can construct the position matrix of elements  $\mathbf{T}_c^{(m)}$  following the FEM connection information of each element under both local and global coordinate systems. Thus, the global stiffness and mass matrices of the footbridge can be formed to establish the three dimensional finite element model

$$\mathbf{K}_T = \sum_{m=1}^{ne} \mathbf{T}_c^{(m)T} \bar{\mathbf{K}}_e^{(m)} \mathbf{T}_c^{(m)} = \sum_{m=1}^{ne} \mathbf{T}^{(m)T} \mathbf{K}_e^{(m)} \mathbf{T}^{(m)} \quad (3)$$

$$\mathbf{M}_T = \sum_{m=1}^{ne} \mathbf{T}_c^{(m)T} \bar{\mathbf{M}}_e^{(m)} \mathbf{T}_c^{(m)} = \sum_{m=1}^{ne} \mathbf{T}^{(m)T} \mathbf{M}_e^{(m)} \mathbf{T}^{(m)} \quad (4)$$

where  $ne$  is the total number of elements of the footbridge model;  $\mathbf{T}^{(m)}$  is the freedom transform matrix from element coordinate system to global coordinate system, which is the product of coordinate transformation matrix  $\mathbf{T}_a^{(m)}$  and position matrix  $\mathbf{T}_c^{(m)}$  of the  $m$ th element

$$\mathbf{T}^{(m)} = \mathbf{T}_a^{(m)} \mathbf{T}_c^{(m)} \quad (5)$$

The stayed cables can be constructed by using steel cable, which can be modelled by using cable elements based on the finite element method. The element stiffness matrix  $\mathbf{K}_{l,e}$  in the LCS is given by

$$\mathbf{K}_{l,e} = \begin{bmatrix} \mathbf{k}_c & -\mathbf{k}_c \\ -\mathbf{k}_c & \mathbf{k}_c \end{bmatrix} \quad (6)$$

In which: the submatrix  $\mathbf{k}_c$  consists of the linear stiffness matrix  $\mathbf{k}_l$  and the nonlinear stiffness matrix  $\mathbf{k}_{nl}$

$$\mathbf{k}_c = \mathbf{k}_l + \mathbf{k}_{nl} \quad (7)$$

The mass matrix of the cable can be expressed by using the lumped mass assumption. To examine the dynamic responses of the footbridge, the finite element model of the cable-stayed footbridge is established with the aiding of commercial package ANSYS as shown in Figure 5.

$$\mathbf{K} = \mathbf{K}_T + \sum_{i=1}^{nl} \mathbf{K}_l^i \quad (8)$$

$$\mathbf{M} = \mathbf{M}_T + \sum_{i=1}^{nl} \mathbf{M}_l^i \quad (9)$$

Figure 5. Finite element model of the cable-stayed footbridge.

where  $\mathbf{K}$  and  $\mathbf{M}$  are the stiffness matrix and mass matrix of the footbridge;  $\mathbf{K}_T$  and  $\mathbf{M}_T$  are the stiffness matrix and mass matrix of the deck and tower;  $\mathbf{K}_l$  and  $\mathbf{M}_l$  are the stiffness matrix and mass matrix of the bridge cables in the GCS.

The mass and stiffness matrices for all the cables can be constructed by summarizing the element matrices of each individual cable. In addition, the mass and stiffness matrices of the transmission tower-line system can be established by combining the contribution of towers, deck and cable.

#### 4 DYNAMIC PROPERTY

The finite element model of the cable-stayed footbridge is established with the aiding of the commercial package ANSYS as shown in Figure 5. The cables of the footbridge are simulated by using the link elements while the steel box girder is simulated by using shell elements. The two concrete piers are modeled by using three dimensional beam elements. The tower is fabricated using steel plate and is also simulated by using shell63 elements. The deck, tower and cable are constructed by using steel and the pier is constructed by using concrete. It is well-known that there exists some sag for the fixed cable subjected to self-weight. The axial stiffness of the cable may be affected by the sag, which can be modified based on Ernst expression:

$$E_{eq} = \frac{E}{1 + \frac{(wl)^2 AE}{12T^2}} \quad (10)$$

In which:  $E$  is the Young's modulus of the material,  $A$  is the cross-section area of the cable,  $T$  is the tension force of the cable,  $w$  is the weight of the cable per meter;  $l$  is the projected length of the cable on horizontal plane.

The basic material parameters are listed in Table 1. The natural frequencies and modal shapes are computed by using subspace iteration algorithm.

The first six natural frequencies and modal shapes are listed in Table 2 and Figures 6 to 11, respectively. It is found that the first natural

first and second order torsional rotation modes of the bridge deck, respectively. The fourth and the sixth mode shapes are the second and third order vertical vibration modes of the bridge deck, respectively. These observations are different to those of the common long span cable-stayed bridge.

## 5 CONCLUSIONS

The natural frequencies and mode shapes of a cable-stayed footbridge is actively investigated in this study. The deck, tower and cable are simulated by using the shell element, beam element and cable element, respectively. The stiffness and mass matrices of the deck and tower are constructed by using the finite element method. The stiffness matrix of the cable is the combination of the linear stiffness matrix and nonlinear stiffness matrix. The mass matrix of the cable is the lumped mass matrix. The axial stiffness of the cable affected by the sag is modified based on the Ernst expression. The made observation indicate that the first mode shape is the lateral vibration of tower. The second mode shape is the vertical vibration of the deck. The third one is the first order torsional rotation of the deck. These observations are different

to those of the common long span cable-stayed bridge.

# Wind-induced dynamic responses of a transmission tower with legs at different height

Y.J. Wu

Zhongshan Power Supply Bureau, Guangdong Power Grid Corporation Co. Ltd., Zhongshan, China

B. Chen, X.X. Song & X.F. Gong

Key Laboratory of Roadway Bridge and Structural Engineering, Wuhan University of Technology, Wuhan, China

**ABSTRACT:** The wind-induced dynamic responses of a transmission tower-line system subjected to strong wind are conducted in this study. A real transmission tower-line system with legs at different height constructed in China is taken as an example to investigate the structural responses subjected to wind loadings. The finite element model of the transmission tower-line system is constructed by using the commercial package. The equation of motion of the transmission tower-line system under wind is established. The wind loading are applied on the tower-line system to study the structural dynamic responses and evaluate the structural performance.

**Keywords:** transmission tower-line system; time history; dynamic responses; wind loading

## 1 INTRODUCTION

To be a typical spatial steel structure, the transmission tower-line system is widely used as electrical power infrastructures throughout the world. The transmission tower is a high-rise structure with small damping and is prone to strong wind loadings [1–3]. It is frequently reported across the world that the excessive vibration of a transmission tower under dynamic excitations may induce the structural damage and even failure [4–6]. Up to now, many wind-induced damages of the transmission tower and lines have been reported and failure of the towers under wind loading has been documented in many literatures. During the past two decades, many theoretical analyses and experiments have been carried out to reveal the performance and responses of transmission tower-line system [7–8]. Therefore, it is necessary to evaluate the performance of transmission tower-line systems subjected to wind loading.

The wind-induced dynamic responses of a transmission tower-line system subjected to strong wind are conducted in this study. A real transmission tower-line system with legs at different height constructed in China is taken as an example to investigate the structural responses subjected to wind loadings. The finite element model of the transmission tower-line system is constructed by using the commercial package. The equation of motion of the transmission tower-line system under wind is

established. The wind loading are applied on the tower-line system to study the structural dynamic responses and evaluate the structural performance.

## 2 ANALYTICAL MODEL OF TRANSMISSION TOWER-LINE SYSTEM

### 2.1 Structural model of transmission tower

The transmission tower and line can be modeled by using the three dimensional spatial beam elements and the cable elements, respectively. The element stiffness matrix  $\mathbf{K}^{(i)}$  and mass matrix  $\mathbf{M}^{(i)}$  of the  $i$ th element in the global coordinate system can be obtained by using the element stiffness matrix  $\mathbf{K}_e^{(i)}$  and mass matrix  $\mathbf{M}_e^{(i)}$  in the local coordinate system through the transforming of the location matrix. The stiffness matrix  $\mathbf{K}_T$  and mass matrix  $\mathbf{M}_T$  of a transmission tower in the global coordinate system can be developed by using the position matrix of element freedom.

$$\mathbf{K}_T = \sum_{i=1}^{nm} \mathbf{T}^{(i)T} \mathbf{K}^{(i)} \mathbf{T}^{(i)} \quad (1)$$

$$\mathbf{M}_T = \sum_{i=1}^{nm} \mathbf{T}^{(i)T} \mathbf{M}^{(i)} \mathbf{T}^{(i)} \quad (2)$$

where  $nm$  is the total element number of the transmission tower;  $\mathbf{T}^{(i)}$  is the freedom transform matrix

from element coordinate system to the global coordinate system.

### 2.2 Model of transmission tower-line system

The transmission tower is a typical spatial structure constructed by using steel members, which can be modelled by using beam and truss elements based on the finite element method. The element stiffness matrix  $\mathbf{K}_{l,e}$  of the transmission line in the local coordinate system can be expressed as

$$\mathbf{K}_l^i = \begin{bmatrix} \mathbf{k}_c & -\mathbf{k}_c \\ -\mathbf{k}_c & \mathbf{k}_c \end{bmatrix} \quad (3)$$

In which: the submatrix  $\mathbf{k}_c$  consists of the linear stiffness matrix  $\mathbf{k}_l$  and the nonlinear stiffness matrix  $\mathbf{k}_{nl}$

$$\mathbf{k}_c = \mathbf{k}_l + \mathbf{k}_{nl} \quad (4)$$

The stiffness matrix and mass matrix of the whole tower-line system in the global coordinate system are given by

$$\mathbf{K} = \mathbf{K}_T + \sum_{i=1}^{nl} \mathbf{K}_l^i \quad (5)$$

Figure 1. Model of the transmission tower.

Figure 2. Model of the transmission tower-line system.

$$\mathbf{M} = \mathbf{M}_T + \sum_{i=1}^{nl} \mathbf{M}_l^i \quad (6)$$

where  $nl$  is the total number of the transmission lines;  $\mathbf{K}$  and  $\mathbf{M}$  are the stiffness matrix and mass matrix of the transmission tower-line system;  $\mathbf{K}_T$  and  $\mathbf{M}_T$  are the stiffness matrix and mass matrix of the transmission tower;  $\mathbf{K}_l$  and  $\mathbf{M}_l$  are the stiffness matrix and mass matrix of the transmission line.

To investigate the dynamic responses of the transmission tower-line system subjected to the monsoon wind, the finite element model of the transmission tower can be constructed by using the commercial package ANSYS as shown in Figures 1 and 2.

## 3 EQUATION OF MOTION UNDER WIND LOADING

### 3.1 Wind loading

The wind excitations of transmission tower-line system are simulated by spectral representation approach. The stochastic wind fields  $f_j^0(t)$ ,  $j = 1, 2, \dots, n$ , can be simulated by the following series

$$f_j(t) = 2\sqrt{\frac{\omega_{up}}{N}} \sum_{m=1}^j \sum_{l=1}^N |H_{jm}(\omega_{ml})| \cos(\omega_{ml}t - \theta_{jm}(\omega_{ml}) + \phi_{ml}) \quad (7)$$

where:  $N$  is sufficiently large number;  $\omega_{up}$  is upper cut-off frequency, with the condition that, when  $\omega > \omega_{up}$ , the value of  $\mathbf{S}^0(\omega)$  is trivial;  $\phi_{ml}$  represents a sequence of independent random phase angles, uniformly distributed over the interval  $[0, 2\pi]$ ;  $\omega_{ml}$  is double-indexing frequency;  $H_{jm}(\omega)$  is a typical element of matrix  $\mathbf{H}(\omega)$ , which is defined with Cholesky decomposition of cross-spectral density matrix  $\mathbf{S}^0(\omega)$ ;  $\theta_{jm}(\omega)$

Figure 3. Time histories of wind velocity.

is complex angle of  $H_{jn}(\omega)$ . Figure 3 displays the simulated time histories of wind velocity.

### 3.2 Equation of motion

The equation of motion of the transmission angle tower-line system subjected to wind loading can be expressed as

$$\mathbf{M}\ddot{\mathbf{x}}(t) + \mathbf{C}\dot{\mathbf{x}}(t) + \mathbf{K}\mathbf{x}(t) = \mathbf{W}(t) \quad (8)$$

where  $\mathbf{M}$ ,  $\mathbf{C}$  and  $\mathbf{K}$  are the mass, damping and stiffness matrices of the tower-line system, respectively;  $\ddot{\mathbf{x}}(t)$ ,  $\dot{\mathbf{x}}(t)$  and  $\mathbf{x}(t)$  are the displacement, velocity and acceleration responses of the transmission tower-line system, respectively;  $\mathbf{W}(t)$  is the dynamic wind loading.

## 4 DYNAMIC RESPONSES UNDER WIND LOADING

To examine the structural wind-induced dynamic responses, a real transmission tower-line system with legs at different height constructed in the coastal areas in the southern China is taken as the example structure. The height and the root distance of the tower are 47.5 m and 7.9 m, respectively. The tower is constructed by using Q235 steel. The in-plane and out-of-plane directions are denoted as X and Y directions, respectively. The dynamic responses of the transmission angle tower subjected to strong wind loading are computed. Two loading cases are considered in the study: (1) wind loading in x direction (in-plane direction); (2) wind loading in x direction (out-of-plane direction).

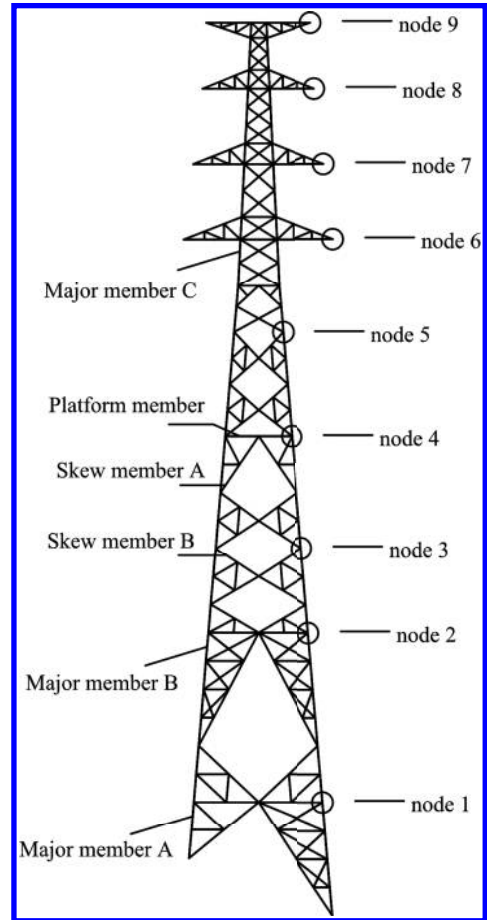

Figure 4. Distribution of crucial nodes and members.

The dynamic responses of the transmission line subjected to strong wind loadings with a speed of 37.94 m/s are investigated. Many crucial nodes and members are selected to examine the structural dynamic responses as shown in Figure 4.

Figures 5 and 6 display the time histories of dynamic responses on top of the tower under different wind direction. The curves in Figures demonstrate that the wind-induced dynamic responses for the out-of-plane vibration are much larger than those of the in-plane vibration. The peak displacements corresponding to the in-plane and out-of-plane vibration are about 0.22 m and 0.58 m, respectively. In addition, the peak velocities corresponding to the in-plane and out-of-plane vibration are about 0.13 m/s and 0.45 m/s, respectively. Similar observations can be made from the peak acceleration responses. It can be seen from Figures 7 and 8 that the time histories of dynamic responses of the lowest cross arm (node 6). It is seen that the responses at the lower part of the tower are much smaller than those on top of the tower. The wind-induced responses in the out-of-plane direction are substantially larger than those of the in-plane vibration, which

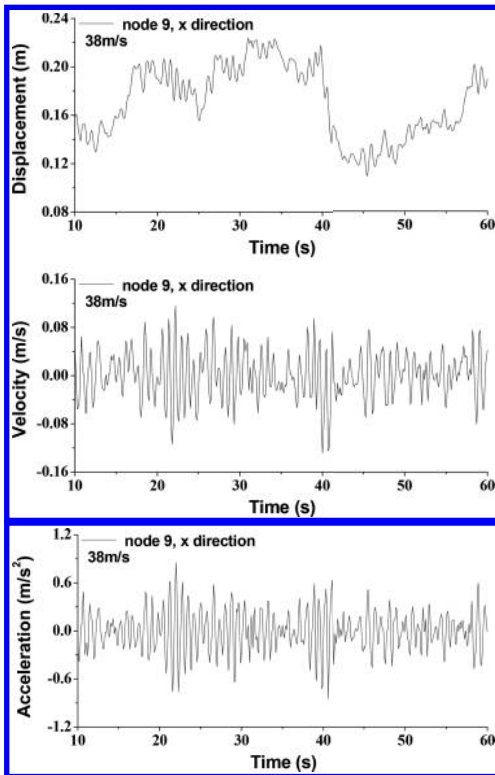

Figure 5. Time histories of dynamic responses on top of the tower (node 9) in x direction.

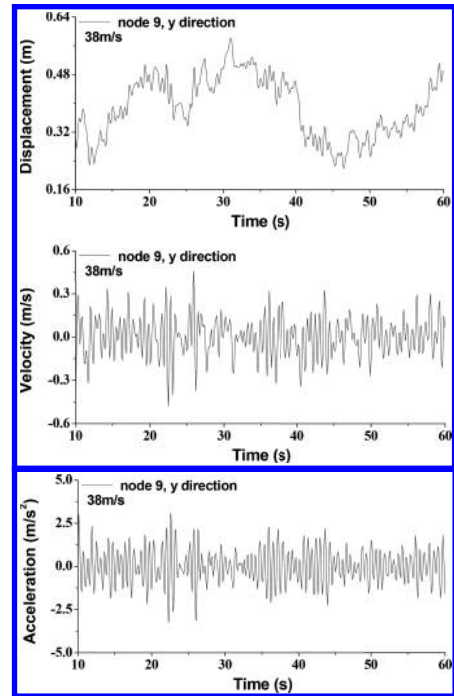

Figure 6. Time histories of dynamic responses on top of the tower (node 9) in y direction.

Figure 7. Time histories of dynamic responses of the node 6 in x direction.

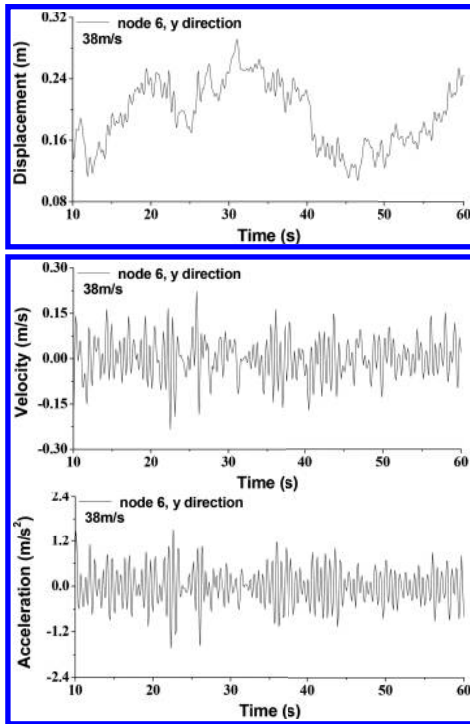

Figure 8. Time histories of dynamic responses of the node 6 in y direction.

Figure 9. Stress distributions of crucial members.

is similar to the observation of the tower top. The possible reason is that the in-plane stiffness of the tower top is larger than the out-of-plane stiffness due to the contribution of the transmission lines in the longitudinal direction. Figure 9 also indicates the stress distributions of crucial members.

## 5 CONCLUSIONS

The dynamic responses of a transmission tower system with legs at different height subjected to strong wind loading are actively examined in this study. The finite element model of the transmission tower-line system is constructed by using the commercial package. The equation of motion of the transmission tower-line system under wind is established. The wind loading are applied on the tower-line system to study the structural dynamic responses and evaluate the structural performance. The made observations indicate that the wind-induced dynamic responses for the out-of-plane vibration are much larger than those of the in-plane vibration.

## The interference effect on aerostatic coefficients of beam in parallel bridge

J. Wang

School of Civil Engineering, Xi'an University of Architecture and Technology, Xi'an, China  
NatHaz Modeling Laboratory, University of Notre Dame, South Bend, IN, USA

J.X. Liu

Wind Tunnel Laboratory, Chang'an University, Xi'an, China

**ABSTRACT:** In order to study the aerodynamic interference effects on aerostatic coefficients of box beam between parallel continuous rigid frame bridges with high pier and long span, sectional model wind tunnel tests of segments of the beam are made by the introduction of factor. The distance between the two beams, height difference and wind attack angles, were changed during the wind tunnel test to study the effects on aerodynamic interferences of aerostatic coefficients of beam. The tests were designed for 12 conditions. The results have shown that the aerodynamic interference effects on aerostatic coefficients of beam in parallel bridges cannot be ignored. The aerodynamic interference effects on parallel bridge beam are shown mainly as follows: The drag coefficient of beam downstream dropped and upstream changed but not changed significantly. There are also the aerodynamic interference effects of lateral force coefficient and torque coefficient between the beams upstream and downstream.

**Keywords:** aerodynamic interference effects; aerostatic coefficients; box beam; parallel bridge

### 1 INTRODUCTION

In recent years, highway network in the western region is extended to loess gully region on a large-scale. When the highway routes pass through the mountains and highland region, the high-pier span continuous rigid frame bridge is often the preferred bridge type. Besides the characteristics of high-pier and large span, the long-span continuous rigid-frame bridge is also arranged with up and down separation arrangement, that is, parallel bridge. For the twin deck continuous rigid frame bridge with high-pier and long-span, the wind load on main beam should obtain aerostatic coefficients by wind tunnel test, in addition, we must also consider the airflow obstruction and interference to study the mutual aerodynamic interference effects of the parallel bridge beams [1–3]. And the aerodynamic interference factor is introduced to define the aerodynamic interference effects of the aerodynamic coefficients of the main beam [4, 5].

### 2 EXPERIMENT RESEARCH

The aerodynamic interference effects on aerostatic coefficients of main beam were investigated by means of section model wind tunnel test in some parallel long-span continuous rigid frame bridge

with high-pier. The wind tunnel test was conducted at Chang'an University wind tunnel laboratory, CA-1 atmospheric boundary layer wind tunnel. Beam model is tested by the vertical end supporting method. Different wind attack angle  $\alpha$  can be obtained by turning the angle turntable. The wind angle range is:  $\alpha = -10^\circ$  to  $+10^\circ$ , the interval is  $1^\circ$ , a total of 21 wind attack changes. Test wind speed  $V = 20$  m/s.

The width of beam model is  $B = 0.314$  m. The average height of beam model is  $H_p = 0.141$  m. The average aspect ratio of beam model is  $\frac{B}{H_p} = 2.227$ . Figure 1 is the section model of the beam model. Figure 2 is the picture of test model of beam. Figure 3 is the diagram of the wind attack angles in the beam

Figure 1. Section model of beam.

Figure 2. Test model of beam.

Figure 3. Wind attack angle in beam force test.

Table 1. Beam test conditions table of aerodynamic coefficient effect on beam.

Test conditions	Test model location	Distance D (m)	Bridge deck height $\Delta H$ (m)	Wind attack angle ( $^{\circ}$ )
1	Beam of single bridge	/	/	-10 to 10
2	Upstream	0.5	0	
3		7	0	
4		7	2.45	
5		14	0	
6	Downstream	42	0	
7		0.5	0	
8		7	0	
9		7	2.45	
10		7	-2.45	
11		14	0	
12		42.35	0	

segments model force test. As the main factors affecting aerostatic coefficients of parallel bridge include the spacing between beams and the wind attack angle, test conditions are shown in Table 1. The test results of aerodynamic influence effects on aerostatic coefficient of beam haven't been listed here due to the space.

### 3 THE TEST RESULTS OF AERODYNAMIC INFLUENCE EFFECTS ON AEROSTATIC COEFFICIENT OF BEAM

#### 3.1 The influence of different distances upstream to beam aerostatic coefficient

Figure 4 shows respectively aerostatic coefficient curve under different distance upstream changing with wind attack angle, but also gives the curve of single bridge beam [6, 7].

It can be seen from Figure 4, aerodynamic interference effect of aerostatic coefficient of beam in parallel bridge under different distance upstream is shown as follows: The aerostatic coefficient decreased slightly or changed little compared with the single bridge. The interference effect is not obvious. The change of upstream aerostatic

coefficient with the distance between the beams in the parallel bridge has no obvious regularity. However, overall, the aerostatic coefficient becomes closer and closer to the single bridge, expecting the curve of the distance  $D = 14$  m to have some jumps, so the aerostatic coefficient is the close to that of single bridge. The attack angle and distance are the important factors that impact aerodynamic interference effect in parallel bridges.

#### 3.2 The influence of different distance downstream to beam aerostatic coefficient

Figure 5 gives respectively the result of aerostatic coefficient curve under different distance downstream changing with wind attack angle, but also gives the curve of single bridge beam.

It can be seen from Figure 5, aerodynamic interference effect of aerostatic coefficient of beam in parallel bridge under different distance downstream is shown as follows: When the beam is located downstream, the drag and toque coefficient decreased generally compared with the single bridge, and they tend to close to the case of the single bridge with the distance increases. It shows

Figure 4. Aerostatic coefficients of beam upstream under different distance changing with wind attack angles.

that the interference effect is weaker and weaker. But even if when the distance  $D = 42.35$  m, the aerodynamic interference effect is still obvious. For the lift coefficient, the regularity of the influence by the distance is not strong. But it is also that the curve of lift coefficient is closest to that of single bridge when the distance is farthest.

Figure 5. Aerostatic coefficients of beam upstream under. Different distance changing with wind attack angle. (a) Drag coefficient. (b) Lift coefficient. (c) Torque coefficient.

### 3.3 The influence of height difference upstream and downstream to beam aerostatic coefficient

Figure 6 shows respectively aerostatic coefficient curve when the upstream distance  $D = 7$  m, under no height difference and a height difference  $\Delta H = 2.05$  m, and when the downstream distance  $D = 7$  m under no height difference and a height difference  $\Delta H = \pm 2.45$  m changing with wind attack angle, but also gives the curve of single bridge beam.

(a) Drag coefficient.

(b) Lift coefficient.

(c) torque coefficient

Figure 6. Influence of height difference upstream and downstream to aerodynamic interference of beam.

It can be seen from Figure 6, the height difference upstream has influence on beam aerodynamic interference, but the influence is very small and almost negligible. The height difference downstream has obvious influence on beam aerodynamic interference. The details are shown as follows: The aerostatic coefficient under the condition of no height difference is very different compared to that under the condition of positive and negative

Figure 7. Drag coefficient aerostatic interference factor under different spacing downstream changing with wind attack angle.

height differences. And the two aerostatic coefficient curves with the change of the wind attack angle under positive and negative height differences still showed a symmetrical relationship. The aerostatic coefficient curve with the change of the wind attack when the difference is positive has the same rule with the curve of no height difference. In a word, to the factor of height difference, its impact on downstream is larger than the impact on upstream.

#### 4 INTERFERENCE FACTOR

The aerodynamic interference effects on the beam in parallel bridges show as the impact on aerostatic coefficient upstream and downstream, so the aerodynamic interference factors are defined respectively for the coefficient upstream and downstream:

$$IF_{SH,SV,SM,XH,XV,XM} = \frac{\text{aerostatic coefficient in parallel bridge}}{\text{aerostatic coefficient in single bridge}} \quad (1)$$

where, SH, SV, and SM are the drag, lift, and torque coefficient factor of the beam upstream, respectively. XH, XV, and XM are the drag, lift, and torque coefficient factor of the beam downstream, respectively.

Figure 7 gives the aerodynamic interference factors curve of drag coefficient downstream changing with different spacing and wind attack angle, respectively.

#### 5 CONCLUSIONS

The aerodynamic interference effects on aerostatic coefficients of beam in the parallel continuous

rigid frame bridges were studied by wind tunnel test. The following conclusions are obtained.

The aerodynamic interference effect of aerostatic coefficient of beam in parallel bridge under different distance upstream and downstream is shown as follows: The aerodynamic coefficient upstream and downstream has both been changed compared with the single bridge. And the coefficient downstream changes significantly, showing complex shielding and wake interference effect. The distance between the parallel bridge and the wind attack angle are two main factors that influence the aerostatic coefficients of the beams. However, they have little impact on the upstream, and significantly, affect the downstream.

# Study on the effect of batch piling of coal on silo wall

T.J. Tao, M.S. Zhao & Q. Kang

Guizhou Xinlian Blasting Engineering Group Co. Ltd., Guiyang, Guizhou, China

**ABSTRACT:** Displacement and stress of silo wall influenced by batch piling are studied based on the finite model of the reinforced concrete shallow coal bunker. The results show that asymmetric loading produces larger deformation of the wall compared with symmetric loading. This is because in symmetric loading, the maximum displacement occurs at the top of the wall, the free end, and the maximum stress occurs at the foot of the wall, consistent with a cantilevered arrangement. These distribution patterns are relatively consistent with the mechanical property of the wall. The stress curve exhibits a sharp negative gradient as the stress decreases and then steadily increases to a crest at 10 m, after which it decreases through to the top of the wall.

**Keywords:** numerical analysis; reinforced concrete shallow coal bunker; displacement; stress

## 1 INTRODUCTION

The need to provide space for the diverse and ever increasing needs of mankind has been at the forefront of innovations by designers and engineers alike. These innovations are aimed at satisfying different requirements; of interest to this paper is the requirement of a larger unobstructed space for various usages such as sports arena, conference venue, theaters and general-purpose halls.

In China, reinforced concrete bunkers are in common use in the coal storage systems and are designed in accordance to the Code for Design of Reinforced Concrete Silo, GB 50077-2003. The bunker walls are routinely exposed to both normal pressure and vertical frictional shear or traction produced by the material being stored. Additional loads could include seismic and wind loads, stresses created by temperature differences, potential expansion of the stored material, and differential settlement of the foundation. Failure of a bunker typically results in its total collapse owing to the lack of redundancy in the load path. Adgen et al noted that silo failure is often brittle and sudden, which means no much warning is seen before the collapse.

A research done by Sun Weiwei et al. deduced that differential temperature changes exert a significant influence on the design of reinforcement in silos. The code of design specifies that for silos of diameter >40 m, the atmospheric temperature's influence should be taken as 6–8% of the horizontal circular stress due to the stored material. Most studies, however, focus on the effects of heat transfer through the silo wall, i.e. heat conductivity.

This paper explores the effect of batch piling on the displacements and the stresses of the silo wall.

## 2 FINITE MODEL OF THE SILO WALL

### 2.1 Finite model

A finite element model is built to simulate the pressure exerted by the coal pile on the wall, considering loading different quadrants at a time. The case study for this paper is a reinforced concrete silo being utilized for coal storage. The first phase of the project involved the construction of two super-critical coal-fired thermoelectric generation units,

Figure 1. FE model for calculating the effect of batch loading.

and set aside an expansion site for two more coal fired power unit. It is cylindrical with an internal diameter of 55 m and height of 18 m. The wall thickness is tapered from 1.37 m at the bottom to 0.8 m at the top. The silos roof structure is a double-layered latticed shell structure with a net height of 42.3 m.

### 2.2 Load combination and loading pattern

Basically, to simulate batch loading, it is assumed that the storage space is divided into four quadrants and each loading combination is analyzed.

## 3 DISPLACEMENT ANALYSIS

The plot of the displacement vector is shown in the below figures.

As shown in Figure 2, the displacement values change minimally for load cases 1 to 3; however, there is a significant change for load case 4.

Table 1. Load combination and loading patterns.

Load case	Load combination	Load pattern
1	1.2 (load from the roof structure) + 1.3 (load due to coal pressure)	
2	1.2 (load from the roof structure) + 1.3 (load due to coal pressure)	
3	1.2 (load from the roof structure) + 1.3 (load due to coal pressure)	
4	1.2 (load from the roof structure) + 1.3 (load due to coal pressure)	

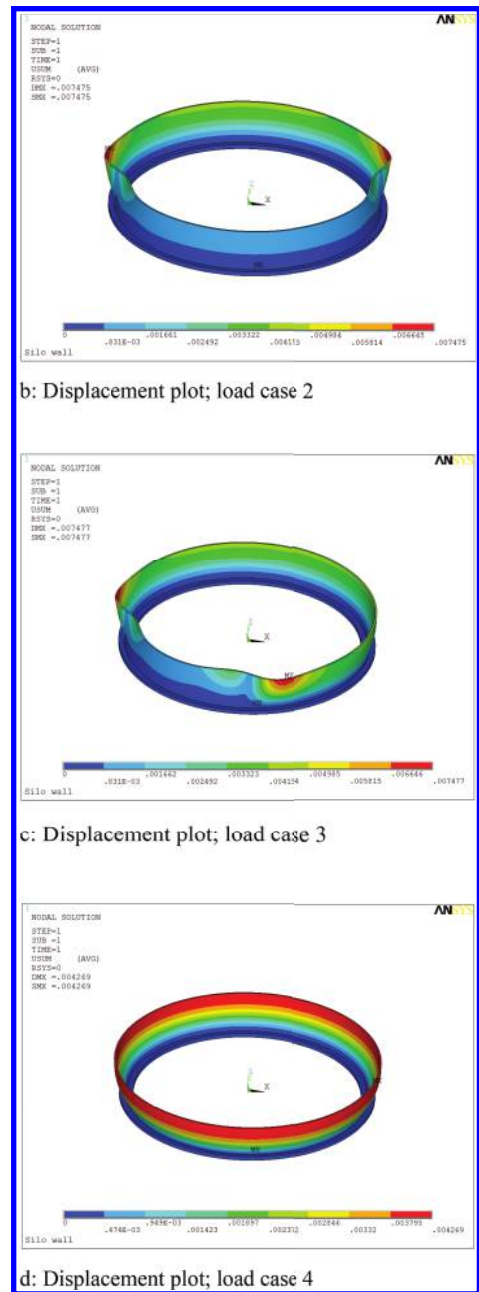

Figure 2. Displacement plot for the four load cases.

This could be attributed to the fact that load cases 1, 2 and 3 are all asymmetric load case, and load case 4 presents a symmetrical loading on the silo wall. As shown in Figure 3, the coal produces a maximum displacement of 0.005 m. The maximum displacement occurs at the top of the wall, the free end.

Figure 2. (Continued).

## 4 STRESS ANALYSIS

The stress values for the four load cases are given in Table 2. The plot of the displacement vector is shown in the below figures.

As shown in Figure 4 and Figure 5, the coal produces a maximum stress of 6.02 N/mm<sup>2</sup>. The maximum stress occurs at the foot of the wall, consistent with a cantilevered arrangement. These distribution

Figure 3. Displacement along the wall height.

Table 2. The stress values for the four load cases.

Load case	Radial stress	Axial stress	1st principal stress	3rd principal stress
1	2.76	-7.71	2.81	-7.78
2	2.76	-7.70	2.81	-7.78
3	2.76	-7.71	2.81	-7.78
4	2.17	-6.39	2.17	-6.43

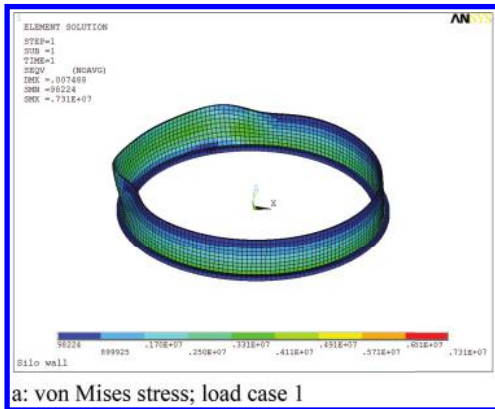

Figure 4. (Continued).

Figure 4. von Mises stress plot for the four load cases.

patterns are relatively consistent with the mechanical property of the wall. On the other hand, the stress curve exhibits a sharp negative gradient as the stress decreases in the range of 0–6 meters. Then, it steadily increases to a crest at 10 m, after which it decreases through to the top of the wall.

Figure 5. Stress distribution along the wall height.

## 5 CONCLUSIONS

From the analysis results, the following can be deduced:

1. The displacement values change minimally for load cases 1 to 3; however, there is a significant can for load case 4. This could be attributed to the fact that load cases 1, 2 and 3 are all asymmetric load case, and load case 4 presents a symmetrical loading on the silo wall.
2. Asymmetric loading produces larger deformation of the wall compared with symmetric loading. This is because in symmetric loading, the coal produces a maximum displacement of 0.005 m. The maximum displacement occurs at the top of the wall, the free end.
3. The maximum stress occurs at the foot of the wall, consistent with a cantilevered arrangement. These distribution patterns are relatively consistent with the mechanical property of

the wall. The stress curve exhibits a sharp negative gradient as the stress decreases in the range of 0–6 meters. Then, it steadily increases to a crest at 10 m, after which it decreases through to the top of the wall.

# An algorithm for random cave geometry generation in Karst landform

Xue-jiao Cui

*Guizhou Xinlian Blasting Engineering Group Co. Ltd., Guiyang, Guizhou, China*

Chong Shi

*Institute of Geotechnical Engineering, Hohai University, Nanjing, Jiangsu, China*

**ABSTRACT:** A new algorithm, which can randomly generate Karst cave geometry, was developed in this work. Each Karst cave geometry was regarded as a polyhedron. All the suppositional polyhedra, which represent the Karst caves, are cast into the research domain according to the random distribution rule of the Karst caves. Then, the solid polyhedra are transformed into void to model the Karst caves. Thus, the resultant domain is the rock mass that contains Karst caves. Two supernumerary algorithms, the merging neighboring points algorithm and the threshold value interception algorithm, were also employed to obtain caves with random shape and distribution according to the real caves' shapes, area ratios, radius ranges, distributions and smoothness. The method proposed in this work provides a way to numerically simulate Karst caves.

**Keywords:** Karst cave; merging neighboring points algorithm; threshold value interception algorithm; geometrical model

## 1 INTRODUCTION

Karst caves are usually with no fillings or weakly filled. Since the huge difference in mechanical property between the cave surface and the rock mass, there would be a great change during the propagation of the blasting seismic wave. Therefore, a reasonable caves distribution model is the essential base of evaluating the influence of Karst geological conditions on blasting effect. Many scholars home and abroad have generated huge researches on the random cave models and their numerical calculation methods. Yong Ye and Lianguo Dong used High Order Difference Method to numerically simulate a series of caves with different sizes, shapes and fillings, and analyzed the caves' features of change, seismic reflection, etc., on kinematics and dynamics. Huiyan Yang, etc. put forward the modeling principles for the fracture-cave reservoir and primarily studied the 3D geologic modeling method of the fracture-cave carbonate reservoir. Xiangyang Hu, etc. put forward the modeling method of the multi scale Karst facies-controlling fractured-cavity reservoirs. Based on the deterministic modeling, the discrete large cave model and the discrete large fracture model were built. Based on the 3D regular network model, Chenchen Wang, etc. built the networks for Karst caves, big fractures and small fractures with different physical dimensions. Then he put forward a coupling algorithm. Based on the

Karst cave network, the multi-scale network model of carbonate was built by appropriately adding big and small fractures. Xian Xi, etc. put forward two methods for modeling random Karst caves, the merging neighboring points algorithm and the threshold value interception algorithm, and built different models by using different methods. All of these studies did not give a definite description of cast position and intersect estimation during the casting, and just using single method, the merging neighboring points algorithm or the threshold value interception algorithm, has its limit. For example, the merging neighboring points algorithm is not suitable for the case that there are multiple caves with different sizes in each cave distribution area.

In this paper, the local cave radius  $R$  is used to describe the cave's discrete degree on large scale, and the area ratio  $S$  is used to describe local space density in every cave distribution area. By choosing  $R$  and  $S$ , and taking the intersect estimation between polyhedron blocks as the core, different cave models could be built easily and the real complicated caves could be quickly and accurately described.

## 2 KARST CAVE GENERATION

### 2.1 Polygonal cave

There are mainly two ways to generate the polygonal cave in previous researches. One is the method

of using the sequences of random angel increment  $\{1 \dots \theta_i \dots \theta_n\}$  and random side length  $\{1 \dots r_i \dots r_n\}$  in the polar coordinate frame to generate blocks, which was put forward in studying random concrete blocks modeling, the other is to generate rigorous convex polygons by prolongating triangles under a certain principle. The blocks generated by the first method are smoother and their shapes are easier to control by parameters, while long sides and sharp angels are easier to appear by the second method, and there are few parameters for controlling the blocks' shape. Hereby the first method is improved according to the accumulation body's characteristics and applied.

There are two schemes to generate polygons and the generation results are shown in Figure 1(a) and (b). Apparently, blocks generated by the first scheme is smoother and have less concave edges than those by the second. Users can choose different ways to generate blocks based on different circumstances. The introduction of the two schemes is as follow.

Scheme 1. When generating an n-sided polygon, firstly of all generate a sequence of random radiuses  $\{1 \dots r_i \dots r_n\}$ . The range is from  $r_0 - \Delta r$  to  $r_0 + \Delta r$ . So

$$r_i = r_0 + (2 \cdot \xi - 1) \cdot \Delta r \quad (1)$$

in which  $\xi$  is the pseudo-random number within the interval (0, 1) (all the following  $\xi$  are the same),  $r_0$  is the average value of the random radius  $r_i$ , and  $\Delta r$  is the radius amplitude. Then generate a sequence of random angle increments  $\{1 \dots \Delta\theta_i \dots \Delta\theta_n\}$ . The range of  $\Delta\theta_i$  is from  $2\pi/n - \eta \cdot 2\pi/n$  to  $2\pi/n + \eta \cdot 2\pi/n$ . So

$$\Delta\theta_i = \frac{2\pi}{n} + (2 \cdot \xi - 1) \cdot \eta \cdot \frac{2\pi}{n} \quad (2)$$

in which  $\eta$  is a coefficient between 0 and 1. Apparently, the smaller  $\eta$  is, the bigger the amplification of the angle increment is and the more equal the random angel generated is.

Figure 1. The generated configurations of the two schemes under dissolution ratio 35%.

To make sure the sum of all  $\Delta\theta_i$  is  $360^\circ$ ,  $\Delta\theta_i$  should be processed by the following equation firstly, and then used in the sequence.

$$\Delta\bar{\theta}_i = \Delta\theta_i \cdot \frac{2\pi}{\sum \Delta\theta_i} \quad (3)$$

Generate blocks with Sequence  $\{1 \dots r_i \dots r_n\}$  and Sequence  $\{1 \dots \Delta\theta_i \dots \Delta\theta_n\}$  in the polar coordinate (see Fig. 2). The size of the blocks should be the same, that is  $r_0$  is the same, waiting for the scaling.

Scheme 2. Similar to the way of generating radius sequence in Scheme 1, firstly generate a sequence of random radiuses  $\{1 \dots r_i \dots r_n\}$  according to Formula 1, whose range is from  $r_0 - \Delta r$  to  $r_0 + \Delta r$ .

Then generate a sequence of random angles  $\{1 \dots \theta_i \dots \theta_n\}$ , in which  $\theta_i$  is from 0 to  $2\pi$ .

$$\theta_i = \xi \cdot 2\pi \quad (4)$$

Since  $\theta_i$  is interspersed and the sequence of angles need to be in the ascending order,  $\{1 \dots \theta_i \dots \theta_n\}$  is precessed to make it in an ascending order.

Generate blocks with Sequence  $\{1 \dots r_i \dots r_n\}$  and Sequence  $\{1 \dots \theta_i \dots \theta_n\}$  in the polar coordinate. The size of blocks should be the same.

For Scheme 1 and 2, if strict convex polygons should be generated, concave vertexes could be deleted. Traverse each vertex and make sure each vertex lies on the right side of the counterclockwise vector of its surrounding two vertexes. If not, delete the vertex. What needs to emphasize is that deleting vertexes once cannot make sure the generation of convex polygons. After each deleting, polygons need to be checked until all concave vertexes are deleted.

Figure 2. The configuration of the generated polygonal block.

## 2.2 Smooth blocks

Since angles among adjacent points of smooth blocks are the same, the formula of n-sided ( $n > 15$ ) smooth blocks' angle sequence  $\{1 \dots \theta_i \dots \theta_n\}$  is

$$\theta_i = i \cdot \frac{2\pi}{n}. \quad (5)$$

For smooth blocks' radius sequence  $\{1 \dots r_i \dots r_n\}$ , the random number generating method for polygon caves will lead to bumpy surface and disorder. Therefore the radius sequence should be processed by series smoothing, and then generated in polar coordinates. The series processing formula of the radius sequence is

$$r_i = r(\theta_i) = r_0 + \sum_{j=1}^m \alpha_j \cos(j\theta_i + \beta_j) \quad (6)$$

in which  $r_0$  is average radius,  $m$  is number of radius generated in the sequence,  $\beta_j$  is a random number within the interval  $[0, 2\pi]$ , and  $\alpha_j$ 's expression is

$$\log\left(\frac{\alpha_j}{r_0}\right) = -p \cdot \log(j) - b \quad (7)$$

## 3 MEASUREMENT OF THE SIZES OF CAVE BLOCKS

### 3.1 Measurement of cave blocks' width and inclination

The block's width is the length of the shortest line through a block, or it could be considered as the particle size. Take an n-sided polygon for example. The measuring method is as follow: (1) Taking the i-th side as the base, transverse the vertical lines of all the  $n - 2$  vertexes to the side and find the longest vertical line  $l_{\max}(i)$ ; (2) Transverse all the n sides and find the shortest one among all the n sides' longest vertical lines  $\min(l_{\max}(i))$  ( $i = 1 \dots n$ ), like DF in Figure 3. The width of the block Width is  $|DF|$ , and the inclination of the counterclockwise vector  $\overline{AB}$  is the block's inclination  $\alpha$ .

### 3.2 Measurement of cave blocks' length

A cave block's length can be understood as the block's stretch distance along its inclination's direction. Take the block in Figure 3 for example. The calculating method is as follow: (1) Calculate the unit vector  $\vec{e}$  of the vector  $\overline{AB}$ ; (2) The projection distance of the vector  $\overline{AC}$  in the direction of the vector  $\overline{AB}$  is

$$proj(i) = \overline{AC} \cdot \vec{e} \quad (8)$$

Figure 3. Measurement of the cave block's size.

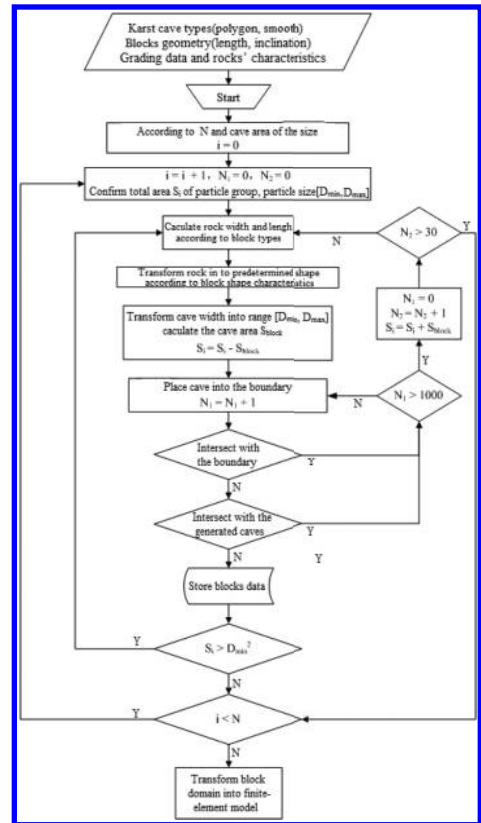

Figure 4. Flowchart for random generation of D-RBM caves.

in which  $proj(i)$  along direction of  $\overline{AB}$  is positive, and that along the opposite direction is negative.

(3) Transverse all the  $n - 2$  vertexes, and find  $\min(proj(i))$  and  $\max(proj(i))$  ( $i = 1 \dots n - 2$ ). The block's length is

$$Length = |\max(proj(i)) - \min(proj(i))|$$

$$(i - 1 \dots n - 2) \quad (9)$$

Based on the principle above, the D-RBM system was composed. Its modeling progress includes 5 parts: (1) generating blocks, (2) scaling and deforming blocks based on the grading data and rocks' characteristics, (3) putting blocks into the area within the boundary and making sure there is no overlapping among blocks, (4) calculating the entity model based on generated data of blocks' profile, (5) deleting generated blocks and the rest is rock with Karst caves. The program flow chart is as shown in Figure 4.

## 4 PLACING OF CAVE BLOCKS

### 4.1 Block placing progress

The block placing progress includes block generation, trail placing, intersection estimation, place adjustment and final defined placing. Details are as follow: (1) Before the placing, choose a random grain size  $D$  from the grain size interval  $[D_p, D_{i+1}]$  of the block's graduation as the block's grain size and scale it to the grain size. If the block has a dip angle, rotate the rock to the certain angle based on its dip angle; (2) Place the block into the boundary and estimate whether it intersects with the boundaries; (3) If not, then estimate whether it intersects with other fixed blocks; (4) If not, the place of the block is defined. If there is intersection in Step 2 or 3, adjust its position and repeat Step 2 and 3 until its place is finally determined.

### 4.2 Intersection estimation between blocks

The study of intersection estimation between blocks is mature in the computational geometry. The computing and estimation of simple polygons cost quite a lot of time and resources of the system, while the estimation of convex polygons is much simpler. Since the number of model blocks generated by the system is huge and the estimation times would grow with the number of fixed blocks, the convexification of all polygons before the estimation is essential.

The intersection estimation of polygons is based on positions of the vertex and the line, and those of lines. It has been solved in the Geometry of Vector.

(1) Estimation of the vertex lying on the right of the line. Suppose there are Vector  $\overline{AB}$  and Vertex  $C$ , their coordinates are  $(x_A, y_A)$ ,  $(x_B, y_B)$ , and  $(x_C, y_C)$ . Make Vector  $\overline{AC}$ , and then  $\overline{AB} = (x_B - x_A, y_B - y_A)$ ,  $\overline{AC} = (x_C - x_A, y_C - y_A)$ . Calculate  $\overline{AB} \times \overline{AC}$ :

$$\overline{AB} \times \overline{AC} = \begin{vmatrix} x_B - x_A & y_B - y_A \\ x_C - x_A & y_C - y_A \end{vmatrix} \quad (10)$$

If  $\overline{AB} \times \overline{AC} > 0$ , then  $C$  is on left of  $\overline{AB}$ . If  $\overline{AB} \times \overline{AC} < 0$ , then  $C$  is on right of  $\overline{AB}$ . Or  $C$  is on  $\overline{AB}$ .

(2) Intersection estimation of two line segments. Put simply, the intersection estimation of two line segments is to estimate whether the two points of one line segment are on the same side of those of the other. Suppose there are  $\overline{AB}$  and  $\overline{CD}$ , in order to estimate whether Point  $C$  and  $D$  are on the different sides of Point  $A$  and  $B$ , make  $\overline{AC}$  and  $\overline{AD}$  (see Fig. 5). According to (1), that Point  $C$  and  $D$  are on the different sides of Point  $A$  and  $B$  means:

$$(\overline{AB} \times \overline{AC}) \cdot (\overline{AB} \times \overline{AD}) < 0 \quad (11)$$

Similarly, that Point  $A$  and  $B$  are on the different sides of Point  $C$  and  $D$  means:

$$(\overline{CD} \times \overline{CA}) \cdot (\overline{CD} \times \overline{CB}) < 0 \quad (12)$$

Apparently, when the above two conditions are established, Line Segment  $AB$  and  $CD$  intersect.

(3) Intersection estimation of two polygons. There are two ways to estimate whether two polygons intersect or not: estimating whether any vertex of one polygon is in the other one and estimating whether there are intersecting lines. When estimating whether Block 1 and 2 (Fig. 6) intersect, transverse all vertexes of Block 1. If there is any vertex in Block 2 (any vertex of Block 1 is on the left of all counterclockwise vectors of Block 2), the two blocks intersect.

It is noteworthy that: when all vertexes of Block 1 are outside of Block 2. There are cases of inclusion and penetration, like Fig. 7 and 8. Conduct

Figure 5. Lines intersection.

Figure 6. Blocks intersection.

Figure 7. Inclusion of two blocks.

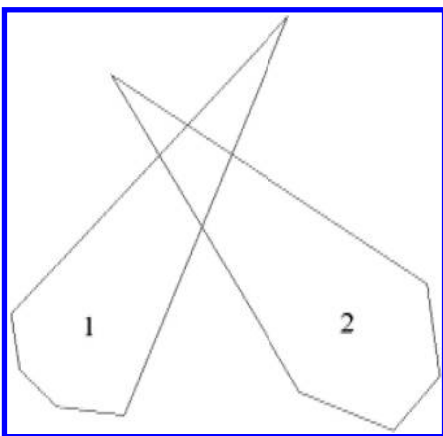

Figure 8. Penetration of two blocks.

the same estimation progress of Block 1 to Block 2. For the case of penetration, the two blocks can be testified non-intersected only when all the sides of Block 1 and 2 are testified non-intersected.

### 5 3D RANDOM CAVE MODEL GENERATED

1. Cave model generated in rectangle area (polygon unit) (Fig. 9 and 10).
2. Cave model generated in rectangle area (circle unit) (Fig. 11 and 12).
3. Cave model generated in circle area (polygon unit) (Fig. 13 and 14).
4. Cave model generated in circle area (circle unit) (Fig. 15 and 16).

Figure 9. Distribution of Karst cave.

Figure 10. Generated 3D profile.

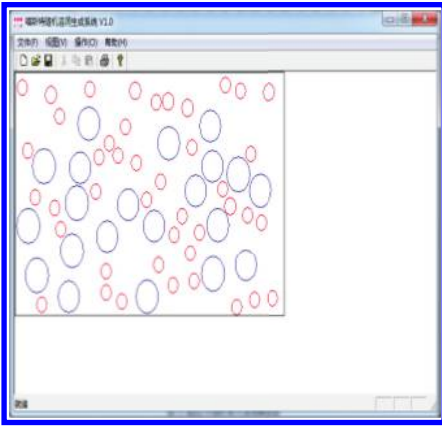

Figure 11. Distribution of Karst cave.

Figure 14. Distribution map of cave model in ansys.

Figure 12. Karst cave model diagram in ansys.

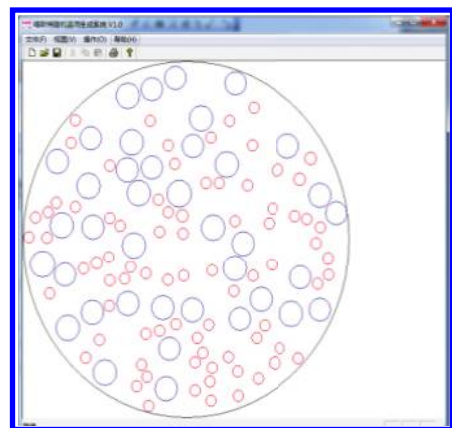

Figure 15. Distribution of Karst cave.

Figure 13. Distribution of Karst cave.

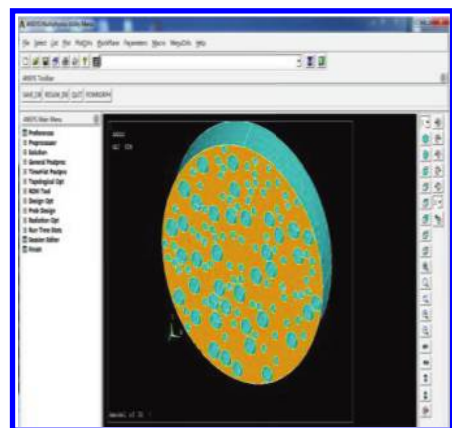

Figure 16. Distribution of cave in ansys.

Figure 17. Profile of 3D model (Front side).

Figure 18. Profile of 3D model (After the side).

## 6 CONCLUSION

1. The Karst cave is a un-uniform discontinuum body, the rock mass of which is complicated and disordered. The non uniformity of its microscope rock mass greatly defines its mechanical property and failure mechanism. So its 3D form is very complicated and un-uniform. If it is simplified as a 2D form, it would be convenient to study the un-uniform cave.
2. By using the local cave radius  $R$  to describe the cave's discrete degree on the large scale, the area ratio  $S$  to describe the local space density in every cave distribution area, and by choosing  $R$  and  $S$ , different cave models could be built easily and the real complicated caves could be quickly and accurately described.

Based on the above, by using the merging neighboring points algorithm and the threshold value

interception algorithm while controlling the element shape, the area ratio, the radius range, the uniformity, the smoothness and the generation area, the generating method of the Karst cave random geometry model was proposed. The generated cave models meet the reality and the randomness of their distribution could be achieved. What's more, the software developed in this study can connect directly with ANSYS and import the generated cave models and their characteristics together into ANSYS. Its convenience of generating cave models provides a good platform for numerical analysis of the Karst cave.

## Research on the wind-induced vibration response of adhesive integral-lift scaffold

Weimin Pan, Ningning Kong, Xin Ye & Guohua Li

*School of Mechatronics Engineering, Henan University of Science and Technology, Luoyang, China*

**ABSTRACT:** The adhesive integral-lift scaffold is a kind of new scaffold with economic, safe and convenient that can be applied to the high-rise building construction, especially super high-rise building construction. In this paper, three different kinds of finite element models of the adhesive integral-lift scaffold were established and their dynamic characteristics were analyzed, which were compared to select the scaffold model of conforming to the actual natural frequency of vibration as a calculation model and give the method of the wind vibration coefficient that conforms to the wind vibration response of the studied scaffold. The theoretical results by calculating of the wind vibration coefficient that affects wind load were compared with the results by selecting of actual engineering, which provides the basis to study and optimize the calculation method of wind load on scaffold.

**Keywords:** adhesive integral-lift scaffold; finite element models; wind vibration response; natural frequency

### 1 INTRODUCTION

The adhesive integral-lift scaffold is a new scaffold developed rapidly at the beginning of this century, which has the important influence to the progress of construction technology. It can satisfy the needs of construction technology and safety protection when workers operate on the outside of buildings in the structure, installation and decoration of construction. It has the characteristics of economical, security and convenient because it makes a high and suspended operation to a lower operation and operation in a frame. The adhesive integral-lift scaffold, as shown in Figure 1, refers to the scaffold with roll-over protector and anti-dropping device, which is attached to the

Figure 1. The adhesive integral-lift scaffold during the structure construction.

engineering structure of a certain height. It can climb or decline step by step with the engineering structure by its own lifting equipment and device. It mainly includes the frame structure of scaffold, adhesive bearing, roll-over protector, anti-dropping device, elevator mechanism and control device.

With the increase of structure height, the economy of the adhesive integral-lift scaffold is more obvious. Especially when the height of the building is more than 80 meter, the applicability and economy of the adhesive integral-lift scaffold is particularly prominent. So, it is suitable for high-rise building construction, especially super high-rise building construction. Then, the wind load on scaffold has become the dominant design load, which plays a decisive role in the safety of using the scaffold. If the problem of wind load is solved, the design can be without limiting by height. Therefore, the calculation method of the wind load on scaffold is a primary and urgent task. The wind is formed by air flow from the place where the big pressure to the small pressure. The airflow is formed to the high pressure air curtain by the block of the structure. So, wind load is produced on the structure of different sizes. Wind load is a kind of random dynamic load. In order to analysis conveniently, it can be divided into average wind and fluctuating wind. Fluctuating wind load is the dynamic component of wind, which makes the structure of the random vibration. The correction coefficient that is affected on the fluctuating wind of the wind

effect is called the wind vibration coefficient. Now, the calculation method of Wind load on scaffold most based on *load code for the design of building structures* (GB50009-2001), which provisions the wind load standard values of perpendicular to the surface of buildings. It can be calculated by using Equation (1) as follows:

$$W_k = \beta_z \mu_s \mu_z W_0 \quad (1)$$

where  $W_k$  = wind load;  $\beta_z$  = wind-induced vibration coefficient;  $\mu_s$  = shape coefficient of wind load;  $\mu_z$  = wind pressure height coefficient; and  $W_0$  = fundamental wind pressure. This paper mainly studies on the wind-induced vibration coefficient of the adhesive integral-lift scaffold.

## 2 ESTABLISHMENT OF THE FINITE ELEMENT MODEL

To study the wind load on the adhesive integral-lift scaffold, the first step is the establishment of the finite element model based on a three-dimensional model. The erection height of the scaffold frame in this paper is set as 14.72 m, which includes 7 steps, with each measuring 1.84 m, and the protective structure that is also 1.84 m. The width of the frame is 0.68 m. In addition, the model also has the main frame support at the bottom and reinforced truss rods. According to the three-dimensional model, as shown in Figure 2, three finite element models, namely one truss, two trusses and three trusses, respectively, are established by using ABAQUS, as shown in Figures 3–5. The beam element analysis unit is mainly used for analysis, appoint direction is the default direction of the beam, beam section is consistent with the actual component section, and its each joint is bolt rigid connection. Structural material properties are elasticity modulus  $E = 2.1 \times 10^5 \text{ N/mm}^2$ , Poisson's ratio  $\mu = 0.3$ , and density  $\rho = 7850 \text{ kg/m}^3$ .

Figure 2. The three-dimensional model of the adhesive integral-lift scaffold.

Figure 3. The finite element model of one truss.

## 3 DYNAMIC CHARACTERISTIC ANALYSIS OF THE ADHESIVE INTEGRAL-LIFT SCAFFOLD

The adhesive integral-lift scaffold is strongly influenced by wind load on the study. The effect on the structure of average wind is equivalent static wind, and the effect on the structure of fluctuating wind will cause structural vibration. In order to ensure that the adhesive integral-lift scaffold can work safely and reliably in high-rise, especially super high-rise, building construction, the dynamic characteristic analysis of the wind load on scaffold is very important. In addition, the analysis and cognition dynamic characteristic of structure is the basis of the wind-resistant design and stability analysis of the structure. Considering the computational efficiency and accuracy of the results, by using ABAQUS finite element software to extract the characteristic value of the first five-order natural

Figure 4. The finite element model of two trusses.

vibration frequency when the scaffold finite element models are one truss, two trusses and three trusses, respectively, as shown in Table 1, and the vibration mode of scaffold is shown in Figures 6–8.

In theory, with the trusses increases of the finite element model, the calculation of dynamic characteristics is more close to the actual situation. However, this will increase the calculation workload. And the frequency of previous order plays a major role in the wind-induced vibration response, as can be seen in Table 1. The calculation results of the first-order vibration frequency when the finite element models are one truss, two trusses, and three trusses that are similar, and their differences were 6.0% and 2.4%. So in order to simplify the calculation, this paper takes the finite element model of one truss as a calculation model. It also takes the first-order vibration frequency  $\omega_1 = 1.0999$  as the representative of the dynamic characteristics of the whole scaffold. Analysis of dynamic characteristics of the scaffold can be used in the following calculation of wind vibration coefficient.

Figure 5. The finite element model of three trusses.

Table 1. The first-five order natural vibration frequency of the scaffold.

	One truss	Two trusses	Three trusses
First order	1.0999	1.0372	1.0132
Second order	1.4539	1.2223	1.1350
Third order	3.2529	3.0945	2.7272
Fourth order	4.3567	3.5287	3.0416
Fifth order	5.3426	3.8659	3.2917

#### 4 CALCULATION AND RESULTS OF THE WIND-INDUCED VIBRATION COEFFICIENT

After organizing references, this paper gives the wind vibration coefficient expressions when the scaffold is at the climbing stage or declining stage. The wind vibration coefficient expression of climbing stage is as follows:

$$\beta_z = 1 + \frac{\sqrt{\eta^2 \cdot \xi_1 \lambda_1 + 2\varphi\eta \cdot \xi_2 \lambda_2 + \varphi^2 \cdot \xi_3 \lambda_3}}{\mu_{z_n}} \quad (2)$$

Figure 6. The vibration mode of one truss.

Figure 7. The vibration mode of two trusses.

where  $\xi_1, \xi_2, \xi_3$  = pulse power coefficient under the common action of building structure and scaffold, and the expression is given as follows:

$$\xi_1 = \int_{-\infty}^{+\infty} \omega_s^6 (\omega_s^2 + 4\zeta_s^2 \omega^2) \frac{r}{|D|^2} S_f(\omega) d\omega \quad (3)$$

$$\xi_2 = \int_{-\infty}^{+\infty} \omega_s^5 (\omega_1^2 \omega_s - \omega_s \omega^2 + 4\zeta_1^2 \omega_1 \omega^2) \frac{r}{|D|^2} S_f(\omega) d\omega \quad (4)$$

$$\xi_3 = \int_{-\infty}^{+\infty} \omega_s^2 [(\omega_1^2 - \omega^2)^2 + 4\zeta_1^2 \omega_1^2 \omega^2] \frac{1}{|D|^2} S_f(\omega) d\omega \quad (5)$$

where  $\lambda_1, \lambda_2, \lambda_3$  = pulse influence coefficient when considering pressure fluctuation and spatial correlation, and the expression is as follows:

$$\lambda_1 = \sum_{i=1}^n \sum_{j=1}^n \phi_{i1} \phi_{j1} \rho_{ij} \mu_{fi} \mu_{zi} \mu_{fj} \mu_{zj} \quad (6)$$

$$\lambda_2 = \sum_{i=1}^n \phi_{i1} \rho_{ni} \mu_{fi} \mu_{zi} \mu_{fn} \mu_{zn} \quad (7)$$

$$\lambda_3 = (\mu_{fn} \mu_{zn})^2 \quad (8)$$

where  $\eta$  = ratio of shape coefficient of wind load between building structure and scaffold, and the expression is as follows:

$$\eta = \mu_s / \mu_{ss} \quad (9)$$

where  $\mu_s$  can be used when checking in the relevant formulas and tables of *load code for the design of building structures* (GB50009-2001);  $\mu_{ss}$  can be used at the suggested value of shape coefficient of wind load in practical engineering;  $\varphi$  = wind coefficient of scaffold, 0.8 = suggested value;  $\mu_{zn}$  = wind pressure height coefficient of building structure construction, which can be used when checking in the relevant formulas and tables. The table of calculating values can be selected in the references.

Figure 8. The vibration mode of three trusses.

Table 2. The comparison of the result of two kinds of wind vibration frequency.

	Theory coefficient	Actual coefficient
Climbing stage	1.577	1
Declining stage	1.589	1

The expression of wind-induced vibration coefficient when the scaffold is declining is given as follows:

$$\beta'_z = 1 + \frac{\sqrt{\phi_1^2 \eta^2 \cdot \xi'_1 \lambda'_1 + 2\phi_1 \phi \eta \cdot \xi'_2 \lambda'_2 + \phi^2 z_i^{2\alpha} \cdot \xi'_3 \lambda'_3}}{\mu_{zi}} \quad (10)$$

where  $\xi'_1, \xi'_2, \xi'_3$  = pulse power coefficient under the common action of building structure and scaffold,  $\xi_1 = \xi'_1, \xi_2 = \xi'_2, \xi_3 = \xi'_3$ ;  $\lambda'_1, \lambda'_2, \lambda'_3$  = pulse influence coefficient when considering pressure fluctuation and spatial correlation, and the expression is given as follows:

$$\lambda'_1 = \lambda_1 \quad (11)$$

$$\lambda'_2 = \sum_{j=1}^n \phi_{1j} \rho_{ij} \mu_{fj} \mu_{zj} \mu_{fj} \mu_{zi} \quad (12)$$

$$\lambda'_3 = \frac{(\mu_{fj} \mu_{zi})^2}{z_i^{2\alpha}} = \frac{(\mu_{fj} \mu_{zi})^2}{z_i^{2\alpha} \cdot (\mu_{fj} \mu_{zn})^2} (\mu_{fj} \mu_{zn})^2 = z_n^{2\alpha} \cdot \lambda_3 = H^{-2\alpha} \cdot \lambda_3 \quad (13)$$

where  $\lambda'_2, \lambda'_3$  can be selected in the references.  $\phi_1$  = first vibration mode of building structure in the first particle, the corresponding vibration mode frequency of the adhesive integral-lift scaffold, its calculating method can also be used from the relevant formulas and tables of *load code for the design of building structures* (GB50009-2001);  $z_i$  = height of scaffold;  $\mu_{zj}$  = wind pressure height coefficient in the height of scaffold, it can be used from the relevant formulas and tables;  $\alpha$  = ground roughness index. In this paper, the comparison between calculating theory wind vibration coefficient and the actual coefficient of project with selecting each coefficient is given in Table 2.

## 5 CONCLUSION

In this paper, the dynamic characteristic of the scaffold is analyzed by establishing three different finite element models. We took the scaffold model of one truss as the calculation model, and obtained the scaffold vibration frequency. It was applied to the calculation of wind vibration coefficient, so the theory value of wind vibration coefficient was obtained, which was compared with the actual result of project selected. So, it provides the basis for the research of wind load calculation method of scaffold.

# Finite element analysis for a composite rib floor slab of steel fiber foam concrete

Yabo Wang, Gaofeng Dou, Chuanhao Xi, Lei Qian & Hanting Liu  
*Jilin Jianzhu University, Chanchun, Jinlin, China*

**ABSTRACT:** A new type of fabricated steel fiber foam concrete rib floor slab (henceforth referred to as “composite slab”) and its process flow of manufacture are simply introduced. Based on the finite element analysis with software ABAQUS, the finite element simulations are conducted in one-way “composite slab” and two-way “composite slab”, and their mechanical performance analysis is compared. The fine mechanics behavior of two-way “composite slab” is stated, which can provide a reference for the application of “composite slab”.

**Keywords:** fiber-reinforced concrete; foamed concrete; rib floor slab

## 1 A BRIEF INTRODUCTION OF COMPOSITE SLAB

“Composite slab” is a new type of pre-cast slab, the bottom of which is 2-centimeter steel fiber-reinforced concrete slab with steel mesh in it. The upper portion of the slab is a multi-ribbed structure, which uses ordinary concrete. The width and height of the rib are 6 cm and 8 cm, respectively. There is a reinforcement cage made up of carrying steel and stirrup in the multi-ribbed structure. Since the distance between carrying steel is smaller, the stirrup uses a S-shaped hook. The space between the multi-ribbed structures is filled by the foamed concrete, and then the upper portion of the multi-ribbed structure is casted by the 2-centimeter steel fiber-reinforced concrete slab, which does not have steel mesh in it.

When making “composite slab”, the steel fiber-reinforced concrete slab in the bottom should be poured first, then casting ribbed structure, and curing concrete for a period of time. This is followed by casting the foamed concrete in the space between the multi-ribbed structures and curing it. When it has a definite strength, the surface should be made smooth and clean, and then casting the steel fiber-reinforced concrete in the upper layer. Since the dimensions of all the parts of “composite slab” are small, it is better to use the smaller cobblestone, which is convenient for construction. When mixing the steel fiber-reinforced concrete, the steel fiber and other materials should first be dry-mixed

to make the steel fiber mix well, and then they are mixed with water.

## 2 CHARACTERISTICS OF ONE-WAY SLAB AND TWO-WAY SLAB

According to the theory of elastic thin plate, when the ratio of the long side and short side of the floor exceeds a certain value, the load of the one-way slab can transfer by the bending and shearing action along the “short side direction of the floor”. The load transfer along the long side direction can be ignored. Two-way slab has bending and shearing action in both directions, which can deliver the load along the long side and short side directions at the same time. The stress characteristic of the two-way slab is different from that of the one-way slab [1]. The floor bending in only one direction or mainly in one direction is called the one-way slab, while the floor bending in both directions that cannot be ignored in any direction is called the two-way slab [2]. Mechanical and deformation performance of the two-way slab is much better than that of the one-way slab. Thus, the two-way slab can enhance the bearing capacity and reduce the plate thickness. Meanwhile, it can strengthen the integrity and stiffness of the floor. However, the structure of “composite slab” is comparatively complex. In order to have quantified concepts about its mechanical property, we made a finite element simulation calculation of the one-way “composite slab” and the

two-way “composite slab” to compare the analysis of their mechanical behavior.

### 3 A BRIEF INTRODUCTION OF CALCULATION EXAMPLE AND THE MODELING APPROACH

#### 3.1 Material constructive model

Normal concrete uses the elastic-plastic constitutive relation, because the model uses the monotonous static loading plan. So based on the data of the plastic-damage model of C30 concrete in reference 3, the damage factor is not input, but it uses the elastic-plastic constitutive relation. This is because the constitutive relation of steel fiber-reinforced concrete is relevant to concrete strength and the type of steel fiber. So far, there has not been a unified constitutive relation model of steel fiber-reinforced concrete [4]. So the constitutive relation of steel fiber-reinforced concrete is mainly reflected by the modification of the constitutive relation of normal concrete and its elasticity modulus. The steel uses a double straight line ideal elastoplastic model.

#### 3.2 A brief introduction of the finite element model

The size of the one-way “composite slab” is  $3.6\text{ m} \times 1.2\text{ m}$ ; the size of the two-way “composite slab” is  $3.6\text{ m} \times 3.6\text{ m}$ ; the bottom is steel fiber-reinforced concrete; and its steel fiber content is 1.5%. The strength grade is CF30 and the upper part is a multi-ribbed structure, whose width and height are 6 cm and 8 cm, respectively. Multi-ribbed is ordinary concrete C30. All the concrete elements are an eight-node linear reduced integration entity unit (C3D8R). Multi-ribbed and steel fiber-reinforced concrete at the bottom is divided by the method of partition and gives them different properties, such as one-way slab shown in Figure 1.

The steel mesh in the steel fiber-reinforced concrete slab at the bottom is HPB300, and its

Figure 1. The diagram of the bottom of the one-way “composite slab” and its multi-ribbed structure.

diameter is 6 mm, the steel distance is 190 mm, steel mesh, as shown in Figure 2. The carrying steel in the multi-ribbed structure is HRB400 and its diameter is 8 mm, stirrup in the multi-ribbed is HPB300 and its diameter is 6 mm, the reinforcement cage in the multi-ribbed structure, as shown in Figure 3. All the steel elements are a two-node linear three-dimensional truss element (T3D2), which is applied to the separation-type model with the concrete element, and the steel unit is embedded in the concrete element, proceeding with the degree of freedom coupled to simulate the bond between steel bar and concrete [5].

Because the volume-weight of foamed concrete is  $200\text{ kg/m}^3$ , which is mainly used to fill the gaps, it does not belong to the main stress structure. So in order to simplify the calculation model, there is no simulation of foamed concrete and it directly ties the 2-centimeter steel fiber-reinforced concrete slab to the top surface of the multi-ribbed structure. Mesh generation is very important for finite element calculation. If the mesh is too coarse, the calculation results are not accurate enough; if the mesh is too dense, it will take a lot of computing time. So it needs to ascertain the mesh density reasonably [6]. When defining a tie, it needs to distinguish the master-slave surface, and the slave surface mesh should be denser than the master surface mesh [6]. The upper steel fiber-reinforced concrete slab is as the master surface, as shown in Figure 4, whose element size is 0.07. The top surface of the multi-ribbed surface is as the slave surface, whose element size is 0.05.

Figure 2. The diagram of the steel mesh at the bottom of the one-way “composite slab”.

Figure 3. The diagram of the rib frame of the one-way “composite slab”.

Figure 4. The diagram of the upper steel fiber-reinforced concrete slab of the one-way “composite slab”.

The boundary condition of the one-way “composite slab” is  $U_1 = 0, U_2 = 0, U_3 = 0$ , imposed on the two short sides of the one-way slab. The quadrilateral boundary condition of the two-way “composite slab” is  $U_1 = 0, U_2 = 0, U_3 = 0$ . The area load imposed on the one-way slab is  $40 \text{ KN/m}^2$ , while the area load imposed on the two-way slab is  $60 \text{ KN/m}^2$ .

In the implicit analysis program (e.g. ABAQUS/Standard), the material with softening and rigid-ity weakening traits will make calculation difficult to convergence. In the constitutive equation, it can adopt the viscoplastic regularization to solve the problem partially [7]. When defining the viscosity coefficient of concrete, the greater the viscosity coefficient, the more rigid the structure is, i.e. it is just like a more sticky liquid that is more difficult to flow; the smaller the viscosity coefficient, the lower the computational efficiency [8]. We find that when the viscosity coefficient is less than 0.1, it is difficult to converge through valuing the viscosity coefficient. In order to reduce the calculated quantity, the viscosity coefficient is defined as 0.3 on the premise that it does not affect the result precision.

#### 4 THE FINITE ELEMENT RESULTS OF ABAQUS

von Mises stress of steel mesh at the bottom of the one-way “composite slab” is shown in Figure 5. Its stress of the middle steel element varies with load curve, as shown in Figure 6. When the area load is  $11 \text{ KN/m}^2$ , the curved section appears, which indicates that the lower part concrete of the floor has already cracked. This is mainly by the steel to bear load effect, and when the area load is  $31.6 \text{ KN/m}^2$ , steel yield, the member is already broken.

von Mises stress of steel mesh at the bottom of the two-way “composite slab” is shown in Figure 7. Its stress of the middle steel element varies with load curve, as shown in Figure 6. When the area load is  $18.5 \text{ KN/m}^2$ , the curved section appears,

Figure 5. von Mises stress diagram of steel mesh at the bottom of the one-way “composite slab”.

Figure 6. Stress of the middle steel element varied with load curve of the one-way “composite slab” and the two-way “composite slab”.

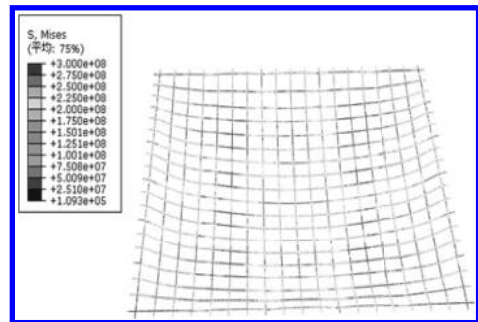

Figure 7. von Mises stress diagram of steel mesh at the bottom of the two-way “composite slab”.

which indicates that the lower part concrete of the floor has already cracked. This is mainly by the steel to bear the load effect, and when the area load is  $46.5 \text{ KN/m}^2$ , steel yield, the member is already broken.

The cracking load of the  $3.6 \text{ m} \times 3.6 \text{ m}$  two-way “composite slab” improves by 68%, compared with the  $3.6 \text{ m} \times 1.2 \text{ m}$  one-way “composite slab”, and the failure load improves by 42%. The deflection limit value of the floor flexural member is

$l_0/200$ , where  $l_0$  is the effective span of the member [1]. The effective span of both the one-way “composite slab” and the two-way “composite slab” is 3.6 m, so their deflection limit value is 0.018 m. The deflection of the one-way “composite slab” is shown in Figure 8. The load-deflection curve of its middle element is shown in Figure 9. As can be seen from the figure, when the deflection of the floor is 0.018 m, its corresponding load is 26.4 KN/m<sup>2</sup>. The deflection of the two-way “composite

Figure 8. The deflection diagram of one-way “composite slab”.

Figure 9. The load-deflection curve of the one-way “composite slab” and the two-way “composite slab”.

Figure 10. The deflection (m) diagram of the two-way “composite slab”.

slab” is shown in Figure 10. The load-deflection curve of its middle element is shown in Figure 9. As can be seen from the figure, when the deflection of the floor is 0.018 m, its corresponding load is 38.5 KN/m<sup>2</sup>. By comparison, the normal use of the limited load of the two-way “composite slab” is improved by 46%.

So we can see that the mechanical performance of the two-way “composite slab” is much better than that of the one-way “composite slab”. However, restricted by the capacity of hoisting and transportation equipment in the assembled structure, floor is impossible to be made as a whole two-way “composite slab”, but it must be divided into several floor slabs, after hoisted in position, connecting them together to form the two-way slab. So if we can find a safe, reliable and reasonable joint that can make the one-way “composite slab” to deliver the load effect effectively, then it can improve the mechanical performance of the structure.

## 5 CONCLUSIONS

1. “Composite slab” is a new type of pre-cast slab within foamed concrete filling, which can keep warm and sound-insulated well, and the steel fiber-reinforced concrete has a preferable ductility and dissipative capacity. The mechanical performance of its one-way slab and two-way slab can meet the requirements, and they can be applied to the assembled structure and are especially applicable to the north cold area.
2. The mechanical performance of the two-way “composite slab” is much better than that of the one-way “composite slab”, whose cracking load improves by 68%, normal use of limited load improves by 46%, and failure load improves by 42%. If we can find a reasonable joint that can make the one-way “composite slab” to combine with the two-way “composite slab” to deliver the load effect effectively, then it is good to improve the carrying capacity of the structure. Meanwhile, it can also strengthen the integrity and stiffness of the floor.
3. Now the mechanical performance of “composite slab” remains restricted to the finite element simulation analysis, and the bond slip between steel and concrete is shown by the EMBEDDED technology, which is slightly different from the practical engineering. In addition, there is no experiment conducted on the actual construction member, so the corresponding structure test is also needed in order to compare with the finite element model and carry out validation analysis.

# Finite element analysis of steel reinforced recycled aggregate concrete axial compression short column

Bing Wang & Xiao Liu

School of Architectural and Civil Engineering, Shenyang University, Shenyang, China

Lu Gao

School of Civil Engineering, Lanzhou University of Technology, Lanzhou, China

**ABSTRACT:** In this paper, the steel recycled concrete axial compression short column has been analyzed by the finite element analysis using finite element analysis software ABAQUS. We get the ultimate bearing capacity of steel replacement rate under different regeneration concrete stub columns, and give each part temperature peak stress cloud contrast. The results showed that with the increase of recycled coarse aggregate replacement ratio, the concrete stress slightly increased, the ultimate bearing capacity of the component also gradually increased.

**Keywords:** steel reinforced recycled aggregate concrete; axial compression; column; the finite element

## 1 INTRODUCTION

With the rapid development of global economy, the speeding up of urbanization, and the increasing increase in the amount of concrete, natural resources are mined, and a large amount of construction waste are produced. At the same time, with people on the performance of structure and construction waste reuse requirements increase, recycled concrete as a kind of new building materials in the construction field has been researched, popularized, and applied. Research shows that steel reinforced recycled aggregate concrete by steel improves the bearing capacity of components, increases the ductility and durability of the structure, improves the seismic performance of the concrete structure, and it can realize the recycling of construction waste to achieve energy conservation and environmental protection. Steel reinforced recycled aggregate concrete column as the main structural component of construction overcome shortcomings of the simple structure of recycled concrete [1–4]. In this paper, the steel recycled concrete axial compression short column has been analyzed using finite element analysis by finite element analysis software ABAQUS.

## 2 THE CONSTITUTIVE RELATIONS OF STEEL AND RECYCLED CONCRETE

### 2.1 Steel

The steel stress-strain model using bilinear model, as shown in Figure 1.

The elastic modulus of steel is defined  $E_S = 2.06 \times 10^{11} N/mm^2$  Poisson's ratio  $\nu_s = 0.3$ .

### 2.2 Recycled concrete

The constitutive relation of recycled concrete by Xiao Jianzhuang [5] which considers the replacement ratio of recycled coarse aggregate concrete under temperature stress-strain curve

Make  $y = \sigma/f_c, x = \epsilon/\epsilon_0$

$$y = \begin{cases} ax + (3 - 2a)x^2 + (a - 2)x^3 & x < 1 \\ \frac{x}{b(x - 1)^2 + x} & x \geq 1 \end{cases} \quad (1)$$

Figure 1. The constitutive relation curves of steel.

$$a = 2.2 (0.748\gamma^2 - 1.231\gamma + 0.975) \quad (2)$$

$$b = 0.8 (7.6483\gamma + 1.142) \quad (3)$$

In the formula:  $\gamma$ —Replace rate of recycled coarse aggregate.

The concrete plastic damage model based on ABAQUS software, the basic parameters of the plastic potential equation and the yield surface equation is similar to the ordinary concrete: the dilation angle is 30, the eccentricity is 0.1, compressive strength of concrete under biaxial and uniaxial compressive strength ratio is 1.16, tension and compression the second invariant meridian stress

ratio (K) is 0.6667, and the viscosity parameter is 0.0001. Concrete tensile softening performance using the energy criterion to describe the damage.

### 3 THE PROCESS OF FINITE ELEMENT MODELING

This paper designed a set of all the fire steel recycled concrete axial compression short column components. Basic parameters are as follows: Component length is  $L = 900$  mm, section size is  $B \times D = 300$  mm  $\times$  300 mm, H-beam section size is  $h \times b \times tw \times t = 150$  mm  $\times$  150 mm  $\times$  9.3 mm  $\times$  9.3 mm, the

Figure 2. The component model for the finite element analysis.

Table 1. The stress nephogram.

Replace rate of recycled coarse aggregate (%)	Concrete	Steel	Reinforced	Ultimate bearing capacity (KN)
0				5376
50				5504
100				5909

strength of recycled concrete is C60, steel is chosen Q345, longitudinal reinforced is 4B16, stirrup is B8@200, the strength of steel are HRB335, and the protective layer thickness is 30 mm.

Concrete, steel and end plates using an 8-node solid element (C3D8R), reinforced using a 2-node truss element (T3D2). The interface model of steel and recycled concrete (Surface to Surface contact) is composed of bond slip in the normal direction of interface contact and tangential direction. The rebar cage embedded in recycled concrete. Both ends of the column is fixedly connected, and the U3 is released in the direction of loading end displacement. The component form as shown in [Figure 2](#).

#### 4 MODEL ANALYSIS

This paper analyzes the ultimate bearing capacity of the peak stress nephogram of influence of different substitution rate of steel reinforced recycled aggregate concrete.

It can be seen from [Table 1](#), concrete and end plate corner connection undergoes the phenomenon of stress concentration, and the central component concrete high stress value; steel middle stress is larger, both ends gradually decreased; the longitudinal steel basically reached the yield limit, the stirrup with the replacement ratio of recycled coarse aggregate increase stress decreased.

At the same time, with the increase of recycled coarse aggregate replacement ratio, the concrete stress slightly increased; the ultimate bearing capacity of the component also gradually increased. This is because with the increase of recycled coarse aggregate replacement ratio, the bearing capacity of recycled concrete is slightly higher, which makes recycled concrete contribution to the bearing capacity increase.

#### 5 CONCLUSION

With the increase of recycled coarse aggregate replace rate, bearing capacity of recycled concrete

increased under the same concrete strength, the steel reinforced recycled aggregate concrete limit bearing capacity also increases. This shows that steel reinforced recycled aggregate concrete component with reasonable mixture ratio has better mechanical properties.

# Research and development of visual monitoring system for prestressed steel structure

Zhancang Li

Tianjin Vocational Institute, Tianjin, China

**ABSTRACT:** Prestressed steel structure is an important measure of the construction level of a nation. For prestressed steel structure construction, both in the construction phase, or in the normal use stage, to monitor their health status is necessary. In order to make the monitoring more vivid, concrete, and humane, we developed the visual monitoring system by using three-dimensional (3D) technology. The system consists of real-time communication subsystem, 3D display subsystem and safety warning subsystem. By observing the 3D model, we can know the monitoring data of the real buildings. At last, the safety warning for the prestressed steel structure was implemented.

**Keywords:** prestressed steel structure, visualization; monitoring

## 1 INTRODUCTION

Nowadays, building a resource-saving society has become a time theme in China. For building construction, it has to be made not only safe and suitable, but also artistic and economic. Benefit by the advantages of high strength, light weight and low cost, the prestressed steel structure has been used more and more in the projects of gymnasiums, warehouses, and so on. As a result of the complexity of prestressed structure, the normal use of structure has been directly affected. To avoid the damage which projects may cause and to extend the life-span, the damage of structure has to be found out in time. For this reason, it is an urgent situation to build a monitoring system of prestressed steel structure<sup>[2]</sup>. By using real-time communication technology and three-dimensional (3D) technology, the visual monitoring system have been designed and developed, this paper introduced the core technology, realization method and application of the system.

## 2 OVERALL DESIGN OF THE MONITORING SYSTEM

Prestressed steel structure 3D visualization real-time monitoring is a system engineering, including the sensor technology, communication technology, 3D modeling technology, software development technology, database technology, and image processing technology etc. According to the functions required by the system, the working model of the system is shown in [Figure 1](#).

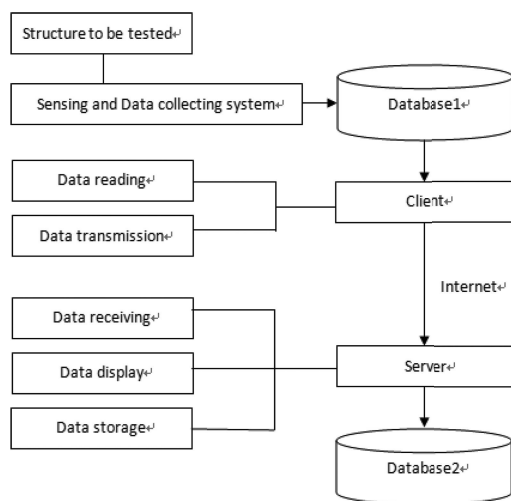

Figure 1. Working model of monitoring system.

The monitoring work is divided into the following parts.

### 2.1 Sensing and data collecting part

According to the prestressed structure to be measured, establish the finite element model of the structure, calculate and analyze stress of the structure, then determine the type, quantity and location of sensor. After that, arrange internet sensors in determining position of the structure. At last, select data collecting devices, read out the

monitoring data from the sensor through the data collecting equipment and store in the database.

### 2.2 Real-time transmission part

The real-time transmission of monitoring data part is realized by “client” and “server” in Figure 1. The client read monitoring data from the database and transmit it to the server by certain frequency; the server implements the receiving, storing, 3D display, and safety warning of monitoring data.

### 2.3 D visualization

After receiving monitoring data real-time from remote client, the server software realizes the 3D display of monitoring data by loading 3D model. When monitoring data exceeds a preset safe range, the warning bell and high light display security early warning will be carried out.

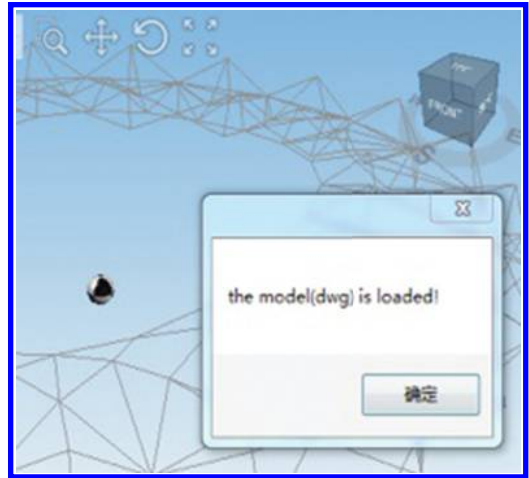

Figure 2. Loading model.

## 3 DEVELOPMENT OF THE MONITORING SYSTEM

The techniques and methods of the realization of each part are introduced, respectively, as follows.

### 3.1 Implementation of sensing and data collecting part

The mature equipment and solutions can be used in the sensing and data collecting part of the system. This project adopts sensing devices and data collecting equipment provided by Data Taker China Limited.

### 3.2 Implementation of real-time transmission part of monitoring data

Monitoring data real-time transmission means to read monitoring data in Figure 1, which is collected in sensing and data collecting system from database and make a real-time transmission to the remote monitoring center, this function will be realized by the monitoring software developed.

As shown in Figure 1, the monitoring adopts C/S system structure, the client realizes the reading and transmission, the server realizes the receiving and storage. Between client and server, socket technology is used for communication.

C/S structure is a structure of software system<sup>[6]</sup>, it can make full use of the advantage of client and server hardware environment at both ends to assign the tasks to the client and server to reduce the communication fee of the system. Socket<sup>[5]</sup> is a basic operation unit which supports TCP/IP protocol of network communication, it can be seen as two-way

communication endpoints among different hosts process, with a correlation function of the socket to complete the communication process. It is like a transport layer interface operated for application layer, application program sends or receives remote data through the interface.

The process of socket communication between client and server is as follows:

1. The server creates a socket and listens at a port and is in a block.
2. The client creates a socket and connects to the server.
3. The server accepts the connection, ready to receive data and is in a block.
4. The client sends data and prepares to receive data.
5. The server receives the data and sends the data.
6. The client exits.
7. The service stops serving.

Considering the target platform and the efficiency of the system, we choose object-oriented programming design language and Studio Visual developing tools.

On the client side, create a connection—oriented network socket, request connection to the server based on the server’s IP address and port: if connection succeeds, create network stream object for data transmission according to the network socket. In a single thread, the monitoring data is read from the scene database and is transmitted to the remote server by the network stream object.

In the server side, create a network socket, and open the monitor. When a client connection requests, create a network socket in the server for communication with the client, when data

arrives, receive the monitoring data and realize the data storage, due to the advantages of the simple deployment and high efficiency of SQLite database, project selects SQLite database.

### 3.3 The realization of 3D visualization display and the safety warning

Visualization technology is methods and techniques, which makes use of computer graphics and image technology to transfer data into graphics or images displayed on the screen or on the software form and makes the interactive processing.

3D visualization is a combination of data and 3D model, which displays the data on the 3D model, monitoring stuff can master the real sensor data on the corresponding position in real-time so as to grasp health status of the structure. The realization of 3D visualization monitoring steps is as follows.

#### 3.3.1 Create the three dimensional model of prestressed steel structure

Using Auto CAD, Revit or other 3D modeling softwares to create the 3D model of the prestressed steel structure, according to the sensor on the structure, mark on the 3D model corresponds to the position.

#### 3.3.2 The loading of the 3D model

For the loading of 3D models, the dynamic connection library EyeShot provided by third party Software dev Dept is used. EyeShot is a good solution for software developers to load 3D graphics into a form application. We can use it to translate, scale and rotate the 3D model on its own application form.

For the realization of loading for 3D model, create a custom control, inherit component SingleViewport Layout provided by EyeShot. The latter provides the functions of loading, operating, and saving 3D model (DWG format). The paper realizes the loading of DWG and MDL (custom) format. After a successful loading, the model can be scaled, rotated, moved and so on. 3D model loading interface is shown in Figure 3.

#### 3.3.3 The addition, setup and deletion of the simulation monitoring points

Simulation monitoring point is a vivid simulation of true monitoring position on the prestressed steel structure, each simulation monitoring point match with an actual monitoring point and its monitoring point sensor, simulation monitoring point carries the coordinate of the point, corresponding sensor identification, and information like monitoring point safety warning limit data. Each simulation monitoring point match with an actual

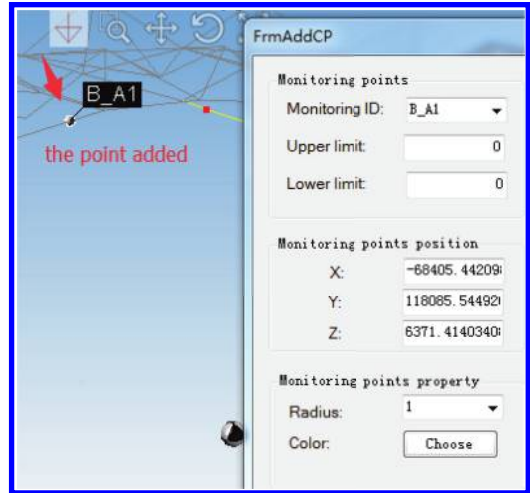

Figure 3. Add monitoring points.

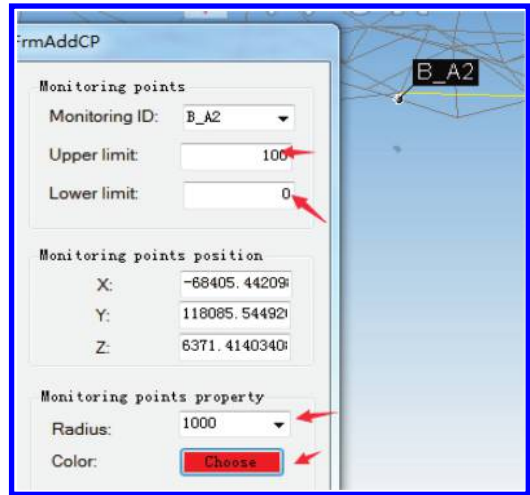

Figure 4. Editing of monitoring points.

monitoring point and its monitoring point sensor, simulation monitoring point carries the coordinate of the point, corresponding sensor identification, and safety warning limit of the point. Each simulation monitoring point is represented by a sphere, as shown in Figure 3, the red arrow in the figure points at the sphere, which is the simulation monitoring point that have been added.

When we need to edit the attributes (color, radius or safety range) of simulation monitoring points for any reasons, we can right-click the sphere, open the “Edit model” dialog to reset the attributes of simulation monitoring points, as shown in Figure 4. When you need to delete the

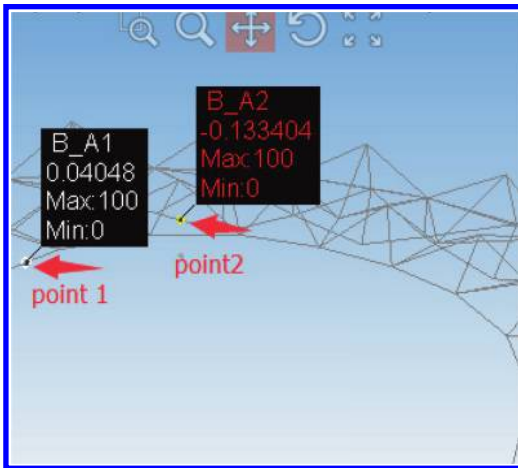

Figure 5. Visualization monitoring.

simulation monitoring point, right—click the ball, select “Delete” menu item from the context menu to delete it.

### 3.3.4 3D visualization display and safety warning

When the model is in a displaying mode, the current value of the actual monitoring sensor will be displayed in real-time at the simulation monitoring point position, when the value received is in the safe range, it will be displayed with white font on the model, when beyond the safe range, the bell sound and a red display will be activated as a security warning, as shown in Figure 5. The monitoring value of “monitoring point 1” is in the safe range, and no alarm; The monitoring value of “monitoring point 2” is beyond the safe range and it will automatically activate alarm and will be displayed in red font with high light so as to realize the safety warning.

## 4 CONCLUSION

According to the content of the whole design, we achieved the collecting of monitoring data real-time transmission of data, 3D visualization display, and the safety warning respectively. The features are the real-time transmission of monitoring data and visualization monitoring, in which real-time transmission part realized self-connection between the client and the server and simplified the configuration and deployment of the software. The visualization monitoring part solved the difficulties of the

loading of 3D model, the additions of simulation monitoring points and safety warning through the dynamic link library by third party to realize the visualization monitoring, and enabled the monitoring stuff mater the status of prestressed steel structure health in real-time through the observation of 3D model.

This system passed a comprehensive test in Guang Zhou university sports venue and Xuzhou stadium project, both designed by Beijing Institute of architectural, and it was put into use, The system improved the way of prestressed steel structure monitoring, the monitoring accuracy and the working efficiency are improved, and it makes the monitoring work more humane.

The deficiency of this paper is the lack of research on the sensor system and the data collecting system. There is no specification for the interface between monitoring software and data acquisition system, data format or structure of the database is not unified, which will bring some inconveniences after replacing the sensing system. The lack of research on the further application of monitoring data, the striving direction in the future is to make full use of the monitoring data, the systematic assessment of prestressed steel structure performance variation so as to scientifically evaluate the health status to provide reference for reinforcement and maintenance of the structure.

## Ballast particle model and initial packing numerical simulation

W.J. Shao & S.L. Lian

*The Key Laboratory of Road and Traffic Engineering, Ministry of Education, Tongji University, Shanghai, China*

**ABSTRACT:** The shape of ballast particles has an important effect on the settlement and deformation of ballast bed. When the research of the settlement of ballast bed is carried out by using the discrete element method, an accurate shape model of ballast particles needs to be established. However, the application of polyhedral model of ballast particles can handles this problem rather well. In the article, the polyhedral model of ballast particles is first generated by the convex hull generation method. Meanwhile, the approach to bounding sphere packing is used to accelerate the packing process of polyhedral model of ballast particles on basics of packing of ballast particles under gravity. The results show that the initial packing process of polyhedral model of ballast particles can be speeded up through the above mentioned way. And it in turn accelerates the whole packing process of ballast particles.

**Keywords:** discrete element method; ballast particle model; heavy haul railway; sphere packing

### 1 INTRODUCTION

During operations of the heavy haul railway with 30 tons in axle load, the problem of roadbed settlement has grown more important. But traditional research methods rest on the assumption of a continuous medium, which are inadequate to access the effects of shape and crush of ballast particles on the roadbed settlement. Consequently, when considering the effects of the shape of the ballast particles, a model of irregular shaped particles has been adopted to simulate them.

The clusters and clumps are being used to model real ballast particles in the discrete element method, which have been proposed first by the McDowell team (McDowell et al. 2005). And in terms of numerical simulation, the two models are applied to the engineering practices by Indraratna (Indraratna 2013 & Christian 2012). Furthermore, by comparing the experimental results, the validity of these two models are verified by him. However, the number of spheres are bonded together to form a ballast particle in these two models. Because of this way, it will lead to the existence of interspace and overlap in the particles, so the density of the particles is not uniformly distributed.

In order to overcome this shortcoming, a model of irregular polyhedral particles (Tutumluer 2009, Joseph 2013 & Jan 2014) has been adopted to simulate the ballast particles. And the rapid packing algorithm for spherical particles is employed to accomplish the initial packing of polyhedral model of ballast particles.

### 2 THE CONSTRUCTION OF POLYHEDRAL MODEL OF BALLAST PARTICLES

According to Code for Designing Heavy Haul Railway (Ministry of Railways of the People's Republic of China 2011), 1st graded ballast should

Figure 1. A polyhedral model of ballast particles.

be applied in the heavy haul railway with 30 tons or above in axle load. Thus, a series of cuboids needs to be established in accordance with the size of square whole screen of the 1st graded ballast.

And a certain number of points are randomly inserted into the cuboid in the light of the requirements of slenderness ratios. As shown in Figure 1, a polyhedral model of ballast particles can be generated through computing the convex hull (Barber 1996 & Wang 2011) of these points.

Owing to the randomness of the inserted point, the model might be shaped in needle-like or flake-like. Therefore, the shortest distance and the longest distance of the polyhedral model should be found so as to calculate the slenderness ratios. And the values of slenderness ratios will be used as a criteria for determining whether it meet the requirements of flake index and acicular index.

### 3 THE BOUNDING SPHERE OF POLYHEDRON BALLAST PARTICLE

The benefits of using the spherical model of particles are the simplicity of geometry description. Another advantage of the model can be used to quickly determine whether it is in contact with each other. What's more, the packing process of it is relatively simple and fast to calculate. By using the packing of the spherical model, the packing process of polyhedron model of ballast particles can be speeded up. But it is necessary for the polyhedral model of ballast particles to find the bounding sphere. Then the above mentioned method can be adopted to achieve the initial packing process.

When it comes to computing the bounding sphere, a method of calculation has been proposed by Jack Ritter (Ritter 1990). In the article, a numerical calculation of the bounding sphere is made in the same method. First, it is necessary to find six points which have the maximum and minimum values of  $x$ ,  $y$ , and  $z$  from a vertex set of  $V_i$ . Then the length of the line segment linking any two points chosen from them would be calculated. The longest length of it is named  $d_1$ , which has the corresponding vertices  $A_1$  and  $B_1$ .

1. Find the midpoint  $P_1$  of a line segment joining the vertices  $A_1$  and  $A_2$ . And the sphere  $Q_1$  with center  $P_1$  and diameter  $d_1$  is calculated.
2. Traverse the remaining vertices and determine whether the remaining vertices are in the sphere calculated in the first step. If vertex  $A_i$  is in the sphere  $Q_1$ , the next vertex  $A_{i+1}$  would be tested in the same process. Otherwise, it is necessary to create connection lines between vertex  $A_i$  and center  $P_1$ , which would intersect the sphere  $Q_1$  at the point  $B_i$ . Then the length of the line segment linking the vertices  $A_i$  and  $B_i$  would be

computed and named  $d_i$ . As shown in Figure 2, the sphere  $Q_i$  with center  $P_i$  and diameter  $d_i$  is computed in the same way;

3. Repeat the above mentioned procedure to determine the sphere  $Q_i$  which contains all vertices.

Finally, the bounding sphere of polyhedron ballast particle is calculated and depicted as shown in Figure 3.

Figure 2. The schematic diagram of the calculation of the bounding sphere.

Figure 3. The bounding sphere of polyhedron ballast particle.

#### 4 THE INITIAL PACKING OF POLYHEDRON BALLAST PARTICLE

After the bounding sphere of polyhedron ballast particle model is solved, they can be packed with a geometric based compression algorithm which is proposed by Han (Han 2005). The core idea of the algorithm is described below:

In case of the 2D circle particle, the problem is shown in Figure 5. A is the target circle to be compressed, the remaining circle are A's neighbor. Unit vector of the compression direction is  $n_e(x_n, y_n)$ . The coordinate of A circle center is  $(A_x, A_y)$ , H's center coordinate is  $(H_x, H_y)$ ; as shown in Figure 4, the maximum moving distance of A just touching H is  $l_{max}$  calculated with the equation:

$$l_{max} = l_s - \sqrt{(r_A + r_H)^2 - l_t^2}$$

where:  $l_s = (H_x - A_x)x_n + (H_y - A_y)y_n$   
 $l_t = (H_x - A_x)y_n + (H_y - A_y)x_n$ .

Loop over A's neighbor circle to calculate the minimum of the allowable moving distance in the original paper. The neighbor circle quantity is 7, so solution procedure must be conducted for 7 times. However, if circle A moves along the specified direction, circle C, D, and F are never touching with A. So the judgment condition is used to reduce the neighbor circle quantity. Before calculating the allowable moving distance, the direction vector which A's center to one of circle should be calculated. Then the angle between the direction vector and compression direction are calculated. If the angle is greater than 90 degrees, the circle is removed from the neighbor list. Less than 90 degrees, the distance from the circle to the

compression direction are computed. If the distance is greater than the sum of A's radius and its radius, the circle is removed from the neighbor list. Loop over A's neighbor circle, the neighbor circle quantity can be reduced. For example, A's final neighbor circle are G and H. Finally, the calculation speed of A's minimum allowable moving distance can be increased.

All spheres are looped over and moved, and then a loop global compression is accomplished. Because of the spheres are compressed in the assigned orientation, the local arches are formed. In order to overcome this difficulty, a local compression is performed in which the compression direction is different from the global compression. After the global and local compression is performed, the packing density is significantly increased.

After the packing process of bounding sphere is accomplished, coordinate conversion between polyhedron ballast particle and bounding sphere is carried out. The bounding spheres are replaced by the polyhedron ballast particle. Then the polyhedron ballast particles are initially packed.

#### 5 ILLUSTRATIONS

A box is designed to test the validation of the above method; it is  $70 \times 30 \times 45$ cm. With the method stated above, the packed bounding sphere in the box is shown in Figure 5. Correspondingly, Figure 5 shows the initial packing of polyhedron ballast particle.

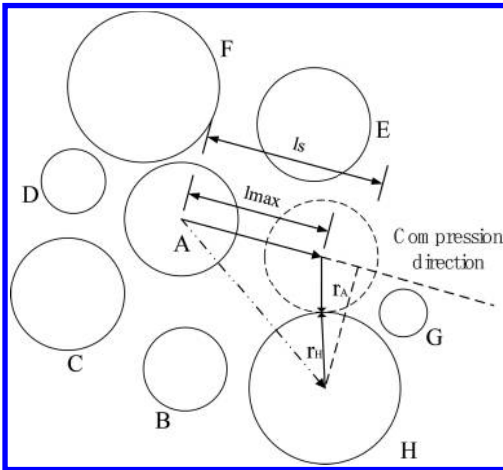

Figure 4. Moving distance of sphere A.

Figure 5. The packed bounding sphere in the box.

Figure 6. The initial packing of polyhedron ballast particle in the box.

In Figure 6, the number of bounding sphere is 2911, the packing density is 0.323. It takes 336.7 seconds to complete the initial packing of polyhedron ballast particle. Because the volume of polyhedron ballast particle is less than its bounding sphere. As shown in Figure 6, the interspace between the polyhedron ballast particles is bigger. Its packing density is less than 0.323. In order to increase the packing density, random packing under gravity must be performed after the initial packing. The purpose of the paper is to describe a quick initial packing method of polyhedron ballast particles, so random packing under gravity isn't expounded.

## 6 CONCLUSIONS

1. The theory of convex hull can be used to establish the polyhedron ballast particle model of irregular shape; but slenderness ratio must be calculated to determine whether the ballast particle model is needle shaped or flaky particle.
2. Bounding sphere is packed quickly, so the initial packing of polyhedron ballast particle model can be speeded up.

## The comparison of integration methods in cellular material model

Lei Hou & YunQing Feng

Department of Mathematics, Shanghai University, Shanghai, China

**ABSTRACT:** The complex contact problem of cellular composite materials is studied in this paper. The problem is translated into a set of nonlinear fluid-structure coupling partial differential equations. The equations are discretized by the finite element method and finite difference method. Three kinds of integration methods—Gauss, Gauss-Lobatto and Newton-Cotes to compute numerical integration are used in the calculation of numerical solution. Then we can analyze the three numerical integration methods to the influence of numerical solution of nonlinear fluid-structure coupling equations.

**Keywords:** finite element; cellular material

### 1 INTRODUCTION

With the development of economic environment, shortage of energy, timber and other resources is becoming serious, which lead to enormous pressure on the scientific research. Facing with such severe situation, the most important task at present is to minimize resource consumption and environmental damage. Fortunately, the advent of cellular composite materials alleviates these problems. Cellular material is a new material. Its advantages of light texture, strength, stiffness, heat insulation, sound insulation, et al are proposed by [4]. It is recycled and has a high economic value. Currently, cellular materials have been widely used in the construction industry, which has great significance for the conservation of resources and improving the ecological environment. However, its numerical simulation is difficult because of the complexity of material microstructure and the diversity of material properties. International engineering (IEEE, IAENG) think high performance computing technology can be combined with mathematical models to simulate the deformation of the material. An example of such a model has been proposed by Fleck and James [5,6]. Paper [1] attempts to use a set of nonlinear fluid-structure coupling partial differential equations to describe the problem of complex contact surfaces of cellular composite materials.

Now a large number of finite element software can effectively simulate the cellular material deformation and other issues. The problem of complex contact surface of cellular materials are shown in [Figure 1](#) and [Figure 2](#) using Dyna. However, due

Figure 1. Stress distribution of cellular materials' contact surface.

Figure 2. Stress distribution of cellular materials' contact surface in time 0.1.

to too much emphasis on versatility, these software ignore the further analysis to computing formats and results. Due to these considerations, the paper is devoted to study and explore better finite element computing format and numerical integration method for solving nonlinear fluid-structure coupling equations.

$$\begin{cases} \frac{\partial u}{\partial t} = \frac{1}{\rho} \nabla \cdot \tau - (u \cdot \nabla) u \\ \frac{\partial \tau}{\partial t} = \frac{2\eta}{\lambda} D - \frac{1}{\lambda} e^{\frac{\varepsilon \lambda}{\eta_0} (\tau_{11} + \tau_{22})} \tau \\ \quad - (u \cdot \nabla) \tau [\nabla u \cdot \tau + (\nabla u \cdot \tau)^T] \\ \quad - \xi [(D \cdot \tau) + (D \cdot \tau)^T] \\ u|_{(x,y) \in \Gamma} = u_\Gamma, \quad u|_{t=t_0} = u_0 \\ \tau|_{(x,y) \in \Gamma} = \tau_\Gamma, \quad \tau|_{t=t_0} = \tau_0 \end{cases} \quad (1)$$

here  $\rho$  is density,  $\xi$  is the shear factor,  $\eta$  is the viscosity,  $\lambda$  is the relaxation factor,  $u$  is the velocity,  $\tau$  is the stress.

## 2 THE DISCRETION OF COUPLING EQUATIONS

This article use finite element method and finite difference method to solve the coupling equations. The spatial variables are discretized by the finite element method and the time variable is discretized by semi implicit Euler methods. After that, we get large linear equations. For the spatial variables, we use high order shape function—Lagrange three shape function to construct interpolation function. It can avoid the phenomenon of the unit is too rigid and reduce the error caused by finite element discretization.

The first step to construct the finite element interpolation function is to determine the interpolation nodes. This paper uses the zeros of the Lobatto polynomial as the interpolation nodes, constructing Lagrange 16 double three polynomial shape functions. The following problems are considered in the standard element  $-1, 1 \times -1, 1$  square area. The rectangular area divided into four  $2 \times 2$  units, denoted as ① unit, ② unit, ③ unit, ④ unit. Then we use the zeros of the Lobatto polynomial as the interpolation nodes of rectangular mesh and get a  $2 \times 2$  in-equidistant interpolation nodes in each unit.

One-dimensional Lagrange shape functions are as follows:

$$\begin{aligned} L_1(\xi) &= -5/8(\xi^2 - 1/5)(\xi - 1) \\ L_2(\xi) &= 5\sqrt{5}/8(\xi - \sqrt{5}/5)(\xi^2 - 1) \\ L_3(\xi) &= -5\sqrt{5}/8(\xi + \sqrt{5}/5)(\xi^2 - 1) \\ L_4(\xi) &= 5/8(\xi^2 - 1/5)(\xi + 1) \end{aligned}$$

We can get the two-dimensional Lagrange 16 double three shape function, expressed as

$$\varphi_1(\xi, \eta) = L_1(\xi)L_1(\eta), \dots, \varphi_{16}(\xi, \eta) = L_2(\xi)L_3(\eta)$$

here,  $L_i(\eta)$  is one-dimensional Lagrange shape function.

Now, finite element and finite difference methods are used to discrete coupling equations. In equations(1), we set  $u = iu_1(x, y, t) + ju_2(x, y, t)$  as velocity field(Vector). Here,  $u_1(x, y, t)$   $u_2(x, y, t)$  are expressed as x and y components of velocity  $u$ .

$\tau = \begin{pmatrix} \tau_{11}(x, y, t) & \tau_{12}(x, y, t) \\ \tau_{21}(x, y, t) & \tau_{22}(x, y, t) \end{pmatrix}$  is a stress field(Tensor).

Here  $\tau_{11}(x, y, t)$ ,  $\tau_{12}(x, y, t)$ ,  $\tau_{21}(x, y, t)$ , correspond to four component of stress  $\tau$ . We also have  $\tau_{12}(x, y, t)$ ,  $\tau_{21}(x, y, t)$ .

The coupling equations actually contains 5 component equations. The coupling equations(1) expand into five component equations according to the above five components:

$$\frac{\partial u_1}{\partial t} = \frac{1}{\rho} \left( \frac{\partial \tau_{11}}{\partial x} + \frac{\partial \tau_{12}}{\partial y} \right) - \left( u_1 \frac{\partial u_1}{\partial x} + u_2 \frac{\partial u_1}{\partial y} \right) \quad (2)$$

$$\frac{\partial u_2}{\partial t} = \frac{1}{\rho} \left( \frac{\partial \tau_{12}}{\partial x} + \frac{\partial \tau_{22}}{\partial y} \right) - \left( u_1 \frac{\partial u_2}{\partial x} + u_2 \frac{\partial u_2}{\partial y} \right) \quad (3)$$

$$\begin{aligned} \frac{\partial \tau_{11}}{\partial t} &= \frac{2\eta}{\lambda} \frac{\partial u_1}{\partial x} - \frac{1}{\lambda} \tau_{11} - \frac{\varepsilon}{\eta_0} (\tau_{11} + \tau_{22}) \tau_{11} \\ &\quad - \left( u_1 \frac{\partial \tau_{11}}{\partial x} + u_2 \frac{\partial \tau_{11}}{\partial y} \right) + (2 - 2\xi) \frac{\partial u_1}{\partial x} \tau_{11} \\ &\quad + \left[ (2 - \xi) \frac{\partial u_1}{\partial y} - \xi \frac{\partial u_2}{\partial x} \right] \tau_{12} \end{aligned} \quad (4)$$

$$\begin{aligned} \frac{\partial \tau_{22}}{\partial t} &= \frac{2\eta}{\lambda} \frac{\partial u_2}{\partial y} - \frac{1}{\lambda} \tau_{22} - \frac{\varepsilon}{\eta_0} (\tau_{11} + \tau_{22}) \tau_{22} \\ &\quad - \left( u_1 \frac{\partial \tau_{22}}{\partial x} + u_2 \frac{\partial \tau_{22}}{\partial y} \right) + (2 - 2\xi) \frac{\partial u_2}{\partial y} \tau_{22} \\ &\quad + \left[ (2 - \xi) \frac{\partial u_2}{\partial x} - \xi \frac{\partial u_1}{\partial y} \right] \tau_{12} \end{aligned} \quad (5)$$

$$\begin{aligned} \frac{\partial \tau_{12}}{\partial t} &= \frac{\eta}{\lambda} \left( \frac{\partial u_1}{\partial y} + \frac{\partial u_2}{\partial x} \right) - \frac{1}{\lambda} \tau_{12} - \frac{\varepsilon}{\eta_0} (\tau_{11} + \tau_{22}) \tau_{12} \\ &\quad - \left( u_1 \frac{\partial \tau_{12}}{\partial x} + u_2 \frac{\partial \tau_{12}}{\partial y} \right) + \left[ \left( 1 - \frac{\xi}{2} \right) \frac{\partial u_2}{\partial x} - \frac{\xi}{2} \frac{\partial u_1}{\partial y} \right] \tau_{11} \\ &\quad + \left[ \left( 1 - \xi \right) \left( \frac{\partial u_1}{\partial x} \right) + \frac{\partial u_2}{\partial y} \right] \tau_{12} + \left[ \left( 1 - \frac{\xi}{2} \right) \frac{\partial u_1}{\partial y} - \frac{\xi}{2} \frac{\partial u_2}{\partial x} \right] \tau_{22} \end{aligned} \quad (6)$$

We discrete variables of the above five equations (2–6). Only discrete results of the equation (2) are given here. Other equations are similarly available. The discrete results of the equation (2) can be written as:

$$\begin{aligned} & \{A\}_{16 \times 16}^n \{u_i\}_{16 \times 1}^n \\ &= \frac{1}{\rho} \left( \{B_1\}_{16 \times 16}^n \{\tau_{11}\}_{16 \times 1}^n + \{B_2\}_{16 \times 16}^n \{\tau_{12}\}_{16 \times 1}^n \right) \\ & - \left( \sum_{m=1}^{16} u_1(m) \{E_1(m)\}_{16 \times 16}^n \right) \{u_i\}_{16 \times 1}^n \\ & - \left( \sum_{m=1}^{16} u_2(m) \{E_2(m)\}_{16 \times 16}^n \right) \{u_i\}_{16 \times 1}^n \end{aligned} \quad (7)$$

here,  $\{A\}_{16 \times 16}$ ,  $\{B_1\}_{16 \times 16}$ ,  $\{B_2\}_{16 \times 16}$ ,  $\{E_1(m)\}_{16 \times 16}$ ,  $\{E_2(m)\}_{16 \times 16}$  are the corresponding stiffness matrix.

Then, we use the semi implicit Euler method to get discrete time variable of equation (2). First, we rewrite the semi discrete scheme (7) as:

$$\begin{aligned} & \{A\}_{16 \times 16}^n \left\{ \frac{\partial u_i}{\partial t} \right\}_{16 \times 1}^n \\ &= \{F(\tau_{11}, \tau_{12})\}_{16 \times 1}^n - \{G(u_1, u_2)\}_{16 \times 16}^n \{u_i\}_{16 \times 1}^n \end{aligned} \quad (8)$$

Second, we can get the semi implicit Euler scheme:

$$\begin{aligned} & \frac{1}{\Delta t} \{A\}_{16 \times 16}^n \{u_i\}_{16 \times 1}^{n+1} - \frac{1}{\Delta t} \{A\}_{16 \times 16}^n \{u_i\}_{16 \times 1}^n \\ &= \{F(\tau_{11}, \tau_{12})\}_{16 \times 1}^n - \{G(u_1, u_2)\}_{16 \times 16}^n \{u_i\}_{16 \times 1}^n \end{aligned} \quad (9)$$

### 3 THREE KINDS OF NUMERICAL INTEGRATION

Considering the complexity of the integrand, we use three kinds of integral methods—Gauss, Gauss-Lobatto and Newton-Cotes to compute numerical integration in the calculation of stiffness matrices [8,10].

For one-dimensional numerical integral formula of Gauss type, when  $n = 3$ , integral nodes are  $\pm 0.3398810$ ;  $\pm 0.9061793$ , the corresponding coefficients of integral formula are 0.6521452, 0.2369269. For one-dimensional numerical integral formula of Gauss-Lobatto type, when  $n = 3$ , integral nodes are  $\pm 1$ ;  $\pm 0.447214$ , the corresponding coefficients of integral formula are 1/6; 5/6. For one-dimensional numerical integral formula of Newton-Cotes type, when  $n = 3$ , integral nodes are  $\pm 1$ ;  $\pm 1/3$ , the corresponding coefficients of integral formula are 1/8; 3/8.

In two-dimensional case, we take numerical integration approach of choosing the same number of integration points along the x, y direction.

$$I = \int_{-1}^1 \int_{-1}^1 f(x, y) dx dy = \sum_{i=1}^n \sum_{j=1}^n W_i W_j f(x_i, x_j) \quad (10)$$

here,  $W_i, W_j$  are weight coefficients.

Of course, the way of two-dimensional integration is not unique. The stiffness matrix is not the

same obtained by different numerical integration, which lead to the different calculation error.

### 4 NUMERICAL RESULTS

In this section, numerical results obtained by the above numerical integration are presented. The test domain is in  $[0,4] \times [0,4]$  square. We simulated the domain's velocity and stress change under the action of different force. Grid deformation is used to shows the change in the velocity field. In this paper, the space step  $h = 1$  and time step  $\Delta t = 1$  are chosen in the finite element method. The initial position is shown in Figure 3

The following each figure has three mesh deformation diagrams corresponding to three numerical integration methods. In Figure 4, the results are obtained by using Gauss, Gauss-Lobatto and Newton-Cotes integration on  $T = 2$ . The mesh deformation results using three numerical integration on  $T = 3$  are shown in Figure 5.

The following tables show the numerical solution of velocity field  $u$  on mesh node with finite

element method, the mesh node number may refer to [3]. Due to external forces acting on the upper and lower bounds, so the numerical solutions of the grid nodes on this boundary are not given. The following formula:

$$u = \sqrt{u_1^2 + u_2^2} \quad (4.1)$$

is used to calculate the effective velocity.

We set initial value are  $u_1 = 0.08$  and  $u_2 = 0$ . It is easy to know  $u = 0.08$  according to (11). Table 1 lists numerical results of the stress on the grid nodes using the three numerical integration methods when  $T = 2$ . The numerical results of the stress using the three numerical integration methods on  $T = 3$  are shown in Table 2.

## 5 CONCLUSION

We have presented three kinds of numerical integration methods for solving a finite element problem for the coupling equations. Different numerical integration methods lead to the numerical solutions vary widely. Therefore, in order to reduce calculation errors, we should choose the appropriate numerical integration methods. Some other numerical integration methods to improve accuracy of numerical solution will be discussed in the future.

**ABSTRACT:** It is a meaningful and challenging task to exactly grasp the temperature of conducts in an operational transmission line. A typical uniform temperature distribution of a specific section of overhead conduct is assumed by traditional methods, but several experiments found that this is not true and temperature differences existed in the radial direction. To accurately solve the radial temperature field of conducts, a numerical simulation method is proposed based on 2-D steady-state heat transfer control functions, in which main heat gains and heat loss of conducts are considered. The method has been applied to the type-JL/LB1A-300/50 Aluminum Conductor Steel Reinforced (ACSR) conductor. The results proved the existence of an inappropriate temperature difference in the radial direction of conduct.

**Keywords:** overhead conductor; radial temperature field; numerical simulation

### 1 INTRODUCTION

Along with the rapid economic development, the consumption of electric power has increased significantly over the past few years. Inadequate power supply, especially in peak hours, has become an increasingly critical problem. To resolve this problem, except for upgrading the existing power grids and constructing new transmission lines, another alternative is to dynamically increase the current-carrying capacity of overhead lines in service. Dynamic capacity-increase technology can fully tap the potential of existing lines, and it has the advantages of small investment and quick return. It can provide a higher current-carrying capacity than that determined by formulas in specifications, because it determines the threshold of current-carrying based on the thermal equilibrium theory and using the information of conductor temperature, ambient temperature and wind speed. To ensure the stability and safety of power grid operation when this technology is applied, a critical and difficult task is to exactly determine the temperature of operating lines.

The traditional methods based on the thermal equilibrium theory assume a uniform temperature within the conductor (Peng et al. 2008 & IEEE Std. 2003), but, in fact, it is not the true. Some experimental measurement results indicated that temperature differences within a conductor may reach up to 5–15°C (Douglass et al. 1985). Actually, some radial temperature field analyses of typical

conductors were conducted by introducing several simplifications. For example, conductor models established by Black et al. (1988) and Morgan & Findlay (1993) use assumptions that distances between the neighboring metal wires in the steel core and the aluminum strand are neglected, and that the steel core and the aluminum strand are homogeneous cylinder and cylinder hollow cylinder, respectively, and tightly contact between two layers. Therefore, in a simple way, the effective radial thermal conductivity was adopted to simulate radial thermal transfer within the complicated structure of the conductor. The computational accuracy of this method is largely dependent on whether the effective radial thermal conductivity adopted is reasonable or not, but it is rather difficult to determine precisely. Recently, some FE model-based methods were proposed to simulate the radial temperature field of the conductor (Zhao et al. 2007, He & Li 2010). This method enables us to establish a model fully according to the actual structure of the conductor. Until now, few studies have comprehensively analyzed the effects of the distribution pattern of voids within the conductor, contacts among metal wires, and convention conditions on the temperature field of the conductor.

Therefore, this paper establishes a more delicate conductor model based on 2-D steady-state heat transfer control functions, in which the main heat gain and heat loss of conducts, the void distribution and the contact between metal wires are

considered, and then develops a numerical iterative method for the accurate solution of the radial temperature field of the conductor, and finally applies it to the type-JL/LB1A-300/50 Aluminum Conductor Steel Reinforced (ACSR) conductor.

## 2 RADIAL HEAT TRANSFER WITHIN A CONDUCTOR

Heat within an overhead conductor is generated by electrical ohmic losses. The core is hotter than the surface of the conductor, thus heat radially transfers to the surface, and then dissipated to the surrounding air through heat convections and heat radiations. There are two parallel radial heat transfer paths for concentric-lay-stranded conductors: (1) asperities and air gaps at the contact points between the crossing wires and (2) triangular and rectangular voids between adjacent layers. Morgan & Findlay (1993) studied the radial heat flow in a current-carrying multi-layer stranded conductor, and found that most of the heat transfers through the air gaps at the contacts between strands and through the voids between adjacent layers.

IEEE Standard (2013) concluded the main factors that influence the radial temperature distribution within an aluminum conductor, including the magnitude of the electric current in aluminum layers, electric resistance of aluminum wires, geometric shape of strands (e.g. circular, trapezoidal or "Z"-shaped), number of strand layers, aging situation (e.g. corrosion and bird-caging), contact area and contact forces between layers. Among them, the first two factors mainly affect the magnitude of heat generated within a conductor, and the latter four mainly influence the number and distribution of air gaps and voids in the conductor. The existence of air gaps and voids largely affects the actual radial temperature distribution. Therefore, it must be properly considered in the simulation of radial temperature distribution of the conductor using numerical methods.

## 3 SOLUTION OF THE RADIAL TEMPERATURE FIELD

### 3.1 Two-dimensional steady heat transfer equation

Heat transfer through strands and voids within a conductor accords with the 2-dimensional (2D) steady heat transfer control equation, and thus the heat equilibrium equation in the whole cross-sectional area  $\Omega$  is established as follows (He & Li 2010):

$$k(T_{,xx} + T_{,yy}) + s = 0, (x,y) \in \Omega \quad (1)$$

and the equilibrium equation of heat dissipation at the boundary of the conductor  $\Gamma$  is as follows (He & Li 2010):

$$q_n = -k(T_{,x}n_x + T_{,y}n_y) = \alpha(T_s - T_a), (x,y) \in \Gamma \quad (2)$$

where  $T$  is the two-dimensional temperature field in the conductor;  $T_{,xx}$ ,  $T_{,yy}$ ,  $T_{,x}$  and  $T_{,y}$  are the second and first derivative of coordinates  $x$  and  $y$ , respectively, with materials of the conductor being assumed to be isotropic;  $k$  is the thermal conductivity of the metal or air;  $s$  is the heat gain rate per unit volume and its value varies in different areas of a conductor;  $q_n$  is the heat loss rate in the outward normal direction of the conductor's surface;  $n_x$ ,  $n_y$  are the  $x$  and  $y$  components of the normal direction  $n$ , respectively;  $\alpha$  is the composite coefficient of heat dissipation; and  $T_s$  and  $T_a$  are the surface temperature of the conductor and the ambient temperature, respectively.

Using the principle of virtual work to obtain partial integrations of Equation (1), and then introducing to the boundary conditions of Equation (2), we obtain the following equation as follows:

$$\int_{\Omega} \delta T_{,i} k T_{,i} d\Omega + \int_{\Gamma} \delta T \alpha T d\Gamma = \int_{\Omega} \delta T s d\Omega + \int_{\Gamma} \delta T \alpha T_a d\Gamma \quad (3)$$

### 3.2 Heat gain and loss of transmission conductor

ACSR conductors have been widely used in the existing overhead transmission lines for their large current-carrying capacity and stable performance. Given that the main sources of heat gain and loss for different conductors are different, ACSR conductors are chosen for further discussion. For a typical cross-section of ACSR conductors, it consists of outer-layer aluminum strands and inner-layer steel strands.

Heat sources of a conductor mainly include two parts: current heating (or Joule heating) and solar heating. Since the inner steel core cannot be directly affected by sunshine, current heating is the only heat source considered for it. The heat gain rate of steel core per unit volume is as follows:

$$S_s = \frac{P\lambda(\lambda+1)}{A_s} \quad (5)$$

where  $\lambda$  is the current ratio of steel core  $I_s$  to aluminum strands  $I_a$ ;  $A_s$  is the cross-sectional area of the steel core; and  $P$  is the total heat gain rate. For the

outer-layer aluminum strands, solar heating should be taken into consideration, and thus the heat gain rate per unit volume is as follows:

$$S_a = \frac{P(\lambda + 1)}{A_a} + \frac{\gamma_{sSD}}{A_a} \quad (6)$$

where  $S$  is the solar radiation intensity;  $\gamma_s$  is the solar radiation absorptivity of the conductor, which falls in the range of 0.27–0.95; and  $D$  is the external diameter of the conductor.

Convective cooling  $P_c$  and radiative cooling  $P_r$  are two major ways of heat loss for ACSR conductors. The composite thermal dissipation coefficient of the conductor's surface in Equation (2) can be determined as follows:

$$\alpha = \frac{P_c + P_r}{(T_s - T_a)A} \quad (7)$$

where  $A$  is the side superficial area per length.

### 3.3 Main procedure of the numerical solution

The equation of the radial temperature field indicates that several critical parameters are the function of mean temperature or surface temperature of the conductor, such as thermal conductivity of air, heat gain rate of the steel core and aluminum strands per unit volume, and composite coefficient of heat dissipation. Hence, a series of numerical iterations are used to obtain a stable solution of radial temperature field of the conductor. The main procedure of the numerical iterative solution is concluded as follows:

1. Establish a geometry model for the cross-section of a conductor by the FE method;
2. Set an initial temperature field of the conductor  $T_n^i (n = 0)$ ;
3. Calculate the mean temperature and surface temperature of the section based on the temperature field of the conductor at the  $n$ th step  $T_n^i$ ;
4. Solve the thermal conductivity of air, heat gain rate per unit volume, and composite coefficient of heat dissipation at the  $n$ th step;
5. Solve the temperature field of the conductor at the  $(n + 1)$ th step after introducing the boundary conditions in Equation (2);
6. Repeat steps (3–5) if  $\sum_{i=1}^N |T_{n+1}^i - T_n^i| > tol$ , otherwise output computational result of the temperature field.

Here,  $N$  is the number of Degrees of Freedom (Dof) of the FE model;  $T_n^i$  and  $T_{n+1}^i$  are the temperature of the  $i$ th node at the  $n$ th and  $(n + 1)$ th step; and  $tol$  is the tolerance.

## 4 NUMERICAL SIMULATION OF THE RADIAL TEMPERATURE FIELD

### 4.1 Conductor model for temperature field analysis

As an example, the FE model of the type-JL/LB1A-300/50 ACSR conductor is established according to the geometrical parameters of this conductor. The FE model of the type-JL/LB1A-300/50 ACSR conductor is established and shown in Figure 1b. It is composed of 5804 nodes and 11076 elements.

### 4.2 Radial temperature field of the conductor in the natural convection condition

To determine the radial temperature field of the aforementioned conductor in a typical operational environment, some fundamental computational parameters are input as follows: Alternating Current (AC)  $I_{ac} = 500$  A; Direct Current (DC) resistance  $R_{dc} = 0.0916$   $\Omega/\text{km}$ ; resistivity of the steel core  $\rho_s = 20 \times 10^{-8}$   $\Omega \cdot \text{km}$  and aluminum strand  $\rho_a = 2.8 \times 10^{-8}$   $\Omega \cdot \text{km}$ ; thermal conductivity of the steel core  $k_s = 80$   $\text{W}/(\text{m} \cdot ^\circ\text{C})$  and aluminum strand  $k_a = 237$   $\text{W}/(\text{m} \cdot ^\circ\text{C})$ ; and solar radiation  $S = 900$   $\text{W}/\text{m}^2$ .

First, the radial temperature field of the conductor in the natural convection condition is simulated. The wind speed for the natural convection condition is  $V_w = 0$  m/s. Using the numerical iterative solution in Section 3.3, the results can be obtained. The heating rates of the steel core and the aluminum strand are  $S_a = 1.2 \times 10^5$   $\text{W}/\text{m}^3$  and  $S_s = 1.2 \times 10^4$   $\text{W}/\text{m}^3$ , and the composite coefficient is  $\alpha = 10.5$   $\text{W}/(\text{m}^2 \cdot ^\circ\text{C})$ . Figure 2 shows the radial temperature field of the type-JL/LB1A-300/50 ACSR conductor in the natural convection condition. The results indicate that the highest temperature exists in the aluminum strands of the inner layer, and then in the innermost layer of the steel core, with the lowest one being the outermost layer of aluminum strands. The maximum temperature difference within the conductor is around 4.5°C.

Figure 1. Type-JL/LB1A-300/50 ACSR conductor (unit: mm).

Figure 2. Radial temperature field of the conductor in the natural convection condition (unit: °C).

Some reasons behind the above phenomena are as follows: (1) heat gain rate of aluminum strands is much larger than that of the steel core, and thus the former gains more heat and transfers to the steel core inside; (2) because the steel core of the innermost layer is far from the air convection boundary, the temperature of this layer is relatively high; (3) heat generated in the outermost layer of aluminum strands can be directly dissipated to the surrounding air; therefore, this layer has the highest heat loss rate.

It can also be found that significant differences exist in different strands of the outermost layer. Due to various conditions of contacts between strands, pore distributions and porosities, the actual heat paths and heat transfer efficiencies can be quite different for different local regions of the conductor. The actual contact between strands and contact area does have some effects on the radial temperature field. To study the influence of changing contact locations between strands and the radial temperature field, the contact points between two outermost layers are changed by rotating the outermost aluminum layer in the clockwise direction. Compared with the original temperature field shown in Figure 2, temperature fields for 120° and 240° clockwise rotations are shown in Figure 3. After a comparison, it is found that more heat is transferred from the centre to the surface of a conductor if adjacent aluminum layers closely contact or have less porosity, otherwise heat gathers in the inner layer and causes a local high temperature.

#### 4.3 Radial temperature field of the conductor in the forced convection condition

Furthermore, the radial temperature field of the conductor in the forced convection condition is simulated. In the forced convection condition,

Figure 3. Radial temperature field of the conductor considering different contact positions (unit: °C).

Figure 4. Radial temperature field of the conductor in the forced convection condition (unit: °C).

the wind speed  $V_w$  is assumed to be 0.6 m/s and the wind direction  $d$  is 30°. Using the aforementioned method, the heat gain rates of the steel core and the aluminum strand are determined as  $S_s = 1.1357 \times 10^4 \text{ W/m}^3$  and  $S_a = 1.1736 \times 10^4 \text{ W/m}^3$ , and the composite coefficient of heat dissipation is  $\alpha = 14.4009 \text{ W/(m}^2 \cdot \text{°C)}$ . Figure 4 shows the temperature field of the ACSR conductor in the forced convection condition. Comparing the results in the natural convection condition, we found that: (1) the distribution patterns of the temperature field in different convection conditions are almost the same; (2) the highest temperature of the conductor in the forced convection condition is 12°C lower than that in the natural convection condition; (3) the maximum difference in temperature within a conductor in the forced convection condition is approximately 4°C, and it is very close to that in the natural convection condition. In conclusion, convection conditions have great effects on the average temperature, but a little effect on the radial temperature difference of the conductor.

## 5 CONCLUSIONS

This paper proposes a new computational method for solving the radial temperature field of the

conductor, and then applies it to the type-JL/LB1A-300/50 ACSR conductor. The results proved the existence of an inappropriate temperature difference along the radial direction of conducts, and found that the radial temperature field of the conductor is mainly influenced by the combined effects of the thermal conductivity of metal materials in conductors, contact conditions among strands and external convections.

# Analysis and optimization of the slab transition story support system

S.Y. Xu, S.H. Deng & S.R. Zhu

Beijing University of Civil Engineering and Architecture, Beijing, China

**ABSTRACT:** Research on the construction of the transition story simulation model is proposed. For the first time, the bearing capacity of the concrete story is taken into account. Through a simulation analysis method of a two-story underground and first floor transition story, which are optimized for a multi-story plate frame construction process, the formation of a relatively safe and economical construction technique is ensured, which is verified by a scientific, rational and feasible method. The results showed that the optimization of the transition story support system, which considered the vertical load transfer law, could enable the floor fully to play its role to share the part of the construction load, and make the scaffold template safer, more reliable, economical and reasonable.

**Keywords:** slab transition story; support system; structural design; construction technology

## 1 INTRODUCTION

The transition story system is commonly seen among the high-rise buildings. The transition story has shown a great value and is increasingly well applied. The transition story template support system is one of the key factors in the total construction, and heavily related to the quality and cost of the whole projection.

The load of the members of the support system bearing decreases level by level in the transfer process during the casting construction. This phenomenon shows that each floor could bear its weight and consist the support system in association with the scaffold, exerting the function of support. However at present, the calculation for the transition story template support system is heavily relied on experience, which is excessively safe but leads to wasting. In the current method for designing the support system such as the practical manual for the scaffold of building construction, the transition story concrete casting construction load is applied and the viewpoint that the weight of floors below completely moves down through the support members is adopted. The calculating method corresponding to the viewpoint is adopted without taking the bearing capacity of each floor into consideration. It leads to the common phenomenon that the more support members appear on the lower floors, which increases the difficulty and the cost, and also delays the construction period on its part.

Therefore, the research on the transition story support system is a necessary task. The optimization design of the transition story support system,

which considers the vertical load transfer law, could make the system much more reasonable.

## 2 ESTABLISHMENT MODEL

Simulating the practical process through the FEM analysis software “ANSYS” safely, only single-span slab was taken to analyze the model. The support members were simulated by the unit “PIPE16”, while the beam, slab and the column by the unit “SOLID65”.

On account of simplifying the model, the connection between the support members and the ground was rigid. The connection of the columns and the ground was the same. After dividing the grid and combining the joints, the support

Figure 1. The frame model.

Figure 2. The distribution of the scaffold.

Figure 3. The grid division.

Figure 4. The application of boundary conditions and loads.

members and the slab shared a same joint. They could contact and influence each other.

Figures 1–4 show the analytical model.

### 3 THE OPTIMIZATION OF THE CONSTRUCTION METHOD

#### 3.1 The contraction of solutions

Solution 1: the full load is borne by the template system of each story and moves down to the base.

The materials of the support system need to occupy larger quantities, and take a longer time.

Solution 2: it is designed according to the improved calculation method, when constructing the roof of the first story (the transition story), and the strength of the roof of B2 reaches 100%, while B1 reaches 75%. So, when designing the template support system, it should be considered to remove the roof template and supports of B2 and B1, and place the supports again, so the concrete slab could bear parts of the load. The B2 system bears 100% of the load, and B1 bears 50%.

Solution 2 is much better by contrast. This solution makes the floor fully play its role, in which the scaffold turnover is better and the support system is more secure, reliable, economical and reasonable.

#### 3.2 The improved solution of the constructions

Without considering to bear the load of the transition story transferred, the supports of the roof template of B1 and B2 is placed every  $900 \times 900$  mm to meet the force requirements. Until the construction of the roof of B1, the design strength of B2 reaches 100%. The keel and template of B2 are removed, and the steel tube is re-supported every  $900 \times 900$  mm. The supports of the roof template of B1 are placed every  $900 \times 900$  mm. During transition story pouring, the scaffold members of B1 and B2 are removed and allowed to deform adequately, then the scaffold members of B1 are re-supported after deformation according to every  $450 \times 450$  mm, and then the members of B2 re-supported in the same way. Compared with the former solution, this one could reduce the number of supports and make the scaffold and keel turnover better.

## 4 THE CALCULATION OF THE TEMPLATE SUPPORT SYSTEM AFTER OPTIMIZATION

#### 4.1 The simulation process of construction

When constructing the transition story, the strength of the roof of B2 reaches 100% while B1 reaches 75%. Therefore, we consider B1 and B2, the age and the construction measures of the support system, and then use the concrete slabs to bear load and apply a re-support method. Figure 5 shows the re-support model before construction, and Figure 6 shows the deformation.

During the pouring of the transition story, the scaffold members of B1 and B2 are removed and allowed to deform adequately, and then the scaffold members of B1 are re-supported after deformation, so the load of the scaffold members of B1 bearing is less than that not adopting this method. This can reduce the number of scaffold of B1, and then the

Figure 5. Calculation model.

Figure 6. The vertical displacement of the component joint.

Figure 7. The grid division and the load application.

scaffold members of B2 are re-supported, and the load of the scaffold members of B2 bears is less than that not adopting this method in the same way.

#### 4.2 The construction of the transition story

Pouring concrete of the transition story after re-support, Figure 7 shows the grid division and load application on this model.

## 5 ANALYSIS OF THE CALCULATION RESULT

After modeling and applying the load, we run ANSYS to analyze the model. Simulation results are shown in Figure 8 and Figure 9.

Through the above analysis, we obtain the stress of scaffold supports. The rule between stress and levels is shown in Figure 10.

Through the axial force calculation of supports, we obtain the rule of transition, and then compare the stress of supports on each floor, where the maximum appeared on the first floor while the minimum appeared on B2. So, if we increase the distance of the scaffold and keep the stress of supports uniform, then the number and the expense of scaffold could be saved, and the utilization could be well improved. From the economical comparison of the major material between the solutions before and after optimization, we can conclude that the solution optimized could save reinforcement and concrete, a lot of steel, the labor and the cost.

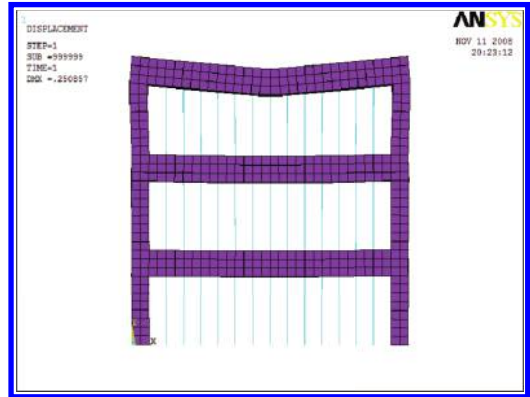

Figure 8. Displacement of the component.

Figure 9. The vertical displacement of the joint.

Figure 10. The stress of the supports of the scaffold (MPa).

## 6 CONCLUSION

Through the above discussion, we can conclude that with a reasonable computer-assisted calculation and manual checking, a breakthrough can be achieved in engineering design. Scientific and rational construction organization can be arranged to achieve the most benefit in practical engineering. When meeting template construction projects similar to this one, if the age strength of the lower floor concrete reaches the template removal conditions, the template is first removed and then the support

system is re-supported, which could make the floor redistribution capacity exert best. The construction measures of the supports are strengthened and implementation of quality of design is emphasized, so these actions can make the frame body more practical and economical. This method for the design of the transition story continuous support system has a wide range of adaptability, convenient usability, a wide application prospect and obviously social and economic benefits.

# Research of roof waterproof technology of steel structure factory building

H. Chen, C.H. Wei & H.L. Li

Chongqing Creation Vocational College, Yongchuan, Chongqing, China

**ABSTRACT:** Due to the high structural strength and a shorter construction cycle before enterprise production, the steel structure factory buildings are now widely applied for current industry. However, under the limitation of construction skills and color steel roof structure, roof leakage is an inevitable problem, which generally exists in steel structure factory buildings. Regarding the defects and limitations in current engineering application as well as deficiency of current engineering skills, this paper proposed the waterproof structure of color steel roof, which can effectively prevent the leakage problem in steel structure factory buildings.

**Keywords:** steel structure; roof; waterproof

## 1 INTRODUCTION

With the increase in construction technology level, during current factory building construction, steel structure is more often adopted. On the one hand, the advanced design theory and high structure strength of steel make less steel usage for today's construction; on the other hand, the standardized and factorization production as well as small machine's lifting work make lower labor intensity and accelerate the construction speed [1] to quickly enter into enterprise production. Current steel structure factory building consists of steel pillar, steel beam and steel purlin. Even though it is very firm in structure, there are big and small gaps existing in the corners of the structure caused by the effect of the large steel structure itself and the unqualified mounting technique of workers. These gaps are the major cause for roof leakage as well as the general problem for current domestic steel structure buildings—"steel roof suffers leakage" [2]—a widespread statement in the engineering construction industry. After completing the construction of steel structure factory building, an additional specialized treatment for roof leakage is often troublesome and costs labor and materials. Therefore, solving the leakage problem is directly related to the normal usage of steel factory buildings during enterprise production. In this paper, waterproof structure of color steel factory building can effectively solve the above problems, and further reinforce the waterproof effects of the factory building, making a simple and quick steel mounting process.

## 2 COMPOSITION AND IMPLEMENTATION OF WATERPROOF STRUCTURE

### 2.1 Roof structure

The waterproof structure of color steel factory building includes steel pillar 1 and steel I-beam 2, and the steel I-beam 2 that is fixed on pillar 1; several evenly laid purlins 3 are fixed on steel I-beam 2. Above purlin 3, there fixed a color steel roof plate 4 parallel to the corresponding purlin 3. Above color steel roof plate 4, there laid roof pressure plate 5; Above roof pressure plate 5, there are several evenly distributed positioning humps 6, and the humps 6 together with roof pressure plate 5 will be produced by a uniform punch forming process. Each positioning hump 6 is equipped with a positioning hole 7.

### 2.2 Steel wall structure

Beside purlin 3, there was fixed a pressure color steel wall plate 8, and in order to enhance the anti-collision ability and avoid deformation due to external force, we adopted the pressure color steel wall plate 8 with a thickness of 15 mm. Between pressure color steel wall plate 8 and purlin 3, we installed an L-type angle steel 9, specifically, the inner side of L-type angle steel 9 was welded on corresponding purlin 3, while the outer side of the angle 9 was riveted to the pressure color steel wall plate 8. Between the pressure color steel wall plate 8 and steel pillar 1, there was installed a U reinforcement connector 12, of which one side was

welded on pillar 1, and the other side was riveted to pressure color steel wall plate 8. Through installing U reinforcement connector 12, the joint strength under pressure color steel wall plate 8 can be effectively enhanced, realizing a more firmly fixing and avoiding shake and looseness.

### 2.3 L-type end bar of the roof

Above roof pressure plate 5, there was mounted L-type end bar 10, and at the upper end of end bar 10, there was set waterproof bevel 13, while the lower end of end bar 10 was in vertical shape, horizontally attaching with the roof pressure plate 5. In addition, the end bar 10 covered some of positioning humps 6 above the roof pressure plate 5, on the positioning holes of covered positioning humps 6, there was mounted self-tapping screws 11, successively penetrating the end bar 10, roof pressure plate 5, and roof plate 4, and locking end bar 10 with roof pressure plate 5. In this process, the focus should be given that the inclination angle of waterproof bevel 13 should be equal to the inclination angle of the side face of positioning hump 6. The waterproof bevel 13 can effectively reduce the probability of rainwater leaking from the gaps of the structure, thus basically avoiding the rainwater leakage problem. In addition, the other end (lower end) of the end bar 10 was vertically attached to the outer side of pressure steel wall plate 8, and the end bar 10 was tightly riveted to the pressure steel wall plate 8. Therefore, the end bar 10, on the one hand, can separate the corners of the structure, realizing the purpose of preventing rainwater leakage, and on the other hand, it enhance the joint strength, improving the tensile capacity of the factory building.

The specific connecting form is shown in Figure 1.

Figure 1. Composition of waterproof structure of color steel factory building.

1-Steel pillar, 2-steel I-beam, 3-Purlin, 4-Color steel roof plate, 5-Roof pressure plate, 6-Positioning hump, 7-Positioning hole, 8-Pressure steel wall plate, 9-Angle steel, 10-End bar, 11-self-tapping screw, 12-U reinforcement connector, 13-Waterproof bevel.

## 3 APPLICATION OF THE WATERPROOF STRUCTURE

The color steel plate, applied in steel factory building construction, plays a major role in waterproofing, wind proofing as well as enhancing the stability of the whole structure; in short, its major function is to keep out wind and rain. Therefore, it entails a higher requirement of waterproofing and anti-leakage ability of color steel itself and the engineering interconnection technique within; especially, the connecting status between steel work pieces to a great degree affects the waterproof performance of the whole structure. At present, normally, flexible waterproof materials [3] are adopted for waterproof roof construction of most steel structure factory building, which solve the leakage problem in most parts of the structure. However, for the intersection portion between the structure wall and the roof, gaps still exist, resulting in deficient waterproof performance by flexible waterproof materials.

This paper proposed a waterproof structure of color steel factory building, which is mainly used in the intersection portion between the structure roof and the wall (area with poor waterproof performance). After completing installation of steel wall and roof, we cover pressure steel roof plates and pressure steel wall plates with the L-type steel end bar, and then using self-tapping screw and rivets to connect pressure steel roof plates and pressure steel wall plates, which can further secure the fixation between them, and cover the gaps between them, greatly enhancing the waterproof ability of the structure. In addition, the proposed waterproof structure can create convenience for factory building construction and later maintenance, and extend the service life of the steel roof plate, which can achieve better performance in solving the leakage problem compared with conventional flexible waterproof materials. Therefore, the structure proposed in this paper can be widely applied in roof waterproofing of color steel structure factory buildings.

## 4 QUALITY CONTROL OF WATERPROOF STRUCTURE CONSTRUCTION

The key point of quality control of the proposed waterproof structure is the lap joint between color steel plates. In the lap joint, we first use rib-plates connecting technique and then fix it by self-tapping screws. In this connecting form, the plate lap joint was fixed with purlin by self-tapping screw, and attention should be paid that between the self-tapping screw and steel, we must add rubber gasket and sealing gum [4], which can prevent

the formation of rigid connection between the end bar and the pressure steel roof plate, getting rid of the occurrence of shakes. In order to prevent rainwater leaking from the gaps between the roof rib-plate and the end bar, we should pay attention during the production that the lap joint between the end bar and the roof plate should contain more than two rib-plates and seal the joint gaps in the lap joint zone. The specific method is to set hidden glue with a width of no less than 2 cm. Moreover, we should strictly control the raw material quality, and conduct specialized treatment to qualified raw materials, for example, rust-proof treatment to self-tapping screws.

## 5 ADVANTAGE AND DISADVANTAGE OF THE WATERPROOF STRUCTURE

Compared with other color steel waterproof structures, the waterproof structure proposed in this paper possesses many advantages. We set reinforcement connector between the pressure steel wall plate and the steel pillar, and one end of the reinforcement connector is welded to the pillar, and the other end of reinforcement connector is riveted to the pressure steel wall plate. Through adjusting the reinforcement connector, we can increase the connecting strength between the pressure steel wall plate and the lower part of the pillar, preventing the shaking movement of the pressure steel wall plate. The pressure steel roof plate and pressure steel wall plate applied in this structure are color steel, wherein, the thickness of the pressure steel roof plate is 5 cm, and the thickness of the pressure steel wall plate is 15 cm. The application of the color steel plate can effectively reduce the weight of the structure, and makes the structure possess a better thermal barrier effect. On one end of the end bar, we set waterproof bevel, for which the inclination angle is the same as that of the positioning hump. Through adjusting the inclination angle of the waterproof bevel, we can further prevent the rainwater leaking from the structure gaps. With the collective function of the waterproof bevel and positioning humps, the rainwater leakage can be fully prevented.

This waterproof structure is designed on the basis of the color steel plate being the roof plate. Through installing the pressure steel roof plate and pressure steel wall plate, a circle can be formed surrounding the steel pillar and roof plate, so as to fundamentally solve the leakage problem and to further enhance the protection effect of the waterproof structure. In addition, possessed with

an excellent thermal barrier performance, good property in bending resistance and pressure resistance, as well as lightweight, the color steel plate can make the installation process more easy and simple, reducing the labor intensity and further extending the service life of factory building.

However, this structure also has some limitations. When combining the roof plate with the cement wall, it is suggested to adopt side retracting connection processing for twice, and while retracting side processing, we should keep a certain angle, and keep fully sealed, and add sealing glue between the retracted sides in advance [5]. The defect is that if the processing is done properly, the waterproof ability will be damped. For example, high tensile strength is necessary to consider for choosing the end bars. When the tensile strength is poor, there may be cracks occurring at the corners of the structure.

## 6 CONCLUSIONS

The promotion and application of steel structure factory buildings can provide convenience for our industrial production. With the emergence of various color steel roofs, the waterproof problem becomes a vital issue in the application of steel structure factory buildings. This paper proposed a waterproof structure, possessing distinguished advantages, which can replace the conventional flexible waterproof materials that have deficient waterproof ability in some particular zones such as gables, gutters and parapets. This new structure has a broader application prospect in the waterproof treatment of color steel roof. In the near future, it will be widely applied.

# Investigation of the effectiveness of vertical load on bending responses for a pile subjected to combined lateral and vertical loads

Fuliang Mei & Guiling Li

*Institute of Mechanics, Jiaxing University, Jiaxing, China*

**ABSTRACT:** Influence of vertical load on bending responses for a partially embedded pile under combined lateral and vertical loads is investigated. The calculated results for a specific pile show that the vertical load can give rise to the additional bending moment and horizontal displacement, and that it has a small influence on maximum horizontal displacement and extreme bending moment when its value is small, but it has a remarkable influence on them when its value is great enough; as its value further increases, the pile may be unstable.

**Keywords:** pile-soil interaction; vertical load; lateral load; bending response; state space method; sub-grade reaction model with three parameters

## 1 INTRODUCTION

In many a circumstance, a number of piles are used to be subjected to combined lateral and vertical loads. In consequence, the prediction of responses for a single pile under lateral and vertical loads simultaneously is urgently an important event in the design, construction and application of pile foundation.

Based on a sub-grade reaction method, a wealth of solutions for a single pile subjected to combined lateral and vertical loads include the following: finite element ones (Karthineyan et al., 2006; Karthigeyan et al., 2007; Zheng et al., 2009), power series ones (Zhao et al., 1987; Wang et al., 2005; Li et al., 2005), and variation principle ones (Han et al., 2000). In the aforementioned solutions, the coefficient of sub-grade reaction is assumed to remain constant or linearly increase with depth (Wang et al., 2005), while it is equal to be zero in the vicinity of ground, so that there is a certain difference between these results and the practical ones. Previously, a three-parameter model, which can authentically represent the distribution of sub-grade reaction with depth and lateral deformation-resisting capability of soil in the vicinity of ground, has been presented for predicting the responses of a pile subjected to a lateral load in the literature (H.L. Wu et al., 2000; B.H. Wang et al., 1999; H. Matlock et al., 1960). Zhang L. et al. (2011) obtained the semi-analytical solution of responses for a pile subjected to oblique loads by using the three-parameter model proposed in H.L. Wu et al. (2000).

In this article, a state space method to solve internal forces and deformations for a partially embedded pile under vertical and lateral loads is given. State space equations for the pile shafts above and below ground are derived according to Euler-Bernoulli's and Winkler' linear elastic beam theory and a sub-grade reaction model with three parameters, and also state space equations for sub-sections above and below ground based on the sub-section approximation approach are presented. The expressions of internal forces and deformations for all the sub-sections are deduced from the matrix theory, boundary conditions and continuity-smooth conditions at the interface between two adjacent sub-sections. Finally, the influence of vertical load on bending responses for a partially embedded pile under combined lateral and vertical loads is investigated.

## 2 STATE SPACE SOLUTION

Consider a uniform cross-section and partially embedded pile subjected to a combined lateral and vertical load, as shown in [Figure 1](#), where  $N_p$ ,  $Q_p$  and  $M_p$  are vertical load, horizontal load and moment load on the pile head, respectively.  $H_0$  and  $H_1$  are the pile lengths above and below ground, respectively.

The force analysis and a local coordinate system for the pile shaft above ground are illustrated in [Figure 2](#), where  $u_g(x)$ ,  $\varphi_g(x)$ ,  $M_g(x)$ ,  $Q_g(x)$  and  $N_g(x)$  are horizontal displacement, declination, moment, shear force and axial force at a depth  $x$ , respectively.

Figure 1. Schematic diagram of a pile under lateral and vertical loads.

Figure 2. Force analysis of a pile shaft above ground.

We can deduce a set state space equations above ground from Euler-Bernoulli's beam theory as follows:

$$\frac{d}{dx} \begin{Bmatrix} u_g(x) \\ M_g(x) \\ Q_g(x) \\ \phi_g(x) \end{Bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & -N_g(x) \\ 0 & 0 & 0 & 0 \\ 0 & 1/EI & 0 & 0 \end{bmatrix} \begin{Bmatrix} u_g(x) \\ M_g(x) \\ Q_g(x) \\ \phi_g(x) \end{Bmatrix} + \begin{Bmatrix} 0 \\ 0 \\ q(x) \\ 0 \end{Bmatrix} \quad (1)$$

where  $EI$  is the pile flexural stiffness,  $N_g(x) = N_p + f_0 x$ , in which  $f_0$  denotes the growth factor of axial force resulting from self-weight, and  $q(x) = q_0 + \Delta q x / H_0$ , in which  $q_0$ ,  $q_0 + \Delta q$  are the distributed loads at the pile head and ground, respectively. It can be noted that Equation (1) is a set of non-homogeneous differential equations of the coordinate  $x$  with variable coefficients.

Similarly, the force analysis and a local coordinate system for the pile shaft below ground are depicted in Figure 3, in which  $u(z)$ ,  $\phi(z)$ ,  $M(z)$ ,  $Q(z)$  and  $N(z)$  are horizontal displacement, rotation angle, moment, shear force and axial force at a depth  $z$ , respectively.

We can obtain another set of state space equations below ground according to Winker's linear elastic foundation beam theory as follows:

$$\frac{d}{dz} \begin{Bmatrix} u(z) \\ M(z) \\ Q(z) \\ \phi(z) \end{Bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & -N(z) \\ -k(z)b & 0 & 0 & 0 \\ 0 & 1/EI & 0 & 0 \end{bmatrix} \begin{Bmatrix} u(z) \\ M(z) \\ Q(z) \\ \phi(z) \end{Bmatrix} \quad (2)$$

where  $N(z) = N_p + f_0 H_0 + f_1 z$ , in which  $f_1$  also is the growth factor of axial friction due to combined self-weight and lateral friction of the pile, say,  $f_1 = \gamma_c A_s - \mu \tau / 2$ , here  $\gamma_c$ ,  $A_s$ ,  $\mu$  and  $\tau$  stand for the specific gravity under water, cross-section area, pile perimeter, limit friction [4], respectively; the coefficient of sub-grade reaction  $k(z)$  is calculated, according to H.L.Wu et al. (2000), as  $k(z) = m(z_0 + z)^n$ , in which  $z_0$  is the equivalent depth standing for the lateral deformation-resisting capability of soil at the ground,  $m$  the proportionality coefficient of the soil, and  $n$  the resistance index of the soil. It can also be noted that Equation (2) is a set of homogeneous differential equations of the coordinate  $z$  with variable coefficients.

Figure 3. Force analysis of a pile shaft below ground.

When the pile head is free, the state space variables (at  $x = 0$ ) is given by

$$\begin{aligned} & \begin{bmatrix} u_g(0) & M_g(0) & Q_g(0) & \varphi_g(0) \end{bmatrix}^T \\ & = \begin{bmatrix} u_g(0) & M_p & Q_p & \varphi_g(0) \end{bmatrix}^T \end{aligned} \quad (3)$$

where  $u_g(0)$  and  $\varphi_g(0)$  are the horizontal displacement and rotation angle to be determined.

When the pile base is free, the state space variables (at  $z = H_1$ ) is given by

$$\begin{aligned} & \begin{bmatrix} u(H_1) & M(H_1) & Q(H_1) & \varphi(H_1) \end{bmatrix}^T \\ & = \begin{bmatrix} u(H_1) & 0 & 0 & \varphi(H_1) \end{bmatrix}^T \end{aligned} \quad (4)$$

here,  $u(H_1)$  and  $\varphi(H_1)$  are the horizontal displacement and rotation angle to be determined.

When the pile base is fixed, the state space variables (at  $z = H_1$ ) is expressed by

$$\begin{aligned} & \begin{bmatrix} u(H_1) & M(H_1) & Q(H_1) & \varphi(H_1) \end{bmatrix}^T \\ & = \begin{bmatrix} 0 & M(H_1) & Q(H_1) & 0 \end{bmatrix}^T \end{aligned} \quad (5)$$

here,  $M(H_1)$  and  $Q(H_1)$  are the bending moment and shear force to be determined.

Continuity-smooth conditions at the ground can be represented as follows;

$$\begin{aligned} & \begin{bmatrix} u_g(H_0) & M_g(H_0) & Q_g(H_0) & \varphi_g(H_0) \end{bmatrix}^T \\ & = \begin{bmatrix} u(0) & M(0) & Q(0) & \varphi(0) \end{bmatrix}^T \end{aligned} \quad (6)$$

It can be noted that the exact solutions for Equations (1) and (2) are directly difficult to solve. Thus, we have to use a numerical method. To avoid difficulties in directly solving Equations (1) and (2) with variable coefficients, two pile shafts above and below ground are divided into  $N_0$  and  $N_1$  uniform sub-sections according to a sub-section approximation approach. Here, two sub-section lengths above and below the ground are  $\Delta x = H_0/N_0$  and  $\Delta z = H_1/N_1$ , respectively. Then, two local coordinate systems for a sub-section above and below ground are depicted in Figure 4, respectively.

When  $N_0$  is large enough, the axial force  $N_{gi}$  and the horizontally distributed load  $q_i$  for the  $i$ th sub-section above the ground are assumed to be constant, and they are calculated as follows:  $N_{gi} = N_p + f_0(2i-1)\Delta x/2$  and  $q_i = q_0 + \Delta q(2i-1)\Delta x/(2H_0)$  ( $i = 1, 2, \dots, N_0$ ), respectively. And a set of state space equations for the  $i$ th sub-section above ground are as follows:

Figure 4. Schematic diagrams of sub-sections and local coordinate systems.

$$\begin{aligned} \frac{d}{d\bar{x}} \begin{Bmatrix} u_{gi}(\bar{x}) \\ M_{gi}(\bar{x}) \\ Q_{gi}(\bar{x}) \\ \phi_{gi}(\bar{x}) \end{Bmatrix} & = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & -N_{gi} \\ 0 & 0 & 0 & 0 \\ 0 & 1/EI & 0 & 0 \end{bmatrix} \begin{Bmatrix} u_{gi}(\bar{x}) \\ M_{gi}(\bar{x}) \\ Q_{gi}(\bar{x}) \\ \phi_{gi}(\bar{x}) \end{Bmatrix} \\ & + \begin{Bmatrix} 0 \\ 0 \\ q_i \\ 0 \end{Bmatrix} \quad (i = 1, 2, \dots, N_0) \quad (7) \end{aligned}$$

where  $u_{gi}(\bar{x})$ ,  $M_{gi}(\bar{x})$ ,  $Q_{gi}(\bar{x})$  and  $\phi_{gi}(\bar{x})$  are the horizontal displacement, the bending moment, shear force and rotation angle at a depth  $\bar{x}$ , respectively.

Let

$$\mathbf{H}_{gi} = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & -N_{gi} \\ 0 & 0 & 0 & 0 \\ 0 & 1/EI & 0 & 0 \end{bmatrix} \quad \mathbf{B}_{gi} = \begin{Bmatrix} 0 \\ 0 \\ q_i \\ 0 \end{Bmatrix}$$

Based on the matrix theory, we can obtain a set of relationship equations between two state space variables at the top and bottom of the  $i$ th sub-section above ground:

$$\mathbf{U}_{gi}(\Delta x) = \mathbf{T}_{gi} \mathbf{U}_{gi}(0) + \mathbf{A}_{gi} \quad (8)$$

where  $\mathbf{U}_{gi}(\Delta x) = [u_{gi}(\Delta x) \ M_{gi}(\Delta x) \ Q_{gi}(\Delta x) \ \varphi_{gi}(\Delta x)]^T$  and  $\mathbf{U}_{gi}(0) = [u_{gi}(0) \ M_{gi}(0) \ Q_{gi}(0) \ \varphi_{gi}(0)]^T$  are the state space variables at the bottom and top of the  $i$ th sub-section above ground, respectively:

$$\mathbf{T}_{gi} = \exp(\mathbf{H}_{gi} \Delta x), \quad \mathbf{A}_{gi} = (\mathbf{T}_{gi} \mathbf{H}_{gi}^{-1} - \mathbf{H}_{gi}^{-1}) \mathbf{B}_{gi}$$

When  $N_1$  is large enough,  $N_j(z)$  and  $k_j(z)$  for the  $j$ th subsection are also assumed to be constant, and are calculated as follows:  $N_j = N_p + f_0 H_0 + f(2j-1)\Delta z/2$  and  $k_j = m(z_0 + (2j-1)\Delta z/2)^n$  ( $j = 1, 2, \dots, N_1$ ), respectively. And another set of state space equations for the  $j$ th sub-section below ground are given as follows:

$$\frac{d}{d\bar{z}} \begin{Bmatrix} u_j(\bar{z}) \\ M_j(\bar{z}) \\ Q_j(\bar{z}) \\ \phi_j(\bar{z}) \end{Bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & -N_j \\ -k_j b & 0 & 0 & 0 \\ 0 & 1/EI & 0 & 0 \end{bmatrix} \begin{Bmatrix} u_j(\bar{z}) \\ M_j(\bar{z}) \\ Q_j(\bar{z}) \\ \phi_j(\bar{z}) \end{Bmatrix} \quad (j=1, 2, \dots, N_1) \quad (9)$$

where  $u_j(\bar{z})$ ,  $M_j(\bar{z})$ ,  $Q_j(\bar{z})$  and  $\phi_j(\bar{z})$  are the horizontal displacement, bending moment, shear force and rotation angle at a depth  $\bar{z}$ , respectively.

Let

$$\mathbf{H}_j = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & -N_j \\ -k_j b & 0 & 0 & 0 \\ 0 & 1/EI & 0 & 0 \end{bmatrix}$$

In a similar way, we also can attain another set of relationship equations between two state space variables at the top and bottom of the  $j$ th subsection below ground as follows:

$$\mathbf{U}_j(\Delta z) = \mathbf{T}_j \mathbf{U}_j(0) \quad (j=1, 2, \dots, N_1) \quad (10)$$

where  $\mathbf{U}_j(\Delta z) = [u_j(\Delta z) \ M_j(\Delta z) \ Q_j(\Delta z) \ \phi_j(\Delta z)]^T$  and  $\mathbf{U}_j(0) = [u_j(0) \ M_j(0) \ Q_j(0) \ \phi_j(0)]^T$  stand for the state space variables at the bottom and top of the  $j$ th sub-section below ground, respectively, and  $\mathbf{T}_j = \exp(\mathbf{H}_j \Delta z)$ . From Equations (3)–(6), (8) and (10), a set of relationships between two state space variables at the pile head and base are obtained as follows:

$$\begin{aligned} \mathbf{U}_{N_1}(\Delta z) &= \mathbf{T}_{N_1} \cdots \mathbf{T}_j \cdots \mathbf{T}_1 \mathbf{T}_{gN_0} \cdots \mathbf{T}_{gi} \cdots \mathbf{T}_{g1} \mathbf{U}_{g1}(0) \\ &\quad + \mathbf{T}_{N_1} \cdots \mathbf{T}_j \cdots \mathbf{T}_1 (\mathbf{T}_{gN_0} \cdots \mathbf{T}_{gi} \cdots \mathbf{T}_{g2} \mathbf{A}_{g1}) \\ &\quad + \mathbf{T}_{gN_0} \cdots \mathbf{T}_{gi} \cdots \mathbf{T}_{g2} \mathbf{A}_{g2} + \cdots + \mathbf{A}_{gN_0} \end{aligned} \quad (11)$$

where  $\mathbf{U}_{N_1}(\Delta z) = [u(H_1) \ M(H_1) \ Q(H_1) \ \phi(H_1)]^T$  and  $\mathbf{U}_{g1}(0) = [u_g(0) \ M_g(0) \ Q_g(0) \ \phi_g(0)]^T$  are the state space variables at the pile head and base, respectively. Let  $\mathbf{T}_{N_1} \cdots \mathbf{T}_j \cdots \mathbf{T}_1 \mathbf{T}_{gN_0} \cdots \mathbf{T}_{gi} \cdots \mathbf{T}_{g1} = \mathbf{\Omega}$  and  $\mathbf{T}_{N_1} \cdots \mathbf{T}_j \cdots \mathbf{T}_1 (\mathbf{T}_{gN_0} \cdots \mathbf{T}_{gi} \cdots \mathbf{T}_{g2} \mathbf{A}_{g1} + \mathbf{T}_{gN_0} \cdots \mathbf{T}_{gi} \cdots \mathbf{T}_{g2} \mathbf{A}_{g2} + \cdots + \mathbf{A}_{gN_0}) = \mathbf{\Gamma}$ .

where  $\mathbf{\Omega}$  is a fourth-order matrix and  $\mathbf{\Gamma}$  is a second-order column vector. When both the pile head and base are free, the substitution of boundary conditions Equations (3) and (4) into Equation (11) gives rise to two equations for finding  $u_g(0)$  and  $\phi_g(0)$  at the pile head as follows:

$$\begin{Bmatrix} u_g(0) \\ \phi_g(0) \end{Bmatrix} = - \begin{bmatrix} \Omega_{11} & \Omega_{14} \\ \Omega_{41} & \Omega_{44} \end{bmatrix}^{-1} \times \left( \begin{bmatrix} \Omega_{12} & \Omega_{13} \\ \Omega_{42} & \Omega_{43} \end{bmatrix} \begin{Bmatrix} M_p \\ Q_p \end{Bmatrix} + \begin{Bmatrix} \Gamma_1 \\ \Gamma_4 \end{Bmatrix} \right) \quad (12)$$

When the pile head is free while the pile base is fixed, the substitution of Equations (3) and (5) into Equation (11) yields two equations for finding  $u_g(0)$  and  $\phi_g(0)$  at the pile head:

$$\begin{Bmatrix} u_g(0) \\ \phi_g(0) \end{Bmatrix} = - \begin{bmatrix} \Omega_{21} & \Omega_{24} \\ \Omega_{31} & \Omega_{34} \end{bmatrix}^{-1} \times \left( \begin{bmatrix} \Omega_{22} & \Omega_{23} \\ \Omega_{32} & \Omega_{33} \end{bmatrix} \begin{Bmatrix} M_p \\ Q_p \end{Bmatrix} + \begin{Bmatrix} \Gamma_2 \\ \Gamma_3 \end{Bmatrix} \right) \quad (13)$$

Hitherto, all the internal forces and deformations at the base of the  $i$ th and  $j$ th sub-sections can be calculated step by step by means of Equations (8) and (10) after  $u_g(0)$  and  $\phi_g(0)$  are determined from Equation (12) or Equation (13). Thus, the above solution is called as a state space one.

### 3 EFFECT OF VERTICAL LOAD ON BENDING RESPONSES

In order to investigate the influence of a vertical load on the bending responses, we consider a uniform cross-section and partially embedded pile, in which calculated parameters are taken as follows:  $H_0 = 15$  m,  $H_1 = 30$  m,  $b = 1.8$  m,  $EI = 9.275 \times 10^6$  kN·m<sup>2</sup>,  $q(x) = 0$ ,  $f_0 = 62.345$  kN/m,  $Q_p = 300$  kN,  $M_p = 200$  kN·m,  $N_p = 10000$  kN,  $z_0 = 0.4$  m,  $n = 0.5$  and  $m = 6 \times 10^3$  kN/m<sup>3.5</sup>. We assume that both file head and base are free and the axial force reduces gradually up to zero from the ground to the pile base in a linear fashion. Figures 5–8 show the relationships between bending responses and vertical load for three sets of different lateral loads:  $M_p = 200$  kN·m,  $Q_p = 200$  kN;  $M_p = 600$  kN·m,  $Q_p = 200$  kN;  $M_p = 600$  kN·m,  $Q_p = 400$  kN.

It can be found from Figures 5–7 that the maximum horizontal displacement, maximum bending moment and horizontal displacement at the ground increase slowly with increasing vertical load when the vertical load is small, but they rise rapidly with increasing vertical load when

Figure 5. Maximum horizontal displacements versus vertical load.

Figure 8. Depth at which maximum moment occurs versus vertical load.

Figure 6. Maximum moment versus vertical load.

Figure 7. Horizontal displacements versus vertical load.

the vertical load is big. This effectiveness is called as the  $P-\Delta$  one. Therefore,  $P-\Delta$  effectiveness should not be neglected when both vertical load and pile length above ground are great enough. Additionally, the vertical load has a much greater contribution to the bending responses when both

applied horizontal load and bending moment on the pile head are large enough.

In general, the bending responses for the pile subjected to lateral loads and the compressive responses for the pile under vertical loads are separately calculated, and then the above-mentioned bending and compressive responses are superimposed as those for the pile subjected to the above combined lateral and vertical loads. This theory does not take into account the additional bending responses due to axial force. If the horizontal displacement and the axial force are much smaller, the additional bending responses due to the axial force also are considerably small. But if the horizontal displacement and the axial force are large enough, while the pile length above ground is particularly large, neglecting the effect of the additional moment and additional deformation resulting from the axial force on the bending responses can produce a much greater error.

It also can be found from Figure 8 that the depth where the maximum moment occurs decreases with increasing vertical load.

#### 4 CONCLUSIONS

The state space solution for a partially embedded pile under combined lateral and vertical loads is presented. And the influence of vertical load on the bending responses for a specific partially embedded pile is investigated. On this basis, we can draw the following conclusions: the vertical load can give rise to the additional bending moment and horizontal displacement, and it has a little influence on maximum horizontal displacement and extreme bending moment when its value is small, but it has a remarkable influence on them when its value is great enough; as its value further increases, the pile may be unstable.

**ABSTRACT:** The technique of integral lifting for steel structure acquires rapid development, but the key factor for the hoisting construction safety economy is how to determine the location of lifting. This article takes some integral lifting for steel truss structures as the example, and selected 3 kinds of lifting schemes based on the location and quantity of lifting spots, in accordance with the structural characteristics and forms. This study analyzes and models the 3 kinds of lifting schemes of lifting reaction force, stress ratio, and displacements with MIDAS-Gen, taking economical efficiency and feasibility into account to find out the optimum feasible program. By analyzing and summarizing the location of the lifting spots, the rational collocation principles of the integral lifting of irregular steel structure were found. The conclusions offer references for similar engineering.

**Keywords:** steel roof; integral lifting; lifting spots; contrast of the plan

## 1 INTRODUCTION

In recent years, with the application of steel structure and the development of construction industry, various kinds of the new steel structure systems are springing up constantly. As a consequence, the new technologies, workmanship, and equipment are applied in engineering construction, among which the integral lifting technology develops faster. The integral lifting technology widely applies in the engineering of steel structure, which is developing toward macro-scale and largeness. It has the advantages of less installing height, short period, less scaffold engineering, high security, and so on. The steel structural engineering of National Library Phase, Xiamen West Passenger Station, and Fuzhou International Convention and Exhibition Center adopts the integral lifting technology, with this technology construction costs have been saved, it reduces the time, and has achieved great economic and social efficiency.

The key to a successful integral lifting of irregular steel structure engineering lies in the location of the lifting spots. The influence factors of the project are extensive. This article takes some integral lifting for steel truss structures as the example, makes a detailed analysis on the lifting spots of integral lifting of irregular steel structure engineering.

## 2 GENERAL SITUATION OF THE PROJECT

The project is an integrated super high rise building. It takes a total land area of 932901 m<sup>2</sup> and construction area is 690719 m<sup>2</sup>. The main structure of the project contains 3 parts, they are T1 (58-storey) building, T2 (60-storey) building, and T3 building. They are connected by the skirt building on 11-storeys above ground (2 storeys under ground). The main building is connected by the steel structure at the storey from 43 to 49, the structure form at the storey from 43 to 44 is a space truss structure and it is a frame structure system at the storey from 44 to 49. The elevation of the steel structure is +232.000 m. This project is lifting the space truss structure, the elevation of it is +198.900 m, ranging from 43 to 44 storeys. The space truss structure is 8 m high, the widest span is about 71.6 m, and the weight of steel is about 2729t. The area of the lifting is shown in [Figure 1](#). The model of the space truss structure is shown in [Figure 2](#).

### 2.1 Making sure the location and the number of the lifting points

The lifted structure and the supporting structure for lifting are directly linked to the technology of the integral lifting. Hence, to make sure the location and the number of the lifting spots,

Figure 1. The lifting area.

Figure 2. The model of the structure.

we must take the two factors into consideration, based on mechanical characteristics of the structure itself and comprehensive survey of the economics and safety.

### 2.2 Making sure the location of the lifting points

To make sure the location of the lifting spots, the following principles should be considered:

1. No matter the lifted structure symmetry or not. We should take the center of gravity as the center of symmetry to arrange the lifting spots to assure that the lifting force of each lifting appliance is similar. Only in this way can we purchase equipment easily and the whole process works stably.
2. Lifting spots should choose as far as possible in the location that is good for the structural strain, and avoid inducing the additional stress. Hence the lifting spots should be arranged on or near the truss joints or supports.
3. Heavily influenced by the lifting support structure, the lifting spots in the top chord or the down chord of the structure are arranged. If the lifting spots in the top chord are arranged, then the supporting structure for lifting cannot be arranged on the same storey of the

lifted structure. At this time, the spreaders can be directly welded on the top chord as shown in Figure 3. If the lifting spots in the down chord are arranged, then the supporting structure for lifting can be arranged on the same or the top storey of the lifted structure. Such a hole is unfavorable to the structure stress, so in general, decorate the corbel on each side of the down chord to fix the steel strand, as shown in Figure 4.

### 2.3 Making sure the number of the lifting points

For consideration of economic effectiveness and operation, the lesser the number of the lifting spots, the better they are. But taking safety into consideration, the more the number of the lifting spots, the better they are; in this way, we can ensure that there is safety in the lifting process. So, it is important to take the actual requirement in the lifting process into consideration, and make an analysis on different proposals. At last we find out the proposal to be both safe and economical.

Figure 3. The spreaders arranged on the top chord.

Figure 4. The spreaders arranged on the down chord.

### 3 THE SCHEMES TO ARRANGE THE LIFTING POINTS AND THE CONTRAST OF THE PLANS

According to the characteristics of the project, and to bring forward 3 kinds of lifting schemes for consideration, the above all have been combined with the arrangement principles. Plan 1 is based on the structural characteristics, the location of lifting spots being arranged in a symmetrical way; Plan 2 based on the stress form of the structure, the location of lifting spots arranged on the three sides of the up chord; Plan 3 based on Plan 2, but put the lifting spots arranged on the down chord. In addition, Plan 1 and Plan 2 make the comparison on the structure; Plan 2 and Plan 3 make the comparison on the lifting spots which should be arranged on the top or the down chord.

#### 3.1 The schemes to arrange the lifting points

Plan 1 is adopting the scheme of 10-lifting-spots to lifting the steel truss structures. The lifting spots arranged on the steel truss structures, which connected with T1 and T3. Figure 5 shows the scheme of Plan 1.

Plan 2 is adopting the scheme of 15-lifting-spots to lifting the steel truss structures. Based on Plan 1, Plan 2 added five lifting spots on the steel truss structures, which connected with T2. Figure 6 shows the scheme of Plan 2.

Plan 3 is adopting the scheme of 15-lifting-spots to lifting the steel truss structures. Plan 3 arranged the lifting spots on the down chord that is different from Plan 2. Figure 7 shows the scheme of Plan 3.

Figure 5. The lifting spots arrangement diagram of Plan1.

Figure 6. The lifting spots arrangement diagram of Plan 2.

Figure 7. The lifting spots arrangement diagram of Plan 3.

### 4 CONTRAST OF THE PLANS

The structure was analyzed by software MIDAS after that construction the model of the structure in CAD. Taking the weight of the structure joints into consideration, while setting the parameter of the structure, we find that the parameter of gravity coefficient is 1.3 and the parameter of dynamic coefficient is 1.1. Loading the vertical constraint as boundary condition, it is loaded on the horizontal constraint spring bearing to prevent the movement in a horizontal way in the process of lifting. The stiffness of the spring is an infinitesimal amount.

Figures 8–10 show the lifting reaction force of each lifting spot as well as the stresses and displacements of chord member of truss of Plan 1.

Figures 11–13 show the lifting reaction force of each lifting spot as well as the stresses and displacements of chord member of truss of Plan 2.

Figures 14–16 show the lifting reaction force of each lifting spot as well as the stresses and displacements of chord member of truss of Plan 3.

#### 4.1 The comparison of plan 1 and plan 2

The comparison of Plan 1 and Plan 2 are shown in Table 1.

In view of the lifting reaction force, it is seen that in Plan 1, the gap between the lifting force is too big. The maximum lifting force is 11292.6 kN, it means that we need an elevator with an elevating power of 1129t. At present, the maximum lifting force of the commonly used hydraulic elevator is 405t. That is to say, we have to arrange three elevators with the maximum lifting force of 405t on D10 and design a special spreader for the D10. However, the minimum lifting force is 391.07 kN at D07; it is too small to consider. The lifting force of each spot is relatively uniform and meets the requirement of the hydraulic elevator.

In view of the displacements of the member bars, it is seen that in Plan 1, the maximum displacement is 120.25 mm in the member bars connected with T2. Although it is lower than the limit deformation ( $L/200 = 300$  mm), it creates an inconvenience with

Figure 8. Lifting reaction force of Plan 1.

Figure 12. The displacements of the member bars of Plan 2.

Figure 9. The displacements of the member bars of Plan 1.

Figure 13. The member bars stress ratio of Plan 2.

Figure 10. The member bars stress ratio of Plan 1.

Figure 14. Lifting reaction force of Plan 3.

Figure 11. Lifting reaction force of Plan 2.

Figure 15. The displacements of the member bars of Plan 3.

Figure 16. The member bars stress ratio of Plan 3.

Table 1. The comparisons of Plan 1 and Plan 2.

	Maximum lifting force/kN	Minimum lifting force/kN	Maximum displacements /mm	Maximum stress ratio
Plan 1	11292.58	391.07	120.25	0.98
Plan 2	3617.21	1250.80	52.40	0.85

the truss structures closure. In Plan 2 the maximum deformation is in the largest span and meets the requirements of deformation.

In view of the member bars stress ratio it is seen that in Plan 1, the maximum stress ratio is 0.98 (bigger than 0.9), the stress approaches near the yield strength. In Plan 2 the maximum stress ratio is 0.85 (less than 0.9), which has enough safe margin.

Although the number of lifting spots of Plan 1 is less than Plan 2, taking all factors as a whole, Plan 2 is better than Plan 1.

#### 4.2 The Comparison of Plan 2 and Plan 3

The comparison of Plan 2 and Plan 3 are shown in Table 2.

In view of the lifting reaction force, it is seen that the lifting force of D07 and D11 is smaller than the other lifting spots in the part 3. The two spots can be cancelled.

In view of the member bars position it is seen that the maximum displacement in Plan 3 is larger than that in Plan 2, but they meet the requirements of deformation.

In view of the member bars stress ratio, it is seen that in Plan 3, the maximum stress ratio is 0.58 (more or less than 0.9), which has enough safe margin.

Because of the lifting spots arranged on the down chord, each of the lifting spot needs two elevators, the number of the elevators used in Plan 3 is twice as much as it is in Plan 2. It is hard to control the cost and can not be conducive to improve

Table 2. The comparisons of Plan 2 and Plan 3.

	Maximum lifting force/kN	Minimum lifting force/kN	Maximum displacements /mm	Maximum stress ratio
Plan 2	3617.21	1250.80	52.40	0.85
Plan 3	4565.50	330.03	56.32	0.58

synchronization. Taking all factors as a whole, Plan 2 is better than Plan 3.

Through comparison and analysis, take the safety, maneuverability and economy into consideration, Plan 2 is the best scheme.

## 5 CONCLUSION

The way to arrange the integral lifting for irregular steel structure was more complicated than that for regular steel structure.

By analyzing and summarizing the location of the lifting spots, we find out the rational collocation principles of the integral lifting for irregular steel structure. The conclusions offer references for similar engineering.

- Try to balance the Lifting Force of each lifting-spot
- Make the processing and installation technology of the temporary measures on the lifting spots as easy as possible.
- Try to minimize the influence on the original structure.

# Free vibration analysis on paraboloidal shells of revolution using the Wittrick-Williams algorithm with the consideration of shear deformation and rotary inertia

X.D. Chen

School of Naval Architecture and Civil Engineering, Jiangsu University of Science and Technology, Zhangjiagang, Jiangsu, P.R. China

**ABSTRACT:** This paper analyzed the free vibration of paraboloidal shells of revolution with the consideration of shear deformation and rotary inertia using the Wittrick-Williams algorithm. The vibration of paraboloidal shells of revolution is decomposed into a series of one-dimensional vibration problems. Dynamic stiffnesses of these one-dimensional problems are computed using the ODE solver COLSYS and the Wittrick-Williams algorithm is applied. Numerical examples demonstrated that the present method is applicable and accurate for free vibration analysis of paraboloidal shells of revolution.

**Keywords:** free vibration; paraboloidal shells; Wittrick-Williams algorithm; Hamiltonian governing equations

## 1 INTRODUCTION

Parabolic shells of revolution are widely used in many engineering branches, e.g. civil, mechanical, aeronautical and marine engineering. Investigation on the free vibration of paraboloidal shells of revolution can provide basic parameters for further dynamic analysis, and is of great theoretical and practical significance.

Many researchers investigated the free vibration of paraboloidal shells of revolution<sup>[1][2]</sup>. The above research is based on the traditional thin shell theory. Recently, Kang and Leissa<sup>[3]</sup> conducted three-dimensional analysis on the free vibration of complete paraboloidal shells; Tornabene and Viola<sup>[4]</sup> proposed free vibration analysis of parabolic shells using generalised differential quadrature method based on the first-order shear deformation theory; Al-Khatib and Buchanan<sup>[5]</sup> analyzed the free vibration of a paraboloidal shell of revolution using the three-dimensional finite element method. For moderately thick paraboloidal shells, conventional 2D shell theory with the consideration of transverse shear deformation and rotary inertia is necessary.

In this paper, dynamic stiffness method is employed to obtain the natural frequencies of paraboloidal shells. Governing equations are degraded into a series of one-dimensional vibration problems with respect to different circumferential wave number  $n$ . Ordinary Differential Equations (ODE) solver COLSYS<sup>[6]</sup> is used to solve these

one-dimensional problems and obtain the dynamic stiffnesses. Together with the Wittrick-Williams algorithm<sup>[7]</sup> (refer to W-W algorithm in the context) and bisection, undamped natural frequencies of paraboloidal shells of revolution are found.

## 2 BASIC EQUATIONS

The paraboloidal shell and coordinate system are shown in Figure 1. In  $Oxz$  plane, the meridian equation is

$$z = c \left[ 1 - \left( \frac{x}{a} \right)^2 \right] \quad (1)$$

Figure 1. The diagram of a paraboloidal shell of revolution meridian and its coordinates.

Note that  $u$ ,  $v$  and  $w$  are the displacements in the middle surface of the paraboloidal shell along the meridian, circumferential and normal directions.  $\varphi$  is the angle between the radius of curvature and the positive direction of  $z$  axis;  $\theta$  is the circumferential direction. Young's modulus of the paraboloidal shell is  $E$ , Poisson's ratio is  $\nu$ , density is  $\rho$  and thickness is  $h$ .

According to the moderately thick shell theory, the strain-displacement relationship of a paraboloidal shell of revolution is

$$\{\boldsymbol{\varepsilon}\} = [\mathbf{L}]\{\boldsymbol{\Delta}\} \quad (2)$$

where the strain  $\{\boldsymbol{\varepsilon}\} = \{\varepsilon_{\varphi\varphi}, \varepsilon_{\theta\theta}, \varepsilon_{\varphi\theta}, \chi_{\varphi}, \chi_{\theta}, \chi_{\varphi\theta}, \gamma_{\varphi}, \gamma_{\theta}\}^T$ , and  $\{\boldsymbol{\Delta}\} = \{u, v, w, \psi_{\varphi}, \psi_{\theta}\}^T$ .  $\psi_{\varphi}$  and  $\psi_{\theta}$  are angles along the  $\varphi$  and  $\theta$  directions, respectively.

Similarly, the force-strain relationship of a paraboloidal shell of revolution is

$$\{\mathbf{N}\} = [\mathbf{D}]\{\boldsymbol{\varepsilon}\} \quad (3)$$

where  $\{\mathbf{N}\} = \{N_{\varphi}, N_{\theta}, N_{\varphi\theta}, M_{\varphi}, M_{\theta}, M_{\varphi\theta}, Q_{\varphi}, Q_{\theta}\}^T$ , and matrix  $[\mathbf{D}]$  can be found in Ref. [8].

Denote  $dA$  the area of an infinitesimal portion in a shell of revolution,  $dA = rRd\alpha d\beta$ . The total strain energy  $U$  for free vibration of the shell of revolution can be integrated along the whole middle surface  $S$

$$U = \iint_S \frac{1}{2} \{\boldsymbol{\varepsilon}\}^T [\mathbf{D}]\{\boldsymbol{\varepsilon}\} dA \quad (4)$$

The total free vibration kinetic energy is obtained as

$$T = \frac{\rho}{2} \iint_S \left\{ h \left[ \left( \frac{\partial u}{\partial t} \right)^2 + \left( \frac{\partial v}{\partial t} \right)^2 + \left( \frac{\partial w}{\partial t} \right)^2 \right] + \frac{h^3}{12} \left[ \left( \frac{\partial \psi_{\varphi}}{\partial t} \right)^2 + \left( \frac{\partial \psi_{\theta}}{\partial t} \right)^2 \right] \right\} dA \quad (5)$$

The dynamic displacement functions are

$$\{\boldsymbol{\Delta}\} = \begin{cases} u = u_n(\varphi) \cos n\theta \sin \omega t \\ v = v_n(\varphi) \sin n\theta \sin \omega t \\ w = w_n(\varphi) \cos n\theta \sin \omega t \\ \psi_{\varphi} = \psi_{\varphi n}(\varphi) \cos n\theta \sin \omega t \\ \psi_{\theta} = \psi_{\theta n}(\varphi) \sin n\theta \sin \omega t \end{cases} \quad (6)$$

where  $n$  is the circumferential wave number and  $\omega$  is a circular frequency.

According to the Hamilton principle,

$$\delta \int_{t_1}^{t_2} (U - T) dt = 0 \quad (7)$$

Since time interval  $(t_1, t_2)$  is arbitrary, the symplectic components (generalised displacements and forces) can be obtained from equation (7) after displacement substitution and integration manipulation. Also, the vibration governing equations of paraboloidal shells of revolution can be expressed in the Hamilton form

$$[\mathbf{J}]\{\mathbf{z}'\} = [\mathbf{S}]\{\mathbf{z}\} \quad (8)$$

where  $()'$  denotes the derivative with respect to  $\varphi$ .

$$[\mathbf{J}] = \begin{bmatrix} \mathbf{0} & -\mathbf{I} \\ \mathbf{I} & \mathbf{0} \end{bmatrix} \quad (9)$$

$\mathbf{I}$  is a fifth-order identity matrix;  $[\mathbf{S}]$  is a symmetric tenth-order matrix; and  $\{\mathbf{z}\}$  is the combination of both internal forces and displacements

$$\{\mathbf{z}\} = \{q_1, q_2, q_3, q_4, q_5, p_1, p_2, p_3, p_4, p_5\}^T \quad (10)$$

Expression of  $[\mathbf{S}]$  and  $\{\mathbf{z}\}$  can be found in Ref. [9].

According to the definition of stiffnesses, mathematically apply the boundary conditions in Eq. (11) to equation (8) in turns,

$$\{\mathbf{d}\}^e = \{\mathbf{e}_j\}, \quad j = 1, \dots, 10 \quad (11)$$

where  $\{\mathbf{e}_j\}$  is a unit vector with the  $j$ -th element equals to one; and the element-end displacement vector is

$$\{\mathbf{d}\}^e = \{q_1(\varphi_a), q_2(\varphi_a), q_3(\varphi_a), q_4(\varphi_a), q_5(\varphi_a), q_1(\varphi_b), q_2(\varphi_b), q_3(\varphi_b), q_4(\varphi_b), q_5(\varphi_b)\}^T \quad (12)$$

Note that the element-end force vector is

$$\{\mathbf{F}\}^e = \{-p_1(\varphi_a), -p_2(\varphi_a), -p_3(\varphi_a), -p_4(\varphi_a), -p_5(\varphi_a), p_1(\varphi_b), p_2(\varphi_b), p_3(\varphi_b), p_4(\varphi_b), p_5(\varphi_b)\}^T \quad (13)$$

The shell segment element dynamic stiffness matrix  $[\mathbf{k}]^e$  is formulated in Eq. (14).

$$[\mathbf{k}]^e = \{ \{\mathbf{F}\}_{j=1}^e, \{\mathbf{F}\}_{j=2}^e, \{\mathbf{F}\}_{j=3}^e, \{\mathbf{F}\}_{j=4}^e, \{\mathbf{F}\}_{j=5}^e, \{\mathbf{F}\}_{j=6}^e, \{\mathbf{F}\}_{j=7}^e, \{\mathbf{F}\}_{j=8}^e, \{\mathbf{F}\}_{j=9}^e, \{\mathbf{F}\}_{j=10}^e \} \quad (14)$$

Elements of force vector  $\{\mathbf{F}\}^e$  are solved numerically using COLSYS. The global dynamic stiffness matrix  $\mathbf{K}$  of the shell of revolution is assembled in a straightforward way according to regular element location vectors.

### 3 WITTRICK-WILLIAMS ALGORITHM

The W-W algorithm does not solve eigenvalues directly but count the number of frequencies below a given value  $\omega^*$  of interest. The expression of the W-W algorithm is

$$J = J_0 + J_K \quad (15)$$

where  $J$  is the number of frequencies exceeded by a specific trial frequency  $\omega^*$ ;  $J_K = s\{\mathbf{K}(\omega^*)\}$  is the sign count of the global dynamic stiffness matrix  $\mathbf{K}$  and equals to the number of negative elements on the diagonal of an upper triangular matrix obtained from  $\mathbf{K}$  by applying standard Gaussian elimination without row exchange;  $J_0$  is the number of frequencies still exceeded by  $\omega^*$  when segment elements are clamped at both ends and can be guaranteed to be zero should there are enough shell segments along the meridian.

If there are not enough shell segments along the meridian,  $J_0$  can be accumulated from  $J_0^e$  of each shell segment element over the whole meridian

$$J_0 = \sum J_0^e \quad (16)$$

Further discussions on the calculation of  $J_0$  can be found in Ref [9].

### 4 NUMERICAL EXAMPLES

#### 4.1 Example 1: free vibration of a free-fixed paraboloidal dome

Tornabene and Viola<sup>[4]</sup> calculated the lowest five natural frequencies of a free-clamped parabolic dome using the generalized differential quadrature method with the data given in Table 1. The geometric and physical parameters of the paraboloidal dome are: height  $H = 2$  m, thickness  $h = 0.1$  m,  $a = 4$  m,  $c = 2.133$  m,  $\rho = 7800$  kg/m<sup>3</sup>, Young's modulus  $E = 2.1 \times 10^{11}$  N/m<sup>2</sup>, and Poisson's ratio  $\nu = 0.3$ . Results obtained from the present dynamic stiffness method are also tabulated in Table 1 for comparison with corresponding  $(n, m)$  combinations.

Table 1. The lowest five natural frequencies of a free-clamped dome (Hz).

Order	$(n, m)$	Present	Ref. [4]
1	(2, 1)	91.68	91.24
2	(3, 1)	132.33	131.29
3	(4, 1)	154.79	154.91
4	(1, 1)	160.63	157.99
5	(5, 1)	168.19	169.46

Table 2. Frequencies  $\Omega = \omega c \sqrt{\rho/G}$  for a paraboloidal shell cap with  $a = c$ .

$n$	Present	Ref. [5]
0	1.798	1.774
1	1.162	1.159
2	1.180	1.166
3	1.157	1.133
4	1.283	1.240

Table 3. Frequencies  $\Omega = \omega c \sqrt{\rho/G}$  for a paraboloidal shell cap with  $a = 2c$ .

$n$	$m$	Present	Ref. [5]
0	1	0.6998	0.6955
	2	0.8004	0.7896
	3	0.9263	0.9177
1	1	0.6058	0.6043
	2	0.7325	0.7252
	3	0.8793	0.8612

The results obtained from the present method agree very well with data from Ref. [4], showing good convergence and accuracy of the proposed method.

#### 4.2 Example 2: free vibration of a fixed paraboloidal cap

Al-Khatib and Buchanan<sup>[5]</sup> analysed fixed paraboloidal shell caps with  $\nu = 0.3$ ,  $h = 1/20c$ . The apex of paraboloidal shells is closed. To avoid singularity at the apex, a commonly-applied small circular hole<sup>[10]</sup> is employed at the apex so that singularity can be avoided without reducing accuracy. Table 2 listed the lowest natural frequencies when  $a = c$  with  $n$  from 0 to 4; Table 3 gave the first three frequencies when  $a = 2c$  with  $n = 0$  and 1, respectively. Both results from the present method and the Ref. [5] are given for comparison.

The data from the present method reach good agreement with that from Ref. [5], demonstrating that the proposed dynamic stiffness method is capable of analysing the free vibration of apex-completed paraboloidal shells of revolution.

### 5 CONCLUSIONS

The formulation established in this paper is applicable to the free vibration analysis of a variety paraboloidal shell of revolution. Results from the present method are well validated with that from existing literatures. The proposed method can be

straight-forwardly extended to other shape shells of revolution, e.g. spherical, elliptical, hyperbolic shells and etc.

# R-Function Theory method for free vibration of slip clamped trapezoidal shallow spherical shell

Shanqing Li & Hong Yuan

MOE Key Laboratory of Disaster Forecast and Control in Engineering, Institute of Applied Mechanics, Jinan University, Guangzhou, China

**ABSTRACT:** In this paper, the R-Function Theory (RFT) is applied to solve the free vibration of slip clamped trapezoidal shallow spherical shell. Firstly the fundamental solution of the biharmonic operator, the boundary equation and the R-function are used to construct the quasi-Green's function. Then the model governing differential equation of the problem is reduced to the Fredholm integral equation of the second kind by Green's formula. The singularity of the kernel of the integral equation is overcome by choosing a suitable form of the normalized boundary equation by the R-function. A numerical example shows that this method is an effective numerical method.

**Keywords:** R-function; Green's function; integral equation; free vibration; shallow spherical shell

## 1 INTRODUCTION

In the paper, the R-function theory proposed by Rvachev [1] are utilized. The free vibration of slip clamped trapezoidal shallow spherical shell is studied. A quasi-Green function is established by using the fundamental solution and the boundary equation of the problem. This function satisfies the homogeneous boundary condition of the problem, but it does not satisfy the fundamental differential equation. The key point of establishing the quasi-Green function consists in describing the boundary of the problem by normalized equation  $\omega=0$  and the domain of the problem by inequality  $\omega>0$ . There are multiple choices for the normalized boundary equation. Based on a suitably chosen form of the normalized boundary equation, a new normalized boundary equation can be established such that the singularity of the kernel of the integral equation is overcome. For any complicated area, a normalized boundary equation can always be found according to the R-function theory. Thus, the problem can always be reduced to the Fredholm integral equation of the second kind without singularity. Using the present method, Li and Yuan solved successfully the free vibration of clamped thin plates [2], the simply-supported thin plate [3,4] and shallow spherical shells [5,6]. For the first time, the proposed R-function theory method is applied to study the free vibration problem of slip clamped trapezoidal shallow spherical shell. The numerical example demonstrates the efficiency and the feasibility of the R-function theory method.

## 2 FUNDAMENTAL EQUATIONS

The governing differential equations of the free problem of slip clamped trapezoidal shallow spherical shell [7] can be expressed as follow

$$\nabla^4 \varphi(\mathbf{x}, t) - \frac{Eh}{R} \nabla^2 w(\mathbf{x}, t) = 0, \quad \mathbf{x} \in \Omega, \quad (1)$$

and

$$D \nabla^4 w(\mathbf{x}, t) + \frac{1}{R} \nabla^2 \varphi(\mathbf{x}, t) + \bar{m} \frac{\partial^2 w(\mathbf{x}, t)}{\partial t^2} = 0, \quad \mathbf{x} \in \Omega, \quad (2)$$

where  $\nabla^4 = (\partial^2/\partial x_1^2 + \partial^2/\partial x_2^2)^2$  is the biharmonic operator,  $\varphi$  is the stress function,  $w$  is the radial deflection of the shell,  $R$  is the radius of curvature of the shell,  $\mathbf{x} = (x_1, x_2)$ ,  $\Omega$  is the domain of the trapezoid of shallow spherical shells in Cartesian coordinates,  $t$  is time; and  $D = Eh^3/(12(1-\nu^2))$  is the flexural rigidity of the shell, in which  $h$  is the thickness of the shell, and  $E$  and  $\nu$  are Young's modulus and Poisson's ratio, respectively.

The slip clamped boundary conditions can be written as

$$w|_{\Gamma} = \frac{\partial w}{\partial n}|_{\Gamma} = \varphi|_{\Gamma} = \nabla^2 \varphi|_{\Gamma} = 0, \quad (3)$$

where  $\nabla^2 = \partial^2/\partial x_1^2 + \partial^2/\partial x_2^2$  is the Laplace operator, and  $\Gamma = \partial\Omega$  is the boundary of the domain  $\Omega$ .

Making use of Eqs. (1) and (3), we can easily obtain

$$\nabla^2 \varphi = wEh/R. \quad (4)$$

Substituting Eq. (4) into Eq. (2) yields

$$D\nabla^4 w + \frac{Eh}{R^2} w + \bar{m} \frac{\partial^2 w}{\partial t^2} = 0. \quad (5)$$

The model governing differential equation can be obtained as follow

$$D\nabla^4 W(\mathbf{x}) + \frac{Eh}{R^2} W(\mathbf{x}) - \bar{\omega}^2 \bar{m} W(\mathbf{x}) = 0, \quad \mathbf{x} \in \Omega \quad (7)$$

$$W = 0, \quad \frac{\partial W}{\partial n} = 0, \quad \mathbf{x} \in \Gamma. \quad (8)$$

where  $W$  is the model function.

### 3 INTEGRAL EQUATIONS

Let  $\omega = 0$  be the normalized boundary equation of the first-order on the boundary  $\Gamma$ , i.e.[1]

$$\omega(\mathbf{x}) = 0, \quad |\nabla \omega| = 1, \quad \mathbf{x} \in \Gamma \text{ and } \omega(\mathbf{x}) > 0, \quad \mathbf{x} \in \Omega. \quad (9)$$

The quasi-Green function can be established as follows:

$$G(\mathbf{x}, \xi) = -r^2 \ln r - e(\mathbf{x}, \xi), \quad (10)$$

$$\text{and } e(\mathbf{x}, \xi) = -r^2 \ln R_1 + 2\omega(\mathbf{x})\omega(\xi), \quad (11)$$

where  $r = \|\xi - \mathbf{x}\| = \sqrt{(\xi_1 - x_1)^2 + (\xi_2 - x_2)^2}$  and  $R_1 =$

$$\sqrt{r^2 + 4\omega(\xi)\omega(\mathbf{x})}, \quad (12)$$

in which  $\mathbf{x} = (x_1, x_2)$  and  $\xi = (\xi_1, \xi_2)$ . Obviously, the quasi-Green function  $G(\mathbf{x}, \xi)$  satisfies the following condition

$$G(\mathbf{x}, \xi)|_{\xi \in \partial\Omega} = 0 \quad \text{and} \quad \left. \frac{\partial G(\mathbf{x}, \xi)}{\partial n} \right|_{\xi \in \partial\Omega} = 0. \quad (13)$$

In order to reduce the boundary value problems Eq. (7) and Eq. (8) into an integral equation, the following Green's formula of sets of function  $C^4(\Omega)$ , i.e.,  $U, V \in C^4(\Omega \cup \Gamma)$ , is applied

$$\begin{aligned} & \int_{\Omega} (V\nabla^4 U - U\nabla^4 V) d\xi \Omega \\ &= \int_{\partial\Omega} \left[ V \frac{\partial}{\partial n} (\nabla^2 U) - \frac{\partial V}{\partial n} \nabla^2 U - U \frac{\partial}{\partial n} (\nabla^2 V) \right. \\ & \quad \left. + \frac{\partial U}{\partial n} \nabla^2 V \right] d\xi \Gamma. \end{aligned} \quad (14)$$

Replacing  $U$  and  $V$  in Eq. (10) by  $w$  and Green quasifunction  $G$ , noticing that  $(1/8\pi)r^2 \ln r$  is the fundamental solution [6] of the biharmonic operator, and using Eqs. (7), (8) and (13), we can easily obtain

$$W(\mathbf{x}) = \int_{\Omega} W(\xi) K(\mathbf{x}, \xi) d\xi \Omega, \quad (15)$$

where

$$\begin{aligned} K(\mathbf{x}, \xi) = & -\frac{1}{8\pi} \left( \frac{\partial^4}{\partial \xi_1^4} + 2 \frac{\partial^4}{\partial \xi_1^2 \partial \xi_2^2} + \frac{\partial^4}{\partial \xi_2^4} \right) e(\mathbf{x}, \xi) \\ & + \frac{1}{8\pi} \left( \frac{Eh}{DR^2} - \frac{\bar{\omega}^2 \bar{m}}{D} \right) G(\mathbf{x}, \xi). \end{aligned} \quad (16)$$

Substituting Eq. (11) into Eq. (16), we can obtain the expression of  $K(\mathbf{x}, \xi)$  in detail.

$K(\mathbf{x}, \xi)$  in Eq. (16) appears discontinuous only if  $R_1 = 0$ , i.e., both  $\mathbf{x} = \xi$  and  $\omega = 0$  come into existence. Actually, when  $\mathbf{x} = \xi$ , Eq. (16) can be reduced to

$$\begin{aligned} K(\mathbf{x}, \xi)|_{\mathbf{x}=\xi} = & \frac{1 + \omega \nabla^2 \omega - (\nabla \omega)^2}{\pi \omega^2} - \frac{1}{4\pi} \omega \nabla^4 \omega \\ & - \frac{1}{4\pi} \frac{k - \bar{\omega}^2 \bar{m}}{D} \omega^2. \end{aligned} \quad (17)$$

To make the kernel of the integral equation  $K(\mathbf{x}, \xi) \in C(\Omega \cup \partial\Omega)$ , A normalized boundary equation will be constructed to ensure the continuity of  $K(\mathbf{x}, \xi)$  in the following. It can be easily testified that

$$\omega = \left[ 3\omega_0 + \omega_0^2 \nabla^2 \omega_0 - \omega_0 (\nabla \omega_0)^2 \right] / 2, \quad (18)$$

where  $\omega_0 = 0$  is the normalized equation of the boundary  $\Gamma$ , i.e.,  $\omega_0$  satisfies Eq. (9). Obviously, equation  $\omega$  is also a normalized boundary equation of the first-order.

Based on a suitably chosen normalized boundary equation  $\omega_0 = 0$ , a new normalized boundary equation  $\omega = 0$  can be constructed by using Eq. (18), which ensure the continuity of the integral kernel  $K(\mathbf{x}, \xi)$  everywhere in the integral domain.

In order to obtain numerical results of the boundary problem, the integral equation (15) can be discretized into the homogeneous linear algebraic equation. The determinant of the matrix of coefficients of homogeneous linear algebraic equations Eq. (15) must be equal to zero. So, the natural frequency  $\bar{\omega}$  or  $f = \bar{\omega}/(2\pi)$  can be obtained by solving the equation.

#### 4 NUMERICAL EXAMPLE

A slip clamped trapezoidal shallow spherical shell is shown in Figure 1, and we set  $a = e = 1.2$ ,  $b = d = 1.0$ , and  $c = 1.1$ . The following reference parameters are used: the radius of curvature of the shell  $R = 3$ , the thickness of the shell  $h = 0.1$ , Poisson's ratio  $\nu = 0.3$ , Young's modulus  $E = 3 \times 10^9$ , and mass density per unit area  $\bar{m} = 780$ . According to the theory of R-function [1], a normalized boundary equation of the first rank  $\omega_0 = 0$  can be constructed from the following equation:

$$\omega_0 = \omega_1 + \omega_2 + \omega_3 - \sqrt{\omega_1^2 + \omega_2^2} - \sqrt{\omega_1^2 + \omega_3^2} - \sqrt{\omega_2^2 + \omega_3^2} + \sqrt{\omega_1^2 + \omega_2^2 + \omega_3^2},$$

where

$$\omega_2 = \left( \frac{ac}{a-b} + \frac{c}{a-b} x_1 - x_2 \right) / \sqrt{1 + \left( \frac{c}{a-b} \right)^2} \geq 0,$$

$$\omega_3 = \left( \frac{ac}{a-b} - \frac{c}{a-b} x_1 - x_2 \right) / \sqrt{1 + \left( \frac{c}{a-b} \right)^2} \geq 0,$$

and  $\omega_1 = (c - x_2)x_2/c$ .  $\omega_1 = 0$ ,  $\omega_2 = 0$  and  $\omega_3 = 0$  denote various parts of the boundary of trapezoidal shallow spherical shell, respectively. Numerical results by the R-Function Theory (RFT) and ANSYS Finite-Element Method (FEM) are shown in Table 1 for comparison. Numerical results by

Figure 1. Slip clamped shallow spherical shell.

Figure 2. Division of trapezoidal integral domain.

Table 1. Natural frequency  $f$  of slip clamped trapezoidal shallow spherical shell.

R	The mode rank					
	1		2		3	
	RFT	FEM	RFT	FEM	RFT	FEM
3	69.242	69.086	85.020	85.487	114.95	115.92
5	64.046	63.880	80.844	81.339	111.89	112.89
7	62.537	62.370	79.655	80.158	111.04	112.05

$11 \times 11$  trapezoidal integral domain of the R-Function Theory (RFT) show fine agreement with the FEM solution by  $200 \times 200$ . It shows the advantages and efficiency of the present method.

#### 5 CONCLUSIONS

In the present paper, the R-function theory is applied to study the free vibration of slip clamped trapezoidal shallow spherical shell. Compared with ANSYS finite element solution, it shows good agreement. R-function theory can also be used to effectively solve various boundary value problems in engineering by constructing a trial function that satisfies the boundary conditions and by combining with the method of weighted residuals such as the variational method and the spline-approximation [7–8].

## Reducing blasting vibration technique of the hole-bottom air space charging

M.S. Zhao, Q. Kang & T.J. Tao

*Guizhou Xinlian Blasting Engineering Group Co. Ltd., Guiyang, Guizhou, China*

**ABSTRACT:** The effects of hole-bottom layer air ratio on blasting vibration intensity, blasting vibration frequency as well as vibration lasting time were studied, and the effects of hole-bottom layer air ratio on the band advantage of blasting seismic wave frequency duration and frequency band energy ratio were studied based on the energy theory. And according to the real problems of earth excavation blasting of Zunyi City, Pu District II East Road on the 5th practical still room area, the test of bottom hole air interval charge was done. The test results showed that: the hole-bottom air space charge is an effective means to reduce the blasting vibration, and the optimum air layer ratio in test conditions in fractured rock is recommended as 15%.

**Keywords:** hole-bottom air space charging; air ratio; frequency band; blasting vibration; stress

### 1 INTRODUCTION

The hole-bottom air space charging can improve blasting effect, reduce the blasting vibration effect. So it has been widely used in engineering. Many scholars have studied on the mechanism of the hole-bottom air space charging from many aspects such as the detonation wave theory, numerical simulation, dynamic photoelastic test, dynamic test, model test, and ceiling materials. Lv Shuran thinks that the hole-bottom air space charging is the best through the comparison experiment of different axial spacing. Gu Dazhi carry on many field tests in a mine of Aluminum Group and the results show that if the hole-bottom air gap length is 0.8 m, the vibration reduction rate can reach 10%~15%. Liu Weizhou study on vibration reduction test in mine of Aoshan states that the hole-bottom air space charging can reduce 5.9%~16.1% blasting vibration. Above research provides a reference for reducing vibration control by using the hole-bottom air space charging. However, there is still no study about the effect of the best air space ratio (but no air layer length and the length of the charge ratio) on blasting vibration reduction. Until now, the index of reduction blasting vibration effect is the reduction of the blasting vibration intensity about this research. However, the harmful effect of blasting vibration is the result of three elements interaction. The above studies indicate that the energy of blasting seismic wave can comprehensively effect three elements' interaction of blasting vibration.

So this project is the Zunyi city Sinpo District No. two East Road No. 5 room area earthwork excavation by using the hole-bottom air space charging to study the effect of air space ratio on blasting vibration intensity, vibration frequency, and duration of blasting vibration. Also to explore the use of energy is studied from the point of view of hole-bottom air layer in proportion of blasting seismic wave of dominant frequency continuous time, frequency band energy ratio. In order to conduct a detailed explanation on the vibration reduction effect of the hole-bottom air interval space charging. Our purpose is to provide a new method for determining the best air decking proportion.

### 2 FIELD TEST

Zunyi Road No. 2, Sinpo District No. 5 East District Housing earthwork excavation has complex environment. South, southwest, and southeast of blasting area has residential distribution. The west of blasting area has Dongcheng Avenue viaduct. The distance to the nearest edge to the residents of the blasting area is about 40 m. The nearest distance of the viaduct is about 50 m. Blasting excavation step height is 10 m, the pore size is 140 mm, hole spacing is 5 m, row spacing is 4 m, hole depth is 11.5 m, block length is 4.5 m, continuous loading, use 3 period between holes. Using 5 row detonator by hole detonation and the biggest single charge is no more than 90 kg. There are two aspects of the main problems: one is the effect of

Table 1. Hole-bottom air space charging elements.

Stemming length/m	Charge length/m	Air layer length/m	Air ratio/%
4.5	7	0	0
4.15	7	0.35	5
3.8	7	0.7	10
3.45	7	1.05	15
3.1	7	1.4	20

Figure 1. Measuring signal.

blasting vibration. A few houses have wall cracks; another is the size is too big around the hole that increases the operation cost and reduce the production efficiency. So in order to reduce the harm of blasting vibration and reduce the large orifice, hole-bottom air space charging has been used in this project. Under the condition that there is no change in the single dose, improve loading height, reducing orifice blocking scheme. The development of different air layer proportion according to the actual situation of the hole-bottom air interval charge of single hole blasting vibration test. The specific parameters are shown in Table 1. Select the blast center distance is 40 m. Analysis of vertical signal in different working conditions shows the following: Hole-bottom air layer ratio of 0% (i.e. continuous charge) was recorded for S1, hole-bottom air layer ratio is 5% was recorded for S2, and so on. The bottom of the hole air layer to a ratio of 20% was recorded as S5. The measured blasting seismic wave is shown in Figure 1.

### 3 DATA ANALYSIS

In order to compare the influence of air layer proportion on blasting seismic wave peak particle vibration velocity, we use the difference date between the continuous charging particle vibration velocity peak and different air layer ratio of

blasting seismic wave peak particle vibration velocity. The vibration reduction rate.

$$\delta = \frac{V_0 - V}{V_0} \times 100\% \quad (1)$$

$V_0$  is blasting vibration peak velocity of the continuous charge;  $V$  is the peak velocity of blasting seismic wave in different proportion of air layer.

Formula (1) can calculate blasting seismic wave vibration reduction rate of different air decking ratio of Figure 2. Figure 2 shows that if the air layer proportion is between 5% and 20%, the vibration reduction rate is 8.5%–22%. And with the increase of air decking ratio, vibration reduction rate increases.

In order to compare the influence of air layer, the proportion on the total energy of blasting seismic wave and the ratio index of total energy of blasting seismic wave of continuous charge to blasting seismic wave energy of different air proportion layer is analyzed. That is

$$\gamma = \frac{S_i}{S_1} (i = 1, 2, 3, 4, 5) \quad (2)$$

By use AOK time-frequency distribution of blasting vibration signals of different conditions for time-frequency analysis, we get the total energy calculation of the signal. Then calculate the blasting seismic wave energy of different proportion air layer and continuous blasting seismic wave energy ratio. The statistics is in Figure 3. Figure 3 shows: with the increase of the proportion of the air layer, the total energy of blasting seismic wave reduction. This means that with the increase in the proportion of air layer, explosive for rock breaking energy is greater and the energy for blasting earthquake is less.

Because the frequency band energy can directly reflect the vibration intensity of the corresponding frequency band vibration components, to obtain

Figure 2. Effect of air ratio on reduction effect.

Figure 3. Effect of air ratio on total energy of blasting seismic wave.

Figure 4. Effect of air ratio on the frequency band energy duration.

the response characteristic of the buildings of different frequency band vibration component, energy sustained time and structure of low cycle fatigue damage accumulation effect, and non elastic structures is related to the destruction. So the ratio of the frequency band energy duration to frequency band energy is regarded as index to study on energy characteristics of blasting vibration wave under different conditions. First, the use of wavelet analysis, to signal under different working conditions of the 7 layer decomposition and reconstruction. Then, the reconstructed signal of different frequency bands for AOK is analyzed. We get the time-frequency contour and 3D spectrum and calculate the energy band frequency band energy ratio. In order to compare the influence of air layer proportion on blasting seismic wave frequency band energy characteristic. The statistics under different frequency band energy duration is shown in Figure 4, the band energy ratio in Figure 5.

Figure 4 shows that: (1) with the increase of the air layer proportion, the duration of different frequency band energy is extending and the accumulation effect of low cycle fatigue damage of the structure is enhanced. It is clearly not conducive to the safety of the building; (2) the duration of the blasting vibration signal energy in different frequency bands is different. The duration of the test conditions from low frequency to high frequency becomes shorter. The frequency of the high frequency part of 500–1000 Hz is longer and its duration time is almost the whole course of blasting vibration. This is mainly due to noise stay in the high frequency part. And along with the whole process of blasting vibration, due to different frequency and duration, the energy ratio is also different.

Figure 5 shows that (1) the advantage of blasting vibration signal energy is mainly concentrated in the low-frequency part of the 0–125 Hz. The maximum energy exists in the main frequency band. High frequency energy accounted for a

Figure 5. Effect of air ratio on the frequency band energy ratio.

smaller proportion. But there is still a distribution; (2) the air layer ratio has a bigger effect on the frequency band energy ratio of the blasting seismic wave. With the increase in the proportion of the air layer of blasting seismic wave, the structure natural frequency that is close to the D7 frequency band energy ratio gradually increases. This is a hazard for blasting vibration controlling.

From the above analysis, it shows that if the hole-bottom air space charging is used, with the increase of the proportion of the air layer, the total energy of blasting seismic wave and the peak particle vibration velocity is reduced, the duration of main frequency is extended, and main frequency is decreased. The ratio of D7 frequency band energy that is close to the natural frequency of buildings is increased. Therefore, the vibration reduction of the best air layer ratio should be selected according to total blasting seismic wave energy and considering the building response more sensitive D7 frequency band energy ratio. In order to facilitate the comparison of different air layer ratio of D7 band absolute energy, taking the blasting seismic wave D7 frequency band energy ratio of different air layer with the continuous charge ratios for total energy.

Figure 6. Effect of air ratio on the ratio of D7 band energy to the total energy of continuous charge.

$$\eta = E_2 * r \quad (3)$$

So by Formula (3), the total energy is calculated with different air layers compared to continuous loading ratio. Figure 6 shows when the air layer ratio is 15%, D7 band energy accounts for a minimum proportion of total energy of continuous charging. Therefore, this project selects the air layer ratio as the best ratio to reduce blasting vibration and the proportion of large orifice.

The on-site construction according to the proportion of the best air layer and the usual blasting method under the same conditions are compared. The wall cracks of houses surrounding blasting area were significantly reduced and the orifice blocks are effectively reduces so that it did improve the production efficiency of blasting. It can be considered that the best proportion of air layer by the method to determine the vibration reduction is comprehensive, scientific, and rational.

#### 4 CONCLUSIONS

The effects of hole-bottom layer air ratio on blasting vibration intensity, blasting vibration frequency as well as vibration lasting time were studied, and

the effects of hole-bottom layer air ratio on the band advantage of blasting seismic wave frequency duration and frequency band energy ratio were studied based on the energy theory. And according to the real problems of earth excavation blasting of Zunyi City, Pu District II East Road on the 5th practical still room area, the test of bottom hole air interval charge was done. The test results showed that: the hole-bottom air space charge is an effective means to reduce the blasting vibration, and the optimum air layer ratio in test conditions in fractured rock is recommended as 15%.

**ABSTRACT:** Based on the 04th section of Beijing Yanfang line subway modular construction, this paper summarizes the shortcomings of the traditional pier column construction and introduces the construction technology of pier column reinforced bar in details; as well as analyzes the economy, construction period, social benefits generated by the application of modular construction. The engineering practice indicates that modular construction can effectively shorten the construction period, reduce project cost and improve the quality of the project, and achieve good results in the practical application, and will be one of the developing directions of construction industrialization in the future.

**Keywords:** modular construction; pier column; viaduct subway

## 1 INTRODUCTION

Compared with the construction of traditional subway, modularization is an advanced idea of construction (Li et al. 2009, Yu et al. 2010, Li et al. 2014). The superiority of that is it could cut down construction period of elevated subway according to reducing construction work on site. Adopting the method of modularization, a large number of processes of construction were accomplished in the factory, which improve the safety of construction, ensure the quality of construction, and save the period of construction and engineering cost meantime. However, while the efficiency of construction was enhanced by using modularization, the difficulty of construction, for instance, the links like process, transport, and hoisting of the module's enlargement of pier's reinforced bars, faced bigger risks and challenges. It is being researched by scholars of engineering that how to organize, plan, and modularize the elevated subway (Xu et al. 2011).

## 2 THE ENGINEERING OVERVIEW

Beijing subway line Yanfang is the west extension of Beijing line Fangshan, the project was started by the end of 2013, and was completed by the end of 2016 according to the plan. The total length of the 04th interval of line Yanfang is 4440.802 m. All of it designed to elevated station and laid down elevated line in interval, it costs

376.8 million according to contract. Scope of construction including: Dazicaowu station~interval of north of Yancun station, north of Yancun station, behind interval of north of Yancun station, in-and-out interval and the west extension elevated interval reserved in line Fangshan, the mileages are: K12 + 137.943 ~ K15 + 090.996, including 118 m of the station, SK0 + 000 ~ SK1 + 605.749, including 118 m of the station, total length is 4440.802 m. All stations and intervals are elevated; all of the pier columns under of all intervals are 169 altogether that constructed on the basis of modularization.

The pier column under of intervals adopt the shape of magnolia that is Y type mainly, individual pier column adopt column type, pier column of intervals contain type of A, B, and C mainly, structure types of those are shown in Table 1.

Table 1. Pier column structure types statistics.

Type	Height (m)	Dimension (m)	Span (m)
A2	$10 < H \leq 12.5$	$2.3 \times 2.0$	$L \leq 40$
A3	$12.5 < H \leq 15$	$2.5 \times 2.3$	$L \leq 40$
B1	$H \leq 11$	$1.6 \times 1.6$	$L \leq 40$
B1'	$H \leq 11$	$1.6 \times 1.6$	$L \leq 40$
B2	$11 < H \leq 16$	$2.0 \times 2.2$	$L \leq 40$
C1	$H \leq 12$	$2.7 \times 1.8$	–
C2	$10 < H \leq 12.5$	$2.5 \times 2.0$	$L \leq 40$
C3	$12 < H \leq 18$	$2.7 \times 2.5$	–

The heaviest pier column reinforcing cage is DY—33, with 15.5 m height and 22.696 t weight.

### 3 THE DISADVANTAGES OF THE TRADITIONAL TECHNOLOGY

Generally, traditional processes of pier column construction are: embedding main bars of pier column before binding reinforced bars of cushion cap, after the strength of concrete at the bottom of cushion cap by more than 70% of the design strength that bear the loads from simulate pouring of upper concrete and other constructions enough, subsequent processes could be started including baiting, binding, and reinforcing stiff reinforcement cage made from reinforced bars of pier, connecting vertical reinforced bars one by one, binding horizontal reinforced bars, installing pier mould, dismantling stiff reinforcement cage, pouring concrete by segment and then dismantling mould, and curing concrete finally. Thus, pouring of whole pier column has been completed.

The disadvantages of traditional process of construction are as follows: 1) stiff reinforcement cage must be installed before binding reinforced bars, then the stiff reinforcement cage should be dismantled, that waste not only period but also labor; 2) when binding reinforced bars, it is difficult to control the verticality of vertical reinforced bars and the quality of concrete cover that lead to a low speed of binding reinforced bars; and 3) the safety of construction facing a large risk because of numerous work of hoisting on site (Yang et al. 2011).

### 4 MODULAR CONSTRUCTION PROCESSES

According to the investigation on site, combining with the project's characteristics of the 04th interval of line Yanfang, the processes of construction are determined as listed below: locating and setting out cushion cap → binding reinforced bars of cushion cap → processing reinforced bars of pier column to integral → locating and setting out reinforced bars of pier columns → binding and hoisting reinforcement cage of pier columns → pouring and roughening surface concrete of cushion cap → locating and setting out mould → reinforcing pier column (pier column's passageway adopt the type of truss) → installing mould and pouring concrete of pier column (pouring once when the concrete's thickness less than 12 m) → pouring the second concrete after roughening (more than 12 m) → dismantling the mould → curing concrete.

## 5 KEY TECHNOLOGIES OF MODULAR CONSTRUCTION

### 5.1 Processing of reinforced bars' modularity

Setting up centralized processing shed for reinforcing bars in steel plant, which equipped NC cutting machine, NC bars bending machine, threading of straight thread machine etc. After the primary material passed the inspection, cutting, welding and bending them in processing shed of reinforced bars, then complete binding reinforced bars on ground manipulator. For individual components which contain plenty of reinforced bars, integral processing first and assembling in advance, transporting to work site separately and assembling finally.

In order to reduce the deformation of reinforcement cage during hoisting, adding crossed reinforced bars, which the same model number as main bars and welding to main bars every 3 m. For the cages which higher than 12 m connected by sleeve of straight thread, controlling index of processing and binding in an allowable deviation strictly and control structure size of reinforcement cage accurately. According to various embedded components in advance settled in manipulator the reinforced bars could through it. Consequently, the integration of reinforcement cage could ensure when hoisting that avert the deformation of reinforcement cage which cause concrete cover thicker or thinner and reduce quantity of reinforced bars' work effectively meanwhile improve efficiency of subsequent procedures of mould, as shown in Figure 1.

### 5.2 Transport of reinforcing cage

The reinforcement cage transported by flat-car, set up temporary pedestal in the car that ensure the stability of reinforcement cage in transportation.

Figure 1. Processing of reinforcing cage.

### 5.3 Hoisting and fixing reinforcement cage

Take C1 type for an instance, welding 4 main reinforced bars and I-steel belong to hanger, on each corner of cage top, welding hanger by I12b-steel, each hanger has six suspension centers, the diameter of lifting steel wire rope is 20 mm, as shown in the Figure 2.

Reinforcement cage of pier inserted into cushion cap by two 80 t auto cranes then reinforced in bottom, when the height of the reinforcement cage of pier columns less than 12 m, hosting once and insert reinforcement cage into cushion cap as shown in the Figure 3.

Reinforcement cage's facade pulled by 20 mm diameter cables, where set 3 cables and set 2 in the

Figure 2. Fixing and reinforcing reinforcement cage.

Figure 3. Lifting of reinforcing cage.

side, amount to 10 cables. It is 1 m \* 1 m \* 2 m prefabricated concrete (each 5.2 t) connect cables into 60° settled in ground and the hooker of prefabricated concrete connect with cables, as shown in Figure 4.

### 5.4 Matched mould of pier column

Mould of pier column adopts standardized design, produced by professional factory, each mould section of the pier column is 2 m high, and each panel is 6 mm thick. The dorsal bars reinforced by U-steel. And fixing the mould by the split bolts which are around 25 mm in diameter.

Column of pier column mould assembled separately on the ground, sealing the edge joint by clamping rubber strip in, and then filling in the gaps and flattening with paint filler. Curve of pier column mould and the beams should be hoisting block by block. Transporting mould separately to site and fixed after inspecting the previous assemblage of mould.

Combine cranes with fixing of formed mould, horizontal position follow control line and verticality controlled by theodolite, next set steel wire ropes around pier column as climb line that one end fixed in cage of mould and another fixed in ground anchors, according to chain block adjust till it is vertical and ground anchors stabilized. Embedded reinforced bars previously in cushion cap for fixing mould of pier column that prevent bottom of mould from shifting as shown in Figure 5.

### 5.5 Pouring and curing concrete of pier column integrally

Confirm all reinforced bars and preembedded piece have been completed, pouring concrete of the cushion cap. Then roughening manually and washing clean that the contact surface of cushion cap with pier column flat, clean and no loose, its better that the leakage of stone is 1/2. Pouring whole flat

Figure 4. Fixed mooring rope and ground anchor.

Figure 5. Installation of pier column formwork.

interval symmetrically and horizontally layer by layer, control the thickness of concrete in 30 cm. Pay attention to correct the deviation of preem-bedded piece meantime to guarantee the density and smooth surface without heel block's mark of concrete. Taking notice of wiping and compaction when pouring to the top of pedestal, especially the reserve of anchor bolt holes. Watering and curing concrete after final set, covering non-woven fabrics on the surface of pier to maintain wetness, dismantling mould and packaging it with plastic membrane, and watering to maintain wetness during the period of curing. Using grass mat package concrete and add plastic membrane inside and outside if the temperature too low. The period of curing must more than 7 days and it is better that the frequency of watering is based on whether the surface of concrete is wet or not.

## 6 THE EFFECT OF APPLICATION

It is beneficial for quality controlled and inspected, improving work efficiency and machine utilization that blanking and integral processing of reinforced bars adopt standardized work in factory. In addition, it could reduce the waste of raw material and cut down the cost of construction. Besides, owing to the decrease in work period, modular construction is advantageous in synthesis cost.

According to the application of modular construction, the pier columns and cushion caps could construct in parallel, transform procedures effectively, improve the continuity and balance of pier construction. Take C1 type as an example again,

C1 in factory processed to integrated, saving the amount of work of build-up and dismantle scaffold platform which should do in traditional construction which cut down the period of construction on site from 21 days to 3 days so that the total period shorten to 18 days to provide guarantee for the project completed on schedule.

Moreover, the construction of line Yanfang elevated subway adopts modular construction technology, which is the first in Beijing region, and rarely applied construction of subway in domestic. The successful application of modular construction obtain high evaluation form the owner and supervision, at the same time, attracted plenty of counterparts come to learning, won the honor for the enterprise and created a good social benefits.

## 7 CONCLUSIONS

The 04th interval of line Yanfang adopted modular construction, realized optimization of the construction technology and avoided the defects of the traditional construction. Furthermore, modular construction is advanced, reliable and applicable, reasonably save construction cost, improve the efficiency of the construction, safety, quality, and overcome the limit time of project. Owing to the benefits of economy, period and society, the modular construction technology could guide the construction of elevated subway actively and the achievements are worthy to be promoted and applied widely.

# Effect of metakaolin quantity on the mechanical properties of high-performance concrete

HongBin Liu

State Key Laboratory of Coal Resources and Safe Mining,  
China University of Mining and Technology, Beijing, China

KaiLu Xiao, WeiQi Tang, WeiZhe Ma, ZhengQi Shi & XiGuang Li

School of Mechanics and Civil Engineering, China University of Mining and Technology, Beijing, China

**ABSTRACT:** The effects of five different metakaolin volumetric fractions on the mechanical properties of high-performance concrete were investigated by the cubic compressive, splitting tensile and flexural tensile tests. It is shown that the increasing content of metakaolin can improve the mechanical properties of concrete, and the high-performance concrete can be achieved at the metakaolin volumetric fraction of 15%. In addition, the relationships between the test strengths with the content of metakaolin are empirically formulated.

**Keywords:** high-performance concrete, metakaolin, mechanical properties

## 1 INTRODUCTION

With the development of science and technology, the high-performance concrete has become the development direction of modern concrete technology. Mineral admixture is generally used in high-performance concrete, such as, silica fume, slag, and fly ash. Due to its higher activity, silica fume has been widely used, but it has some disadvantages, such as its low yield, high cost and high energy consumption in China. In order to meet the requirements of sustainable development and environmental protection, it is particularly important to find a suitable active mineral admixture to replace silica fume.

Kaolin ( $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$ ) is a clay mineral with kaolinite as the main ingredient, rich in silicon, zinc, magnesium, aluminum and other minerals. China is the first country to discover and use kaolin, no coal calcined kaolin reserves rank fifth in the world, accounting for the world's total output of 78%. Calcined at a certain temperature (500–900°C), kaolin can be dehydrated to form a white powder of metakaolin (referred to as MK). The average particle diameter of metakaolin is 1–2  $\mu\text{m}$ . The main components are  $\text{SiO}_2$  and  $\text{Al}_2\text{O}_3$ , and the contents of these two components are more than 90%. Compared with other mineral fume admixtures, the content of  $\text{Al}_2\text{O}_3$  in metakaolin is high, and hydration products of cement hydration reaction with calcium hydroxide are calcium aluminate

and C-S-H cementitious material Metakaolin has a high volcanic ash activity that controls the alkali aggregate reaction effectively, and improves the tensile strength, permeability and corrosion resistance of concrete. Thus, the application prospect of MK is extremely broad<sup>[1–7]</sup>.

Based on the Reactive Powder Concrete (RPC) preparation principle and method<sup>[8]</sup>, we study the effects of different MK volumetric fractions on the mechanical properties of high-performance concrete. This paper aims to provide an experimental basis and reference for promoting the engineering application of metakaolin.

## 2 PHYSICAL PROPERTIES AND VOLCANIC ACTIVITY OF METAKAOLIN

**Physical properties of MK.** The average particle size of metakaolin is 1–2  $\mu\text{m}$ , and the contents of  $\text{SiO}_2$  and  $\text{Al}_2\text{O}_3$  are more than 90%. Table 1 presents the chemical composition of metakaolin.

**Volcanic ash activity.** Murat studied the absorption ability of  $\text{Ca}(\text{OH})_2$  by using metakaolin, and found the main hydration products to be mullite CSH-I, hydration gehlenite  $\text{C}_2\text{AH}_8$  and a small amount of calcium aluminate hydrate<sup>[1]</sup>:

Table 1. Chemical composition of metakaolin.

SiO <sub>2</sub> (%)	Al <sub>2</sub> O <sub>3</sub> (%)	Fe <sub>2</sub> O <sub>3</sub> (%)	TiO <sub>2</sub> (%)	CaO (%)	MgO (%)	K <sub>2</sub> O (%)	Na <sub>2</sub> O (%)	Loss on ignition (%)
55.06	44.12	0.76	0.24	0.17	0.06	0.55	0.06	0.62

Table 2. Ingredients and mix proportion of concrete.

		Cement (C)	Metakaolin (MK/C)			
S00	0.22	1.00	0.00	1.2	1.5	Room temperature curing for 28 days
S05		0.95	0.05			
S10		0.90	0.10			
S15		0.85	0.15			
S20		0.80	0.20			

### 3 EXPERIMENTAL OVERVIEW

**Mixing ratio and specimen preparation.** Table 2 lists the material ingredients and mixing ratios for the specimens of high-performance concrete. It included P.O42.5 Portland cement and fine quartz sand with grain sizes ranging between 0.15 and 0.63 mm. Metakaolin was supplied by a company in Henan Province, and Sika superplasticizer (water reducing ratio > 30%, solid content 37.2%, and bulk density 1.077 g/cm<sup>3</sup>) was employed.

During specimen preparation, cement, MK, and quartz sand were mixed evenly at the designated mixing ratio. The mixed water and superplasticizer were added and mixed for 3 min. The mixture was poured into a rectangular mold with a size of 100 mm × 100 mm × 100 mm and 40 mm × 40 mm × 160 mm, and vibrated to form on a vibrating table. The specimens were first cured at an ambient temperature for 24 h before demolding, and then cured at room temperature curing for 28 days.

**Testing method and equipment.** According to “the standard for ordinary concrete test” (GB/T 50081-2002), the compression strength and the splitting strength test was carried out by a 3000 kN high rigidity testing machine at the State Key Laboratory of Coal Resources and Safe Mining of China University of Mining and Technology (Beijing). Adopting the load control mode, the test speed values were 0.9 MPa/s and 0.09 MPa/s, until the failure of the specimen, with each ratio being tested for 3–6 samples.

Flexural tensile strength was tested by a 100 kN universal testing machine at China University of Mining and Technology (Beijing). Adopting the displacement mode, the test speed value was 0.05 mm/min, with each ratio being tested for 3–6 samples.

Table 3. Measured strength with different metakaolin volumes.

No.	Cement	MK	Compressive strength (MPa)	Splitting tensile strength (MPa)	Flexure tensile strength (MPa)
S00	1.00	0.00	91.09	4.57	6.38
S05	0.95	0.05	94.01	5.05	7.19
S10	0.90	0.10	97.31	5.20	7.21
S15	0.85	0.15	120.06	6.91	8.59
S20	0.80	0.20	110.85	6.32	7.59

Note: data represent the average values of the 3–6 samples.

**Test results and analyses.** Table 3 lists the compressive strength, splitting test results of the tensile strength and the bending strength at different metakaolin contents. Figures 1–3 show the relationship between the compressive strength, the splitting tensile strength, and the flexure tensile strength at different metakaolin contents.

The experimental results show that: ① the compression strength, the splitting strength and the bending strength increased with the increasing metakaolin content. Compared with MK content of 0%, at the compressive strength of 5%, 10%, 15% and 20%, MK contents in concrete increased to 3.21%, 6.83%, 31.81% and 21.69%, respectively. The splitting strength increased by 10.51%, 13.84%, 51.23% and 38.31%, and the bending strength increased by 12.69%, 12.99%, 34.58% and 18.96%, respectively. ② When the volume of MK was below 10%, each strength parameter increased slowly, and the strength of 5% and 10% volume was closed. When the MK volume

Figure 1. Relationship between compression strength and volumetric contents of MK.

Figure 2. Relationship between the splitting tensile strength and volumetric contents of MK.

Figure 3. Relationship between flexural tensile strength and volumetric contents of MK.

exceeded 15%, the strength increased significantly, but the strength of concrete decreased when the volume of MK increased to 20%. This shows that it is not beneficial to increase the metakaolin content above 15%.

In summary, metakaolin volume is significantly associated with the mechanical properties of concrete, and there exists an optimal volume. The suitable volume of metakaolin is about 15%.

Figures 4–6 plot the relationships of the normalized compressive strength  $f_{cu}/f_{cu,0}$ , the normalized splitting tensile strength  $f_{t,sp}/f_{t,sp,0}$  and the normalized flexural tensile strength  $f_{t,flx}/f_{t,flx,0}$  with 0% MK content, where the  $f_{cu,0}$  indicates 100 mm cube the compressive strength of 0% MK volumetric fraction;  $f_{cu}$  is the cubic compressive strength;  $f_{t,sp}$  is the splitting tensile strength; and  $f_{t,flx}$  is the flexural strength. Thus, the relationships between the test strengths with the content of MK are formulated.

$$\frac{f_{cu}}{f_{cu,0}} = \begin{cases} 0.99833 + 0.7\rho & 0 \leq \rho \leq 10\% \\ -0.48 + 22.5\rho - 70\rho^2 & 10 < \rho \leq 20\% \end{cases} \quad (2)$$

$$\frac{f_{t,sp}}{f_{t,sp,0}} = \begin{cases} 5.01 \times E^{-2} + 1.41 \times E^{-3}\rho - 7.18 \times E^{-5}\rho^2 & 0 \leq \rho \leq 10\% \\ -5.61 \times E^{-2} + 1.64 \times E^{-2}\rho - 5.04 \times E^{-4}\rho^2 & 10 < \rho \leq 20\% \end{cases} \quad (3)$$

Figure 4. Relationship between the normalized cubic compressive strength and volumetric content of MK.

Figure 5. Relationship between normalized splitting tensile strength and volumetric content of MK.

Figure 6. Relationship between normalized flexural tensile strength and volumetric content of MK.

$$\frac{f_{l,fb}}{f_{cu,0}} = \begin{cases} 7.01 \times E^{-2} + 2.65 \times E^{-3} \rho - 1.74 \times E^{-4} \rho^2 \\ 0 \leq \rho \leq 10\% \\ -2.93 \times E^{-2} + 1.61 \times E^{-2} \rho - 5.21 \times E^{-4} \rho^2 \\ 10 < \rho \leq 20\% \end{cases} \quad (4)$$

#### 4 CONCLUSIONS

This paper studies the influence of MK content on the mechanical properties of high-performance concrete, and the following conclusions can be drawn:

1. The metakaolin content can improve the mechanical properties of concrete effectively. The concrete compressive strength, splitting tensile strength, and flexural strength of concrete all appear to increase with the increasing MK volume; however, there exists an optimal volume content. The result of this study shows

that the MK admixture of 15% is the appropriate value.

2. The empirical relationship formulas for concrete's compressive strength, splitting tensile strength, and flexural strength changing with metakaolin admixture are obtained. Thus, they can be used as a reference for engineering application.

# Study on mechanical behavior and thermal properties of recycled brick concrete mixed with cinder insulation

Chunhong Chen, Yongxiang Wu & Yi Lei

Department of Civil Engineering, Changzhou University, Changzhou, Jiangsu, China

Feng Li

School of Mathematics and Physics, Changzhou University, Changzhou, Jiangsu, China

**ABSTRACT:** This paper engaged in the recycled aggregate concrete insulation blocks derived from waste concrete. Based on the method of overall effectiveness, the mix proportion of recycled concrete insulation block with modified cinder and glazed hollow bead was optimized by using the orthogonal experimental principle, contrast test and variance analysis. Mechanical strength and thermal conductivity of blocks were tested. Results showed that the insulation block with optimum mix proportion could meet quality requirements of QGB B (390 mm × 240 mm × 190 mm) 800 Mu5.0 0.30 GB 26538-2011 in terms of Chinese standard.

**Keywords:** recycled aggregate concrete; insulation block; mix proportion; overall efficacy coefficient; mechanical strength; thermal conductivity

## 1 INTRODUCTION

According to statistics, in recent years, average generation of construction waste such as waste concrete and bricks is up to 20 million tons per year in China [1]. Vast majority of construction waste are deposited in the open air or landfill, which not only occupy the land, but also cause serious secondary environmental pollution [2–3]. Recycled coarse and fine aggregate, which were prepared by the machining process of crushing, screening, removing impurities and other processes from construction waste block, have low density, high porosity, high water absorption and heat insulation performance [4–5], can be used to produce thermal insulation energy-saving blocks by replacing partial or all of natural aggregate. Then the blocks are applied to the bearing and enclosure structure of buildings. It can solve the shortage of natural aggregate and some problems such as construction waste dumps, land occupation and environmental pollution, can more solve the problem of wall insulation, which is the effective way to the recycling of construction waste.

In this paper, taking compressive strength, flexural strength and thermal conductivity as assessment indicators, and taking the QGB B (390 mm × 240 mm × 190 mm) 800 Mu5.0 0.30 excellent products in Chinese standard GB26538/2011 as the goal, the mix proportion was optimized by

orthogonal test results with total efficiency coefficient method. Meanwhile, comparative tests were made to study the effects of cinder on the mechanical behavior and thermal conductivity.

## 2 EXPERIMENTAL

### 2.1 Raw material

Grade 42.5 ordinary Portland cement was from Jiangsu Yangzi Plant. Fine grinding slag was from Yangzhou steel Factory, with a specific surface area of 460 m<sup>2</sup>/kg. Fly ash was manufactured by New Materials Company of Yangzhou, with a specific surface area of 458 m<sup>2</sup>/kg. Polypropylene Fiber (PF) namely TB-19 with a length of 12 mm was used. Glazed hollow bead was from Jiangsu Huawei Jia Construction Materials Company, and its physical properties were shown in Table 1. Recycled aggregates were prepared from waste concrete by the machining process of crushing, screening, washing

Table 1. Physical properties of the glazed hollow bead.

Granularity (mm)	Bulk density (kg/m <sup>3</sup> )	Water absorption (%)	Thermal conductivity (W/(m <sup>2</sup> ·K))
0.5–1.5	50–200	20–50	0.028–0.054

and drying. Then recycled aggregates with size of 5–20 mm were chosen as recycled coarse aggregates and with diameter less than 5 mm as recycled fine aggregate. Cinder was prepared by the same process as recycled aggregates, and with diameter of 4.75 mm–9.5 mm was chosen to replace concrete coarse aggregate. Basic properties of recycled aggregates were shown in Table 2 and Table 3.

### 2.2 Mix proportion

Optimize mix proportion by following steps: First, selecting the total amount of cementitious material, mixing amount of cinder ash, mixing amount of recycled fine aggregate and the glazed hollow bead as four influence factors, basic mix proportion was designed referring to the additional water method, whose main purpose was to pick reasonable levels of influence factors. Second, orthogonal experiments were designed, range analysis and variance analysis were made to identify the reasonable matching relationship between each factor. Orthogonal experiment was L9 (3<sup>4</sup>), factor levels were shown in Table 4, in which factors of A, B, C, D respectively represented cementitious materials, cinder content, glazed hollow bead content and recycled fine aggregate content. Finally, the mix proportion with the best overall performance was optimized based on total efficiency coefficient method.

### 2.3 Concrete hollow block type design

In order to meet building energy requirement of 65% in the hot summer and cold winter area, block

Table 2. Physical properties of recycled coarse aggregates.

Figure 1. Four rows of hollow block.

needs higher thermal performance. Reasonable considered the number of hole rows, hole arrangement, block wall thickness, air layer thickness and other factors, heat transfer distance can be longer in the block, thereby can reduce the thermal conductivity of the block and increase its thermal insulation performance [6–8]. The block type was shown in Figure 1. Block hole rate was 44%, staggered arrangement of four rows of holes could effectively increase the thermal resistance of the block and improve thermal performance of the walls [9–10]. The bottom of the block was totally enclosed, also most of the surrounding wall, so mechanical properties of the block was better [11], which made blocks hard to be destroyed in links of the manufacture, transportation, masonry and usage.

### 2.4 Test methods

Tests of compressive cube strength and splitting tensile strength were performed due to Chinese Standard GB/T50081-2002. Thermal insulation performance was evaluated by thermal conductivity and the test was due to Chinese Standard GB10294-2008.

## 3 RESULTS AND ANALYSIS

Results of orthogonal test and normalization process were shown in Table 5 and Table 6.

### 3.1 Cube compressive strength

Range and variance analysis of compressive strength of recycled concrete insulation block were shown in Table 7 and Table 8. According to Table 7, the influence degree of various factors on 28d cube compressive strength of the block was: A (cementitious materials content) > B

Table 5. Test results for assessment indicators.

(cinder content) > C (glazed hollow bead content) > D (recycled fine aggregate content). Table 8 showed that the amount of cementitious materials had more influence on compressive strength and the influence was significant, also the amount of cinder. The compressive strength improved with increasing the amount of cementitious materials, reduced with increasing the amount of cinder. It was because more amount of cementitious materials could make recycled concretes be more dense. Low aggregate strength and high porosity of cinder itself had adversely effect on compressive strengths of recycled concrete.

### 3.2 Flexural strength

Range and variance analysis of flexural strength of recycled concrete insulation block were shown in

Table 9 and Table 10. Table 9 showed that the influence degree of various factors on flexural strength was: C > D > B > A. Flexural strength was lower with increasing the amount of glazed hollow bead and recycled fine aggregates. It was because the powder and mud content of recycled fine aggregate prepared from waste concrete were larger, furthermore many micro cracks produced while crushing, which reduced flexural strength of recycled concrete. Glazed hollow beads had low intensity and certain hydrophobicity, would fill in the cementitious materials and aggregates. Then it weakened caking property between cementitious materials and aggregates, which reduced flexural strength of recycled concrete. From Table 10, the influence of the amount of glazed hollow beads and fine aggregates on flexural strength was significant.

### 3.3 Thermal conductivity

Range and variance analysis of thermal conductivities of recycled concrete block were shown in Table 11 and Table 12. Table 11 showed that the influence degree of various factors on thermal conductivities was: C > B > A > D. The effect of the amount of glazed hollow beads on thermal

Test number	Cementitious materials (kg/m <sup>3</sup> )	Recycled fine aggregate content (%)	Cinder content (%)
1	350	50	0
2	350	50	30
3	350	50	50
4	350	50	70

Table 14. Contrast test results.

Test number	Compressive strength (MPa)	Flexural strength (MPa)	Thermal conductivity (W/(m <sup>2</sup> ·K))
1	15.0	4.1	0.6113
2	10.2	3.2	0.5904
3	8.3	2.6	0.5710
4	5.9	1.8	0.5477

conductivity was largest. Increasing the amount of content, thermal conductivity was less and thermal insulation performance was better. Table 12 also illustrated the effect of the amount of glazed hollow beads on thermal conductivity coefficient was significant, also the amount of cinder. It suggested that thermal insulation properties could increase when cinder replaced a part of recycled coarse aggregates.

Table 5 showed that overall effectiveness of NO. 1, NO. 4 and NO. 9 were larger, while the thermal conductivity of NO. 4 was the lowest and the strength meet the requirements, therefore the optimum mix proportion was NO. 4.

### 3.4 Contrast test

In order to further discuss the influence of cinder on the strengths and insulation performance of recycled concrete blocks, contrast tests were done with optimal mix proportion, which specific mix proportion and results were showed in Table 13 and Table 14. Table 14 showed that, compressive

strength, flexural strength and thermal conductivity of the block obviously reduced with the increase of the amount of cinder, and declined more significantly with the replacement of cinder ash more than 50%. It was because that most cinder had porous block structure and light weight, furthermore some particulate debris produced during crushing cinder, and also damaged the cinder internal, which would further reduce concrete strength. Therefore, the proper amount of cinder should be chosen to meet the strength requirement [12]. Meanwhile, the cinder surface was irregular, relatively loose and had low density, so cinder replacement coarse aggregate had good heat preservation and heat insulation.

#### 4 CONCLUSIONS

Cementitious materials consumption was the main factor affecting compressive strengths of blocks, compressive strength was greater with increasing its amount. The amount of glazed hollow beads and replacement rate of recycled fine aggregate were main factors affecting the flexural strength, with increasing the amount of glazed hollow beads and recycled fine aggregate, flexural strength decreased.

The amount of glazed hollow bead was main factor affecting thermal conductivity, the thermal conductivity was lower with increasing its amount.

Contrast tests showed that with the increase of cinder content, the strength of blocks reduced and insulation performance improved, so the appropriate cinder content should be selected.

With optimal mix proportions, cementitious material  $350 \text{ kg/m}^3$ , cinder content 30%, glazed hollow beads content 70%, and recycled fine aggregate replacement rate of 50%, recycled concrete blocks could meet the quality requirements of QGB B (390 mm × 240 mm × 190 mm) 800 Mu5.0 0.30 GB 26538-2011 in terms of Chinese standard.

## Calculation of Poisson's ratio of laminate composite

Y.R. Li, H.B. Jiang & W.S. Chen

Logistics College, Naval University of Engineering, Tianjin, China

**ABSTRACT:** Poisson's ratio calculation of laminate is a complex problem, which is usually researched by experimental or numerical methods. This paper attempts to establish a simple calculation model to obtain Poisson's ratio formula by the analytical method. Using equivalent force instead of shear stress, equal strain law of each single plate in laminate was used to establish simultaneous equations, with which Poisson's ratio formulas would be obtained. The results show that the normal direction Poisson's ratio under the action of longitudinal force is equal to the weighted sum of Poisson's ratios of each single plate according to volume fraction, and Poisson's ratio in lateral direction (non-normal direction) is inversely proportional to the lateral elastic modulus of the laminate, and is proportional with the sum of the products of Poisson's ratio, elastic modulus and volume fraction of each single plate.

**Keywords:** laminate composite; Poisson's ratio; analytic calculation; shear stress; equivalent force

### 1 INTRODUCTION

Poisson's ratio calculation of the laminate is a complex problem, which is usually researched by experimental or numerical methods [1–6]. This paper attempts to establish a simple calculation model to obtain Poisson's ratio formula by the analytical method.

### 2 CALCULATION MODEL AND FORCE ANALYSIS

A laminate consisting of two single plates and the coordinate system is shown in [Figure 1](#).

If there is  $x$ ,  $y$ , or  $z$ -axis direction load stress on the laminate, then the junction surface of the

two single plates will produce shear stress because the elastic modulus and Poisson's ratio of each single plate are different, and the two-layer plate would generate the same deformation by the shear stress. If the direction of the load stress is parallel to the  $y$ -axis, two sets of virtual forces  $\pm P_x$  and  $\pm P_z$  in each symmetric end of each single plate could be set instead the shear stress in the junction surface, and the magnitude of the virtual forces could be determined by the law of equivalent strain, i.e., virtual force and shear stresses produce equal strains. By this way, each single plate could be isolated, which makes the calculation easier. This calculation method is called the shear stress equivalent replacement calculation method.

### 3 POISSON'S RATIO CALCULATION UNDER THE ACTION OF LONGITUDINAL FORCE

Referring to [Figure 1](#), we first study the strains produced by the load stress in  $x$ -axis direction (longitudinal direction).

The first layer (lower layer) single plate  $x$ -axis direction strain  $\varepsilon_{1x}$  is equal to the sum of the strain  $\varepsilon_{1\sigma x}$  caused by load stress  $\sigma$ , strain  $\varepsilon_{1P_{xx}}$  caused by virtual force  $P_x$  and strain  $\varepsilon_{1P_{zx}}$  caused by virtual force  $P_z$ :

$$\begin{aligned} \varepsilon_{1x} &= \varepsilon_{1\sigma x} + \varepsilon_{1P_{xx}} + \varepsilon_{1P_{zx}} \\ &= \frac{\sigma}{E_{1x}} + \frac{P_x/A_{1x}}{E_{1x}} - \mu_{1xz} \frac{P_z/A_{1z}}{E_{1z}} \end{aligned} \quad (1)$$

Figure 1. A laminate consisting of two single plates and its coordinate system.

The second layer (upper layer) single plate  $x$ -axis direction strain  $\varepsilon_{2x}$  is equal to the sum of the strain  $\varepsilon_{2\sigma x}$  caused by load stress  $\sigma$ , strain  $\varepsilon_{2P_{xx}}$  caused by virtual force  $P_x$  and strain  $\varepsilon_{2P_{zx}}$  caused by virtual force  $P_z$ :

$$\begin{aligned}\varepsilon_{2x} &= \varepsilon_{2\sigma x} + \varepsilon_{2P_{xx}} + \varepsilon_{2P_{zx}} \\ &= \frac{\sigma}{E_{2x}} - \frac{P_x/A_{2x}}{E_{2x}} + \mu_{2xz} \frac{P_z/A_{2z}}{E_{2z}}\end{aligned}\quad (2)$$

where  $A_{1x}$ ,  $A_{2x}$ , respectively, represent the first and second layer plate cross-sectional areas (perpendicular to the  $x$ -axis);  $E_{1x}$ ,  $E_{2x}$ , respectively, represent the elastic modulus of the first and second layer plates ( $x$ -axis direction); and  $\mu_{1xz}$ ,  $\mu_{2xz}$ , respectively, represent the first and second layer plates in the  $x$ -axis direction and Poisson's ratio under the  $z$ -axis direction force. Laminate longitudinal strain  $\varepsilon_x$  is equal to the first plate longitudinal strain  $\varepsilon_{1x}$ , and also equals the second plate longitudinal strain  $\varepsilon_{2x}$ :

$$\varepsilon_x = \varepsilon_{1x} = \varepsilon_{2x} = \frac{\sigma}{E_x} \quad (3)$$

where  $E_x$  represents the laminate elastic modulus in the  $x$ -axis direction. By formulas (1), (2) and (3), we get the following two equations:

$$\frac{\sigma}{E_x} = \frac{\sigma}{E_{1x}} + \frac{P_x/A_{1x}}{E_{1x}} - \mu_{1xz} \frac{P_z/A_{1z}}{E_{1z}} \quad (4)$$

$$\frac{\sigma}{E_x} = \frac{\sigma}{E_{2x}} - \frac{P_x/A_{2x}}{E_{2x}} + \mu_{2xz} \frac{P_z/A_{2z}}{E_{2z}} \quad (5)$$

where  $A_{1z}$ ,  $A_{2z}$ , respectively, represent the first and second layer plate cross-sectional areas (perpendicular to the  $z$ -axis); and  $E_{1z}$ ,  $E_{2z}$ , respectively, represent the elastic modulus of the first and second layer plates ( $z$ -axis direction).

Similar methods can be used to study the  $z$ -axis direction strain. The first layer plate strain in the  $z$ -axis direction is given by

$$\varepsilon_{1z} = -\frac{\mu_{1zx}\sigma}{E_{1x}} - \frac{\mu_{1zx}P_x/A_{1x}}{E_{1x}} + \frac{P_z/A_{1z}}{E_{1z}} \quad (6)$$

The second layer plate strain in the  $z$ -axis direction is given by

$$\varepsilon_{2z} = -\frac{\mu_{2zx}\sigma}{E_{2x}} + \frac{\mu_{2zx}P_x/A_{1x}}{E_{2x}} - \frac{P_z/A_{2z}}{E_{2z}} \quad (7)$$

where  $\mu_{1zx}$ ,  $\mu_{2zx}$ , respectively, represent the first and second layer plates in the  $z$ -axis direction and Poisson's ratio under the  $x$ -axis direction force.

The first layer plate strain in the  $z$ -axis direction is equal to the second layer plate strain in the same direction, i.e.

$$\begin{aligned}-\frac{\mu_{1zx}\sigma}{E_{1x}} - \frac{\mu_{1zx}P_x/A_{1x}}{E_{1x}} + \frac{P_z/A_{1z}}{E_{1z}} \\ = -\frac{\mu_{2zx}\sigma}{E_{2x}} + \frac{\mu_{2zx}P_x/A_{1x}}{E_{2x}} - \frac{P_z/A_{2z}}{E_{2z}}\end{aligned}\quad (8)$$

By simultaneous equations (4), (5) and (8), we get  $x$ -axis direction equivalent force  $P_x$

$$\begin{aligned}P_x &= \frac{A_{1x}A_{2x} \left\{ \begin{aligned} &A_{1z}E_{1z} [E_{1x}(1 - \mu_{2xz}\mu_{2zx}) \\ &\quad - E_{2x}(1 - \mu_{1xz}\mu_{2xz})] \\ &+ A_{2z}E_{2z} [E_{1x}(1 - \mu_{1xz}\mu_{2zx}) \\ &\quad - E_{2x}(1 - \mu_{1xz}\mu_{1zx})] \end{aligned} \right\} \sigma}{A_{1x}E_{1x} [A_{1z}E_{1z}(1 - \mu_{2xz}\mu_{2zx}) \\ &\quad + A_{2z}E_{2z}(1 - \mu_{1xz}\mu_{2zx})] \\ &\quad + A_{2x}E_{2x} [A_{1z}E_{1z}(1 - \mu_{1xz}\mu_{2zx}) \\ &\quad + A_{2z}E_{2z}(1 - \mu_{1xz}\mu_{1zx})]} \\ &= \frac{V_1V_2A_x \left\{ \begin{aligned} &V_1E_{1z} [E_{1x}(1 - \mu_{2xz}\mu_{2zx}) \\ &\quad - E_{2x}(1 - \mu_{1xz}\mu_{2zx})] \\ &+ V_2E_{2z} [E_{1x}(1 - \mu_{1xz}\mu_{2zx}) \\ &\quad - E_{2x}(1 - \mu_{1xz}\mu_{1zx})] \end{aligned} \right\} \sigma}{V_1E_{1x} [V_1E_{1z}(1 - \mu_{2xz}\mu_{2zx}) \\ &\quad + V_2E_{2z}(1 - \mu_{1xz}\mu_{2zx})] \\ &\quad + V_2E_{2x} [V_1E_{1z}(1 - \mu_{1xz}\mu_{2zx}) \\ &\quad + V_2E_{2z}(1 - \mu_{1xz}\mu_{1zx})]} \quad (9)\end{aligned}$$

where  $V_1$ ,  $V_2$ , respectively represent the volume fraction of the first and second layer plates.

If every single plate is isotropic, formula (9) can be simplified as follows:

$$\begin{aligned}P_x \\ A_x &= \frac{V_1V_2 \left\{ \begin{aligned} &V_1E_1 [E_1(1 - \mu_2^2) - E_2(1 - \mu_1\mu_2)] \\ &\quad + V_2E_2 [E_1(1 - \mu_1\mu_2) - E_2(1 - \mu_1^2)] \end{aligned} \right\} \sigma}{V_1E_1 [V_1E_1(1 - \mu_2^2) + V_2E_2(1 - \mu_2\mu_1)] \\ &\quad + V_2E_2 [V_1E_1(1 - \mu_1\mu_2) + V_2E_2(1 - \mu_1^2)]}\end{aligned}\quad (10)$$

If all products of Poisson's ratio are neglected, then formula (10) can be further simplified to

$$\begin{aligned}
P_x &\approx \frac{V_1 V_2 (E_{1x} - E_{2x})}{V_1 E_{1x} + V_2 E_{2x}} A_x \sigma \\
&= \frac{V_1 V_2 (E_{1x} - E_{2x})}{E_x} A_x \sigma
\end{aligned} \quad (11)$$

By simultaneous Equations (4), (5) and (8), we also can get the  $z$ -axis direction equivalent force  $P_z$

$$\begin{aligned}
P_z &= \frac{E_{1z} E_{2z} A_{1z} A_{2z} (A_{1x} + A_{2x}) (\mu_{2x} - \mu_{1x}) \sigma}{A_{1x} E_{1x} [A_{1z} E_{1z} (1 - \mu_{2xz} \mu_{2zx}) \\
&\quad + A_{2z} E_{2z} (1 - \mu_{1xz} \mu_{2zx})] \\
&\quad + A_{2x} E_{2x} [A_{1z} E_{1z} (1 - \mu_{1xz} \mu_{2zx}) \\
&\quad + A_{2z} E_{2z} (1 - \mu_{1xz} \mu_{2zx})]} \\
&= \frac{E_{1z} E_{2z} V_1 V_2 A_z (\mu_{2x} - \mu_{1x}) \sigma}{V_1 E_{1x} [V_1 E_{1z} (1 - \mu_{2xz} \mu_{2zx}) \\
&\quad + V_2 E_{2z} (1 - \mu_{1xz} \mu_{2zx})] \\
&\quad + V_2 E_{2x} [V_1 E_{1z} (1 - \mu_{1xz} \mu_{2zx}) \\
&\quad + V_2 E_{2z} (1 - \mu_{1xz} \mu_{2zx})]}
\end{aligned} \quad (12)$$

If every single plate is isotropic, formula (12) can be simplified as follows:

$$P_z = \frac{E_1 E_2 V_1 V_2 A_z (\mu_2 - \mu_1) \sigma}{V_1^2 E_1^2 (1 - \mu_2^2) + 2V_1 E_1 V_2 E_2 (1 - \mu_1 \mu_2) + V_2^2 E_2^2 (1 - \mu_1^2)} \quad (13)$$

If all products of Poisson's ratio are neglected, then formula (12) can be simplified to

$$\begin{aligned}
P_z &= \frac{E_{1z} E_{2z} V_1 V_2 A_z (\mu_{2x} - \mu_{1x}) \sigma}{(V_1 E_{1x} + V_2 E_{2x}) (V_1 E_{1z} + V_2 E_{2z})} \\
&= \frac{E_{1z} E_{2z} V_1 V_2 (\mu_{2x} - \mu_{1x}) A_z \sigma}{E_x E_z}
\end{aligned} \quad (14)$$

By Equations (1) and (6), the  $z$ -axis direction Poisson's ratio under the  $x$ -axis direction force is

$$\begin{aligned}
\mu_{zx} &= -\frac{\varepsilon_z}{\varepsilon_x} = -\frac{\varepsilon_{1z}}{\varepsilon_{1x}} \\
&= -\frac{\frac{\mu_{1zx} \sigma}{E_{1x}} - \frac{\mu_{1zx} P_x / A_{1x}}{E_{1x}} + \frac{P_z / A_{1z}}{E_{1z}}}{\frac{\sigma}{E_{1x}} + \frac{P_x / A_{1x}}{E_{1x}} - \mu_{1xz} \frac{P_z / A_{1z}}{E_{1z}}}
\end{aligned} \quad (15)$$

By formulas (11) and (14), formula (15) can be simplified as follows:

$$\begin{aligned}
\mu_{zx} &= \frac{A_{1z} E_{1z} \mu_{1zx} (1 - \mu_{2xz} \mu_{2zx})}{A_{1z} E_{1z} (1 - \mu_{2xz} \mu_{2zx})} \\
&\quad + \frac{A_{2z} E_{2z} \mu_{2zx} (1 - \mu_{1xz} \mu_{1zx})}{A_{1z} E_{1z} (1 - \mu_{2xz} \mu_{2zx})} \\
&\quad + \frac{A_{2z} E_{2z} (1 - \mu_{1xz} \mu_{1zx})}{A_{1z} E_{1z} (1 - \mu_{2xz} \mu_{2zx})} \\
&\quad + \frac{V_1 E_{1z} \mu_{1zx} (1 - \mu_{2xz} \mu_{2zx})}{V_1 E_{1z} (1 - \mu_{2xz} \mu_{2zx})} \\
&\quad + \frac{V_2 E_{2z} \mu_{2zx} (1 - \mu_{1xz} \mu_{1zx})}{V_1 E_{1z} (1 - \mu_{2xz} \mu_{2zx})} \\
&\quad + \frac{V_2 E_{2z} (1 - \mu_{1xz} \mu_{1zx})}{V_1 E_{1z} (1 - \mu_{2xz} \mu_{2zx})}
\end{aligned} \quad (16)$$

If all products of Poisson's ratio are neglected, then formula (16) can be further simplified to

$$\begin{aligned}
\mu_{zx} &= \frac{V_1 E_{1z} \mu_{1zx} + V_2 E_{2z} \mu_{2zx}}{V_1 E_{1z} + V_2 E_{2z}} \\
&= \frac{V_1 E_{1z} \mu_{1zx} + V_2 E_{2z} \mu_{2zx}}{E_z}
\end{aligned} \quad (17)$$

Formula (17) shows that, under the action of longitudinal force, Poisson's ratio in lateral direction (non-normal direction) is inversely proportional to the lateral elastic modulus of the laminate, and is proportional to the sum of the products of Poisson's ratio, elastic modulus and volume fraction of each single plate.

The strains in the  $y$ -axis direction of each single plate are as follows

$$\varepsilon_{1y} = -\mu_{1yx} \frac{\sigma}{E_{1x}} - \mu_{1yx} \frac{P_x / A_{1x}}{E_{1x}} - \mu_{1yz} \frac{P_z / A_{1z}}{E_{1z}} \quad (18)$$

$$\varepsilon_{2y} = -\mu_{2yx} \frac{\sigma}{E_{2x}} + \mu_{2yx} \frac{P_x / A_{2x}}{E_{2x}} + \mu_{2yz} \frac{P_z / A_{2z}}{E_{2z}} \quad (19)$$

The laminate  $y$ -axis direction Poisson's ratio under the  $x$ -axis direction force is given by

$$\begin{aligned}
\mu_{yx} &= -\frac{\varepsilon_y}{\varepsilon_x} = -\frac{(H_1 \varepsilon_{1y} + H_2 \varepsilon_{2y}) / H}{\varepsilon_x} \\
&= -\frac{V_1 \varepsilon_{1y} + V_2 \varepsilon_{2y}}{\varepsilon_x} \approx V_1 \mu_{1yx} + V_2 \mu_{2yx}
\end{aligned} \quad (20)$$

This formula shows that the normal direction Poisson's ratio by the longitudinal force is equal to the weighted sum of Poisson's ratios of each single plate according to the volume fraction.

#### 4 POISSON'S RATIO CALCULATION UNDER THE ACTION OF NORMAL FORCE

Referring to Figure 1, we now study the strains produced by the stress in the  $y$ -axis direction (normal direction).

The first layer (lower layer) single plate  $z$ -axis direction strain is given by

$$\begin{aligned}\varepsilon_{1z} &= \varepsilon_{1\sigma z} + \varepsilon_{1P_{xz}} + \varepsilon_{1P_{zz}} \\ &= -\mu_{1zy} \frac{\sigma}{E_{1y}} - \mu_{1zx} \frac{P_x/A_{1x}}{E_{1x}} + \frac{P_z/A_{1z}}{E_{1z}}\end{aligned}\quad (21)$$

The second layer (upper layer) single plate  $z$ -axis direction strain is given by

$$\begin{aligned}\varepsilon_{2z} &= \varepsilon_{2\sigma z} + \varepsilon_{2P_{xz}} + \varepsilon_{2P_{zz}} \\ &= -\mu_{2zy} \frac{\sigma}{E_{2y}} + \mu_{2zx} \frac{P_x/A_{2x}}{E_{2x}} - \frac{P_z/A_{2z}}{E_{2z}}\end{aligned}\quad (22)$$

The  $x$ -axis direction strains of each layer plate are given by

$$\begin{aligned}\varepsilon_{1x} &= \varepsilon_{1\sigma x} + \varepsilon_{1P_{xx}} + \varepsilon_{1P_{zx}} \\ &= -\mu_{1xy} \frac{\sigma}{E_{1y}} + \frac{P_x/A_{1x}}{E_{1x}} - \mu_{1xz} \frac{P_z/A_{1z}}{E_{1z}}\end{aligned}\quad (23)$$

$$\begin{aligned}\varepsilon_{2x} &= \varepsilon_{2\sigma x} + \varepsilon_{2P_{xx}} + \varepsilon_{2P_{zx}} \\ &= -\mu_{2xy} \frac{\sigma}{E_{2y}} - \frac{P_x/A_{2x}}{E_{2x}} + \mu_{2xz} \frac{P_z/A_{2z}}{E_{2z}}\end{aligned}\quad (24)$$

By  $\varepsilon_{1z} = \varepsilon_{2z}$  and  $\varepsilon_{1x} = \varepsilon_{2x}$ , we get the following equations:

$$\left\{ \begin{aligned} & -\mu_{1zy} \frac{\sigma}{E_{1y}} - \mu_{1zx} \frac{P_x/A_{1x}}{E_{1x}} + \frac{P_z/A_{1z}}{E_{1z}} \\ &= -\mu_{2zy} \frac{\sigma}{E_{2y}} + \mu_{2zx} \frac{P_x/A_{2x}}{E_{2x}} - \frac{P_z/A_{2z}}{E_{2z}} \\ & -\mu_{1xy} \frac{\sigma}{E_{1y}} + \frac{P_x/A_{1x}}{E_{1x}} - \mu_{1xz} \frac{P_z/A_{1z}}{E_{1z}} \\ &= -\mu_{2xy} \frac{\sigma}{E_{2y}} - \frac{P_x/A_{2x}}{E_{2x}} + \mu_{2xz} \frac{P_z/A_{2z}}{E_{2z}} \end{aligned} \right. \quad (25)$$

Ignoring the product form Poisson's ratios, approximate solutions of virtual forces are given as follows:

$$\begin{aligned}P_x &\approx \frac{A_{1x}A_{2x}E_{1x}E_{2x}(E_{2y}\mu_{1xy} - E_{1y}\mu_{2xy})\sigma}{E_{1y}E_{2y}(A_{1x}E_{1x} + A_{2x}E_{2x})} \\ &= \frac{V_1V_2E_{1x}E_{2x}(E_{2y}\mu_{1xy} - E_{1y}\mu_{2xy})}{E_{1y}E_{2y}(V_1E_{1x} + V_2E_{2x})} A_x \sigma\end{aligned}\quad (26)$$

$$\begin{aligned}P_z &\approx \frac{A_{1z}A_{2z}E_{1z}E_{2z}(E_{2y}\mu_{1zy} - E_{1y}\mu_{2zy})\sigma}{E_{1y}E_{2y}(A_{1z}E_{1z} + A_{2z}E_{2z})} \\ &= \frac{V_1V_2E_{1z}E_{2z}(E_{2y}\mu_{1zy} - E_{1y}\mu_{2zy})}{E_{1y}E_{2y}(V_1E_{1z} + V_2E_{2z})} A_z \sigma\end{aligned}\quad (27)$$

The first layer (lower layer) single plate  $y$ -axis direction strain is given by

$$\begin{aligned}\varepsilon_{1y} &= \varepsilon_{1\sigma y} + \varepsilon_{1P_{xy}} + \varepsilon_{1P_{zy}} \\ &= \frac{\sigma}{E_{1y}} - \mu_{1yx} \frac{P_x/A_{1x}}{E_{1x}} + \mu_{1yz} \frac{P_z/A_{1z}}{E_{1z}}\end{aligned}\quad (28)$$

The second layer (upper layer) single plate  $y$ -axis direction strain is given by

$$\begin{aligned}\varepsilon_{2y} &= \varepsilon_{2\sigma y} + \varepsilon_{2P_{xy}} + \varepsilon_{2P_{zy}} \\ &= \frac{\sigma}{E_{2y}} + \mu_{2yx} \frac{P_x/A_{2x}}{E_{2x}} + \mu_{2yz} \frac{P_z/A_{2z}}{E_{2z}}\end{aligned}\quad (29)$$

The  $y$ -axis direction total strain of the laminate is given by

$$\begin{aligned}\varepsilon_y &= \frac{H_1\varepsilon_{1y} + H_2\varepsilon_{2y}}{H} = V_1\varepsilon_{1y} + V_2\varepsilon_{2y} \\ &= V_1 \left( \frac{\sigma}{E_{1y}} - \mu_{1yx} \frac{P_x/A_{1x}}{E_{1x}} + \mu_{1yz} \frac{P_z/A_{1z}}{E_{1z}} \right) \\ &\quad + V_2 \left( \frac{\sigma}{E_{2y}} + \mu_{2yx} \frac{P_x/A_{2x}}{E_{2x}} + \mu_{2yz} \frac{P_z/A_{2z}}{E_{2z}} \right)\end{aligned}\quad (30)$$

The laminate  $x$ -axis direction Poisson's ratio under the  $y$ -axis direction force is given by

$$\begin{aligned}\mu_{xy} &= -\frac{\varepsilon_x}{\varepsilon_y} = -\frac{\varepsilon_{1x}}{\varepsilon_y} \\ &= -\frac{-\mu_{1xy} \frac{\sigma}{E_{1y}} + \frac{P_x/A_{1x}}{E_{1x}} - \mu_{1xz} \frac{P_z/A_{1z}}{E_{1z}}}{V_1 \left( \frac{\sigma}{E_{1y}} - \mu_{1yx} \frac{P_x/A_{1x}}{E_{1x}} + \mu_{1yz} \frac{P_z/A_{1z}}{E_{1z}} \right) + V_2 \left( \frac{\sigma}{E_{2y}} + \mu_{2yx} \frac{P_x/A_{2x}}{E_{2x}} + \mu_{2yz} \frac{P_z/A_{2z}}{E_{2z}} \right)}\end{aligned}\quad (31)$$

The equivalent forces  $P_x$  and  $P_z$  in formula (31) are determined by formulas (26) and (27).

The laminate  $z$ -axis direction Poisson's ratio under the  $y$ -axis direction force could be calculated by a similar method.

## 5 CONCLUSIONS

1. Poisson's ratio of laminate composite could be approximately calculated by the analytical method.
2. The normal direction Poisson's ratio under the action of longitudinal force is equal to the

weighted sum of Poisson's ratios of each single plate according to the volume fraction.

3. Under the action of longitudinal force, Poisson's ratio in the lateral direction (non-normal direction) is inversely proportional to the lateral elastic modulus of the laminate, and is proportional to the sum of the products of Poisson's ratio, elastic modulus and volume fraction of each single plate.

# The effects of nanophase SiO<sub>2</sub> for the performance of epoxy resin

Y.J. Jin

Jilin Jianzhu University, Changchun, China

SH.J. Wang

The City College of Jilin Jianzhu University, Changchun, China

**ABSTRACT:** This article mainly researches on the uniform dispersion of technology for nanophase SiO<sub>2</sub> in epoxy resin. The tensile test, shock test and scanner electric glass are applied for studying the structure and performance of the compound material. The results indicate that the nanophase SiO<sub>2</sub> are uniformly dispersed in the epoxy resin radical and the mechanical performance of epoxy resin is improved, which will produce the action of increasing strength and increasing toughness for epoxy resin.

**Keywords:** epoxy resin; nanophase SiO<sub>2</sub>; increasing strength; increasing toughness

## 1 INTRODUCTION

Epoxy resin is a thermosetting resin, which has excellent mechanical properties, electrical properties and chemical properties, and it is widely used in fields such as machinery, chemicals, electrical and electronic and aerospace. But the epoxy resin has some disadvantages, such as crosslinking curing crisp poor impact resistance and resistance to stress cracking ability. Introduction of nanoparticles proves to be an effective method in epoxy resin, and it has become a hot research (Shang et al. 2005; Kormmann et al. 2001). Nanomaterials have been shown to have excellent performance because of their unique surface effect, volume effect and the quantum effects that conventional fillers do not have. Nanoparticles have small particle size, surface energy, are easily reunited, and different from the conventional particles that can exist between particles. How to solve the agglomeration problem to achieve a rapid, uniform dispersion of nano-particles in the matrix becomes the key performance of composite material (Liu et al. 2002; Hui et al. 2004).

## 2 EXPERIMENTAL SECTION

### 2.1 The main materials

Epoxy resin takes WSR6101(E-44), which has double A made in Wuxi Resin Industry. Nano silica is provided by Hangzhou Wan Jing New Material Co. Ltd. Its performance is presented in Table 1. It can be seen from Table 1 that nanophase SiO<sub>2</sub> has a surface area of 250 ± 30 m<sup>2</sup>/g and an average particle diam-

eter of 15 ± 5 nm. Curing agent (ethylenediamine) is made by Shanghai Reagent Factory. Acetone is produced by Xi'an Reagent Factory.

### 2.2 Specimen preparation

The powdered nano-SiO<sub>2</sub> is added to a solution of an appropriate amount of acetone, and treated with ultrasonic waves for 30 minutes. The pot in an oil bath is heated to about 130 °C after stirring the solution, and an epoxy resin mixed solvent removed, the epoxy resin and nano-SiO<sub>2</sub> reaction is about 1H. A curing agent (ethylenediamine) stoichiometric is mixed and poured into the vacuum degassing of steel mold coated with a release agent after cooling, the cured completely is cooled after demolding, and the mechanical properties of the test piece are analyzed.

### 2.3 The performance testing and tensile testing

The tensile properties are tested according to the GB1040-79 standard test. The machine used is LJ-500 type.

### 2.4 The impact testing

The impact properties are tested according to the GB1043-79 standard test. The machine used is CHARPY X CJ-40-type.

### 2.5 SEM

The particle morphology of material is observed by the transmission electron microscope and the scanning electron microscope. The machine type

Table 1. The performance parameters of nano-silica.

Name	Performance	Particle size (nm)	Specific surface area (m <sup>2</sup> /g)	Content (%)	Ignition loss (%) 950°C × 2 h
Nano-silica	White powder	15 ± 5	250 ± 30	≥99.5	≤6

is the S-570 scanning electron microscope (Hitachi Ltd, Japan).

### 3 RESULTS AND DISCUSSION

#### 3.1 The mechanical properties of E-44/nm SiO<sub>2</sub> composite material

Nano-SiO<sub>2</sub> with different amounts affects the mechanical properties of E-44/nm SiO<sub>2</sub> composite. It takes the epoxy resin as the base to be incorporated material SiO<sub>2</sub> to find five points dosage of 0%, 2%, 4%, 6%, and 8%, which are measured impact values and the tensile value and the test piece is observed nano-SiO<sub>2</sub> ash on PC impact, tensile impact. Table 2 gives the mechanical properties of nm SiO<sub>2</sub> composite material.

It can be seen that the nm SiO<sub>2</sub> epoxy resin concrete has a toughening effect, within a certain range, as shown in Figure 1 and Figure 2. The impact strength and tensile strength of the composite material obtained are gradually increased with the nm SiO<sub>2</sub> increasing of the content, when nm SiO<sub>2</sub>/E-44 is 2/100 (mass ratio). These two properties reach a maximum value (1.24 J/m, 1.43 MPa), and the material of two kinds of performance declines with the amount of nm SiO<sub>2</sub> increasing.

Nano silica is a light amorphous white powder. It is non-toxic, tasteless, and non-polluting. The microstructure of nano-silica is flocculent and mesh. This special structure makes it to have unique properties, especially its dispersion in the material when combined with polymer chains to form a three-dimensional network structure. So, it can improve the basic properties of the material, such as strength and elastic.

In the study of composite systems by ultrasonic treatment, nm of SiO<sub>2</sub> particles are uniformly dispersed in an epoxy matrix, the matrix impact nm of SiO<sub>2</sub> between the particles, and the matrix can produce a large number of silver streaks (or micro-cracks) between the particles, which is also plastically deformed. Therefore, it absorbs greatly impact energy to achieve toughening effects. Nm SiO<sub>2</sub> is added in an amount within a certain range, if it increases the resulting silver streaks and plastic deformation will increase, the toughening effect will also be better. In addition, its particle diameter is small, has a large surface area, a large

Table 2. The mechanical properties of nm SiO<sub>2</sub> composite material.

SiO <sub>2</sub> contents (%)	0	2	4	6	8
Tensile value (MPa)	0.26	1.43	0.38	0.47	0.36
Impact values (J/m <sup>2</sup> )	0.65	1.24	0.75	0.64	0.60

Figure 1. The effects of nanophase SiO<sub>2</sub> to tensile of PC.

Figure 2. The effects of nanophase SiO<sub>2</sub> to impact of PC.

proportion of atoms within the surface layer with an epoxy resin for the nanoscale particles. It can sufficiently adsorb, bond, couple with the use of silane coupling agent, and enhance the interfacial adhesion of the particles and the matrix, which are conducive to the stress transfer between the particles and the matrix, improving the ability to bear the load. Therefore, the enhancement and toughening of the base body are simultaneous. If nm SiO<sub>2</sub> is added in an amount of more than a critical value, it will result in a short distance between

the nanoparticles, the silver streaks of the material by an external force generated when too much, and very large plastic deformation, thus it will be evolved into a large cracking, leading to the decline in the strength and toughness of the material.

The content of nanophase  $\text{SiO}_2$  effects the tensile of PC is shown in Figure 1, and effects the impact of PC are shown in Figure 2.

### 3.2 Electron microscopic analysis of E-44/nm $\text{SiO}_2$ composite material

Figure 4 shows a SEM image of an epoxy resin nano-composite material. It can be seen from the

Figure 3. The transmission electron microscope of nano-silica.

Figure 4. The SEM photo of E-44/nm  $\text{SiO}_2$  composite material.

figure that the nano-composite epoxy system force will produce a lot of crazing. Nano- $\text{SiO}_2$  particles are added to the epoxy resin, the surface of nano- $\text{SiO}_2$  particles has lack of coordination, a large specific surface area characteristics, so that it shows strong activity with the oxygen atoms of the epoxy-like molecules that are prone to key cooperation, and enhance the bond force between the molecules. As part of nano- $\text{SiO}_2$  particles are distributed in the gap of the polymer chain, and a high degree of liquidity, the strength and toughness of epoxy are increased and thus nano- $\text{SiO}_2$  particles are increased greatly.

## 4 SUMMARY

In summary, nano- $\text{SiO}_2$  can enhance toughened epoxy resin (Jin 2010; Xiao & Jin 2009) within a certain range of dosage. In E-44/nm  $\text{SiO}_2$  composites, the ratio of the best use of nano- $\text{SiO}_2$  and epoxy resin is 2/100 in a relatively uniform dispersion.

**ABSTRACT:** Magnesium slag cementitious material was prepared successfully using the magnesium slag-furnace slag-clinker system and different activators in this paper. The effect of the activator on the mechanical property of the material was studied. The hydration and microstructure of this composite cement were analyzed by X-ray diffraction and scanning electron microscopy, and the interaction mechanism was researched. The results show that the activity of magnesium slag was enhanced significantly by adding a small amount of the activator. Combined activators have the best effect. The activators have no effect on the species of hydration products of magnesium slag cementitious materials mortar, which are composed of Aft, C-S-H,  $\text{Ca}(\text{OH})_2$ .

**Keywords:** magnesium slag; activators; interaction mechanism; cementitious materials

## 1 INTRODUCTION

Magnesium slag is the sub-product generated in the production of metallic magnesium. Magnesium slag is obtained by the reduction of dolomite by Fe- (Si), resulting in several oxides, being constituted of dicalcium silicate ( $2\text{CaO}\cdot\text{SiO}_2$ ), which is also present in cements and slags (Oliveira et al. 2004). It was nothing more than a latent hydraulic binder and must be activated in practice to react and provide strength. It has been recognized that alkali additions can activate pozzolanic materials to set and harden in their own right (Darko K. et al. 2002). The result showed that cementitious materials composed of magnesium slag and little clinker did not meet the engineering demand in the previous study. By learning from the use of other slags, furnace slag was added to magnesium slag cementitious materials. Magnesium slag cementitious materials consisted of clinker, magnesium slag, furnace slag and activators, consisting of sodium silicate, gypsum and sodium silicate.

## 2 EXPERIMENTAL PROCEDURE

### 2.1 Materials

Magnesium slag was supplied by Dong Feng Colored Metal Industry of Jilin. Furnace slag and clinker were supplied by YaTai Cement Industry.

Details of the chemical composition of the materials used are given in Table 1. Activators were liquid sodium silicate, sodium sulfate, and gypsum. Liquid sodium silicate was bought from the market, and the modulus of sodium silicate was 1.5, with a consistency of 49%. Sodium sulfate was of industrial grade chemical reagent. Gypsum was supplied by YATAI Cement Industry of Jilin, and the content of  $\text{SO}_3$  is 40%.

### 2.2 Specimens and test methods

The original materials were ground in the ball grinding mill according to the proportion fixed in the previous study until the final fineness was 3.6%. Liquid sodium silicate was added by dissolving in water, but gypsum and sodium silicate were added by mixing with the other dry materials. Determination of strength was tested according

Table 1. Chemical composition (by mass) of raw materials (%).

Materials	$\text{SiO}_2$	$\text{Al}_2\text{O}_3$	$\text{Fe}_2\text{O}_3$	CaO	MgO	Others
Clinker	22	5	6	64	1.5	1.5
MS	31.78	2.61	7.73	48.53	8.42	1.65
FS	30.67	17.98	0.73	40.03	8.50	2.09

\*MS refers to magnesium slag, FS refers to furnace slag.

to the GB/T 17671-1999 test. Water requirement of normal consistency, setting time and soundness of the material were tested according to the GB/T1346-2001 test. Fineness of the material was tested according to the GB/T 1345-2005 test. A water-to-binder ratio of 0.5 was used. The type of X-ray machine used was Ultimalv, which operates under the following conditions: 40 kV, 20 mA. The type of SEM machine used was KYKY2800.

### 3 RESULTS AND DISCUSSION

#### 3.1 Determination of minerals of magnesium slag

The minerals phases of magnesium slag were determined by XRD. The result is shown in Figure 1.

It can be seen from Figure 1 that the mineral phases of magnesium slag were  $C_2S$ ,  $MgO$  and  $CF$ . Magnesium slag can harden because there was plenty of  $C_2S$ , which was the mineral of Portland cement.

#### 3.2 Effect of activators on the magnesium slag cementitious material

The experiment was conducted according to the proportion fixed in the previous study (clinker:magnesium slag:furnace slag ratio 35%:32.5%:32.5% by mass). The effects of the single activator and composite activators were studied.

As shown in Table 2, the mechanical properties of magnesium slag cementitious material were enhanced by adding the activator, and the combined activators have the best effect on the material. The hydration process and mechanism can be explained as follows. The hydration of clinker and hydrolyzation of sodium silicate resulted in a high concentration of  $OH^-$ . The structure of magnesium slag and furnace slag is destroyed under the high concentration of  $OH^-$ . It can be described as

Figure 1. Curves of XRD-ray analysis.

Table 2. Effect of the activators on the mechanical property of magnesium slag cementitious material.

No.	Activator		Compressive strength/MPa		Flexural strength/MPa	
	Kind	Dosage/%	3d	28d	3d	28d
1		0	10.6	25.8	2.45	3.90
2	a	1.5	10.9	28.3	2.60	4.70
3	b	2	15.4	30.3	3.55	5.2
4	c	3	12.9	30.5	2.92	6.2
5	a+ b + c	0.5 + 2 + 2	14.7	42.7	3.52	7.3

\*a indicates sodium silicate, b indicates sodium sulfate, c indicates gypsum.

the breaking of Me-O (Me ≡ Ca, Mg), Si-O-Si, Al-O-Al and Al-O-Si bonds in the slag grains, resulting in high concentrations of ions such as  $H_3SiO_4^-$  and  $H_3AlO_4^{2-}$  in the solution. These ions react with  $Na^+$ , which result in some hydration products of natrolite, The reactions proceed according to the following equations (Xu et al. 2004):

The above reaction absorbed lots of  $Ca^{2+}$  and other ions, which accelerated the rate of the destruction of magnesium slag and furnace slag gradually. At the same time, gypsum and sodium sulfate provided the  $SO_4^{2-}$  ions that reacted with  $C_4AH_{19}$ . Thus, the Aft was produced when gypsum and sodium sulfate were added. The products formed at later times filled in the porous area; furthermore, these products formed a compacted net structure through superposition. The result was that the strength of the material was enhanced finally.

The cementitious material had good mechanical properties, with the compressive strength of 42.7 MPa and the flexural strength of 7.3 MPa. Properties of the material were also tested. The water requirement of normal consistency was 34.4%, the initial time was 116 min, the final time was 175 min, and the soundness of the material corresponded with the standard of cement.

#### 3.3 SEM observations

The microstructure of this composite cement was analyzed by scanning electron microscopy, and as a comparison, two SEM images were

obtained. Figure 2 shows the micrographs of this material.

It can be obviously noted that there exists quite a large difference in the microstructure of the magnesium slag cementitious materials whether the activator was added. The latter generally exhibits compacted and continued integrated morphological characteristics, while the former exhibits some incompact area, i.e., some remaining porous area. We can see this result from the above figure where lots of needle core product exists in the material, and little product linked to each other. It was proved that both magnesium slag and furnace slag hydrated incompletely, with the microstructure of the products showing a compacted structure correspondingly. It proved that the activators accelerate the rate of hydration, and more hydration products were formed.

### 3.4 X-Ray Microanalysis (XRD)

The hydration products have much effect on the properties of cement, such as durability and other mechanical properties. So, the kinds of hydration

Figure 2. SEM images of magnesium slag cementitious material mortar (28d).

Figure 3. XRD patterns of magnesium slag cementitious materials mortar.

products were analyzed by XRD, and the result is shown in Figure 3.

From Figure 3, we can observe that Aft, C-S-H,  $\text{Ca}(\text{OH})_2$  existed in the hardened cement.

## 4 CONCLUSION

Magnesium slag cementitious material was prepared successfully using the magnesium slag-furnace slag-clinker system and several activators, whose performance was in accordance with the standards of composite cement of 32.5 MPa. The activity of magnesium slag was enhanced significantly by adding a small amount of the activator. The cementitious material performed well mechanically when the activators were combined. The species of hydration products of this material were Aft, C-S-H,  $\text{Ca}(\text{OH})_2$ .

# Effect of lithium on the microstructure and properties of Al-Mg-Si-Li alloys with different Si contents

Z.K. Zhao, Q. Gao, Y. Yao, B.Z. Liu, D. Zhang & G.Q. Wang

Materials Science and Engineering School, Shandong Jianzhu University, Jinan, P.R. China  
Shandong Engineering Research Center for Clean Foundry, Jinan, P.R. China

**ABSTRACT:** The effect of lithium on the microstructure and properties of Al-Mg-Si-Li alloys with different Si contents was investigated. The microstructure was observed by optical microscopy, the phases were determined by X-ray diffractometry, and the mechanical properties were determined by a tensile tester. The result shows that Li reduces the ratio of eutectic in Al-Si-Mg alloys: the alloy containing 20.0 wt.% Si can not obtain the eutectic microstructure completely. The ratio of the eutectic is increased and the constituent of the eutectic is coarsened with the increment of the Si content. Being modified by the Al-P master alloy, the primary Si is refined and granulated, and the ratio of the eutectic is increased. Al-15 wt.% Si-0.3 wt.% Mg-1.1 wt.% Li alloys have excellent mechanical properties: the tensile strength, the yield strength and elongation of the alloys are 265 MPa, 137 MPa and 1.8%, respectively.

**Keywords:** Li; Si content; Al-Mg-Si-Li alloys; microstructure; properties

## 1 INTRODUCTION

Al-Si-Mg alloys have been widely used in the automotive industry due to their good casting characteristics and mechanical properties. Si is the major alloying element, which imparts good castability, high wear resistance and hardness. A small addition of Mg improves solution treatment and age hardening characteristics of these alloys. The mechanical properties of Al-Si-Mg cast alloys depend not only on a chemical composition, but also, more importantly, on microstructural features such as morphologies of dendritic  $\alpha$ -Al, eutectic Si and  $Mg_2Si$  that present in the microstructure.

Lithium is added to Al-Si alloys to decrease the density and improve the specific strength and elastic modulus. Al-Si-Li alloys containing 3.6–8 wt.% Li and 5–14 wt.% Si have been developed by a rapid solidification technique, where the alloys have a low density, high elastic modulus and high ratio modulus [Dubost1987]. The triangle and oval primary Si phases are present in the microstructure of Al-7.0 wt.% Si-0.3 wt.% Mg -xLi alloys, and the precipitation is inhibited to make the alloys have lower elongation and strength [Gröbner 2001]. However, there is no report about the effect of Li on the microstructure and properties of Al-Si-Mg-Li with different Si contents. In the present work, 1.1 wt.% Li was added into Al-Si-Mg-Li alloys containing 7.0%wt.% Si, 12 wt.% Si, 15 wt.% Si or 20 wt.% Si, respectively, to investigate the

microstructure and properties of Al-Mg-Si-Li alloys with different Si contents.

## 2 EXPERIMENTAL SECTION

Composition of the alloys studied is given in Table 1, which were melted in a vacuum furnace and cast in a metal mould under argon. The alloys were modified by the addition of 1.0 wt.% Al-P master alloy provided by Shandong University.

Microstructure of the alloys was observed by using an optical microscope. The different phases of the alloys were analyzed by X-ray diffractometry. The tensile strength was determined by the tensile tester at a constant rate of 1 mm/s using bars of diameter 10 mm and length 50 mm.

Table 1. Chemical composition of the tested alloys.

Item	Si (wt.%)	Li (wt.%)	Mg (wt.%)	Al (wt.%)	Remark

### 3 RESULTS

#### 3.1 Microstructure of as-cast Al-Si-Mg-Li alloys with different Si contents

Figure 1(a)–(c) shows the microstructure of unmodified Al-Si-0.3 Mg-1.1 Li as-cast alloys with different Si contents. Figure 1(a) shows that the microstructure of the alloys containing 7.0 wt.% Si consists of eutectic, granular Si, together with an amount of fine particles in the primary  $\alpha$ -Al matrix. When the Si content in the alloy is 12.0 wt.%, the ratio of the eutectic increases to 50% approximately, and Si becomes coarse block,

Figure 1. Microstructure of unmodified Al-Si-Mg-Li as-cast alloys with (a) 7.0 wt.% Si, (b) 12.0 wt.% Si, (c) 20.0 wt.% Si.

triangle or needle, and the particles in the  $\alpha$ -Al matrix become coarsened, as shown in Figure 1(b). In the alloy containing 20.0 wt.% Si, the ratio of the eutectic is about 70%, and the primary  $\alpha$ -Al was refined. There are two kinds of Si: granular Si and large block Si, as shown in Figure 1(c). Comparing the eutectic among the three alloys, the ratio of the eutectic increases with the increment of the Si content; however, the ratio of the eutectic is far lower than that of the Li-free alloys. When the Si content is up to 20.0 wt.%, there is still 20% of the primary  $\alpha$ -Al remaining. It should be mentioned that Si in the eutectic is coarsened as the Si content increases.

Figure 2 (a)–(c) shows the microstructure of Al-Si-0.3 Mg-1.1 Li as-cast alloys with different Si contents and the alloys were modified by the 1.0 wt.% Al-P master alloy. The microstructure containing 12.0 wt.% Si shows the oval primary  $\alpha$ -Al phase, eutectic and Si, as shown in Figure 2(a). Figure 2(b) shows the microstructure of the alloy containing 15.0 wt.% Si, the  $\alpha$ -Al is refined, approximately 60% of eutectic occurs, and Si is also refined and granulated. When Si content is 20.0 wt.%, the coarse stick particles are distributed in the  $\alpha$ -Al matrix, which constitutes the eutectic, besides the coarser Si, as shown in Figure 2(c). Comparing the microstructure of the three modified alloys, the ratio of the eutectic increases and the ratio of the primary  $\alpha$ -Al decreases with the increment of the Si content, and the primary  $\alpha$ -Al almost disappears when the Si content increases up to 20.0 wt.%. The constituent of the eutectic is coarsened as the Si content increases. The modified alloys containing 15.0 wt.% Si have the excellent microstructure.

Comparing the microstructure of the unmodified alloys and the alloys modified by the Al-P master alloy, modification of the Al-P master alloy plays an important role for microstructure improvement of Al-Si-Mg-Li alloys, especially for the alloys with the Si content exceeding 12 wt.%. It is the modification of the Al-P master alloy that increases the ratio of the eutectic, and refines and granulates the primary Si, but coarsens the constituent of the eutectic.

#### 3.2 X-ray diffractometry

Figure 3 shows the X-ray diffraction patterns of Al-Si-0.3 Mg-1 Li alloys with 7.0 wt.% Si, 12.0 wt.% Si or 15.0 wt.% Si. Diffraction peaks corresponding to  $\alpha$ -Al, Si and LiAlSi were marked, which shows that the eutectic may be Al-LiAlSi binary eutectic in the as-cast structure [Kadanner1976]. The intensity of the peaks corresponding to Si and LiAlSi is enlarged as the Si content increases, which indicates that the amount of Si and LiAlSi increases with the increment of the Si content.

Figure 2. Microstructure of modified Al-Si-Mg-Li as-cast alloys with (a) 12.0 wt.% Si, (b) 15.0 wt.% Si, (c) 20.0 wt.% Si.

Figure 3. X-ray diffraction patterns of Al-Si-0.3 Mg-1 Li alloys with (a) 7.0 wt.% Si, (b) 12.0 wt.% Si, (c) 15.0 wt.% Si.

Table 2. Mechanical properties of unmodified Al-Si-Mg-Li alloys with different Si contents.

Item	Si content (wt.%)	Tensile strength (MPa)	Yield strength (MPa)	Elongation (%)
U1	7.0	245	89	1.3
U2	12.0	162	78	1.0
U4	20.0	234	85.6	1.2

Table 3. Mechanical properties of modified Al-Si-Mg-Li alloys with different Si contents.

Item	Si content (wt.%)	Tensile strength (MPa)	Yield strength (MPa)	Elongation (%)
M2	12.0	217	84	1.3
M3	15.0	265	137	1.8
M4	20.0	215	82	1.5

### 3.3 Mechanical properties

The mechanical properties of unmodified alloys with different Si contents are listed in Table 2. It can be seen from the table that the unmodified alloys containing 7.0 wt.% alloy have excellent mechanical properties, and the tensile strength is 245 MPa, the yield strength is 89 MPa and the elongation is 1.3%. When the Si content is 12.0 wt.%, the mechanical properties decrease due to the block, triangular or needle primary Si. However, the alloys containing 20.0 wt.% Si have better mechanical properties than those containing 12 wt.% due to the granulation of Si. Table 3 lists the mechanical properties of modified alloys with different Si contents. It can be seen that the alloys containing 15 wt.% Si have excellent mechanical properties, which are superior to those of the alloys containing 12 wt.% Si or 20 wt.% Si.

Comparing the mechanical properties between the unmodified alloys and the modified alloys, it is found that the mechanical properties of the modified alloys are far more excellent than those of the unmodified alloys when the Si content is 12.0 wt.%. When the Si content is 20.0 wt.%, the modification of the Al-P master alloy makes the elongation improve, but the tensile strength is reduced.

## 4 DISCUSSION

Li plays a significant role in the microstructure of Al-Si-Mg alloys. When 1.1 wt.% Li is added into the Al-7.0 wt.% Si-0.3 wt.% Mg alloy, a little of primary Si occurs, which is due to the reduction

of the eutectic. The ratio of the eutectic is just about 50%, which is only a half of the Al-12 wt.% Si alloy. However, the alloy containing 20.0 wt.% Si cannot achieve the eutectic microstructure completely. Given all the above-mentioned factors, the eutectic composition and primary phases are modified by Li.

AlLiSi is a primary phase in Al-Si-Li alloys [Gröbner 2001], and Mg<sub>2</sub>Si is present in the  $\alpha$ -Al matrix when the alloys contain 0.3 wt.% Mg, though Mg<sub>2</sub>Si was not characterized by X-ray diffractometry due to low Mg content. The particles distributed in the  $\alpha$ -Al matrix may be Mg<sub>2</sub>Si, and the eutectic might be the ternary eutectic of Al-Si-AlLiSi. It is the depletion of Si from the primary Si and AlLiSi that causes the reduction of the eutectic.

P and Al form an intermediate phase (AIP) at high temperatures. The crystal structure of the AIP phase is similar to that of Si and is sphalerite type. So, the AIP phase can be used as a heterogeneous nucleation of the primary Si phase, and the final aim is mainly to refine the primary Si phase. But P cannot change the eutectic Si phase. The ratio of the eutectic is improved by the Al-P master alloy due to the reduction of Si depletion during the reaction of P and Li.

## 5 CONCLUSIONS

Li reduces the ratio of the eutectic in Al-Si-Mg alloys, and the alloy containing 20.0 wt.% Si cannot

achieve the eutectic microstructure completely. The ratio of the eutectic is increased and the constituent of the eutectic is coarsened with the increment of the Si content. Being modified by the Al-P alloy, the primary Si is refined and granulated, and the ratio of the eutectic is increased. Al-15 wt.% Si-0.3 wt.% Mg-1.1 wt.% Li alloys have excellent mechanical properties: the tensile strength, the yield strength and elongation of the alloys are 265 MPa, 137 MPa and 1.8%, respectively.

# Laboratory study on performance of semi-flexible mixture

Lu Zhang

China Agricultural University, Beijing, China

Huoming Wang & Rukai Li

China Merchants Chongqing Communications Research and Design Institute, Chongqing, China

**ABSTRACT:** The semi-flexible pavement refers to matrix asphalt mixture (the void ratio is up to 20%~28%) filled with special mortar in which cement is the major constituent. By laboratory testing of rutting, resistance performance and fatigue characteristics were studied. The results showed that: semi-flexible mixture has excellent high temperature stability, while the test temperature is 70 °C and the tire pressure is 1.0 MPa, the dynamic stability are more than 6000. Compared to the conventional asphalt mixture, the semi-flexible pavement can adapt better to high temperatures and heavy resistance road deformation need. The temperature has a significant effect on the fatigue properties of the semi-flexible mixture: the lower the temperature, the higher the material ultimate tensile strength, however, under such condition, the fatigue life decline faster.

**Keywords:** road engineer; semi-flexible mixture; anti-rutting performance; four-point fatigue bending; fatigue life

## 1 INTRODUCTION

The semi-flexible pavement refers to matrix asphalt mixture (the void ratio is up to 20%~28%) filled with special mortar in which cement<sup>[1,2]</sup> is the major constituent. Researches indicate that semi-flexible pavement with high-temp rutting resistance, low temperature crack resistance and endurance are better than bituminous mixture<sup>[3,4,5]</sup>. Compared with the cement concrete pavement, this pavement has lower modulus and improved traffic comfort and endurance. Additionally, semi-flexible pavement has excellent oil, acid, heat, slippery resistance and water stability, and it is easy to colored up. Based on the above properties, semi-flexible pavement has become a research hot spot in recent years; in some areas experiment have been made by paving semi-flexible pavement to improve the increasingly prominent rutting problem. In this thesis, study of semi-flexible pavement rutting performance and the influence caused by temperature & load have been made through laboratory tests, study of the fatigue characteristics of semi-flexible mixture under different temperature has been made by Four-point bending test, and the logarithm equation of the fatigue life at different temperatures has been concluded by regression analysis.

## 2 SEMI-FLEXIBLE MIXTURE DESIGN

Through the former achievements of this research and many experiments which concentrate on the mix proportion of mother-asphalt mixture, the mix proportion adopted in this thesis can meet the specification of Marshall Stability test and the mother—asphalt mixture and asphalt content adopted in this research is laboratory-made asphalt. And the portion, amount of mixture as well as the Marshall Stability test result are given in [Table 1](#) and [Table 2](#)<sup>[6,7,8]</sup>.

Through many experiments, we get the mortar mix ratio which can meet the need of the mechanical property and mobility. Studies have shown that the admixture of fly ash mortar or polymer helps to improve the performance<sup>[6,8]</sup>. And the physical and mechanical property indices of the mortar

### 3 RESEARCH ON THE RUTTING RESISTANCE PROPERTIES OF THE SEMI-FLEXIBLE MIXTURE

Rutting test has been adopted to make research on the resistance to deformation of semi-flexible mixture, taking into account the impact of temperature, load, and water to resistance to deformation, the test results are as follows.

#### 3.1 Temperature effects on the rutting test results

Asphalt is a viscoelastic material, to which the temperature has evident effect on its deformation resistance<sup>[4]</sup>. The temperature for the rutting test is 60 °C and 70 °C, while the test wheel ground pressure is 0.7 MPa. The asphalt is SK70 Class A road petroleum asphalt; SBS modified bitumen uses laboratory preparation with 4% of SBS content; and asphalt test results are shown in Table 5. The test results satisfies the Technical Specifications for Construction (JTG F40-2004)<sup>[9]</sup>. The AC-20 mixture has followed the specification, the composition and mixture volume indicators of which are shown in Table 6 and Table 7.

And the results are given in Table 8 and Figure 1, Figure 2.

From the experimental results, the dynamic stability of semi-flexible material is 6000 (times/mm) or more when the temperature is 60 °C or 70 °C. When the temperature increased 10 °C, the dynamic stability declined to 9886 from 11225, with a decrease of 11.9%. In contrast, the dynamic stability of ordinary AC-20 declined from 1890 to 1120 by, with a decrease of 40.7%; and the dynamic stability of SBS modified AC-20 decreased by 31.2%, from 3850 to 2650.

Therefore, it is obvious that the temperature has the greatest impact on ordinary AC rutting dynamic stability; the second greatest on the SBS modified AC and the least on semi-flexible materials.

#### 3.2 Impact of load on rutting test results

In recent years, rutting has occurred to the conventional asphalt pavement because of the increasingly prominent phenomenon of overloading and beyond limitation transportation. Series of measures has been adopted to alleviate the rutting of asphalt pavement, such as high viscosity modified asphalt, low-grade asphalt, high-modulus asphalt concrete, the use of skeleton dense gradation, etc., which have eased to some extent the asphalt pavement rutting, but they are still not effective for the conventional asphalt pavement enough confronting overload and beyond limitation transportation; and rutting still occurs from time to time.

Semi-flexible material is between cement concrete and asphalt mixture; it is the complex of concrete and asphalt, with greater rigidity and better flexibility, integrating the cement and asphalt advantages. From research and practice, semi-flexible material is an effective way to resolve the current rutting problem.

Experimental results show that test wheel ground pressure boasts a good correlation with the weight, for when the weight each increases about 50%, the test wheel ground pressure increases about 0.1 MPa. Thus, rutting test under different load can be made by adjusting the wheel ground pressure to simulate overload. The results are shown in Table 9 and Figure 3.

From the test results, as the test wheel ground pressure increases, all materials' dynamic stability showed reduced trends. When the test wheel ground pressure is from 0.7 MPa to 1.1 MPa (Equivalent to 200% overload simulation), the dynamic stability of ordinary AC-20, SBS modified AC-20 and semi-flexible materials, has decreased 58.5%, 51.2%, 23.5% relatively.

Thus, the use of modified asphalt can provide a more significant improvement in the temperature

Table 5. Test results of asphalt index.

Test material	Dynamic stability (times/mm)		Residual dynamic stability (%)
	Before soaking	After soaking	
Ordinary AC-20	1850	1365	73.8
SBS modified AC-20	3800	3012	79.3
The semi-flexible mixture	11250	9958	85.2

sensitivity of asphalt, but it is with limited improvement to the load sensitivity. The use of semi-flexible materials can improve both temperature sensitivity and load sensitivity. Even under the road 200% overload conditions, the dynamic stability of semi-flexible materials is also 8000 (times/mm) or more.

### 3.3 Soaking rutting test

In order to test the stability of water of semi-flexible material, soaking rutting test has been conducted. The track plate was saturated in 60 °C water for 5 hours, and then stability test was carried out under conditions of 60 °C for temperature and 0.7 MPa for pressure. The results are shown in Table 10.

From the test results, the soaking rutting residual dynamic stability of ordinary AC-20, SBS modified AC-20 and semi-flexible materials were 73.8%, 79.3%, 85.2%. Based on previous findings, it can meet the requirements of road performance when the residual dynamic stability achieved 70%. It is necessary to adopt high-quality asphalt or other measures to make the residual dynamic stability to achieve more than 80%. The soaking rutting residual dynamic stability of semi-flexible materials was 85.2%, indicating that the water stability is very good.

## 4 RESEARCH ON THE FATIGUE PROPERTY OF THE SEMI-FLEXIBLE MIXTURE

Four-point bending test has been carried out to make research on the fatigue property of the semi-flexible mixture. Taking into account the impact of temperature on the fatigue properties, fatigue performance test has been conducted under three different temperatures (5 °C, 20 °C, 40 °C) and the four stress levels: stress intensity ratios of 0.2, 0.3, 0.4 and 0.5. Corresponding to each intensity ratio, there are 5 items for test and the load frequency is controlled at 10 Hz.

The results are shown in Figure 4 and Table 11. It can be observed in Figure 4 that with increased test temperature, the mixture of semi-flexible pavement breaking strength decreases.

It can be seen from the three temperature fatigue tests results and fatigue curve equation in Figure 5

Figure 4. Temperature impact on breaking strength.

Table 11. Fatigue test results under different temperatures and different stress levels.

Temperatures (°C)	Stress-ratio ( $\sigma/\sigma_c$ )	Logarithmic fatigue life $\lg N_f$		Breaking strength (MPa)
		Average	Standard deviation (S)	
5	0.2	5.2254	0.1567	6.21
	0.3	4.4654	0.2458	
	0.4	3.8685	0.1451	
	0.5	3.1451	0.1784	
20	0.2	4.6321	0.0739	4.32
	0.3	3.9218	0.2843	
	0.4	3.4067	0.1781	
	0.5	3.0395	0.2445	
40	0.2	3.5945	0.1475	1.96
	0.3	3.1034	0.0987	
	0.4	2.8811	0.1237	
	0.5	2.3802	0.1179	

Figure 5. Temperature impact on fatigue life.

Table 12. Fatigue life equation of semi-flexible mixture under three different temperatures.

Temperature (°C)	Fatigue equation	Correlation coefficient
5	$\lg N_f = -6.8378 \sigma/\sigma_s + 6.5693$	0.9981
20	$\lg N_f = -5.2929 \sigma/\sigma_s + 5.6025$	0.9793
40	$\lg N_f = -3.8652 \sigma/\sigma_s + 4.3426$	0.9803

and Table 12, that the fatigue equation slope under 40 °C is significantly less than that is under 5 °C, which demonstrates that semi-flexible mixture has a significant viscoelastic characteristics; although the ultimate tensile strength is low, the rate of decline in fatigue life is more gentle as the stress intensity ratio increases. Semi-flexible mixture will be more brittle under 5 °C, the fatigue life decline faster as the stress intensity °C ratio increases, and lower the temperature, the faster the fatigue life declines.

## 5 CONCLUSION

Through the semi-flexible mixture rutting and four-point bending fatigue test studies, the following conclusions have been obtained:

1. From the experimental results, we can see that the dynamic stability of semi-flexible mixture under 60 °C and 70 °C are above 6000 (times/mm).

The dynamic stability decreases as the temperature increases, for which ordinary AC decreases the fastest, and the SBS modified AC the next, and semi-flexible mixture decreases the slowest.

2. The use of modified asphalt can significantly improve temperature sensitivity, but it is of limited improvement to the load sensitivity. The semi-flexible mixture can improve both temperature sensitivity and load sensitivity. Even with 200% overload, the dynamic stability of semi-flexible mixture is above 8000 (times/mm).
3. With the same stress level, the semi-flexible mixture fatigue life dropped as the temperature increases; and semi-flexible mixture is to some extent brittle at 5 °C, this feature should be considered during actual use.

## Preparation of $C_3S$ by the sol-gel method

C.L. Zhang, P. Song & Q. Wang

University of Jinan, Jinan, Shandong, China

**ABSTRACT:**  $C_3S$  mineral was synthesized by the sol-gel method, using TEOS as the silicon source,  $Ca(NO_3)_2 \cdot 4H_2O$  as the calcium source, EtOH as the co-solvent and saltpeter solution as the catalyst. XRD was used to analyze the influence of process parameters, such as pre-firing temperature, calcination temperature and heat preservation time, on the  $C_3S$  mineral. It can be concluded that the formation of  $C_3S$  was faster and easier at temperatures ranging from 1350°C to 1400°C.

**Keywords:** sol-gel method;  $C_3S$ ; TEOS

### 1 INTRODUCTION

Portland cement that mainly contains cement clinker, suitable content of gypsum and admixtures is a kind of hydraulic cementing material<sup>[1]</sup>. Cement clinker consists of four kinds of minerals, such as tricalcium silicate ( $C_3S$ ), dicalcium silicate ( $C_2S$ ), tricalcium aluminate, ( $C_3A$ ) and tetracalcium aluminate iron oxide ( $C_4AF$ ). The hydration process of cement that is influenced by many factors is very complicated. In addition to the hydration temperature, additives and admixtures, the key factor is properties of the four main components of cement clinker.

When studying the hydration process of cement, scholars have usually regarded the monomineral as the object of study, in order to avoid the interference of other factors<sup>[2-6]</sup>.  $C_3S$  is doped with  $CaF_2$ . It reduces the hydration degree, chemical combined water, hydration exothermic rate and compressive strength of one day age<sup>[7]</sup>.

When cement clinker minerals are prepared by the traditional high-temperature solid-state sintering method, it is necessary to add a mineralizer and other components in order to decrease the preparation temperature of cement clinker minerals. Consequently, this introduces other ingredients, and thus affects the purity of the single mineral and its properties. Tricalcium silicate ( $C_3S$ ), which is the main mineral of Portland cement, has a faster rate of hydration reaction. Hydration products of  $C_3S$  provide the early strength of cement<sup>[8-9]</sup>. The conventional method of cement clinker minerals with high-temperature sintering furnace has some shortcomings. In this experiment, in order to solve this problem, the sol-gel method, which is new and efficient, was adopted to get  $C_3S$ .

Sol-gel method<sup>[10]</sup> has some advantages including simple manufacture process, high-purity product, good uniformity and low preparation temperature, because it uses liquid reagents as raw materials<sup>[11]</sup>. Through XRD and SEM, samples were analyzed by the microscopic test for increasing the purity of  $C_3S$ .

### 2 EXPERIMENTAL PROCEDURE

#### 2.1 Materials

Tetraethylorthosilicate ( $Si(OC_2H_5)_4$ , TEOS) was selected as the silicon source.

Calcium nitrate tetrahydrate ( $Ca(NO_3)_2 \cdot 4H_2O$ ) was chosen as the calcium source.

Anhydrous ethanol ( $C_2H_5O$ , EtOH) acted as the co-solvent.

Saltpeter solution (4 mol/L) and deionized water were the catalysts.

#### 2.2 Experimental process

##### 2.2.1 Preparation of xerogels

First, the mixture of TEOS, EtOH and deionized water at a certain ratio was added into the saltpeter solution dropwise at a temperature of 30°C. The mixture became a transparent solution by stirring constantly.  $C_3S$  sol was synthesized from the transparent solution and calcium nitrate tetrahydrate solution by stirring frequently. By standing in oven at 60°C,  $C_3S$  gel was obtained, and then converted into xerogels in the oven at 70°C.

##### 2.2.2 Sample preparation

The preliminary heat treatment of xerogels was carried out for removing EtOH, extra deionized water, and structural water of calcium nitrate.

This was beneficial for promoting later solid-phase reactions. The powdered gel that had undergone the heat treatment was pressed into a round slice ( $\Phi 13 \times 2$  mm). The round slice was calcined in a high-temperature furnace heated by  $\text{MoSi}_2$ . The calcination system condition was as follows: warming at a rate of  $4^\circ\text{C}/\text{min}$ , keeping at a constant temperature, quenching in the air.

### 2.3 Test method

Quality change rule and heat flow change caused by chemical reactions during the calcining process of xerogels were determined. The thermal analysis curve was generated by the TGA/DSC1/1600HT Simultaneous Thermal Analysis Instrument (Mettler, Switzerland).

The phase composition of the sample was measured by the D8-ADVANCE X-ray diffractometer (Bruker, Germany).

Micro-structural aspects and micro-constitution were observed by the Guanta FEG 250 field emission scanning electron microscope (FEI, USA), whose resolution was as high as 130 eV.

## 3 RESULTS AND DISCUSSION

### 3.1 Material analysis

#### 3.1.1 The analysis of silicon source

With EtOH as the solvent and saltpeter solution as the catalyst, TEOS and deionized water were adequately hydrolyzed at a temperature of  $30^\circ\text{C}$ . Silicate polymer was obtained through stirring until the appropriate viscosity, aging and drying in the oven. Figure 1 shows the SEM photograph of silicate polymer, and Figure 2 shows the XRD

Figure 1. SEM photograph of the silicate polymer.

Figure 2. XRD pattern of the silicate polymer.

pattern of silicate polymer. Broad peak from  $20^\circ$  to  $30^\circ$  was found in the XRD pattern of silicate polymer without the characteristic peaks of the crystalline silicon dioxide. The result showed that the hydrolytic product of TEOS was amorphous silicon dioxide.

#### 3.1.2 The analysis of calcium source

Calcium source ( $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ ) was dissolved in the co-solvent (EtOH) and dried in the oven at  $70^\circ\text{C}$ . The matter phase of the sample was analyzed by X-Ray Diffraction (XRD).  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  was decomposed at the temperature of  $70^\circ\text{C}$ , yielding  $\text{Ca}(\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$  and  $\text{Ca}(\text{NO}_3)_2$  (see Fig. 3). Calcium source was heat treated at temperatures of  $520^\circ\text{C}$ ,  $540^\circ\text{C}$  and  $560^\circ\text{C}$ , and then analyzed by X-Ray Diffraction (XRD), as shown in Figure 4. The samples still contained a large amount of  $\text{Ca}(\text{NO}_3)_2$ , a small amount of  $\text{Ca}(\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$  and a small amount of CaO at  $520^\circ\text{C}$ . When the temperature was up to  $560^\circ\text{C}$ , the samples contained only a large amount of CaO and  $\text{Ca}(\text{NO}_3)_2$ .

Figure 5 shows the DSC-TG curve of the calcium source heated from room temperature to  $800^\circ\text{C}$ . DSC analysis found that there was a decalescence peak at  $100^\circ\text{C}$ , and the TG curve had a smaller drop. This is because the residual solvents and the free water from the calcium source absorbed heat. The another decalescence peak began to appear at about  $162^\circ\text{C}$ , which was caused by the dehydration reaction of  $\text{Ca}(\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$ .

As shown in Figure 5, there were two obvious decalescence peaks near  $553^\circ\text{C}$  and  $611^\circ\text{C}$ , respectively. Each peak corresponds with one phase transition process. As the same time, the weight loss from  $550^\circ\text{C}$  to  $620^\circ\text{C}$  in the TG curves is attributed to the two-step decomposition of  $\text{Ca}(\text{NO}_3)_2$ : the first step is that  $\text{Ca}(\text{NO}_3)_2$  was decomposed into

Figure 3. XRD pattern of the calcium source dried at 70°C.

Figure 4. XRD pattern of the calcium source dried at different temperatures.

Figure 5. DSC-TG curve of the calcium source.

calcium nitrite ( $\text{Ca}(\text{NO}_2)_2$ ) and oxygen; the second step is that  $\text{Ca}(\text{NO}_2)_2$  was decomposed into  $\text{CaO}$  and nitrous oxide.

### 3.1.3 DSC-TG analysis of the xerogel

Figure 6 shows the SEM photograph of the xerogel granules. As shown in Figure 6, granules were porous. DSC-TG curve of the xerogel is illustrated in Figure 7. As can be seen from the Figure 7, the decalescence peak at 127°, caused by the decalescence of residual solvents from the xerogel granules and structure water from calcium nitrate can led to the weight loss in the TG curve. According to the DSC-TG curve of the calcium source, the main weight loss shown in Figure 7 can be attributed to the two-step decomposition of  $\text{Ca}(\text{NO}_3)_2$ . The decalescence peak at 644°C, with the weight loss in the TG curve, is caused by the silicate polymer formed by the hydrolyzation of TEOS under the

Figure 6. SEM photograph of the xerogel.

Figure 7. DSC-TG curve of the xerogel.

high-temperature condition resolved into nanometer silica.

### 3.2 The heat treatment of xerogel

#### 3.2.1 Pre-sintering process

Heat treatment of the xerogel included pre-sintering and calcinations. According to the DSC-TG curve of the xerogel, the weight loss ratio reached up to 60 percent. The specimens were pre-sintered, in order to increase the speed of atomic migration in the high-temperature calcination process, and to make the best of activity of the new ecology CaO.

Based on the DSC-TG curve of the xerogel, seven pre-sintering temperatures were set up, namely 510°C, 520°C, 540°C, 560°C, 580°C, 590°C and 600°C. The XRD analysis of the specimens pre-sintered at different temperatures at the heat preservation time of 60 min is shown in Figure 8. As shown in Figure 8, the specimens pre-sintered at 560°C contained CaO and transition phase. While at 580°C, the transition phase of the specimens disappeared, and the diffraction peaks of C<sub>2</sub>S appeared. Meanwhile, one of the great advantages of the sol-gel method, which is the reduction of C<sub>2</sub>S firing temperature (the firing temperature of C<sub>2</sub>S is above 800°C by the traditional high-temperature solid-state sintering method), is illustrated in this experiment.

#### 3.2.2 Calcination process

The XRD analysis of the specimens sintered at different temperatures at the different heat preservation times is shown in Figure 9. The C<sub>3</sub>S mineral diffraction peaks initiated at 1350°C. Compared with the diffraction peaks (0.5957 nm and 0.1777 nm) and the change in the temperature from 1200°C to 1350°C, the C<sub>3</sub>S mineral diffraction

Figure 8. XRD pattern of the specimens pre-sintered at different temperatures at the heat preservation time of 60 min.

Figure 9. XRD pattern of the specimens at different temperatures at different heat preservation times.

Figure 10. SEM photograph of C<sub>3</sub>S at 1400°C.

peaks increased faster from 1350°C to 1400°C. Compared with the diffraction peak (0.1701 nm) from 1200°C to 1350°C, the CaO diffraction peak at 1400°C was weakest. The diffraction peak intensity indicated the content of the mineral. In consequence, it was concluded that the formation of C<sub>3</sub>S was faster and easier at temperatures ranging from 1350°C to 1400°C.

SEM photos of C<sub>3</sub>S at 1400°C are shown in Figure 10. As can be seen from Figure 10, C<sub>3</sub>S with a uniform particle size has a network structure.

## 4 CONCLUSIONS

The sol-gel method can be used to prepare the C<sub>3</sub>S mineral easily. During the pre-sintering process, the specimens pre-sintered contained the transition phase. In this experiment, the formation temperature of the C<sub>2</sub>S mineral is 580°C, which is lower than the temperature with the traditional high-temperature solid-state sintering method. It can be concluded that the formation of C<sub>3</sub>S is faster

and easier at temperatures ranging from 1350°C to 1400°C.

# Study of durability of concrete mixed with cement reducing agent

S.Z. Yue

Department of Architectural Engineering, North China Institute of Science and Technology, Sanhe, China

Y.F. Zuo

Institute of Technical Information for Building Materials Industry of China, Beijing, China

**ABSTRACT:** In this paper, the durability of concrete mixed with cement reducing agent was researched. The results showed that the ability of anti-carbonation, chloride ion penetration resistance and anti-freezing capacity of concrete could be improved obviously after mixing with cement reducing agent in concrete. The three properties of concrete were slightly reduced with the increase of cement reducing rate, but still better than the reference concrete.

**Keywords:** concrete; cement reducing agent; cement reducing rate; durability of concrete

## 1 INTRODUCTION

The cement reducing agent used in concrete, also known as synergistic agent, is a new additive to promote the application of construction market in recent years. The role is to make the cement units of concrete reduced by 8%~15% after mixing with cement reducing agent and ensure comprehensive performance of concrete at the same time (Peng 2011, Sun 2014). With the use of cement reducing agent, it can cut down the dosage of gelatinous material, which is very important in terms of the rapid development of China's construction industry. According to the China Leading Institution of Industry Research database latest data (AskCIData) show that in 2014 China commercial concrete production reached 1,554,127,400 cubic meters, if less per cubic concrete 0.035t gelatinous materials it can be reduced by about 54.4 million tons of gelatinous material. Therefore, promote the use of reducing agent, not only has the technical and economic sense, but also in promoting the sustainable development of China's construction industry, in particular, environmental protection is of great significance.

At present, many research was reported about cement reducing agent of concrete and get consistent affirmation (Chang 2011, Zhang 2012). However, there is rarely study about the mechanism of cement reducing agent and impact on concrete durability and not deep enough. Improve the work in this area will be provide the necessary theoretical guidance and technical support for cement reducing agent promotion (Sun 2014). In this paper, an in-depth research was did to the durability of concrete mixed with cement reducing

agent to look forward to providing the necessary theoretical guidance and technical support for cement reducing agent promotion.

## 2 MATERIALS

### 2.1 Cement

Cement: Jidong P.O. 42.5, Ordinary Portland cement. Its performance was shown in [Table 1](#).

### 2.2 The fly ash

The fly ash: Huaneng Power Plant. Its performance was shown in [Table 2](#).

Table 1. The cement performance.

Standard consistency (%)	Setting time (min)		Strength of cement mortar (MPa)			
	Initial setting time	Final setting time	Flexural strength		Compressive strength	
			3d	28d	3d	28d
27.6	199	273	5.2	8.3	22.8	47.1

Table 2. The fly ash performance.

Fineness (%)	Loss on ignition (%)	Water demand ratio (%)
8.7	1.1	98

### 2.3 Grounded furnace slag

Grounded furnace slag: Specifically for experiments designed. Its performance was shown in Table 3.

### 2.4 Fine aggregate and coarse aggregate

Fine aggregate: fineness modulus 2.4, silt content 0.3%, apparent density 2.65 g/cm<sup>3</sup>, grading qualified.

Coarse aggregate: 5 mm–25 mm continuous gradation, apparent density 2.7 g/cm<sup>3</sup>, packing density 1.55 g/cm<sup>3</sup>.

### 2.5 Admixture

Admixture: naphthalene super plasticizer (liquid, industrial grade, NS, solid content 38%), home-brew AC cement reducing agent (micro dispersant) (yellow, solid content 30%, liquid).

## 4 EXPERIMENTAL DESIGN

Concrete mix ratio was shown Table 4.

In the table, the mix ratio of A-1 was specified in GB8076-2008. The mix ratio of B-1 and C-1 was used the same with C30 and C50 in actual project. A-2, B-2 and C-2 were the same with A-1, B-1 and C-1 respectively except cement reducing agent which admixture were changed to 0.06%. In A-3, B-3 and C-3, the total dosage of gelatinous material were reduced 30 kg compared with A-1, B-1 and C-1. And the total dosage of gelatinous material of A-4, B-4 and C-4 were reduced 45 kg compared with A-1, B-1 and C-1. For all the samples, at the same time with the changing of the mix ratio, the total dosage of gelatinous material were reduced equivalent to the aggregate according to the sand ratio to ensure the volume-weight have no different.

## 5 RESULTS AND DISCUSSIONS

The results were shown in Table 5.

First of all, to group A, the mix ratio of A-1 was specified in GB8076-2008, and other samples were added with cement reducing agent. According to the comparison, the ratio of 200 times freeze-thaw compressive strength was the lowest in A-1 which did not add cement reducing agent only. To A-2, A-3 and A-4, the minimum of A-4 which was 90% and the cement reducing rate was added most, but 200 times freeze-thaw compressive strength still 4.8% higher than A-1 (Fig. 1). For all of the concrete samples mixing with cement reducing agent, A-2, A-3 and A-4, the penetration depth of chloride ion were less than A-1. In the three concrete samples, the maximum was A-4 which was 12.2 mm, but still 2.5% less than A-1 (Fig. 2). To carbonation depth, A-2, A-3 and A-4 were also less

Table 5. Result of durability test.

Number	Ratio of 200 times freeze-thaw compressive strength (%)	Penetration depth of chloride ion (mm)	Carbonation depth (mm)
A-1	84	12.5	1.12
A-2	96	11.6	1.01
A-3	92	12.0	1.07
A-4	90	12.2	1.09
B-1	89	15.6	1.30
B-2	99	14.6	1.24
B-3	95	15	1.25
B-4	94	15.1	1.27
C-1	92	13.2	1.13
C-2	99	12.1	1.02
C-3	95	12.6	1.08
C-4	95	12.7	1.09

Figure 1. The ratio of 200 times freeze-thaw compressive strength to group A (%).

Figure 2. The penetration depth of chloride ion to group A (mm).

than A-1. A-4 was the maximum and the carbonation depth was 1.09 mm, 27.5% less compared with A-1 (Fig. 3). Comparing A-2, A-3 and A-4, with the reduction of the total dosage of gelatinous material, the ratio of 200 times freeze-thaw compressive strength was reduced and the penetration

Figure 3. The carbonation depth to group A (mm).

Figure 4. The ratio of 200 times freeze-thaw compressive strength to group B (%).

depth of chloride ion and carbonation depth were increased gradually.

To group B, the mix ratio of B-1 was used the same with C30 in actual project. To B-2, B-3 and B-4, the freeze-thaw compressive strength were higher than B-1. The minimum of B-4 which was 94% and the cement reducing rate was the most, but 200 times freeze-thaw compressive strength still 5% higher than B-1 (Fig. 4). For all of the concrete samples mixing with cement reducing agent, B-2, B-3 and B-4, the penetration depth of chloride ion were less than B-1. B-4 was the maximum and the penetration depth of chloride ion was 15.1 mm, 3.3% less compared with B-1 (Fig. 5). To carbonation depth, B-2, B-3 and B-4 were also less than B-1. B-4 was the maximum and the carbonation depth was 1.27 mm, 2.4% less compared with B-1 (Fig. 6).

To group C, the mix ratio of C-1 was used the same with C50 in actual project. To C-2, C-3 and C-4, the freeze-thaw compressive strength were higher than C-1. The minimum of C-4 which was 95% and the cement reducing rate was the most, but 200 times freeze-thaw compressive strength still 3% higher than C-1 (Fig. 7). For all of the concrete samples mixing with cement reducing agent, C-2, C-3

Figure 5. The penetration depth of chloride ion to group B (mm).

Figure 6. The carbonation depth to group B (mm).

Figure 7. The ratio of 200 times freeze-thaw compressive strength to group B (%).

Figure 8. The penetration depth of chloride ion to group C (mm).

Figure 9. The carbonation depth to group C (mm).

and C-4, the penetration depth of chloride ion were less than C-1. C-4 was the maximum and the penetration depth of chloride ion was 12.7 mm, 3.9% less compared with C-1 (Fig. 8). To carbonation depth, C-2, C-3 and C-4 were also less than C-1. C-4 was the maximum and the carbonation depth was 1.09 mm, 3.7% less compared with C-1 (Fig. 9).

## 6 CONCLUSIONS

The results showed that adding cement reducing agent in concrete could improve the ability of anti-carbonation of concrete, chloride ion penetration resistance, anti-freezing capacity. With the increase of the cement reducing rate, the ability of anti-concrete carbonation and chloride penetration resistance, freeze-thaw slightly lower capacity, but better than the reference concrete. The addition of mineral admixtures can increase the ability of concrete anti-concrete carbonation and chloride penetration resistance, freeze-thaw.

# Residual stress influence on stability of thin-walled box section column of high-strength steel

Lei Gao, Kebin Jiang, Xiaohui He & Linyue Bai

*College of Field Engineering, PLA University of Science and Technology, Nanjing, Jiangsu, China*

**ABSTRACT:** The residual stress has a significant influence on the stability of column, but experimental data are difficult. So we study the influence on the stability of thin-walled box section column of high-strength steel (the nominal yield stress of 745 MPa to 800 MPa) caused by different residual stresses by using finite element analysis software ANSYS. Based on elastic-plasticity large deflection theory of the thin steel plate and arc length method, the study finite element model was modeled. As to residual stresses, we read it in the element integral point through the preparative initial-stress document. Through the study, we find that residual compressive stress has larger influence on the stability of column than residual tensile stress; the stability of the column is sensitive to the variation of residual stress while slenderness ratio is moderate.

**Keywords:** residual stress; thin-walled box section; high-strength steel; stability coefficient

## 1 INTRODUCTION

Residual stresses always exist in steel structure components as the result of process, transportation, and fabrication<sup>[1]</sup> and welding residual stresses are mainly stress in welding components. The critical stresses of the actual axial compressive column are smaller than the critical stresses of ideal axial compressive column largely due to the existence of the welding residual stress. The residual stresses, especially the welding residual stress, have a great effect on the column stability coefficient, so they have been considered in the design specifications of steel structure<sup>[2]</sup>. The research of the high-strength steel gradually increased with more and more high-strength steel used in skyscraper, bridge, etc.<sup>[3-6]</sup>; however, research about residual stress effects on stability coefficient of high-strength steel components was lacking. High-strength thin-walled box-section steel has been used in movable bridge in china.<sup>[7]</sup> The special fabrication technique was used, first two channel steel components were formed through cold bending method, then the two channel steel components were welded into thin-walled box section. Welding certainly generates welding residual stress for the reason of local high temperature. In this article, based on elastic-plasticity large deflection finite element theory of the thin-walled steel plate, the column's ultimate bearing capacity is achieved by using the arc-length method<sup>[8-9]</sup> to track the column load-displacement curve and the range of decline, in the meantime

the stability coefficient of column is achieved. The different residual tension stress and compressive stress influences on stability of thin-walled box section column of high strength steel were studied. The effects on the stability coefficient of column with different slenderness ratio were also studied, and then some meaningful conclusions were got to supply reference to design.

## 2 RESIDUAL STRESS OUTLINE AND DISTRIBUTION

There are many reasons for creating residual stress, mainly including uneven heating and cooling in welding process, uneven cooling of the steel's different parts in the process of rolling steel, the plastic deformation of components after cooling, the thermal contraction in the edge of plant after thermal cutting, etc<sup>[1]</sup>. We mainly study the effects of welding residual stress generating during the process of welding. Welding residual stress can be divided into transverse residual stress and vertical residual stress. The reason of transverse residual stress is the uneven heating among different parts of the same cross-section, and the uneven heating among different parts along axial leads to the vertical residual stress. As to stability calculation for components, the distribution of vertical residual stress is primary.

Researchers have managed to measure the welding residual stress a long time ago, which has

a great influence on the stability coefficient of construction members<sup>[10]</sup>. The measurement techniques of residual stress consist of mechanical method and physical method. Aimed at studying macroscopic residual stress, mechanical methods, also known as stress releasing method, are classic measurement methods of residual stress and belong to destructive test, mainly include sectioning method, hole-drilling, ring-core method, etc.<sup>[1,11]</sup> Physical methods can test both macroscopic residual stress and microstructural residual stress as a non-destructive testing, mainly including the magnetic testing, X-ray method, Scanning electron microscopy, ultrasonic method, etc.<sup>[1]</sup>

As to the square pipe welded together by two pieces of channel steel, the stress releasing method was used by Zhongquan<sup>[10]</sup> Zhang to confirm the maximum residual stress on cross-section existing  $0.1\sigma_y$  ( $\sigma_y$  is the yield stress of sample steel) of the weldless side wall. Afterwards, the influence of residual stress was considered when Zuyan Shen<sup>[11]</sup> and others studied the ultimate strength of stiffened elements by using curved shell finite element method. In the meantime, they measured the residual stress distribution of the square tube by the stress releasing method, the residual tensile stress was  $\sigma_{rt} = 0.832\sigma_y$  and residual compressive stress was  $\sigma_{rc} = 0.0839\sigma_y$ , as shown in Figure 1.

The welding residual stress of cold-formed thin-walled steel structure has been tested by Feng Zhao, and others<sup>[13,14]</sup>, the study indicates that the residual stress varied along the thickness direction of cross section and the residual stress in the both sides of cross section is equal and opposite. Recently some welding stress of high strength were measured and some distribution rules were put forward.<sup>[12,15]</sup> But the test data was gained with difficulty and

Figure 1. Distribution of residual stress.

discretion, so numerical simulation method is an important method to study residual stress.

Actually, the residual stress in components we used compounded of cold-formed residual stress and welding residual stress, so the distribution is very complex. In addition, different components or welding manner also result in different distributions of residual stress. In order to study the problem conveniently, we adopt the reduced-form residual stress pattern shown in Figure 1. Researchers believe that the stabilizing influence of compressed members caused by residual stress is concerned with the distribution of residual stress. It is worst when the slenderness ratio of bar is around 90, and the impact would reduce either when the value increase or decrease<sup>[13]</sup>. But there is still no search about the influence on stability coefficient of construction members caused by high-tensile steel components residual stress. It is necessary to carry out a study on the influence of the stability coefficient of high-tensile steel components caused by welding residual stress.

### 3 ESTABLISHMENT OF THE FINITE ELEMENT MODEL

The basic finite element model is built by using the finite element analysis software ANSYS12.0 as the working platform<sup>[9]</sup>. For the finite element numerical simulation, the material property was modeled by the multi-linear isotropic hardening model (MISO) according to the material test data<sup>[16]</sup>. In order to consider geometric deformation and residual stress, the shell element 181 was used in model. By adding two pieces of rigid plant (with large elastic modulus) to the ends of the member, we can simulate the rigid surrounding assumption and impose constraints and loads conveniently. The hinged-constraint is used to restrain the central node of both sides of the plate when the constraints are imposed. The flange width is 0.6 times the web width; the web height to thickness ( $h/t$ ) is 30.

Two geometric imperfections were introduced to the FEM model. One was the initial overall imperfection and the other was the local imperfection of the component. The initial overall imperfection was simulated by assuming the beam shape as a half sine wave. For lower grade steel, statistic imperfection amplitude employed in current Chinese code is  $L/1000$ , where  $L$  represents the length of the column<sup>[2]</sup>. Due to lack of statistic data, the amplitude suggested by the Chinese code was adopted in the simulation. The initial local imperfection of the component plate was assumed to be the same as the first order local buckling mode of the beam when only the local buckling of the components come out. The maximum amplitude of the

local imperfection denoted by  $\Delta_0$  takes the expression suggested by Antonio F. M<sup>[17]</sup>as:

$$\frac{\Delta_0}{b} = 0.1 \times \frac{b}{t} \times \frac{\sigma_y}{E} \quad (1)$$

The residual stress is applied in two ways: a) apply the residual stress directly based on the initial data of residual stress provided by the model. B) apply the treated thermal load. We choose way a, although the difference between the two results are very small<sup>[12,15]</sup>. The residual stress is introduced by reading the preparative initial-stress document and is applied on the element integral point, and 5 element integral points are chosen by every shell 181 element.

Using ANSYS Parametric Design Language (APDL), the analysis model was established and solved. The basic program sketch of stability calculation is such as Figure 2. According to the above discussions the FEM model was formed as shown in Figure 3.

Figure 2. Program sketch of stability calculation.

Figure 3. FEA model.

#### 4 THE CALCULATION RESULTS AND ANALYSIS FOR FINITE ELEMENT MODEL

The finite element models are established to analyze different residual stress influences on the thin-walled box section of high-strength steel with different slenderness ratios. The value of residual tensile stress are  $\sigma_{rt} = 0.7\sigma_y, 0.8\sigma_y, 0.9\sigma_y, 1.0\sigma_y, 1.1\sigma_y,$  and  $1.2\sigma_y,$  and residual pressure stress are  $\sigma_{rc} = 0.1\sigma_y, 0.15\sigma_y, 0.2\sigma_y, 0.25\sigma_y, 0.3\sigma_y,$  respectively.

In order to study the different residual stress influence on stability of column, we chose slenderness ratio 70 as study example and the results are shown in Table 1.

It can be seen from the table that the change of the stability coefficient caused by residual compressive stress is larger than that caused by residual tensile stress. Maximum difference of stability coefficient is 7.41% when the range of residual compressive stress changes from  $0.1\sigma_y$  to  $0.3\sigma_y,$  while maximum difference of stability coefficient is just 1.3% when the residual tensile stress change is from  $0.7\sigma_y$  to  $1.2\sigma_y.$  Thus, we can get the conclusion that the effect of residual compressive stress is more significant for the stability coefficient of thin-walled box section of high strength steel column.

In order to study the influence of different compressive stress on stability factor of thin-walled box section of high strength steel column with different slenderness ratios, the value of residual tensile stress is fixed. The value of the residual tensile stress was fixed at  $0.8\sigma_y,$  and the residual compressive stress is set at  $\sigma_{rc} = 0.1\sigma_y, 0.15\sigma_y, 0.2\sigma_y, 0.25\sigma_y, 0.3\sigma_y,$  respectively. The slenderness ratio ranging from 20 to 120 was studied. We achieved the influence on stability coefficient of thin-walled box section made of high-strength steel component caused by different residual compressive stress and different slenderness ratio. (shown in Table 2).

Figure 4 is drawn to indicate the difference in stability coefficient of columns with different slenderness ratio caused by different residual compressive stresses.

The influence of slenderness ratio caused by changes of residual compressive stress can be found from Table 2 and Figure 4 that residual compressive reaches to a maximum with the increase of slenderness ratio stress, and then drops down with the increases of slenderness ratio until it get smoothly. While the slenderness ratio is 60, the stability coefficient of the column is sensitive mostly to residual compressive stress. Influence of stability coefficient caused by changes of residual compressive stress is more than 5% while the slenderness ratio ranges from 30 to 90, it is less than 5% when the slenderness ratio is larger or smaller.

Table 1. Thin-walled column for high-strength steel stability coefficients under different residual stress.

$\sigma_{rt}$	$\sigma_{rc}$						Maximum and minimum difference %
	$0.7\sigma_y$	$0.8\sigma_y$	$0.9\sigma_y$	$1.0\sigma_y$	$1.1\sigma_y$	$1.2\sigma_y$	
$0.1\sigma_y$	0.3050	0.3048	0.3051	0.3052	0.3055	0.3056	0.25
$0.15\sigma_y$	0.3020	0.3019	0.3021	0.3025	0.3026	0.3026	0.22
$0.2\sigma_y$	0.2961	0.2962	0.2986	0.2983	0.2987	0.2989	1.30
$0.25\sigma_y$	0.2903	0.2906	0.2915	0.2912	0.2920	0.2929	0.88
$0.3\sigma_y$	0.2841	0.2838	0.2845	0.2859	0.2863	0.2867	0.97
Maximum and minimum difference %	7.37	7.41	7.21	6.73	6.71	6.58	

Note: The stability coefficient  $\phi = P_u/P_y$ ,  $P_u$  is the load carrying capacity which has got through FEM analysis,  $P_y = A \times \sigma_y$ , where  $A$  is area of column.

Table 2. The stability coefficients of different slenderness ratio column under different residual compressive stress.

$\sigma_{rc}$	$\lambda$										
	20	30	40	50	60	70	80	90	100	110	120
$0.1\sigma_y$	0.933	0.804	0.703	0.624	0.554	0.462	0.375	0.305	0.251	0.209	0.177
$0.15\sigma_y$	0.925	0.784	0.680	0.588	0.530	0.450	0.369	0.302	0.249	0.209	0.177
$0.2\sigma_y$	0.921	0.774	0.664	0.559	0.502	0.434	0.360	0.296	0.245	0.205	0.173
$0.25\sigma_y$	0.91	0.750	0.631	0.533	0.471	0.416	0.351	0.291	0.241	0.202	0.171
$0.3\sigma_y$	0.90	0.739	0.610	0.516	0.439	0.402	0.338	0.286	0.239	0.200	0.169
Maximum and minimum difference %	3.16	8.65	15.19	20.96	26.46	15.08	10.81	6.53	5.23	4.74	4.72

Figure 4. The margin of stability factor under different slenderness ratio.

Thus there is little effect of stability coefficient caused by residual compressive stress on long or short column, however the effect on the moderate-length column is larger which should be considered during design procedure. It is considered that the design for equivalent rigidity (the overall stability

critical stress is equal to the local web critical stress is the optimal design generally.

Take the thin-walled box section column of high strength steel as an example, the local critical pressure of plate is

$$\sigma_{cr} = \frac{k\pi^2 E}{12(1-\nu^2)} \left(\frac{t}{b}\right)^2 \quad (2)$$

$k$  is a buckling coefficient,  $E$  is yang's elastic modulus,  $t$  and  $b$  is thickness and width of plate.

The ideal integral stability critical stress is

$$\sigma = \frac{\pi^2 E}{\lambda^2} \quad (3)$$

If equation (2) is equal to equation (3), then we can get

$$\lambda = \sqrt{\frac{12(1-\nu^2)}{k}} (b/t) \quad (4)$$

In this equation the buckling coefficient is still difficult to confirm. As for the web, one side of web is tensioned and the other side is pressed as a result of the initial imperfection. We study the

press-side only. Actually, the buckling coefficient of press-side web restrained by upper and lower flange ranges from 1.28 (the buckling coefficient of column which is an end fixed and an end simply supported) to 4 (buckling coefficient of column which is simply supported ends). We take that middle value to be  $k$  which is 2.5,  $\nu$  is 0.3,  $b/t$  is 30, then we can get the value of  $\lambda$  as close to 60. It can explain why the stability coefficient of column whose slenderness ratio is 60 is sensitive mostly to residual compressive stress.

## 5 CONCLUSION

Based on the finite element analysis software ANSYS as the working platform, we study the effects on the stability of thin-walled box section column made of high-strength steel caused by residual stress by applying the preparative residual stress documents to the integral point, and we achieved the following conclusion:

1. Adopting finite element SHELL 181, we can simulate the influence on the stability coefficient caused by residual stress through applying the diverse preparative residual stress document to integral point.
2. The influence on stability coefficient of high-strength steel caused by residual tension stress and residual compressive stress are different, and the influence caused by residual compressive stress is larger.
3. The influence on stability of column with different slenderness ratio caused by different residual compressive stress is different. The stability of column is sensitive to the variation of residual stress while slenderness ratio is moderate, especially designed for equivalent rigidity (the overall stability critical stress is equal to the local web critical stress). As for the section we researched, the stability of column is most sensitivity to the variation of residual stress while slenderness ratio is 60.

Zhonggen Liu

*Jinlin Jianzhu University, Jilin, China*

**ABSTRACT:** Application of high modulus asphalt (HiMA) concrete can improve not only rutting resistance, but also the bearing capacity of pavement structure. It is consistent with the long-life pavement construction philosophy.

In this paper, combined with bus lane renewal of Chang'an road in Beijing, three technics are applied to resolve significant rutting on the bus lane: coarse aggregate gap-graded mixture, large Nominal Maximum Aggregate Size (NMAS) and hard asphalt.

First, two types of hard asphalt (Pen(20/30) and Pen(40/60)), which are produced by three methods, are compared. It is illustrated that hard asphalt, that produced by the oxidation method, is best at high-temperature performance. For mixture, two kinds of HiMA (HiMA(20-25) and HiMA(40-25)) are selected. These two mixtures have same gradation and NMAS, different asphalt Pen(20/30) and Pen(40/60), respectively. Their volumetric characteristics, high-temperature stability, mechanical characteristics, and fatigue resistant are evaluated. The mechanical characteristics include compressive/flexural strength, compressive resilient modulus and dynamic complex modulus, etc.

The results illustrate that HiMA(20-25) has better rutting resistant, bearing capacity, and durability than HiMA(40-25). So the HiMA(20-25) is applied in engineering of the bus lane renewal in Chang'an road.

**Keywords:** hard asphalt; high modulus asphalt mixes; coarse aggregate gap-grade mixes

## 1 INTRODUCTION

In urban roads, rutting on bus lane is a significant damage. Normally, bus axle load is lower than truck (for example: bus axle load is 8–12 tons; truck axle load is 10–18 tons in China). But the bus lane always has characteristics such as: channelized traffic, high tire contact pressure, frequent stops, and acceleration at bus stations and junctions. All these factors result in more serious rutting. So in German, special criterion has been presented that: The bus traffic area should be designed according to the heavy loaded pavement design criterion.

HiMA has been widely used in Europe and America, but has not been utilized on bus lane renewal on urban main roads in china. The objective of this paper is to introduce the laboratory research.

## 2 LABORATORY SCOPE AND RESEARCH APPROACH

In this research, a coarse aggregate gap-graded mixture is adopted. Its Nominal Maximum

Aggregate Size (NMAS) is 25 mm. This gradation is developed by RIOH. The coarse aggregate content (>4.75 mm) is 70%, and filler (<0.075 mm) content is 5%, so it has close skeleton and small air void(6).

Two hard asphalts, that of penetrations, are 20/30(1/10 mm) (Pen 20/30) and 40/60 (1/10 mm) (Pen 40/60), are selected to investigate the effect of binder. For easy statement in this paper, the HiMA mix with binder pen(20/30) is defined HiMA(20-25) (25 represents NMAS of mix) and the other defined HiMA(40-25).

As the NMAS of mix is 25 mm, the specimens are fabricated by modified Marshall compaction tester. The diameter of specimen is 152.4 mm with 95.3 mm standard height. The weight of compact hammer is 10.21 kg and falling height is 453.2 mm; the number of blows is 112 times on each side (equivalent to standard Marshall compaction 75 times for each side). The compaction temperature for HiMA(20-25) and HiMA(40-25) are 155–165°C and 145–155°C, respectively. The bulk density of test specimen is measured by saturated surface-dry method (AASHTO T166). And

the optimum asphalt–aggregate ratio can be evaluated according to specification in China.

In this paper, for comparing the performance of two types of HiMA, two performance tests are carried out.

### 3 DYNAMIC COMPLEX MODULUS ( $E^*$ ) TEST

Simple Performance Tester (SPT) made in Australia is employed during dynamic complex modulus testing. The test specimen is fabricated by SGC with 15 cm in diameter, and then is cored into a cylinder specimen with 10 cm in diameter, 15 cm in height. For temperature level (5°C, 20°C, 40°C, and 55°C) and 8 frequency level (20 Hz, 10 Hz, 5 Hz, 2 Hz, 1 Hz, 0.5 Hz, 0.2 Hz, and 0.1 Hz) are selected.

Different with the USCRMT and UDCRMT, the specimen dimension of SPT is 1:1.5 (diameter/height), and the deformation measurement is side-aspect method, shown in Figure 1.

Dynamic complex modulus master curve is achieved by sigmoid model (Formula 1).

$$\log |E^*| = A_2 + \frac{A_1 - A_2}{1 + e^{-\frac{\log f - x_0}{d_x}}} \quad (1)$$

where  $E^*$  is the dynamic complex modulus, MPa;  $f$  is the loading frequency, Hz; and  $A_1$ ,  $A_2$ ,  $x_0$  and  $d_x$  are the parameters of curve.

When:  $f \rightarrow +\infty$ ,  $\log f \rightarrow +\infty$ ,  $\log |E^*| \rightarrow A_2$ , i.e. maximum dynamic complex modulus;

Figure 1. Dynamic complex modulus master curves of HiMA(20-25) and HiMA(40-25).

When:  $f \rightarrow 0$ ,  $\log f \rightarrow -\infty$ ,  $\log |E^*| \rightarrow A_2 + A_1 - A_2 = A_1$ , i.e. minimum dynamic complex modulus.

And phase angle master curve is achieved by GaussAmp regression (Formula 2)

$$\phi = \phi_0 + \frac{A}{w \times \sqrt{\pi/2}} \times e^{-2 \times \left( \frac{\log f - x_c}{w} \right)^2} \quad (2)$$

where  $\phi$  is the phase angle,  $f$  is the loading frequency in Hz,  $\phi_0$ ,  $A$ ,  $w$ , and  $x_c$  are the parameters of curve.

When  $\log f = x_c$ ; phase angle is the maximum,

$$\text{i.e.: } \phi_{\max} = \phi_0 + \frac{A}{w \times \sqrt{\pi/2}}.$$

### 4 FATIGUE TEST

Cooper tester is employed for evaluating the fatigue performance of material. Because HiMA is mainly serving for pavement bearing layer, stress controlled mode is applied in the test, and the stiffness modulus of mix decreasing to 50% initial modulus is defined as the evaluation criterion.

The dimension of specimen and testing temperature are consistent with flexural strength test. The loading wave is Havesine wave, 10 Hz continuously. There are 5 stress levels in testing, such as 1 MPa, 1.5 MPa, 2 MPa, 2.5 MPa, and 3.5 MPa.

The following two fatigue formulas (Formulas 3 and 4) are used to analyze the fatigue performance of HiMA(20-25) and HiMA(40-25).

$$\log N = a_1 \times \ln \sigma + b_1 \quad (3)$$

$$\log N = a_2 \times \ln(\sigma/\sigma_0) + b_2 \quad (4)$$

where  $N$  is the fatigue life,  $\sigma$  is the stress level of fatigue test in MPa,  $\sigma_0$  is the bending strength in MPa, and  $a_1$ ,  $b_1$ ,  $a_2$ , and  $b_2$  are the regression coefficients.

### 5 DATA ANALYSIS

#### 5.1 Analysis of dynamic complex modulus test

Dynamic Complex modulus  $E^*$  of HiMA(20-25) and HiMA(40-25) are measured by SPT testing equipment according to the method recommended by NCHRP 9-29(10), and the results are shown in Table 1.

According to Table 1, the Dynamic modulus  $|E^*|$  of HiMA(20-25) reaches 21528 MPa at 20°C & 10 Hz, and is about 20% higher than that of HiMA(40-25). Based on the  $|E^*|$  at 10 Hz and different temperatures, the  $|E^*|$  of HiMA(20-25) and HiMA(40-25) under 15°C & 10 Hz could

Table 1. Dynamic complex modulus and phase angle of HiMA(20-25) and HiMA(40-25).

Mixes	HiMA(20-25)			HiMA(40-25)

0.2	23.34	27.92	22.66	26.71	28.03	22.44
0.1	24.49	27.11	21.03	27.62	26.72	20.92

be evaluated. They are around 27000 MPa and 22000 MPa, respectively, which are much higher than the recommended value of general HiMA. The facts above are resulting from the application of hard asphalt and coarse aggregate gap-graded mixtures with large size NMAS and reasonable optimum asphalt-aggregate ratio of mixes.

According to the test data, with 20°C as reference temperature, the  $|E^*|$  master curve is constructed, and the master curve model is referred as sigmoid. And the relevant curve parameters are shown in Table 2 and curves shown in Figure 1.

Figure 1 shows that  $|E^*|$  of HiMA(20-25) is obviously higher than that of HiMA(40-25) at identical frequency. Moreover, the  $A_1$  and  $A_2$  of regression curves indicate that the maximum and minimum  $\log|E^*|$ , the  $A_1$  and  $A_2$  of HiMA(20-25) are all higher than that of HiMA(40-25).

With same shifting factor, the phase angle master curve can also be constructed (Fig. 2). Obviously, the phase angle of HiMA(20-25) is smaller than that of HiMA(40-25) at the same frequency. The phase angle determines the elastic (or viscous) properties of asphalt mixes, the higher phase angle leads to prominent viscosity performance; conversely, the smaller of the phase angle represents better elastic performance.

Table 2. Parameters of dynamic complex modulus & phase angle master curve.

Type	parameters	HiMA(20-25)	HiMA(40-25)
dynamic complex modulus master curve	$A_1$	2.0194	1.9771
	$A_2$	4.5487	4.4924
	$x_0$	-2.5020	-2.1597

	Maximum $\phi$	29.92	31.41

Figure 2. Phase angle master curve of HiMA(20-25) and HiMA(40-25).

Based on the test results, the Gauss curve model is used to construct the phase angle master curve, and the corresponding regression parameters are included in Table 2. The prediction curve of phase angle can be plotted based on regression equations (Fig. 3). The two curves have the same change rule that: with the increasing frequency, the phase angle will reach one peak value (maximum  $\phi$ ), at that point the viscosity reach maximum. But the peak values of the two mixes are different and the frequency corresponding maximum  $\phi$  is not the same, indicated by  $x_c$ . The  $x_c$  of HiMA(20-25) is lower than that of HiMA(40-25). The phase angle increases with the increasing frequency on the left

Figure 3. Phase angle master curve of HiMA(20-25) and HiMA(40-25) (prediction curve).

of peak value, and the two curves coincide with each other. On the right of peak value, the phase angle decreases with the increasing frequency; however, the two curves do not get together, and the interval between the two phase angles of the two mixes is maintained consistently at each identical loading frequency.

## 6 FATIGUE TEST ANALYSIS

Table 3 shows the results of three-point bending fatigue test on HiMA(20-25) and HiMA(40-25). Because of the difference between the two mixes of flexural strength, the fatigue life of the mixes appears largely varied under the same stress. The Figure 4 shows the fatigue life versus stress level, it indicates that large difference exists due to variation of asphalt. The fatigue life of HiMA(20-25) is much higher than that of HiMA(40-25) under the same stress level. The Figure 5 shows the fatigue life versus stress/strength ratio. Curves of the two mixes well coincide with each other. According to the changing trend, the curvature of HiMA(20-25) is slightly higher than that of HiMA(40-25), which represents the higher sensitivity of HiMA(20-25) to the change of stress/strain ratio.

Base on the results, the fatigue equation of two mixes are as follows:

To HiMA(20-25):

$$\log N = -2.7465 \times \ln \sigma + 6.9143 \quad r^2 = 0.9997$$

$$\log N = -2.7465 \times \ln \sigma / \sigma_0 + 1.092 \quad r^2 = 0.9997$$

Table 3. Fatigue test results.

Stress level (MPa)	Fatigue life, $N_f$ (times)	
	HiMA(20-25)	HiMA(40-25)
1	>2,000,000	1,020,636
1.5	610,483	95,496
2	105,181	19,268
2.5	26,090	9,262
3.5	2,873	1,239

Figure 4. Curves of fatigue life versus stress level.

Figure 5. Curves of fatigue life versus stress/strength ratio.

To HiMA(40-25):

$$\log N = -2.2834 \times \ln \sigma + 5.959 \quad r^2 = 0.9951$$

$$\log N = -2.2834 \times \ln \sigma / \sigma_0 + 1.657 \quad r^2 = 0.9951$$

## 7 CONCLUSIONS

For purpose of renewal project of bus lane on Chang'an Road, the corresponding tests on hard

asphalt and HiMA are carried out. The main conclusions are offered.

1. SPT dynamic complex modulus test indicates that the modulus of the two mixes is much higher than that of general HiMAs. It resulted from the use of coarse aggregate gap-graded mixture with large size. Furthermore, based on the analyses of complex modulus master curve and phase angle master curve, it has been discovered that the modulus of HiMA(20-25) is much higher than that of HiMA(40-25); whereas, the phase angle result is converse. HiMA(20-25) performs better on elasticity.
2. During the fatigue test of three-points flexural-tensile by Cooper tester (stress controlled mode), it has been discovered that HiMA(20-25) has better fatigue resistance than HiMA(40-25) at the same stress level, and it is more sensitive to change of stress/strength ratio.

Summarized above, the HiMA(20-25) is applied in engineering of the bus lane renewal in road.

## Self-Compacting Concrete prepared with solid waste

G.X. Han, X.H. An, F. Jin, C.J. Chen & H. Zhou

*State Key Laboratory of Hydrosience and Engineering, Tsinghua University, Beijing, China*

**ABSTRACT:** This study focuses on the development of a novel self-compacting concrete made mainly with Phosphogypsum (PG), Ground Granulated Blast Furnace Slag (GGBFS), steel slag and clinker. The particle size distribution and pH value of PG slurry were tested, and the results showed the properties of PG for hydration of slag was improved. A prolonged setting time of excess-sulfate Phosphogypsum Slag Cement (PSC) was observed, and solved by adding 3% aluminum cement. The PSC showed a slightly higher basic water demand than that of OPC, and more sensitive to water and superplasticizer. Self-compacting concrete using PSC and other mineral fillers showed satisfying fluidity and possessed strength over 40 MPa.

**Keywords:** solid waste; phosphogypsum; self-compacting concrete; excess-sulfate phosphogypsum slag cement

### 1 INTRODUCTION

Phosphogypsum (PG) is a by-product from manufacturing phosphate acid by wet process in fertilizer industry. This powdery waste primarily consists of  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  with soluble impurities such as phosphate, fluoride and residual acid. The annual production of PG is estimated to be 100–280 million tons worldwide, whereas only 15% is utilized as building materials, soil stabilization amendments, and setting controller in Portland cement. In China, more than 22 million tons of PG is generated each year and less than 10% is recycled. (Tayibi et al., 2009, Reijnders, 2007, Yang et al., 2013)

While solid waste is accumulating, the consumption of building materials is increasing with the growing demand for concrete in numerous constructions. The application of solid wastes as building materials in concrete is significant in the conservation and recycling of resources.

Phosphogypsum, fly ash, steel slag, and alkali-activator, such as lime or acetylene sludge, are combined as cementitious materials (Shen et al., 2009, Shen et al., 2007, Qiao et al., 2010, Degirmenci, 2008). The 28 d compressive strength of this material is lower than 15 MPa, which becomes a limitation for their extensive use. Phosphogypsum treated by chemicals can replace natural gypsum and can be used as a conditioning agent in the cement industry (Singh, 2002). Its application range is also limited because of the tiny dosage as a modifier. Calcined PG is used as plaster and composite for masonry (Singh and Garg, 2001) and is also used to produce supersulphate cement (Erdem and

Olmez, 1993). However, the process of calcining consumes a huge amount of energy, which does not make it environment-friendly. Phosphogypsum is also employed as a gypsum to prepare non-autoclaved aerated concrete (Yang et al., 2013), and the use of the product is also limited by its low strength. A non-burnt binder, excess-sulfate Phosphogypsum Slag Cement (PSC), is mainly composed of PG, Ground Granulated Blast Furnace Slag (GGBFS), steel slag and clinker or limestone (Ding et al., 2014, Wan et al., 2013, Huang and Lin, 2011, Huang and Lin, 2010a, Huang and Lin, 2010b). The PG content can exceed 50%, and the 28 d compressive strength can reach 50 MPa. This high PG dosage and the strength equivalent to that of OPC will contribute to the massive utilization of PG as a building material.

Rock-Filled Concrete (RFC) is a novel technology for massive concrete constructions, which was developed in China. This concrete consists of large blocks of rock, usually with a minimum size of 30 cm, and ready-mixed Self-Compacting Concrete (SCC) which has excellent fluidity and segregation resistance. The ready-mixed SCC is poured onto the rock fill body and fills the void between blocks under gravity. RFC mass will be formed after the SCC sets (An et al., 2009, Huang et al., 2008). RFC presents good mechanical properties and impermeability (Mian-song et al., 2008), and has great advantages, such as low heat of hydration, low cost, and low energy consumption (Feng et al., 2008). It has been employed in a number of constructions of hydraulic, transportation, and municipal engineering. As a massive concrete technology, RFC shows potential in recycling solid wastes.

This study successfully prepared SCC using PSC as cementitious material, and SCC utilizing both PSC and mineral fillers, such as limestone powder and fly ash. This PSC-SCC could be employed in RFC construction and other suitable circumstances, which providing an inspiring prospect for extensive utilization of solid waste.

## 2 MATERIALS

Phosphogypsum was supplied by Tongling Chemical Industry Group Co., Ltd. of China. This powder contains 11.5% of water and granular lumps that require grinding before use in the concrete. The Limestone Powder (LP) and Fly Ash (FA) were used as filler. Aluminate Cement (AC) was used to modify the setting time of this binder. The properties of the powder materials are shown in Table 1. The density of each powder material was tested by Beijing Builder Electronic Technology Co., Ltd. using TD-2200 True Density Analyzer.

The fine aggregate, which was artificially graded, is crushed quartz sand with a density of 2.75 and a fineness modulus of 2.86.

The coarse aggregate is limestone gravel with a density of 2.7 and a maximum particle size of 20 mm. The amounts of gravel with sizes ranging from 5 mm to 10 mm and 10 mm to 20 mm were 40% and 60% of the total, respectively.

The Superplasticizer (SP) is R212 polycarboxylate type obtained from SINOCONFIX Co., Ltd. of China.

## 3 TESTING METHODS

### 3.1 Modification of phosphogypsum

The PSC used in this study is proportioned with PG, GGBFS, SS, and clinker at ratios of 47%, 47%, 2%, and 4% in mass.

Phosphogypsum contains granular lumps that cannot be directly used. Water-soluble impurities

such as phosphate and phosphoric acid are harmful to the hydration of GGBFS, which requires an alkaline environment. Phosphogypsum, GGBFS, steel slag, and water were mixed with a proportion of 63:1:3:33 and milled in a polyurethane jar for two hours. The  $\Phi$  290 mm  $\times$  300 mm sized jar contained corundum balls that rotated at a rate of 70 r/min. The paste was stored for 24 h at  $20 \pm 2$  °C in an airtight container to keep the water content stable. The rest of the powder materials and additional water were mixed with the modified PG slurry to prepare PSC paste.

### 3.2 The basic water demand and setting time of PSC

The initial and final setting times of PSC were tested according to the Chinese standards of GBT1346-2011.

The Slump Flows (SF) of PSC slurries with different water to powder ratios were tested, and the relationship between the water to powder ratio and relative SF ( $\Gamma$ ) was determined using a linear fitting method. The W/P-intercept of the line indicated the actual water content of the PSC slurry at which the slurry began to flow (Kazumasa, 1998). This critical water to powder ratio is the basic water demand of PSC, based on which the water to powder ratio of the PSC slurry for SCC is decided.  $\Gamma$  is calculated using the equation below:

$$\Gamma = \left( \frac{SF}{60 \text{ mm}} \right)^2 - 1$$

### 3.3 The mix design procedure of SCC

The mixing procedure of PSC-SCC is demonstrated in Figure 1. In this study, W/P is the ratio of water to powder by absolute volume, and sand ratio (S%) is the ratio of fine aggregate to mortar by absolute volume. SP% is the percentage of SP by weight in all the powder materials.

P4	47	0	47	2	4	3	1.7	2.9

Figure 4. Slump flow of PSC-SCC.

## 4 RESULTS AND DISCUSSION

### 4.1 Properties of modified PG paste and PSC

The Particle Size Distribution (PSD) of Modified PG (MPG) is illustrated in Figure 2. The MPG is slightly coarser than OPC, with a mean particle diameter of 17.37  $\mu\text{m}$  compared to 15.43  $\mu\text{m}$  of OPC.

The pH value of the water separated from the PG slurry increased from 6.5 to 10 after modification, which is favorable to the hydration of GGBFS.

The basic water demand of PSC was 1.16 compared to 1.09 of OPC, as shown in Figure 3. Although the intercept of the former was slightly higher, the latter had a sharper slope, which meant

Table 3. Fluidity and compressive strength of PSC-SCC.

No.	W/P	SP/%	S/%	G/L	AC/%	SF/mm	VF/s	7 d/MPa	28 d/MPa
C1	0.84	1.75	49	325	0	650	130.59	–	–
C2	1.00	0.65	46	325	0	700	18.32	2.7	32.23
C3	1.10	0.50	46	325	3%	625	12.47	28.12	44.70

Table 4. Properties of PSC-SCC with different fillers.

No.	W/P	SP %	Proportion of powder materials %							AC/%	S %	G (L)	SF/mm	VF/s	7 d/MPa	28 d/MPa
			PG	LP	FA	GGBFS	SS	Clinker								
C3	1.1	0.5	47	0	0	47	2	4	3	46	325	625	12.47	28.12	44.7	
C-L	1	0.7	30	25	0	40	2	3	3	46	300	667	14.2	26.85	44.13	
C-F	1.1	1	30	0	30	35	2	3	3	46	300	623	24.97	19.06	40.45	

the relative SF of the slurry changed to the same extent and the change of water to powder ratio of the SSC slurry was smaller than that of the OPC. Thus, the fluidity of the SSC slurry is more sensitive to water than that of the OPC slurry. Furthermore, the SSC slurry is more sensitive to SP dosage in fluidity because the SP effectively disperses powder particles and releases the free water.

As shown in Table 2, both of initial and final setting times are much longer than those of the binder by using pure gypsum (G) instead of PG. Some impurities that cannot be removed by this modifying method still exist and hinder the setting of the binder. Researchers found that washing PG with a milk of lime solution, another alkaline modifying agent, cannot yield a satisfying result in terms of reducing the setting time retardation. (Potgieter et al., 2003). Thus, some uncertain impurities exist in the PG result in the retardation of the binder and cannot be removed using alkaline agents, such as steel slag or lime.

Meanwhile, a binder with pure gypsum has a longer setting time than that without any gypsum. Even though calcium sulphate activates the hydration of GGBFS (Gruskovnjak et al., 2008), the setting time of the binder will be prolonged by the dilution effect when the dosage of gypsum is high enough. Furthermore, the retardation caused by the impurities of PG is more severe than that by the dilution effect, and the use of alumina cement at a dosage of 3% can obviously shorten the setting time of PSC.

#### 4.2 Fluidity and compressive strength of PSC-SCC

Concrete with a water to powder ratio of 0.84 has a satisfying SF value, but it is too viscous to

have a proper VF value. As the W/P value rises, the VF value declines rapidly. The W/P value has a remarkable effect on the viscosity of concrete. Both C2 and C3 meet the qualification of SCC. The mix with a powder ratio of 1.10 has satisfying fluidity and relatively lower cost. Its initial condition is shown in Figure 4.

The 7 d strength of C2 is merely 2.7 MPa. The poor early strength is probably the consequence of the setting retardant caused by the hazardous impurities from phosphogypsum. The addition of aluminum cement obviously improves both the 7 d and 28 d strengths of C3.

#### 4.3 Fluidity and compressive strength of SCC with different fillers

Comparing with C3, the volume of gravel is reduced, but the VF value of C-F rose significantly, reaching the criterion of SCC. This could be attributed to the using of fly ash, which is much finer than the other powder.

C-L and C-F both showed a good performance on fluidity after proper adjustment, and possessing a similar compressive strength with C3.

## 5 CONCLUSIONS

Self-compacting concrete using PSC and other mineral fillers, such as limestone powder and fly ash, are successfully prepared, with good fluidity and compressive strength over 40 MPa at 28 d.

The phosphogypsum slurry becomes alkaline after wet-milled with steel slag, thereby providing a favorable environment for the hydration of GGBFS. Excess-Sulfate phosphogypsum-slag cement has a slightly higher basic water demand

than OPC, and it is more sensitive to water and superplasticizer.

Impurities causing a prolonged setting time still exist after the modification of PG. The retardation of setting caused by these impurities is more severe than that by the dilution effect of gypsum. However, the use of 3% aluminum cement shortens the setting time and improves the early strength.

# Experimental study on mechanical properties of fiber reinforced lightweight aggregate concrete after freeze-thaw cycle

Jing Huang, Jianmin Wang & Anqing Liu

College of Civil Engineering and Environment, Ningbo University, Ningbo, Zhejiang Province, China

**ABSTRACT:** We use sludge ceramsite as coarse aggregate to make ceramsite concrete without fibers, HPPF and PANF ceramsite concrete. We study the influence of fiber variety and freeze-thaw cycle on characteristics of surface damage, compressive strength, elastic modulus, and splitting tensile strength via the freeze-thaw test. The results indicate that the incorporation of fibers can effectively restrain cracks in concrete from occurring and developing and improve its frost resistance. Freeze-thaw damage would make cement paste layer become brittle and scale, but mass loss isn't obvious. Compressive strength, elastic modulus, deformation, and splitting tensile strength of concrete after freeze-thaw cycle would reduce.

**Keywords:** fiber reinforced lightweight aggregate concrete; freeze-thaw cycle; mechanical properties

Lightweight aggregate concrete has good property of insulation, frost resistance, seismic performance, crack resistance (shrinkage resistance and creep resistance), anti-fatigue performance, and fire resistance<sup>[1]</sup>. Owing to this, lightweight aggregate concrete has been extensively applied to engineering, such as high-rise buildings, marine structures, long-span bridges, and urban overpass, and its application obtains a high technical and economical value<sup>[2,3]</sup>.

The northeast and northwest cold regions in China have a larger temperature difference between day and night. With time, degradation will occur in some buildings and hydraulic structures after frequent repeated action of freeze-thaw cycle. Further, security of concrete will reduce<sup>[4]</sup>. Cracks develop further when influence of environment becomes intensive, which severely affects normal use and durability of structures and causes inadequate concrete for design requirement, and even results in severe engineering accidents<sup>[5]</sup>. Hence, freeze-thaw damage is an important aspect of durability failure of concrete. It has important theoretical significance, practical value, and economic effect.

At present, researches on related mechanical properties of ceramsite concrete with incorporation of High Performance Profiled Fiber (HPPF) and Polyacrylonitrile Fiber (PANF) after freeze-thaw cycle are relatively few.

HPPF and PANF are incorporated after determining the optimal mix proportion via testing, then conduct the freeze-thaw test. Following that, we observe and analyze characteristics of surface damage of fiber reinforced ceramsite concrete and we perform analysis on difference of mechanical

properties such as compressive strength, elastic modulus, splitting tensile strength after freeze-thaw. As a consequence, we obtain the influence of incorporation of fibers on related mechanical properties of ceramsite concrete after freeze-thaw, then analyze and summarize the reasons.

## 1 INTRODUCTION

### 1.1 Testing material

Fine aggregate, coarse aggregate, cement, fly ash, fibers their specific parameters see [Table 1](#).

### 1.2 Testing equipment

Equipment used in freeze-thaw test is CABR-HDK9 automatic rapid freeze-thaw apparatus manufactured by Luda mechanical device limited company. Type WAW-600C 60T hydraulic servo controlled press is used for testing mechanical properties of test specimens.

### 1.3 Specimen making

Mix proportion of test see [Table 2](#). Specimens need 28 days curing at standard conditions in laboratory. Then take them out and place them at room temperature for one month to achieve air-dried state for subsequent freeze-thaw test. Considering that cubes (its dimension is 100 × 100 × 100 mm) and prisms (100 × 100 × 300 mm) need testing for their cubic compressive strength, splitting tensile strength, and elastic modulus and comparing with control concrete, the number of specimens

Table 1. Specification parameters of HPPF and PANF.

Type	Shape	Density (g/cm <sup>3</sup> )	Com. strength (Mpa)	Young's modulus (Gpa)	Elongation at break (%)	Length (mm)	Diameter (μm)	Melting point (°C)
HPPF	Corrugated	0.91	>500	>7	12~40	25~30	≥100	170
PANF	Grain shape monofilament	1.15~1.20	≥450	≥5	10~40	15~20	10~25	235~245

Table 2. Mix proportion.

Fiber (kg/m <sup>3</sup> )	Ceramsite (kg/m <sup>3</sup> )	Sand (kg/m <sup>3</sup> )	Cement (kg/m <sup>3</sup> )	Fly ash (kg/m <sup>3</sup> )	Water (kg/m <sup>3</sup> )
–	780	550	460	80	210
HPPF: 1.8	780	550	460	80	210
PANF: 0.4	780	550	460	80	210

would be  $(3 + 3 + 5 \times 3) \times 3 \times 2 = 126$ . Divide these specimens into six groups based on fiber type and if under freeze-thaw cycle.

#### 1.4 Test scheme

The automatic freeze-thaw apparatus was used to conduct the freeze-thaw test according to “Standard for test methods of long-term performance and durability of normal concrete” (GB/T 50082-2009). Take half of each kind of concrete for test, put specimens in water whose temperature ranges from 15°C to 20°C till they are in full water-saturated state for 4 days before test. Then take them out and dry the surface for weighing. Each freeze-thaw cycle lasts approximately three to four hours. Thawing time should be controlled to take up 1/3 of the total process. The central temperature of specimens was controlled in the range of -17.5°C to 7.5°C when freeze-thaw cycle ends. All specimens went through 25 times of freezing-thawing.

## 2 TEST RESULTS AND DISCUSSION

### 2.1 Analysis of characteristics of surface damage after freeze-thaw cycle

It is obvious that characteristics of surface change after freeze-thaw cycle. Surface which was smooth obviously becomes coarse, and spalling occurs in the cement paste layer on surface of specimens. In some specimens, microcracks occur on surface. Furthermore, some edges start to fall off.

Figure 1 shows that there are obvious pockmark phenomenon in normal concrete (without fiber), whereas prisms with HPPF and PANF respectively almost didn't have spalling.

Temperature difference caused by freeze-thaw process make internal free water repeatedly crystallize and expand, melt, and shrink, thereby resulting in larger temperature stress that destroys mortar matrix. Mortar surface falls off and leads to pockmark phenomenon. With respect to HPPF, its diameter and elastic modulus are larger in, but relative deformation is less. PANF has smaller filament diameter and performs well in ductility. In addition, the bond between it and cement matrix is superior, which makes fewer pockmark phenomenon and spalling.

### 2.2 Cubic compressive strength

Change in cubic compressive strength in three kinds of cubic specimens is seen Table 3. Table 3 shows that freeze-thaw cycle has a negative effect on cubic compressive strength of lightweight aggregate concrete. In addition, in contrast to fiber reinforced lightweight aggregate concrete, strength of normal concrete reduces less. Moreover, time which normal concrete needs to achieve fracture strength is longer than fiber reinforced lightweight aggregate concrete.

By analyzing these data, we conclude that fiber would bear inner tensile stress in concrete occurred in freeze-thaw cycle, thereby significantly improving concrete crack resistance. When under pressure, compression bearing capacity of concrete increases because of horizontal restraint of fiber. However, tensile bearing capacity of fiber decreases dramatically due to frequent loading and unloading; as a consequence, failure in ceramsite concrete occurs in advance.

### 2.3 Cubic splitting tensile strength

Change in cubic splitting tensile strength of three kinds of concrete after 25 freeze-thaw cycles is seen in Table 4.

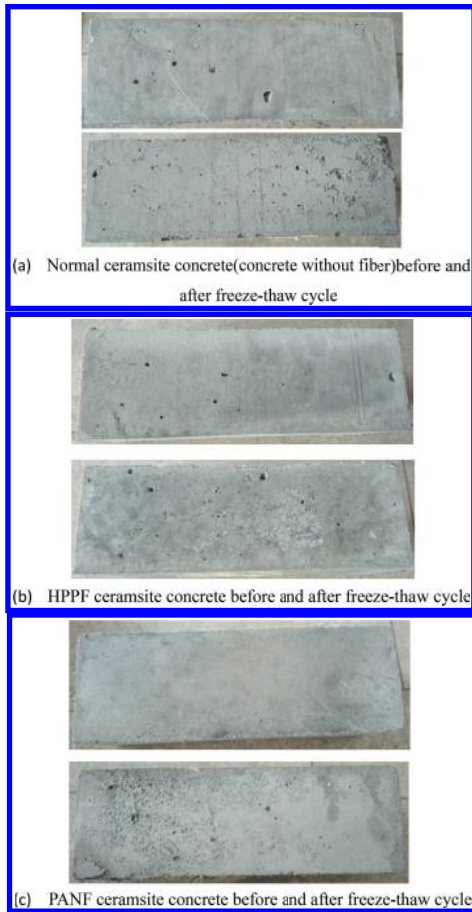

Figure 1. Characteristics of surface damage on prisms among three kinds of specimens before and after freeze-thaw cycle.

Table 3. Change on cubic compressive strength before and after freeze-thaw cycle.

Fiber types	Cubic compressive strength $f_{cu}$ (MPa)		
	Before	After	Reduction rate
Non-fibre	36.2	31.9	11.80%
HPPF	42.7	28.3	33.70%
PANF	40.3	30.3	24.80%

Table 4 shows that splitting tensile strength of ceramsite concrete has an obvious increase before freeze-thaw cycle with fiber incorporated, and enhancement of PANF is superior to HPPF. After freeze-thaw cycle, splitting tensile strength of PANF ceramsite concrete is still higher than the other two. After analysis, these phenomena

Table 4. Change on cubic splitting tensile strength.

Type	Non-fibre		HPPF		PANF	
No.	Before	After	Before	After	Before	After
1	4.77	3.94	4.84	2.83	6.52	4.89
2	5.49	3.16	5.22	2.54	6.19	4.76
3	4.54	3.32	5.56	3.15	6.18	4.79
Average value	4.44	3.14	4.69	2.56	5.67	4.81
Reduction rate	29.28%		45.42%		15.17%	

could be explained by characteristics of PANF such as higher ductility, easy dispersion, acid and alkali resistance, and low temperature resistance. Microfiber disordered distribution lap mutually in concrete restrains air-escape during mixing and molding process, which increases air content and mitigates hydrostatic pressure and seepage pressure during low temperature cycles. Therefore, it has a more obvious enhancement on splitting tensile strength<sup>[6]</sup>. Secondly, crack resistance of PANF is good owing to its small diameter, large quantity in unit volume and short fiber spacing, which increases energy loss during freeze-thaw cycle and effectively restrains cracks because of frost. This is beneficial to the improvement of strength increase and durability of frost thaw resistance in low temperature environment<sup>[7]</sup>. In a word, the improvement in splitting tensile strength of ceramsite concrete of PANF is obvious.

#### 2.4 Prism compressive strength

Table 5 shows change on prism compressive strength of three kinds of concrete before and after freeze-thaw cycle. From the data, we see that freeze-thaw cycle has a negative effect on prism compressive strength of lightweight aggregate concrete and prism compressive strength is lower than cubic compressive strength. HPPF and PANF bear tensile stress produced by concrete shrinkage. It restrains development of inner stress in concrete, postpones crack and increases prism compressive strength of ceramsite concrete. Load-displacement curves of the three kinds of concrete before and after freeze-thaw cycle; see Figure 2.

#### 2.5 Elastic modulus

According to test method on non-fiber concrete in ordinary concrete mechanics performance test method standard<sup>[8]</sup>, we continue to conduct the elastic modulus test on ceramsite concrete. We obtain the elastic modulus of three kinds of ceramsite concrete before and after 25 freeze-thaw

Table 5. Change on prism compressive strength before and after freeze-thaw cycle.

Fiber type	Prism compressive strength $f_{cu}$ (MPa)		
	Before	After	Reduction rate
Non-fibre	36.2	31.9	11.80%
HPPF	42.7	28.3	33.70%
PANF	40.3	30.3	24.80%

(a) normal ceramsite concrete

(b) HPPF ceramsite concrete

(c) PANF ceramsite concrete

Figure 2. Load-displacement curves of prisms of three kinds of ceramsite concrete before and after freeze-thaw cycle.

Figure 3. Elastic modulus measurement and failure mode of three kinds of concrete.

Table 6. Change on elastic modulus before and after freeze-thaw cycle.

Type	Elastic modulus of prism specimens E (MPa)					
	Non-fibre		HPPF		PANF	
No.	Before	After	Before	After	Before	After
1	21356	7256	23011	5795	22028	5735
2	21658	7157	22658	5540	22500	6724
3	20769	7438	21156	5256	21988	5945
Average value	21261	7284	22275	5531	22172	6135

cycles by loading and unloading three times with velocity of 0.5 Mpa/s (apparatus and failure mode of specimens see Fig. 3). Analyzing related data in Table 6, we could conclude that:

1. Elastic modulus of non-fiber ceramsite concrete is lower than HPPF and PANF ceramsite concrete before freeze-thaw cycle;
2. Elastic modulus reduces under freeze-thaw cycle;

3. Change in elastic modulus of non-fiber ceramsite concrete is smaller than HPPF and PANF ceramsite concrete under freeze-thaw cycle.

These phenomena could be explained by following reasons:

1. Non-fiber ceramsite concrete is a brittle material, and has a small deformation, when incorporated fibers, its plasticity enhances, thereby restrains deformation of concrete;
2. The inner structure has been destroyed after freeze-thaw cycle. Consequently, a lot of cracks occur and deformation increase.

### 3 CONCLUSION

1. Degeneration occur in performance of ceramsite concrete after freeze-thaw cycle, mortar, and fine aggregate particles start to spall gradually. Due to effective bonding, some small particles still hang on surface of fiber which has been exposed and form a layer of velvet material, consequently, reduce mass loss.
2. Fibers with uneven surface can form strong mechanical lock effect with hardened cement paste, which increases bonding strength between them, improves plasticity, and tensile strength of ceramsite concrete, simultaneously restrains cracking because of frost, consequently, improves durability and extends the performance life of ceramsite concrete.

**ABSTRACT:** The effect of the types, volume percentage and particle size of aggregates on thermal expansion coefficient of concrete was investigated in this research. Experimental results indicated that the type of the aggregates had remarkable effect on concrete thermal expansion coefficient, while particle size of the aggregates had some obvious effect. The thermal expansion coefficient of concrete increased as the volume percentage of the aggregates decreased. It is of crucial importance to select the suitable type and increase properly the volume percentage of the aggregates in order to improve the concrete volume stability.

**Keywords:** concrete; thermal expansion coefficient; aggregates; volume percentage; particle size

## 1 INTRODUCTION

Thermal expansion coefficient of concrete is the change in length/volume per unit in response to a change in temperature (per unit). This change is often characterized by average thermal expansion coefficient in engineering, which is only affected by the properties of concrete itself instead of environmental interference. It is one of the main physical parameters of the materials; also an important parameter to calculate the deformation under heat. In large scale concrete structures, the temperature increase is around 20–50 °C due to cement hydration. If the thermal expansion coefficient of the concrete is  $10 \times 10^{-6}/^{\circ}\text{C}$  with a deformation joint per 50 meters and the yearly temperature difference is 40 °C, the deformation will be 20 mm, which will have great influence on arranging deformation joints in the engineering. Therefore, the heat deformation in large scale concrete structures is extremely important and has to be carefully considered. Heat deformation of concrete can be reduced by in-depth study of the influence factors of the thermal expansion coefficient and taking effective measures to decrease it, which will bring less damage due to temperature decrease, and hence the service life of the structure can be increased.

So far, many developments have been obtained in the research on thermal expansion coefficient of concrete. Neville et al. (Li Q. 2002) found that the thermal expansion coefficient of concrete, mortar and cement stone was  $7.4\text{--}13.1 \times 10^{-6}/^{\circ}\text{C}$ ,  $10.1\text{--}18.5 \times 10^{-6}/^{\circ}\text{C}$ , and  $11\text{--}20 \times 10^{-6}/^{\circ}\text{C}$ , respectively.

However, the thermal expansion coefficient of cement stone was about  $8.8 \pm 1.2 \times 10^{-6}/^{\circ}\text{C}$ , tested by Lars Kraft et al. (Lars K. 2004). Research results from Meyers et al. (Meyers, S.L. 1950) indicated that the thermal expansion coefficient of cement stone was not a fixed value under the temperature  $-10\text{--}100^{\circ}\text{C}$ ; it depended on the water content, water to cement ratio and the age of the cement paste. The thermal expansion coefficient of the cement stone under wet curing for 28 days was  $15\text{--}20 \times 10^{-6}/^{\circ}\text{C}$ . Few studies have been performed on the research on heat deformation of cement based materials in China. Yuan and Yang (Yuan L. 2001 & Yang J. 2000) made use of optical fiber to measure the deformation of the concrete structures, which is a new method to test the thermal expansion coefficient of cement based materials. Xuan and Shui et al. (Xuan 2007) applied workhorse-1 thermal expansion meter to investigate the heat deformation property of the main components of cement based materials, and compared the difference in heat deformation property of the aggregates and the paste.

The obtained achievements provide a sound basis for the research on the thermal expansion property of concrete. However, few studies have been performed on the effect of aggregates on concrete thermal expansion property. Aggregates take up the largest portion in concrete. It is necessary to investigate the influence of aggregates: type, volume percentage, particle size, etc. on thermal expansion coefficient of concrete, which has great significance on the selection of proper aggregates for large scale concrete structures and improvement of concrete durability.

## 2 EXPERIMENTS

### 2.1 Materials

P.O42.5 cement, II grade fly ash and polycarboxylate superplasticizer were used. Fine aggregates were limestone sands and coarse aggregates were sandstone, limestone and marble. The thermal expansion coefficient and elastic modulus of different types of stones were shown in Table 1.

### 2.2 Measurement of thermal expansion coefficient of concrete

Hand-hold portable deflecting meter was used to measure the length of the concrete specimens between two fixed positions at different temperatures, and then the coefficient of thermal expansion was calculated. The details were as follows. Three specimens were cast for each concrete composition. Four bronze heads were embedded in parallel on the surface of the specimen as the endpoints to measure the length. The size of the concrete and the position of the bronze heads were shown in Figure 1 copperhead.

At certain age, concrete specimens were immersed in the water of the temperature  $T_0$ . After 1.5h, the specimens were taken out and the length  $l(T_0)$  between two bronze heads were measured. Subsequently, the specimens were transferred into a thermostatic water tank for

another 1.5h and the length  $l(T)$  was recorded. Valid data were the average values of the several measurements on the copper heads at each temperature. According to the measured length (between two copper heads) of concrete specimens at different temperatures, the coefficient of thermal expansion of concrete can be calculated based on equation (1).

$$\bar{\alpha} = \frac{l(T) - l(T_0)}{l(T_0)(T - T_0)} \quad (1)$$

where  $\alpha$ : the coefficient of thermal expansion of concrete.  $l(T_0)$ : Distance between two copper heads at temperature  $T_0$ .  $l(T)$ : Distance between two copper heads at temperature  $T$ .

The distance between two copper heads should be tested when the temperature in the center of the specimen was the same as that of water. Two free rolling steel bars were placed in parallel at the bottom of the specimen in order to reduce the restraining force of the concrete as temperature increasing. Foam insulation board was used to cover the surface of the specimen during the measurements at different temperatures, which can reduce the heat exchange with the surroundings upon the open and close of the water tank, maintain a constant water temperature in the tank and decrease the temperature variation of the hand-hold portable deflecting meter during the measurements.

Table 1. Thermal expansion coefficient and elastic modulus of different stones.

	Coefficient of thermal expansion ( $\times 10^{-6}/^{\circ}\text{C}$ )	Elastic modulus (GPa)	Density ( $\text{g}/\text{cm}^3$ )
Marble	5.5	26.6	2.7
Limestone	6.8	35.4	2.7
Sandstone	11.5	16.4	2.6
Cement stone	16	12	1.95

Figure 1. Schematic diagram of the concrete specimen and the embedded bronze heads.

Figure 2. Concrete specimens in water.

### 3 RESULTS AND DISCUSSION

#### 3.1 Effect of the type of aggregates on the coefficient of thermal expansion of concrete

5~25 mm continuous gradation sandstone, marble and limestone were used as coarse aggregates. Limestone sand was used as fine aggregates. The amount of cement and fly ash was  $320 \text{ kg/m}^3$  and  $80 \text{ kg/m}^3$ , respectively. Polycarboxylate superplasticizer was 1% of the total cementitious materials by weight. The water to cement ratio was 0.42 and sand ratio was 40%. The hand-hold portable deflecting meter was used to measure the thermal expansion coefficient of the specimens at certain ages. The results are shown in Figure 3.

The type of the aggregates has remarkable effect on the Coefficient of Thermal Expansion (CTE) of concrete. As shown in Figure 3, the average CTE value of the concrete with sandstone incorporated is 31% higher than that with marble. This is attributed to the difference in the CTE values of the different aggregates. Sandstone has the highest CTE value, followed by limestone. Marble has the lowest CTE value. It can be concluded that the CTE value of the concrete is also high if using the aggregates of a high CTE value, which is consistent with the theory of thermal expansion of composite.

#### 3.2 Effect of the volume percentage of aggregates on the coefficient of thermal expansion of concrete

5~25 mm continuous gradation limestone were used as coarse aggregates. Limestone sand was used as fine aggregates. The weight ratio between cement and fly ash was 4:1. Polycarboxylate superplasticizer was 1% of the total cementitious materials by weight. The water to cement ratio was 0.42 and sand ratio was 40%. The bulk density was  $2400 \text{ kg/m}^3$ . The volume percentage of the

Figure 3. Influence of the type of aggregates on thermal expansion coefficient of concrete.

aggregates was 60%, 70% and 80% of the concrete. The CTE value of the concrete was tested at 3d, 7d, 28d and 49d. The results are shown in Figure 4.

The CTE value of the concrete decreased as the volume percentage of the aggregates increased. As shown in Figure 4, the average CTE value decreased by 9.5% when the volume percentage of the aggregates was increased from 60% to 80%. That is, the CTE value of the concrete decreases by 0.48% when the volume percentage of the aggregates was increased by 1%. This is due to the fact that the CTE value of the aggregates is lower than that of the hardened cement paste. Therefore, the CTE value of the concrete decreases as the volume percentage of the aggregates increases.

#### 3.3 Effect of particle size of the aggregates on the coefficient of thermal expansion of concrete

5~10 mm, 10~20 mm and 20~31.5 mm limestone were used as coarse aggregates. Siliceous river sand was used as fine aggregates. The amount of cement and fly ash was  $320 \text{ kg/m}^3$  and  $80 \text{ kg/m}^3$ , respectively. Polycarboxylate superplasticizer was 1% of the total cementitious materials by weight. The water to cement ratio was 0.42 and sand ratio was 40%. The hand-hold portable deflecting meter was used to measure the thermal expansion coefficient of the specimens at certain ages. The results are shown in Figure 5.

The particle size of the aggregates has obvious effect on CTE values of the concrete. In the aggregate size range of 5~31.5 mm, the CTE value of the concrete increased as the particle size increased. The average CTE value of the concrete with the aggregates of 20~31.5 mm incorporated was about 10% higher than that with the aggregates of 5~10 mm.

The main reason is that different position of the paste has different microstructure. The microstructure of the paste, and the transition zone between aggregates and paste is shown in Figure 6.

Figure 4. Influence of the volume percentage of the aggregates on CTE values of concrete.

Figure 5. Influence of particle size of the aggregates on CTE values of the concrete.

Figure 6. Microstructure of different position of the paste.

It can be seen from Figure 6 that the  $\text{Ca(OH)}_2$  crystal orientation is very obvious. The structure is quite loose and with high porosity. Therefore, the CTE value of this position is a bit lower. No obvious crystal orientation was observed in pure paste, which has a more denser structure with a lower porosity, and hence has a higher CTE value.

The smaller the particle size is, the larger the relative surface area of the aggregates will be. Therefore, the volume percentage of the aggregate-paste transition zone will be also relatively high under the same volume fraction of the aggregates. Thus, the CTE value of the concrete will be relatively low if using the aggregates of small particle size. The aggregates of 20–31.5 mm has a lower surface area compared to small aggregates, leading to less amount of transition zone and higher constraint force from aggregates; and hence the CTE value of this type of concrete is higher.

### 3.4 Theoretical calculation and analysis on the effect of the aggregates on the coefficient of thermal expansion of concrete

Different types of aggregates and hardened cement paste have different thermal expansion property and deformation resistance. Due to this, concrete

with different aggregates incorporated has different CTE values. Therefore, it is necessary to do in-depth calculation and analysis on the thermal deformation property of the concrete with different aggregates incorporated.

Concrete can be regarded as a composite material. The CTE of a composite is determined by its chemical composition, physical structure, and property and content of each component. Thus, the CTE of the concrete is not only directly influenced by the CTE values of the components, but also closed related to the elastic modulus of each component. According to the rule for mixture, the CTE value of the concrete can be approximately expressed by the weighted average of the CTE values of the cement stone and aggregates, when the migration of the water and gas contained in the concrete is not affected by the solid material (Yao W. 2007).

$$\alpha = \frac{\alpha_p E_p V_p + \alpha_s E_s V_s + \alpha_g E_g V_g}{E_p V_p + E_s V_s + E_g V_g} \quad (2)$$

$\alpha, \alpha_p, \alpha_s, \alpha_g$ : CTE values of concrete, cement stone, fine and coarse aggregates, respectively;

$E_p, E_s, E_g$ : elastic modulus of cement paste, fine and coarse aggregates, respectively;

$V_p, V_s, V_g$ : volume percentage of cement paste, fine and coarse aggregates, respectively;

The elastic modulus of the cement stone at 28d was taken as 12GPa and the CTE value was  $16 \times 10^{-6}/^\circ\text{C}$ . Different stones were used as fine and coarse aggregates. The sand ratio was 40%. The volume percentage of the aggregates: limestone, marble and granite, was increased from 60% to 80%. According to equation (2), the theoretical calculation result of the effect of the type and volume percentage of the aggregates on the CTE values of the concrete is shown in Figure 7.

The CTE value of the concrete decreased as the volume percentage of the aggregates increased. As shown in Figure 7, the average CTE value decreased by 10.64% when the volume percentage

Figure 7. Influence of the type and volume percentage of the aggregates on the CTE values of the concrete.

of the aggregates was increased from 60% to 80%. That is, the CTE value of the concrete decreases by about 0.53% when the volume percentage of the aggregates was increased by 1%. This is consistent with the experimental results shown in Figure 4.

Meanwhile, it can be seen from Figure 7 that the type of the aggregates has remarkable influence on the CTE values of the concrete. When the volume percentage of the aggregates was in the range of 60% to 80%, the average CTE of the concrete with sandstone-aggregates was  $12.58 \times 10^{-6}/^{\circ}\text{C}$ , which is about 1.74 times higher than that of the concrete with marble-aggregates incorporated. This is consistent with the experimental results shown in Figure 3. Therefore, it can be concluded that it is of crucial importance to select proper aggregates to decrease the CTE of the concrete and hence to increase the volume stability of the concrete.

#### 4 SUMMARY

The type of the aggregates has remarkable influence on the CTE values of the concrete. This is due to the difference in the CTE values of the different aggregates. It is extremely important to select proper aggregates to decrease the CTE of the concrete and hence to increase the volume stability of the concrete.

The CTE value of the concrete decreased as the volume percentage of the aggregates increased. The CTE value of the concrete decreased by about 0.5% when the volume percentage of the aggregates increased by 1%. The reason is that the CTE value of the aggregates is lower than that of the hardened cement paste.

The particle size of the aggregates has obvious influence on CTE values of the concrete. In the aggregate size range of 5–31.5 mm, the CTE value of the concrete increased as the particle size increased. This is attributed to the fact that different position of the paste has different microstructure.

# Analysis of environmental hazard and leaching characteristics of heavy metals in solid waste

S.H. Zhou, H.Q. Yang, J.J. Yan & J. Su

Changjiang River Scientific Research Institute, Collaborative Innovation Center for Geo-Hazards and Eco-Environment in the Three Gorges Area, China

**ABSTRACT:** The experimental results showed that the heavy metal components could be slowly leached from solid waste in the water environment, and the leaching amount was related to the type of heavy metals. Pb, Zn, and As ions were more easily leaching in an acidic environment. The solid waste-dump region for a long time has a greater risk of heavy metal pollution. The Cr ion leaching concentration of blast furnace slag, the Cd and Cu ion leaching concentration of phosphorous slag, and the Cr, Pb, Cd, Cu ion leaching concentration of fly ash and incineration slag exceeded the standard limit of Class V water from GB3838.

**Keywords:** solid waste; heavy metal; leaching; environmental hazard; effective content; total content

## 1 INTRODUCTION

With the rapid development of China's social economy and the emission of industrial liquid effluents, industrial exhaust, and industrial residue, serious environmental problems ensue. Industrial waste may contain heavy metals. The environmental pollution caused by heavy metal wastes and their harm to health are extremely serious. They endanger the nervous and circulatory systems and some of them are carcinogenic. So many countries have established the strict emission standards and dissolution standards of heavy metals.

Appearing with the environmental problems in recent years, the trace element of solid waste has become a research hotspot [Li Cheng, Yu Qijun, Van der Sloot H.A., et al]. It would be a new issue of concern for them that the environmental pollution was caused by the heavy metal ions leaching from the solid waste in certain conditions [Liu Peng, et al]. In this research, we would use several common solid wastes from China, such as blast furnace slag, phosphorus slag, fly ash, incineration slag etc. The NEN7371 tests were applied to study the dissolution characteristics of Cr, Pb, Cd, Zn, As, and Cu ions from solid waste, and discuss the effect of heavy metals on the environment.

## 2 EXPERIMENTS

### 2.1 Experimental materials

In this research, these chemical reagents was used, including nitric acid (analysis purity), acetic acid

(GR), hydrogen peroxide (GR), hydrofluoric acid (GR), anhydrous ethanol (analysis purity), and demineralized water with a maximum conductivity of 150  $\mu$ S/m.

These common solid wastes were used, including Blast Furnace Slag (for short, BFS), Phosphorus Slag (for short, PS), Fly Ash (for short, FA), and incineration slag (for short, GIS). The chemical composition of solid waste was shown in Table 1.

### 2.2 Test methods

**Sample digestion.** The samples were dried and grinded  $5.000 \pm 0.0001$  g then put into 40 mL HF solution, and then placed on the furnace at  $90^{\circ}\text{C}$ – $100^{\circ}\text{C}$ . After the sample was dissolved completely, and been made to stand at room temperature for 30 minutes, it was then taken out and put into 100 mL measuring flask.

**Quick leaching test of trace element.** The NEN7371 tests were applied to study the dissolution characteristics of Cr, Pb, Cd, Zn, As, and Cu elements in solid waste. In this test, the liquid to solid volume ratio was 50:1, and the environmental

PS	50.3	38.8	4.8	0.1	1.0	–
FA	5.1	59.0	21.6	8.7	1.5	0.7
GIS	20.4	41.7	7.5	13.2	14.3	0.3

temperature was  $20 \pm 2^\circ\text{C}$ . There were two kinds of the leaching liquids, namely acetic acid buffer solution ( $\text{pH} = 7$ ) and nitric-acetic acid buffer solution ( $\text{pH} = 4$ ).  $16.000 \pm 0.0001$  g samples were sieved through  $125 \mu\text{m}$  sieve, and then put into the leaching liquid. The mixtures were stirred to last 6h, and then were filtered with  $0.45 \mu\text{m}$  filter membrane. The clear liquid was shifted into the volumetric flasks after acidification treatment.

Test method of heavy metal ion concentration. With atomic absorption spectrophotometer method, the total content of Cr, Pb, Cd, Zn, and Cu element in fly ash was determined. With atomic fluorescence spectrophotometer method, the total content of As element in fly ash was determined. With atomic absorption spectrometry method, the content of Cr, Pb, Cd, Zn, Cu, and As element among the solution was determined.

### 3 RESULTS AND DISCUSSION

#### 3.1 The total content of heavy metals

The total content of heavy metals in waste shows direct impact on the ecological environment [Shi Huisheng]. The total content of heavy metals in solid waste was calculated and shown in Table 2. From Table 2, it could be found that the contents of heavy metal elements in solid waste could not be ignored. The heavy metal content of BFS content is lower, and that of FA is higher. GIS is extremely high in heavy metal. For example, the Cr content reached to  $433.5 \text{ mg/kg}$ , and the Zn content reached to  $1870 \text{ mg/kg}$ .

Compared to the quality of requirements of Class III soil of GB15618 “environmental quality standard for soils”, all kinds of heavy metal in BFS accorded with the standard requirements, the Cd content in FA and PS exceeded the standard value, and the Cr, Cd, Zn, As, and Cu content in GIS was much more than the standard value except the Pb content.

Table 2. The total content of heavy metals in solid waste.

Type	The total content (mg/kg)					
	Cr	Pb	Cd	Zn	As	Cu
BFS	23.6	12.4	0.1	35.5	0.4	7.5
PS	1.3	2.4	8.7	12.3	26.1	0.3
FA	98.8	82.3	45.5	200.6	18.6	83.9
GIS	433.5	323.1	8.6	1870	18.9	434.7
Class III soil of GB15618	$\leq 300$	$\leq 500$	$\leq 1.0$	$\leq 500$	$\leq 40$	$\leq 400$

#### 3.2 The soluble content of heavy metals

Contents of heavy metal elements in industrial waste can be divided into the total content and soluble content, the latter is often called “the effective content”. The NEN7371 leaching method can be used to test the effective release content of inorganic components in particulate materials or waste under extreme environmental conditions. This method can reflect the possible release amount of heavy metal components in long service concrete, so this method was applied to evaluate the environmental safety of building materials in EU [Kossor D. S., et al].

With NEN 7371 test method, the soluble content of Cr, Pb, Cd, Zn, As, and Cu element was determined and shown in Table 3, and the effective content was shown in Figure 1 and Figure 2.

The test results showed that the soluble content of heavy metals in solid waste was far less than the total content for corresponding. The effective content of heavy metals was in the range of  $8.4\% \sim 66.4\%$ . The effective content of Cu was

Table 3. The soluble content of heavy metal ions from soil waste ( $\text{pH} = 7$ ).

Type	The soluble content (mg/kg)					
	Cr	Pb	Cd	Zn	As	Cu
BFS	10.2	1.5	—	18.4	0.05	4.0
PS	0.4	0.3	5.2	5.0	2.20	0.1
FA	69.3	16.60	25.8	62.6	0.35	58.7
GIS	246.6	120.0	5.0	1017	4.90	288.7
Class III soil of GB15618	$\leq 300$	$\leq 500$	$\leq 1.0$	$\leq 500$	$\leq 40$	$\leq 400$

Figure 1. The effective content of Cr, Pb, As, and Cu.

Figure 2. The effective content of Zn and Cd.

Figure 3. Effect of acid condition on leaching.

highest, and that of As was lowest. From Table 3, the effective content of Cd in FA and PS exceeded the standard value of Class III soil, and the effective content of Cd, Zn in GIS was much more than the standard value.

### 3.3 The effect of acidic condition on the leaching characteristics

It has significant influence of the pH value on the leaching of heavy metal ion. Some researchers [Yu Qijun, Kazuyuki S., Chrysochoou M., et al] had found that some heavy metal ions would decrease the leachability at higher pH solution. The reason may be the decrease of soluble, or the formation of insoluble phase and the re precipitation in solution [Yu Qijun].

In this research, the leaching characteristics of heavy metals from FA in the acid condition (pH = 4) were studied. The experimental results were shown in Figure 3. Compared with the soluble content of heavy metals in pH = 7 leaching liquid, the soluble content of Cr and Cu in pH = 4 leaching liquid was lower, and the soluble content of Pb, Zn, As in pH = 4 leaching liquid was higher. The test results show that acidic solution decreased the leachability of Cr and Cu ions and increased the leachability of Pb, Zn, and As ions. It has less effect of the acidic environment on the leachability of Cd ion. The effect of pH on BFS, PS, GIS was consistent with that on FA.

## 4 ENVIRONMENTAL IMPACT ANALYSIS

How to evaluate the environmental hazards of heavy metals? The researchers adopt various methods, such as the total content method, the simulation test method, the environmental geochemistry method, the chemical speciation method and the indicator plant method etc. [Shi Huisheng].

It is not reasonable to evaluate the influence of solid waste on the ecological environment using the total content method. Obviously, although the total content of heavy metals in solid waste is higher, the solution content possibly is lower. If heavy metal ions in solid waste are inactive, namely not into the recycling ecosystem, these heavy metals are harmless to the environment. In a word, it is reasonable to evaluate the environmental impact analysis using the solution content method. The heavy metal ions concentrations of leaching liquid were detected during the testing process in the soluble content of fly ash. The results were showed in Table 4.

According to the relevant requirements of GB5085.3 “identification standard for hazardous wastes—identification for extraction toxicity”, the

Table 4. The maximum leaching concentration of heavy metals (pH = 7).

Type	The maximum leaching concentration mg/L					
	Cr	Pb	Cd	Zn	As	Cu
BFS	0.20	0.03	—	<0.37	0.01	0.05
PS	0.01	0.01	0.10	0.10	0.04	2.20
FA	1.39	0.33	0.52	1.25	0.01	1.18
GIS	4.93	2.40	0.10	20.34	0.10	4.90
GB5085.3	≤15	≤5	≤1	≤100	≤5	≤100
Class V of GB3838	≤0.1	≤0.1	≤0.01	≤2.0	≤0.1	≤1.0

leaching ion concentrations of Cr, Pb, Cd, Zn, As, and Cu in solid waste were lower than the standard limit. This indicates that BFS, PS, FA and GIS don't belong to hazardous waste. Under certain conditions, the effective contents of heavy metal in solid waste are dissolution. According to the technology requirements of Class V in GB3838 "environment quality standard for surface water", the maximum solution amount of Cr, Pb, Cd, and Cu ions in FA, the maximum solution amount of Cd, Cu ions in PS, the maximum solution amount of Cr ions in BFS, the maximum solution amount of Cr, Pb, Cd, Cu, Zn, and As ions in GIS exceeded the standard limit.

It is reasonable to evaluate the environmental security of heavy metal from the solid waste long-term stacking region by the maximum solution amount of heavy metal [Kossor D.S., et al]. The research results show that the blast furnace slag dumps region for a long time had a greater risk of Cr ions, and the fly ash dumps region for a long time had a greater risk of Cr, Pb, Cd, and Cu ions. The phosphorus slag dumps region for a long time had a greater risk of Cd and Cu ions. The incineration slag dumps region for a long time had a greater risk of Cr, Pb, Cd, and Cu ions.

## 5 CONCLUSIONS

1. The contents of heavy metal elements in solid waste could not be ignored. Compared to the quality requirements of Class III soil of GB15618, the Cd content in FA and PS exceeded the standard value, and the Cr, Cd, Zn, As, and Cu content in GIS was much more than the standard value.
2. The heavy metal components could be slowly leached from solid waste in the water environment. The effective content of Cu was highest, and that of As was lowest. The effective content of heavy metals in GIS was higher than that in BFS, FA, and PS.
3. The acidic solution decreased the leachability of Cr and Cu ions, and increased the leachability of Pb, Zn, and As ions. It has less effect of the acidic environment on the leachability of Cd ion.
4. The blast furnace slag dumps region for a long time had a greater risk of Cr ions, and the fly ash dumps region for a long time had a greater risk of Cr, Pb, Cd, and Cu ions. The phosphorus

slag dumps region for a long time had a greater risk of Cd and Cu ions. The incineration slag dumps region for a long time had a greater risk of Cr, Pb, Cd, and Cu ions.

**ABSTRACT:** We study the frost resistance about city sludge as a raw material to make city sludge sintered shale brick. City sludge sintered shale brick has contrasts with common sintered shale brick about frost resistance experiment in progress of different cycles (10 times, 20 times, 30 times, and 50 times) and studies the effect on sludge contents. Results show that with the increase in the number of cycles, the loss rate of city sludge sintered shale brick's compressive strength and the appearance of quality are larger than common sintered shale brick. The reason is sludge as an organic to produce contents of energy and pores in the high temperature through burning to have influence on frost resistance; with the increase in sludge content, the loss rate of quality and strength increases.

**Keywords:** city sludge; frost resistance; porosity; sludge content

## 1 INTRODUCTION

At present, due to rapid development of economic and GDP, building consumes too much energy and has a close relationship with environment and resources. China's annual waste of resources is about 15 million tons, so waste utilization by more people is brought to attention to, especially the utilization of sewage sludge. City sludge is a sewage treatment plant in the water purification process of solid waste precipitation, and it contains rich hydrocarbon organic compounds and large numbers of pathogenic bacteria, heavy metals, and other harmful substances. It may become a source of pollution and cause of secondary pollution easily if unreasonably used without any safety. Therefore, the disposal of city waste sludge is a priority, which sludge mixes with shale of preparing sintered shale brick, it is a way to save energy and protect ecological environment. Our research group has laid a solid foundation about city sludge and made achievements to certain properties results. However, the frost resistance of city sludge brick is still inadequate.

Frost resistance refers to materials' resistance in freezing and thawing cycles and free-water, which contains tiny pores that freeze to produce expansion and migrate to the icing area resulting in a great pressure on materials. With the time going by, expand-energy gradually extends from external

to internal to result in cracking and peeling. Therefore, it has reduced the freeze resistance, the material quality, compressive strength<sup>[1-3]</sup>.

## 2 RAW MATERIALS AND TEST METHODS

### 2.1 Raw materials

#### 2.1.1 Shale

We choose shale brick from factory in Liuzhou city of Guangxi where it is taken from near the village place in the ball mill after it dries and breaks to form powder, its components include  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{CaO}$ , and  $\text{MgO}$ . The standard shale particle size distribution are as follows [Table 1](#).

Table 1. Shale particle size distribution.

No.	Particle size (mm)	Quality proportion (%)
1	>2	10
2	1.5~2	12
3	0.5~1.0	38
4	0.25~0.5	15
5	<0.25	25

Table 2. City sludge index.

PH	Color	State	Taste
6.8	Black or brown	Fluid	Stench

Figure 1. XRD composition of sludge.

### 2.1.2 Sludge

City sludge: sludge from the primary sink of the sewage treatment plant in Liuzhou, Guangxi. The basic properties of city sludge are shown in Table 2, Figure 1 shows that the composition percentages of the sludge are: SiO<sub>2</sub> 83%, KCl 12%, (KAl<sub>2</sub>(AlSi<sub>3</sub>O<sub>10</sub>)(OH)<sub>2</sub> 1.7%, CaNH 1.9%, Mg(OH)<sub>2</sub>0.6%, Li<sub>2</sub>CrF<sub>6</sub> 0.4%, and Mn<sub>1.7</sub>Fe<sub>1.3</sub> 0.3%.

### 2.2 Sintering progress

The brick is making use of sludge and shale as a certain mixture, adding content of water to adjust the mixture of water content and repeatedly mix, it is sealed at 20±1°C and molded after 24 h of aging suppression in relative maintenance of 100% humidity, brick model is made for wood and size is 240 mm × 115 mm × 53 mm. The specific process is that the wet model dries during 1.5 h after sun by drying in oven at 105°C, the second step is to place it in the high-temperature laboratory, programmable to roast according to the setting temperature to fire at temperature of 950°C and it takes 2 h to cool furnace.

### 2.3 Test method

The frost resistance experiment box is a Beijing—Shuzhiyilong instrument. The test is carried out with reference to national standard/T GB 2542–2012 [4], the damage rate of quality and intensity are used as the evaluation frost resistance.

The appearance of test sample (city sludge brick and common sintered shale brick) is better before testing. We divide them into three groups and include 10 bricks per group (1–4 group for city

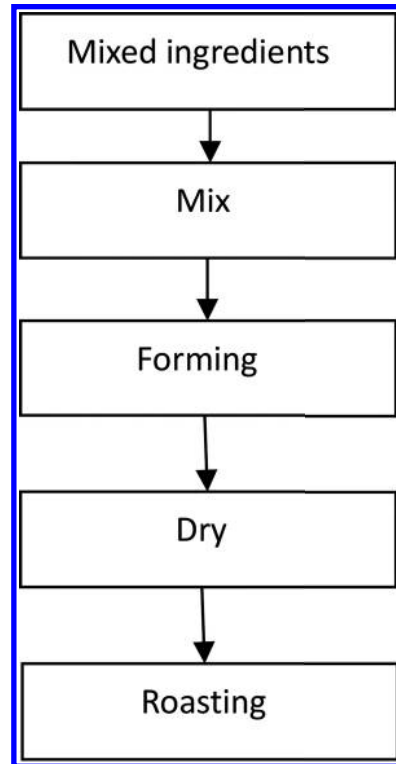

Figure 2. Preparation process of city sludge shale brick.

Figure 3. Freeze-thaw test machine.

sludge sintered shale brick, 5–8 group fired common brick, 9–10 contrast sample), it is tested 10 times, 20 times, 30 times, and 50 times, and the loss rate of quality and strength is measured. According to the laboratory test, the methods and steps are as follows:

1. Samples removing from the place of curing is immersed in water of 10 to 20°C and taken

out after 24 h, comparison samples should be retained in the standard curing room until the completion of the cycles of frost resistance.

2. After the soaking, one should use a damp cloth to wipe the surface moisture then put into the oven at  $105 \pm 5^\circ\text{C}$  for drying (during the dry process, the two difference weighing is less than 0.2%, and the two weighing interval is 2 h) to refer to  $M_1$ .
3. Regulation of freezing and thawing box should be controlled at  $15 \pm 2^\circ\text{C}$ , the specimens should be placed on the bracket at a distance of at least 20 mm spacing, if the temperature rises, until it accurately reaches to  $-15^\circ\text{C}$  to begin freezing (it should be about 4 hours), then the samples should be placed in a higher specimen 20 mm water to keep the temperature at about  $15^\circ\text{C}$ . Water should be used to thaw 4 hours, thaw time must not be less than the entire freeze-thawing cycle of 1/4 of the freeze—thawing cycle.
4. After each freezing and thawing cycle, we should check the appearance whether it has cracking, peeling, and missing angle phenomenon.
5. By freeze-thaw cycle for 10 times, 20 times, 30 times, and 50 times the samples kept the dry-box to weigh dry quality.  $M_2$ . By the ratio of  $M_1$  and  $M_2$  divide the  $M_1$  to get loss rate of quality.
6. Then the dried samples are soaked again in water for 10 to  $20^\circ\text{C}$  during 24 h, after which they will be placed in the center of the plate to be smoothed and loaded until the trial location reads the compressive strength.

### 3 RESULTS AND DISCUSSIONS

#### 3.1 The city sludge about frost resistance test data

Before freezing and thawing of the city sludge sintered shale brick strength has an average value of 15.6. After freezing and thawing strength has an average value of 14.31, loss rate of an average value of  $8.25\% < 25\%$  and loss rate of quality of an average value of  $1.1\% < 2\%$ , F50 after testing strength has an average value of 14.03 and loss rate of average  $10.05\% < 25\%$  and loss rate of quality has an average value of  $1.4\% < 2\%$ , strength grade is MU10 to fit the provisions of the freezing and thawing test.

Based on visual observation, city sludge sintered shale brick is smooth and has no missing angle, cracks and no dregs phenomenon before testing; after 10 times of freezing and thawing, we observe the appearance of the specimen to find that the overall is still good. Thus individual sample is found on the surface in which subtle cracks and no dregs phenomenon exist when we touch them

Figure 4. Effect of cycles of quality loss rate.

Figure 5. Effect of cycles on the strength loss rate.

Figure 6. Freeze-thaw phenomenon.

by hand. After 20 times, the appearance of the bricks has an alloy exfoliation phenomenon, and some of samples have a slight missing angle and dregs phenomenon. After 30 times, the appearance is observed at the surface of the crack and spall at different levels. After 50 times of freezing and thawing, the appearance is observed at the surface of the crack and spall, even serious missing angle phenomenon as shown Figure 6.

In Table 3, Table 4, Table 5, and Table 6, with repeated times increase, the loss rate of quality and compressive strength of city sludge sintered shale brick gradually increase. When the freeze-thaw cycle is 50 times, the loss rate of quality reaches 1.4% and average strength loss rate reaches 10.05%, but the frost resistance of city sludge sintered shale brick is poorer than common sintered shale brick, it is a reason that during the process of sintering, city sludge burns and leaves a small content of ash after high temperature as organic, leading to produce a large number of uniform pores which is like capillary hole, it can begin to freeze the water in the low temperature and produce a certain expansion

stress on the surrounding; with the time goes, the bricks gradually generates a minor crack to extend the internal pore and provide favorable conditions for the next time, so that the crack is larger than before resulting in damage such as missing angle.

### 3.2 The influence of sludge amount on the freezing resistance

With contents of sludge increase, the bricks produce the porosity and have missing angle, crack, slag and other phenomenon, and it is true that sludge contains large contents of organic produces. Too much heat leading to the moisture and volatile

Figure 7. Effect of frost resistance of sludge content.

escaping in the sintering process to form interconnected pores resulting in the increase of porosity and continuing to absorb a lot of water, it is shown in Figure 7 that loss rate of city sludge sintered shale brick quality and strength tend to move to an upward with the content increase [5-7].

#### 4 CONCLUSIONS

1. By utilizing city sludge and agricultural waste sawdust production, it protects ecological system and saves energy to create social benefits, making new contributions to meet the green energy-saving civil engineering.
2. In the article, one designs the city sludge shale sintered brick about frost resistance. The experiment shows that with increasing cycles of freezing and thawing, the quality and intensity of city sludge sintered shale brick and the common sintered shale brick are lost, but it illustrates that city sludge sintered shale brick is much greater, because the city sludge has a higher loss after burning in high temperature and the process of roasting. Organic volatile substances and a small content of ash exist to produce a large number

of homogeneous pores. The water freezes to produce expansion stress at low temperatures resulting in a decline in the frost resistance.

3. With the increase of the contents of sludge, sintering process of burn-out forms a large number of pores leading to loss rate of quality and strength, which tends to rise. Then frost resistance shows to decrease, but having reached the strength of sintered brick loss rate of less than 25%, the loss rate of quality does not exceed 2%.

**ABSTRACT:**  $\text{Li}_x\text{FePO}_4$  ( $x = 1.0, 1.02, 1.04, 1.05$ ) cathode material was prepared by high temperature solid-state method. The structure and morphology of  $\text{Li}_x\text{FePO}_4$  were characterized by Scanning Electron Microscopy (SEM) and X-Ray Diffraction (XRD). Mastersizer 3000 was used to analysis the particle size of the material. Electrochemical performance of the cathode material was researched by Land 2001. The results showed that the samples with different content of Li kept the olivine structure of  $\text{LiFePO}_4$ . And the optimal sample of  $\text{Li}_x\text{FePO}_4$  was the  $x$  equal to 1.02. At 0.2 C, 0.5 C and 1 C rate, the optimal sample ( $\text{Li}_{1.02}\text{FePO}_4$ ) has initial discharge capacities of 151.3 mAh/g, 148.8 mAh/g and 143.8 mAh/g.

**Keywords:** free lithium; lithium iron phosphate; electrochemical properties

## 1 INTRODUCTION

Lithium-ion batteries with high rate performance have attracted considerable interest as cathode material. In recent years, the research and development of the lithium ion battery anode material have attracted much attention in industrial countries<sup>[1-3]</sup>. Zhang Dongyun has studied the “Property and Structure of carbon-coated  $\text{LiFePO}_4$ ”. This paper presented that carbon coated on the surface of  $\text{LiFePO}_4$ , which could inhibit the grain growth and cause the smaller size<sup>[2]</sup>. Hongbo Shu has studied “Effective enhancement of electrochemical properties for  $\text{LiFePO}_4$  materials by Na and Ti co-doping”, this paper showed that the Na and Ti co-doped samples kept the olivine structure of  $\text{LiFePO}_4$ , but Na and Ti could improve the electrochemical performance of the material<sup>[4]</sup>.

The influence of lithium content on the performance of  $\text{LiFePO}_4$  didn't document in the literature. In the synthesis process of  $\text{LiFePO}_4$ , a part of lithium will volatilize in high temperature. Therefore in the process of preparation of  $\text{LiFePO}_4$  the lithium should slightly excess. In the paper, different lithium contents were studied in the process of synthesising  $\text{LiFePO}_4$ .

## 2 EXPERIMENTAL $\text{Li}_x\text{FePO}_4/\text{C}$

### 2.1 Instruments and reagents

Lithium dihydrogen phosphate was produced by Guoli material co., LTD in sichuan province.

Lithium carbonate was produced by Xilong Chemical Co., Ltd. Ferrous oxalate was produced by Hubei hao yuan material technology co., LTD.

Scanning electron microscopy (Inspect S50, FEI Company), Electrothermal blowing dry box (110-0A, Tian jin), X-ray diffraction (U1timal IV, Rigaku), Electronic balance (BSA423S-CW, Sartorius), Laser particle size analyzer (Mastersizer 3000, Malvern Instruments Ltd.), Electric blue test (CT2001A, Wuhan blue electric technology co., LTD) Glovebox (Universal (2440/750) MIKROUNA (CHINA) CO., LTD).

### 2.2 $\text{Li}_x\text{FePO}_4$ preparation and characterization

The  $\text{Li}_x\text{FePO}_4$  composite was prepared via High temperature solid phase method using  $\text{LiH}_2\text{PO}_4$ ,  $\text{FeC}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$ ,  $\text{LiCO}_3$ , Citric acid as raw materials, all the chemicals are analytical grade. The synthesis steps are as follows. The stoichiometric amounts of  $\text{LiH}_2\text{PO}_4$ ,  $\text{LiCO}_3$ ,  $\text{FeC}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$  were mixed in ethanol and ball milled under the speed of nearly 300 revolutions per minute for 4 h. Then, the mixture was dried at 80 °C in the oven for 5 hours. After drying, the mixture was calcined in  $\text{N}_2$  atmosphere at 450 °C for 4 h and 700 °C for 4 h under  $\text{N}_2$  (the purity of 99.99%) atmosphere, the heating rate was 3 °C/min. The vacuum tube furnace (HEFEI KEJING materials technology co. LTD) was used for the preparation of composite electrode material.

The purity and structure of the material were detected with X-Ray Diffraction (XRD) (U1timal IV, Rigaku) using  $\text{Cu K}\alpha$  radiation. Scanning Electron

Microscopy (SEM) (Inspect S50 FEI) was used to observe the particle morphology. Laser particle size analyzer (Mastersizer 3000, Malvern Instruments Ltd.) Electrochemical measurements were carried out using Land CT2001 A (Land., Wuhan blue electric technology co., LTD China).

### 3 RESULTS AND DISCUSSION

#### 3.1 XRD analysis of the cathode material

Figure 1 shows the XRD patterns of the different Li content of  $\text{Li}_x\text{FePO}_4$ . The XRD patterns of the different content of Li samples are similar to the standard of orthorhombic  $\text{LiFePO}_4$ . The XRD patterns shows a pure  $\text{LiFePO}_4$  phase without any obvious evidence of other impurities. This indicates that the content of Li ion does not change the crystal type of  $\text{LiFePO}_4$ .

#### 3.2 Particle size analysis

Figure 2 was the pore size distribution of  $\text{Li}_{1.02}\text{FePO}_4$ . From Figure 2 it can be seen that the median diameter (D50) keeps unchanged in the last tests. It remained at about 2.8  $\mu\text{m}$ .

Figure 1. XRD patterns of  $\text{Li}_x\text{FePO}_4$  ((1)  $x = 1.0$ , (2)  $x = 1.02$ , (3)  $x = 1.04$ , (4)  $x = 1.05$ ).

Figure 2. Pore size distribution.

Figure 3. SEM images of  $\text{Li}_x\text{FePO}_4$  ((1)  $x = 1.0$ , (2)  $x = 1.02$ , (3)  $x = 1.04$ , (4)  $x = 1.05$ ).

### 3.3 SEM analysis of the cathode material

Figure 3 was the the morphologies of the material  $\text{Li}_x\text{FePO}_4$  ((1)  $X = 1.0$ , (2)  $X = 1.02$ , (3)  $X = 1.04$ , (4)  $X = 1.05$ ). The  $\text{Li}_x\text{FePO}_4$  is composed of irregular particles. The Figure 3 with different content of lithium didn't change a lot. Only in the Figure 3(2) the particle size distribution looks more homogeneous. The Figure 3(4) with the content of lithium at 1.05 the particles present agglomeration phenomenon.

### 3.4 Electrochemical performance of $\text{Li}_{1.02}\text{FePO}_4$

Figure 4 shows the initial charge and discharge curves of  $\text{Li}_x\text{FePO}_4$  at different lithium content at 0.2 C. From the Figure 4 it can be seen that all samples at 0.2 C have a long flat discharge plateau at around 3.4 V, which indicates that the two-phase redox reaction proceeds via a first-order transition between  $\text{LiFePO}_4$  and  $\text{FePO}_4$ <sup>[5, 6]</sup>. Sample 2 at 0.2 C has a discharge capacity of 151.3 mAh/g. The first discharge capacity of samples 1, 2, 3 and 4 are 145 mAh/g, 151.3 mAh/g, 147.2 mAh/g and 140.1 mAh/g.

Figure 4. The initial charge and discharge curves of  $\text{Li}_x\text{FePO}_4$  ((1)  $X = 1.0$ , (2)  $X = 1.02$ , (3)  $X = 1.04$ , (4)  $X = 1.05$ ).

Figure 5. Cycling performance of  $\text{Li}_{1.02}\text{FePO}_4$  at different rates.

These results suggest that the lithium contents of  $\text{Li}_x\text{FePO}_4$  have an influence to electrochemical properties of the materials.

Figure 5 shows the  $\text{Li}_{1.02}\text{FePO}_4$  sample discharge cycle performance at different rates. From the Figure 5, it can be seen that the discharge specific capacity for the first time at 0.2 C, 0.5 C, 1 C respectively are 151.3 mAh/g, 148.8 mAh/g and 143.8 mAh/g. The optimum material with the lithium content at 1.02 the capacity attenuates a little. And after 50-cycle the capacities remain above 99% after 50 cycles at 1 C.

## 4 CONCLUSIONS

$\text{Li}_{1.02}\text{FePO}_4$  cathode material was successfully synthesized by High temperature solid phase method using  $\text{LiH}_2\text{PO}_4$ ,  $\text{LiCO}_3$ ,  $\text{FeC}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$  as raw materials. The impact of different lithium content on the microstructure and electrochemical performance of the material were studied. The XRD results showed that content of lithium did not change the olivine structure. At 1 C rate,  $\text{Li}_{1.02}\text{FePO}_4$  has initial discharge capacities of 143.8 mAh/g, and the discharge capacities remain above 99% after 50 cycles at 1 C.

**ABSTRACT:** This article analyzes the significance of recycling waste concrete, comparison of domestic and international research on the utilization of recycled concrete, and finds a solution to the needs of contemporary society on the concrete contradictions, and construction waste and other problems. After sorting the waste concrete crushing aggregate made of different series, then with a certain percentage of natural aggregate concrete made of recycled aggregate. The best ratio of recycled aggregate and natural aggregate has been identified, by the experiment, using compressive strength as the standard, with the slump as the base.

**Keywords:** recycled aggregate concrete; sustainable development; best ratio

### 1 INTRODUCTION

Since twenty-first century, with the process of city urbanization unceasingly rising, demand on concrete, the most extensive application building materials, and the most important material base of city, is also increasing rapidly. Relevant data show that the number of waste concrete from dismantling, being generated by new constructing, and emissions by ready mixed concrete mixing station and precast plant's is enormous in the world every year. The number of waste concrete is  $3 \times 10^7$  t/y in Japan, it is  $6 \times 10^7$  t/y in USA, and it has reached  $1 \times 10^8$  t/y in China, accounted for 50%–60% of construction waste, and it showed an increasing trend year by year<sup>[1]</sup>. This does not include a large number of abandoned concrete caused by natural disaster and the collapse of structures generated by war. If these huge wastes can become resources, its value and meaning is inestimable.

In this paper waste concrete will be made into different series of aggregates after being treated by sorting broken and then into recycled concrete by being mixed with natural aggregates in a certain proportion. Using compressive strength as the standard, with the slump as the base, by the experiment, the best proportion of recycled aggregate and natural aggregate has been identified, and the feasibility of reuse of waste concrete was discussed.

### 2 CONCEPT OF RECYCLED CONCRETE AND SIGNIFICANCE OF REUSE WASTE CONCRETE

Concrete of the old buildings or structures disintegration is crushed and gradated to become coarse aggregates (Fig. 1, Fig. 2), which replace parts of the mixture of sand and gravel to make up concrete, known as recycled concrete, or recycled aggregate concrete. Recycled concrete is a kind of environmental protection concrete using the broken waste concrete as aggregate, and a product under the condition of sustainable development strategy<sup>[2, 3]</sup>.

Dosage the biggest sand in concrete raw materials have been considered to be an inexhaustible,

Figure 1. Simple crushing waste concrete.

Figure 2. Recycled coarse aggregate.

and the optional mining for a long time, resulting in landslides, river diversions, destroyed the aggregate natively sustainable development of ecological environment. And the formation of natural sand and need after a long geological time, which means we may be about to face the situation of natural aggregate up. Chinese high quality natural aggregate (river sand and pebble) has dried up in some areas. In many areas eligible concrete sand is in short supply, and in some cities, the high performance concrete sand even can't be found. But at present our treatment methods of waste concrete are not much, the traditional processing method is mainly to the suburbs open-air pile up or landfill, which would cause adverse impact on the environment. If a large number of waste concrete can be reused after recycling and disposal, we can not only save the natural aggregate resources, but also reduce waste and environmental pollution in cities. Production process of concrete material recycling is beneficial to advocate the construction of resources saving, environment friendly society now, to adhere to the scientific concept of development, to adhere to sustainable development, to build a harmonious society, and especially beneficial for harmony of man and nature, so it has a great significance [4].

### 3 STATUS OF APPLICATION AND STUDY ON RECYCLED CONCRETE AT HOME AND ABROAD

Europe after the second world war, Japan, the United States and other countries began the research and development of recycled concrete work, held in Brazil in 1992 United Nations conference on environment and development will be the earth environment question was put to a very high position, many countries will be the recycling of the urban construction waste as one of the target of environmental protection and sustainable

development, some countries have worked out the corresponding technical specification [5, 6].

Many abroad studies on recycling process of recycled aggregates are all according to the specific engineering condition of their own, as described below.

#### 3.1 Japan

Type Due to their small size, relatively scarce resources, Japan attaches great importance to the waste concrete as to the development and utilization of renewable resources. As early as in 1977, the Japanese government has made the use of recycled aggregate and recycled concrete, and successively built to handle all the concrete waste regeneration processing plants, production of recycled concrete and recycled aggregate, the production of the largest production of 100 t can be processed per hour. Japanese industry association has formulated the recycled fine aggregate and recycled coarse aggregate quality standards and management methods, and on a large scale of production and application of recycled concrete [7].

#### 3.2 The United States

Super fund law, enacted by the U.S. government, regulates that any production enterprises with industrial waste, must properly handle itself, shall not, without tipping at will. Since 1982, the ASTM C—33—82 “concrete aggregate standard” will be broken hydraulic cement concrete included into the coarse aggregate. Around the same time, the U.S. army Engineers association (Society of American he Engineers, SAME) also in the relevant standards and guidelines encourage the use of recycled concrete aggregate [8].

#### 3.3 Europe and other countries

Netherlands is among the first countries to carry out research and application of the recycled concrete. As early as 1980s, the Netherlands is made about the use of recycled concrete aggregate preparation of plain concrete and reinforced concrete and prestressed reinforced concrete specification. The specification defines the use of recycled aggregates on clarify the technical requirement of the concrete, and pointed out that if the content of recycled aggregates in the aggregate (weight) is less than 20%, the production of concrete is completely according to the design and preparation methods of common and natural aggregate concrete. Germany reinforced concrete committee in 1998, proposed “Application guide of the use of recycled aggregates in the concrete,” which require recycled aggregates concrete must be

completely accords with the national standards of natural aggregate concrete<sup>[9]</sup>.

### 3.4 China

Study on recycled concrete in our country is late, and has become a hot spot in the field of concrete research now. Most of the application of the current domestic construction waste recycled aggregate is in a state of careful test, lack of a system of applied basic research, and perfect technical regulations or standards.<sup>[1]</sup> In practice, the situation of the domestic and foreign also has a certain gap, often lack the relevant identification of waste concrete classification standard, control the quality of the recycled concrete has the certain difficulty. So when use, should be carried out on the performance of the recycled aggregates and recycled concrete test. Large-scale application of recycled concrete also has many problems, some basic indicators and technical parameters is not complete, thus the system study of recycled concrete is necessary<sup>[10]</sup>.

## 4 EXPERIMENTAL STUDY ON COMPRESSIVE PERFORMANCE

### 4.1 Overview on the basic properties of recycled concrete

Recycled aggregate has low intensity, high water absorption, and large surface roughness compared with natural aggregate. Therefore, the basic property of recycled concrete is different from that of natural aggregate concrete. Recycled concrete uses recycled aggregate. Thus, the strength of the recycled concrete are closely linked with that of waste concrete used. In the condition of the same water cement ratio, the higher the strength of recycled aggregate is, the higher the strength of recycled concrete is. In general, the strength of waste concrete by building demolition is about C20. As the Water Cement ratio (W/C) is 0.6 and the recycled aggregates completely replace the natural aggregates, its compressive strength of 28 d can be up to 23.5 MPa, fully meet to the actual application demand. In the same condition of W/C, with the increasing of replacement rate of recycled aggregate, the concrete slump gradually become smaller. Apparently, the workability of fresh concrete is obviously influenced by recycled aggregate because of its surface roughness, high porosity, and high water absorption rate. With the increase of the amount of recycled aggregate replacement, the slump loss of concrete increases gradually. It is closely related with that recycled aggregate surface water absorption needs some time to reach equilibrium<sup>[11, 12]</sup>.

Because various performance of recycled aggregate is different from that of natural aggregate, special study should be conducted on the mixture ratio of recycled concrete, according to the characteristic of recycled aggregate, in order to effectively promote the recycled concrete. Southeast University professor Zhang Yamei<sup>[13]</sup> has studied three series recycled concretes of C20, C30, and C40, and preliminarily discussed the mix proportion design of recycled aggregate concrete. The research results show that when the design strength is C20, the strength of recycled concrete made by the ordinary concrete mix ratio is higher than that of the reference concrete, but its work performance reduced significantly. On the basis of this, she put forward letting recycled aggregate preabsorb water. This method is consistent with that suggested by Shi Wei<sup>[14]</sup>, which based on free water cement ratio, for recycled aggregate's high water absorption ratio. That is, the recycled concrete mixing water consumption is divided into two parts, one part is for aggregate adsorption, known as adsorbed water, it is the water consumption from aggregate starting adsorbing water to saturation state of dry surface; another part is the mixing water consumption, in addition to evaporation, this part water is used to improve the liquidity of mixed complexes and participate the hydration reaction of cement. The amount of adsorbed water is determined according to the tests, mixing water consumption is determined according to the design method of ordinary concrete mixture ratio<sup>[15]</sup>. In practice, the two parts of water are added together.

During the design of mixture ratio, recycled concrete performance can be improved by mixing the recycled concrete aggregate with the natural aggregate and adding admixture or additive etc. In the test of Saroj et al, the performance of recycled concrete has been greatly improved by adding 10% fly ash. The concrete manifestation is that not only the shrinkage strain, permeability and water absorption of recycled concrete is close to that of ordinary concrete but also the acid resistance of recycled concrete is greatly improved. Zhang Yamei<sup>[13]</sup> made up recycled concrete with the strength of 54.6 MPa, by using only recycled aggregate as coarse aggregate, and mixing with high efficiency water reducing agent and fly ash. Xing Zhenxian<sup>[16]</sup> made up recycled concrete with the strength of 40.4 MPa by using waste concrete aggregate with the matrix strength of C20–C25, adding with superplasticizer which makes the water cement ratio decrease to 0.35. Thus, mixture proportion design of recycled concrete is more complex than that of ordinary concrete, however, as long as proper measures were taken, satisfactory mechanical properties of recycled concrete can be obtained.

#### 4.2 Experiment method and data analysis

Experimental conditions and parameters are as follows: test block's design strength is C30, water cement ratio is 0.41, and sand rate is 32%.

Test method: design seven groups of recycled concrete with different replacement ratios (ratio of recycled aggregate and natural aggregate) of: 0, 10%, 30%, 10%, 70%, 90%, 100%; each group employ three blocks. Slump of the first group is used as a benchmark. During the preparation process of the rest six groups, their slumps were adjusted continuously to ensure the consistent of the workability and fluidity, which should be in accordance with the first group. Then draw a graph by comparing ultimate strength values of 7 groups recycled concrete with different proportions, to find out the best proportion. Experiment data are shown in Table 1.

Table 1 shows that the compressive strength of all recycled concretes meet the requirements about strength, and even beyond that of natural aggregate concrete. When the replace rate is 70%, the strength reaches its maximum value, or 34.2 MPa, which is 9.97% higher than that of natural aggregate concrete. Diagram based upon the above data is shown in Figure 3.

Table 1. Ultimate strength values of recycled concretes with different replacement ratios.

No	Replacement ratio %	Measured value KN	Average value KN	Ultimate strength Kpa
1	0	678	707	31.1
2	10	698	671	30.1
3	30	702	763	33.2
4	50	688	713	31.4
5	70	712	789	34.2
6	90	714	743	32.7
7	100	732	749	33.1

Figure 3. Relationship between the replacement ratio and the compressive strength of recycled concrete.

Through Figure 3, we can find that the compressive strength of recycled concrete fluctuates with the increase of the replacement ratio. When the replace ratio is 70%, it reaches maximum. Therefore, the best proportion of recycled aggregate and natural aggregate is 70%.

## 5 CONCLUSIONS

Experimental results show that the recycled aggregate concrete completely meets the requirements of the strength, and has a strong feasibility. Both from the perspective of optimized distribution of resources and the looming environmental protection point of view, this is a very good method.

The biggest obstacle to promote widely recycled concrete is that there are no protection policies in China. If there is no policy, it is a bit unrealistic to only rely on the consciousness of entrepreneurs. Therefore, the country's policy then became the key factor. There are the related specification and use conditions for a long time in such developed countries as Japan, the United States, Europe, and so on. It also is the important reason for the recycled concrete being widely promoted in those countries. With the support of national policy, related laws and regulations, recycling of waste concrete, which benefits both economic and social, would be popularized in our country.

# Discussion on the cause of concrete floor crack

Zhi Neng Tong

Jiangxi Science and Technology Normal University, Nanchang, China

**ABSTRACT:** The reason for formation of cracks in the concrete is very complex. This paper analyzes the same from the angles of the design, construction, and material properties and explores the reasons and influencing factors, describing the mechanism of crack in order to avoid and reduce concrete slab cracks. It also provides a theoretical basis and references for similar engineering and technical services.

**Keywords:** concrete; floor cracks; factors; performance

## 1 INTRODUCTION

In many engineering quality problems, the concrete crack phenomenon is more outstanding. Therefore one must pay attention to the cause of formation and prevention of concrete crack. The concrete is a heterogeneous brittle material, which is mixed with the aggregate, cement, water, and other materials. Due to the concrete construction and its deformation, a series of problems, such as constraint, hardening, and molding, of concrete exist causing many micropores, cavitation and micro cracks. It is because of the existence of these initial defects that concrete showed some heterogeneous characteristics. But due to load and temperature differences in concrete action, micro cracks will constantly extend and get connected, and ultimately form a visible macro crack.

The shrinkage of concrete is the main reason that causes cracks of cast-in-place plate. The concrete, in the condensation process, will change in volume. When the shrinkage stress exceeds the tensile strength of concrete, the concrete will crack. The crack problem of the concrete is widespread and has become a major problem plagued in the construction engineering and technical personnel, following on from the aspects of design, material, and construction operation to analyze the crack causes of construction for the prevention and control measures.

## 2 PRONE SITE OF CRACKS IN CAST-IN-PLACE FLOOR SLAB

1. The cracks in the room. From the site of the residential project, cast-in-place floor cracks, are the most common and widespread and are the largest in number around the house yang

angle at notch housing (including plane shape mutation Yang corner room) in left yang angle 1 meter, namely, in the floor of the negative bending bars and angle of radial rib terminal or lateral occurred about 45 degrees to the ground floor of the diagonal cracks. This is common in the building of a type of any of cast-in-place floor are widespread.

2. Other cracks of floor slab. Except the floor cracks, there are three more common kinds: one kind is pre embedded pipe and line pipe distribution; second class is when turnover materials used in construction temporary more concentrated and less frequent, lifting unloading stacking area, mainly concentrated in the center of the floor, third class is generated for the effects of concrete material and construction technology of position.

## 3 DESIGN FACTOR

The main reason of the cracks in the cast-in-place floor is that the shrinkage of concrete is caused by the shrinkage of concrete and the temperature difference. And the more the floor crack the closer is the roof. From the design point of view, the current design specification focuses on the intensity of the considerations, not fully according to the temperature difference and the shrinkage of concrete and other factors, such as the amount of reinforcement and thus can not reach the requirements. And around the house yang angle due to the longitudinal and transverse direction shear wall or stiffness relatively large floor beam constraints, limiting the freedom of floor slabs of concrete deformation, so in the temperature and shrinkage of concrete changes, plate in reinforcement weak at first cracking, resulting in about 45 degrees of angle cracks. Although the crack

has no effect on the structural safety of the building, but has the leakage defect in the special case of water source, it is the key of crack prevention. According to the above analysis and consideration on the surrounding angle at the floor panel reinforcement to strengthen, negative reinforcement with no separation type cutting, full-length configuration and appropriate encryption bold.

Over the years, the practice has proved that the design of the concrete floor slab basically no longer occurred 45 degrees diagonal crack, can better solve the problem of floor cracks, the effect is remarkable. For the radial steel bar in the corner, the function is small. The reason is not the length of radial steel (about 1.2 meters), the room in the corner of Danyang by double encryption and still strengthen two-way reinforced by separating tectonic setting negative moment short ribs, 45 degree oblique cracks will still be transferred to the inward radial rib at the end or outside, and when the double encryption to strengthen two-way reinforced, longitudinal, transverse two directions has been reinforced to resist and prevent the occurrence and metastasis of the 45 degree angle of the crack, and radial reinforcement often only the upper layer, above the binding often set aside in the aspect of steel plate, steel lead to overlapping, will negative reinforcement plate under pressure, reducing the effective height of plate negative reinforcement, so that the focus on strengthening the double encryption can be reinforced.

#### 4 MATERIAL PROPERTY FACTOR

Concrete is a kind of non homogeneous brittle material which is mixed with sand aggregate, cement, water, and other materials. The main factor affecting the deformation of concrete is.

##### 4.1 *Influence of cement variety*

Cement selection is the key to the problem of contraction. Different varieties of cement shrinkage depends on calcium aluminate three, three sulfur, gypsum content and fineness of cement. And with the application of high strength concrete, cement grade level requirements has been improved, cement consumption will increase, higher caused by hydration heat, concrete shrinkage deformation is greater.

##### 4.2 *The influence of concrete mix proportion in the raw material certain conditions*

The proportion in certain conditions influences the raw material certain conditions, the water cement ratio of concrete shrinkage has a great influence.

Shrinkage of concrete depends on unit quantity of water and cement, and the effect of water is higher than the cement. In water use in certain conditions, shrinkage of concrete increase with the increase of the amount of cement. In water cement ratio under certain conditions, mixed concrete shrinkage increases with the water cement ratio increased significantly increased; in water cement ratio under the same conditions, concrete shrinkage with increasing sand rate and increase, but increase in amplitude is smaller. The reasons for the shrinkage of concrete are the control parameters such as unit water consumption, cement dosage, water cement ratio, sand ratio and so on.

##### 4.3 *Effect of slump*

Pumping concrete in order to satisfy the pumping conditions: slump, good fluidity, easy to produce less local coarse aggregate, mortar. At this time dehydration concrete stem lapse, it will produce crack surface.

## 5 CONSTRUCTION TECHNOLOGY FACTOR

##### 5.1 *The effective protection measures of the reinforced floor of the upper floors*

Floor panel of the lower layer reinforced bar in the concrete floor plate tensile force plays a dual role of resist external load generated by bending moment and prevent the occurrence of concrete shrinkage and temperature cracks, and the dual role of are required to reinforced in reasonable protection layer under the premise to ensure effective. In the actual construction, the floor and the lower layer of the reinforced net in the concrete block and template based on the protection layer is easier to correct control. But when the pad spacing enlarged to 1.5 meters, the reasonable protection of mesh reinforcement layer thickness can not guarantee, so does the aspect to the pad spacing limit at 1.0 meters.

In contrast, the effective protection of the upper floors has been a big problem in the construction. The reason for this is that the floor panel of the upper reinforcement is generally fine is soft, personnel from the stampede immediately after bending, deformation, straining; reinforced distance template of greater height and are not subjected to template based on the protection; various types of cross operation, resulting in many construction workers, walking is very frequent, no settled at will inevitably be a stampede; the upper layer of the reinforcing steel bar mesh support spacing is too large, or even, resulting in upper mesh reinforcement can not be effectively protected.

### 5.2 *Crack embedded pipe at*

Pre embedded pipe, especially at the center of a plurality of line pipe is concrete section are more weakened, which caused by stress concentration, easily lead to cracks occurring in a weak position. When the pre cut line tube with smaller diameter and the standard width of a room housing width is also smaller, and line pipe laying direction and do not coincide in the vertical to concrete shrinkage and tensile direction, generally not occurred floor cracks. On the contrary, when the pre embedded pipe of larger diameter, width and width is larger, and line pipe laying direction and the coincidence in parallel to concrete shrinkage and tension at the same time, it is prone to cracks in the floor. So for thick pipes or a plurality of line pipe distribution should be according to the technical requirements of additional vertical in line tube short steel mesh strengthening. According to the experience, it is recommended additional crack short reinforced by  $\phi$  6-8 mm, the spacing is less than or equal to 150, at both ends of the anchorage length should be not less than 300 mm.

Using radial distribution is suitable for distribution line tube in installation should avoid stereo crossing, cross wiring can be in accordance with the technical requirements of the line box, at the same time in a plurality of line pipe and avoid closely parallel arranged, to ensure that the line pipe at the bottom of the concrete pouring construction smoothly and vibration compacting. And when the line pipe number, so that the export distribution section of concrete greatly reduces when, should according to leave holes in the structural requirements around added under the 2  $\phi$  12 well shaped anti crack structure is reinforced.

### 5.3 *Strengthening the maintenance of floor concrete*

The moisture curing of the concrete on the strength growth and performance improve is very important, especially early proper maintenance can avoid surface dehydration and reduce the

amount of concrete at early age shrinkage cracks occur. However, in actual construction, due to rush time and watering will affect the missile line and construction personnel, so the floor concrete is often lack of adequate and adequate watering maintenance duration. Therefore, construction must insist on Covering Straw sacks or a week or so proper moisture conservation, and suggest using liquid spray curing, so as to reduce the cost and improve the work efficiency, and can avoid or reduce the impact of construction.

## 6 CONCLUSION

After taking the above comprehensive control measures, there may still be a small amount of floor cracks due to various reasons. According to the experience, the upper part of the ground floor leveling thickness of the paint layer can be strengthened by additional leveling layer with steel wire net, steel nets or crack short reinforced, and the upper part is often floor decorative layer covered. The problem is relatively small.

Now the prevention and control of the cast-in-place reinforced concrete floor cracks which are always worthy of attention, although existing methods can control cracks to a certain degree, but the risk of cracks can be still seen everywhere. Only from the design, materials, construction, use and other aspects continue to explore, and constantly seek better ways to further reduce the cracks in cast-in-place reinforced concrete floor slab.

**ABSTRACT:** This paper compares the Hubei En Lai with En Qian highway zhong jian river bridge main span cable tower concrete engineering, and studies the dosage of gelled material, water-binder ratio, fly ash content and the mechanism of sand fineness modulus and the sand ratio on elevation mechanism sand pumping concrete workability and mechanical properties of the influence law. In addition, it studies selected elevation mechanism sand pumping concrete proportion of optimal theory on its workability, mechanical properties and durability properties.

**Keywords:** mechanism of cable tower; pumping concrete, sand; fineness modulus

## 1 INTRODUCTION

Hubei En Lai highway zhong qian river bridge built with the main span ShuangSuoMian steel truss stiffening girder cable-stayed bridge is a twin tower. Its main cable tower adopts the H form structure, whose main tower height is 245 m, by the high pillar, the middle pillar and lower pillar, high beam, the lower beam and the tower, C50 concrete strength level.

Based on the research of gelled material consumption, water-binder ratio, fly ash content and mechanism sand fineness modulus of sand and sand ratio on mechanism elevation pumping concrete workability, and mechanical properties, the mechanism of sand elevation of theory of pumped concrete mix are optimized for the application of pumped concrete mechanism sand in elevation, in order to provide a technical guidance.

## 2 THE TECHNICAL REQUIREMENTS OF CONCRETE

Integrated cable tower concrete pumping construction, structure, performance, the design of cable tower high-performance concrete indicator are as follows:

1. Work performance: concrete slump and the expansion degree should be increased

with pumping elevation. Initial slump control is  $210 \pm 20$  mm, extension control is  $550 \pm 75$  mm, 1 h after the slump loss value 20 mm or less, extension, degree of loss value 75 mm or less. At the same time, the concrete should have good adhesiveness and water retention, pressure-secrete water  $< 30$  ml, and the exudation rate should be  $< 40\%$ . In order to guarantee the uniformity of the concrete, the appropriate controlling concrete slump into the mould should be  $190 \pm 20$  mm, and the extension degree should be controlled to  $500 \pm 50$  mm.

2. Setting time: initial setting time of concrete general appropriate control is about 12h ~ 14h. The initial setting time and final setting time is short, as far as possible to ensure the concrete 36h ~ 48h stripping strength requirements.
3. Strength: design strength grade of concrete is C50, and for 28d preparation, it should be  $\geq 62$ Mpa compressive strength, but not greater than 70Mpa.
4. Durability: aggregate is used in concrete with alkali activity. The chloride ion diffusion coefficient of concrete 28d age (RCM method) is  $\leq 5.0 \times 10^{-12}$  m<sup>2</sup>/s, age 28d anti-freeze performance achieve F150, and carbide performance fully satisfies the requirement of design service life.

### 3 RAW MATERIALS AND TEST METHODS

#### 3.1 The raw materials

1. Cement: huaxin P.O. 42.5 cement.
2. Fly ash: hunan SangZhi F type of grade I fly ash, with the apparent density of 2.17 g/cm<sup>3</sup>, the ignition loss of 1.56%, and the ratio of 93.2%.
3. Coarse aggregate: limestone rubble, 5–20 mm continuous gradation, two-stage blending. No alkali—aggregate reaction activity.
4. Mechanism of fine aggregate: limestone sand and apparent density of 2.712 g/cm<sup>3</sup>, loose pile density of 1601 kg/m<sup>3</sup>, no alkali—aggregate reaction activity. 1<sup>#</sup> mechanism sand fineness modulus of 3.01, the stone powder content is 6.8%, MB 0.5 value; 2<sup>#</sup> mechanism sand fineness modulus of 3.22, the stone powder content is 6.0%, MB0.8 value; 3<sup>#</sup> mechanism sand fineness modulus of 3.41, stone powder content is 6.5%, MB 0.5 value.
5. Water reducing agent: HD poly-carboxylic acid salt and high-efficient water reducing agent, with the dosage of 0.85 ~ 1.15%.

#### 3.2 Test method

1. The concrete mixture performance test  
Slump/extension, pressure bleeding rate, bulk density, air content, such as setting time test method according to the GB/T50080-2002, JTG E30-2005, CECS 203:2006.
2. The hardened concrete mechanics performance test  
Cubic compressive strength and compressive modulus of elasticity of the test method on the basis of JTG E30-2005.
3. Resistance to the chloride ion penetration test  
The concrete resistance to the chloride ion penetration test according to GB/T 50082-2009.

### 4 THE TEST RESULTS AND ANALYSIS

#### 4.1 Benchmark mixture ratio design

##### 4.1.1 Water-binder ratio optimization

The optimization conditions are as follows: fixed 20% dosage of fly ash, sand ratio 44% and design unit weight of 2450 kg/m<sup>3</sup>. A fixed amount of gelled material 475 kg/m<sup>3</sup> and 490 kg/m<sup>3</sup>, and the water-binder ratio are 0.30, 0.31, 0.32, and 0.30. The process of the test should be fine-tuned, and the dosage of water reducing agent should meet the basic requirements for concrete workability. The results are summarized in Table 1.

From Table 1, we obtain the following results: the water-binder ratio below 0.31 and 28d compressive strength of concrete can satisfy the requirements of mixture strength of 62 MPa. Under the condition of the same water/cement ratio, 490 kg/m<sup>3</sup> gelled material is more suitable for pillar height, upper pillar super elevation in pumping concrete construction needs. Comprehensively considering the workability, strength factor, water-binder ratio optimization is 0.31, the dosage of pillar gelled material is 475 kg/m<sup>3</sup> and pillar gelled material consumption is 490 kg/m<sup>3</sup>.

##### 4.1.2 The choice of the dosage of fly ash

Gelled material was fixed to 475 kg/m<sup>3</sup>, water/cement ratio is 0.31, the design unit weight is 2450 kg/m<sup>3</sup>, sand rate is 44%, with 5% of the dosage of fly ash step growth to 35%. Fine-tuning in testing the water reducing agent dosage should meet the basic requirements for workability. The test results are summarized in Table 2.

Table 2 shows that with the increasing dosage of fly ash, there was a downward trend basically, with bulk density and mixture flowing faster. With the increasing dosage of fly ash, 3d, 7d early age strength reduced, which was more complex, and the intensity at 28d changed. Moreover, 15% and

T12	30	215	580 × 550	2445	40.9	55.1	63.4
T13	35	230	570 × 600	2440	41.1	54.9	64.8

Table 3. Sand ratio on concrete workability and strength.

Number	Fineness modulus	Sand ratio (%)	Slump (mm)	Extension degree (mm)	The compressive strength (MPa)		Work item description
					7d	28d	
T14	3.01	40	200	560 × 545	56.2	60.7	Slight analysis pulp, harden
T15		42	230	530 × 540	59.0	64.8	Good, soft
T17		44	215	520 × 500	59.4	63.7	Good, high viscosity
T18	3.22	42	220	570 × 530	58.7	64.5	Good, soft
T6		44	230	550 × 540	59.9	64.8	Good
T19		46	210	500 × 520	57.7	65.7	High viscosity, slow expansion
T20	3.41	44	240	570 × 545	52.6	59.9	Segregation
T21		46	230	555 × 530	54.9	63.7	Good
T22		48	210	550 × 540	58.2	63.7	Good

35% of fly ash concrete strength was basically the same, at about 64.7 MPa, and 20 ~ 30% of fly ash content concrete strength of 28d was basically the same, at about 62.3 MPa.

In summary, the cable tower of benchmark of the main parameters of water/cement ratio was 0.31, with 20% of fly ash, the pillar of gelled material of 475 kg/m<sup>3</sup>, and pillar gelled material consumption of 490 kg/m<sup>3</sup>.

#### 4.1.3 Mechanism sand fineness modulus and the best effect of the sand ratio

Gelled material was fixed to 490 kg/m<sup>3</sup>, the water/cement ratio to 0.31, 20% dosage of fly ash, and dosage of water reducing agent to 1.0%. The results are summarized in Table 3.

From Table 3, we can obtain the following test results: fineness modulus of 3.0, the optimal sand at a rate of 43%; sand fineness modulus of 3.2, the optimal rate of 44%; sand fineness modulus of 3.4, and the optimal rate of 46%. With the increase in mechanism sand fineness modulus, the optimal sand ratio increased. When the fineness modulus was larger, the workability of concrete was poor, and there was a significant adhesiveness deterioration of concrete.

#### 4.2 Cable tower elevation mechanism sand pumping concrete nature of basic research

From the above test, we determined the theory of cable tower pumping concrete mixture ratio, as shown in Table 4. In the concrete construction, A0 was used for the lower pillar and A1 for the high and middle pillar.

##### 4.2.1 Fresh concrete workability

As can be seen from the experimental results summarized in Table 5, A0, A1 two mixture workability, slump and extension degree satisfy the requirement of cable tower construction. Pressure bleeding rate is less than 40% and water performance is good. The initial setting time is more than 12 h, which meets the design requirements.

##### 4.2.2 Hardened concrete mechanical properties and durability

For A0, A1 two towers of concrete hardening concrete mechanics performance test, the results are summarized in Table 6.

From Table 6, we obtain the following test results: two theoretical mixture ratios of 28d the chloride ion diffusion coefficient of  $3.2 \times 10^{-12} \text{ m}^2/\text{s}$

Table 4. Cable tower of the pumping concrete mixture theory.

Number	Dosage of rubber material (kg/m <sup>3</sup> )	Water/cement ratio	Sand ratio (%)	Concrete composition (kg/m <sup>3</sup> )					
				Cement	Fly ash	Water	Sand	Gravel	Admixtures/%

Table 6. Theory of hardened concrete mechanics performance.

Number	The cube compressive strength (MPa)					Modulus of elasticity (10 <sup>4</sup> MPa)			28d D <sub>RCM</sub> (10 <sup>-12</sup> m <sup>2</sup> /s)
	3d	7d	28d	56d	90d	7d	28d	56d	
T0	44.6	56.7	63.3	69.1	74.9	4.20	4.52	4.77	3.20
T1	47.9	59.5	64.9	72.9	76.9	4.16	4.69	4.81	3.12

and  $3.12 \times 10^{-12} \text{ m}^2/\text{s}$ , are less than  $5 \times 10^{-12} \text{ m}^2/\text{s}$ , which meet the requirements of durability.

## 5 CONCLUSION

1. According to the cable tower structure design, concrete pumping construction, we put forward the cable tower of high performance concrete mix proportion design of technical index requirements.
2. We determined the optimal dosage of the water-binder ratio, fly ash and the dosage of gelled material mix gel system of the main parameters, such as water/cement ratio of 0.31, 20% fly ash, the lower pillar of gelled material of 475 kg/m<sup>3</sup>, high and middle pillar gelled material consumption of 490 kg/m<sup>3</sup>.
3. We conducted comprehensive analysis to determine the optimal sand at a rate of 45%.
4. Dosage of gelled material was studied, and the dosage of the water-binder ratio, fly ash and

sand ratio on the workability, pumping properties and strength of concrete, the influence of the comprehensive analysis of selected workability and physical and mechanical performance meet the requirements of the cable tower design of A0, A1 two directional mixture. And the selection of proportion of the two theories of the research of the system, and the mechanical properties, including the construction performance of concrete and long age law of development, meet the requirement of the corresponding technical indicators, and the surplus coefficient and compressive strength are larger.

**ABSTRACT:** We utilize coarse aggregate, fine aggregate, and fine ground admixture made to make high titanium heavy slag to compound the performance of complex high titanium heavy slag pavement concrete. Applying set parameters of bending strength and working property as major examining indexes, we adopt orthogonal experiments and extreme difference analysis method to research the influence of water to binder ratio, sand percentage, and composite powder replacement rate on the performance of high titanium heavy slag, make optimal design for it, seek optimal proportioning, and design a kind of high-performance pavement concrete to popularize in pavement engineering to provide good reference to engineering application.

**Keywords:** complex high titanium heavy slag; high-performance pavement concrete; mixture design; orthogonal experiment; experimental analysis

## 1 INTRODUCTION

High titanium heavy slag is a kind of dense slag that generates from blast furnace slag naturally cooled or hot poured in the air when vanadium-titanium magnetite is smelted in ANSTEEL. Its  $\text{TiO}_2$  content is high up to around 22%; thus, it is called high titanium heavy slag. This project grades and breaks the huge heaps of high titanium heavy slag into coarse aggregate, fine aggregate, and fineground admixture to make compound pavement concrete (hereinafter referred to as “CHTHSPC”). It is a significant measure to apply high titanium heavy slag to the field of engineering construction, as it will help in solving the excessive slag accumulation in ANSTEEL, economizing natural resources, reducing engineering cost, protecting the ecologic environment of the upper reaches of Yangtze River, etc. Following the previous research foundation<sup>[1][2]</sup>, this paper, is also based on the analysis of the technical standards. The aggregates of sand and stone and levigated admixture are used for the road made from high titanium heavy slag. We take the flexural strength index, the most important index for the concrete used for making roads, as the center. Through orthogonal proportion experiment of

the concrete, we select the optimal proportion and design a kind of pavement concrete made from the high-performance high-titanium heavy slag, providing further exploration and verification for the high-titanium heavy slag used to make pavement concrete in Panzhihua.

## 2 ENGINEERING BACKGROUND

The road project of double line of Qingxiangping-Wuguijing belongs to the municipal arterial road project in West District, Panzhihua. The design length, width, and thickness of the road are respectively 6.4 km, 15 m, and 250 mm. The road is mainly used to replace the municipal central prosperous artery to shunt heavy freight locomotives, so the road belongs to the heavy-grade traffic pavement, and its design flexural strength  $R_{28} \geq 5.5$  MPa, and its design grade is secondary road. All the concrete in this section of the road is proposed to adopt high titanium heavy slag thick and thin aggregates to replace ordinary breakstone and sand and mixed with levigated high titanium slag compound micro powder to partly replace cement to confect CHTHSPC 6.4 km.

### 3 EXPERIMENTAL DESIGN

#### 3.1 Selection of raw materials

Thick aggregates. The successive graduation, apparent density 2.72 g/cm<sup>3</sup> and stacking density: 1350 kg/m<sup>3</sup> of the 5–31.5 mm high titanium heavy slag breakstone produced<sup>[3]</sup> by Huanye Co., Ltd.

Thin aggregates. For the high titanium heavy slag produced by Huanye Co., Ltd., the content of its ground-slag: 10%–13%, the modulus of fineness  $M_x = 2.9$ –3.2, the apparent density: 3.14 g/cm<sup>3</sup> and the stacking density: 1680 kg/m<sup>3</sup>.

Composite powder of ground titanium slag<sup>[4]</sup>. See Table 1.

Cement. The selected cement is produced by Huanye Co., Ltd.

#### 3.2 Preliminary mix-proportion calculation

The standard mix-proportion for road concrete is preliminarily calculated as shown in Table 2 through preliminary mix-proportion calculation according to the given design scheme of mix-proportion in Construction Specification for Highway Concrete and Cement<sup>[5]</sup>, and refer to the proportion of plain concrete pavement of the approaches on the south and north of the local Bingcaogang Bridge<sup>[6]</sup>, which has been completed and opened to traffic.

#### 3.3 Optimization design for orthogonal mix-proportion

For further improving mechanical property of CHTHSPC, changes of relevant factors, such as the amount of composite powder, water-binder ratio and sand ratio, should be considered in terms of affecting the mix-proportion of concrete based on the calculation of standard mix-proportion. In this thesis, othogonal design is adopted to learn the

relationship between the property of CHTHSPC and each factor. Then the range of the optimal mix-proportion could be obtained through adjustment.

##### 3.3.1 Parameter determination

Selecting water-binder ratio from 0.46, 0.44, 0.42, 0.40; sand ratio from 33, 34, 35, 36; and composite powder (replacement rate%) from 16, 18, 20, 22 by research. Conducting orthogonal test by orthogonal Table L 9(34) orthogonal Table.

##### 3.3.2 Orthogonal mix-proportion test

Conduct trial concrete mixing based on Property Test Methods for Normal Concrete Mixture and Mechanical Property Test Methods for Normal Concrete. The tested orthogonal mix-proportion and experimental results of concrete under each condition are in Table 3.

## 4 EXPERIMENTAL RESULTS ANALYSIS

#### 4.1 Differential analysis of orthogonal design results

The calculation method of column I factor range  $R_i$  are as follows:

$$R_i = \max(I_i, II_i, III_i, IV_i) - \min(I_i, II_i, III_i, IV_i) \quad (1)$$

The magnitude of range  $R_i$  reflects the magnitude of corresponding factors. The range calculation is as shown in Table 4.

From the Table 4 associated with various factors analysis, conclusions can be drawn:

- The sort order within 7 days of flexural-tensile strength influence for CHTHSPC is: water-binder ratio → the amount of compos-

	R	26	11	0	26	11	0	

ite powder → sand ratio; the sort order within 28 days of flexural-tensile strength influence for CHTHSPC is: water-binder ratio → sand ratio → the amount of composite powder.

- The water-binder ratio is the principal factor which has an impact on CHTHSPC's flexural-tensile strength.
- The sizes of the amount of composite powder is the secondary factor that has an impact on

CHTHSPC's flexural-tensile strength, which is getting smaller with the increase of the amount of composite powder; On the 28th day, the sand ratio took place of composite micro powder dosage and became the secondary factor that has an impact on CHTHSPC's flexural-tensile strength. Mainly, because of accompanying with the development of activation effect by composite micro powder dosage, after 7 days,

the impact factors of flexural-tensile strength for the amount of composite powder began to gradually decrease. Associated with the orthogonal experimental results, to select group 9 from test block group numbers as the application of CHTHSPC's optimal ratio in the pavement engineering.

#### 4.2 Experimental result analysis

- The effect of water-binder ratio on CHTHSPC. According to Table 4, the breaking strength of CHTHSPC goes down with the increase of water-binder ratio, especially the early-stage flexural-tensile strength. However, after the age period increased to 28 days, flexural-tensile strengths of CHTHSPC with different water-binder ratios, including 0.46, 0.44, 0.42 and 0.40, tend to approach each other. Except for 0.46, all flexural-tensile strengths with other water-binder ratios are larger than designed flexural-tensile strength, in compare with the ones with the age period of 7 days. When it comes to Day 28, all flexural-tensile strengths with different water-binder ratios in four groups are between 6.65~7.87, which can totally meet the design requirement. Therefore, the water-binder ratio decides the flexural-tensile resistant performance of CHTHSPC.
- The impact of superfine composite powders on CHTHSPC. As the amount of composite powder in CHTHSPC is not that high, ranging from 16% to 22% only, it merely has a positive impact on the working performance of CHTHSPC, and various mixing amounts of superfine composite powders which include 16%, 18%, 20%, and 22% do not have much flexural-tensile strength influence of CHTHSPC, but high amounts can improve the frangibility of concrete.
- The flexural-tensile strength of CHTHSPC of age 28 days is above 7.0.

### 5 CONCLUSION

- Centered on of bending and breaking strength index of CHTHSPC, the optimum mixture ratio of high-performance pavement concrete is obtained through the orthogonal and proportion tests.
- The flexural-tensile strength of CHTHSPC decreases with the growth of water-binder ratio, especially the early-stage flexural-tensile strength. However, with the prolongation of

age period, flexural-tensile strengths of concrete with different water-binder ratios tend to approach each other. The flexural-tensile resistance performance of CHTHSPC is determined by water-binder ratio.

- Every mixing amount of 16%, 18%, 20%, and 22% of grind stiletto titanium slag composite powder has little flexural-tensile strength influence on CHTHSPC, but can improve concrete's workability and fragility.
- CHTHSPC's 28-day flexural-tensile strength can be above 7.0 MPa; in addition, due to its rough surface, good concrete's interface structure, and prolonged wear-resistance, it is suitable for pavement concrete of heavy and extra heavy road.
- Engineering application. Via pavement investigation of Qing-Wu double line project, analyzing from transport rate and pavement's damaged condition, CHTHSPC's quality is good and the qualified rate is 100%; the amount of cement equals to or is below that of concrete formed by naturalgravel of the same level and working performance, possessing excellent tension resistant performance; over half a year of running, no phenomenon of broken slab or founding has occurred.

**ABSTRACT:** Four recycled aggregate concrete of different replacement ratios was prepared using crushed cube block as recycled coarse aggregate. Replacement ratios varied from 0 to 100%, and a total of 12 prismatic block were loaded on the electro-hydraulic servo testing machine. The destruction process and failure mode were observed, the load-displacement curves of the whole process were obtained and analyzed. It is shown that destruction process and failure mode of recycled aggregate concrete and natural aggregate concrete are similar to each other. With the increase of recycled coarse aggregate replacement ratio, peak stress and peak strain of recycled aggregate concrete show no apparent unity law. Replacement ratio of recycled coarse aggregate makes a greater impact on stress-strain curves of recycled aggregate concrete. With the increase of recycled coarse aggregate replacement ratio, elastic modulus of recycled aggregate concrete gradually become larger, ductility and energy performance of recycled aggregate concrete get better.

**Keywords:** recycled aggregate concrete; axial compression; stress-strain curve; peak stress; peak strain

### 1 INTRODUCTION

After crushing, cleaning and grading, the recycled waste concrete blocks and the natural concrete blocks are mixed to form recycled aggregate by a certain percentage and gradation. Then cement and water are added, so Recycled Aggregate Concrete (RAC) can be formulated<sup>[1-3]</sup>. On the one hand, RAC can resolve the process issue of waste concrete; On the other hand, natural aggregate are instead with construction waste, the consumption of natural aggregates, in the construction industry can be reduced, ease the increasingly scarce natural aggregates pressure, the increasingly scarce pressure of natural aggregates will be eased, social, economic and environmental benefits are obvious. So RAC is considered to be green concrete to achieve sustainable development of building resources<sup>[4-6]</sup>.

At present, universities or research institutes have conducted some research about the performance of the RAC. Peng Gaifei<sup>[7]</sup> of Beijing Jiaotong University crushed and processed two ordinary

concrete were for recycled coarse aggregate, after 620°C heat treatment and pulp attached on recycled coarse aggregate was excluded, RAC was prepared to determine strength index. The results showed the mechanical properties of RAC decreased remarkably. Liu Qingtao<sup>[8]</sup> of Air Force Engineering University adopted the double-doped technology with the use of fly ash of high quality and efficient admixture, experimental research on strength and frost resistance of RAC in airport pavement was carried out. It is shown that the performance of the prepared RAC for pavement is more excellent than one of ordinary concrete, and the request of airport pavement can be met. Based on gray clustering evaluation theory, Lanzhou Jiaotong University Bao Xueying<sup>[9]</sup> Proposed the scheme that RAC coarse aggregate quality level can be assessed comprehensively using a number of parameters, and the usefulness of the evaluation scheme was examined through case study. Padmini A.K.<sup>[10]</sup> studied the effects the recycled aggregate of original concrete made on mechanical behavior of RAC. It is shown that RAC strength is related

to the original concrete strength. RAC strength became higher as original concrete strength became higher, but the relationship was not linear.

Since the majority of recycled aggregate of RAC was from the removed old building, the original internal damage will be bring more or less in the crushing process, leading a large number of internal micro-cracks or cracks in aggregate. Accordingly, axial compressive strength and stress—strain curve of RAC prepared by the recycled aggregate will be affected. Therefore, this paper carried out the axial compressive test of RAC, the stress-strain curve of the whole process was measured. Influence different aggregate replacement ratioed made on axial compressive strength was analyzed. So study about RAC will be enriched, reference for further research and application will be provided for RAC structure.

## 2 DESIGN OF EXPERIMENT

### 2.1 Materials of experiment

P.O 42.5R grade cement, ordinary natural river, urban water and natural coarse aggregate and recycled coarse aggregate were adopted as materials of experiment. Continuous graded gravel was selected as natural coarse aggregate, recycled coarse aggregate was obtained from the crushed test cubes through machine. Recycled coarse aggregate and natural coarse aggregate were screened by the same screen. The maximum particle size of coarse aggregate was 20 mm, and are coarse aggregate were all continuously graded gravel. Recycled coarse aggregate was cleaned for number of times to meet the clay content requirement of recycled coarse aggregate, then recycled coarse aggregate will be dried to achieve the required moisture content for the pouring of RAC.

### 2.2 Mixing ratio of RAC

0% was selected as a benchmark of recycled coarse aggregate replacement ratio, there is four kinds of replacement ratios including 0%, 30%, 70% and 100%, Trial strength of RAC was C40. For RAC of different replacement ratios, the composition of

cement and sand were kept unchanged, and the quality composition ratio of natural coarse aggregate and recycled aggregate was changed under the premise of the equal total mass of coarse aggregate. Mixing ratio of RAC was shown at Table 1. For each replacement ratio, three 150 mm × 150 mm × 300 mm prism standard test blocks were made, and curing was carried out under standard conditions.

## 3 LOADING DEVICE AND TEST METHOD

The current national standard “Test method of ordinary concrete mechanical performance” (GB50081-2002) was referred. Loading was carried out on RMT-201 rocks and concrete mechanic test presses. Testing Machine was shown in Figure 1. In order to obtain the curves of load-displacement of the specimens in the load process, displacement control system was adopted. Loading rate was 0.005 mm/s, by the acquisition system of the loading device, load-displacement curves of the whole process of the specimens were obtained.

## 4 TEST RESULTS AND ANALYSIS

### 4.1 Failure process and failure mode

In the early loading, there were no visible cracks in specimens. When the load was closed to the peak point, there were one longitudinal crack or several parallel longitudinal cracks at the specimen central. After peak point, crack of part of the specimens developed rapidly, the test blocks were split into several pieces, then the specimens were destroyed suddenly and bearing capacity became little, at the same time, test machine could not collect the data of descending branch. Based on the destruction process and form, there was no significant difference between the recycled aggregate concrete and natural aggregate concrete.

### 4.2 Stress-strain curve

Based on the measured load-displacement curves, the stress-strain curve of the whole process of all

Table 1. Mixing ratio of RAC.

Replacement ratio	Water-cement ratio	Sand ratio (%)	Clean water (kg)	Cement (kg)	Sand (kg)	Natural coarse aggregate (kg)	Recycled coarse aggregate (kg)
0%	0.45	32.7	186.8	415.2	587.7	1210.3	0.0
30%	0.45	32.7	186.8	415.2	587.7	847.2	363.1
70%	0.45	32.7	186.8	415.2	587.7	363.1	847.2
100%	0.45	32.7	186.8	415.2	587.7	0.0	1210.3

Figure 1. Testing machine of RMT-201.

the specimens were obtained using equation (1) as shown in Figure 2.

$$\sigma = \frac{N}{A}, \varepsilon = \frac{\Delta l}{l} \quad (1)$$

In which:  $N$ —axial compression of specimen,  $A$ —cross-sectional areas of RAC specimens,  $\Delta l$ —specimen displacement during the load Process,  $l$ —Measuring gauge of specimen, taken as 150 mm.

In Figure 2, each curve was taken from the average of three prism curves. It can be seen from Figure 2, replacement ratio of recycled coarse aggregate has a greater impact on stress-strain curves of RAC, but the curves are made up of the ascent and descent segments, and there are the proportional limit point, the critical stress point, peak point, an inflection point and convergence point in these curves. With the increase of recycled coarse aggregate replacement ratio, the slopes of rising section in the stress-strain curve increase gradually, indicating that the elastic modulus of RAC increase gradually. The declined segments of the whole process curve become more relaxed,

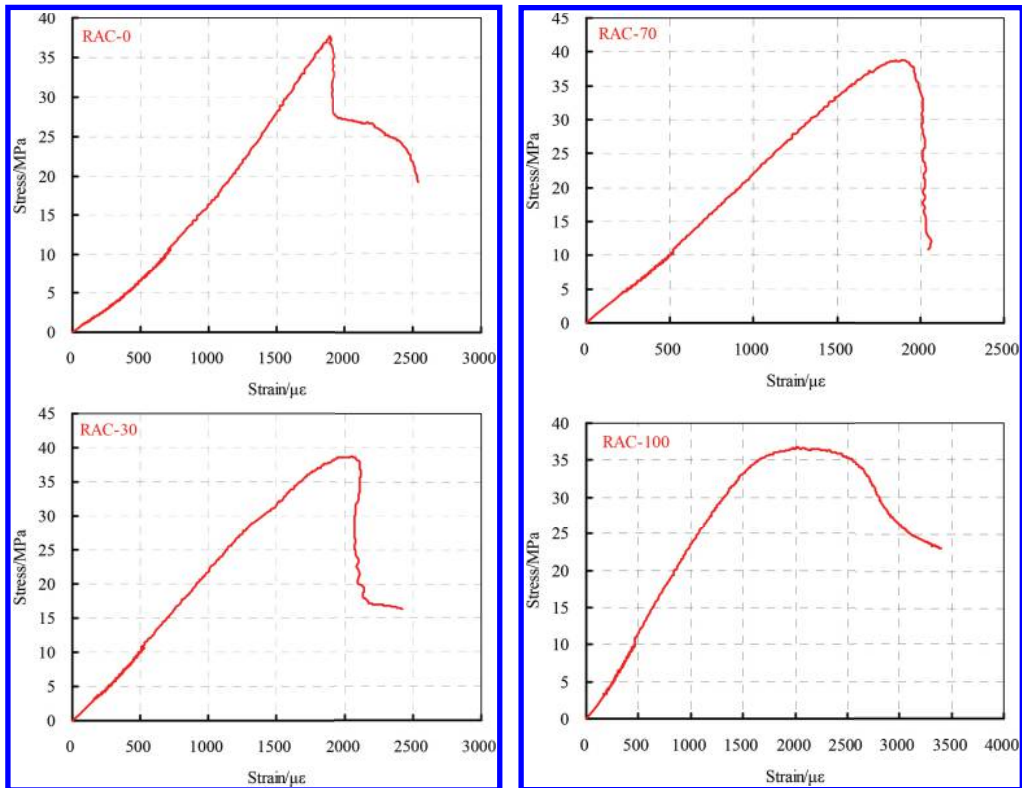

Figure 2. Compressive stress-strain curves of RAC under different replacement ratios.

it is shown ductility of RAC is becoming greater, energy performance is getting better.

### 4.3 Peak stress and peak strain

Peak stress and peak strain of RAC under different replacement ratios were shown in Table 2. It was shown with the increase of replacement ratio, peak stress and peak strain of RAC show no apparent unity law. When the replacement ratio is 70%, the peak stress of RAC is maximum, When the replacement ratio is 30%, the peak strain of RAC is maximum. Figure 3 shows the relationship between the dimensionless peak stress and recycled coarse aggregate replacement ratios, and  $f_c$  represents axial compressive strength of RAC,  $f_{c0}$  represents axial compressive strength when replacement ratio is 0%. Figure 4 shows the relationship between peak strain and recycled coarse aggregate replacement ratios.

It is shown in Figure 3 dimensionless peak stress and recycled coarse aggregate replacement ratio showed a good variation, presenting the basic form of a quadratic function. The fitted relationship is shown as formula (2).

$$y = 0.1954x^2 + 0.1763x + 0.9977 \quad (2)$$

In which,  $y$  represents  $f/f_{c0}$ ,  $x$  represents recycled coarse aggregate replacement ratio, the fitting accuracy is 0.962.

Table 2. Peak stress and peak strain of RAC.

Replacement ratio of recycled coarse aggregate	0%	30%	70%	100%
Peak stress/MPa	37.66	38.69	38.83	36.77
Peak strain/ $\mu\epsilon$	1892	2055	1907	2013

Figure 3. The dimensionless peak stress under different replacement ratios.

Figure 4. Peak strain under different replacement ratios.

Figure 5. Dimensionless curves of stress-strain.

It is shown in Figure 4 peak strain and recycled coarse aggregate replacement ratio showed a good variation, presenting the basic form of a cubic function. The fitted relationship is shown as formula (3).

$$y = 2338.1x^3 - 3642.9x^2 + 1425.8x + 1892 \quad (3)$$

In which,  $y$  represents peak strain,  $x$  represents recycled coarse aggregate replacement ratio, the fitting accuracy is 1.000.

### 4.4 Dimensionless stress-strain curve

Dimensionless analysis about average curve was carried out based on measured stress-strain curves under different replacement ratios, dimensionless curves were shown in Figure 5.

In Figure 5, it is shown with the increase of recycled coarse aggregate replacement ratio,

dimensional curves of stress-strain become steeper. After peak point, curves come into the falling section. However the falling decline curves become more and more moderate, especially, When replacement ratio of recycled coarse aggregate was 100%, the decline falling curves are very moderate, and the post-deformation properties of the specimens are very favorable.

## 5 CONCLUSION

Based on the destruction process and form, there was no significant difference between the recycled aggregate concrete and natural aggregate concrete. With the increase of replacement ratio, peak stress and peak strain of RAC show no apparent unity law.

Replacement ratio of recycled coarse aggregate has a greater impact on stress-strain curves of RAC, With the increase of recycled coarse aggregate replacement ratio, the elastic modulus of RAC become bigger gradually, ductility of RAC is becoming greater, energy performance is getting better.

In this paper, dimensionless stress-strain curves of RAC are obtained, which establishes foundation for compression constitutive equations and further research of RAC.

**ABSTRACT:** With the aim of achieving efficient simulations on the rolling effects in practical engineering and improvement of pavement performance, the mixture ratios of cement stabilized gravels were studied using vibratory compaction method. The maximum dry densities, optimum water contents, unconfined compressive strengths of mixtures obtained by vibratory compaction and static pressure compaction methods were compared, and evaluations on pavement performances were discussed. The experimental results showed that maximum dry density and optimum water content of mixtures by vibratory compaction were as 1.02 and 0.88 times as them by heavy compaction respectively; cement usage could be saved in cement stabilized gravels by vibratory compaction, with the strength requirements guaranteed; and cement stabilized gravels by vibratory compaction exhibited preferable pavement performance than them by traditional methods. The cement stabilized gravels by vibratory compaction could not only save the usage of cements, but also contribute to the improvement of pavement performance.

**Keywords:** cement stabilized gravel; pavement performance; vibratory compaction; mixture ratio design

## 1 INTRODUCTION

China is abundant in natural gravels, especially in the western regions. With the development of expressway constructions, making use of natural gravels from local resources will not only reduce the costs of highway constructions, but also avoid environmental destructions induced by quarrying effectively, which produce remarkable economic and social benefits [1]. As similar to the semi-rigid base materials such as cement stabilized macadam, the improper usage of cement stabilized gravel base will bring about premature damages to pavements, such as cracking, and impair long-term performances of pavements, which may result from the unconformities of methods between design and actual constructions. As is generally known, rolling by vibratory roller is usually adopted in the constructions; however, the compaction and static pressure methods used in the design of materials, cannot simulate the conditions in practical constructions, which gives rise to an invalid field control on the construction quality [2–5].

With the employment of cement stabilized gravel vibro-moulding method, the compaction effect on

the material surface by vibratory roller can be simulated, and steadily dense structure can also be formed in the vibration process [6]. Accordingly, mixture ratio design of cement stabilized gravels and the corresponding pavement performances were studied in present work, with the purpose to solve the problems occurred in the constructions of cement stabilized gravel base, and moreover, to improve the pavement performance and extend the service span.

## 2 EXPERIMENTAL

### 2.1 *Properties of raw materials*

#### 2.1.1 *Cement*

Composite portland cement P.C 32.5 was employed in the experiments, with the technical indexes listed in [Table 1](#), in which three days (3d) compressive strength and flexural strength met the requirements of cement strength grades in Common Composite Portland Cements (GB 175-2007), and the initial and final setting times of cements satisfied the demands in Technical Specifications in the Construction of Highway Pavement Base.

Table 1. Technical indexes of cements.

Technical indexes	Experimental results
Degree of fineness (m <sup>2</sup> /kg)	343
Stability	qualified
3d compressive strength (MPa)	18.3
3d flexural strength (MPa)	3.8
<i>Setting time (min)</i>	
Initial setting time	363
Final setting time	462

Table 2. Technical indexes of aggregates.

Standard of aggregates	Bulk specific gravities
19~31.5 mm	2.660
9.5~19 mm	2.658
4.75~9.5 mm	2.650
0~4.75 mm	0.590

### 2.1.2 Aggregates

By sieving, gravels in the experiment were classified as four standards: 19~31.5 mm, 9.5~19 mm, 4.75~9.5 mm and 0~4.75 mm, in which the crushing value of coarse aggregates was 11.8%, conformed to the claims in Technical Specifications in the Construction of Highway Pavement Base, and the results of bulk specific gravity were presented in Table 2. With reference to gradations in density framework structures, considering a large number of practical experiences and specific conditions in construction sites, aggregate mixtures with dense framework gradation composition were investigated, as shown in Table 3.

### 2.1.3 Water

Underground water was employed in present experiments, in accordance with the standard requirements.

## 2.2 Experimental instruments

Surface vibratory compaction apparatus was adopted, in which vibration frequency could be regulated by the adjustment of rotational speed of electric motor; different magnitudes of exciting force could be obtained with the variations of eccentric mass; and nominal amplitude were varied with the addition or reduction of counterweights. Operational parameters of surface vibratory compaction apparatus were listed as follows, frequency (30 ± 2 Hz), exciting force (7.5 kN), nominal amplitude (1.2 mm) and vibratory compaction time (100 s).

### 2.3 Experimental methods

To overcome the deficiencies in traditional design methods based on heavy compaction and static

Table 3. Gradation compositions of cement stabilized gravels in the experiments.

Sieves sizes (mm)	31.5	19.0	9.5	4.75	2.36	0.6	0.075
Mass percentages (%)	100	67.3	44.8	31.0	20.5	10.6	2.1

pressure moulding, vibratory compaction method and corresponding vibro-moulding method were advanced in view of the summaries of construction experiences at domestic and abroad.

The detailed experiment procedures were illustrated as follows: after bake-drying, 5~6 samples were prepared by the aggregates of different standards, according to predetermined gradation of mineral aggregates, with dry weights being about 5000~6000 g in each samples; preset doses of cement and water were then added, stirred uniformly and put into testing moulds; subsequently, experiments were performed in accordance with the prescriptive vibratory compaction time, in which wet densities and related dry densities were calculated; the experiments were repeated more than 5 times, and the relationship curves between dry density and water were plotted, by which the optimum water contents and maximum dry densities were investigated.

Based on vibratory compaction experiments, the maximum dry density was taken as the standard in the vibro-moulding experiment. Testing models with 98% degree of compaction were obtained, which were taken into standard preservation chamber after weighted and further experiments on mechanical strength and pavement performances would be carried out.

On the basis of the relationship curves of water content and dry density in cement stabilized gravels obtained in vibratory experiments, the optimum water contents and maximum dry densities were determined. Using definitive gradation compositions, experiments were performed on the samples with 3.0%~6.0% cement contents in cement stabilized gravels. The optimum water contents and maximum dry densities of samples with different ratios were discussed extensively using heavy compaction and vibratory compaction methods as introduced in Test Regulations on the Stabilized Materials in Inorganic Binder for Pavement Engineering, and the results were listed in Table 4.

In the current Technical Specifications for the Construction of Highway Pavement Base (JTJ 034-2000), seven days (7 d) unconfined compressive strength under saturated condition was adopted as the index for cement stabilized materials. Concerning the reasonable usage range of the cement stabilized materials were between 3.0% and

Maximum dry densities (g/cm <sup>3</sup> )	2.394	2.402	2.411	2.425	2.431	2.448	2.462	2.473

Table 5. 7 d unconfined compressive strengths of mixtures.

Cement contents	Rs (Mpa)	Rv (Mpa)	Rv/Rs
3.0	3.0	5.2	1.73
4.0	3.8	6.3	1.66
5.0	5.3	8.7	1.64
6.0	6.7	10.5	1.57

6.0%, the cement contents of 3.0%, 4.0%, 5.0% and 6.0% were adopted in the tests, and the cement stabilized gravel models were produced by vibromoulding and static pressure moulding, which were given comparisons herein.

According to Test regulations on the Stabilized Materials in Inorganic Binders for Pavement Engineering (JTG E51-2009), cylindrical specimen were formed on the basis of compaction experimental results, i.e., the maximum dry densities and optimum water contents with different cement contents were used. The specimen were then persevered under the conditions in which the temperature were set within  $20 \pm 2^\circ\text{C}$  and the humidity were set at above 95%, and unconfined compressive strength tests were performed, with the results presented in Table 5.

### 3 RESULTS AND DISCUSSION

#### 3.1 The optimum water content and maximum dry density

As displayed in Table 4, with the variations of the cement contents between 3.0%–6.0%, the optimum water contents of the samples by heavy compaction method were within 4.9%–5.3% while them by vibratory compaction were about 4.1%–4.8%; and moreover, the maximum dry densities by heavy compaction existed between 2.394 g/cm<sup>3</sup>–2.425 g/cm<sup>3</sup>, which were at around 2.431 g/cm<sup>3</sup>–2.473 g/cm<sup>3</sup> when vibratory compaction adopted. To make comparisons between two methods, the average ratio of optimum water content of mixtures by vibratory compaction to it by heavy compaction was 0.88, while the average ratio of maximum dry density between two methods was larger, to be 1.02. Conclusively, among two

methods, larger compactness of mixtures could be obtained by vibratory compaction, in which aggregates were rearranged.

#### 3.2 Unconfined compressive strengths of cement stabilized gravels

It could be easily found from Table 5 that 7 d unconfined compressive strengths of cement stabilized gravels by two moulding methods presented significant differences. 7 d unconfined compressive strengths (Rs) of cement stabilized gravels by static pressure compaction were at around 3.0–6.7 MPa, while 7 d unconfined compressive strengths (Rv) by vibratory compaction were at 5.2–10.5 MPa, i.e., the compressive strengths by vibratory compaction were about 1.65 times than those by heavy compaction. In a word, the mixtures obtained by vibratory compaction provided higher compressive strengths than them by static pressure compaction, with similar material ratios and optimum water contents. Under vibratory compaction, the aggregates became more compact owing to the resonance motion caused by vibration, which led to distinctly larger compressive strengths in the specimens than them by static pressure compaction.

As demonstrated in the experimental results of unconfined compressive strength, the strengths of cement stabilized gravels obtained by static pressure compaction could not satisfied the standard requirements with the cement content being 3.0%, and moreover they were not satisfactory until the cement contents were above 4.0%. However, the mixture obtained by vibratory compaction could meet the standard requirements with the cement content being 3.0%. Illustratively, the strength of materials by vibratory compaction with 3.0%–4.0% cements could be as high as them with 5.0%–6.0% cements by static pressure method. Briefly summarized, the enhancement of material strength could be achieved by vibratory compaction method, and moreover, 20% cement usage could be saved, which presented remarkable economic benefits meanwhile.

#### 3.3 The frost resistance performance of cement stabilized gravels

Freeze-thaw cycle tests of base materials were performed in accordance with Test Regulations

Table 6. Frost resistance performance of cement stabilized gravel mixtures.

Moulding methods	Cement contents (%)	Frost resistance coefficients at different preservation periods (%)		
		14 d	28 d	90 d
Static pressure compaction	3.0	88.4	90.4	92.4
	4.0	90.5	90.7	92.7
	5.0	89.3	91.2	93.6
Vibratory compaction	3.0	94.8	95.7	97.1
	4.0	95.1	96.3	97.8
	5.0	95.5	96.6	98.2

on the Stabilized Materials in Inorganic Binders for Pavement Engineering (JTG E51-2009), in which the specimens were frozen for 16 hours and thawed for 8 hours, repeated for 5 times, and the compressive strength tests were conducted after freeze-thaw cycles finished. Decline of mass after freeze-thaw cycles and frost resistance coefficients K were adopted as the indexes to characterize the frost resistance performance of mixtures.

Experimental results on the frost resistance coefficients of cement stabilized gravels were listed in Table 6, and the relationships of frost resistance with preservation period and cement content were discussed, from which we could observe that frost resistance coefficients increased gradually with the prolong of preservation period. Within the same preservation period, frost resistance coefficients improved steadily with the addition of cement content. It was assumed that, as preservation period or cement content raised, the hydration products of cements increased and then the internal void volume of cement stabilized gravels decreased, which gave rise to better frost resistance performance.

Under similar conditions, the frost resistance coefficients of cement stabilized gravel specimens by vibratory compaction were higher than them by static pressure method, on account of the specimens obtained by vibro-moulding showed more compactness, less internal void volume, and therefore stronger frost resistance.

#### 4 CONCLUSIONS

Vibratory compaction and related vibro-moulding method on cement stabilized gravels were proposed, and mixture ratio design of cement stabilized gravels and their pavement performance were analyzed systematically.

The maximum dry densities and optimum water contents by vibratory and static pressure

compactions were discussed, by which we observed that the optimum water content of cement stabilized gravels by vibratory compaction was as 1.88 times as them by static pressure compaction, and the maximum dry density by vibratory compaction was as 1.02 times as them by static pressure compaction.

By comparisons of the compressive strength in specimens obtained by two methods, the strength of cement stabilized gravels by vibratory compaction was significantly greater than them by static pressure compaction. Obtained by vibratory compaction, cement stabilized gravels with cement contents being 3.0%~4.0% could provide the compressive strength as them by static pressure compaction with 5.0%~6.0% cement content; in other words, the usage of cements could be saved.

Cement stabilized gravel mixtures obtained by vibratory compaction conformed to the rolling mechanisms and effects more reasonably, which could save the usage of cements, enhance the strength and frost-resistance of materials, and reduce the cracks in base, providing remarkable economic and social benefits.

# Contrast on axial compressive strength between FRP and steel reinforced confined concrete

Tuan Wei Bi, Dongsheng Gu & Xuan Zhang

*State Key Laboratory Breeding Base of Mountain Bridge and Tunnel Engineering, Chongqing Jiaotong University, China*

*College of Environmental and Civil Engineering, Jiangnan University, China*

**ABSTRACT:** The research on models of axial compressive strength between FRP confined concrete and reinforced concrete was carried out. Based on typical strength model in the past and the analysis of linear fitting from a large amount of experimental data, a comparative analysis on the coefficient 'k' and the form of compressive strength of models between FRP confined concrete and steel confined concrete was presented. Results indicates that there are quite differences between the coefficient 'k' of two models. However, forms are the same. A conclusion can be drawn that the axial compressive strength model of FRP confined concrete is not safer than the steel confined concrete in contrast.

**Keywords:** FRP cylinder; concrete-filled tubes; axial compressive strength; computational model; fitting analysis

## 1 INTRODUCTION

The bearing capacity and ductility of concrete columns can be improved effectively owing to confined concrete. Massive experimental research of FRP confined concrete columns and reinforced concrete columns have been carried out for many years<sup>[1-2]</sup>. FRP confined concrete and steel tube confined concrete are two of the most common ways of the constraint nowadays. FRP (Fiber Reinforced Polymer) is a high performance material, which is a mixture of fiber material and matrix material (resin) in certain proportion. FRP is light, hard, non-conductive and corrosion resistance. Besides, its mechanical strength is extremely high, but recover ability is highly weaker. Actually, FRP has been aroused widespread interests and heated discussions in recent years. Over the last two decades, a great number of experimental and analytical studies have been conducted to understand and model the compressive behavior of FRP confined concrete. Because it can meet special needs, such as larger span, high-rise, heavier load, lighter weight and so on, for the modern engineering structure thanks to its excellent mechanical properties. Steel tube confined concrete can take advantage of benefits of steel and concrete. And the compressive strength of concrete can be increased in a large scale due to the lateral compression. Moreover, the stiffness of steel will be improved by concrete. Therefore, the bearing capacity can get stronger on

account of the interaction of steel and concrete. In fact, FRP confined concrete and steel tube confined concrete are effective methods to enhance the bearing capacity and ductility of concrete.

## 2 THE PRINCIPLE OF CONFINED CONCRETE

For steel tube confined concrete, concrete supports steel tube and steel tube restrains concrete in the meanwhile. The concrete in tube is in three dimension stress state under pressure so that it can prevent the development of longitudinal crack. As a result, compressive strength and deformation capacity increase relatively. Geometrical stability is enhanced by the support of concrete in tube. In other word, instability and failure of compression gets to be avoided which results in the increase of the bearing capacity. When concrete is stressed in a complex state, its strength, ductility and toughness properties of concrete are all boosted in a certain degree in virtue of the interaction of steel and concrete.

FRP confined concrete is a passive confinement model. Lateral expansion will emerge in concrete columns and hoop tension will appear in FRP. By contrast, FRP in hoop tension will restrain the lateral expansion of concrete columns. So the concrete in tube is in three dimension stress, and the bearing capacity and ductility are both enhanced.

The confinement action exerted by the FRP shell on the concrete core is of the passive type; that is, this pressure arises as a result of the lateral expansion of concrete under axial compression. As the FRP shell is subjected to tension along its hoop direction, the confining pressure ( $f_l$ ) increases proportionally with the lateral expansion until the eventual failure of the system when the FRP shell ruptures. The performances of a large proportion of the existing models were compromised when assessed against a large test database with a parametric range that is much wider than the databases used in the development of these models. At the beginning of loading, the deformation of concrete is larger than FRP outside materials because the difference in stiffness and Poisson ratio between them. Therefore, their circumferential expansion deformation is not the same, and they crush each other resulting in the restraint stress. The early restraint stress delayed the appearance of initial crack of concrete in some degree.

Longitudinal crack turned up gradually with the increase of the axial load. Lateral strain went up rapidly which aggravated the extrusion between the FRP outside materials and core concrete. At the same time, restraint stress got higher preventing the development of longitudinal crack and making the compressive strength of core concrete improved. Finally, FRP will fail to work until maximum of axial load. The entire component will not breakdown until maximum of longitudinal stress. The mechanical model of FRP confined concrete is as shown in Figure 1.

The mechanism of Action and mechanical model between two constraints are similar to each other. The design criterion adopted in ACI 318-991<sup>[3]</sup> for column confinement is based on the premise that confined columns should maintain their concentric capacities after the spalling of cover concrete. This is achieved by providing sufficient confinement to

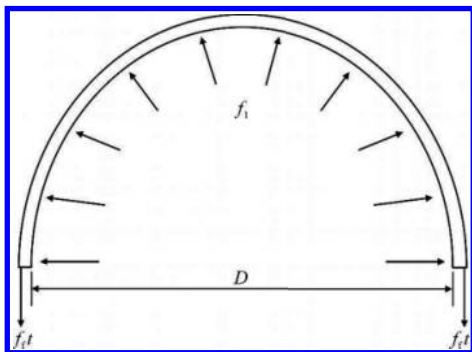

Figure 1. The mechanical model of FRP confined concrete.

the core concrete to attain strength and ductility enhancements. The required volumetric ratio of transverse reinforcement was derived based on the strength gain in core concrete, which was assumed to be  $(f_{cc} - f_{co}) = 4.1f_l$ , where  $f_l$  represents uniform passive confinement pressure.

### 3 INTENSITY MODEL

The model of  $f_{cc}'/f_{co}' = 1 + k f_l/f_{co}'$  is adopted for most existing confined concrete models.  $f_{cc}$  represents axial compressive strength of confined concrete specimen, and  $f_{co}$  represents axial compressive strength of the specimen without lateral pressure constraint.  $f_l$  is defined as lateral restraint force,  $k_1$  is valid coefficient of constraint. The formula first proposed by Richart et al<sup>[4-5]</sup> (1928) in view of active confined concrete.

For compressive strength of concrete filled steel tube, the computational model presented by Richart is as shown below:

$$f_{cc}' = f_{co} + 4.1f_l \quad (1)$$

Domestic and foreign scholars have conducted a lot of research and plenty of computational models concerning compressive strength of FRP confined concrete are proposed.

Intensity calculation model of concrete cylinder confined by stirrup was proposed by Richart<sup>[4-5]</sup> in 1928:

$$f_{cc}' = f_{co} + 4.1f_l \quad (2)$$

Empirical formula raised by Miryachi<sup>[6]</sup> is as shown:

$$\frac{f_{cc}'}{f_{co}} = 1 + 2.98 \left( \frac{f_l}{f_{co}} \right) \quad (3)$$

In 2002, after analyzing a large number of experimental data of FRP confined concrete columns, Lam and Teng<sup>[7]</sup> conclude the model as follows:

$$f_{cc}' = f_{co} + 2.0f_l \quad (4)$$

### 4 EXPERIMENTAL DATA FITTING MODEL

Massive experimental research of FRP confined concrete columns and reinforced concrete columns have been carried out for many years. There are 100 sets of experimental data of the strength of FRP confined concrete columns and 20 sets of experimental data of reinforced concrete columns.

As shown in Figure 2 and Figure 3, the experimental data is made into scatter chart which draws in the ratio of constrain  $f_i/f_{co}'$  as X and the ratio of strength  $f_{cc}'/f_{co}'$  as Y. And then, these scatter are carried on the linear fitting, where  $f_{cc}'$  represents strength of confined concrete,  $f_{co}'$  represents in-place strength of unconfined concrete in column and  $f_i$  represents uniform passive confinement pressure.

After linear fitting of 2 scatter charts, we could conclude the strength models of two different confined concrete:

The strength model of FRP confined concrete columns:

$$\frac{f_{cc}'}{f_{co}'} = 1 + 2.1 \left( \frac{f_i}{f_{co}'} \right) \quad (5)$$

The strength model of reinforced concrete columns:

$$\frac{f_{cc}'}{f_{co}'} = 1 + 5.6 \left( \frac{f_i}{f_{co}'} \right) \quad (6)$$

Figure 2. Scatter chart of FRP confined concrete columns.

Figure 3. Scatter chart of reinforced concrete columns.

Comparing two strength models, discrete degree of FRP confined concrete columns is smaller than discrete degree of reinforced concrete columns. However, when the same constraint is provided, the strength of FRP confined concrete is lower than that of reinforced concrete columns.

## 5 SUMMARY AND CONCLUSION

According to the research content of this paper, there are 3 conclusions as follows:

1. Both FRP confined concrete and reinforced concrete can attain compressive strength and ductility enhancements.
2. According to the active confined concrete intensity model proposed by Richart et al (1928)<sup>[4-5]</sup>, the same form of intensity model is applicable for both FRP and reinforced concrete:  $f_{cc}'/f_{co}' = 1 + k_1 f_i/f_{co}'$ . In addition, the form of linear fitting model is slightly simple. Furthermore, linear fitting model is a relatively ideal model which agrees well with the experimental data collected.
3. The strength of FRP confined concrete is lower than that of a similarly restrained reinforced concrete by contrast of effective confinement factor  $k$  of them.

# Research on the fracture toughness of PC/ABS blend

Ming-Hsiung Ho & Jung-Peng Yeh

*Department of Mechanical Engineering, Taoyuan Innovation Institute of Technology, Zhongli, Taiwan, R.O.C.*

Pin-Ning Wang

*Department of Material and Fiber, Taoyuan Innovation Institute of Technology, Zhongli, Taiwan, R.O.C.*

**ABSTRACT:** In this dissertation, fracture toughness of PC/ABS blend was studied. The specimens were prepared under various injections molding conditions, such as filling time, melting temperature, and mold temperature. The fracture mechanisms were examined using a scanning electron microscopy. The following conclusions can be drawn from the tests. The best injection molding conditions of fracture toughness specimen were filling time of 2 seconds, melting temperature of 260°C, and mold temperature of 55°C. The fracture toughness is varied according to skin layer normalized thickness. The stress-whiten, splits, and fibril-like surfaces were typical fracture mechanisms.

**Keywords:** PC/ABS; blend; injection molding condition; fracture toughness; skin layer

## 1 INTRODUCTION

PC/ABS is product of amorphous, thermoplastic polymer blends on the basis of polycarbonate (PC) and Acrylonitrile-Butadiene-Styrene (ABS). PC/ABS combines the excellent properties of the two materials, ABS formability and PC material mechanical, impact strength, heat resistance, and resistance to weather ultraviolet (UV) properties. The material usually used in household, electrical, electronic automotive interior, exterior parts, precision machine parts, food industry, etc. For parts forming methods, the injection molding method has excellent surface accuracy, short processing cycle, low cost, and can be used to molding complex shapes.

The fracture toughness research in plastic is still quite limited, because of the complex structure of the plastic material and the varied fatigue characteristics. To make plastic materials such as metal materials widely used in industry and vehicle industry, the material fatigue properties must have systematic study and discussion.

Lu, M.L. et al. (1996) they studied elastic-plastic fracture toughness of a PC/ABS blend by the conventional J-integral and the Crack Tip Opening Displacement (CTOD) methods. Abuzar E.O. et al. (2014) has been investigated fracture behavior of ABS polymeric material under the full range of in-plane loading conditions using a new loading device to obtain more reliable results. Li H. et al. (2015) experimentally investigated the mixed-mode fracture of PC/ABS alloy. The appearance,

growth, and coalescence of crazes can be observed in the micro-fracture processes, and the macro-crack propagation direction is finally determined by the coalesced direction of crazes. Lee S.K. et al. (2012) they found that addition of PC could have toughened recycled PMMA matrix under impact test conditions.

Because PC/ABS blend is processed and formed by some factors, it needs to find out suitable conditions for its applications.

In this study, the investigative object of PC/ABS material was using the injection molding method for forming a test specimen and following ASTM E399 standard to explore the material properties under different filling times, melt temperatures, and mold temperatures. It was evaluated that the PC/ABS plastic material properties with molding conditions and low cycle fatigue testing conditions. After the experiment, the specimen fracture surfaces were examined with the scanning electron microscope, in order to understand the related fracture mechanism.

## 2 METHODS

### 2.1 Material

The material used in this study is the GE (General Electric) produces granular PC/ABS plastic. The material brand name is Cycloy-C1110HF. The volume percentage of containing the PC and the ABS is 60% and 40%, and the average density is 1.13 g/cm<sup>3</sup>.

## 2.2 Specimen preparation

The injection mold layout is shown in Figure 1. The test specimens used in experiments are melting glue injection from the tail end.

The molding conditions were filling time set to 2/6/12/14 seconds, melt temperature designed for 200/220/240/260/280°C and mold temperature was set to 35/50/65/80°C. The specimen number and the detailed conditions of the molding are listed in Table 1.

During the injection molding, the material was preheated at 110°C for 4–6 hours to get rid of the moisture before it can be used in an injection molding machine. The specimens were cooled to room temperature in atmosphere, after the specimens being ejected out of the mold.

## 2.3 Fracture toughness test

The Experiment planning and methods were followed ASTM E399 standard. Because of the test

Figure 1. The layout in injection mold.

Table 1. Specimens forming conditions.

Number	Conditions		
	Filling time (s)	Melting temperature (°C)	Mold temperature (°C)
T2	2	260	80
T6	6	260	80

M220	2	220	80
M240	2	240	80
M260	2	260	80
M280	2	280	80
C35	2	260	35
C50	2	260	50
C65	2	260	65
C80	2	260	80

piece initial crack length  $a$ , in accordance with specifications should be between  $0.45 W$  to  $0.55 W$  ( $W = 36$  mm is specimen width). The total length of cracks in this test is to take  $a = 18$  mm, in which the injection molding crack is 7.5 mm. The crack length from 7.5 mm to 16 mm was produced by mechanical processing methods. The last 2 mm is by fatigue pre-crack method.

The specimens were test by MTS 810 100 kN servo-hydraulic testing machine. The PC/ABS specimens with different molding conditions after pre-crack were tensile loading till specimen broke. The load-crack opening displacement data was recording.

The load and displacement data on the slope of the linear range to take five percent deviation obtained material load  $P_Q$ , and calculate the fracture toughness  $K_c$  of the material, the relationship is:

$$K_c = \frac{P_Q}{BW^{1/2}} f\left(\frac{a}{W}\right) \quad (1)$$

and

$$f\left(\frac{a}{W}\right) = \frac{\left[2 + \left(\frac{a}{W}\right)\right] \left[0.886 + 4.64\left(\frac{a}{W}\right) - 13.32\left(\frac{a}{W}\right)^2 + 14.72\left(\frac{a}{W}\right)^3 - 5.6\left(\frac{a}{W}\right)^4\right]}{\left[1 - \left(\frac{a}{W}\right)\right]^{3/2}} \quad (2)$$

After the test, specimen fracture surface was observed by a Scanning Electron Microscope (SEM).

## 3 RESULTS AND DISCUSSIONS

### 3.1 Normalization thickness

As showed in Figure 2, in the pre-crack and pull off surface after the test, the test specimens had whitening phenomenon at fracture surface. This is a stress whiten phenomenon. The phenomenon are also occurs in pure PPO, HIPS, PPO/HIPS blend materials. Moloney (1989) had explained the

Figure 2. The stress whiten in damage area.

phenomenon: Because skin molecule along a direction perpendicular to the tension direction, when the force to make the epidermis molecular forward direction pull in the same direction, causing whitening phenomenon. The color of layer is changed because the molecule orientation rearrange after external force applied. After force applied process, the surface layer has a lower density and a lower light reflectivity than the original material. A is damage area, B is pre-cark area, C is machining crack area.

The SEM microstructure of Compact Tension (CT) test specimen in thickness direction which is perpendicular to the molecular orientation is showed in Figure 3.

Figure 4-6 are the skin layer normalized thickness distribution under different injection mold conditions in the vertical compact tension specimen thickness direction. The figures show that the material's maximum skin layer normalized thicknesses are in mold temperature of 35 °C, melt temperature of 200 °C and the filling time of 2 seconds. The maximum skin layer normalized thickness decreases downwards as the filling time, melt temperature, and mold temperature increases.

Figure 3. The fracture surface of skin and core layers of M280.

Figure 4. The relationship between mold temperature and skin layer normalized thickness.

Figure 5. The relationship between melt temperature and skin layer normalized thickness.

Figure 6. The relationship between filling time and skin layer normalized thickness.

Figure 7. The load—crack open displacement curves under mold temperature conditions.

### 3.2 Fracture toughness

Figures 7-9 show that the load and crack open displacement curves belong to TYPE I as shown in E399, the load that is by 5% deviation slope method to determine  $P_5$  and to locate  $P_{max}$ .

From Figure 10, the mold temperature had little effect on the  $K_{Iq}$ , the difference between the maximum and minimum value is only  $0.84 MPa\sqrt{m}$ , when compared to melt temperature and filling time conditions, the difference value is small.

Figure 8. The load–crack open displacement curves under mold temperature conditions.

Figure 9. The load–crack open displacement curves under mold temperature conditions.

And overall  $K_q$  values at mold temperature conditions are higher than other molding conditions. Although D80 (M260, T2) in mold temperature conditions is order 3, but in the melt temperature and filling time conditions have maximum  $K_q$  value.

Effect of melting temperature from Figures 8–11 observed, the  $K_q$  gradually increased from M200 to a maximum value M260, but M280 namely drop. In Figure 12, under filling time conditions, the time increases, and the  $K_q$  values decline. The  $K_q$  value of T12 and T14 is the smallest. It is showed

Figure 10. The mold temperature conditions for  $K_q$ .

Figure 11. The melt temperature conditions for  $K_q$ .

Figure 12. The filling time conditions for  $K_q$ .

Figure 13. The relation between  $K_q$  and skin layer normalized thickness.

that too long fill time did not help for the fracture toughness. Figure 13 shows the relationship between normalization skin layer thickness and fracture toughness. The data could be divided into two linear regression lines, the two lines intersection

point of the normalized thickness is 0.67 and the value of fracture is  $5.41 \text{ MPa}\sqrt{m}$ . From the point, the optimum injection molding conditions will be filling time 2 seconds, melt temperature  $260^\circ\text{C}$ , mold temperature of  $55^\circ\text{C}$ .

When the skin layer normalized thickness is less than 0.67 and fracture toughness relationship would be  $K_q = -1.83 + (\text{skin layer normalized thickness}) * 10.88$ .

The skin layer normalization thickness greater than 0.67, and the fracture toughness relationship would be  $K_q = 13.51 + (\text{skin layer normalized thickness}) * (-12.16)$ .

### 3.3 Fracture mechanisms

From Figures 2 and 3, the main failure mechanism with a pre-split and pull off during the test, the specimen notched end and crack edges have stress whitening phenomenon. The specimen fatigue pre-crack area with pull-off area of the fracture surface microscopic observations, showing: cracks in the front end of the pre-split region into a laminated sheet-like intermediate core layer of soft material.

Pull off both sides of the zone of hard epidermis tissue, showing the sheet flat section. Intermediate core layer section into hairy pulled fiber, shows the core layer molecular orientation and into a vertical section.

## 4 CONCLUSIONS

The results, process conditions of this chapter for a comprehensive PC/ABS plastic material fracture toughness can be summarized as follows:

1. The destruction of compact tension toughness test specimens from the surface to the center of the fiber orientation can be divided into two regions, the epidermis molecular forward parallel to the direction of flow of melt glue.

The central part of the core layer molecular forward perpendicular to the direction of flow of melt glue.

2. The relation between skin layer normalized thickness and fracture toughness  $K_q$  has a critical value that has a skin layer normalized thickness 0.67 and fracture is  $5.41 \text{ MPa}\sqrt{m}$ .
3. For this optimum value estimates from Figure 13, the injection molding conditions for filling time 2 seconds, melt temperature  $260^\circ\text{C}$ , mold temperature of  $55^\circ\text{C}$ .
4. In skin layer area, the surface is like a sheet of brittle fracturing. The core section has pulled out fiber; it shows the core layer molecular orientation which is perpendicular to the cross section.

**ABSTRACT:** In order to study the dynamic mechanical rheological properties of high modulus asphalt after aging, the strain sweep, viscoelasticity cumulative deformation and low-temperature creeping performance of RTFOT asphalt and PAV asphalt are analyzed by Dynamic Shear Rheological (DSR) and Bending Beam Rheometer (BBR). The result shows that (1) storage modulus  $G'$ , loss factor  $\tan\delta$  and delayed elastic recovery index  $\epsilon_p/\epsilon_L$  can accurately evaluate the mechanical properties of different types of asphalt before and after aging, among them, and aging reduces the high modulus asphalt low-temperature performance; (2) the anti-aging performance are different according to the results of different mechanical rheological indicators. The aging resistance of low-temperature, medium, and high temperature indicators are opposite. Above all, for anti-aging performance of high modulus asphalt, it is suggested to select reasonable experimental parameters and combine with the dominant factor indexes for comprehensive evaluation.

**Keywords:** road engineering; high modulus asphalt; dynamic mechanical rheological properties; low-temperature creeping performance

## 1 INTRODUCTION

High Modulus Asphalt Concrete (HMAC), which originated from Germany is mainly used to solve the plastic deformation which is produced by overloading, and improve high temperature rutting resistance by improving the dynamic modulus of asphalt concrete. HMAC properties is studied and put forward the PG grade range, and the high-temperature rut resistance, low-temperature crack resistance, and water stability are evaluated in literatures [1][2]. The corresponding high modulus asphalt modifiers are developed by studying SBS\PE material performance in literatures [3][4]. The climate, traffic conditions and vehicle operating conditions are quite different from foreign country, so the study of high modulus concrete can not completely refer to foreign research. Therefore, it is necessary to independently research and invent high modulus asphalt binder.

However, the high modulus asphalt research is at an early stage in China. There are no standard about performance evaluation and material composition of the high modulus asphalt concrete. The study

is less in long-term mechanical analysis, anti-aging performance (especially long-term aging states), and so on. In this paper, creep recovery testing, low temperature creeping test and other performance tests under different high modulus asphalt states are carried out by using SHRP. The anti-fatigue performance and crack resistance under different aging states are researched. The reasons for difference of high temperature mechanical properties of different high modulus asphalt basing on delayed elastic deformation recovery features are analyzed by Burgers model.

## 2 RAW MATERIALS AND TEST PLAN

Currently, high modulus asphalt concrete using in highways primarily is on-site modification processing, which can reduce costs and keep the excellent properties of modified asphalt. This test is consistent with the real project. High modulus asphalt is laboratory batch processing product. Test instruments are dynamic shear rheometer and asphalt thin-film oven. Test plan is as follows:

In order to analyze conveniently, three different basis bitumen (Shell 70 #, Panjin 70 # and Liaohe 70 #); According to SHRP standard parameters, long-term and short-term aging tests are developed; In repeated creep test, temperature parameters is 60°C, stress is 100 pa, and 20 cycles is under loading 1 s and unloading 9 s. Three parameters are selected in low temperature stiffness creep experiments (BBR), which are temperature parameter (-5°C, -10°C and -24°C).

### 3 EFFECT OF AGING ON THE VISCOELASTIC PERFORMANCE

Under different working conditions, asphalt shows different viscoelastic performance. It needs to further study viscoelastic performance because of the difference of high modulus asphalt, basis bitumen and modified bitumen. Many studies show that mechanical dynamic performance of modified bitumen is closed to the elastic behavior of material in literatures [5][6]. Through proceeding 20 creep recovery of three kinds of asphalt before and after aging under 100 pa (stress) and 60°C (temperature), this paper analyzes the viscoelastic properties by Burgers model parameters.

Figure 1 shows that strain curve of three kinds of asphalt under former three creep recoveries. Because the main component content of asphalt is different, the creep recovery strain appeared differences with the extension of the time. Creep deformation of Shell basis bitumen is much larger than LH and PJ. Accumulated strain is large with the extension of time, while LH and PJ basis bitumen are smaller and show the recovery ability after loading. As  $T = 150$  s, three strains are 115.6%, 0.63%, and 1.77%. The accumulated strains show a significant difference. At the same time, it explains that sticky ingredients of Shell basis bitumen is the main proportion which basically does not change with time except having a small elastic recovery at beginning, and Shell basis bitumen is viciousness creep deformation while LH and PJ are delayed elastic deformation.

It proposed that strain and compliance of the general basis bitumen depends on temperature dependence is totally different from other modified asphalt in literature[6]. Basis bitumen creep cumulative deformation's dependence on temperature is uniform decline and change is relatively simple, while the modified asphalt is more complicated. Permanent deformation of high modulus asphalt increases significantly, after aging, and the anti-aging ability of three kinds of asphalt have significant differences. PJ asphalt is most affected by the factors, the second is LH asphalt, and Shell asphalt which is minimum. Compared with before

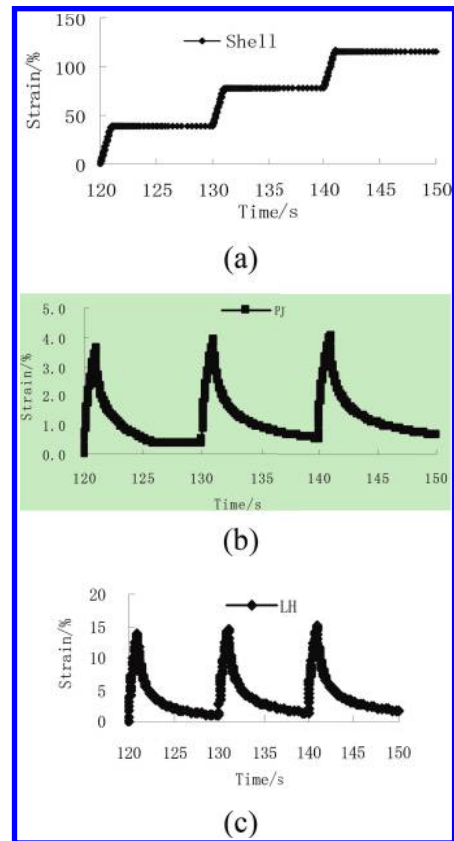

Figure 1. Asphalt before 3 creep state is restored.

aging, PJ asphalt increases 44.871 times, while LH asphalt increases 37.206 times and Shell increases 32.234 times. It shows that accumulative strain of Shell basis bitumen increases in the minimum after aging and PJ improves the sharpest. Four components of asphalt changes after aging, and viscous ingredient ratio increases.

### 4 EFFECT OF AGING ON THE ANTI-FATIGUE PERFORMANCE

Study of fatigue properties of viscoelastic materials contributes to extend the service life of pavement and has important significance to later road maintenance. To test three kinds of asphalt with RTFOT and PAV, fatigue performance is analyzed by using the rheological parameter  $G'$ ,  $\tan(\delta)$  and  $G^*\sin(\delta)$ . The results are shown in Figure 2.

Figure 2 shows:

1.  $G'$  and  $G^*\sin(\delta)$  of three kinds of asphalt further increase with RTFOT and PAV aging, and  $\tan(\delta)$  reduces. Rangeability of the rheological

parameters is different on account of asphalt types. Literature [7] indicates that RTFOT aging can simulate asphalt mixture performance during the construction, and PAV aging can simulate the road running 5–10 years field conditions. It can be used 10 h TFOT to evaluate

its aging-resistant performance on heavy traffic paving asphalt and penetration index to evaluate the fatigue performance before and after aging.

- $G'$  and  $\tan(\delta)$  of Shell asphalt change significantly under different aging states. Sensitivity of  $G'$  reduced with temperature increasing while  $\tan(\delta)$  rising. For PJ and LH asphalt, different aging states influence to  $G'$  is similar to Shell asphalt, while the change of  $\tan(\delta)$  is different.  $\tan(\delta)$  affected by RTFOT aging is weak, and by PAV aging is stronger.  $\tan(\delta)$  of RTFOT and original asphalt decrease with temperature increasing, while  $\tan(\delta)$  of PAV asphalt increases. It shows that PJ\LH high modulus asphalt is different with basis bitumen after aging for a long time. The effect of high modulus composite modifier gradually reduces after a long-term affected on asphalt, which urges the changes of  $G'$  and  $\tan(\delta)$  are similar to basis bitumen. In addition, PAV aging can more accurately reflect anti-aging performance of high modulus modified asphalt for a long time, and found features which are not showed in the short time. It is an important assistance for analyzing and choosing modified asphalt.

## 5 EFFECT OF AGING ON THE LOW TEMPERATURE ANTI-CRACKING PERFORMANCE

In this paper, high modulus asphalt after aging is studied with BBR. Correlation analysis is proceeded by selecting 60 S stiffness modulus (S) and rate of change (m). The data is shown in Table 1.

Table 1 shows:

- Creep stiffness modulus of PAV asphalt increases after aging and creep curve rate reduces. The low temperature rheological properties is reduced by aging, and temperature of asphalt adapt to the low temperature crack resistance improves, which is consistent with the anti-fatigue performance analysis.

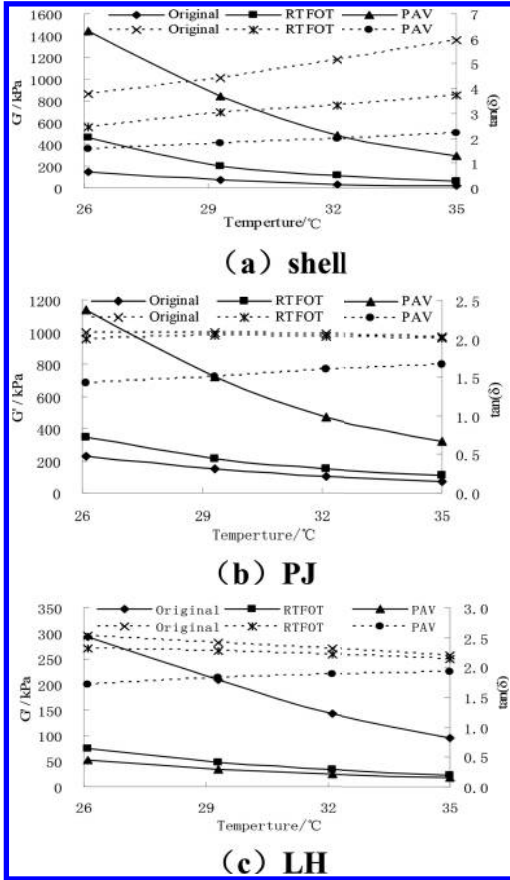

Figure 2. Original asphalt, RTFOT and PAV asphalt  $G'/\tan(\delta)$  along with the change of temperature curve.

Table 1. Three kinds of the original asphalt and PAV asphalt BBR rheological mechanics performance test at different temperatures.

Temperature (°C)	Index	PAV			Original		
		Shell	PJ	LH	Shell	PJ	LH
-5	S/Mpa	65.8	55.6	46.9	45.9	36.6	37.9
	m	0.356	0.413	0.467	0.457	0.484	0.597
-10	S/Mpa	245.5	228.8	189.2	143.3	118.8	123.2
	m	0.296	0.313	0.348	0.369	0.341	0.367
-24	S/Mpa	468.6	368.8	298.5	358.2	278.7	268.9
	m	0.168	0.276	0.307	0.308	0.305	0.317

2. Anti-aging performances of three kinds of asphalt are significantly different. Anti-aging performance of LH asphalt is best and Shell asphalt is the worst. Analysis conclusion about creep stiffness modulus ( $S$ ) and rate of change ( $m$ ) is different with the results of the analysis about high temperature anti-rutting performance and anti-fatigue performance. It mainly exists between PJ asphalt and LH asphalt. Therefore, the analysis of Anti-aging performance about high modulus composite modified asphalt is suggested to be combined with multi-factor index comprehensive evaluation.

## 6 CONCLUSION

1. Aging to high modulus asphalt viscoelastic behavior can have a significant effect. Burgers model analyzes that high modulus asphalt belongs to the delayed elastic recovery deformation, and basis bitumen belongs to viscoelastic rheological deformation.  $\epsilon_L/\epsilon_p$  can evaluate the influence of aging to viscoelastic material delayed elastic deformation which recovers with time increasing.
2. Mechanical rheological parameters  $G'$ ,  $\tan(\delta)$  and  $S$  can accurately reflect the dynamic mechanical rheological properties of different aging states of high modulus asphalt and avoid the problem of conventional index for some defects. But the anti-aging ability evaluation conclusion appears inconsistent phenomenon based on the different mechanical rheological parameters, to evaluate index of medium temperature fatigue performance and high temperature rutting performance.
3. The BBR low temperature susceptibility of high modulus asphalt is reduced after PAV aging. The temperature stability is improved and the low temperature anti-cracking performance is reduced. That is consistent with penetration index (right temperature) of specification evaluating aged asphalt change law. Using BBR low temperature index can further evaluate the low temperature performance of modified asphalt binder. The LH asphalt low temperature anti-cracking performance is better than the PJ asphalt.

**ABSTRACT:** This paper aims at the feasibility of preparing a low-intensity self-compacting regeneration concrete using non-continuous graded recycled coarse aggregates. Using the variable-control method, the influences of different recycled coarse aggregates replacement rates on its performance and the compressive strength of concrete cubes with different ages are investigated. The results show that non-graded recycled coarse aggregate can be formulated into self-compacting concrete to meet performance and strength requirements. When the recycled coarse aggregate replacement rate is 50%, its performance is best. The replacement rate, greater than 50%, has little influence on the concrete strength development. The early strength of prepared low-intensity self-compacting concrete grows fast, so the molds can be removed early. If the curing time is larger than 7 days, the replacement rate has little influence on the strength development.

**Keywords:** non-continuous coarse aggregates; self-compacting recycled concrete; regeneration coarse aggregate; strength

## 1 INTRODUCTION

The self-compacting regeneration coarse aggregate concrete is a technology based on the theory on self-compacting concrete. It is in accordance with the technical route of self-compacting high-performance concrete. Waste brick recycled aggregates, waste concrete and hybrid-brick waste recycled aggregates are used to prepare the concrete with little vibration. The regeneration concrete solves the transport, storage and disposing of waste building materials, so enormous social and economic benefits are achieved and promising future is expected. Regeneration concrete technology is generally considered the most effective solution to the waste concrete (Xiao 2008).

Available research shows that comparing with natural aggregates, recycled aggregates are of high porosity, liquid absorption and mobility due to the attached large amount of cement mortar on the surface. Therefore whether the mobility, through ability and segregation resistance of the regeneration of self-compacting concrete satisfy the requirements is a key (Jia et al. 2014). Comparing with the high-strength self-compacting concrete, the water-cement ratio of the low intensity self-compacting

concrete is larger, so that the mobility of the concrete blend is guaranteed but the segregation resistance and water retention are difficult to meet the requirements. Therefore, the high mobility, segregation resistance and water retention are mutually contradictory to each other. So the reasonable raw material mixture and reasonable choice of additives are necessary to reach the high mobility, segregation resistance and water retention of the fresh concrete (Zhang et al. 2013).

Current research on the regeneration concrete mainly focuses on the traditional concrete, with little attention paid to the recycled coarse aggregates for the high performance concrete. Most of the aggregates used are consecutive gradation recycled coarse aggregates, and research on the simple and economic single grain degradation coarse aggregates is rare. Based on the existing research (Kou & Poon 2009, Liu 2010, Ramanathan et al. 2013), influences of the replacement rate of recycled coarse aggregate on the regeneration self-compacting concrete are studied in order to find the method for preparing a low-intensity self-compacting regeneration concrete using non-continuous graded recycled coarse aggregates.

## 2 MATERIALS AND TEST METHOD

### 2.1 Materials

1. The P•C 32.5 grade combined Portland cement with the apparent density of 3.1 g/cm<sup>3</sup> is used in the test.
2. The Grade I flyash with the apparent density of 2.04 g/cm<sup>3</sup> is used to make up of 20% of the cementitious material.
3. The medium sand with the fineness modulus of 2.36 is used. Its apparent density is 2.65 g/cm<sup>3</sup>. Its bulk density is 1.45 g/cm<sup>3</sup>. And its sand test rate is 45%. The sieve analysis test of sand is showed in Table 1.
4. The 5–20 mm continuous grain size gravel with the apparent density of 2.75 g/cm<sup>3</sup> is used as natural coarse aggregate. Its bulk density is 1.35 g/cm<sup>3</sup>. The percent passing of natural coarse aggregate is showed in Table 2.
5. The 10–20 mm recycled coarse aggregate with broken brick has the apparent density of 2.35 g/cm<sup>3</sup>, the bulk density of 1.23 g/cm<sup>3</sup>, and the water absorption of 4.76%. The percent passing of recycled coarse aggregate is shown in Table 3.

7. The tap water is used.

### 2.2 Test method

The amount of cement, water, sand and fly ash is fixed, with the replace rate of the regeneration aggregates as 30%, 50% and 70%, respectively. Concrete is designed according to the Chinese codes DG/TJ 08-2018-2007 and JGJT 283-2012. The water is divided into two parts: the net and additional amount of water. The net amount of water is calculated based on DG/TJ 08-2018-2007. The additional amount of water is determined by the water absorption ratio of the regeneration aggregates. The coarse aggregates are divided into the natural and recycled aggregates, the amount of which is calculated based on the mass-volume relations. To investigate the influences of different raw materials on the performance of fresh concrete and the cube compressive strength, only the amount of materials investigated is changed during the test, and the amount of other materials is fixed.

### 2.3 Performance evaluation criteria

The study is based on the replacement ratio of the recycled coarse aggregates, which are 30%, 50%, and 70%, respectively. The additional water consumption is 13.70 kg/m<sup>3</sup>, 22.05 kg/m<sup>3</sup>, and 29.90 kg/m<sup>3</sup>, respectively. A slump flow test, a T<sub>500</sub> test and an L-box test (Rod spacing 60 mm) are conducted to examine the performance of fresh concrete. The slump flow test and the T<sub>500</sub> test are conducted in accordance with

Table 5. Test properties and methods for evaluating self-compacting concrete.

Property	Test method	Performance rate	Technical requirements
Fill ability	Slump flow (mm)	SF1	550–655
		SF2	660–755
		SF3	760–850
	$T_{500}$ (s)	VS1	$\geq 2$
		VS2	$< 2$
Clearance through and segregation resistance	L-box ( $H_2/H_1$ )	I Rod spacing 40 mm	$\geq 0.8$
		II Rod spacing 60 mm	

Figure 1. Slump flow test.

Figure 2. L-box test.

the Chinese code JGJT 283-2012, while the L-box test is conducted in accordance with the Chinese code CCES 02-2004. Evaluation details are given in Table 5. Meanwhile, compressive strength values of different concrete cube specimens (150 mm × 150 mm × 150 mm) under 3-days, 7-days and 28-days curing periods are studied in accordance with the Chinese code GB/T 50081-2002. The 60 L compulsory mixer mechanical stirring machine is used for all concrete mixtures, and specimens are placed under standard curing environment. The test procedures are shown in Figures 1–2.

### 3 RESULTS AND ANALYSIS

#### 3.1 Performance of fresh concrete

Firstly, the recycled coarse aggregates are divided into single grains through standard screening procedure, and the gradation adjustment of recycled coarse aggregates is performed in accordance with the Chinese code GB/T 25177-2010. The replacement rates for recycled coarse aggregates are 30%, 50% and 70%, respectively. The test procedure is shown in Figures 1–2, and the results are given in Table 6 and Figures 3–5. According to JGJT 283-2012 and CCES 02-2004, the slump flow rating is SF1 (550–655 mm) when the recycled coarse aggregates replacement rates are 30% and 70%; the slump flow rating is SF2 (660–755 mm) when the replacement rate is 50%;  $T_{500}$  extended time rating is VS1; the L-box test ( $H_2/H_1$ ) rating is grade II.

Figures 3–5 show the fresh concrete slump flow increases along with the recycled coarse aggregates replacement rate. When the replacement rate increases from 30% to 70%, then slump increases first then decreases. It reaches its maximum when the replacement rate is 50% with the slump flow of 700 mm.

The  $T_{500}$  flow time decreases as the recycled coarse aggregates replacement rate increases, and when the replacement rate increases from 30% to 50%, the  $T_{500}$  flow time decreases significantly, and with no further obvious decrease afterwards. When the recycled coarse aggregates replacement rate increases from 30% to 50%,  $H_2/H_1$  obtained by the L-box test increases from 0.80 to 0.85, and the performance of the freshly casted concrete is improved. When the replacement rate increases from 50% to 70%,  $H_2/H_1$  decreases from 0.85 to 0.80, suggesting that the fluidity and filling property of fresh concrete is improved, while the through capacity and segregation resistance decreased. According to the rheology theory, the increase of the recycled coarse aggregates replacement rate in a certain range cause the increase of additional amount of water, which results in the decrease of

Table 6. Results of fresh concrete with different replacements.

Number	Replacement (%)	Slump flow (mm)	$T_{500}$ (s)	L-box		
				$H_1$ (mm)	$H_2$ (mm)	$H_2/H_1$
1	30	640	4.23	90	72	0.80
2	50	700	3.25	100	85	0.85
3	70	650	3.12	100	80	0.80

Figure 3. Slump flow with different replacements.

Figure 4.  $T_{500}$  test with different replacements.

Figure 5. L-box test with different replacements.

the plastic viscosity of concrete mixture, so the fluidity, through capacity and segregation resistance are improved. When the replacement rate is 70%, the additional water amount increases further and the plastic viscosity of the concrete mixture decreases below the critical point at which the performance can be guaranteed, resulting in the decrease of the performance. The test results show that non-continuous gradation of recycled coarse aggregates can be formulated to meet the performance requirements of self-compacting concrete. The best working performance is reached when the recycled coarse aggregates replacement is 50%, with the slump flow of 700 mm,  $T_{500}$  flow time of 3.25 s and  $H_2/H_1$  of 0.85.

### 3.2 Compressive strength of cubes

#### 3.2.1 Failure of specimens

The stresses of self-compacting regeneration concrete specimen increases with the increase of load. Cracks occur in the specimen. Cracks began to appear on the surface in the middle of the test specimen, and then developed gradually along the oblique direction up and down to the corners of the specimen, appearing a V shape in the final. With further increase of stress in the concrete, surface cracks heaved and crushed concrete began to fall, appearing an X-cone shape in the final. From the failure pattern, the destruction of renewable self-compacting concrete is similar to the ordinary concrete, as bonds between aggregates cement are destroyed and no crushing of the recycled coarse aggregates is found. This is in good agreement with Xiao et al. (2004). Figure 6 shows the compressive failure mode of a self-compacting recycled cubic concrete specimen.

#### 3.2.2 Development of cube strengths

The compressive strength values of 3-days, 7-days and 28-days cube concrete specimens under different replacement rates are given in Figure 7.

It can be seen from Figure 7 that for 3 d and 7 d ages, the strengths of concrete with different ages decrease when the replacement rate of recycled coarse aggregate increases from 30% to 50%. However, when the replacement rate increases

Figure 6. Failure mode of cubic specimen.

Figure 7. Cubic compressive strength versus curing time.

from 50% to 70%, there is almost no change of the concrete strength, and the strength development rate is basically the same. For 7 d and 28 d ages, the strength values of concrete with different ages decrease when the replacement rate increases from 30% to 50%. When the replacement rate increases from 50% to 70%, the concrete strength is nearly unchanged. The strength development rate is basically the same under three different replacement rates, which indicates that the replacement rate has a minor influence on the strength development. The reason that strength decrease along with the replacement rate is probably that with the increase of the replacement rate, the additional amount of water increases, and hence the water-cement ratio increases indirectly. Meanwhile, it may also be attributed to the decrease of the performance of the interface between recycled

coarse aggregates and both new and old mortars. In addition, the 28 d compressive strengths of regeneration self-compacting concrete cube specimens prepared under different replacement rates all satisfy the strength requirements. And the early strength develops fast as the 3 d strength can reach the 50% of the design strength; the 7 d compressive cube strength can be more than 70% of the design strength, so that molds can be removed early. The strength development in the late stage is obviously slower than that of the early stage, which is mainly due to the incorporation of polycarboxylate superplasticizer as the early hydration of cement is promoted.

#### 4 CONCLUSIONS

1. Non-continuous graded recycled coarse aggregates can be formulated to meet the working performance requirements of low-intensity self-compacting concrete. The best performance is reached when the recycled coarse aggregates replacement rate is 50%.
2. The 28 d compressive strength values of self-compacting regeneration concrete cube specimen under different replacement rates satisfy the strength requirements of C20 concrete. When the recycled coarse aggregates replacement rate is greater than 50%, the replacement rate has little influence on the concrete strength development.
3. The early strength of prepared low-intensity self-compacting regeneration concrete grows fast and molds can be removed early accordingly. The recycled coarse aggregates replacement rate has little influence on the strength development after 7 days.

# Study on the pre-evaluation of the bench blasting effect based on the uncertainty measurement theory

T.J. Tao, M.S. Zhao & Q. Kang

Guizhou Xinlian Blasting Engineering Group Co. Ltd., Guiyang, Guizhou, China

**ABSTRACT:** In order to resolve the uncertainty problem of influence factors of bench blasting effect pre-evaluation, the pre-evaluation model of the bench blasting effect based on the uncertainty measurement theory was built. Then, this model was used to pre-evaluate the bench blasting effect in Hongshuitai flat engineering. The pre-evaluation results show that the information entropy and confidence identifying criterion were, respectively, used to ascertain the pre-evaluation index weight and identifying criterion. In this way, the pre-evaluation results of this model are found to be more objective, and the pre-evaluation index can be selected flexibly according to the actual situation. The calculation of the evaluation model is found to be simple, so the evaluation results can offer a decision basis for blasting workers to make timely adjustment of the blasting scheme.

**Keywords:** uncertainty measurement theory; bench blasting effect; pre-evaluation; factor index

## 1 INTRODUCTION

With the development of national economic construction, the bench blasting has been increasingly applied in many areas such as mining, cutting shaping of rail and road, and facilities construction of water and hydropower. So, how to achieve an optimum blasting effect has been a topic of concern for the majority of blasting workers. However, in the actual project, as there are many factors that influence the effect of bench blasting, it is difficult to give a reasonable prediction of the blasting effect. Therefore, the study on the pre-evaluation of the bench blasting effect is of important significance for making an optimal blasting scheme to improve the blasting effect and increase the economic efficiency of blasting engineering. For making an accurate prediction of the bench blasting effect and providing a judging decision for improving the blasting scheme, a study on the pre-evaluation of the bench blasting effect is needed. However, current studies on the bench blasting effect are scarce, mainly because there are many influencing factors in evaluating the bench blasting effect, and these factors are often mutually influencing, so it is difficult to make the pre-evaluation of the blasting effect. The current evaluation method for the blasting effect mainly uses AHP, fuzzy mathematics and gray correlation analysis. For example, Ma Li established a comprehensive evaluation model of the blasting effect based on the fuzzy mathematical theory. Hu Xinhua established a comprehensive

evaluation model of the blasting effect based on the AHP and gray correlation analysis. In this model, two layers of gray correlation analysis evaluation mode were used. However, as there is uncertainty in determining the influencing factors of the blasting effect, the model based on fuzzy mathematic, AHP and gray correlation analysis often lost the information, and had defects such as existence of subjective misjudgment in weight distribution and determination. In recent years, the uncertainty measurement theory has been used by many scholars to make a comprehensive evaluation for the multi-factor index, and obtained many achievements. This article uses this theory to establish the pre-evaluation model of the blasting effect and study its practical application.

## 2 UNCERTAINTY MEASUREMENT THEORY

### 2.1 Uncertain measure of a single index

Given  $a_1, a_2, \dots, a_i$  indicates  $n$  factors to be evaluated concerning the object, noting  $A = \{a_1, a_2, \dots, a_i\}$ , which is called the 'domain'; each single-factor pre-evaluation index  $a_i$  has  $j$  evaluation grades  $b_1, b_2, \dots, b_j$ , then  $a_{ij}$  is used to indicate the observed value of single factor  $a_i$  as an object to be pre-evaluated on the  $j$ th evaluation grade  $b_j$ . The single-factor evaluation index  $a_i$ , when it is in the  $j$ th grade of comment, is denoted as  $a_{ij}$ . This paper adopts an expert grading method, providing

that the sum of the value of points on the grade of all the comments about each pre-evaluation factor is 100 points. The related experts will give 0–100, respectively, to each grade  $b_j$  of the comment on each pre-evaluation factor  $a_i$ , marking  $\sum_{j=1}^j a_{ij} = 100$ . The use of  $u_{ij} = a_{ij}/100$  indicates that the observed value  $a_{ij}$  makes  $a_i$  stay at the uncertain measure angle of the grade  $b_j$  of the comment.  $u_{ij}$ , as the result of the measure of ‘degree’, is the possibility measure. From this, we can obtain the measurement matrix of a single pre-evaluation index as the evaluated object:

$$u_{ij} = \begin{bmatrix} u_{i1}, u_{i2}, \dots, u_{ij} \\ u_{21}, u_{22}, \dots, u_{2j} \\ \vdots \quad \vdots \quad \dots \quad \vdots \\ u_{n1}, u_{n2}, \dots, u_{nj} \end{bmatrix} \quad (1)$$

where  $i = 1, 2, \dots, n$ .

### 2.2 Determination of the index weight

What is described about the uncertainty of observed values should be the quantitative measurement of uncertainty as well as the distribution function of observed values, which is called the entropy. Entropy was first brought forward in thermo-dynamics by Clautheus and used to describe the state of a system, and in later years, it was introduced to many domains. For a discrete random variable, its information entropy  $S = -k \sum_{i=1}^k P_i \ln P_i$ , where  $P_i \geq 0$ , where  $\sum_{i=1}^n P_i = 1$ . Entropy has such characteristics as symmetric, non-negative, additive and of extreme value. Given the space of natural state  $X = (x_1, x_2, \dots, x_n)$  is an uncontrollable factor. In the formula,  $x_i$  is the state that has occurred. Given the prior probability distribution of each state that occurred in  $X$  is  $P(X) = \{P(x_1), P(x_2), \dots, P(x_n)\}$ . The uncertain extent of this state is defined as an entropy function:

$$H(x) = -\sum_{i=1}^n p(x_i) \ln p(x_i) \quad (2)$$

where  $0 \leq p(x_i) \leq 1$ ,  $\sum_{i=1}^n p(x_i) = 1$ . The observed value  $x_{ij}$  of the evaluated object of the quality of blasting regarding  $a_i$  makes the uncertain measure of the objects that stay at each grade  $b_i$  of comment become  $u_{i2}, \dots, u_{ij}$ . If the uncertain measure  $u_{ij}$  is regarded as  $p_i$  in  $H(x)$ , then we have

$$H(u) = -\sum_{j=1}^j u_{ij} \ln u_{ij} \quad (3)$$

$$v_i = 1 - \frac{1}{\ln j} H(u) = 1 + \frac{1}{\ln j} \sum_{j=1}^j u_{ij} \cdot \ln u_{ij}$$

$$w_i = \frac{v_i}{\sum_{i=1}^i v_i}$$

where  $W_i$  ( $0 \leq W_i \leq 1$ , and  $\sum_{i=1}^i W_i = 1$ ) is the weight of the pre-evaluation index  $a_i$ .

### 2.3 Comprehensive evaluation system

If the measurement matrix of the single pre-evaluation index concerning the evaluated objects is known, then the classified weights of each index about the evaluated objects are obtained from Formula (3). Let

$$u_j = W \cdot u_{ij} = (w_1, w_2, \dots, w_i) \cdot \begin{bmatrix} u_{11} & u_{12} & \dots & u_{1j} \\ u_{21} & u_{22} & \dots & u_{2j} \\ \dots & \dots & \dots & \dots \\ u_{i1} & u_{i2} & \dots & u_{ij} \end{bmatrix} \quad (4)$$

Then,  $u_i$  is a pre-evaluation vector of the blasting as an evaluated object, describing the classification of uncertainty. In order to obtain the classifications of certainty, the difference in confidence needs to be marked. Because the grade division of comment is in order and because the grade  $b_j$  of the  $j$ th comment is ‘better’ than the grade  $b_{j+1}$  of the  $j+1$  comment, the discrimination criterion for the maximum measure is not suitable to this case. We have to use the discrimination criterion of confidence.

Given the confidence is  $\lambda$ , ( $\lambda > 0.5$ ), then 0.6 or 0.7 is usually adopted. Let

$$j_0 = \min_j \left\{ j : \sum_{j=1}^j u_{ij} \geq \lambda, \quad j = 1, 2, \dots, j \right\} \quad (5)$$

Then, it is judged that the pre-evaluated object of the blasting effect belongs to the  $j_0$ th evaluation grade  $b_{j_0}$ .

## 3 CASE TEST

### 3.1 Establishment of the index evaluation system

The theory and the method of systematic engineering are applied to set up an index system of a complete structure, a substantial content and convenient use for evaluating the quality of blasting, so as to provide a basis for making an accurate prediction of the bench blasting effect and providing a judging decision for improving the blasting scheme. This paper presents bench blasting in Hongshuitai flat engineering, as shown in Figure 1.

Figure 1. Bench blasting in Hongshuitai.

A pre-evaluation index system of the bench blasting effect based on the uncertainty measurement theory was established. The index system for the pre-evaluation of the bench blasting effect is presented in Table 1.

### 3.2 Pre-evaluation of the bench blasting effect

The pre-evaluation grades of each single factor for judging the quality of blasting are classified as follows: fine, good, general, relatively poor and poor, so that the experts give 100 points, respectively, to each evaluation grade of single factors, as given in Table 2.

According to Table 2, the matrix of a single-index uncertain measure is obtained as formula (6):

$$u_{ij} = \begin{bmatrix} 0.21 & 0.43 & 0.25 & 0.09 & 0.02 \\ 0.16 & 0.32 & 0.23 & 0.16 & 0.13 \\ 0.23 & 0.36 & 0.15 & 0.16 & 0.10 \\ 0.18 & 0.33 & 0.14 & 0.21 & 0.14 \\ 0.30 & 0.41 & 0.13 & 0.11 & 0.05 \\ 0.22 & 0.42 & 0.17 & 0.11 & 0.08 \\ 0.31 & 0.41 & 0.13 & 0.11 & 0.04 \\ 0.32 & 0.43 & 0.13 & 0.09 & 0.03 \\ 0.20 & 0.44 & 0.15 & 0.16 & 0.05 \\ 0.35 & 0.41 & 0.15 & 0.6 & 0.03 \\ 0.35 & 0.40 & 0.15 & 0.07 & 0.03 \\ 0.32 & 0.41 & 0.12 & 0.10 & 0.05 \\ 0.23 & 0.47 & 0.17 & 0.08 & 0.05 \\ 0.27 & 0.47 & 0.13 & 0.10 & 0.03 \\ 0.26 & 0.46 & 0.16 & 0.08 & 0.04 \end{bmatrix} \quad (6)$$

By Formula (3) to calculate the index weight of the pre-evaluated factors, we can have  $W = (0.084, 0.017, 0.029, 0.017, 0.068, 0.050, 0.074, 0.089, 0.060, 0.096, 0.090, 0.074, 0.0079, 0.091, 0.084)$ .

Table 1. Index system for the pre-evaluation of the bench blasting system.

First class	Second class
Quality of blasting $A_1$	Drilling cost $a_1$
	Forward and backward strokes $a_2$
	Cost of priming materials $a_3$
	Unit consumption of explosives $a_4$
	Coefficient of bulk increase $a_5$
	Shoveling efficiency $a_6$
	Boulder ratio $a_7$
	Toe $a_8$
Safety of blasting $A_2$	Explosion gas $a_9$
	Explosive shock wave $a_{10}$
	Flying rock $a_{11}$
	Blasting vibration $a_{12}$
	Slope stability $a_{13}$
	Dangerous rock $a_{14}$
	Blind shot $a_{15}$

Table 2. Results of the points that the experts give.

Pre-evaluated factors	Evaluation grade				
	Fine	Good	General	Relatively poor	Poor
$a_1$	21	43	25	9	2
$a_2$	16	32	23	16	13
$a_3$	23	36	15	16	10
$a_4$	18	33	14	21	14
$a_5$	30	41	13	11	5
$a_6$	22	42	17	11	8
$a_7$	31	41	13	11	4
$a_8$	32	43	13	9	3
$a_9$	20	44	15	16	5
$a_{10}$	35	41	15	6	3
$a_{11}$	35	40	15	7	3
$a_{12}$	32	41	12	10	5
$a_{13}$	23	47	17	8	5
$a_{14}$	27	47	13	10	3
$a_{15}$	26	46	16	8	4

By means of Formula (5), we determine the final result of evaluation as follows:  $u = (0.278, 0.425, 0.154, 0.0989, 0.044)$ .

Assuming the confidence  $\lambda = 0.7$ , both the discrimination criterion of confidence and Formula (5) are applied to judge that the grade of pre-evaluation of the blasting effect in this bench blasting is the second, namely 'good'. The way of uncertain measure takes notice of the orderliness of the evaluation space and gives a relatively rational criterion for the discrimination of confidence and the code of points for order, as is just what the fuzzy comprehensive evaluation method does not have at all.

The pre-evaluation of the bench blasting effect in the blasting field in Hongshuitai flat engineering is realized by means of a programmed method, favorable to the improvement at the managerial level on the part of the construction project, promoting the safe, reliable and economical and effective operation of blasting construction.

#### 4 CONCLUSION

1. By applying the theory and method of systematic engineering, it conducts and establishes a pre-evaluation factor index system of the bench blasting effect.
2. A criterion is adopted, respectively, for the discrimination of the information entropy and creditability in determining the weight of each evaluation index and the discrimination criterion, therefore avoiding the defects of the fuzzy comprehensive judgment in these two aspects, making the result of the evaluation more objective.
3. A pre-evaluation of the bench blasting effect in the blasting field is realized by means of a programmed method, favorable to the improvement at the managerial level on the part of the construction project, promoting the safe, reliable and economical and effective operation of blasting construction.

# Dynamic analysis on the ballast track application in urban railway tunnels

Yaqun Wang, Xingchen Zhang & Junhua Chen  
*Beijing Jiaotong University, Beijing, P.R. China*

**ABSTRACT:** Aiming at the ballasted track in urban railway tunnels, based on the coupling dynamics theory, a dynamic analysis model of the vehicle-ballast track-tunnel system is established in this paper. The safety index, vehicle stationarity index, index of track's dynamic response, and vibration index were analyzed dynamically by ABAQUS. Finally, the feasibility of the ballast track in urban railway tunnels can be fully demonstrated from the aspects of track structure, tunnels structure, vehicle safety, and passengers' comfort.

## 1 INTRODUCTION

Urban railway has become a top priority as the public infrastructure in many metropolitans in China; meanwhile, in most of the urban railway lines in China, especially in the tunnel line, the structural form of the ballastless track is usually adopted. However, applications of a large number kinds of ballastless track without independent property rights have led to the increase in the costs in preconstruction. Expense of maintenance and replacement of accessories is also a large expenditure in the late stage.

Elasticity of ballastless track is mainly provided by rail fastenings; therefore, there are more stringent requirements for the fastenings structure design, material selection and technical standards. Beyond that, the adjustment of the track geometric status can only be realized by fastenings [1].

Various levels of vibration damping measures are adopted in order to meet the requirements of environmental protection. Some of them work rather well; nonetheless, the problems of vibration damping cannot be solved in many areas. On the contrary, serious abnormal rail corrugations are caused. These factors have restricted the development of urban railway transit to a certain extent [2].

The concept of building ballast tracks inside tunnels has been adopted in many European cities, namely Paris, London, Helsinki, Moscow, and Berlin, and the tracks have been still in use since the last century. Hence, it is crucial for us to inspire their successful experiences [3].

Coupling dynamics theory is used in this paper [4]. A dynamic analysis model of the vehicle-ballast track-tunnel system is established by procedure software of finite element ABAQUS, analyzing

comprehensively the safety index (wheel-rail force, the derailment coefficient, wheel load reduction rate), vehicle stationarity index (vehicle acceleration), index of track's dynamic response (dynamic stress, dynamic displacement), and vibration index (acceleration of rail, tunnel structure). We can analyze the dynamic characteristics of the ballast track in urban railway tunnels from a structure's point of view, and this includes the track structure, tunnels structure, vehicle safety and passengers' comfort in order to support the argument of ballast track feasibility in railway tunnels.

## 2 DYNAMIC ANALYSIS MODEL

The established dynamic analysis model of the vehicle-ballast track-tunnel system in this paper consists of model for vehicle, model for track, model for tunnel, model for wheel-rail interaction and model for track irregularity.

According to the structure of the vehicle and characteristics of the suspension, we model the vehicle. We regard the train body, two bogies and four wheels as a rigid body. Vehicle model becomes a multi-rigid body system that consists of train body, bogie and wheelset. That is, the whole system can be regarded as the composition of four wheels, two bogies and a body, connected by a two-line spring damper element between each other.

The train body and bogie each has five degrees of freedom, that is, the ups, downs, nod, shifting, roll and yaw. Each wheel has four degrees of freedom, that is, the ups, nod, shifting, roll and yaw. The rotary produced by wheel speed uniformity is not considered. Vehicle model is shown in [Figure 1](#).

Figure 1. Vehicle model.

Figure 2. Tunnel model.

Figure 3. Vehicle-ballast track-tunnel system dynamic analysis model.

When modeling, we simplify the structure of the tunnel, by only considering the inverted arch (using C35 concrete), arch wall (using C35 concrete), invert backfill layer (using C20 concrete), shotcrete layer (using C25 concrete), and part of the wall rock outside of the lining. Tunnel model is shown in Figure 2.

The irregularity of the sample distribution is applied to the left and right rail by the way of

modifying the rail model node coordinates. Vehicle-ballast track-tunnel system dynamic analysis model is shown in Figure 3.

### 3 WHEEL-RAIL COUPLING EFFECT

The coupling action between the wheel and the rail is achieved by the wheel-rail contact. In the system dynamic analysis model, we consider the wheel-rail normal force and tangential force in the following way [4].

#### 3.1 Wheelrail normal force

We calculate the wheel-rail vertical force according to the Hertz nonlinear elastic contact theory:

$$P(t) = \left( \frac{1}{G} \Delta Z(t) \right)^{3/2} \quad (1)$$

where  $G$  is the wheel-rail contact constant ( $m/N^{2/3}$ ); for a cone-shaped tread wheel,  $G = 4.57 R^{-0.149} \times 10^{-8} (m/N^{2/3})$ ; for a worn tread wheel,  $G = 3.86 R^{-0.115} \times 10^{-8} (m/N^{2/3})$ ; and  $\Delta Z(t)$  is the elastic compression between the wheel and the rail at  $T$  moment (m).

Elastic compression between the wheel and the rail includes the wheel loading amount, which can be determined directly by the wheel-rail displacement at wheel-rail contact point:

$$\Delta Z(t) = Z_{wi} - Z_{ri}(t) \quad (i = 1 \sim 4) \quad (2)$$

where  $Z_{wi}$  is the displacement of the  $i$ th wheel at  $T$  moment (m) and  $Z_{ri}(t)$  is the rail displacement under the wheel (m).

When displacement irregularity  $Z_0(t)$  exists in the wheel-rail interface, expressions for the wheel/rail force are given by

$$P(t) = \begin{cases} \left\{ \frac{1}{G} [Z_{wi}(t) - Z_{ri}(t) - Z_0(t)] \right\}^{3/2} \\ 0 \quad (\text{wheel/rail divoced}) \end{cases} \quad (3)$$

#### 3.2 Wheel-rail tangential force

Tangential force will be produced at the contact spot between the wheel and the rail, which is the wheel/rail creep force. Kalker's linear theory is used in this paper. Kalker assumes that the contact area is all adhesion areas and the tangential force distributes symmetrically in his linear theory. Therefore, longitudinal creep force and lateral creep rate are unrelated. The linear relationship between creep

force  $T_x, T_y, M_z$  and the creep rate  $\xi_x, \xi_y, \xi_{sp}$  is as follows:

$$\left. \begin{aligned} T_x &= -f_{11}\xi_x \\ T_y &= -f_{22}\xi_y - f_{23}\xi_{sp} \\ M_z &= f_{32}\xi_y - f_{33}\xi_{sp} \end{aligned} \right\} \quad (4)$$

where  $f_{11}$  is the longitudinal creep coefficient;  $f_{22}$  is the lateral creep coefficient;  $f_{23}, f_{32}$  is the transverse/spin creep coefficient; and  $f_{33} = f_{32}$ ;  $f_{33}$  is the spin creep coefficient.

The creep coefficient can be determined by the following formula:

$$\left. \begin{aligned} f_{11} &= EabC_{11} \\ f_{22} &= EabC_{22} \\ f_{23} &= E(ab)^{2/3}C_{23} \\ f_{33} &= E(ab)^2C_{33} \end{aligned} \right\} \quad (5)$$

where  $a$  is the semi-major axis of the wheel/rail contact ellipse;  $b$  is the semi-minor axis of the wheel/rail contact ellipse;  $E$  is the modulus of elasticity of the wheel and rail material;  $C_{ij}$  is the Kalker coefficient.

Finally, the wheel/rail contact force can be obtained due to creep.

The longitudinal creep force of the left and right wheels is given by

$$\left. \begin{aligned} T_{xl} &= -f_{11} \left( 1 - \frac{l_0}{v} \dot{\psi}_w - \frac{2r_l}{r_r + r_l} \right) \\ T_{xr} &= -f_{11} \left( 1 - \frac{l_0}{v} \dot{\psi}_w - \frac{2r_r}{r_r + r_l} \right) \end{aligned} \right\} \quad (6)$$

The transverse creep force and the spin creep force torque of the left and right wheels are given by

$$\left. \begin{aligned} T_{yl} &= -f_{22} \left( \frac{\dot{y}_w}{v} + \frac{r_l}{l_0} \dot{\theta}_w - \psi_w \right) - f_{23} \left( \frac{\dot{\psi}_w}{v} - \frac{2\delta_l}{r_r + r_l} \right) \\ T_{yr} &= -f_{22} \left( \frac{\dot{y}_w}{v} + \frac{r_l}{l_0} \dot{\theta}_w - \psi_w \right) - f_{23} \left( \frac{\dot{\psi}_w}{v} + \frac{2\delta_r}{r_r + r_l} \right) \\ M_{zl} &= f_{32} \left( \frac{\dot{y}_w}{v} + \frac{r_l}{l_0} \dot{\theta}_w - \psi_w \right) - f_{33} \left( \frac{\dot{\psi}_w}{v} - \frac{2\delta_l}{r_r + r_l} \right) \\ M_{zr} &= f_{23} \left( \frac{\dot{y}_w}{v} + \frac{r_l}{l_0} \dot{\theta}_w - \psi_w \right) - f_{33} \left( \frac{\dot{\psi}_w}{v} + \frac{2\delta_r}{r_r + r_l} \right) \end{aligned} \right\} \quad (7)$$

$$\left. \begin{aligned} M_{zl} &= f_{32} \left( \frac{\dot{y}_w}{v} + \frac{r_l}{l_0} \dot{\theta}_w - \psi_w \right) - f_{33} \left( \frac{\dot{\psi}_w}{v} - \frac{2\delta_l}{r_r + r_l} \right) \\ M_{zr} &= f_{23} \left( \frac{\dot{y}_w}{v} + \frac{r_l}{l_0} \dot{\theta}_w - \psi_w \right) - f_{33} \left( \frac{\dot{\psi}_w}{v} + \frac{2\delta_r}{r_r + r_l} \right) \end{aligned} \right\} \quad (8)$$

where  $r_l, r_r$  are the actual rolling radius of the left and right wheels;  $\delta_l, \delta_r$  is the wheel/rail contact angle; and  $l_0$  is half the track gauge.

In the above formula, the longitudinal creep force of the left and right wheels is in the opposite direction, and the lateral creep force are in same direction.

Kalker linear creep theory is only applicable to situation with small creepages and small spin. For the situation with a large creep rate, high spin or even completely sliding, the linear relationship between the creep forces breaks down. Therefore, we make the following nonlinear correction with Shen theory, in order to adapt to the actual conditions of the simulation calculation of the interaction between the wheel and the rail [5].

Resultant force  $T_r$  of  $T_x$  and  $T_y$  is given by:

$$T_r = \sqrt{T_x^2 + T_y^2}$$

$$T_r' = \begin{cases} \mu N \left[ \frac{T_r}{\mu N} - \frac{1}{3} \left( \frac{T_r}{\mu N} \right)^2 + \frac{1}{27} \left( \frac{T_r}{\mu N} \right)^3 \right], & T_r \leq \mu N \\ \mu N, & T_r > \mu N \end{cases} \quad (9)$$

where  $\mu$  is the maximum static friction coefficient between the wheel and the rail; and  $N$  is the normal force of the wheel/rail contact point [6].

We introduce the correction coefficient  $\varepsilon = T_r'/T_r$ , and then we can obtain the modified creep force (torque) as follows:

$$\begin{cases} T_x' = \varepsilon T_x \\ T_y' = \varepsilon T_y \\ M_z' = \varepsilon M_z \end{cases} \quad (10)$$

### 3.3 Main calculation parameters

Ballast track in urban railway tunnels contains steel, rail fastenings, sleepers, and ballast bed. Among them, the quality of the metro vehicle is 22800 kg, the quality of the bogie is 2550 kg, the quality of the wheel set is 1760 kg, the wheelbase is 2.2 m, and the length of the vehicle is 12.6 m. Using 60 kg/m rail, spacing of rail fastenings is found to be 0.625 m, the vertical stiffness of the fastening system is 75 kN/mm, the lateral stiffness is 40 kN/mm, and the longitudinal resistance is 10 kN/mm. Other related parameters of sleepers and concrete are seen in the relevant standards and related documents.

## 4 RESULTS OF DYNAMIC CALCULATION

The following is part of the typical time history curve of the simulation results after the model calculation. The time history curve is derived from the

Figure 4. Vertical displacement of the rail.

Figure 5. Transverse acceleration of the ballast bed.

Figure 6. Rail stress.

system dynamic response when the train speed is 60 km/h.

Through the established dynamic analysis model of the vehicle-ballast track-tunnel system, we can get the peak value calculation of the model,

as given. We then analyze the safety index, vehicle stationarity index, index of track's dynamic response, and vibration index. Dynamically, we can analyze the dynamic characteristics of ballast in urban railway tunnels from the aspects of track structure, tunnels structure, vehicle safety, and passengers' comfort.

1. The vehicle safety and comfort: the maximum value of the rate of wheel load reduction is 0.412, the derailment coefficient is 0.041, the maximum of the transverse force is 5.54 kN, and the train safety can be ensured. In addition, the vehicle body acceleration is less than the limit value requirement, and standard of the passenger ride comfort can be satisfied.
2. The dynamic response of track structure: track dynamic stress decreases across the table, and the stress of the rail, sleeper and ballast bed is far less than the allowable stress value of the structure. Vibration acceleration also decreases from the top to the bottom, with the overall volume being small. As for the dynamic displacement, the value of structure displacement is small because the urban rail train axle load is lighter than the train.
3. The dynamic response of tunnel structure: the vertical vibration acceleration of the tunnel structure is 0.194 m/s<sup>2</sup>, the lateral vibration acceleration is 0.048 m/s<sup>2</sup>, and the overall volume of the acceleration is minimum. When the train is in running, the vibration will decrease accordingly because of the materials used on the outer wall of the tunnels.

## 5 CONCLUSIONS

This paper analyzed the safety index, vehicle stationarity index, index of track's dynamic response, vibration index of the ballast track in urban railway tunnels dynamically through establishing the dynamic analysis model of the vehicle-ballast track-tunnel system. It is feasible to use ballast track in urban railway tunnels, no matter from which aspect such as the safety of the structure, dynamic response, passenger's comfort and vibration.

It is important to note that due to the lack of measured data of the ballast track in urban railway tunnels, we are unable to test the calculated data from the vehicle-ballast track-tunnel system's dynamic analysis model established in this paper by practice.

Selection of the typical test is recommended in the new-built urban rail traffic tunnel to fully demonstrate the feasibility of the application of the ballast track in urban railway tunnel lines.

**ABSTRACT:** Bleeding is a critical property for successful placement and performance of concrete. In this paper, dormant time and initial bleeding rate were employed to evaluate the effect of different mix design parameters on the bleeding characteristics. The unit water consumption was shown to affect the initial bleeding rate significantly, while the sand-to-aggregate ratio was a key factor in dormant time of bleeding. The water-to-powder ratio can decrease the bleeding in the range of 0.36–0.39.

**Keywords:** fresh concrete, bleeding, mixture proportion

## 1 INTRODUCTION

Bleeding is an important index to measure the workability of fresh concrete. However, the influence factors of concrete bleeding are perplexing. At present, the study on the origin of bleeding and on the performance of concrete is mainly qualitative research, which has not achieved the expected control of bleeding.

The bleeding properties of concrete can be subdivided into the bleeding volume and bleeding rate. According to the dormant time and initial bleeding rate, bleeding of fresh concrete can be divided into four types: early and quickly; early and slowly; lately and quickly; and lately and slowly. Generally, the early and quickly type bleeding occurs in a high water-to-cement ratio (w/b) concrete. The early and slowly bleeding, and lately and quickly bleeding types appear in a medium w/b concrete. The lately and slowly bleeding type occurs in a low w/b concrete.

Concrete mixture proportion has a very important influence on the performance of bleeding. In this paper, the mixture proportion of concrete with different unit water consumption (w/b), fine/total aggregate ratio ( $\beta_s$ ), water-to-powder ratio (w/p) was prepared. The influence of mixture parameters of concrete on dormant time, bleeding rate and bleeding types was investigated.

## 2 EXPERIMENTAL PROCEDURE

### 2.1 Material characterization

The raw materials used in the experiment are listed as follows:

1. Cement: P·O42.5 cement with a compressive strength of 50.2 MPa at 28 curing days.
2. Fly Ash (FA): II grade FA with a Blaine surface area of 411 m<sup>2</sup>/kg, 7% loss on ignition and water requirement ratio of 91%.
3. Ground Granulated Blast Furnace Slag (GGBFS), S75 grade with a Blaine surface area of 411 m<sup>2</sup>/kg.
4. Iron Mill Tailings Powder (IMTP): ground by iron mill tailings with a Blaine surface area of 444 m<sup>2</sup>/kg.
5. Aggregates: sand with a fineness modulus of 2.10 and dust content of 3.3%; coarse aggregate with a continuous gradation of 5–25 mm and crushing index values of 8.2%.

### 2.2 Experimental program and test sequence

**Mix proportion design.** According to the “JGJ55-2000, the specifications for the design of concrete proportion design of ordinary concrete”, concrete mix proportions with the w/b of 0.46, 0.57, 0.78 were designed.

**Specimen prepared and performance test.** Fresh concrete was prepared according to the mixture proportions. The slump and bleeding water content test was conducted in accordance with the Chinese standard GB/T 50080-2002.

The fresh concrete was poured into a mold and cylinder, respectively. Early bleeding concrete would be classified if surface visual bleeding was observed for the test sample in mold after vibration on the vibration table. For the test sample in cylinder, the bleeding rate was measured without vibration, and the dormant time of bleeding ( $t_0$ ) was defined by regression analysis.  $t_0 = 20$  min was considered as the cut-off point of concrete bleeding earlier or later,  $t_0 < 20$  min for the early bleeding type and  $t_0 \geq 20$  min for the late bleeding type.

### 3 RESULTS AND DISCUSSION

#### 3.1 Influence of unit water consumption on bleeding

The mixture proportion of concrete with different w/c (0.78, 0.57, and 0.46) and unit water consumption is given in Table 1. The bleeding rates of concrete samples are tested (see Fig. 1) and the dormant time of bleeding ( $t_0$ ) was calculated. The results are summarized in Table 2.

It can be seen from Figure 1a (w/c = 0.78) that with the increase in unit water consumption for a higher w/c, the concrete bleeding rate is increased and the maximum value of bleeding increases. The variation of the initial bleeding rate is low. But the dormant time of bleeding ( $t_0$ ) of D3 is earlier than that of D1 and D2.

Bleeding can be regarded as free water between the solid particles in fresh concrete floated to the surface. In this process, there is a variety of resistance factors. When the potential energy of the free water is greater than the resistance force, the bleeding occurs.

Figure 1. Influence of unit water consumption on the bleeding rate of concrete.

Table 1. Mix proportion of concrete with different water consumption.

Simple no.	w/b/%	$\beta$ /%	w/kg	c/kg	s/kg	g/kg
D1	0.78	40	200	256	720	1174
D2	0.78	40	220	282	740	1109
D3	0.78	40	243	312	718	1077
D4	0.57	38	190	333	713	1165
D5	0.57	38	205	360	696	1138
D6	0.57	38	220	390	682	1113
D7	0.46	39	200	435	688	1077
D8	0.46	39	220	478	664	1042
D9	0.46	39	235	510	645	1009

Table 2. Bleeding of concrete with different water consumption.

Sample no.	w/b/%	w/kg	Slump/mm	Bleeding	$t_0$
D1	0.78	200	55	Slight	14.85
D2	0.78	220	155	Slight	13.09
D3	0.78	243	200	Seriously	-7.11
D4	0.57	190	70	None	22.11
D5	0.57	205	110	Slight	22.92
D6	0.57	220	140	Slight	22.59
D7	0.46	200	110	None	23.6
D8	0.46	220	150	None	23.2
D9	0.46	235	200	None	24.85

Unit water consumption has a close relationship with bleeding, higher unit water consumption, more free water and higher potential energy of bleeding, which resulted in more serious bleeding manifested as earlier dormant time of bleeding ( $t_0$ ) and higher bleeding rate, and larger bleeding volume in concrete.

With the increase in unit water consumption, free water in concrete is also increased and “bleeding potential energy” is greater, the initial bleeding rate and total bleeding water will be improved, as shown in Figure 1b ( $w/c = 0.57$ ) and Figure 1c ( $w/c = 0.46$ ). On the other hand, the increase in unit water consumption means the decrease in the proportion of solid particles. Bleeding resistance can be decreased dramatically with the solid particles, especially the fine cementitious particles and then the bleeding rate increases, and thus the bleeding occurs earlier. So, it can be considered that unit of water consumption is a key factor of concrete bleeding, especially the dormant time of bleeding at a high  $w/c$ .

For the bleeding performance, the  $w/c$  seems also to play a significant role, as shown in Figure 1. Bleeding is much milder for the lower  $w/c$  concrete.

### 3.2 Influence of the fine/total aggregate ratio ( $\beta_s$ ) on bleeding

A series of concrete mixtures were designed at the water/cement ratio of 0.78, 0.57 and 0.46 and the fine/total aggregate ratio ( $\beta_s$ ) for a single variable. Bleeding was measured and dormant time of bleeding ( $t_0$ ) was defined by the regression analysis. Influence of the fine/total aggregate ratio ( $\beta_s$ ) on the bleeding rate of concrete is shown in Figure 2.

The fine/total aggregate ratio ( $\beta_s$ ) play a significant role on the workability of concrete for a given cement paste volume. Too large or too small  $\beta_s$  both make the workability worse and bleeding will occur. As can be seen from Figure 2, with the increase of  $\beta_s$ , dormant time of bleeding ( $t_0$ ) was prolonged, the amount of bleeding was reduced and the bleeding rate decreased slightly. When  $\beta_s$  is the one and only variable in fine/coarse aggregate binary system, with  $\beta_s$  increase, the specific surface area is monotone increasing and porosity decrease first and then increase. Lower porosity will result in increased resistance of bleeding until a minimum porosity reached. Further increased  $\beta_s$  will result in higher porosity and higher specific surface area. Therefore, there is a reasonable gradation exists for bleeding of concrete system.

It can be seen fine/total aggregate ratio ( $\beta_s$ ) is an important factor affected bleeding rate in the range of 32–40%. As the  $\beta_s$  increased, bleeding was much milder. It seems that  $\beta_s = 40\%$  is acceptable for controlling the bleeding of concrete.

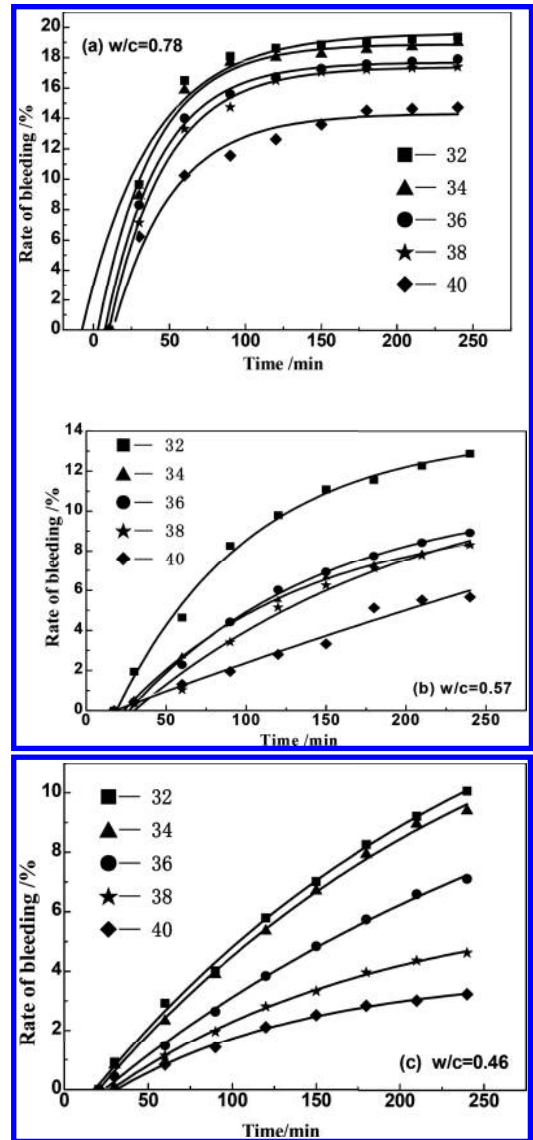

Figure 2. Influence of the fine/total aggregate ratio ( $\beta_s$ ) on the bleeding rate of concrete.

### 3.3 Influence of the water/powder ratio ( $w/p$ ) on bleeding

The influence of the water/powder ratio ( $w/p$ ) on bleeding fixed the fine/total aggregate ratio by 40%, as shown in Figure 3. The relationship between the water/powder ratio ( $w/p$ ) and slump is shown in Figure 4. The composition of powder in concrete samples is listed in Table 3.

At the same water/powder ratio, the powder instead of cement with 15% FA and 15% GGBFS

Figure 3. Influence of the water/powder ratio on the bleeding rate of concrete.

Figure 4. Influence of the water/powder ratio on the slump of concrete.

Table 3. Mix proportion of concrete with different water/powder ratios.

Sample no.	w/p	FA/% <sup>①</sup>	GBFS/% <sup>①</sup>	IMTP % <sup>②</sup>
F1	0.56	0	0	3.3
F2	0.56	15	15	3.3
F3	0.47	15	15	3.3
F4	0.43	15	15	3.3
F5	0.39	15	15	8.3
F6	0.36	15	15	13.3
F7	0.34	15	15	18.3

Note: <sup>①</sup>replacing cement. <sup>②</sup>Iron mill tailings powder, replacing fine aggregate equivalent.

can reduce the bleeding slightly and improve the slump of concrete at the same time. As the IMTP powder replacing fine aggregate mixed into concrete increased, the bleeding rate appeared a peak with w/p = 0.36, corresponding to the slump also

reached the maximum value. When w/p < 0.36 (IMTP > 13.3%), the slump decreased rapidly. It can be seen from Figure 3 and Figure 4 that the bleeding rate and the slump are consistent, i.e. large slump and high bleeding rate is high, and vice versa. Therefore, the w/p in concrete is a major determinant of bleeding and slump factors. It seems that w/p = 39% is acceptable for controlling the bleeding of concrete.

#### 4 CONCLUSIONS

1. The unit water consumption was the key factor of concrete bleeding, especially the dormant time of bleeding at a high w/c.
2. As the fine/total aggregate ratio ( $\beta_s$ ) increased, bleeding was much milder. It seemed that  $\beta_s = 40\%$  was acceptable for controlling the bleeding of concrete.  $\beta_s$  was a key factor of the bleeding rate.
3. Water/powder ratio in concrete was a major determinant factor of bleeding and slump. It seemed that w/p = 39% was acceptable for controlling the bleeding of concrete.

**ABSTRACT:** Track irregularities are the main excitation sources of vehicle vibration that will produce a direct impact on the vehicle's stability and safe running. Because the curved lines are applied greatly in railway lines, the irregularities of curved lines contribute to more intense interactions between wheels and rails that not only increase the wear of wheels and rails and vibration of vehicles, but also cause great damage to the track structure. Therefore, the main objective of this article is the examination of the effects of curved track irregularities on vehicle dynamics during motion along a curved track. For the track irregularity types with different breadths and wavelengths, the effects of track irregularities on vehicle dynamics are different. Based on the data from the curved track irregularity measurements of the Wu-Jiu line by track inspection car, using coherence function and computer simulation of trains running on the track of different irregularity types, the relationship between curved track irregularity and vehicle vibration was studied. First, based on the result of coherence function analysis and power spectrum analysis, the detrimental wavelengths, which will lead to more intense vibration responses, were defined. Second, by inputting the data from the Wu-Jiu line as the excitation source of the proposed model, the model was implemented via the software ADAMS/rail. On comparison with the simulation results, the defined detrimental wavelengths were proposed. The result of this paper can provide a theoretical and practical guidance for the maintenance of geometrically irregular track and relevant management.

**Keywords:** the curved track; track irregularities power spectrum; coherence functions analysis; detrimental wavelengths

## 1 ANALYSIS OF CURVED LINE TRACK IRREGULARITIES CHARACTERISTICS

### 1.1 Irregular areas

The data of this paper come from the on-site measurements of the Wu-Jiu line by track inspection car. The sampling interval is 0.25 m. The spatial frequency is 4. Thus, for every kilometer, the total number of data point is 4001. The curved radius is 680 m. The curved length is 611 m. The average super elevation is 124.2 mm. The train's average speed is 101 km/h. The irregularity data from

inspection car include: left rail y-displacement, left rail z-displacement, right rail y-displacement and right rail z-displacement.

### 1.2 The curved line track irregularity power spectrum analysis

In order to examine the effects of curved track irregularities on vehicle dynamics, the track irregularity power spectra are calculated and the frequency components are analyzed. [Figure 1](#) and [Figure 2](#) show the power spectrum of track vertical profile irregularities. According to these figures, the

Figure 1. PSD of left-z displacement.

Figure 4. PSD of right-y displacement.

Figure 2. PSD of right-z displacement.

Figure 3. PSD of left-y displacement.

dominant frequencies are  $0.1094 \text{ m}^{-1}$ ,  $0.1564 \text{ m}^{-1}$ ,  $0.194 \text{ m}^{-1}$ ,  $0.2448 \text{ m}^{-1}$ ,  $0.2788 \text{ m}^{-1}$  and  $0.3411 \text{ m}^{-1}$ . Therefore, the corresponding wavelengths are 10 m, 6.5 m, 5 m, 4 m, 3.6 m and 2.8 m.

Figure 3 and Figure 4 show the power spectrum of track direction irregularities. From these figures, the dominant frequencies are  $0.09644 \text{ m}^{-1}$ ,  $0.126 \text{ m}^{-1}$ ,  $0.1553 \text{ m}^{-1}$ ,  $0.1885 \text{ m}^{-1}$  and  $0.3147 \text{ m}^{-1}$ . Thus, the responding wavelengths are 10 m, 7.9 m, 6.4 m, 5.3 m and 3.1 m.

## 2 COHERENCE ANALYSIS OF TRACK IRREGULARITIES AND VEHICLE VIBRATION

Coherence analysis can determine the percentage that shows how much output response is induced by input. Hence, the wavelength, which corresponds to the maximum value of coherence functions, can be regarded as the detrimental wavelength. For a single input and a single output, the coherence function can be described as follows:

$$\gamma_{xy}^2(f) = \frac{|s_{xy}(f)|^2}{s_x(f)s_y(f)}, \quad 0 < \gamma_{xy}^2 < 1 \quad (1)$$

here,  $S_x(f)$  is the auto-power spectrum of the signal  $x(t)$ ;  $S_y(f)$  is the auto-power spectrum of the signal  $y(t)$ ; and  $S_{xy}(f)$  is the cross power-spectrum of  $x(t)$  and  $y(t)$ . For most conditions,  $0 < \gamma_{xy}^2(f) < 1$ , which shows that the two physical quantities are coherent to some extent. If the maximum value of coherent function can be found, then this wavelength will induce the greatest vibration.

The coherence functions are adopted to analyze track irregularities and vehicle vertical or lateral vibration accelerations. By studying the coherent

Figure 5. Coherence of left rail vertical irregularities and vertical vibration of vehicles.

Figure 8. Coherence of right rail direction irregularities and lateral vibration of vehicles.

Figure 6. Coherence of right rail vertical irregularities and vertical vibration of vehicles.

Figure 7. Coherence of left rail direction irregularities and lateral vibration of vehicles.

extent of vehicle vibration and track irregularities, the detrimental wavelength scope can be identified. The power-spectrum analysis can present the distribution of dynamic response of vehicle and track irregularities with wavelengths. Thus, in this paper, the combined method of coherent analysis and power spectrum is adopted to define the detrimental wavelengths.

According to the coherent analysis figures and power spectrum figures, the track vertical irregularities affect the vehicles' vertical vibrations significantly, while the track direction irregularities have significant effects on the vehicles' lateral vibrations. When both the power spectrum of vehicle's acceleration and coherent function curved reach the maximum, the wavelength can be regarded detrimental. For track direction irregularities, the detrimental wavelengths are  $1/0.035 \text{ m}^{-1}$  (28.5 m) and  $1/0.2686 \text{ m}^{-1}$  (3.72 m), and for vertical irregularities, the detrimental wavelengths are  $1/0.05078 \text{ m}^{-1}$  (20 m) and  $1/0.3984 \text{ m}^{-1}$  (2.5 m).

### 3 DYNAMICAL SIMULATION CALCULATION

A vehicle-track system can be considered as a dynamic system whose inputs are track irregularities and whose outputs are vertical force, lateral force and vehicles' accelerations. This study used the rail-wheel dynamic model of ADAMS/Rail. By inputting the irregularity data as excitation functions, the vehicles' dynamical responses under different track irregularities were studied. In order to study the effects of different track irregularity types on the vehicles' vibrations, the model inputs each track irregularity type individually. Figure 9 and Figure 10 show the vehicles' lateral

Figure 9. The power spectrum of the vehicles' lateral acceleration induced by left-rail direction irregularities.

Figure 10. The power spectrum of the vehicles' vertical acceleration induced by left-rail direction irregularities.

and vertical acceleration power spectra induced by left-rail direction irregularities. Figure 11 and Figure 12 show the lateral and vertical acceleration power spectra induced by left-rail vertical level irregularities. Figure 13 and Figure 14 show the lateral and vertical acceleration power spectra induced by right-rail vertical level irregularities. Figure 15 and Figure 16 show the lateral and vertical acceleration power spectra induced by left-rail vertical level irregularities.

By calculation, the main frequency scope of the vehicle lateral acceleration spectrum is found to be  $0.02 \text{ m}^{-1}$ – $0.05 \text{ m}^{-1}$ . According to the coherence analysis, the detrimental wavelengths include  $1/0.035 \text{ m}$ , which belong to  $0.02 \text{ m}^{-1}$ – $0.05 \text{ m}^{-1}$ . Furthermore, from Figure 10, the main frequency scope of the vehicle vertical acceleration spectrum is  $0.4 \text{ m}^{-1}$ – $0.5 \text{ m}^{-1}$ . According to the coherence analysis, the detrimental wavelengths include  $1/0.3984 \text{ m}^{-1}$ , which nearly belong to  $1/0.5 \text{ m}^{-1}$ – $1/0.4 \text{ m}^{-1}$ . The simulation results indicate that the detrimental wavelength obtained from coherence functions and from the simulation model can fit.

Figure 15. The power spectrum of the vehicles' vertical acceleration induced by right-rail vertical irregularities.

Figure 16. The power spectrum of the vehicles' lateral acceleration induced by right-rail vertical irregularities.

#### 4 CONCLUSION

The irregularities of curved lines will contribute to more intense interactions between wheels and rails. For different track irregularity types, breadths and wavelengths, the effects of track irregularities on

vehicle dynamics are different. Therefore, the effects of different track irregularity types on vehicle dynamics during motion along a curved track were studied. Based on the power spectrum analysis and coherence function theories, compared with the results of dynamic simulations, some conclusions can be drawn as follows:

1. Combining coherence function and power spectrum analysis, the random track irregularities' detrimental wavelengths can be defined.
2. In this paper, the coherent analysis between the acceleration of a vehicle at the speed of 101 km/p and track irregularities is presented. According to the analysis results, the track vertical irregularities affect the vehicle's vertical vibration significantly, and the most detrimental wavelengths are  $1/0.05078 \text{ m}^{-1}$  (20 m), and  $1/0.3984 \text{ m}^{-1}$  (2.5 m). While the track direction irregularities have a significant effect on the vehicle's lateral vibrations, the most detrimental wavelengths are  $1/0.035 \text{ m}^{-1}$  (28 m) and  $1/0.2686 \text{ m}^{-1}$  (3.72 m). The simulation results of ADAMS/Rail indicate that the defined detrimental wavelengths are dependent.
3. In response to the detrimental wavelengths described in this paper, the special track maintenance is suggested to avoid the track irregularities with the most detrimental wavelengths.

#### ACKNOWLEDGMENT

This research was partly supported by grants 20122BAB206005 and 20132BAB206001 from the Jiangxi Natural Science Foundation of China and the Science Foundation of Educational Committee of Jiangxi Province (KJLD14038).

The authors would like to thank the engineers at the respective departments of the project for their assistance during the field measurement of the test.

## Risk analysis of green building project at the decision-making stage

Wei Xu & Shanshan Liu

*Architectural and Civil Engineering Institute, Inner Mongolia University of Science and Technology,  
Baotou Inner Mongolia, China*

**ABSTRACT:** The decision-making stage is the key to success in a project. From the viewpoint of the contractor, the paper focuses on the analysis of risks before bidding decision-making in the green building project. Based on previous results and past experience, it is at the green construction decision-making stage that the effects of 13 risk factors are identified. The risks are divided into four main aspects such as owner's risk, design risk, policy risk, and management risk. Then the AHP method is used to determine the risk weights and the AHP model is constructed. The relative evaluation criteria are assigned to green buildings. By means of constructing judgment matrix the consistency check is completed. The probability of the 13 risk factors is analyzed. The results show that the risk of the design phase is a key part of influence on project decisions, followed by the owners, management, and policy. It has to be pointed out that the results can help the contractors to identify risk factors, which can be taken measures to avoid. All these provide a theory basis for the further research on risk management of green building during life cycle.

**Keywords:** green building; decision-making stage; risk management; AHP

### 1 INTRODUCTION

In recent years, with the rise of building energy consumption, building energy conservation has become the focus of the construction industry. According to estimates, building energy consumption accounted for about 40% of global energy consumption, so green architecture is the first choice. By 2015, the new green construction area will reach more than 1 billion square meters, in 2020 our country town green building accounted for the proportion of new buildings will rise to 50%<sup>[1]</sup>. Obviously, green building will become the inevitable trend of the future construction. At present, the research of the green building focus on technology evaluation, cost control, and other fields, and understanding of risk is still in the initial stage. Green buildings compared with the ordinary puts forward higher requirements on the construction system, efficient use of resources, reduce the impact on the environment, improve the living comfort, and so on. The risk of green building compared with the ordinary has expanded and changed, concrete manifestations of the expansion of the scope of the risk and the change of risk content<sup>[2]</sup>. Foreign scholars found that, the higher the performance of the building, the higher the safety risk, and the data shown LEED certified project injury rate is 9% higher than the traditional project<sup>[3]</sup>.

In order to ensure the successful promotion of China's green building, this paper based on the perspective of contractor points out the risk of

green building projects to analyze the decision-making stage. This text puts forward the concept of decision-making risk of the green building, based on the existing green building assessment system; the identification of risk factors, using the AHP method to determine the risk in weight and value. These can help the contractors identify the key risk factors of green building, and prepare to effectively cope with the risks of the green building<sup>[4]</sup>.

### 2 THE CONCEPT OF DECISION-MAKING STAGE RISK OF GREEN BUILDING

The risk refers to the uncertainty of loss. Decision-making stage risk refers to the strategic plan of the Target Corp—which is not perfect—lack of understanding of the Target Corp, and choosing the wrong acquisition targets. Green building distinguished from ordinary building is its “green” concept<sup>[5]</sup>. So the concept of decision-making stage risk of green building is: uncertain factors affecting sustainable development of the project in the decision-making stage.

### 3 THE CONCEPT OF DECISION-MAKING STAGE RISK OF GREEN BUILDING

As the green building has its own characteristics and requirements, it is faced with greater risks and higher challenges than traditional architecture,

Table 1. Identification of the decision-making risk.

Goal	Category	Subcategory	Remarks
Decision-making risk $A$	Owner's risk $B_1$	The lack of accurate estimation of the return of long-term investment on green building $b_{11}$	Through the literature
		The funding conditions and management level of owners $b_{12}$	
		Green building investment estimates are inaccurate $b_{13}$	
		The green star target location is not accurate $b_{14}$	
	Design risk $B_2$	The design did not reach the owner's goal about green building $b_{21}$	
		Green design exceeds the level of construction technology $b_{22}$	
	Policy risk $B_3$	Laws and regulations of Green building are not perfect $b_{31}$	
		The change of green building policy $b_{32}$	
		The government bureaucracy and multifarious approval process $b_{33}$	
	Management risk $B_4$	The certification standard of green building is not clear $b_{41}$	
		Without a proper understanding of the market demand for green building $b_{42}$	
		Financial institutions are lack of enthusiasm for green building $b_{43}$	
		The lack of experience in green building consultant $b_{44}$	

thus increasing management difficulty, and making the risk problem more outstanding<sup>[6]</sup>. Risk identification is to find out the possible risk in the project. Recognition method of project decision-making risk is mainly: (1) It can be through the questionnaire survey and consulting experts. (2) According to the previous occurrence of risk events, experience and analysis, statistics, and summary of events, finally obtaining the risk factors that affect the project<sup>[7]</sup>. Qin Xuan by way of a questionnaire survey identified 56 risk factors based on the life cycle of green building in the 'Risk measurement index identification and assessment for green buildings in Haixi region'. It revealed 8 common factors that were extracted to form a risk evaluation function<sup>[8]</sup>. The extracted common factors were classified into three levels: macro, middle, and micro<sup>[9]</sup>. Li Zheng Kun<sup>[10]</sup> points out that the triangle fuzzy analytic hierarchy process and fuzzy comprehensive evaluation method was adopted to calculate the fuzzy comprehensive evaluations of green building project risks, then the key risk factors were identified. This research, based on the basis of previous studies, refers to a large number of literature and carries out the analysis. It is concluded that the risk of project decision-making stage. The decision-making phase of the project risks mainly divided into owner's risk, design risk, policy risk, and risk management. The results are shown in Table 1.

#### 4 TO DETERMINE THE RISK FACTORS OF THE WEIGHTS BY AHP METHOD

##### 4.1 Build the hierarchical analysis model

According to the above results of risk identification, there are mainly 13 risk factors in the decision-making phase of the project. These risk factors are

Figure 1. A hierarchical analysis model of risk factors in the decision-making stage.

divided into four classes, so as to form a hierarchical structure. The hierarchical model is divided into three layers: the goal, the risk in the project decision-making stage, and the category. The four main aspects of the risk decision-making phase of the project are, namely, the owner risk, design risk, policy risk, and risk management. The subcategory: the 13 factors of the category, by using AHP method to establish the hierarchical structure of the risk factor analysis model, as shown in the Figure 1.

##### 4.2 Confirming the relative evaluation criteria, constructing judgment matrix

Judgment matrix is expressed in the form of matrix elements in each level relative to the importance of the upper. In order to make the comparison between various factors get quantitative judgment matrix, the introduction of 1-9 scale, as shown in Table 3, the first is the judgment matrix, the comparison matrix, according to the above principles, reference 1-9 scale settings, and according to the expert and the author's experience and references. The judgment matrix is shown in Table 2.

Table 2. Comparison matrix A-B<sub>1-4</sub>.

R	r <sub>1</sub>	r <sub>2</sub>	r <sub>3</sub>	r <sub>4</sub>
r <sub>1</sub>	1	1/3	3	4
r <sub>2</sub>	3	1	4	5
r <sub>3</sub>	1/3	1/4	1	1/2
r <sub>4</sub>	1/4	1/5	2	1

Table 3. 1-9 scale table.

Scale $a_{ij}$	Definition
1	'i' and 'j' are equally important factors
3	'i' is a little important than 'j'
5	'i' is more important than 'j'
7	'i' is very important than 'j'
9	'i' is absolutely important than 'j'
2, 4, 6, 8	The intermediate state standard value If the comparison between I and j, get the value judgment. $a_{ji} = 1/a_{ij}$ , $a_{ii} = 1$

Table 4. 'RI' value.

n	1	2	3	4	5	6	7	8	9	10	11
RI	0	0	0.58	0.90	1.12	1.24	1.32	1.41	1.45	1.49	1.51

Figure 2. Layers structure calculation results.

4.3 To calculate the maximum characteristic root of judgment matrix and its eigenvector and consistency check

Tested by the consistency index,  $CI = (\lambda_{max} - n) / (n - 1)$   $\lambda_{max}$  it is the biggest characteristic value of comparison matrix 'n' is the matrix order. The value of A is smaller, the closer to the completely consistent judgment matrix. On the contrary, the judgment matrix deviation has a greater degree.

1. For the judgment matrix A,  $\lambda_{max}^{(0)} = 4.21$ ,  $RI = 0.9$  (refer to Table 4)

$$CI = \frac{4.21 - 4}{4 - 1} = 0.07 \quad CR = \frac{CI}{RI} = \frac{0.07}{0.9} = 0.07 < 0.1$$

The extent of the inconsistency of A within the allowable range features vector of A instead of weight vector.

Similarly, through the consistency check on the above principle, the hierarchy drawn from the goal to calculate the factor level is shown in Figure 2.

5 ANALYSIS OF TEST RESULTS

Based on the risk identification and assessment of green building on the decision-making stage, use the AHP to establish the risk quantification model. Based on the comprehensive analysis of the probability of occurrence and harm degree of risk, the importance of risk ranking is realized and the following conclusions are drawn:

1. Project decision stage risk mainly includes the owner's risk, design risk, policy risk, and management risk. Their probability is respectively: 0.272, 0.522, 0.091, and 0.116. That is: design risk > owner's risk > management risk > policy risk. The above shows that in the green building design, there is a key part of the decision-making stage of green building project.
2. The above calculation shows that the owner's risk is mainly the lack of accurate estimation of the return of long-term investment on green building. Design risk is mainly designed to exceed the level of construction technology. Policy risk is mainly green building-related policies and laws are imperfect, risk management is the main financial institutions lack of enthusiasm.
3. The 13 risk factors of green building decision stage, the risk factors affecting the decision-making stage of the occurrence probability and importance: 'Green design exceeds the level of construction technology' > 'The lack of accurate estimation of the return of long-term investment on green building' > 'The design did not reach the owner's goal about green building' > 'The funding conditions and management level of owners' > 'The lack of experience in green building consultant' > 'laws and regulations of Green building are not perfect' > 'Green building investment estimates are inaccurate' > 'The change of green building policy' > 'Financial institutions are lack of enthusiasm for green building' > 'The green star target location is not accurate' > 'The certification standard of green building is not clear' > 'The government bureaucracy and multifarious approval process' > 'Without a proper understanding of the market demand for green building'.

The above results show that: first of all, the owners play an important role in the project decision-making stage, the employer and the contractor of the communication barriers are the root

of the risk, and it will inevitably lead to inconsistent target owners and design target and a series of problems. Second, the policy and the market does not have an accurate grasp, which is a major cause for the green building to cause the error in the decision-making stage. Green buildings, compared to ordinary buildings, have more requirements and market demand, there must be a strict regulation, the policy and the market does not have an accurate grasp, there will be some problems, such as investment estimation is not accurate, cumbersome approval and financing.

## 6 CONCLUSION

Based on the life cycle perspective, green building project's decision-making stage is the key to the success of the project phase, based on the AHP method to analyze the green risk of construction project decision-making stage, which sets up the risk evaluation index system and the risk assessment model of green building. It is concluded that the key risk factors are in the project decision-making stage. The results of the study for the project are to provide a theoretical basis for effective risk management. For the contractor, it is necessary to strengthen the owners understanding, including their funds, credit, and related qualification. So as to reduce the risk of the owners, the contractor should learn from past experience, a correct understanding of the objective demand of the market, grasp the market demand, improve the ability of investment estimation, to reduce the risk of investment, learning green building related laws, regulations, the approval process, etc. Hope that these measures help decision-makers to

identify risk factors for decision-making stage and reduce risk.

# Research on collaborative design application based on BIM

Wei Xu & Yuandong Liu

Architectural and Civil Engineering Institute, Inner Mongolia University of Science and Technology,  
Baotou Inner Mongolia, China

**ABSTRACT:** It is difficult to meet the design requirements of large and complex projects by means of the traditional design mode. The design organization makes use of cooperative design based on BIM. In this way, there are many obstacles in the process of implementation. This paper is concerned with the analysis of the main content of obstacle in the process of BIM based collaborative. The emphasis of this study lies in summarizing 3D collaborative design method under the BIM mode. The major object of their further work will be research into the path of collaborative design based on BIM. The procedure they followed can be briefly described as five steps such as specified target, team organizing, execution plan, specified collaborative platform, and the implementation of the collaborative design. As can be seen from the barriers reduced, the accurate and efficient BIM model of collaborative design will gradually replace the single linear traditional model.

**Keywords:** BIM, cooperative work, collaborative design, collaborative work platform

## 1 THE DEFINITION OF BIM AND COLLABORATIVE DESIGN

### 1.1 *The definition and characteristics of BIM*

Building information model also referred as BIM (Building information Modeling) as a concept was first introduced into the building construction industry in the 1970s. So far, there is no concluded definition for BIM regionally or internationally. USA BIM National Committee defines BIM as a digital expression of the physical characteristics and features of facilities. Hong Kong Polytech University and Tsinghua University BIM team defines BIM as a system based on the digital technology and visualization technology, method of information integration and management of construction project life cycle.

Although the above definitions are distinct, it is widely acknowledged that the essence of BIM is an emerging information technology application in the field of construction engineering. BIM (building information model) is based on the most advanced 3D design and engineering software build “visualization” digital building model. It provides collaborative design platform of “simulation and analysis” for construction project staff and uses the 3D model design, construction, and operation management of the project<sup>[1]</sup>. BIM has the following characteristics:

1. Visualization: BIM can achieve real-time visualization in the whole life cycle of the project

construction, each stage includes a project entity by way of three-dimensional modeling. This is the most fundamental characteristics of BIM.

2. Integration: In the integrated information of BIM established model, it not only includes the form of construction project space and related basic information but also other relevant information in the whole life cycle of projects.
3. Coordination: BIM can coordinate collision problem between all the professional designs in the early stage of the project, and generate coordinate data of available submission. This helps the participants of construction project to coordinate the problem of project.

### 1.2 *Collaborative design based on BIM*

Collaborative design is done through the coordination of different individuals and platforms. Collaborative design is a method of design communication to optimize the final design goal. With the raging concept of green energy-saving and sustainability, it requests people to constantly adapt their design to the requirement of construction. Now a project design not only includes planning, building, structure, HVAC, water supply and drainage, electrical, power, also contains rack, steel structure, intelligence, landscape, etc<sup>[2]</sup>. Collaborative design is not only a simple file reference. The traditional collaborative design system which based on two-dimensional plane visualization is no longer flexible to the project running.

Collaborative design based on BIM breaking “information island” of the traditional design mode, sharing project information to all members of the professional design, replacing the traditional single linear working mode, improving the efficiency of design<sup>[3]</sup>. The essence of collaborative design which is based on BIM has various professional work together under the same model. This way is a special concept which is completely different from construction drawing CAD. This way of design not only meets the current architectural design project requirements of professional collaboration, but also helps to coordinate communication among the design units and construction units. Design unit can be combined BIM technology and collaborative design and provides collaborative work platform that does not exist in the traditional design pattern for the professional design. Each professional design uses this platform to share the design results, collision check and crossover design so that the purpose of improving the design precision and optimization design is achieved.

## 2 COLLABORATIVE DESIGN BASED ON BIM SOLVE THE OBSTACLES

### 2.1 *The influence of the traditional thinking model*

In the traditional thinking of the architectural design, various professional designer works are independent: Architectural design ahead, structural design second, mechanical and electrical equipment design at last. The design process and working mode based on the traditional thinking seriously restricted the implementation of collaborative design.

Designers have resentment of the collaborative design based on BIM, mainly because it has been to use their familiar tools to express the design ideas. Compared with the methods of 3D building information and two-dimensional, there are certain shortcomings. For example, there are some blind areas in display<sup>[4]</sup>. Learning BIM will consume part of designer’s energy, which affects the design personnel individual or design unit interest within a certain period.

In addition, the project managers have a certain resentment of the collaborative design based on BIM. Although the long term, the design of enterprises from the traditional design pattern to the collaborative design mode transition is based on BIM which can greatly improve work efficiency, save unnecessary costs, get a lot of money income. But the enterprise will be affected in the short-term interests. What is more worried about using BIM technology is to change design mode and

management mode, which may eventually lead to the failure of the project.

### 2.2 *BIM software support functions less*

Project personnel involved in BIM is common feelings of most of the BIM-related software applications not like the long traditional software meeting the engineering requirements in the process of collaborative design based on BIM. Block collaborative design implementation based on BIM has two main problems:

#### 1. BIM model diagram unable to meet the project specification requirements

Although the mainstream BIM core modeling software is based on the BIM model output 2D drawings, these softwares are all foreign products<sup>[5]</sup>. The expression and the details from the BIM model output of the horizontal and vertical part information section drawings of two dimensions is not consistent with requirements of our country projects, resulting in two-dimensional drawings BIM export cannot be directly applied to the project. So design units in China are often not only with the BIM output of 2D drawings but also to the BIM output of the secondary processing using of traditional software, wasting unnecessary manpower, reducing the efficiency.

#### 2. Information flow between the software

Although associated with BIM software variety, there was no software on the market today that can simultaneously satisfy all the necessary functions of the BIM design projects. Therefore, BIM design project generally needs to be applied to multiple softwares through which the information flow between software transfers becomes the key factor of collaborative design<sup>[6]</sup>. Now, however, almost the import or export of all across software platform model can result in the loss of information. This greatly affected project implementation with collaborative design based on BIM. Many domestic software vendors are used for traditional BIM software and professional software, but it is difficult to completely solve the problem of poor information flow between BIM software in a short period of time. So, BIM design will be mainly used in local projects, local specialty, and the local process in the future transition period<sup>[7]</sup>.

## 3 THE PROMOTION OF COLLABORATIVE DESIGN BASED ON BIM

The promotion of collaborative design based on BIM have different kinds of obstacles. This paper

mainly research on the approach of promoting collaborative design based on BIM, also touches on its application in the design industry.

### 3.1 Specify the BIM object

Specifying the BIM object is to clarify the results of project achieved by using BIM technology, which is the core of project implementation of BIM. According to the project using BIM technology in different stages, the main object is not the same. In the design stage, the main goal of BIM is to realize the collaborative design. The main way of application has demonstration project, design modeling, and 3D coordination.

### 3.2 Headings

The BIM design team constitutes by BIM manager, BIM engineer, BIM coordinator, and BIM modeler according to their role played in the whole process. The responsibilities of these four positions are shown in Figure 1.

BIM manager as the most important role must have a thorough understanding of the entire design process, from concept design to design documentation to contract administration. Certain knowledge of project management is also required in order to specify the plan, management team, the implementation of the monitoring plan, etc. In addition, BIM manager bears the responsibility of communicating with clients and understand their intention, and inform the client if BIM technology can be potentially helpful to achieve their requirements over the proposal.

BIM coordinator is to assist the communication between BIM manager and BIM designers. BIM manager is very scarce talent in BIM project, in general, who will be responsible for multiple projects at the same time. Therefore, the BIM managers do not devote themselves into one single BIM project. The main duty of the BIM coordinator is to assist BIM manager in their work, including the specified implementation plan and supervise the work process. In addition to this work, the BIM coordinator is also responsible for building collaborative work platform and managing coordination model of BIM component library.

Figure 1. BIM design team responsibilities.

Apart from BIM manager and BIM coordinator, a BIM project team also includes multiple experienced BIM designer and BIM modeler who specialized in using the BIM software. BIM designer or engineer is mainly divided into three professional of construction, structure, electrical, and mechanical. BIM engineers of different professional each lead a BIM modeling team composed of the professional BIM modeler. BIM engineer is responsible for arranging the specific work for the professional staff in BIM modeler and coordinate with problems of the professional team in the process of BIM modeling.

### 3.3 Specify the BIM implementation plan

Compared with the common design approach, the collaborative design based on BIM demands high hardware and more resources. Therefore, design units accept the commission of the BIM projects and determine the BIM target, giving full consideration to the project and the design team, forecast problems may arise in project, forecasting feasible implementation plan. BIM implementation plan of construction project should include the project information, application goal, the specific content of the work mode, and resource requirements.

### 3.4 Building of BIM collaboration platform

Building of BIM collaboration platform is the foundation of collaborative design used in BIM technology in construction projects. First, by combining the design personnel information with the related construction project information. Second, based on the personnel related information, aim to determining the project BIM model split principle, detail and delivery standards. Finally create essential project template and share coordinates and folders in the collaborative work platform. Collaborative work platform to realize the collaborative design based on BIM among different professions, its core is to achieve a smooth information exchange process between different professional deliveries (Fig. 2).

In addition to realize the seamless exchanged transfer process between different professional BIM model information, the collaborative work platform has another function that is to achieve comprehensive and efficient management information which includes information management and personnel management.

Information management includes two aspects of information sharing and information security. A BIM model file storage space is far more than an ordinary CAD file. As a unified platform of collaborative work platform for the professional work together, which meets the characteristics of

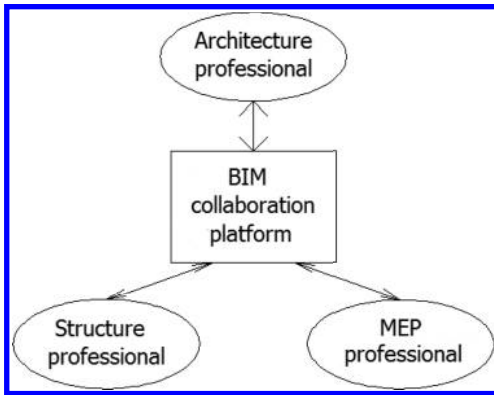

Figure 2. The professional relationship in the BIM collaborative design.

producing a large number of data transmission and improve the design efficiency, realize the sharing of information. Meanwhile, the collaborative work platform as a unified platform to ensure the information security of BIM project. The BIM project contains related information of core technology.

In personnel management, the designers need their own user name, log into collaborative work platform, and have their own working set and corresponding operation permissions. Such a clear division of responsibilities, the responsibility to the people promote the smooth implementation of the plan in accordance with the implementation of BIM project.

### 3.5 Implementation process of the BIM project collaborative design

Collaborative design includes two kinds of collaborative design of the same professional within and different professional. The former is the professional design personnel in the respective model collaborative conflict in place, the latter is the professional person in charge of collaborative models in conflict between the professional.

The structure and mechanical and electrical professional to start drawing at this stage, first the construction of the professional establish their own center files, second the structure and the electrical professional establish the professional file center through building professional established construction center files. Professional internal divided by the working set, professionals with links manner. After major changes from 2D to 3D, eventually reaching a full professional BIM collaborative design stage that is truly collaborative design by the complex transition cooperation.

## 4 CONCLUSION

Along with the social development, the large and complex projects increase gradually. The traditional design methods have been approved gradually losing its capability to meet the design requirements. Collaborative design based on BIM changed the single linear model of the traditional cooperated work, which meets the construction design should achieve the high standard requirements. But there are many obstacles in the implementation process. In this paper, putting forward the paths in the design units through studying the implementation barriers of collaborative design based on BIM. It contains five steps of the choice of target, the work team, execution plan, collaborative work platform construction, and the collaborative design process implement. This allows the designers to be able to working and communicating with contractors on the same platform, thus achieving the cross collaboration design which both sides can have a correct and instant understanding of the division of labor resource. With BIM technology development, the application obstacles of collaborative design based on BIM will reduce gradually. Eventually BIM platform will become a trend in the construction, which will lead to the change of design industry.

# Experimental study on smoke propagation in titled underground tunnel fires

J.M. Li, Z.H. Huang & C. Chen

*Beijing University of Technology, Beijing, China*

J. Chuang & Y. Li

*Beijing General Municipal Engineering Design and Research Institute Co. Ltd., Beijing, China*

**ABSTRACT:** Fire safety in tunnels is a concern due to the large traffic flow, especially in a tunnel with a great slope. Experimental studies on the smoke spread in a small-scale titled tunnel are carried out. Effects of the titled gradients and longitudinal ventilation speed on the temperature distribution and smoke stratification downstream from the fire along the tunnel will be studied. The results show that the smoke spread upwards much faster with the slope gradient increasing, and a thick smoke layer was formed when smoke moved to the upward part of the tunnel and filled it up. The ventilation speed had a great influence on temperature distribution along the tunnel. Lower ventilation speed should be kept at the start of the fire to ensure the smoke layer not be destroyed downstream of the fire to give the tunnel users more time to escape.

**Keywords:** underground tunnel; reduced-scale model; smoke spread; fire

## 1 INTRODUCTION

In order to mitigate the traffic congestion problems, more and more urban tunnels have been and will be constructed due to the heavy traffic in dense urban areas in China in recent years. Comparing with other kinds of tunnels, traffic in urban tunnels may have larger traffic volumes due to its special site. Fire accidents may occur due to the collision of the cars, the engine overheating, the mechanical or electrical failure, etc. Fire safety in these kinds of tunnels is becoming a major issue following the catastrophic losses experienced in the Mont Blanc tunnel fire in 1999 and the Gotthard tunnel fire in 2001. Consequences of a tunnel fire can be very serious, which might lead to tragic injuries and fatalities, considerable infrastructural damage, loss of income due to the breakdown in operation and loss of public confidence in the use of road tunnels. Due to the confined conditions, such fires can be more severe, in terms of rate of growth and temperature, than that in the open field<sup>[1,2]</sup>.

To assess the hazards arising from tunnel fires and draw some effective mitigation strategies, fully understand the smoke and heat propagation in tunnels is necessary. Knowledge about smoke and fire spread in tunnels has generally been obtained from large scale testing. However, sometimes large scale testing is expensive, time consuming and

logistically complicated to perform. The information obtained is often incomplete due to the limited number of tests and the limited instrumentation. Reduced-scale tests can be used as a complement to large scale testing. They can provide information which is difficult to obtain otherwise as their relatively low cost allows for parameter studies<sup>[3,4]</sup>.

The urban tunnel always having slopes comparing with other kinds of tunnels, and the slope would influence the smoke spread greatly due to the stack effect. Although there were a lot of works having been done on studying the smoke spread in tilted tunnels by experimental or numerical methods<sup>[5-8]</sup>, smoke movement pattern in these kind of tilted tunnels is not fully understood, further studies are needed<sup>[9]</sup>.

## 2 REDUCED-SCALE MODEL EXPERIMENT

A 1/6 scale tunnel model with rectangular cross section was constructed by the fire glasses boards, and the model tunnel itself is 6 m long, 1.5 m wide, and 1.3 m high, as shown in [Figure 1](#). Similarity rules impose a strict conservation of Froude number so that, for a geometrical reduction factor  $\alpha$ , velocities are given in the scale  $\alpha^{1/2}$  and both flow rates and heat release rates are scaled according to  $\alpha^{5/2}$ <sup>[10]</sup>.

Figure 1. Reduced-scale model tunnel.

Figure 2. Distribution of the thermocouples.

Different titled gradients of 0, 3% and 5% were built by raising the one end of the model tunnel. Smoke spread in these three tunnels would be studied respectively.

Longitudinal ventilation was achieved by driving inlet air flow by a fan at one end. The rotational speed, and thereby the capacity, could be controlled using an electrical device coupled to the motor. Longitudinal ventilation velocities of 0 m/s, 0.6 m/s, 0.9 m/s and 1.2 m/s are used in the test series.

The fire source was a 0.3 m × 0.3 m (L × W) porous bed burner with its top surface set flush with the tunnel floor, LPG was used as fuel, metered through a rotameter. Fire sizes of 57 kW was produced by changing the flow rate of the LPG respectively in the experiments, these fire sizes correspond to fires of approximately 5 MW when the scaling procedure was applied. They thus represent typical vehicle fire sizes in urban traffic tunnel<sup>[11]</sup>. The burner is located at the center of the tunnel, 0.3 m away from the tunnel entrance.

Thermocouple trees (K-type) distributions in longitudinal direction along the tunnel were shown in Figure 3, and vertical distributions of thermocouples in one thermocouple tree were also shown in Figure 2, measuring the temperatures at the relative positions.

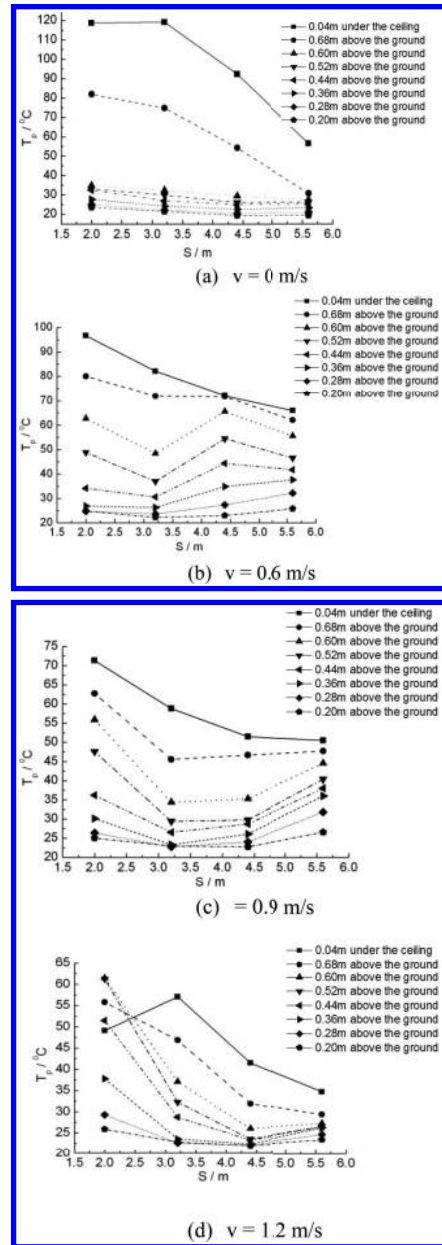

Figure 3. Temperature distributions along the tunnel under different longitudinal ventilation velocities (level tunnel).

### 3 RESULTS AND DISCUSSION

Vertical temperature distributions at different height above the tunnel floor at the center-line of the tunnel and longitudinal temperature distributions along the tunnel under different

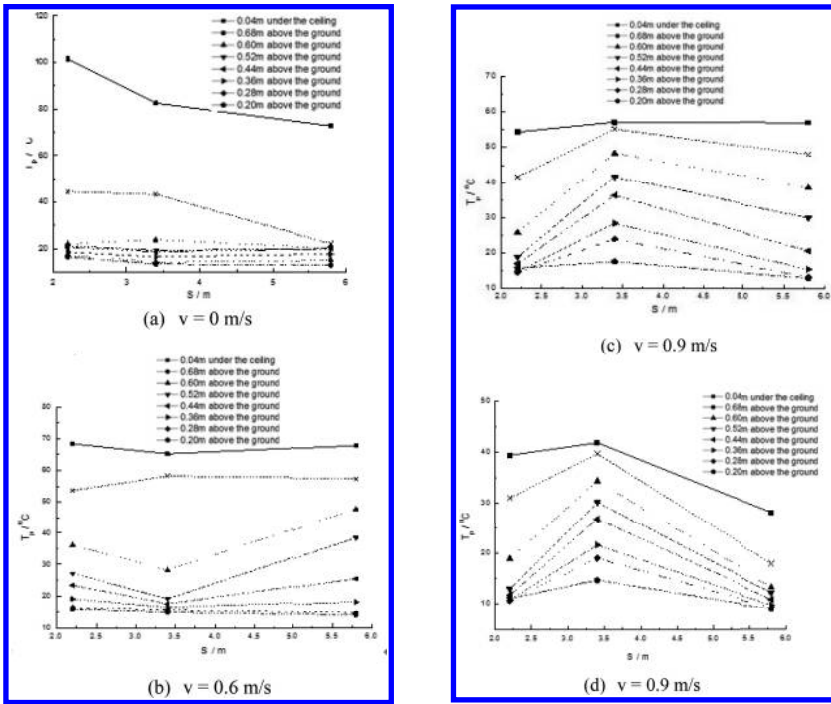

Figure 4. Temperature distributions along the tunnel under different longitudinal ventilation velocities (tunnel slope = 3%).

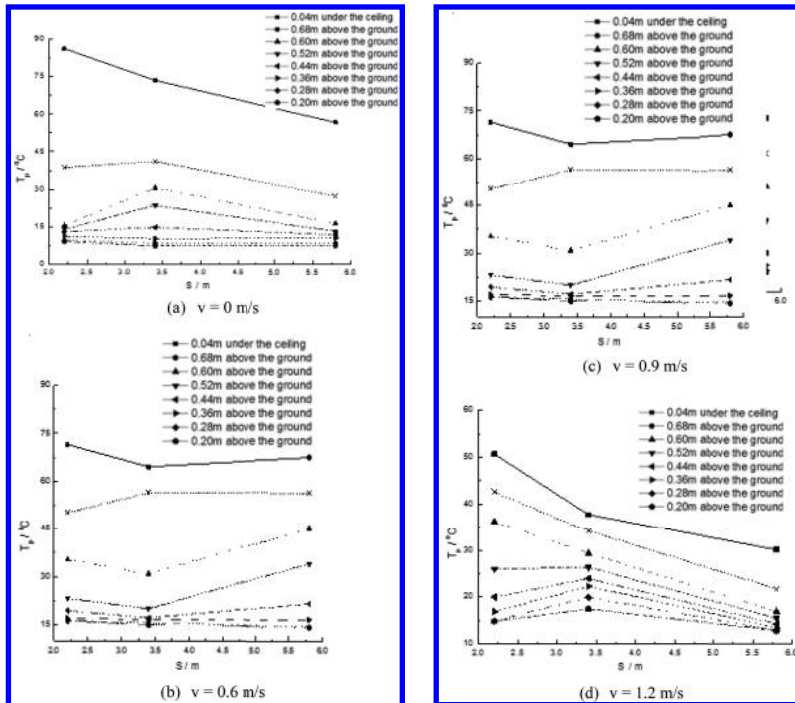

Figure 5. Temperature distributions along the tunnel under different longitudinal ventilation velocities (tunnel slope = 5%).

longitudinal ventilation velocities and different inclined gradient for fire size of 60 kW were shown in Figure 3, 4 and 5 respectively. It can be found that the temperature of the smoke is higher at the zone close to the fire source, and it will be cooling down when it propagates along the tunnel due to the combined effects of the convective heat exchange with walls and mixing between the smoke the fresh air layer. The smoke stratification is found clearly along the tunnel with no ventilation. With the longitudinal ventilation speed increasing, temperature at the higher position above the tunnel floor would decrease due to the flame deflected by the wind, hot smoke will spread at the lower level, this lead to the longitudinal temperature gradients become small, and temperature at the zone far away from the fire source would increase. At the mean time, the vertical temperature gradients were also found to be reduced along the tunnel, and this means that the stratified smoke would be disturbed. This might be dangerous for the tunnel users at downstream of the fire, they need to pass through the hot smoke layer to escape from the tunnel. With the gradient of the slop becoming large, higher temperature would be found at the downstream from the fire, another factor the main factor to hot smoke is found to spread much faster to the top exit than that in the level tunnel. This might be dangerous for the occupant's evacuation.

### 3 CONCLUSION

The smoke spread in a titled tunnel with different titled gradients under different longitudinal velocity is studied by the reduced-scale model test in this paper. The results show that hot smoke spread much faster to the top exit due to the stack effect in a titled tunnel than in the level one, and a thick smoke layer is formed when smoke moved to the upward part of the tunnel and filled it up. This will be dangerous for the occupant's escaping. Some special smoke control measures should be taken when the fire occurs in a tunnel with slope. The ventilation speed is found to have a great influence on temperature distribution along the tunnel, maximum temperature in tunnel due to the fire would be reduced, and the smoke stratification would be distributed when the longitudinal ventilation speed becomes large. Lower ventilation speed should be adopted at the beginning to ensure the smoke

downstream of the fire keep stratified to give the tunnel users more time to escape. The results might be useful for the smoke control design and operation in these kinds of tunnels.

# Joint operation of water quantity and water quality based on dualistic water cycle

J. He, S.P. Gu & L.S. Suo

Hohai University, Nanjing, China

**ABSTRACT:** With the rapid development of China's economy, water shortage and pollution are serious in many river basins. Water storage projects have the potential to simultaneously improve the water supply guarantee and protect the water's environment. In this paper, the degree of water supply guarantee and the degree that standard water quality reaches are defined. Based on dualistic water cycle framework, the hydrological model and the water supply system are integrated. Then multi-objective optimization model for water quantity and quality in River Basin is established. An example proved that water supply indicators and water quality indicators significantly improved. The rationality and validity of the model can be verified. The model provides an effective way to reduce water shortage and water quality deterioration in river basin.

**Keywords:** water quantity and quality; operations optimization; river basin; dualistic water cycle

## 1 INTRODUCTION

With the rapid development of China's economy and urbanization, water shortage and water pollution is becoming more and more serious. Water quality of many rivers is worse than Class III. On one hand, this is due to natural factors, such as the large difference between the space-time distributions. On the other hand, multi-objective optimization of water projects is absent for water quantity and quality. The basic idea of this paper is to integrate precipitation, runoff, water supply, consume, return, and projects operation. Thus, the joint operation optimization model of water quantity and quality is established. The ideas considered are as follows: a) based on dualistic water cycle system on natural and artificial rules, nature, society, economy, and environment factors are combined into an organic system; b) by defining the guarantee degree of water supply and then reaching degree of water quality standard, an optimization model is established. It is more reasonable than ever to avoid results that depart from the actual.

## 2 SYSTEM DESIGN BASED ON DUALISTIC WATER CYCLE

### 2.1 Basic dualistic water cycle framework

Under modern conditions, large-scale human activities cause hydrological cycles showing a significant Natural-Artificial duality (Wang, H. et al. 2006). The first is duality of cyclic nature, which

means the water cycle of human community often involves the natural cycle and artificial cycle to maintain dynamic relations between the two cycles; the second is dual function of water services, which means water, in its conversion process, supports socio-economic system and ecological systems (Wang, H. et al. 2010).

According to the theory of dual water cycle, the basin water resource allocation is based on mutual coupling of natural water production and social water use. Natural water circulation describes the process from slope to the river, social circulation focuses on water regulation, supply, use, and drainage. It means the joint operation optimization models of water quantity and water quality include hydrological model, water quality model, simulation model of project operation, and optimization model.

Hydrological model calculates evapotranspiration and runoff from precipitation in each sub-basin and gets the export flow of each sub-basin. The export water of each sub-basin enters downstream of the river or enters a reservoir if there is a project at sub-basin export. According to water user location, the water is allocated to the right place for human living use, industrial use, agricultural use, and ecological use. The dualistic water cycle system of a river basin is shown in [Figure 1](#).

### 2.2 Basic unit definition and system design

Natural water cycle model calculates runoff from precipitation every 24 hours. So large basins should be divided into several sub-basins according to the

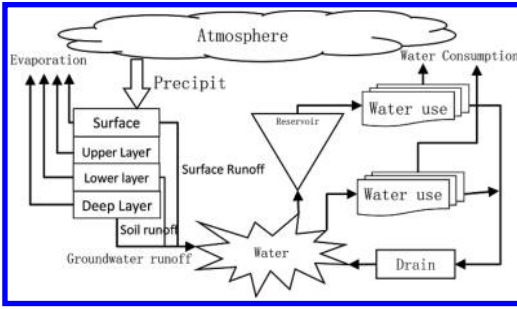

Figure 1. Dualistic water cycle system of a river basin.

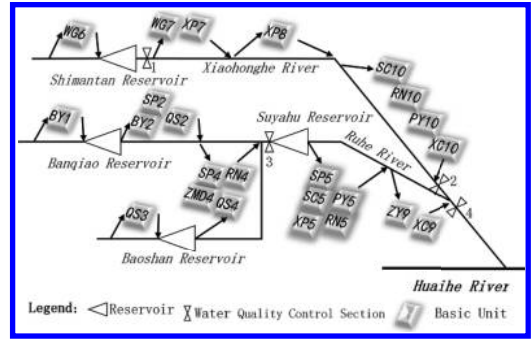

Figure 3. Topological relation of the system.

Figure 2. The definition of the basic unit.

hydrological model. Since artificial collateral cycle focuses on water demand and uses each period, the basin is divided into several user partitions according to administrative districts. To solve inconsistent time and space scales of natural cycle and artificial cycle, the basic unit is defined as numbered polygons, made by overlaying administrative region layer on sub-basin layer by GIS software. An example is shown in Figure 2 in section 4.

This method has obvious advantages. Each basic unit can completely belong to a particular sub-basin or user district to facilitate decomposition and polymerization. It is the smallest independent area producing and consuming water inside. It also exports or imports water. It keeps integrity and independence to facilitate description of the relationship between multiple water sources and multiple users. The topological relations between sub-basins for producing water, project for storing water, and user districts for consuming water are convenient to be established. It is the foundation of the joint operation optimization model for water quantity and quality.

### 2.3 Topological relations of the system

Based on the definition of the basic unit, topological relations between water producing, water project operation, water supply, water return, and

sewage discharge can be determined. The example of topological relations can be seen in Figure 3 in section 4. According to Figure 3, the system can be simulated stepwise from upstream to downstream.

## 3 WATER QUANTITY AND QUALITY JOINT OPERATION OPTIMIZATION MODEL

### 3.1 Water quality model determination

Because of too many water quality indicators, the optimization model is impossible to control all indicators. Since concentration of various pollutants generally being associated, so long as key indicators are controlled, other indicators will be synchronized to be improved. According to the characteristics of river water quality, select  $COD_{Mn}$  as the representative of the pollution index (Liu, Y.N. et al. 2009). The purpose of the model is to find out optimization strategy in the statistical sense to control the average annual concentration of pollution, so steady-state one-dimensional river water quality model is appropriate to calculate pollutant concentration along river.

### 3.2 Objective functions

#### 3.2.1 Guarantee degree of water quantity

If guaranteed water amount (Zhang, S.P. et al. 2014) or probability is selected as objective function of the model, maybe water shortage in a number of unit period is too large but not distinguishable. The certain periods sacrifice to save water to benefit other periods. But even small number of period with large water shortage rate is unacceptable in the actual. To overcome these problems, the relative water shortage rate is better for objective function. This paper defines guarantee degree of water quantity as key indicator. The guarantee degree of water quantity equals to ratio

of water supply and water demand, and equals to 1—water shortage rate. It is the basis of the objective function. The objective function of water quantity is average of the minimum guarantee degree each year. See Equation 1.

$$\max_G S(G) = \frac{1}{Y} \sum_{y=1}^Y \left( \min_{t \in [1, T]} \frac{\sum_i \sum_j \sum_k G_{kij}^{(t)}}{\sum_i \sum_j X_{ij}^{(t)}} \right)^{(y)} \quad (1)$$

where,  $y$  = the year number, ranging 1 to  $Y$ ,  $Y$  = the number of years;  $t$  = period number in a year, ranging 1 to  $T$ ,  $T$  = the number of periods;  $k$  = the reservoir number;  $i$  = unit number;  $j$  = the department number of water use, including living use, production use, and ecological use;  $G_{kij}^{(t)}$  = water supply of project  $k$  to department  $j$ , unit  $i$ ;  $G$  = the plan  $\{G_{kij}^{(t)}\}$  constituted by  $G_{kij}^{(t)}$ ;  $X_{ij}^{(t)}$  = water demand of department  $j$ , unit  $i$ ;  $S(G)$  = average of minimum guarantee degree each year.

Equation 1 fits to situation of small water shortage, focusing on controlling the maximum water shortage rate. In situation of big water shortage, it is appropriate to control the average guarantee degree in place of the minimum each year. In addition, arithmetic mean cannot restrict very low guarantee degree appearing because of linear relationship, nonlinear geometric mean is better. The objective function is Equation 2.

$$\max_G S(G) = \frac{1}{Y} \sum_{y=1}^Y \left( \sqrt[T]{\prod_{t=1}^T \frac{\sum_i \sum_j \sum_k G_{kij}^{(t)}}{\sum_i \sum_j X_{ij}^{(t)}}} \right)^{(y)} \quad (2)$$

### 3.2.2 Reaching standard degree of water quality

The water quality optimization means to make use of water storage capacity of projects to improve the water quality along river. If the improvement of water quality level is set as high as possible (Liu, B.J. et al. 2009), or it is only controlled by constrains (Shao, D.G. et al. 2000), will result in depletion of all water supply capacity. It is unacceptable. Relative indicator seems reasonable (Zhang, Y.Y. et al. 2010). Therefore, this paper defines reaching standard degree as the index of how close is water quality indicator to certain standard (such as Class III standard), see Equation 3.

$$\varphi_{il} = \begin{cases} \frac{\mu_l^*}{x_{il}(G)} & x_{il}(G) > \mu_l^* \\ 1 & x_{il}(G) \leq \mu_l^* \end{cases} \quad (3)$$

where,  $G$  = the plan  $\{G_{kij}^{(t)}\}$ , same as Equation 1;  $x_{il}(G)$  = COD<sub>Mn</sub> concentration in period  $t$  at river section  $l$ ;  $\mu_l^*$  = water quality standard, namely,

COD<sub>Mn</sub> concentration of class III water standard at  $l$  river section;  $\varphi_{il}$  = reaching standard degree of water quality in period  $t$  at river section  $l$ .

This definition facilitates the flexibility to choose right target standard in accordance with local requirements or water functional division standard, so as to effectively guide the behavior of water resources management. The objective function is defined to control the closeness to standard in each river section and each period. Take the geometric mean to raise the low end value. Assumed the standard is level of class III water COD<sub>Mn</sub>, water quality objective function see Equation 4.

$$\max \Phi(G) = \frac{1}{Y} \sum_{y=1}^Y \left( \sqrt[T]{\prod_{t=1}^T \left( \frac{1}{L} \sum_{l=1}^L \varphi_{il} \right)} \right)^{(y)} \quad (4)$$

where,  $\Phi(G)$  = multi-year average of reaching standard degree of water quality.

### 3.3 Main constraints

Main constraints of the model are relationship of decomposition and polymerization. The first is the water balance between water projects and their subordinate units, see equation 5; the second is water balance between sub-basin and its subordinate units, see equation 6; the third is the water balance between water user district and its subordinate units, see equation 7.

$$V_{k,t+1} = V_{k,t} + I_{k,t} - \sum_{i \in I_k} G_{i,t} - O_{k,t} - S_{k,t} \quad (5)$$

where,  $I_k$  = members of units controlled by project  $k$ ;  $V_{k,t}$  = project  $k$  beginning storage capacity in period  $t$ ;  $V_{k,t+1}$  = project  $k$  end storage capacity in period  $t$ ;  $I_{k,t}$  = project  $k$  inflow in period  $t$ ;  $O_{k,t}$  = project  $k$  abandon water in period  $t$ ;  $G_{i,t}$  = project  $k$  supply unit  $i$  water including living use, production use, and ecological use in period  $t$ ;  $S_{k,t}$  = project  $k$  loss of water with evaporation and infiltration in period  $t$ .

$$R_{b,t} + U_{b-1,t} - \sum_{i \in I_b} G_{i,t} + D_{b,t} = U_{b,t} \quad (6)$$

where,  $I_b$  = members of units in sub-basin  $b$ ;  $R_{b,t}$  = sub-basin  $b$  production of water in period  $t$ ;  $U_{b-1,t}$  = sub-basin  $b$  import water from upstream sub-basin  $b - 1$  in period  $t$ ;  $G_{i,t}$  = sub-basin  $b$  supply unit  $i$  water in period  $t$ ;  $D_{b,t}$  = sub-basin  $b$  return water from user in period  $t$ ;  $U_{b,t}$  = sub-basin  $b$  export water to downstream in period  $t$ .

$$\sum_{i \in I_c} L_{i,t} + \sum_{i \in I_c} A_{i,t} = \sum_{i \in I_c} D_{i,t} + \sum_{i \in I_c} E_{i,t} \quad (7)$$

Table 1. Optimization solutions comparison.

Solutions	Water supply	Ave* GD**	Min GD**	COD <sub>Mn</sub>	RSD***
	10 <sup>6</sup> m <sup>3</sup>			mg/l	
Basic solution	1215	99%	91%	25.6	44.5%
Opt.Solution 1 (Recommend)	1212	99%	98%	19.6	54.5%
Opt.Solution 2	1211	99%	96%	19.5	54.5%

\*Ave = Average; \*\*GD = Guarantee Degree; \*\*\*RSD = Reaching Standard Degree.

where,  $I_c$  = members of units in district  $c$ ;  $L_{i,t}$  = unit  $i$  receiving water in period  $t$ ;  $A_{i,t}$  = unit  $i$  using water locally in period  $t$ ;  $E_{i,t}$  = unit  $i$  consumption of water in period  $t$ ;  $D_{i,t}$  = unit  $i$  getting return water in period  $t$ .

## 4 EXAMPLE OF THE MODEL

### 4.1 Introduction and definition of basic unit

Hongruhe River is a tributary of Huaihe River in east China. It is composed of Xiaohonghe River and Ruhe River. In this paper, research area is the basin of Bantai watershed, area 11,280 km<sup>2</sup>. There are 4 large reservoirs in the basin, named Shimantan Reservoir, Banqiao Reservoir, Baoshan Reservoir, and Suyahu Reservoir. The area involves a total of 11 county-level administrative regions, and is also made of 10 sub-basins to produce water. The definition of basic unit is shown in Figure 2. Whole area is divided into 24 units, encoded as BY1, BY2, etc. The letters portion represents county-class area. The digital portion represents sub-basin code. For example, the sub-basin numbered as 7 decomposed to WG7 and XP7. The region named as WG can be decomposed to WG6 and WG7.

### 4.2 Topological relationship

Based on dualistic water cycle in the basin, the system topological relationship is shown in Figure 3. The river control sections of water quality numbers 1 to 4, correspond to Shimantan section, Xincui section, Xiatus section, and Bantai section.

### 4.3 Data and calculation

According to the joint optimization model of water quantity and quality, input the precipitation data, runoff data, sewage discharge data (1997–2006), and water demand data of the planning year (2030). The average of annual water demand is 1227 million m<sup>3</sup>. Non-optimization calculations results are basic indicators for comparing. Operation rules of prioritize order is living

water, ecological water, industrial water, agricultural water, and each part have different water consumption rate. Non-optimization results show that water shortage mainly exists in Xiaohong River valley. Due to the lack of reservoir capacity, the minimum Guarantee Degree is low by 65.7%.

### 4.4 Results and solutions

In order to solve the model, multi-objective particle swarm optimizer is designed. The program running results prove that water quantity and quality indicators are better than non-optimization results in each reservoir control areas. Two typical Pareto solutions are compared in Table 1.

Solution 1 greatly enhances the minimum monthly guarantee degree; it increased from 65.7% to 91.6%. The maximum water shortage rate decreased from 34.3% down to 8.4%. In all water quality control sections, average COD<sub>Mn</sub> concentration decreased from 25.6 mg/l to 19.6 mg/l. The reaching standard degree to Class III increased by 10%.

In comparison, solution 1 and solution 2 both ensure average guarantee degree to 99%, meantime COD<sub>Mn</sub> of solution 2 is 19.5 mg/l, little less than solution 1, almost the same. But the minimum monthly guarantee degree is 96%, less than 98% of solution 1. In summary, we recommend solution 1.

### 4.5 Evaluation

The example illustrates that the joint operation optimization model of water quantity and quality can greatly enhance the guarantee degree of water quantity and significantly improve the reaching standard degree of water quality. The rationality and effectivity of the model was verified.

## 5 CONCLUSION

The joint operation optimization model of water quantity and water quality in river basin based on dualistic water cycle, gives a way to reduce the

severe situation on water supply and water environment. The features of the model are as follows:

- a. The definition of guarantee degree for water quantity and reaching standard degree for water quality provides reasonable objective functions.
- b. Since system topology is based on realistic water cycle, the model is convenient to be adjusted. So the model has good applicability.
- c. The model can give fully utilize potential of water storage projects by optimal policy with a long series of runoff.

The model solution is given under various certain runoff conditions. In next research, rule optimization with stochastic runoff will be improved.

**ABSTRACT:** The long-span double-layer steel bracket for the roof of squat silo is designed and the vertical deflections of structure are calculated by finite element software SAP2000, which is compared with the actual measured results of this structure by loading experiment on site and the rationality of simulated deflections is fully verified. Then, this software is used to analyze the internal force, stress ratio, and overall stability of double-layer steel bracket. It can be seen from the analysis result that all structural members meet the requirements of corresponding design specification. Therefore, the section of steel members can provide a reference for the design of similar engineering project in the future.

**Keywords:** steel structure; bracket; long-span; design

## 1 INTRODUCTION

The concrete dome or single-layer steel reticulated shell is used for the roof of squat silo which is mostly applied in the food industry at present from the need of building function of storage. But for long-span squat silo, the direct use of concrete dome will lead to increasing construction difficulty and construction period of project becomes longer<sup>[1]</sup>. The design of steel bracket for roof of squat silo should take into account the self-weight of steel structure and concrete dome which is supported by the steel bracket, the other vertical loads, wind load, snow load, and various construction live loads and so on<sup>[2-3]</sup>. If the technical scheme at the construction site is unreasonable, there is global or local instability and even overall collapse of structure under the construction condition at the steel bracket. The high strength of steel material cannot be used fully and designed bracket is not economic<sup>[4-5]</sup>. So, the strength and overall stability of steel support on the roof of squat silo should be carefully considered. This problem can better be solved by the use of double-layer steel bracket with the various bracing members inside. A typical kind of design of long-span double-layer steel bracket for roof of squat silo as an actual engineering example is introduced in this paper and its

strength and stability are analyzed, which provides a reference for similar engineering design.

## 2 DESIGN OF STEEL BRACKET

### 2.1 *The selection and arrangement of structure*

The circle or conical structure is the main form for the roof of squat silos, in particular, the conical thin shell has more advantages. As for conical shell, the formwork erection and pouring concrete on the steel bracket at the process of construction are much easier than for spherical shell because the conical shells only have radii in one direction<sup>[6,7]</sup>. The design of double-layer steel bracket for the conical roof of squat silo is mainly discussed in this paper.

The height of this conical steel bracket for roof of squat silo is about 4.14 m, the diameter of conical ring beam at the bottom is about 25.9 m, and the diameter of the upper platform similar to the traditional concrete structure is about 8 m. The 20 radial steel beams connected by 6 ring steel beams are uniformly arranged around the structure. From bottom to top, the vertical steel braces are set down on the fourth ring beam and many other braces are placed inside of structure. The detail design of steel bracket is shown in [Figure 1](#).

Figure 1. Three-dimensional diagram of steel bracket.

### 2.2 Key point of structural design

The single-layer steel bracket for the roof of squat silo will lead to excessive deflection when the span is large. The maximum deflection usually occurs at the middle of radial beam which needs to be set with vertical braces and diagonal braces<sup>[8]</sup>. Also, a larger deflection value is produced at the center of upper structural platform, and so this location should be also set using diagonal braces, which will increase the vertical stiffness of upper structural platform and improve the whole stiffness of steel bracket. Because steel bracket is a completely symmetrical structure, the internal feature of structure is illustrated by taking a piece of the inner brace. A detailed drawing is shown in Figure 2.

### 2.3 Load distribution

The main bearing loads of steel bracket are dead load and variable load. Dead load includes the weight of steel structure by itself and concrete dome. Variable load includes the live load of roof, construction load, and wind load perpendicular to the structural surface. Specific load calculation is based on the way the surface load is distributed on the surface of the double-layer steel bracket. The design load of region i is  $q = 11.82 \text{ kN/m}^2$ , region ii is  $q = 9.95 \text{ kN/m}^2$ , and region iii is  $q = 9.91 \text{ kN/m}^2$ . The design load at each partition is shown in Figure 3.

### 2.4 Section design of steel members

The structural analysis model used for steel bracket is created by finite element software SAP2000 and the surface loads are applied on the upper surface of the structure. The appropriate sections and materials of designed steel members that can satisfy requirements of the related design specifications

Figure 2. A piece of inside brace.

are shown in Table 1. RB1 is expressed as the first ring beam, RB2 is the second ring beam counting from bottom to the top, and so on. CB is expressed as the center braces of upper platform and TB is the tie bar between the fifth ring beam and sixth ring beam.

### 3 ANALYSIS OF EXPERIMENT AND THEORY

#### 3.1 Deflection values of loading experiment on site and theoretical analysis

According to the loading experiment on site shown in Figure 4 and Figure 5, the maximum applied load is 500 t and the largest deflection at the center of steel platform is 30.3 mm. The actual measured deflection and calculated deflection are shown in Table 2. Position 1 to 6 in Table 2 is, respectively, the middle point of the first ring beam to the sixth ring beam counting from down to up. The position 7 is the center of upper platform and position 8 is the middle point of radial beam.

Figure 4. Steel bracket on site.

Figure 5. Loading experiment.

Table 2. The contrast of deflection values.

Position	Measured deflection/mm	Calculated deflection/mm	Error /%
1	3.1	3.5	12.9
2	10.5	11.2	6.7
3	14.5	12.8	-11.7
4	8.2	8.0	-2.4
5	12.2	10.8	-11.5
6	4.5	3.7	-17.8
7	30.3	27.2	-10.2
8	11.1	9.7	-12.6

The contour map of overall deflection for the steel bracket is shown in Figure 6.

#### 3.2 Comparison of experimental results and theoretical analysis

It can be seen from the comparison of experimental data and the deflection calculated by software SAP2000 that these simulative deflections are close to the actual measured values obtained from the loading experiment on site. It also shows that this finite element method simulating steel bracket is relatively accurate, and so the numerical calculation method is used to analyze the internal force, stress ratio, and overall stability of double-layer steel bracket. What is more, whatever the experimental result of 1/852 or calculated result of 1/963, the ratio of deflection at the middle of radial beam to the total length is far less than the given allowable ratio of 1/250 which is provided by the design code for the steel structure. Of course, it can also be seen from Table 2 that these deflection values of loading experiment on site are a little different from calculated data of theoretical analysis because there are maybe the following inevitable deviations at the process of actual steel construction:

1. The installation error that exists at the steel members. Connections at the ends of bars do not achieve the ideal rigid joint or hinged joint. Because the different connection types will affect the effective length of bar, the deflection of bar is not the same.
2. There are inevitable initial bending of members, initial eccentricity at the node and the initial stress due to various reasons such as the steel transportation and manufacturing process.

Figure 6. Overall deflection.

## 4 STRESS RATIOS OF MEMBERS

The stress ratio distribution of steel bracket is shown in Figure 7. It can be seen from Figure 7 that the stress ratios of most members are about 0.65 to 0.8 and the stress ratios of very little bars are less than 0.3. So not only can the strength requirement be met, but it can also make full use of the steel strength and does not cause a lot of steel material waste.

## 5 OVERALL STABILITY OF STRUCTURE

Structural stability analysis is different from strength calculation. It is mainly because of the difference between the external applied load and the internal resisting capacity of structure that leads to the sharply increasing structural deformation. The purpose of stability analysis is to determine the buckling modes and buckling loads where the structure becomes unstable.

The function of buckling analysis included in the software SAP2000 is used to calculate overall structural stability for the steel reticulated shell. The eigenvalue  $\lambda$  is sometimes called buckling factor or safety factor. The ultimate buckling load is equal to the product of buckling factor multiplied by the given load. When the buckling factor is greater than 1, the given loads must be increased in multiples of the buckling factor and the structures that cause buckling. If the buckling factor is less than 1, the applied load on the steel structure must be reduced to prevent buckling.

The first-order and second-order buckling modes of double-layer steel bracket for the roof of squat silo are respectively shown in Figure 8 and Figure 9. The first-order buckling factor under the action of vertical load is 4.8. The overall instability of steel structure will occur only when the applied loads are enlarged 4.8 times the standard values of dead load and live load. Because the buckling factor of 4.8 is greater than the buckling safety factor of 4.2 given by technical specifications for space

Figure 7. Stress ratio.

Figure 8. The first-order buckling mode.

Figure 9. The second-order buckling mode.

frame structures, the overall stability requirement of double-layer steel bracket of the latticed shell will be satisfied.

## 6 CONCLUSIONS

1. The above designed long-span double-layer steel bracket used for the roof of squat silo has good structural strength and overall stability, which can satisfy the technical requirements included in the related design specifications. The section of steel members can provide a reference for the design of similar engineering projects in the future.
2. The simulative deflections through finite element analysis are close to the actual measured values obtained from the loading experiment on site. The experimental deflection of 1/852 and calculated result of 1/963 are far less than the given allowable ratio of 1/250.
3. The first-order buckling factor used for evaluating overall stability of the double-layer steel

bracket under the action of vertical load is 4.8 and is greater than 4.2 given by technical specifications for space frame structures.

**ABSTRACT:** This paper takes the indemnification house construction project task assignment model as the entry point of the study, with problem-oriented method, and by site visiting, etc., studies the reasonable assignment mechanism of Guangzhou indemnification housing construction tasks shared by the city and by districts, building the weight model with expert evaluation, and on the basis of model analysis, relevant suggestions are raised in the conclusion.

**Keywords:** indemnification housing; task assignment; weight model

## 1 INTRODUCTION

From 2011, Guangzhou has begun the trial of indemnification housing construction tasks shared by the city and the districts. In three years of practice, certain achievements are obtained, and certain obstacles are met. The main problems in the obstacles are the issues of how to effectively establish the assignment model shared by the city and by the districts for the indemnification housing construction tasks with the principles of equal rights and responsibilities. With such background, this study tries to take problem study as the orientation, by site investigations, obtaining relevant information, and on such basis, the indemnification housing construction tasks assignment model is built, to provide foundation and reference for the reasonable assignment of indemnification housing construction tasks in Guangzhou and in cities of same type.

## 2 STATEMENTS IN RELEVANT DOCUMENTS

Construction of indemnification housing is an important measure to realize the policy of the central government “home to live in”. During the period of the 12th 5 Year Plan, the target of construction to build 3.6 million sets in the indemnification housing projects may basically solve the insufficient supply problem of the indemnification housing<sup>[1]</sup>. The research shows that construction of indemnification housing has practically solved

the housing issues of some straitened people. Current large-scale construction of indemnification housing in our country has its reasonability<sup>[2]</sup>. But, behind the completion of the indemnification housing construction many problems are still existing.

In the construction of indemnification housing, insufficient land and shortage of funds are two main problems, which are seriously hindering the progress and effects of the indemnification housing construction tasks<sup>[3]</sup>. Studies and experiences in other countries show that when the funds for indemnification housing construction are not sufficient, the better and effective solution is to use funding leverage, to absorb social capitals or revitalize stock assets<sup>[4-5]</sup>. In China, many experts are of the opinion that<sup>[6-7]</sup> leverage of financing with administrative funding should be sufficiently utilized in the indemnification housing construction, and the assets of indemnification housing construction should be securitized and capitalized, and the model of public-private cooperation should be used in the financing for indemnification housing construction. In other countries, the governments actively provide lands for the indemnification housing construction is the key of solution of such issues<sup>[8]</sup>.

Many studies show that either funding issue or land issue, the sources usually may be summarized as problem of upper-level system. The appraisal mechanism and land finance as the reality have seriously affected the progress and quality of the completion of the indemnification housing tasks<sup>[9]</sup>. Our experts have many researches and studies in this respect.

Mr. Wang Yueping<sup>[10]</sup> has studied the behavior changes of local governments in the indemnification housing construction with the theories of reasonable selections and new institutionalism, etc., and he has found that the behavior changes of local governments are mainly limited by the financial system, the authority structures of different levels of governments, and the relationship of local benefits, etc.

Different hierarchies studies and analysis have been done by the experts in the respects such as the completion situation of the indemnification housing construction tasks, the problems facing, their causes and solutions, etc., providing foundation for the followed studies. The indemnification housing construction practice in other cities are worth learning and reference. In this paper, the intention is to try to build the indemnification housing construction task assigning model as the follow-up study on the basis of the studies and researches of so many experts, and to raise relevant suggestions, as the supplement and verification to the relevant studies.

### 3 INDEMNIFICATION HOUSING CONSTRUCTION TASK ASSIGNING MODEL BUILDING

#### 3.1 *Brief introduction of changes of the sharing situation between the city and the districts for the indemnification housing construction from 2011 to 2014*

In recent years, in the Guangzhou indemnification housing construction, the mode changed

from mainly responsible by the city to the mode of mutually sharing by the city and the districts, it is shown in the transfer of the housing security tasks to the districts step by step. According to the data provided by Guangzhou Housing Management Bureau (see Table 1), the building coefficient  $\Gamma$  the proportion of tasks between the city and the districts is measured:

$$\Gamma = yt/(1 - yt) \tag{1}$$

yt: proportion of indemnification housing construction task assignment of city level itself in year t (of which t = 2011...2014).

The smaller  $\Gamma$  value shows the heavier tasks at the district level layer. Table 2 shows that the  $\Gamma$  value drops from 2.02 to 0.99.

From Drawing 1, we may see that the  $\Gamma$  value changing tendency is like a parabola, dropping together with the time lasting. The decomposition of the indemnification housing tasks is mainly by the mutual sharing between the city and the districts.

#### 3.2 *Building up the task assignment estimated model: weight model*

As the assigned tasks of the districts in the past years are of large occasionality and subjectivity, it is hard to take them for the scientific estimates. For this reason, on the basis of the task volumes of the past years, certain variables are added and the expert evaluation is also added to establish the weight model.

Table 1. 2011–2014 indemnification housing construction tasks quantity and percentage in districts (unit: flats,%).

	2011		2012		2013		2014

① *The setting principle and selection variables*  
 Model is based on the actual situations of the districts, with the principles of “construction by demands, shared by the city and the districts, equal rights and responsibilities, balancing

among areas”. Considering the short comings of the deduced model, first it is suggested to take the application volumes of indemnification housing into consideration of indemnification housing construction task assignment indexes, while

Table 5. Indemnification housing assignment weights in districts.

District	Financial income	GDP	Indemnification housing application volume	Regular residents	Clerk quantity	Inspection volume
Weight coefficient	0.45	0.3	0.25	0.05	0.1	-0.15

Table 6. District housing security task volume proportions.

District	Annual financial income	GDP	Annual application volume	Regular residents	Annual inspection volume	Clerk quantity	Total percentage of undertaken task volume
Weight coefficient	0.45	0.3	0.25	0.05	-0.15	0.1	1
Yuexiu	3.22%	4.60%	7.84%	0.46%	-5.86%	1.14%	11.39%
Haizhu	2.80%	1.68%	7.57%	0.35%	-4.08%	1.01%	9.33%
Liwan	3.19%	2.21%	5.10%	0.61%	-3.61%	1.39%	8.89%
Tianhe	4.00%	5.37%	1.68%	0.56%	-0.37%	1.01%	12.25%
Baiyun	1.18%	1.36%	0.39%	0.18%	-0.16%	0.25%	3.21%
Panyu	3.57%	2.57%	1.41%	0.88%	-0.48%	0.63%	8.57%
Huadu	5.01%	2.61%	0.35%	0.69%	-0.28%	1.01%	9.40%
Huangpu	3.61%	1.75%	0.29%	0.10%	-0.06%	0.51%	6.20%
Luogang	7.50%	3.65%	0.04%	0.15%	-0.01%	0.13%	11.46%
Nansha	4.56%	1.74%	0.12%	0.37%	-0.03%	0.25%	7.02%
Conghua	2.04%	0.55%	0.16%	0.23%	-0.03%	1.27%	4.21%
Zengcheng	4.33%	1.91%	0.05%	0.41%	-0.03%	1.39%	8.06%
Total	45.00%	30.00%	25.00%	5.00%	-15.00%	10.00%	100.00%

adding some independent variables are shown in Table 3. In order to assure the objectivity of the model calculation, mainly the average data of 2012 and 2013 of the annual application volume and annual inspection volume are taken.

From 2011 to 2014, the city level itself has undertaken separately 66.91%, 72.85%, 65.53% and 49.65% of the indemnification housing construction tasks, and the remaining parts are assigned among the districts according to their demands and construction abilities. According to above form the proportions of the relevant indexes of the districts are calculated, as shown in Table 4.

#### ② Assignment of weight coefficient

By sufficient demonstration of model A and model B, combining with site visit, we may find that different variables are playing different functions in the assignments of the tasks. Considering the basic principles of the mutual sharing between the city and the districts of "construction by demands, shared by the city and the districts, equal rights and responsibilities, balancing among areas", the weight of financial income is appropriately raised, and the relevant weights evaluations are listed in Table 5.

According to the importance of the relevant factors of the indemnification housing tasks and the actual situations of the districts, the relevant factors are evaluated by expert scoring method. By the evaluations of the indexes, the indemnification housing proportions undertaken by districts are calculated with the results in Table 6.

It has to be emphasized that it is only the proportions of public-rental housing, excluding demolition settlement housing, construction volume of which should be calculated by the actually involved quantity of the large sized or emphasized projects in the cities in all the years.

## 4 MODEL ANALYSIS

Therefore the model is a choice. Surely it is obvious that it is an indemnification housing construction task city and district sharing model among districts based on certain preconditions such as equal rights and responsibilities, right resources distributions, multiple housing security products (including rental allowance), it is feasible only when above conditions are available. At the same

time, it should be realized that there is no unified standard of indemnification housing construction task assignment proportion between the city and the districts. The assignments of indemnification housing construction task between the two level layers of city and district, in its nature, is the transfer of public affairs and responsibilities among different governmental management layers. Different assignment proportions and methods will lead to different results. Combining with practice of other cities, it is sure that when “Funds transferring with projects, rights transferring with responsibilities” is realized, any types of proportions may be admitted and accepted by the parties. In the contrary, huge obstacles and difficulty may appear in the promotion.

## 5 CONCLUSION

The original mode of the indemnification housing construction task shared by the city and the districts in Guangzhou has obtained certain achievements, but there are still many difficulties and obstacles. By document study and empirical study it is confirmed that that the mode of construction task share by the city and the districts is with strong realistic necessity. But if current resources configuration is not making important adjustments, putting the indemnification housing construction task to the district level fully would not get good result. Therefore, the limited resources must be adjusted and the original rules for rights and responsibilities must be refined and regulated. Only above this, the built indemnification housing construction task assignment model may provide important foundation for reference in the refining of the indemnification housing construction task assignment between the city and the district layers.

# Research on spatial morphology characteristics of traditional “bottom-up” settlements—a case study of Licha Village and Xiangang Village in Gaoyao, Guangdong Province

Yan Lin & Jian-guo Wang

*School of Architecture, Southeast University, Nanjing, China*

**ABSTRACT:** The research of traditional “bottom-up” way of urban development serves as an approach to reflect on the current mainstream “top-down” planning and construction way. Through integration of field research, graphic analysis and theoretical generalization, and by selecting Licha Village and Xiangang Village in Gaoyao, Guangdong Province as case study, the paper probes into characteristics of roads, public spaces and building clustering way in traditional settlement spaces. It concludes that, in traditional “bottom-up” settlements, roads present natural and organic morphological characteristics under the influence of human’s action modes; public spaces are rich in levels, flexible in utilization and concerned about comfort degree of utilization; building clustering way is affected by natural topographic conditions, appropriate residential density and spacing. Also, the paper points out that, the main spatial morphology characteristics of such settlements are to fully reveal characteristics of natural topographic features, to be adaptable by adjusting space according to conducts of daily life, and to be rich both in spatial morphology and geographical features. The paper intends to provide a reference for correction and improvement of urban construction approaches.

**Keywords:** bottom-up; urban design; spatial morphology of traditional settlement; “Eight Trigrams villages” of Gaoyao, Guangdong Province

## 1 INTRODUCTION

In the process of rapid urbanization of China, most domestic cities are planned and constructed by following the “top-down” mode, which leads to poor practicability and lack of local characteristics in terms of urban community. During the same period, numerous vernacular settlements built in the “bottom-up” mode, compared with cities with the “top-down” construction means, have more unique spatial morphology characteristics, the sense of place belonging and practicability in life. Through field research on typical traditional settlements, the paper intends to delve into the morphology characteristics, residents’ behavior characteristics and spatial utilization habits of traditional “bottom-up” settlements, attempting to provide a reference for improving urban construction way by reflecting on and interpreting the spontaneous formation mechanism of traditional settlement spaces.

The paper selects two traditional settlements in the Xijiang River Basin, i.e. Licha Village and Xiangang Village in Gaoyao, Zhaoqing of Guangdong Province as main research objects (Fig. 1).

Built in the Southern Song Dynasty with a history over 700 years, Licha Village, relying on mountains and waters around, presents a circular shape with radius of 90 m in general and gets its name of “Eight Trigrams village” from the eight trigram shape of houses constructed in rows by conforming to the topography. Currently, the well preserved and virtually unpopulated village is already developed into a tourist scenic spot. Xiangang Village, another “Eight Trigrams village”, although similar to Licha Village in spatial morphology, has an area ten times of that of Licha Village with radius being 300 m. with over 600 years history, 8,900 residents and three administrative villages, the village scale falls in between a village and a town.

Since the two villages adopt the traditional “bottom-up” construction way and well preserve spontaneously formed spatial morphology of traditional settlement so far, with the two as research samples, the interpretation of morphology characteristics concerning traditional settlements may bring significant basic research value for analysis of the “bottom-up” development way.

The physical space environment of settlements largely incorporate roads (including streets,

Figure 1. Satellite map of “Eight Trigrams” villages.  
Source: Google map.

sidewalks, steps, alleys, etc.), buildings (including residential and public buildings, etc.), and public spaces (such as squares, natural landscapes, sketch sculptures, etc.). The paper intends to study the spatial morphology of traditional settlements in the perspectives of road, public space and building clustering way.

## 2 SPATIAL FEATURES OF ROADS

In traditional settlements, apart from compliance with the natural topography and catering for facilities (mainly drainage) requirements, the formation of roads is greatly affected by human’s action modes. Characterized by slow speed, physical fatigue limit and strong randomness of path, human action is thus leading to the natural and organic forms of roads.

### 2.1 Spatial composition of roads

Both built on an island surrounded by water, the two villages are similar in overall structure of roads: outside villages is a loop of carriageway, and inside lie alleys arranged in compliance with hills. To the specific, the 5 m wide outer ring cement road serves for vehicles and pedestrians and has roads leading outside every one or two hundred meters; mainly serving for pedestrians, internal roads are changeable since they have to adapt to hills and connect all dwellings. The links between the outer ring roads and internal roads of Licha Village and Xiangang Village are gatehouses and footpaths perpendicular to the outer ring roads respectively (Fig. 2).

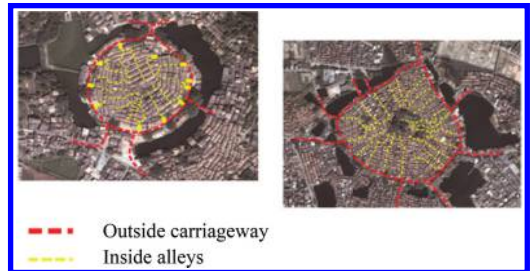

Figure 2. Overall structure of roads of the two villages.  
Source: The author draw.

Internal roads, serving for pedestrians only and being the typical “bottom-up” construction, is the focus of the research. Seen from the internal traffic space composition of the villages, not all spaces have roads, thus the traffic system formed by internal roads might as well be interpreted as accessible space beyond inside for people.

Taking Licha Village as an instance, the internal traffic space can be divided into three forms as below (Fig. 3):

1. The space under eaves such as corridor under gatehouse, freely accessible ancestral hall with side-room opened: unlike general ones in cities, the width of spaces under eaves in Licha Village is about the same as other roads and even superior in terms of identification and road conditions, thus, the guide tempting access shall be an indispensable part of traffic system.
2. Open space such as vacant area in front of and behind gatehouse, small square in front of public building and mountain top square: the space

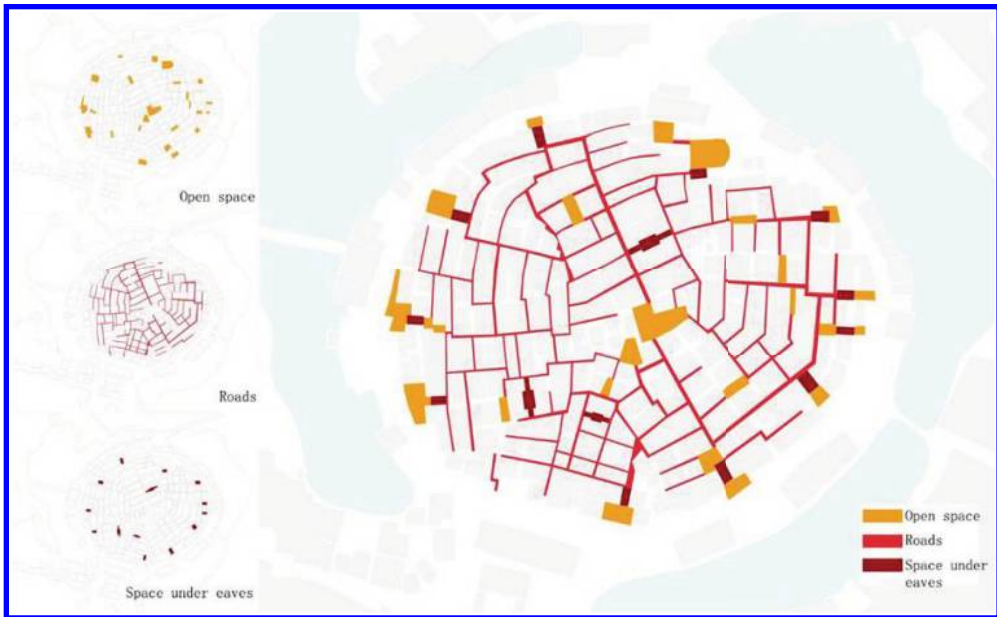

Figure 3. The internal traffic space of Licha Village.  
Source: The author draw.

may accommodate some special behaviors such as worship in ancestral hall and water taking in wellbay. But it is hard to be distinguished from roads due to its limited spatial scale (generally 3–8 m<sup>2</sup>). Incorporated into road system, the space is basically used for passing through.

3. Road space with diverse road forms such as roads serving as main alleys (upward direction along the hill), cross alleys assuming main entry function (along contour line direction) and cracks. Such combination of roads in diverse forms generates complex traffic organization type inside villages.

Yet judged from practical utilization situation, form types with distinct features of roads are still be seen partially (Fig. 4). The local form of roads can be divided into three types as below according to combination relationship among roads (Fig. 5):

1. Fishbone type: in this road type, obvious main alleys are available along building gable and branches perpendicular to main alleys are available to connect building entrance. Most fishbone roads are found along village radius direction and a few long main alleys start from peripheral gatehouse and terminate at mountain top.
2. Cross alley type: in this road form, roads in front and back sides of buildings are much wider than

those along gables, making cross alleys become the main road in this area. Buildings on both sides of the road mostly follow contour line and building entrances can be found on both sides of some cross alleys.

3. Free type: this road type is not definite in spatial logic or can be called residual space beyond buildings. The road presents irregular road network structure or irregular road shape, such as triangle and trapezoid spaces.

## 2.2 Road pavement

As for Licha Village, most road spaces are narrow, but the relationship of paving modes, pavement materials, drainage and plant configuration is complex. Pavement components include the ground near the building generally paved with rubbles or cement, drainage ditch set along building exterior walls or in road centre according to the actual situation and the pavement for pedestrians mainly laid with large stones.

Being about 300–400 mm wide and 1000 mm–1300 mm long, stones for pedestrian roads constitute appropriate road width for one person and for accommodating one's feet exactly if laid horizontally and vertically respectively. Road width is basically determined by stone dimensions and a multiple of single stone dimension. Behavioral momentum is inclined to be transformed into

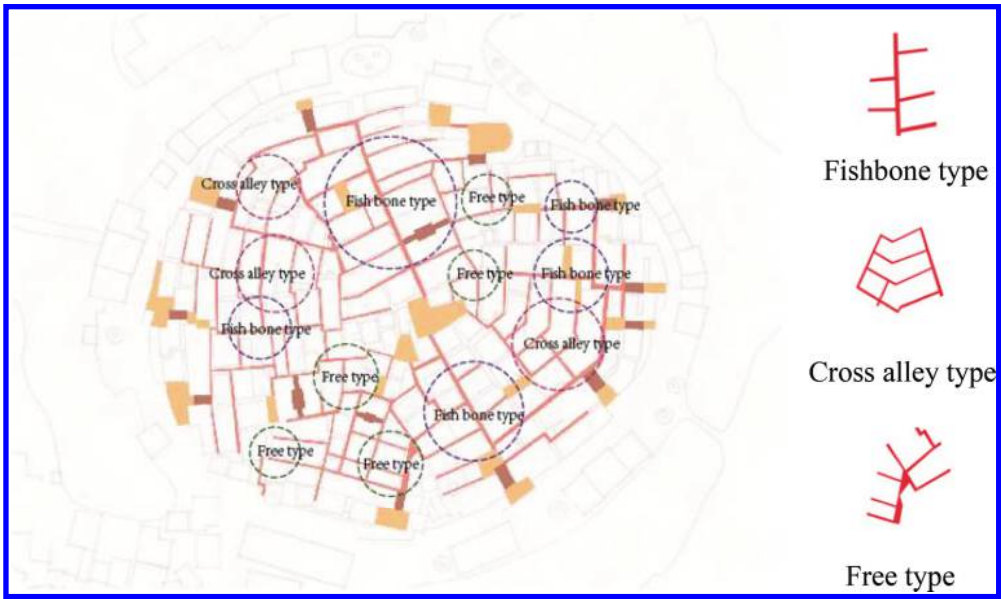

Figure 4. Local form of roads.  
Source: The author draw.

Figure 5. Three types of roads.  
Source: The author draw and shot.

paving mode of materials and especially the paving form, as can be seen in most places. For example, the laying location of stones shall avoid drainage ditch and the laying direction shall give a hint to building entrance; straight roads are rarely seen at

any position, even main alleys; some places may even present abrupt change in width or strange shapes. All these have something to do with human's walking flexibility (Fig. 6).

The importance of roads is more related to elaborate degree of road construction than the road width. Some important roads, although the width is suitable for one pedestrian only, are complex in the stone laying and elaborate in the interface with drainage ditch; some unimportant roads with spacious space leave very limited pavement for pedestrians with other spaces overgrown with weeds to fail passing (Fig. 7).

### 2.3 Impact of bicycles on roads

In terms of bicycles, compared with walking, they just improve the speed and release fatigue and as a daily action relying on body, do not require a lot for road conditions. Therefore, the utilization of bicycles falls into a phenomenon of the "bottom-up" influence on road space.

When it comes to Licha Village, the utilization of bicycles has some impact on its road traffic: although bicycles are basically active on external roads so far, bicycle trace in the village and especially bikeway on several entry steps (bikeways are built late) are still found. Take the step of Suiyuan Village platform, torsion of bikeway and step are formed due to inconsistency between turning radius requirement of bicycles and existing

Unimportant road: spacious space with limited pavement

Figure 7. The expression of importance of roads.  
Source: The author shot.

step conditions, and bikeways are built in the step center with view to individual handedness (Fig. 8).

Seen from the analysis above, roads deriving from the “bottom-up” settlement mode are paved as per human action needs and vary with objective conditions. Therefore, the actual road information, unlike urban planned road network with the “top-down” construction, cannot be accurately read from site plan as the current situation is much more complex than the drawing with the roads shaded by massive roofs. In most cases, roads are built along with houses and constrained by many other factors, as they have to give way to buildings, plants and even drainage ditches. Human’s free actions make roads become one of the most flexible components of the settlements.

Figure 8. The step of Suiyuan Village platform.  
Source: The author shot.

### 3 CHARACTERISTICS OF PUBLIC SPACE

The abundance of public space is determined by diversification of human community public activities. Therefore, compared with other functional spaces, the public space has the most diverse forms, rich elements and multi-layered types.

#### 3.1 Composition of public space

Taking Licha Village as an example, its public space can be divided into three types according to the spatial scale, composition content and applications (Fig. 9):

1. Wellbay—the space relevant to facilities: the research finds that, the inner and outer diameters of well are 550 mm and 770 mm respectively; the ground around the well is built into a rectangular area (being auxiliary operating space of wellbay) with stones to be distinguished from other areas, with side length being 2,100 mm (about three and half steps) and area being 4 m<sup>2</sup>.
2. Ancestral hall—the space relevant to special activities (worship): the space is hard to define, since externally, the outer spaces of wine course of the village are mixed with other waterfront recreational areas, and internally, they are linked with road system. The actual space for sacrifice rites is limited, ranging from 1–2 m<sup>2</sup> to 4–5 m<sup>2</sup> and requiring incense arranging position. The importance degree of worship space is related to complexity level of altar form. And other auxiliary worship activities such as assembly, communication and leisure activities shall share the space.
3. Leisure space—the space relevant to leisure activities: such space enjoys the most diverse forms and the leisure activity space with intact form basically locates at places with desirable landscape. These spaces have something in

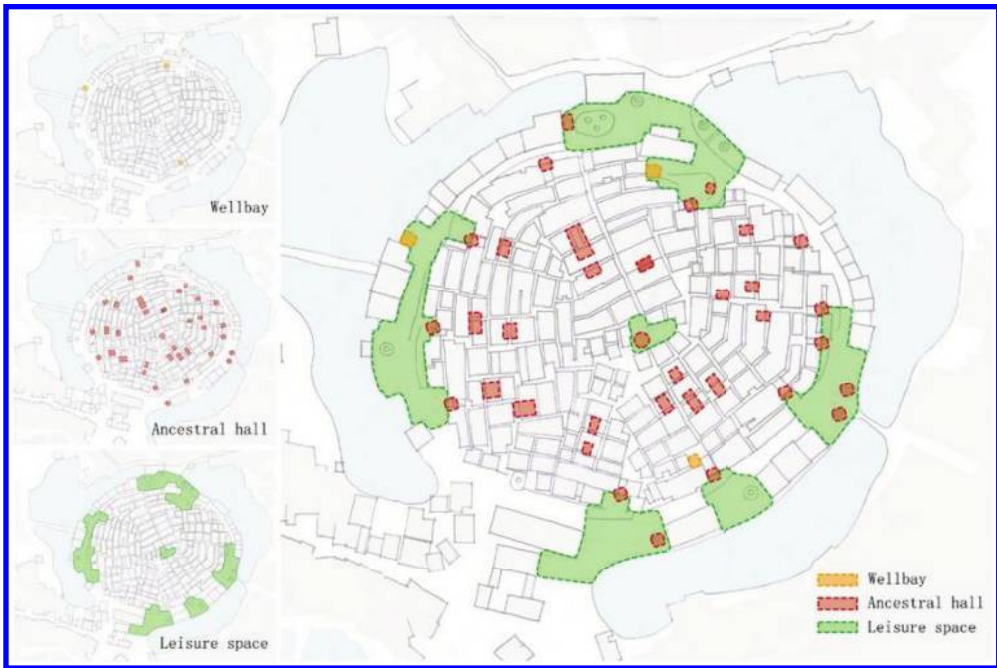

Figure 9. Composition of public space.  
Source: The author draw.

common: for waterfront, it is related to the village terrain and the hilly topography of “Eight Trigrams Village” results in a relatively spacious waterfront space; big tree logo-banyan trees with large volume are common there and comfortable shade space is available under trees; public buildings around-leisure activities are easily associated with public activities; spatial link with all entrance & exits-either exits leading outside or gatehouse leading inside, as leisure activity space prefers places with large flow of people.

Yet in fact, the public space with the intact image is always so interconnected and nested that it is hard to be clearly distinguished from other types, thus together forming public activity nodes, which center on waterfront of outer ring roads in terms of the two villages (Fig. 10–11). This implies that site selection of residential public activity space is closely related to the comfort degree of environment and rich degree of landscape. In total, Licha Village has five public activity nodes and Xiangang Village eleven.

### 3.2 Typical public nodes

To further understand the concrete forms of public nodes, the paper implements pacing research on three typical public nodes (Fig. 12).

Figure 10. Public nodes in Licha Village.  
Source: The author draw.

#### Node 1: “Four in one” public node of Xiangang Village

Being a waterfront leisure space to the south of Xiangang Village, the public node, through pacing, is generally 28-step (about 18 m) long and 16-step (about 9.6 m) wide. In this limited space, four space levels may be seen: a 3.5 m × 6 m slightly lofty worship space, a 2.5 m × 5 m chess

Figure 11. Public nodes in Xiangang Village.  
Source: The author draw.

Figure 14. Paving plan of node 1.

Source: The author draw.

Figure 13. Paving section of node 1.  
Source: The author draw.

Figure 16. Paving section of node 2.  
Source: The author draw.

space under tree, a 6 m × 6 m TV viewing space under roof and a leisure activity space accommodating seats and sports facilities. Each space is so limited that it is directly related to body dimension (Fig. 13–14).

Node 2: Public node of Suiyuan Village in Licha Village

Located at the north entry of Licha Village and connected with Suiyuan Village platform leading inside, the node's spaces include Suiyuan

Village platform for worship events, outdoor space at entrance of wine hall including Suide Well and worship space and leisure space under tree of waterfront. These spaces are relatively spacious, independent and equipped with special application, yet they have territory feeling of one space and dramatic visual interconnectiveness (Fig. 15–16).

Node 3: Public node at entry of Xiangang Village. Being the entry to the south of Xiangang Village, the node includes a rest platform with long strip stone benches of diverse dimensions to cater for different sitting habits. The different spacing of stones makes single-row or face-to-face sitting available, some longer stones enables lying and the ring-shape stone benches around trees are also popular since they create a dependency feeling by leaning on trees (Fig. 17–18).

Through observation and experience, it is found that these public spaces possess abundant levels, such as the “four in one” node, which realizes multi-level activities via a small-scale space separated from an intact site, and Suiyuan Village, the level of which is divided as per spatial elevation difference. But as for lots of spaces without fixed applications to be served as corridors, squares, gathering spaces and even doors, residents tend to develop their talents and wisdom to make them work interestingly. Since seats constitute the most significant part of public space with leisure function or any sitting space may be called public leisure space, the comfort degree of sitting become one vital factor to judge the vitality of the space.

Source: The author draw.

## 4 BUILDING CLUSTERING WAY

As human shelters, buildings arise with inhabitation and are one of the most fundamental constituent substances of settlements. As buildings in traditional settlements are mostly built by residents themselves and the development of building and update of environment are fueled according to the actual life needs and mutual learning of technical skills, the building clustering way is always a reflection of residents’ living habits and conditions.

### 4.1 Integral form of building clustering

The integral form of building clustering of the two villages seems to be specially planned and designed, both presenting irregular shape—the eight trigram shape. This design is related to the topography for one thing: the relatively rounded edges of lonely island make the architecture complex boundary become circular due to land boundary limit; with hills rising toward island center, houses are built against slopes to cater for construction and use habits, so houses are arranged in the direction that follows the contour line, presenting ring shape; the sunlight in Lingnan area is so sufficient that the sunny side and night side of mountain slope can both satisfy residents’ normal life, so houses are evenly distributed in all sides of the hills. On the other hand, with view to flood control and defense needs, most civilian houses are built on higher elevation of hills and the most external buildings are relatively closed to take on “self-defense” gesture. Meanwhile, the eight trigram shape derives from geomancy and faith, as data shows, exquisitely arranged Licha Village has hidden mystery of Hetu Luosliu (the ancient Chinese mythological fiction) and the construction as per eight basic graphics in the *Book of Changes*—the Eight Trigram symbol is to express villagers’ best wishes for being prosperous both in family and purse and keeping life thriving.

But through careful scrutiny on the architectural form of the two villages, it is found that, constrained by actual construction situation, they are somewhat in a mess and quite distinct from the established eight trigram shape. They are composed of several building groups following a few of unified directions other than even and orderly rings, with Licha Village having five directions and Xiangang Village six (Fig. 19). The consistent orientation is formed due to two reasons: first, it is easily be found in adjacent houses since houses are actually constructed one by one; second, it is related to the distribution of extended family, as it is said in the very early period, the Su and Cai families in Licha Village settled in the east or southeast of hills and later the Cai family moved

Figure 19. The directions of clustering.  
Source: The author draw.

Figure 21. The main roads of the villages.  
Source: The author draw.

Figure 20. The position of ancestral halls.  
Source: The author draw.

to the west. As the most significant building of an extended family, ancestral halls are located in the center of building groups in all directions and have relatively intact exterior space (Fig. 20). The sequence of building construction is thus clear: first to guarantee the favorable position of ancestral hall and other buildings are expanded outward gradually by clinging to the ancestral hall. In contrast, the junction of building groups seems to be very casual, leaving numerous “residual” spaces in irregular shapes.

#### 4.2 Building arrangement rule

Observed separately, the two villages are both arranged evenly with sparse buildings having dramatic contrast in scale. Individual residential building generally has three rooms with depth of 4–6 m. The building spacing is basically 1.2–1.5 m that allows two people passing side by side and wider if building entrances are available on both sides.

Besides the above similarity, compared in the same scale, main mountain roads of the two have similar spacing, mostly being 40–50 m (Fig. 21). It means, in micro environment, actual construction

environment is not affected by the overall structure of villages but by the scale necessary to lives of residents.

In general, the integral form of buildings, although constrained by natural topography, has some randomness on the premise of compliance with natural environment and group needs. But the clustering form of buildings (especially residential buildings) itself is even and rational, since they always present relatively consistent density and spacing and regular repetition, with queer buildings rarely seen.

### 5 MORPHOLOGY CHARACTERISTICS OF THE “BOTTOM-UP” SETTLEMENT SPACE

Through above research on roads, public spaces and building clustering way, the spatial morphology characteristics of Licha Village are listed below:

1. To fully reveal characteristics of natural topography  
Settlement form is directly affected by topography, which is conspicuous in traditional settlements where human tend to adopt corresponding strategies to adapt to environment in most cases due to their limited nature transformation ability. It is found that the life boundary is directly constrained by territory area, the arrangement direction of buildings and road trend are directly affected by topography, and public spaces prefer places with favorable natural landscape. The similarity in form structure of the two villages with diverse scales discloses that, the areas with the same natural topography type are easy to form the settlements similar in form ethics, as the form characteristics of settlements are interconnected with characteristics of natural topography.
2. To adjust space according to conducts of daily life  
During spontaneous construction, human always build the individual space based on daily behavior needs. The construction of residential

buildings, road pavement and living facilities are daily necessity to people and constantly created and altered during use and as time passed by, human tend to adjust the established spaces to make environment reach a balanced state suitable for life. Thus, the space enjoys a progressive development way.

3. To be rich in environment form and regional features

Due to local materials and building technology limitations, the construction way and architecture style in the same region seem to be relatively unified. But the outdoor space of traditional settlements has rich forms, especially the small-scale public spaces, which are full of vigor due to their strong relevance with residential life. Public spaces are abundant in type levels and distinctive in dimension, form and application. It is the unified architecture image and diversified outdoor space that endow the overall environment of traditional settlements with rich forms and regional characteristics.

Thus it can be seen that, the traditional “bottom-up” built settlements are characterized by acting according to local conditions and circumstances and constructing appropriate space according to human needs. Modern cities shall be developed by referring to the “bottom-up” development path, hoping to reserve the desirable nature of cities by revering characteristics of natural environment and giving consideration to lifestyle and occasion needs of natives while digging the development potential of cities.

## 6 CONCLUSIONS

Based on the research above, the paper draws the following conclusions:

1. In traditional settlements, apart from compliance with the natural topography and catering for facilities (mainly drainage) requirements, the formation of roads is greatly affected by human’s action modes, as the combination way of roads and pavement tend to vary with building locations, human’s main path directions and practical applications. Characterized by agility, human action thus endows road forms with the natural and organic features.
2. The rich degree of public space is determined by diversity of human groups’ public activities. As for public space in settlements, its spatial level is achieved through small-scale division

and definition of elevation difference; as for lots of spaces without fixed applications, they tend to be flexibly utilized as per residents’ needs and habits. The utilization frequency of public space depends on its actual comfort degree.

3. As buildings in traditional settlements are mostly built by residents themselves, the development of building and update of environment are fueled according to the actual life needs and mutual learning of technical skills. The integral form of buildings, although constrained by natural topography, has some randomness on the premise of compliance with natural environment and group needs. But buildings themselves always present relatively consistent density and spacing and regular repetition.
4. Main spatial morphology characteristics of “bottom-up” settlements are to fully reveal characteristics of natural topography, to adjust space according to conducts of daily life and to be rich in environment form and regional features. That is to be characterized by acting according to local conditions and circumstances and constructing appropriate space according to human needs.

**ABSTRACT:** The landscape tower is an important composition element of view in the regional environment. It plays a significant role in discerning the regional environment, stressing the local culture and controlling the sequence of spaces. This paper probes into the project of landscape tower in Zunyi Normal College with the overall design by several dimensions as the landscape planning design, external space design and the architectural design. This paper also deeply analyzes the sight, the volume, the texture and some other elements in the process of design.

**Keywords:** landscape tower; campus; symbolic; view analysis; volume analysis

## 1 INTRODUCTION

In ancient times, the tower is a symbol of religious belief. While in modern times, it has become a representative landmark of the city and region. The “landmark”, which has been described in detail by Kevin Lynch in *The Image of City*, has a significant meaning for beautifying the environment and figuring the shape of the city [1]. It needs to be unique and with a certain fixed style and format [2]. As a carrier of local culture, the landscape tower fully demonstrates deep cultural details and charms the campus. This paper discusses the design strategies and conception of the landscape tower in Zunyi Normal New College for creating a campus cultural characteristic.

## 2 PROJECT PROFILE

The new school in Xipu belongs to Zunyi Normal College. It contains three campuses namely the northern, the southern and the eastern. The school managers felt it is necessary that the cultural tradition should be protected and continued; therefore, a new landscape tower laden with cultural significance was built in the northern campus. The new landscape tower, which is designed in

steel structure with 42 meters high, is located on the top of the retained mountain, 900 levels above the ground. Judging from the location, the east of the site towards the entrance of the campus, Fine Arts Building and the music-dance Building are on its south and west, respectively, while the reserved forest on its north.

## 3 DESIGN CONCEPT

### 3.1 *Site analysis*

The designing concept of the landscape tower follows the principles of campus landscape planning, which is defined as “according to the mountain topography and rooting in regional culture and indigenous landscape.” As a result, shaping the landscape tower as a node on the northern landscape belt is our starting point. The new tower should be integrated into the framework of the planning of the campus; meanwhile, it should have its own peculiarity. Therefore, we retain the flat area on the top of the mountain as the base of the tower. The tower is kept far away from teaching buildings so that pressure from evacuation can be reduced. Besides, the tension of space, which is formed by the distance and morphological differences, will make it easier to blend the building

structure with landscape organization together. People on the road can easily see the tower because the main entrance of the campus is 866 meters above the ground and 34 meters lower than the tower, which makes the tower look much higher than it was. The location and the master plot plan of the tower are shown in Figure 1 and Figure 2.

### 3.2 The spatial construction

The level on the base of the tower is 38 meters higher than the main entrance. The top of the tower is 80 meters high, which is the highest point of the reserving terrain on the northern campus. The tower changed the flat sky-line of the campus, and has a positive impact on the improvement of the campus' overall planning and carries on the spirit of exploitation and enterprising in Zunyi meeting. Among the various factors determining the richness of space, the details of its interface, that is, the place where the space comes into contact,

Figure 1. The overall plan of the three campuses.

Figure 2. The surroundings of the tower (the red point indicates the location of the tower).

with the outside is particularly important [3]. This place ought to be designed taking into account not only the exigencies of outward appearance but the demands made on the boundary from within. Therefore, the square under the tower is divided into multi-level, fluency garden by the base and the structures around the tower so that the properties of space change from the resting space to the commemorative space. In addition, the square on the mountain gets its genius loci by the memorial of the landscape tower. This is similar to Chinese landscape paintings, which never depict the visual image statically, but rather convey a perception of the experience of traveling amidst the real landscape of natural beauty, accompanied by memories and imagination [4].

### 3.3 The shape design

As a well-known city, Zunyi, which is the turning-point place of China's Revolution, has its specialties like the bamboo shoot and the red sandstone (see Fig. 3 and Fig. 4). In addition, our designing concept comes from their symbol. Growing from ground with the fluency water around it, the tower raises and contracts like a common bamboo shoot in local place, steadily rising towards the sky. Symbolic forms can bring some connotation to space, that is, it can give different meanings to different people to understand [5].

We try to employ symbolic measures to represent the revolutionary tradition in Zunyi city, so the structural form of the tower is given the meaning of "twist". The landscape tower has vivid shapes and neat edges, while its base is triple-tired from inside

Figure 3. The dispositions of the material of the tower.

Figure 4. The conception of the landscape tower.

to outside and clustered around by the structures. The interesting form is fashioned by changing details and small textures. The tower is a triangular prism in shape and topped by indented cutting, the combination of which makes them look like bamboo shoots just breaking out of the earth. Also, the spiraling structural members take concerted with uplifted stairs, creating tortuous climbing experience to visitors. The first-floor plan and the section of the tower are shown in Figure 5 and Figure 6, respectively. The design of the bionic form conveys

the philosophy of “unity of the heaven and human beings” and represents the moral of rising steadily for higher education.

### 3.4 The landscape design

The program emphasizes “person’s participation”: not only it is a work of art to be appreciated from different locations and various angles, but also a landmark in campus students, which can simply recognize their position. The landscape tower is located on the highest point of central landscape belt with a fine extensive view. It is also an important node of the main landscape axis. Two groups of appendages are set around the base to form the layout of radiation so that the surroundings get more harmonious. The design combines original water sources with elevation planning so that the ladder of cascades and the path to the hill top can be integrated together. Also, the vegetation around the tower is set in a well-conceived composition. Meanwhile, the tower can also serve as a sightseeing platform and illuminant.

### 3.5 Continually perfected design

In order to suit for the inner environmental order, some factors such as the axial counterpoint of the tower, harmonious with the surroundings, and landmark of character have to be considered. We keep the balance of the relationship between “see” and “be seen”. Nature observed is immanent: it has an extraordinary allure because it bequeaths the “consciousness” of an immanence in nature—the sense of that man is part of the landscape [6]. So, this paper combines the urban design theory, making a conclusion that the landscape tower should be controlled in 40 meters high for good vision as well as budgetary control.

Figure 5. The first-floor plan of the landscape tower.

Figure 6. The section of the landscape tower.

Figure 7. The tower of the square plan.

After analyzing the plan shapes in square, circular and triangle, we found that the triangle plan is more practical than the circular plan and more compact than the square plan. It is even closer to our initial designing concept, which represents the moral of rising steadily like a bamboo shoot. With repeated siftings, the triangle plan was chosen instead of the traditional hexagon and octagon. The other two plans are shown in Figure 7 and Figure 8. The sketch of the triangle tower is shown in Figure 9.

Figure 8. The tower of the circular plan.

Figure 9. The sketch of the triangle tower.

## 4 HIGH DEGREE OF THE DESIGNING RESULT

### 4.1 High quality of architecture details

Homely but looking at the future, architects' ambition was to create a manifesto for public space design: not just a decoration, but an urban strategy [7]. The above ideas were followed at the stage of designing exploration. By the redefinition of construction and by making it glow in the dark, the steel structure and the local red sandstone were adopted to make a contrast with the penetrating and lightsome glasses. The tower body is barred with LED light to stand out the spiraling steel members. Besides, in order to strengthen the visual impression, the base of the tower is up lightly while the top is hung over the down lightly.

### 4.2 Energy-saving technology

The tower was set up with the solar energy and wind power combined electric device so that the supply of electricity of water pump and automatic mechanism can be ensured. Based on the natural ventilation effect, the wind suction was set at each

Figure 10. The rendering of the landscape tower.

Figure 11. The lighting effects of the landscape tower.

level and the shutter was set on the top to regulate the temperature of the room by organized wind pressure and hot press. As the natural ventilation in summer will predominate in organizing the wind pressure while hot press is in winter, which makes it to control the ventilation quantity with the automatic mechanism on the top of the tower, the greenhouse effect of the glass building can be fully used; therefore, the temperature of the room can meet the demand.

## 5 CONCLUSION

With the development of living standards, people will get a higher aesthetic level in the regional architecture and landscape designing. Meanwhile, the landscape tower gets increasing attention from the general public. This paper mainly probes into the project of the landscape tower in Zunyi Normal New College, which not only is the summary and thinking for the preceding stage, but also the suggestions and ideas for the landscape tower design. When this tower was designed, it was just the 80th anniversary of Zunyi Conference convened. This paper hopes that people can introspect this period of history as well as look into the future when they visit the landscape tower.

# Analysis of building materials transparency effects on building space

H.H. Hu & X.H. Ding

Department of Architectural Engineering, Huaiyin Institute of Technology, Huaian, Jiangsu, P.R. China

**ABSTRACT:** From the perspective of transparency of building materials, building materials of different transparency and performance practices are researched, and the impact of materials transparency on building space is analyzed.

**Keywords:** building materials; transparency; building space

## 1 INTRODUCTION

Architecture is the unification of technology and art. The progress of the construction is mainly in the construction of function and form, construction technology and the development of art and performance on the use of building materials. From a certain perspective, a history of architecture is also the history of materials. It is said that architecture is frozen music, then building materials are the movement of the beat note. A reasonable and effective use of each note alone would compose a wonderful and moving music. The 21st century science and technology changes with each passing day, and new building materials emerge in endlessly. The different material performances lead to the architectural design process in structure and art, and great changes have taken place in all aspects. Architectural art form is also changing. So, the progress of the construction and development and innovation of construction material and use are inseparable. Building materials itself also exist various attributes, including the transparency of materials largely affects the performance of the architectural space.

## 2 THE INFLUENCE OF TRANSPARENCY ON THE MATERIAL

A translucent material and visual penetration to define the transparency of the building can be divided into an opaque, transparent and translucent interposed between transparent and opaque. Therefore, the material may be classified as an opaque material, a transparent material, and a translucent material. The influence of the transparency of the material is generally associated with increasing transparency, decreasing material color saturation, gradually weak texture clarity,

gradually weak roughness, increased weakness in the body taste and sense of weight, and vice versa. These three different transparent materials, having completely different visual effects and lighting effects, form the shape of the space and the atmosphere, and the impact on people's psychological feeling that is completely different.

## 3 BUILDING MATERIALS' TRANSPARENCY EFFECTS ON BUILDING SPACE

### 3.1 *Opaque material*

Opaque and translucent materials do not have the penetrating gaze. Common opaque materials are wood, stone, brick, concrete, and metal, which all have different natural attributes and characteristics, such as their texture and texture, background color and texture, shine and reflection, color and other surface properties and features, shaping space shape and atmosphere.

Wood is a natural organic material, being lightweight, strong and flexible, easy to get and used for simple construction. Its diverse texture, color and texture provide designers with a rich choice. Natural wood has good perception and touch, giving elegant, relaxed, comfortable and warm feeling, can produce other construction materials that are not natural aroma and unique beauty and a comprehensive "environmental" content, in line with modern close to nature, i.e. green concept. Different specifications, timber and construction practices in different varieties of texture formed are different, and the impact on the architectural space is also different (Fig. 1).

Stone is one of the most basic materials. It has a solemn, classical, durable quality. Different types of stone have a different texture and background.

Figure 1. Wood building.

Figure 2. Wright's fallingwater.

Different species, different colors, different textures, different processing methods and different design methods can create a variety of stone walls. Stone size, proportion, shape, and assembled way arrangement patterns also affect the final texture effects of the wall (Fig. 2).

Brick is a clay and cement mixture of long box body, because of the inherent characteristics of the art, classic charm and low cost, dual aesthetic and economic attractiveness and revival. Brickwork in the visual and tactile nature easily gives simple, homely feeling. Constructed with brick masonry building with a rich texture, it will be displayed to the rich local. Brick facade design should primarily consider the overall tone and texture of the walls, tile size and proportion, arrangement, and pointing width.

Concrete is made of cement, sand, water and a mixture of small stones, because in the construction industry in the magical performance as "gray gold." It is not only the basic framework for building materials, but also with durability and distinctive artistic expression, its rough and rustic character ensures that the structural details are fully expressed. It may present shape only by its restrictions template, depending on the flow of concrete, freezing and hardening characteristics template pouring process improvements, will form the concrete and sensory effects of a different nature. Common types of concrete include cast fair-faced concrete, precast concrete and decorative concrete.

A lot of metal materials are used for the development of synthetic polymer industry, aluminum, steel and for civil construction. Sheet metal cover panel consists of a stainless steel plate, color steel plate, aluminum plate, galvanized steel, and plated plastic panels. The common denominator is the ease of installation, superior durability, and good decorative effect. From the visual experience in terms of building soil improvement features using

traditional materials such as wood and stone, there are machines craft gloss, precision and intensity. As the Arab world's cultural center in Paris, France (Fig. 3), using aluminum decorative concrete structure inside the package, as a whole like a skin stretched out to form a highly rhythmic pattern, unique bright shining metal. For example, the Bird's Nest: the main body of revolution by a series of radiation door type steel truss around the bowl seating area, the spatial structure of simple science, architectural and structural integrity and unity design creative, unique for domestic buildings.

### 3.2 Transparent material

Transparent material because of its transparency, and lost the opaque material rich simple sense, but it has yet another warm hide. Glass material is now the most common application of a wide range of transparent materials.

Glass material is now the most common application of a wide range of transparent materials. During the long construction history, the glass is the most landmark building materials; it completely changes the traditional architectural form, as well as the construction of spatial relations with people. Before the 18th-century building, mostly opaque materials such as stone, brick and wood building were used, where the building appeared thick and closed. Until the end of the 19th century, metal and glass were widely used, and modern architecture movement subverts the traditional to the pursuit of transparent quality, with transparent building skin gradually expanding, even as the main body of the construction epidermis, building by the previous close, hard to open and transparent. In the early 20th century, designed by Belem, Germany ge turbine locomotive, and designed by gro skin uz FaGu

Figure 3. The Arab world's cultural center in Paris.

Figure 4. Fagus factory.

factory (Fig. 4), it may be said that the beginning of Western modernism architecture used a large area of the transparent glass walls, with buildings becoming simple, transparent, and light.

Glass material of transparency, other opaque material is unable to match the material properties and construction performance potential. Completely transparent glass material transparent, connect fully, not only give a person the feeling of pure, crystal clear light, but also convey the pure, psychological feeling of freedom. It is transparent, connects fully, but still has a physical presence. Due to the hard glass, impermeability can satisfy the rain, such as safety containment building functional requirements. At the same time, the glass material unique pervious to light quality can make the outside natural light transmission to the building, make interior space becomes bright, warm and soft, to meet the visual and psychological needs. At the same time, it can create a completely different building from the traditional building in opaque material, and give a person the visual perception and the space effect. Completely transparent glass material can let the line of sight through building inside and outside, people can from the construction of external perspective to the building interior space, structure and decoration can also see from building interior building outside of the natural beauty, life in which people can feel the outside world through transparent glass time, light, weather, and the change of seasons. Therefore, it makes the construction of indoor and outdoor penetrate each other, and in harmony with the surrounding natural environment and perfect together. Application of transparent glass blurred the boundary of the architectural space, the sense of isolation and closed, weakened the architecture and dispelling the architectural dimension sense, and give a person with a transparent, open, visual and psychological feeling of lightness (Fig. 5).

Glass products have good pervious to light, transparent, heat insulation, heat preservation

Figure 5. Farnsworth house.

performance, so widely used in construction. Especially, the emergence of a new type of glass, such as safety glass, thermal insulation glass, laser glass, glass block and expand its application space, and improving the performance of building. In addition to the windows and doors, it can also be used for exterior wall, roof, awning and railings and other parts. Shanghai grand theatre using a novel net printing white glass curtain wall glass from top to bottom with fine white dot from small to large, the architectural appearance during the day there is a fine gauze of hazy transparent texture, reflected light and night translucent. Due to the high strength, heat insulation, sound insulation, glass block and water resistance and good pervious to light the advantages of not through the line of sight, very suitable for quiet, hidden places.

### 3.3 *Translucent material*

Translucent material transparency in a transparent and opaque materials between a fuzzy state, presents a kind of like that does not fully appear, hazy vision effect, with numerous levels and possibility of change. Neither like transparent material perspective and transmit the light completely, nor like opaque material completely blocking the line

of sight and light. “In a transparent and opaque materials some ambiguous condition between the interesting to both the characteristics of the two, present a transparent have qualitative feeling, and this trait changed the architectural space and form, also changed the way architecture and communication”.

Building common translucent materials are paper, poly-carbonate vinegar, ETFE film, and through the study of the processing of the transparent material such as glass and translucent glass material, such as frosted glass, silk screen printing glass, glass block, and u-shaped glass. In addition, through to the opaque material for a variety of processing and translucent material, such as thin and pervious to light stone, perforated metal plate, aluminum louvers, and wire mesh.

Translucent material used in construction can the fuzzy boundaries between opaque and transparent, ever changing space form. While assure indoor illicit close sex, and can provide sufficient

for building internal space and the soft natural light, to avoid the traditional building materials is too depressing to surround close feeling. Natural light through a translucent material happens reflection, refraction, and a large number of diffusion, which is layer upon layer filter, avoids the transparent glass the shortcoming of the light is too strong, play a sunshade. Night, soft and radiant with indoor lamplight, building into a lightsome, pure light, the whole building show a kind of quiet, hazy, implicit beauty. That is like concealed, unreal dim light image, make the building has a subtle dynamics, also conveys a mysterious color, give a person with infinite daydream space (Fig. 6).

#### 4 CONCLUSION

In numerous property characteristics of the material, the influence degree of the transparency of space can be said to be the biggest of all. During the long architectural history, it has experienced from opaque to transparent, and changes to translucent. For transparent materials, opaque, translucent material, the shape of the building space form is completely different visual effect and smooth shadow effect, influence on people’s psychological feelings also completely different.

In addition, three kinds of materials through a certain way of processing, its transparency can be change, also can be mutual transformation, resulting in numerous levels of transparency, enrich the variety of building materials, also provides the new concept of space form and the possibility of more.

As an architect, the use of materials is an important link in building design, choice of materials is one of the important ways to express the design concept of architects, which is a very important means of expression. Reasonable selection of different transparent materials can create a rich variety of architectural space.

**ABSTRACT:** Urbanized hydrological process and its consequent urban waterlogging presents a major challenge to urban planner and civil engineer. This paper aimed to improve urban drainage ability through landscape architectural measures based on Storm Water Management Model (SWMM). The west campus of China Agricultural University is selected as a case of typical build-up regions in Beijing. This optimization process includes to model the infiltration ability of subcatchments, flooding volume of nodes with overload time of conduits in the platform of SWMM, to locate the potential water accumulation area using the spatial information of the above three parameters, and to choose the suitable design method of ecological landscape infrastructures for different water hazard zones. It is hoped to contribute the solid belt between the quantitative evaluation model and parametric landscape planning and design.

**Keywords:** SWMM; storm water; landscape architecture; drainage engineering; Beijing

## 1 INTRODUCTION

Water is the important resource supporting human life and activities. However, in the context of rapid urban development, urban hydrology and process have changed that lead to a series of urban environment problems, such as the shortage and pollution of water, as well as urban waterlogging, etc. There is no doubt that how to prevent urban waterlogging by optimizing the drainage infrastructure has become one hotspot in the field of urban hydrologic infrastructure and civil engineering. The Storm Water Management Model (SWMM) is a comprehensive simulation model developed by USA Environmental Protection Agency. It provides a flexible platform for examining the impacts of drainage network structure on hydrologic response (Meierdiercks et al. 2010).

The aim of this paper is based on SWMM to integrate the quantitative capacity evaluation of current drainage networks into the landscape improvement measures. It is hoped to contribute the solid belt between the quantitative evaluation model and parametric landscape planning and design.

## 2 METHODOLOGY

SWMM can simulate the rainfall and runoff process in the whole city. The steps consist of generalizing subcatchments, preparing the database of sewer, inputting the parameter data and analyzing simulation results.

### 2.1 Generalization of the case area

The case area is a typical built-up area in Beijing. It is located in the west campus of China Agricultural University (Fig. 1), which occupies an area of 33.3 ha, including teaching and dormitory buildings, squares and roads, stadium area and green spaces (Fig. 1). It is calculated that the pervious surface is 6.16 ha, accounted for 18.5% of the total area; alternatively, the impervious surface accounts for 81.5%, about 26.14 ha.

A separate sewer system was built in the case area, and connected with the city's drainage network via three outlet points. The primary sewer is along the east-west direction, while secondary sewer along the north-south direction. The whole system was generalized as 49 subcatchments,

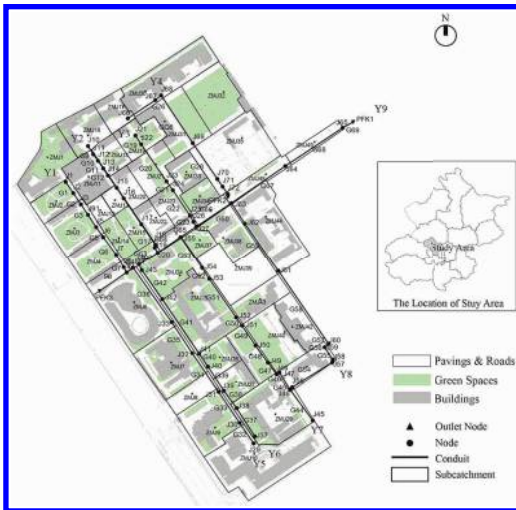

Figure 1. The location and generalized map of case area.

73 nodes (including gutters and inspection wells), 70 conduits and 3 outlet nodes (Fig. 1).

## 2.2 Establishment of the basic database

The parameters were divided into two categories: the measured parameters and the calculated parameters. The measured parameters include the area of subcatchment, the pervious area of subcatchment, the slope of subcatchment, the invert elevation of node, the maximum depth of node, the diameter of conduit and the length of conduit.

The calculated parameters refer to the typical values in the user manual of SWMM model. In this case, for green spaces are the main permeable surfaces, this paper utilized the Horton infiltration model to simulate the process of subcatchment runoff. The required parameter values are as follows: maximum infiltration rate ( $f_0$ ) = 76.2 mm/h, minimum infiltration rate ( $f_\infty$ ) = 38.1 mm/h and attenuation coefficient ( $\alpha$ ) =  $2 \text{ h}^{-1}$  (Zhao, S.Q. et al. 2009). Then we use the nonlinear reservoir to simulate the confluence calculation. Here, the value of depression storage capacity of permeable surfaces is 12 mm (Cong X.Y. et al. 2006) and its manning coefficient is 0.03 (Rossman L.A., 2005); the value of depression storage capacity of impervious surface is 2 mm (Cong X.Y. et al. 2006) and its manning coefficient is 0.011 (Rossman L.A., 2005); the value of sewer's manning coefficient is 0.013 (Rossman L.A., 2005). In the process of simulation, the runoff flow volume is calculated by dynamic wave formula.

According to the statistic rainfall data in the hydrologic handbook of Beijing, three scenarios of rainfall frequency were set as follow: P = 5%, P = 10% and P = 20% (Fig. 2).

Figure 2. Rain volume data under the different scenarios.

Figure 3. Change of surface elevation and invert elevation from J1 to J9.

## 2.3 Optimization of parameters for higher nodes

On the basis of sewer data, the invert elevation and buried depth have been collected from section Y1 to section Y9. Figure 3 shows the change of surface and invert elevation about section Y1 (node J1 to J9), which depicts that the invert elevation of node J5 is obviously higher than adjacent nodes' invert elevation. The stormwater within the sewer should have flow from J1 to J9, while the raised node (J5) would conduct congestion of J1 to J5. Therefore, these nodes are defined as the potential risk point. Here, it would be much more reasonable to simulate the actual hydrologic process by replacing the “pump” button with the “link” button. Thus, Y1, Y2, Y7 and Y9 have been optimized.

## 3 RESULT

### 3.1 Synthesis of runoff simulation

As Table 1 shows, with different rainfall frequency, runoff volume raises with increasing rainfall frequency. The runoff volume contains two parts: one part flows into the sewer network; the other part is the stagnated runoff at the surface depression as the overland flow converges.

### 3.2 Analysis of the surface infiltration ability

Subcatchment infiltration volumes under three scenarios indicate that the infiltration capacity of ZMJ1, ZMJ3, and other red ones in Figure 4 is higher than black ones. From the generalization map (Fig.1), it is showed that subcatchments with higher infiltration capacity are in the north

Table 1. The runoff summary under three different scenarios.

Scenarios	Total precipitation/mm	Total infiltration/mm	Total runoff/mm	Flood node	Surcharge conduit
P = 5%	276.23	32.74	243.94	41	42
P = 10%	213.02	31.051	182.286	40	40
P = 20%	153.3	27.668	125.842	39	39

Figure 4. The proportion of rainfall infiltration of total rainfall.

Table 2. The flooding node summary under different scenarios.

Node	Hours flooded (h)			Maximum rate (L/s)			Total flood volume (10 <sup>6</sup> L)		
	P = 5%	P = 15%	P = 20%	P = 5%	P = 15%	P = 20%	P = 5%	P = 15%	P = 20%
J6	10.05	6.72	2.10	167.87	146.37	124	1.815	1.073	0.618
J7	15.23	12.73	8.57	92.88	81.47	69.6	1.720	1.299	0.743
J29	2.10	1.15	1.08	248.94	191.89	132.62	0.917	0.675	0.454
J30	3.60	2.02	1.20	21.11	20.86	19.88	0.142	0.076	0.063
J31	16.17	16.00	15.68	559.06	471.99	381.08	6.309	4.588	2.986
J48	10.13	6.88	2.10	11.38	10.76	11.3	0.258	0.148	0.071
J49	15.60	15.42	15.13	172.99	143.58	113	1.712	1.251	0.799
J50	12.53	11.13	7.00	106.36	87.05	66.97	0.781	0.526	0.320
J51	15.23	14.98	13.13	2.79	2.77	2.79	0.117	0.104	0.073
J27	16.22	15.77	14.63	300.67	265.56	231.66	4.799	3.935	2.782
J63	17.05	16.65	15.93	537.51	449.70	358.5	6.730	5.371	4.031
J64	17.42	16.98	16.22	83.99	69.95	55.37	0.989	0.784	0.589

where many green spaces are located. However, in the south, there are more buildings and pavements to meet the daily needs of teaching and pedestrian commuting. Thus, less surface runoff would infiltrate, and more surface runoff might challenge to the sewer drainage network in the southern area.

### 3.3 Analysis of the node ability

Nodes are the join of sewer drainage network, comprised of rainwater inlet and inspection wells. Based on hours flooded, maximum flow rate and total flood volume, Table 2 records the nodes easy to overflow under the different rain frequency. These nodes are mainly located in the regions with

more impervious surfaces or narrower pipelines. More impervious surface respectively leads to more instantaneous rainwater volume, while narrower pipes only support parts of rainwater. This results in the flooding around these nodes.

### 3.4 Analysis of the conduit ability

Figure 5 displays the conduit sectors which would overload under different rain frequency, particularly G7, G21, G42, G41, G48, G53–50, G64 and G66–69 (with red colors). It results from the limit of pipeline diameters. Most of these overload sectors have pipes with the diameters of 300 mm or 400 mm. But the new canal sections' diameters are 1,000 mm, such as the whole sector of Y6 and

Figure 5. The flooded hours of congested conduits under different scenarios.

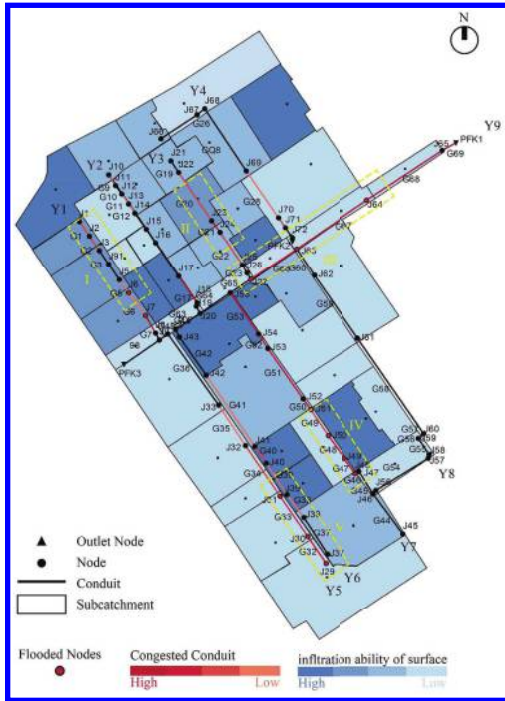

Figure 6. The generalized map of hazard area.

Figure 7. Stormwater facilities.

some sectors of Y5 and Y9. Additionally, the layout pattern of nodes among conduits affects the drainage ability too. Where there is few rainfall gutters, it is easier to accumulate rainwater, such as the downstream of Y7 and Y9.

## 4 DISCUSSION

### 4.1 The potential water hazard zone

Combining the analytical result of surface infiltration, nodes and conduits, this paper concluded five potential water hazard zones, displayed in Figure 6.

These water accumulation zones include three types. The first has the lower nodes and narrower pipelines, such as zone I and zone II. The second has more impervious paving which increases the runoff volume and the overload risk, such as zone IV and V. The last one, as the primary discharge canal, has much more input volumes than output, such as zone III.

### 4.2 The improvement measures

In the north, where the drainage capacity is better than the south, but there still are some sectors

existing waterlogging risk, for instance, the upper part of the Y1 (zone I) and the middle of Y3 (zone II). Aiming at these risk point, the suggestion is relieving the pressure of drainage network and improving the drainage ability by stormwater facilities (Fig. 7a). However, in the southern region with limited spaces (zone IV & V), replacing the impervious pavement by pervious surface and expanding green roofs are recommended (Fig. 7b). As for zone III, it is suggested to distribute the discharge pressure from secondary pipeline via the above methods.

## 5 CONCLUSION

SWMM has a good effect on the simulation and evaluation of rainstorm process in urban typical region. Based on SWMM, this paper have located the potential water hazard zones and provided the corresponding green stromwater infrastructure, which is a more scientific and reasonable method for landscape engineering practices. It provides the technical support for contributing the solid belt between quantitatively evaluating the capacity of existing drainage infrastructures and improving its bug by the low impact method.

# Analysis on the river channel landscape design of Lianjiang River New Town

Yifeng Du

*Zhuhai College of Jilin University, Guangdong, China*

**ABSTRACT:** River channel is an important resource for the existence and development of humans, and the material carrier of cultural inheritance. Well-designed river channel landscape not only dramatically improves the urban outlook, but also may bring good social, environmental and economic benefits. This article carries out a comprehensive analysis to summarize the features and characteristics of Lianjiang River New Town's river channel landscape design in order to provide direction and reference for the future river channel landscape design.

**Keywords:** landscape design, river channel, Lianjiang River New Town

## 1 INTRODUCTION

River channel is an important resource for the existence and development of humans, and the material carrier of cultural inheritance. Well-designed river channel landscape not only dramatically improves the urban outlook, but also may bring good social, environmental and economic benefits. The practices of many cities testify to this. Proper understanding of the urban river channel landscape is the premise of making a good design. The understanding of the urban river channel landscape shall be analyzed from the perspective of landscape ecology. The key point is to make account of the huge ecological function and entertainment value of the urban river channel landscape. Water is the most basic condition for life, and the aquatic ecosystem is considered to be the most important ecosystem. A complete urban river channel landscape consists of riverbed, sandbank and river bank forest belt. Such spatial structure that provides a good living environment and migration corridor for various fishes, birds, insects, small mammals as well as plants is a self-maintainable and self-renewable natural garden in the urban area. Meanwhile, rich historic and cultural traces are retained in the urban river landscape owing to the close relation between urban rivers and urban development. Therefore, the urban river channel landscape can be thought of as a landscape with the most active vitality and changes.

Lianjiang River New Town river channel landscape design project is a quite typical river channel landscape design, located in Guangdong and adjoining to the Haimen Port, only a 10-minute

drive from the Shenzhen-Shantou Highway. It is a key new urban area in governmental planning with convenient transportation and broad land resources as well as a bright future prospect for development entrusted by the government. The design pays great attention in combination with peripheral environment, and simultaneously considers a future development planning on account of the position, particularly in order to carry current functions and reserve a development opportunity for the future. The landscape design shall reflect the harmony between man and nature, pays great attention to connect with surrounding landscape environment around architecture, for example venue, context, transportation, terrain, garden path and planting for greening. In addition to satisfying functions, it provides the condition for tourists to view the scenery, and a growth space for the plants, thus to achieve a harmonious coexistence friendly condition between man and nature.

## 2 INTRODUCTION TO PROJECT BACKGROUND AND BASE

The planning area is located in the north of the Lianjiang River, Chaoyang District, Shantou, Guangdong, adjoining the Chaoyang urban area with a total length of 500 meters and width of 40 meters. The total area of the project is approximately 20,000 square meters. This region is a part and parcel of Lianjiang River New Town. Moreover, it is an important region for the communication between Chaoyang District and Chaonan District. As the Shenzhen-Shantou Highway passes

through Chaoyang District, the base gets a convenient transportation, only a 10-minute drive from the Highway, half hour drive from the Xiamen-Shenzhen Railway Station (Chaoyang Station), 30-min drive from the Shantou urban area, and 40-minut drive from the Chaoshan International Airport. Chaoyang District, in which Lianjiang River New Town is located, has massive outstanding tourist resources, Wenguang Tower, Dongshan Scenic Area, Lingshan Temple, Haimen Lianhua Peak Scenic Area, and Heping Grand Peak Scenic Area, which provide high-quality tourist resources for Chaoyang District and even for Chaoshan.

Chaoyang District has abundant cultural details. Heroes-praising Dance, paper-cut and flute set music are honored as the three treasures in folk art. Traditional art and crafts such as the Chao Opera, woodcarving, stone carving, wood clay as well as folk customs cultural events including Guiyu Color Street Awning Exhibition and Gu Rao Sacrificial Fete enjoy a high reputation at home and abroad.

The base has a smooth geography. At present, it is used for agricultural purpose, and the terrain structure is quite solid, which is quite good for reducing the construction hardness and provides a good platform for landscape design.

### 3 DESIGN THINKING ANALYSIS

With a total length of 500 meters and width of 40 meters, the Lianjiang River new town river channel landscape design project is situated in the north side of the Lianjiang River, Chaoyang District, Shantou, Guangdong, and covers the total area of approximately 20,000 square meters. The landscape planning design includes several aspects as follows: square, water body, green land, building, sculpture, billboard, and lighting fixture. The design is based on the following principles:

1. Sustainable development of natural ecology: the design shall adequately consider diverse plants with long life to sustain and enrich plant diversity. The overall and partial disposal methods shall meet requirements such as ergonomics, rich landscape terrace and material and type variation.
2. Suitability: classify venue function according to different groups and design different function zones to meet the demand of different groups; resort to small functional items to make the landscape zone manifest and serried.
3. Spatial segmentation based on the venue geology: use the uniform and individual plane type matching with landscape elements with varied geometric levels to build the diverse spatial sense of the road environment.

4. Visualization: adequately resort to varied elements of the landscape design, and provide cooperation in terms of design diagram, material application, quality sense, plant shape and color, plane style, and strengthen visual impact and aesthetics of the sidewalk and walkway.

### 4 DESIGN PLAN ANALYSIS

The eco-superior principle is followed throughout the river channel landscape design by involving high-level technologies and high standard landscape design in order to coordinate with the local ecological environment to the maximum extent and to obtain a perfect combination of landscape and environmental protection, thus creating the most resplendent river channel landscape in Lianjiang River New Town, and even in the entire east Guangdong region.

#### 4.1 *Design idea*

As the Chaoshan people have the custom of catching fish since old times, and this project is right along the river channel, fishery is involved in the landscape design elements. Unique modeling of fishing boat and special texture of fishing net are implanted into the design, making people to pay attention to the fishery culture while seeing the view. Meanwhile, along with the increasingly strengthened environmental consciousness, the green environmental friendly scenic areas are increasingly favored by tourists, and a great deal of energy conservation environmental protection science and technologies are adopted in the Lianjiang River New Town river channel landscape design. Besides, with the subject bright design proposal, this project can achieve the combination of science and technology and environmental protection as well as the integration of modern and nature.

#### 4.2 *Design style*

The design style of Lianjiang River New Town river channel landscape is a combination of modern style and new Asian style. Modernistic characteristic is reflected in the simplification on the basis of modernism, stressing the idea of "less is more", with trees embellishing the hard scenery, forming activity spaces for the stream of people, local treatment stressed and intense color contrast to stress the advancing freshness and fashion. The new Asian style is also adopted by using modernism hard scenery combining with Asia's landscape gardening idea, i.e. applying a modern technique to the Asian traditional botanical garden form, retaining the traditional charm in bold innovation

of the local culture element, demonstrating a new kind of Asian style.

## 5 LANDSCAPE PLANNING ANALYSIS

### 5.1 *Design of garden path*

The design of garden path first satisfies the basic function, and coordinates the relationship between path planning and ambient environment, making the path planning manifest the harmonious unification of function beauty and art beauty. In this plan, a long main path connects all nodes to each viewing site with various tracks in-between, providing a convenient channel for tourists, especially the integration of tree shade makes the entire path system closer to the nature. Meanwhile, steps over water embellishes the road system and increases vitality to the Lianjiang River New Town river channel landscape. Fishing net modeling is used as nodes for path distribution, connecting major landscapes, thus forming the overall landscape design. Besides, the nodes scatter like various rare treasures caught by fishing nets in rivers.

### 5.2 *Design of landscape architecture*

Landscape architecture functions as an embellishment and a resting place for tourists during sight-seeing. In this project, the design idea of the main landscape architecture is to use the modeling of fishing boat in the landscape architecture, compared with a person, only one who has experienced enough adventure can be more self-confident on life journey.

### 5.3 *Design of greening*

The all-round urban green landscape considers the plant's ecological habit as well as its ornamental value; we not only understand the plant's own texture, beauty, color and greening effect, but also pay attention to the portfolio group beauty of plant varieties and harmony with the surrounding environment and other geological and environmental conditions. Different plant dispositions in the green space form a diverse botanical garden viewing space, create a different landscape effect, and add splendor to the urban landscape. The selection of reasonable plants is crucial for the success of the green land landscape as well as the main factor for forming urban green land style and creating different feeling.

Different plant dispositions in the green space form a diverse botanical garden viewing space, create a different landscape effect, and add splendor to the urban landscape. This project applies

a large footprint of green plants to manifest the design idea of green space protection. In order to obtain a peaceful and neat leisure environment, the project has planted a great deal of landscape plants in partition of the landscape architecture. The airborne greening over the landscape architecture and plants in part of the landscape nodes mainly are palms that can prevent direct sunlight on the main line and guarantee a broad vision. Other landscape regions are mainly planted with green bushes, forming a level contrast in plant disposition. As Guangdong varies little in seasons, planting of alternative vegetation of different climate manifests the seasonal variation. At the same time, planting divides a relatively peaceful space, which enables the surrounding populace a relatively peaceful leisure environment in the open space away from urban noise.

### 5.4 *Design of water scene*

Water is one of the essential substances for human living as well as the aspiration and source for the artistic creation. Along with the urban development, people demand a higher quality of urban public space environment and urban landscape art. "Water" is introduced into people's life as an important landscape essential factor, using water to make environment space art creation has become one of the important means for architects and landscape designers in creating an urban space landscape environment. In addition, large area of water can also absorb dust in the air and purify air, which is of great help to the health of urban inhabitants.

The water scene design of this project pays great attention to the function of river channel landscape in Lianjiang River New Town, combining with the peripheral development environment, using the height scattered musical fountains and shallow pool to build a overpowering fountain water scene, trying to make a true urban square water scene with current relevance that fits the disparity in ages and humane backgrounds and be loved by the populace.

### 5.5 *Design of square*

The square is a broad and smooth open-air space in the traditional city center, which manifests the richness and complexity of city life. Modern square has many functions including a place for citizens to walk, rest, holding assembly or concert, or starting flea markets. The landscape design of this project considers the peripheral environment for future development quantity, as well as relations between land limit and amount of space occupied. This square covers an area of 0.5 hectare. The square

ground uses buried lamp belt, integrates the element of fishing net, and uses the straight line staggered design. In the meantime, it uses the new tread dynamoelectric floor tiles, which reduces the operation cost besides environmental protection.

## 6 NEW TECHNOLOGY APPLICATION IN LANDSCAPE PLANNING

### 6.1 *Wind electricity complementary street light*

In this project, the designer adopts an innovative street light design that is powered by solar energy and wind energy. It not only uses sustainable energy power for illumination, but also has a fashionable modeling. In virtue of its large capacity accumulator cell and highly effective power technology, this kind of street light hardly needs the urban electrical network's electric power, thus reduces the burden of urban electrical network, and effectively reduces the administration expenditure of Lianjiang River New Town.

### 6.2 *Electricity generation floor tile*

In recent years, with more importance attached to the environment importance, our demand on clean energy also becomes more. Thus, the electricity generation floor tile comes out. Its principle is as follows: once step on it, 5% of the electric energy converted will be collected for lighting one LED in the center of the tile; the remaining 95% electric energy can be directly applied to other purposes or saved in the battery for other purposes.

Electricity generation floor tile is used in this project. It is made by stainless steel and renewable material, its green surface is made of recycling old tires, the internal piezoelectricity part is made by secondary aluminum, and its process of electricity generation is pollution-free. The service life of this floor tile is 20 years. In consideration of the large number of tourists in the future, the electricity generation floor tile will make a significant progress in Lianjiang River New Town. The coordination of large capacity accumulator cell and new technology will greatly reduce the power supply pressure without doubt, i.e. both energy-saving and environmental friendly.

### 6.3 *Water-permeable brick*

Water-permeable brick is a new high-permeable road surface material, while comparing with an ordinary brick, with its biggest feature being the high permeability coefficient. In rainy days, rain water can permeate promptly underground, or be stored in the gap between bricks, thus reducing ponded water on the road. Water-permeable brick can beautify the environment, and can prevent the outflow of precious water resources, which has good social, environmental and ecological effects. The application of water permeable brick in Lianjiang River New Town, on the one hand, adds a pretty color to the landscape, and, on the other hand, makes a contribution to water resources protection.

## 7 CONCLUSION

Rivers have always been the origin of life since the ancient times. River channel is an important resource for the existence and development of humans, and the material carrier of cultural inheritance. At present, the river channel landscape design is the focus of new town construction, whether the waterfront landscape is characteristic, or whether it has the vitality, depends on whether we can fully unearth and inherit the local nature and historical culture. Lianjiang River New Town river channel landscape design is based on Chaoyang District's profound cultural details, in line with natural skin texture, cultural infiltration, and continued design idea. It uses a diverse landscape modeling means to express and strengthen the cultural connotation of landscape, and has given the landscape brand-new vitality.

# The principles of the spatial layout for the traditional villages in the Northwest Plateau of Sichuan based on the ecological concept

J.W. Hou, Y. Cao & W. Zhu

*Urban and Rural Development College, Sichuan Agricultural University, Dujiangyan, Sichuan Province, China*

P.F. Qiu

*Bazhong Urban Planning Bureau, Bazhong, Sichuan Province, China*

**ABSTRACT:** This paper reviewed the ecological concept and its significances based on its history. The features of ecological concept to integrate in planning were also reviewed. By employing the ecological concept, this paper proposed some principles to solve the environmental problems faced by the Northwest Plateau of Sichuan by integrating the ecological concept with planning. The results showed that equality, respect of history, moderate development, and integrated were important principles, which should be integrated to the village planning in this region.

**Keywords:** the Northwest Plateau of Sichuan; traditional village; the principles of the spatial layout; ecological concept

## 1 INTRODUCTION

Since the ecological planning that was studied from the perspective of a single discipline in 1980, Chinese ecological planning has been framing a set of Chinese characteristic theoretical systems of ecological planning after 30 years of development. Nowadays, ecological planning is classified as the concept category, which should be integrated, guided and constrained in land ecological planning, urban ecological planning, and landscape ecological planning to advance the sustainable development of urban and region (He, X. et al. 2013).

According to the research results of scholars, the ecological status of the Northwest Plateau of Sichuan is not optimistic. The ecological protection situation of the Northwest Plateau of Sichuan is grim with problems, such as wetland shrinkage, wetland degradation (Zhou, H.M. et al. 1999), grassland desertification (Zhang, G.Y. & Zhang, L.X. 2013), vegetation degradation (Chen, L.K. et al. 2013), weakened biodiversity (The Academic Group in Sichuan Academy of Social Science Researching on the Tableland Pastoral Areas' Developing Policies in Upper Reaches of the Yangtze River 2013), and frequent geological disasters.

Under the new urbanization background, how to guide the development of villages by the ecological concept becomes significant, especially for the villages in the Northwest Plateau of Sichuan under the dramatic ecological threat.

## 2 ECOLOGICAL CONCEPT

### 2.1 *Significance of ecological concept*

The evolution of the ecological concept contributes significantly to solve environment problems and sustainable development. First, it pointed out a fundamental solution to the environmental issues (Song, Y.Q. 2005). The starting point of the evolution of ecological connotation is to solve the environmental problems faced by humans, which is the synchronized way for humans to look for a solution to the environmental issues. Second, it is a guideline for current practical works. The continuous development of ecological concept would guide the practical work in a clear direction.

### 2.2 *Features of ecological concept*

In the eye of ecology, the world is regarded as an organism, including human, natural and society. Based on that, ecological implications from the initial 'residence status of creature' extend to the 'existence of the state of the life system', which endowed the ecological concept with four characteristics (Xue, W.C. 2003). The first characteristic is integration. It means the abandonment of the conception that humans occupy *a priori* absolute dominance in the whole world (Xue, W.C. 2003). In other words, on the value orientation, the ecological world view is inclined to 'non-anthropocentrism'. It is impossible to achieve sustainable development

if humanity still adheres to the 'over nature', 'dominate nature' and other concepts.

The second characteristic is organism (Xue, W.C. 2003). In this point, the whole world and everything in the world are taken as an organism. The organic link between them is emphasized. Humans are no exception. Human beings, environment relied by humans, and other living organisms in the same environment all constitute an organic ecosystem. All of them are ecological factors in the world of this ecosystem. The close intrinsic relevance between human beings and other ecological factors also constitutes the human growth and order of life.

The third characteristic is equality. Several ecological factors constitute an ecosystem. They coexist and interact within this ecosystem equally. As one of the ecological factors in earth's ecosystems, humans are equal with other ecological factors. The past values 'anthropocentrism' are inconsistent with the concept of equality of ecological characteristics.

The fourth characteristic is individuality. In the ecological concept, integration, diversity and self-growth are emphasized at the same level. Individuality implies the law and order of a variety of different ecosystems (Xue, W.C. 2003). In a word, to achieve sustainable development, human beings should respect other ecological factors in the ecosystems, identify their value of existence, and are not free to interfere in its development law.

### 3 PRINCIPLES OF SPATIAL LAYOUT OF THE VILLAGE BASED ON THE ECOLOGICAL CONCEPT

#### 3.1 *The features of the Northwest Plateau of Sichuan*

The Northwest Plateau of Sichuan is located in Aba Tibetan and Qiang Autonomous Prefecture in the northwest of Sichuan Province in China. The area of the Northwest Plateau of Sichuan is around 166,000 square kilometers. It is part of the Qinghai-Tibet Plateau, and one of the four pastoral areas in China, and is also the largest animal husbandry based in Sichuan.

In 2008, Aba, Ganzi were included in 'the farming and pasturing transitional areas with a vulnerable ecosystem in the southwest mountain region'. The wavy terrain, the complexity of the geological structure, the visible change of vertical variation of water/thermal conditions, hypoplasia of soil depths, barren soil, and sparse vegetation are the phenomenon of ecological fragility in this region. To some extent, ecological vulnerability limits the development and construction in this region, which causes a great challenge to the sustainable development of this region.

The sparsely populated, the complexion of the ethnic groups, and the fragility of the ecological environment are the three characteristics of the Northwest Plateau of Sichuan.

#### 3.2 *The principle of equality*

In the eye of ecology, any factor in the same organic ecosystem has no priority. The reasonable value of ecological movement would only sustain when there is a symbiotic interaction and self-growth between one factor and the others (Xue, W.C. 2003). Therefore, as a part, every factor is equal within the ecosystem, which is regarded as the whole.

First, equality exists between man and the natural environment. It emphasizes that the equality between man and the natural environment is not just the equality between man and organisms, but also equality between man and other organic life, such as rocks, rivers and soil. There are rich resources, including biological resources, mineral resources and land resources in the Northwest Plateau of Sichuan, which are 'vulnerable groups' compared with humans. According to the ecological concept, other living organisms should be respected fully when designing the planning, such as respecting the wild life habits to ensure its survival growth environment of integrity, using the land resources rationally, and exploiting mineral resources rationally.

Second, equality exists between different ethnic people. The elimination of the ecological crisis is not to achieve the equality relationship between man and nature, but to achieve the equality of human relations (Xiong, Y.B. 2013). In the Northwest Plateau of Sichuan, the ethnic composition is complex with diversity of ethic culture and different levels of development. Integrating the ecological concept, the principle of equality of planning should fully consider the development of the local culture when planning with mutual respect between people, between ethnic groups and between civilizations.

#### 3.3 *The principle of the respect for history*

The principle of the respect for history is shown in the following aspects. First, it is reflected in the respect for the original village's spatial pattern. The vernacular settlement is gradually caused by the specific conditions of nature and geography as well as the development of cultural histories (Meng, H.N. et al. 2008). Besides, the external morphology of the village reflects the local nature and geography as well as the characteristics of cultural histories. Thus, to some extent, the interaction between human activities and the external development of the natural environment has created the

form of the village. Furthermore, those villages that linger to this day are the result from a state of sustainable development. The state takes shape because we humans are frequently in contact with nature. Therefore, the continuation of the spatial pattern of the original heritage village is not only to inherit the historical context, but also to maintain harmonious development between man and nature. What's more, it implements the necessary requirement of 'ecological' concept. Second, it shows the respect for the village's tangible cultural heritages, including traditional architectures and structures. Third, it shows the respect for the village's intangible cultural heritage, including traditional custom, which means planners should consider the specific space for worship, traditional festivals and other needs when planning.

### 3.4 *Moderate development principle*

With a fragile ecological environment, the Northwest Plateau of Sichuan is the water conservation of the Yangtze River and the Yellow River in the upper reaches. Moreover, it is the most important part of the 'Chinese water tower'. Therefore, the natural carrying capacity should be fully considered when designing the planning of the villages in this region. The over-exploitation should be prohibited. On the other hand, since the area is sparsely populated, the development scale of the village should be determined by scientifically forecasting the population in the future. To avoid 'empty village', 'ghost village' and to eliminate unnecessary waste and reduce ecological pressure, blindly expanding a village or building a new village should be prohibited.

### 3.5 *Livable industry principles*

While protecting the environment, a good living environment should be created to villagers. Thus, planning should be based on a clear picture of the local natural ecological background and topography and natural mechanism to maximize the preservation of biodiversity (Song, Y.Q. 2005). Besides, the creation and maintenance of a high level life also needs the scientific industry structure as the economic support. According to the Shenzhen, experience in building low-carbon cities, villages in the Northwest Plateau of Sichuan industrial planning should always adhere to the 'ecology' of development. The development direction and structure of the industrial planning should be based on the village's geographic conditions, resources and other environmental conditions. Furthermore, the infrastructure layout is intimately connected with the industrial distribution (Shen, Q.J. 2000). Therefore, when planning

the infrastructure, not only the local natural and geographical conditions, but all sorts of time outside of the human history should be considered. The infrastructure planning should consider a more long-term effect of human behavior.

### 3.6 *Integrated principles*

On the one hand, integration means the ecological harmony between the historical environment and the natural environment (Song, Y.Q. 2005). The historical environment is full of information resources (Song, Y.Q. 2005). Historical information resources can be converted into energy in certain situations, which helps to save energy and protect the natural environment. Besides, the protection of historical environment means reuse. It is a waste of resources and not conducive to the natural environment protection that demolishes everything to reconstruction. But appropriate reuse will play a catalytic effect for the natural environment. Thus, there is a close relationship between the protection of historical environment and nature conservation. On the other hand, the integration of the environment is reflected in the synchronous development of the artificial and the natural environment. During the production of human life activity, man must absorb the material and energy from nature to meet human survival needs (Shen, Q.J. 2000). To achieve this goal, measures have been taken by humans based on the traditional 'anthropocentrism'. However, to implement the 'ecological' concept, human needs change their conception from the 'anthropocentrism' development model to the 'eco-centrism' paradigm, which lays the ecological basis for human survival and sustainable development (Hu, D. 1996).

## 4 SUMMARY

In this paper, the ecological concept was reviewed from its history. The significances and features of ecological concept to integrate in planning were also reviewed. To explore a way to solve the fragile environment problems that the Northwest Plateau of Sichuan faced, the ecological concept was introduced in planning. Specific to the characteristics of the Northwest Plateau of Sichuan, equality, respect of history, moderate development, and integrated principles were proposed to provide some reference to the village planning in this region.

**ABSTRACT:** Carrying out an evaluation of the suitability of gentle-slope hilly lands for urban construction is a precondition and a crucial base for the analysis of development potential thereof, and will provide a firm base for establishing reasonable objectives, and layout as well, for the integrated development thereof. With integrated development and utilization of gentle-slope hilly lands as well as effective ecological protection therein in mind, this paper has established a system of indicators, methods and grading proposal for suitability evaluation to be made at county-level throughout Yunnan Province of its gentle-slope hilly lands. This system of suitability evaluation indicators and methodology have been adopted in “The Technical Guidelines of Yunnan Province for County-Level Preparation of Specialized Planning for Integrated Development and Utilization of Gentle-slope Hilly Lands (Trial)” to be an authentic guide for the preparation of such plans province-wide.

**Keywords:** gentle-slope hilly land; construction land; suitability evaluation; index system; evaluation method; county level

## 1 INTRODUCTION

In recent years, the contradiction between protecting arable land and ensuring construction land is being aggravated by rapid urbanization. As one of typical mountainous provinces in west China, it is very rigorous to protect arable land, especially the quality cultivated land in flatland. For properly dealing with the relationship between urbanization and farmland protection and containing the disorderly expansion of urban construction in flatland, it sets out on a characterized path of urbanization development and promotes the economic and social

sustainable development in Yunnan Province. In 2011 the Government of Yunnan Province devised the important strategy of “Protecting Farmlands in Flatlands and Building Cities & Towns on Mountains”. At the same time, Yunnan Province was listed by the Ministry of Land and Resources of China as one of the pilot provinces for comprehensive exploitation and utilization of unused land and wasteland on the gentle slope of low mountains and hills.

It shall give a priority to the planning for comprehensive development and utilization of gentle-slope hilly land. Therefore, according to the arrangement of the government of Yunnan Province in recent years, it made specialized preparation for comprehensive development and utilization planning of gentle-slope hilly land in county

---

\*Supported by National Natural Science Foundation of China (41261018).

level. For scientifically preparing the rational and feasible specialized planning of comprehensive development and utilization of gentle-slope hilly land in county level, it shall first take the suitability evaluation by adopting scientific and reasonable evaluation indicator system and method. In line with the principle of adjusting measures to local conditions, it evaluates following parts in gentle slopes of low mountains and hills: geological disasters, earthquake fault zone, mineral resources, soil erosion, construction suitability and ecological suitability. Especially, it divides the gentle slopes of low mountains and hills into suitable area and limited area for urban construction and concludes the suitability evaluation on the construction land. It can provide theoretical basis for preparing planning goal and layout of comprehensive development and utilization of gentle-slope hilly land by making construction land suitability evaluation in gentle-slope hilly areas and calculation land resources potential in one county. Therefore, it is of great practical significance in carrying out suitability evaluation for urban construction in gentle-slope hilly areas in a deep-going way.

## 2 INDICATOR SYSTEM OF SUITABILITY EVALUATION FOR URBAN CONSTRUCTION IN GENTLE-SLOPE HILLY AREAS

In Yunnan, the gentle-slope hilly land refer to the low mountainous areas at an inclination between 8 and 25 degrees beyond the range of designated flatland (the intermountain basin, valley bottom and other flatland with the slope  $\leq 8^\circ$  and continuous area  $\geq 1 \text{ km}^2$ ) (Zhang et al., 2007; Yang et al., 2014).

The most essential link in the suitability evaluation is to reasonably select and determine the

evaluation factors (Yang, 2015). Upon the requirement of comprehensive development and utilization planning and ecological protection in gentle-slope hilly areas, it shall screen and determine the evaluation factors according to the significance of mode of land use as well as present situation of land use and the nature of construction. Evaluation factors include general factors and special factors.

Firstly, it shall take qualitative analysis on the special factors. The area involved in following situations shall be determined as unsuitable for construction: any irreversible geological disasters and other natural disasters, 500 meters within the scope of the earthquake fault zone, important minerals below construction, mineral properties, concerning with basic farmland protection areas, constructive expansion prohibited zone, nature reserve core or buffer, important water source, state public welfare forest or provincial public welfare forest.

The general factors mainly include topography and morphology (slope, direction, relief form and relative elevation), geological and earthquake conditions (rock and soil type, foundation bearing capacity and fault distance), natural geological disasters (types of geological disasters, geological hazards and soil erosion), social and economic conditions (traffic conditions and urban crowding effect) and human factors (land use type).

In the suitability evaluation of construction land, it makes analysis the special factors and general factors respectively, and uses “extreme conditions method” (also known as a veto) to directly determine the suitability or unsuitability of evaluation units for urban construction by analyzing the special factors. This method can effectively ensure the accuracy of the evaluation results (Yang et al., 2013).

In conclusion, in this article, the indicator system of land suitability evaluation for construction in gentle-slope hilly areas refers to [Table 1](#).

Table 1. Indicator system of land suitability evaluation for construction in gentle-slope hilly areas.

Aggregative indicator	First grade indexes	Second grade indexes	Evaluation factor	Index type	Remarks
General factors	Natural conditions	Topography and morphology	Gradient	M	
			Relative height difference	M	
			Exposure	O	Alternative
		Morphology	O		
		Seismic geology condition	Lithology type	O	Alternative
			Bearing capacity of foundation soil	O	
			Fault distance	M	
		Natural geologic hazard	Types of geo-hazards	O	Alternative
			Susceptibility of geological hazards	O	
	Soil erosion		M		
	Social and economic condition	Traffic conditions		M	
		Urban agglomeration effect		Influence of main towns	M
	Human factors	Land use		Land-use type	M
Special factors	The area involved in following situations shall be determined as unsuitable for construction: any irreversible geological disasters and other natural disasters, 500 meters within the scope of the earthquake fault zone, important minerals below construction, mineral properties, concerning with basic farmland, constructive expansion prohibited zone, nature reserve core or buffer, important water source, state public welfare forest or provincial public welfare forest.				

Notes: M is required and O, optional.

### 3 METHOD OF SUITABILITY EVALUATION FOR URBAN CONSTRUCTION IN GENTLE-SLOPE HILLY AREAS

In this article, it takes the multifactor weighted summation method to calculate score and determine suitability grades with qualitative analysis results on the basis of special factor analysis. The confirmation of evaluation units will affect the application value and the accuracy of the evaluation results. For accurately reflecting the spatial difference of suitability of construction land in the planning area and reasonably using every inch of land, it takes regular grid (suggested 50 × 50 m) as the basic unit of the construction land suitability evaluation.

Using present land use map as the base map, the evaluation takes the multifactor weighted summation method and grading on the Arc-GIS platform on the basis of field investigation and the topographic map and other relevant information. It determines the weight of indicators by using Analytic Hierarchy Process (AHP) or expert investigation method (Delphi method). The evaluation model is as follows:

$$P = \sum_{i=1}^n Wi \times Ai$$

in which,  $P$  is integrated evaluation value;  $Ai$  is a quantitative score of single index (centesimal system) (refer to Table 2);  $Wi$  is the weight of single index (refer to Table 3).

### 4 GRADING OF LAND SUITABILITY FOR URBAN CONSTRUCTION IN GENTLE-SLOPE HILLY AREAS

According to the evaluation results, the suitability degree of gentle-slope hilly land for construction is divided into four different levels, namely: first class, second class, third class and unsuitable (refer to Table 4). It shall arrange the construction land on the area of high suitability and take corresponding engineering measures to meet the construction requirements for the third class area. For the inappropriate area, it shall be arranged as forestation or farming land rather than urban construction according to land rearrangement planning, forest land use planning and general land use planning in combination with the local agricultural development conditions, natural geographical conditions and the way of life and production.

Table 2. Marking table of evaluation factors of land suitability for construction in gentle-slope hilly areas.

Evaluation Factors	Reference Value			
	80~100	60~80	40~60	0~40
Gradient	≤8°	8°~15°	15°~25°	≥25°
Relative height difference	≤10m	10~25m	25~50m	≥50m
Exposure	S, SE - SW	E, W, W - SW, S - SE	W - NW, E - NE	N, NW - NE
Relief Form	Simple & Complete	Relatively complicated and complete	Complicated and segmented	Serious broken and segmented
Lithology type	Stiff soil or rock	Medium stiff soil	Medium soft soil	Weak soil
Bearing capacity of foundation soil	≥250 KPa	250~180 KPa	180~100 KPa	≤100 KPa
Fault distance	≥3000 m	3000~2000 m	2000~1000 m	1000~500 m
Types of geo-hazards	Single hazard, no harmful	Relatively small and less harmful	Relatively complicated and seriously harmful	Very complicated and seriously harmful
Susceptibility of geological hazards	No susceptible area of hazard	Low susceptible area of hazard	Medium susceptible area of hazard	High susceptible area of hazard
soil erosion	N/A	Low	Medium	Serious
Traffic accessibility	≤1000 m	1000~2000 m	2000~3000 m	≥3000 m

Table 3. Reference weights of evaluation indicators of land suitability for construction in gentle-slope hilly areas.

Aggregate indicator	First grade indicator	Weights	Second grade indicator	Weights	Evaluation factor	Weights
General factors	Natural conditions	0.76	Topography and morphology	0.31	Gradient	0.12
					Relative height difference	0.10
					Exposure	0.09
			Morphology			
			Seismic geology condition	0.24	Lithology type	0.11
					Bearing capacity of foundation soil ;	
	Fault distance	0.13				
	Natural geologic hazard	0.21	Types of geo-hazards	0.12		
			Susceptibility of geological hazards			
			Water and soil erosion		0.09	
	Social and economic condition	0.16	Traffic conditions	0.10	Traffic accessibility	0.10
			Urban agglomeration effect	0.06	Influence of main towns	0.06
Human factor	0.08	Land utilization	0.08	Land-use type	0.08	
Total	1.00		1.00		1.00	

Table 4. Grading of land suitability for construction in gentle-slope hilly areas.

Suitability	Appropriateness	Score	Description
Suitable land	First class	≥80	Very suitable for construction; good natural conditions, social and economic conditions and human factors, little limiting factors
	Second class	80~60	Suitable for construction; good natural conditions, social and economic conditions and human factors, and some limiting factors; to take measures to improve for construction
	Third class	60~40	Having certain natural conditions, limited social and economic conditions and human factors; to take corresponding economic and engineering measures to improve for construction
Unsuitable land	Unqualified	<40	Unsuitable for construction, with adverse and limited factors / special factors

## 5 CONCLUSIONS

To take suitability evaluation of gentle-slope hilly land for construction is the premise and foundation of potential analysis of exploiting gentle-slope land in low mountainous and hilly areas. Furthermore, it shall provide basic information for preparing planning goal and layout scheme of comprehensive development and utilization of slope land. The suggested indicator system and method of suitability evaluation for construction in gentle-slope hilly areas has been absorbed in “*The Technical Guidelines of Yunnan Province for County-Level Preparation of Specialized Planning for Integrated Development and Utilization of Gentle-slope Hilly Lands (Trial)*” as an authentic guide and the direction of the special planning preparing province-wide. As of June 2013, it has completed preparation of special comprehensive development and utilization planning (2012–2016) in 110 counties (cities or districts) except 19 counties (cities or districts) due to location of alpine and cold region or other reasons. According to the special planning, it has 649 suitable construction plots in gentle-slope hilly areas and covers an area of 338,905 hectares, including 159,396 hectares for construction with a budget of RMB584.28 billion Yuan.

## ACKNOWLEDGEMENTS

This article is the result of project (No. 41261018) Supported by the National Natural Sciences

Foundation of China. We thank Department of Land & Resources of Yunnan Province and Planning and Design Institute of Land & Resources of Yunnan Province for their friendly helps.

## A brief discussion about design research on traditional residence renovation as a resort hotel

Ying Shi

*School of Architecture, South China University of Technology, Guangzhou, China*

*State Key Laboratory of Subtropical Building Science, South China University of Technology, Guangzhou, China*

Zhenhua Zhuo

*School of Architecture, South China University of Technology, Guangzhou, China*

**ABSTRACT:** With the strong development of China's social economy, tourism, such as vacation and business, is in high-speed growth as well as the hospitality industry. People begin to pay more attention to vacation tourism, and more traditional villages try to renovate traditional residence into a boutique resort hotel. This article discusses how to replace the function of traditional residence into a resort hotel on the premise of properly keeping its characteristics, and satisfy the function of the resort hotel.

**Keywords:** resort hotel; traditional residence; renovation

### 1 COMBINATION OF TRADITIONAL RESIDENCE AND RESORT HOTEL

With the strong development of China's social economy, tourism, such as vacation and business, is in high-speed growth as well as the hospitality industry. In the meantime, as people are increasingly demanding on the quality and variety of life, the pure ornamental type of tourism can not meet the needs of tourists to tourism product diversity. People tend to prefer a travel in which they can obtain both visual beauty and cultural experience, and scenic spots of strong cultural characteristics such as ancient villages and ancient towns. When the tourist season comes, an endless stream of tourists can be seen everywhere in famous traditional scenic spots in China.

On the other hand, with the development of modern cities, a large number of traditional villages and ancient towns are forgotten, in which exist a large number of traditional residences. Many of these traditional residences are being demolished or abandoned, and only a few with high historical and artistic value ones are properly protected. How to treat this architectural cultural heritage is a challenge that we must face. Making flexible use of these traditional local-style dwelling houses is an important way. In the process of traditional residence switching to other functions, it is a necessary demand to repair and renovate a large number of these residences, which to a certain extent protects them and make them alive.

According to the existing experience abroad, the complete block and houses can be developed again, as a way of protection, while the unique ones usually make the best boutique hotels and stores. In order to protect the old city residential heritage, the European government has a special department for guidance for the renovation of ancient residence, no matter from the law or technology, and they strictly control the style of the buildings. For example, Paris, which has a long history as Beijing, has over 1200 hotels, and most of them are renovated from traditional residence, such as France Perth Hotel, built in the nineteenth Century to twentieth Century, 60 years ago, where the castle was transformed into a hotel (Fig. 1).

Figure 1. France Perth Hotel.

In order to renovate traditional residence into boutique hotels, the elevation, structure, decoration of traditional residence needs to be repaired, and through reasonable management, traditional residence can obtain a good economic benefit. We can use a part of the economic benefit to make persistent protection of traditional residence, and in this way, it may bring sustainable development of the good condition. With more and more tourism development, the ancient villages and towns attract more and more visitors to experience a new way of vacation. Traditional residence becomes boutique hotels through renovation, improving the environment and introducing modern facilities. Thus, in this way, tourist accommodation problems in these traditional villages can be effectively solved and traditional residence obtains good protection and inheritance at the same time. These resort hotels, which are renovated from traditional residences, not only emphasize the traditional hotels' residential function, but also make the regional and cultural experience more valued. On the one hand, there are quaint houses, secluded courtyards and chairs with history and memories; on the other hand, there are leisure time, delicious coffee, fascinating light and elegant furniture. The combination of these diversified elements seems not to be tough but makes the traditional residence shining with glory. This method of renovation brings an impressive holiday experience to visitors. What's more, it promotes the sustainable development of traditional residence and reduces the traditional villages' environmental stress given by the excess population so as to make the Chinese traditional regional heritage well-preserved without being influenced by rapid urban development and numerous old town renewal. This combination not only makes the resort hotels more cultural, but also protects the Chinese traditional residence effectively.

## 2 THE STRATEGY ON THE TRANSFORMATION OF TRADITIONAL RESIDENCE INTO RESORT HOTEL

There are generally two kinds of modes for the transformation of traditional residence into resort hotel: one is the transformation of the ancient village into resort hotel; the other is the transformation of courtyard residence into resort hotel.

### 2.1 *Transformation of the ancient village into resort hotel*

Resort hotels that are transformed from ancient village are located in the beautiful scenery and general scenic suburbs or near the village, with most of the original inhabitants being move out.

This transformation model should be based on the style, quality level and other factors, taking different transformation and protection modes on the abandoned traditional residence. When protecting and renovating traditional residences, we should also take into consideration the settlement pattern and the surrounding environment of traditional village. By analyzing the traditional settlement pattern, especially using the traditional gathering space, such as water, village, pond and trees, Temple Square in front, to create a public space, can be convenient for visitors to leisure activities, and life feel the atmosphere of traditional settlements. In the renovation of the protection of the natural environment, we should pay more attention to the traditional farmland, rivers, streams, forests and other protection landscape geomancy, and should forbid random destruction. For the settlement of the landscape, tree log activities can be made and regional characteristics can be created on the part of the landscape space node, such as Shaoxing Kaiyuan Resort by Da Yu (Fig. 2), Yu Ling Cun transformation, buildings to form a loose river of natural ecological environment, focusing on the overall planning of Yuling Village, without destroying the village stage, every tree and bush, brick, stone, patio, streets, Xiang River Boat Quay, such as scenery of Jiangnan folk customs reflect the gain by contrast.

### 2.2 *Transformation of the courtyard into resort hotel*

These houses are generally located in the old city or tourist resort area, and are generally historic houses into the courtyard. This transformation model should reduce architectural form, general layout, plane, facade, internal structure and decoration of the traditional residence deeply. When we renovate these traditional residences, we should try to retain the original appearance and focus on the protection of the mansion, halls, courtyards

Figure 2. Retaining the traditional settlement pattern and the surrounding environment of Shaoxing Kaiyuan Resort Da Yu.

Figure 3. Suzhou flower hall, third Court Village Landscape.

and natural environment of nodes. For example, Hua jian tang-Tan hua fu (Fig. 3) was the four-courtyard combination of Suzhou Pan's old house, according to the drawings and monograph in 1952 Mr Chen Congzhou painted as an important reference and careful restoration, while retaining the original pan Zhai; according to the needs of modern life and the hotel function was improved, at the same time in the courtyard carefully arranged waterside pavilions, embodies the garden of Suzhou the essence of the landscape.<sup>[1]</sup>

### 3 THE PRINCIPLES ON TRANSFORMATION OF TRADITIONAL RESIDENCE INTO RESORT HOTEL

The transformation of traditional residence to resort hotel would meet many conflicts; at the same time, there are also various standards bound in those processes. For example, the height of the floor to the roof is about 4.5 to 6 meters, which is higher than the modern residential space. In this way, the above room may be too empty and cause visual discomfort, so we can enrich the vertical space by increasing the thermocline in the transformation process. For example, Hua jiang tang Yan yuan (Fig. 4) in Si chuan increases the thermocline in the room to be the tourist activities space. The tourist can see the courtyard through the skylight.

Traditional residence mostly use civil structure, and most of these structures are very old. So, there are some security risks in the traditional residence and cannot meet the needs of modern living. We should renovate the traditional residences by passing on exterior wall renovation, replacing wood component, renovating roof, and strengthening the main structure. In addition, the structure of traditional residence is generally flammable, not conducive to building fire. Therefore, we should

Figure 4. Sunshine courtyard room small thermocline of Hua jiang tang Yan yuan.

Figure 5. Aman fayun resort.

design reasonable evacuation stairs and improve the fire resistance of combustible materials. Fire hydrant, fire extinguishers should be placed in the obvious position, at the same time in the courtyard of the pool can be used as fire water source.

When the transformation of traditional residence, there are two kinds of commonly used methods; one is the "repair old as the old". For example, Hangzhou Amanfayun Resort (Fig. 5) was retained and preserved in the transformation process of village of old houses the original walls, woodwork and famous and ancient trees, in the process of construction of new buildings, and the construction process of the old building, with mud, straw, suiwa compaction, and build a road some were still on the wall, the wall covered with a layer of brown film, even the new public toilets and other mountain houses maintained a unified style, to achieve a "repair old as the old" effect.<sup>[2]</sup>

Another method is to emphasize the "new" and "old" contrast. The transformation will build or transform part of the modern materials and styles, such as glass curtain wall and frame structure. This method can easily damage the body of traditional residence. For example, as part of the Zhou zhuang

Figure 6. The transformation of traditional residence completely dismantled the internal structure.

residential (Fig. 6), in order to transform into the inn, the whole building was demolished, and then rebuilt as antique buildings. This practice has caused great damage to the traditional residence, so attention should be paid to the process of reform. In fact, some new additions should be hidden, such as cabling infrastructure and structure reinforcement, and the old part should be explicit as far as possible to retain the original structure and decoration.

#### 4 CONCLUSION

Nowadays, globalization and localization development has become the mainstream of architecture.

How to treat the valuable traditional residence is a worthwhile topic, which should not be ignored and blindly overthrown. “Fusion and transformation” is an effective method, which not only respects and protects the traditional residence, but also makes use and creates value. Because of their own cultural values, traditional residence fulfills people’s personal and cultural pursuit, and effectively keeps the traditional architectural style and the traditional cultural heritage while they are renovated to resort hotels.

# Finite element analysis of confined precast concrete shear wall

Li Jun Dou & Ming Ling Gao

Changchun Institute of Technology, Changchun, China

**ABSTRACT:** This article mainly studies the end of the prefabricated shear wall with steel constraints, the internal distribution of reinforcing welded together with steel. In case of the axial compression ratio unchanged, discuss the different height-to-width ratio on the properties of the shear wall stress research. Design of a total of 1 general whole cast-in-situ shear wall contrast specimen and the constraint of 3 precast prefabricated shear wall specimens, a total of two groups. The results of finite element analysis show that: in general, cast-in-situ monolithic shear wall, the concrete crushing, and exit the work first. With the decrease in the aspect ratio, the bearing of capacity is increasing in precast constraint prefabricated shear wall.

**Keywords:** steel confined; prefabricated; shear wall; finite element analysis

## 1 INTRODUCTION

With the development of the city, the problem of environment is becoming more and more serious; people's awareness of the environmental protection is becoming more and more stronger. The development of housing industrialization can help mankind to protect the environment, improve the environment condition, and realize the sustainable development path.

Housing industrialization is to make the construction of production from extensive to intensive, from the traditional field of large-scale operations to the industrial machinery manufacturing plant. It can save labor, improve labor productivity, save resources, avoid the unnecessary waste of material mass, control the construction production waste effectively, and protect the environment.

Prefabricated shear wall structure is an important one of the components of housing industrialization. Many of them used for high-level and high-rise buildings, bearing horizontal direction and vertical load stress in the main, providing a better overall stability for overall structure, improving stiffness requirements, and superior performance characteristics in the energy dissipation capacity. It is applied widely in high seismic fortification intensity area. At present, although many studies of prefabricated shear wall has a progress, the influence factors of prefabricated shear wall mechanics not only just one or several factors can decide, but also to be connected by multiple factors influence each other. So far, the study of the prefabricated shear wall had a long way to go. There is a lot of research for new prefabricated shear wall structure will also continue to be developed and researched.

With steel reinforced concrete, composite structure can effectively improve the ductility performance of the structure. At the same time, the stress performance and energy consumption have a raise. The structure can help to ensure the reliability. It is used in important structure in prefabricated shear wall structure.

## 2 SPECIMEN DESIGN

### 2.1 Shear wall design

In order to study the influence of different height-to-width ratios on mechanical properties, design of geometry size is 700 mm \* 800 mm \* 800 mm, 1600 mm \* 800 mm \* 800 mm, 2500 mm \* 800 mm \* 800 mm<sup>[1]</sup>, as in the following figure.

Two kinds of section forms are designed, one is with steel reinforced concrete composite structures, the other is general reinforced concrete column structure (Fig. 2).

## 3 THE FINITE ELEMENT ANALYSIS

### 3.1 Summary

ABAQUS is one of the most advanced large-scale general finite element softwares in the world, with a large ability of solving nonlinear mechanics analysis function and is advanced. At present, it has been widely used in some complex and ultra structures of engineering analysis. It also has a lot of different kinds of unit model, material model, such as reinforced concrete and metal, rubber, polymer materials, such as soil rock geological

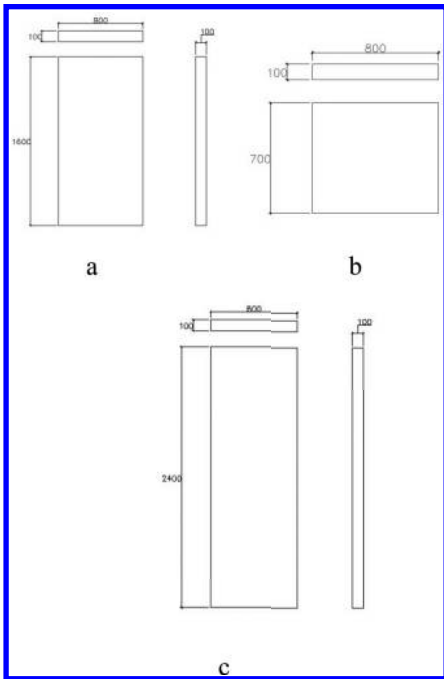

Figure 1. Physical dimension of shear walls (unit: mm).

Figure 2. Steel reinforcement of shear walls (unit: mm).

materials, and detailed analysis of the process. Based on the analysis of different materials, under complex loading process and contact condition of complex nonlinear combination problem, it can achieve more satisfactory results. When a nonlinear problem analysis, ABAQUS can automatically select the corresponding load increment and convergence limit, not only can choose the appropriate parameter, but also can adjust the parameters to ensure continuous get accurate solution in the process of analysis.

### 3.2 Modeling

Select the corresponding finite element unit type, steel truss, steel chooses entity model, and wall-board choose solid model. With reference to “Code for design of concrete structures<sup>[1]</sup>” and “Code for design of steel structures<sup>[2]</sup>” input the constitutive relation of concrete, steel bar, and steel. Selected parts of cross-section features, specified cross-section shape, define material, and enter the corresponding reinforcement area. And assembly, creating analysis step, placed inside the steel and concrete in the entire model. Meshing seeding in the first place, and then use rules of hexahedral unit division. Parts of model adopt quadratic integral unit completely. On the bottom of the wall boundary conditions are set to completely fixed with the ground ( $U1 = U2 = U3 = UR1 = UR2 = UR3 = 0$ ), uses the uniform set axial pressure, refer to “technical specification for concrete structures of tall building”, way to control the displacement under horizontal loading, exert<sup>[3]</sup> maximum displacement and the ratio of height to 1/1000, the following figure.

### 3.3 The results of the finite element analysis

1. 100 km on SW-1 shear wall axial force, horizontal displacement of 0.0016 m, the results are as follows:

Results show that at the bottom of concrete sustains the main stress. At the top of the body has much area with a large displacement.

Table 1. The parameters of experimental specimens.

Specimen number	Cross-section type	Wall body geometry size	Horizontal bar	Vertical reinforcing steel bar	H-beam section size (mm)
SW-1	1)	a)	$\phi 6@100$	14 $\phi 6$	
SW-2	2)	b)	$\phi 6@100$	14 $\phi 6$	60 × 60 × 5 × 4
SW-3	2)	a)	$\phi 6@100$	14 $\phi 6$	60 × 60 × 5 × 4
SW-6	2)	c)	$\phi 6@100$	14 $\phi 6$	60 × 60 × 5 × 4

Note: At the end of shear wall at both ends of the SW-1 double limb hoop configuration; SW-6/7 2/3/4 / cross section of steel at a rate of 1.00%; the SW-5/5-5 of section steel at a rate of 1.25%.

Table 2. Parameters and bearing capacity table.

Specimen number	Cut across than	Axial compression ratio	Steel area $A_s$ (mm <sup>2</sup> )	Horizontal bar gap (mm <sup>2</sup> )	Shear capacity V (KN)
SW-1	2	0.13	0	100	51
SW-2	0.875	0.13	800	100	117
SW-3	2	0.13	800	100	86
SW-6	3	0.13	800	100	78

Figure 3. Model of shear wall.

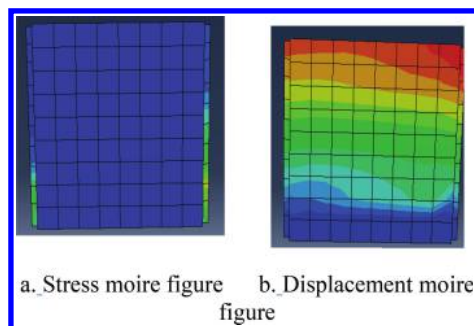

Figure 5. Results of SW-2.

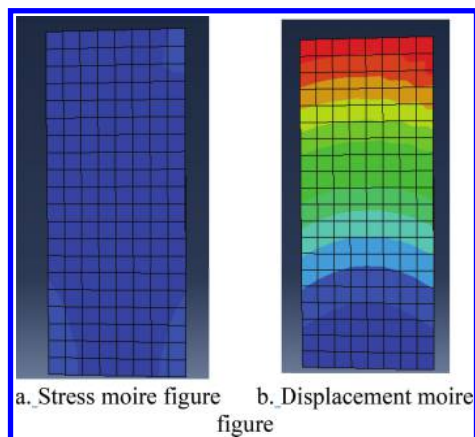

Figure 4. Results of SW-1.

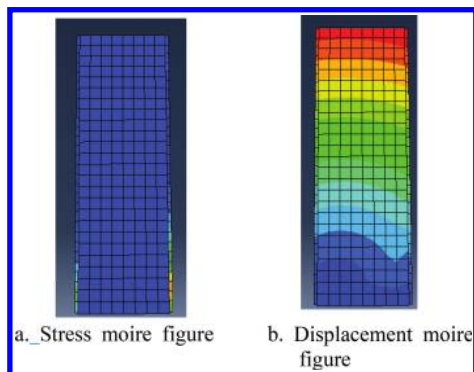

Figure 6. Results of SW-3.

2. Analyze the SW-2 shear wall  
The results showed that at the bottom of H-steel sustains the main stress. At the top of the body has little area with a large displacement.
3. Analyze the SW-3 shear wall  
The results showed that at the bottom of H-steel sustains the main stress. At the top of the body has little area with a large displacement.

4. Analysis of the SW-6 shear wall  
The results showed that at the bottom of H-steel sustains the main stress. At the top of the body has much area with a large displacement.

### 3.4 Comparative analysis

Through comparative analysis of shear wall with H-steel and general shear wall, it show the wall with H-steel than general shear wall has larger capacity reserve. Under the condition of the maximal displacement in a given specification, with the increase of aspect ratio the displacement

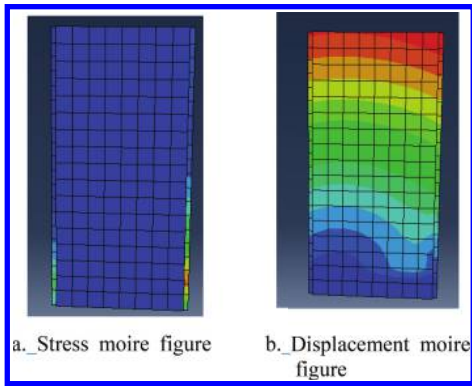

Figure 7. Results of SW-6.

increases obviously, at feet of the steel yield stress also increase. In the bottom of the steel yield failure first. The performance of the concrete characteristics is finer than the general shear wall. It is concluded that the shear wall with steel constraints can be very good to have the first force and energy dissipation effect.

#### 4 CONCLUSION

1. Equipped with steel shear wall play a role in constraining concrete, sustaining load in the previous, protecting concrete, providing higher bearing capacity.
2. With the increase in aspect ratio, displacement scope also increases, larger stress mainly appears at the bottom of H-steel.

# Research on the unification of architecture and art, technology and art in architecture—Take I.M. Pei’s Architectural Design Works for Example

Liqun Guo

Doctor Student in School of Art and Design, Wuhan University of Technology, Jiangxia District, Wuhan, China  
The School of Arts and Design, Wuhan Institute of Technology, Jiangxia District, Wuhan, China

**ABSTRACT:** Building technology and art have the dialectical unifying relationship, and Ieoh Ming Pei’s architectural goal is to seek harmony and unity between them. This article mainly discusses the detail management and design methods in Ieoh Ming Pei’s works, helping to understand the unification of architecture and art, and the combination of technology and art.

**Keywords:** I.M. Pei; architectural; technology; art

## 1 INTRODUCTION

With the development of society, the construction requirement is getting higher and higher. In other words, with the development of social economy, the requirements of architecture will become higher as people’s living standards increase. Although the construction and functions of modern society become more and more complex, the nature of the buildings functionality stays constant, the architecture works with the perfect combination of modern technology and artistic attributes will attract more attention.

Ieoh Ming Pei is one of the most successful world architects of the twentieth century, and he is also the most influential modernist architect in the world as well. Pei has designed many landmark buildings, and gets a lot of symbolization in architecture industry’s highest honor international awards. Through the analysis of his works, it is not difficult to see that Pei’s focus on the unification of architecture and art as well as the combination of technology and art.

## 2 THE UNIFICATION OF ARCHITECTURE AND ART

With the development of society, the construction Ieoh Ming Pei once said: “Architecture and art though somewhat different, but essentially the same, my goal is to seek harmony and unity between the two.” Pei always regards the building as an independent art, and makes full use of the rich architectural space and resources in the sculpture, paintings, and other art forms. These design methods are commonly used in Pei’s architectural

designs to achieve the unification of architecture and art.

### 2.1 *The building as an independent work of art*

Sculpture is a typical feature within many of Ieoh Ming Pei’s works of architecture. When he noticed purification in the morphology of buildings, he specializes at portraying the building using a variety of geometry, the architectural and artistic unity, such as the Des Moines Art Center, East Wing of The National Gallery in Washington, and Iverson Museum of art. These architectural specimens have the appearance of sculptural style. (Figs. 1, 2, and 3).

### 2.2 *The usage of the rich architectural space of modern sculptures and paintings*

Ieoh Ming Pei are of the opinion of that the abstract sculptures can enrich large modern architectural

Figure 1. Des Moines Art Center.

Figure 2. East wing of national gallery.

Figure 3. The Everson Art Museum.

structures, and architecture and art should maintain closeness. Choosing a style or theme of unity within modern sculpture, painting and other works of art can enrich architectural space, to become a part of the whole building's design, processing techniques of architecture and art unity are often used by Ieoh Ming Pei. Such as The National Gallery's famous Calder Henry Moore's sculpture and the tapestry works by Spanish artist Huang Milo [1], Iverson art museum entrance use Henry Moore's sculptures, the French Fragrance Hill Hotel use famous Chinese painter Zhao Wuji's works, well embodying Ieoh Ming Pei's design concept and unification of architecture and art.

### 3 THE COMBINATION OF TECHNOLOGY AND ART

#### 3.1 *The building as an independent work of art*

Ieoh Ming Pei accomplishes geometry as an artistic form for the combination between technology and art. Pei's successful architectural works make a great use of geometry, such as the Louvre Pyramid, the Washington National Gallery's East Pavilion,

the Miho Museum in Japan, and Bank of China in Hong Kong.

Le Louvre Museum in Pyramid is one of the most representative buildings designed by Ieoh Ming Pei, and it is also a very typical architectural work showing the combination of technology and art. From the artistic perspective, the stable triangular Pyramid form is very suitable for the old rear roof form of Le Louvre museum building; Pyramid's glass surface can reflect Le Louvre museum's old palace, and helps people indoor to see the old palaces through it, which skillfully makes the Pyramid to integrate into the surrounding environment; Pyramid's highly transparent glass also injects light to the ancient Le Louvre Museum for a special charm. In addition, the north, south, east sides of this large glass Pyramid all has a five meter high glass Pyramid and seven triangular fountain, it becomes a beautiful geometric scenery complementing each other with the main Pyramid. From a technical perspective, the four sides of Pyramid is from by 673 pieces of diamond glass, and the total weight of Pyramid is 200 tons, of which the glass net weighs 105 tons, the metal stent is only 95 tons [2]. The load of the metal stent is more than its own weight, that fully embodies the unique use of modern science and technology in Pyramid. (Fig. 4).

In the Design of Washington's National Gallery's East Pavilion, Pei's extreme application of this method created the perfect combination of technology and art. First is the layout, the irregular trapezoidal area that combines two large triangles and a small triangle, forming the overall framework of the museum architecture and space form. The internal space is divided in strict accordance with the triangles and the deformation of the form. It carries on the segmentation to the whole space, so that each sub space has a strict correspondence on the whole. The whole sequence of space is filled with change, and is highly unified. On the technical level, the triangular atrium skylight roof structure of triangular, using a slide bearing support, not only solves

Figure 4. Louvre pyramid.

the problem of thermal expansion, but also covers the top of the lighting equipment, in addition to the snow and rain water drainage system. In order to solve the problem of strong ultraviolet sunlight producing damage to the art exhibition, Ieoh Ming Pei is also developing tubular aluminum louvers, this barrier can reduce light and heat projected into the exhibition interior, and transition any remaining room light on the art into soft and stable. In addition, glass skylights placed in addition to the hot-line, melt the snow accumulated on the roof; made of synthetic rubber, small channels discharge rain water into the drains hidden within the walls. The technical treatment of these series creates a triangular atrium space filled with a warm, comfortable and pleasant feeling. (Figs. 5-7).

The use of geometry is also reflected in the design of Ieoh Ming Pei's Japanese Miho Museum. Affected by Japan's Natural Park Act, less than 20% of the Japanese Miho museum is exposed above ground. The top of the triangular structure is made up of many different sizes, intertwined as a geometric painting. From afar, roof peaks and undulating curves are interconnected as if it is one, in the artistic sense. In the waterproof aspect; the basement walls of the library collection are insulated with thermal insulation material to avoid a frosting phenomenon caused by the temperature difference between indoor and outdoor. In order to prevent seepage of mountain soil, the construction site is covered with a cold and corrosive resistant foundation and Swiss waterproof agent and finally a layer of cement. Carefully designed shockproof walls 20 meters high, provide good protection and security to the architecture and the separated ground floor. (Fig. 8).

Ieoh Ming Pei designed the Hong Kong Bank of China Tower, which makes full use of the building structure to create geometric elements, in turn the combination of art and technology has created a classic masterpiece. This work was completed in 1990 and is the tallest skyscraper in Hong Kong, the whole building (70 floors, 315 meters high) uses only the four corners of the giant 12-storey steel columns for support, no internal pillars are

Figure 5. East Wing of National Gallery Aerial View.

Figure 6. East Wing of National Gallery General.

Figure 7. East Wing of National Gallery's Atrium.

Figure 8. Japanese Miho Museum.

used [3]. In the square construction of the buildings foundation, stands four groups of diagonally placed triangular facades varying in height, like the bamboo trees to give a full vigor, "rising" feeling, and the buildings base is rooted with the granite stones from the Great Wall of China, like the bamboo tree symbolizing a booming future of development for Hong Kong and China, spreading its wings and soaring high. (Fig. 9).

The designs of Le Louvre Museum Pyramid, The National Gallery in Washington East Hall, Japanese Miho Museum and Hongkong Bank of China fully embodies Ieoh Ming Pei's design theories of using triangle geometry to modeling architectural space and the perfect combination of technology and art characteristics.

Figure 9. Hong Kong Bank of China Tower building's appearance.

### 3.2 Detail management

Ieoh Ming Pei architectural works pay great attention to detail and technologies, in particular, his designs always regard detail for god. He said: "A good design, not only has a good idea, but also in detail." [4]

As one of Ieoh Ming Pei's beloved works—Iverson Art Museum for example, its shape is created by the use of concrete with a sculptural architecture style. People who understand concrete know that concrete is a kind of rough and easy deformation of building materials, especially in the joint continuous irrigation portion and is easily prone to cracks and crevices, and every little flaw can lead to permanent defects.

Construction of the Iverson museum of art, Ieoh Ming Pei adopted the method in NCAR (American National Center for Atmospheric Research)—all the main outer wall surfaces are smooth and seamless as marble, glowing red granite plaques, the museum and the surrounding red sandstone and brick city buildings all blend seamlessly into one harmonious whole. The architecture benefits from Ieoh Ming Pei's design not only for his good idea, but also by his handling of each architectural detail. Especially in the construction of large concrete surface areas that are chiseled out to form oblique textures, which contrasts to the relationship between

certain and uncertain cut textures, and because it entirely belongs to the same material, the overall effect is unity and coordination.

In the design of East Wing, The National Gallery in Washington, the treatment of the construction details are admirable. In order to save costs, exterior building stone of East Wing, The National Gallery in Washington is very thin, but for the purpose of quality and visual effect, Pei adopted the double wall structure. [5] The wall has paved a layer of ordinary brick wall firstly, and then use the stainless steel strip to fix on the wall, finally the marble is covered on the outstanding wall. For creating solid and perfect effect, each piece of stone is cutting to fit evenly into the preset position. In order to prevent the building stone from experience thermal expansion and contraction, a 1/8 inch gap between the stones has been reserved, and the gap is also filled with an expansion joint, and the gap is filled with neoprene tape which is painted with the same color of the marble stone, so the whole wall looks smooth, neat and beautiful. Especially the corner node (traditional oblique tenon joints) is inlaid with neoprene tape to make up the insufficient and unsightly bevel butt in the marble.

## 4 CONCLUSION

New technology, new materials and new equipment in today's era not only enhance the quality of people's lives, but also improve the level of architectural design. However, the technical skill is still low, and the artistic architecture is few and far between. This article focuses on the outstanding architectural works of Ieoh Ming Pei's success as an example, from the building as an independent work of art and the usage of the rich architectural space of modern sculpture works to analyze the design style of the unification of architectural works and art works; from the usage of geometry and detail management to introduce the combination of art and technology in Pei's works, intended to provide certain inspiration and reference value to the contemporary architects.

**ABSTRACT:** The traditional residence features of our national longitudinal valley areas in Hengduan Mountains in the southwest present a unique style, while, in recent years, the large-scale concrete square-box architecture activities have appeared. Newly built houses lose the aesthetic value of traditional residence and cut off the development venation of dwellings, which suffer a barrage of criticism. This paper selects middle-upper basin of Nu-Jiang River as research area, and makes contrasting analysis about thermal performance of conventional building materials-concrete hollow block and conventional building materials-wooden flute, immature soil with the method of the physical environment test. The test results show that the former is provided with better environmental suitability, which verifies that under the overall background of protecting forest resources, hollow brick is of great significance in promotion. On the basis of this, it analyzes those existing problems in current brickwork houses, and proposes optimization design scheme for residential buildings, referring to more attention to national characteristic decorations and form expression, as well as the structural measures of reinforcing structure and adapting to climatic characteristics.

**Keywords:** concrete hollow block; Nujiang River drainage basin; new-type territorial dwellings

## 1 INTRODUCTION

In the past, our national house cladding material of masonry structure is mainly of agglutination loam brick. To save land resources, our country starts to research a series of new building materials to replace agglutination loam brick step by step. At present, one of the widely used building materials in our national rural areas is concrete hollow block. Research results on this building material mainly are reflected in economic benefits, physical properties (thermal insulation and sound insulation property) of material and several problems to be prevented in the process of construction. Please see literature [1] to [4] for more details about the research results. These researches mainly refer to the aspect of engineering practice application, but to ignore the research on aesthetic values of

material. It is even more so in architectural practice, so that the society throws doubts upon the newly built concrete dwellings.

Longitudinal valley areas of Hengduan Mountains in West China are national nature protection area, multi-ethnic mixed area, and extremely distressed area. The typical vertical three-dimensional climate makes the types of traditional residence in this area diversified, respectively including pile dwelling type of bamboo split house, well-frame house, immature soil house, etc. All these types present bright regional characteristics. However, local civil firewood and dwelling structure lead to a huge consumption of fire wood, which consists of principal factors of local forest resources consumption mode and quantity. According to some statistics, for a 70 m<sup>2</sup> well-frame house, its roof, wall, and floor need total 43.3 m<sup>3</sup> woods with 84.0 m<sup>3</sup>

forest resource consumption; furthermore, a well-framed house is the dwelling type with the largest consumption of forest resources among all traditional residence types [5]. With the sudden increase tendency of national minority population, forests cannot bear the heavy burden, which leads to forest changed into meadow, meadow desertification, and other ecological crisis. To prevent further degeneration of forest resources, local government carries out the policy of closing hillsides to facilitate afforestation, and encourages local people to adopt slag hollow brick as the primary building material for new dwellings. The results cause that “barrack” type of brickwork dwellings appear on a large scale. Relevant researches show that those problems like uncomfortable dwelling and rigid appearance exist in newly built dwellings, which leads to the author’s exploration toward concrete hollow brick application in regional architecture. Researches in this paper are expected to standardize the application mode of new-type building materials in less developed areas, guide brickwork dwellings to actively adapt to local climate, and reflect minority culture traditions, and get newly built brickwork dwellings stepping on development road of regional architecture.

## 2 OVERVIEW

Nu-Jiang River originates from Tanggula Mountains in Qinghai-Tibet Plateau, directing to the south once entering into Yunnan and then directing to Burma renamed as Salween River, and finally flowing into Andaman Sea of the Indian Ocean. The east side of upper-an-middle drainage basin is Biluo Snow Mountain, and west side is Gaoligong Mountain. The flowing areas are from alpine and gorge region of two mountains infibulating a river which is Nujiang Canyon. Nujiang Canyon presents a reverse “V” tendency from north to south, mainly containing Gongshan and Fugong County (northern latitude  $26^{\circ}28' \sim 28^{\circ}23'$ , east longitude  $98^{\circ}08' \sim 99^{\circ}02'$ ). The ridges at both sides of Nujiang Canyon have over 3000 m average elevation, while the average canyon depth is more than 2000 m. The deepest point is Bingzhongluo area in Gongshan County, reaching 3500 m.

Quanzhou is subtropics hilly monsoon climate, and the difference in latitude and elevation leads to difference in air temperature. The latitude has different air temperatures from different elevations, or the same elevation has different air temperatures from different latitudes, which forms a prominent three-dimensional climatic feature. Once the elevation increases above 100 m, the air temperature will decline by  $0.59^{\circ}\text{C}$ ; once latitude directs northward by  $1^{\circ}$ , the air temperature will decline by  $1.2^{\circ}\text{C} \sim 1.7^{\circ}\text{C}$ . Compared with horizontal

Figure 1. Nu-Jiang River region environment.

climate difference, vertical climate difference is more prominent. The diversified landforms and different microclimate characteristics generate diversified microenvironmental habitation.

This paper takes the Baizi District of warm temperate zone in the north of Nujiang Canyon—Bingzhongluo as research area (Fig. 1). Gongshan County has abundant rainfall capacity, and, from February, to October the whole year is a long rainy season with extremely abundant rainfall capacity. Gongshan areas stay in low-temperature climate all year round. It will be winter in rainy days with insufficient heat, and it is a typical clammy climate. The annual mean rainfall capacity in Bingzhongluo is 1657.3 mm; annual average temperature is  $13.1^{\circ}\text{C}$  to  $15.4^{\circ}\text{C}$ ; the average temperature of the coldest month is  $5.9^{\circ}\text{C}$ , while the average temperature of hottest month is above  $20^{\circ}\text{C}$ , and it is warm temperate zone climatic region. The research site is located in Chongding Village, situated in northern latitude  $28^{\circ}01'38''$  and east longitude  $98^{\circ}37'31''$  with 1580 m elevation.

## 3 ADAPTATION OF HOUSE MATERIALS AND ENVIRONMENT

### 3.1 Test object and test result

#### 1. Test object

This time of test is forwarded in winter with research objects (Fig. 2) as representative dwellings R1 (immature soil house), R2 (well-frame house, two floors), and R3 (brickwork house). The three architectural structures locate in a same courtyard, and the difference in outdoor environment can be ignored. R1 is a traditional immature soil—flat pedestal house with an 80-year history and the thickness of wall reaches 0.5 m. And it consists of soil, macadam, and straw by punning. R2 is a newly built family hotel with two floors in the structure of

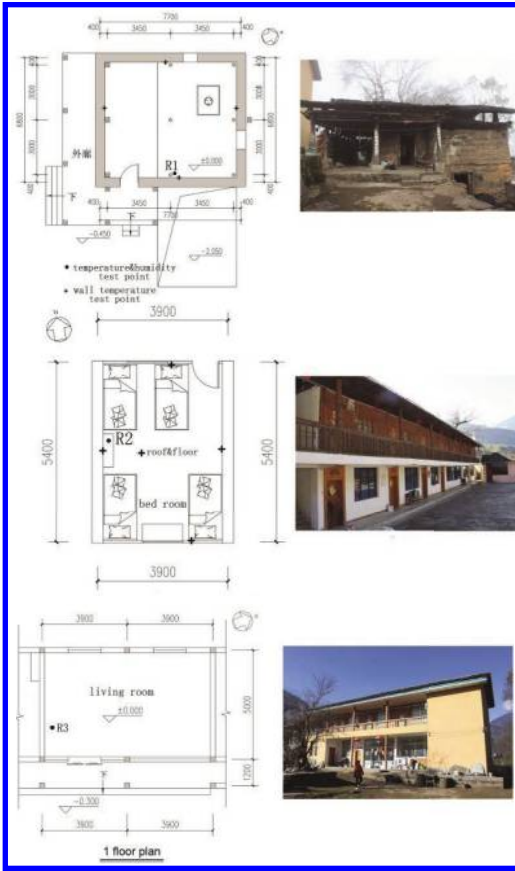

Figure 2. Survey rooms and survey points.

concrete and wooden frame. The wall of first floor is hollow brick masonry, and the second floor is simulated traditional well-frame wall by overlaying half round solid wood with up-and-down two ends chipped off. Its thickness is 5 cm, and the internal surface of wall is stuck with about 3 mm wooden board as facing material. The test object is a room in the middle of second floor. R3 is a newly built brickwork house with two floors. This house is built with concrete frame structure, and masonry wall is from hydraulic-pressure slag hollow block. The block size is 390\*200\*190, and the thickness of wall is about 22 cm (including 10 mm plaster layer of its internal and external surfaces).

The test time is 12:00, December 8, 2010 to 12:00, December 10, and it is rainy from 6:00, December 9 to 6:00, December 10. In Gongshan areas, the amount of precipitation is large, and average relative humidity reaches above 78% all year round. Thus it can be seen that it is of great practical significance to take physical environment test toward houses in rainy days, and to know more

about the indoor temperature and humidity in rainy days in winter.

## 2. Test result

### 1. Indoor and outdoor air temperature

Figure 3 is relative air humidity test result of indoor and outdoor air. This time of test experiences a sunny day and an overcast day. During test period, average outdoor temperature is 11.06°C. In whatever sunny day or rainy day, the appeared time of minimum and maximum air temperatures, respectively, are 5:00~5:30 and 16:00~17:00; daily range in sunny day is 7.6°C, and daily range in rainy day is 3.6°C. The test results of various rooms are shown as below: ① for immature soil house (R1), the indoor average temperature is lower than outdoor air temperature, and both its minimum and maximum air temperatures appearing in sunny days, respectively are 9.5°C and 12.3°C. The daily range is 2.8°C. In rainy days, range ability of indoor temperature is very little, and the daily range is 1.3°C. Therein, 7:00~9:00 is minimum temperature, 10.1°C; Indoor temperature at night rises slowly with opposite variation trend toward outdoor temperature. We can find that for clammy areas, indoor temperature of immature soil house changes a little, and it has favorable heat insulation performance; however, humidity within the house is large (medial humidity reaches 80.4%). Besides, no heat resource is available indoor, which results in lower indoor temperature than outdoor temperature. The earth houses in cold and arid regions of China's northwest are provided with the climate characteristics of hot summer and warm winter. By contrast, earth buildings cannot give play to the thermal insulation properties in clammy regions. ② For the dry-type house (R2), the indoor mean temperature was slightly higher than outdoor temperature, and its minimum value and maximum value, respectively, were 10.3°C and 13.3°C, both happened in fine days. The daily range was 3°C.

Figure 3. Indoor and outdoor air temperature.

During rainy days, the temperature change was not very little with 0.9°C daily range for the whole day. And the indoor temperature during 10:00 to 11:30 was 10.7°C, which was the lowest in that day; at night, the indoor temperature basically remained unchanged. 3) For the brick house, the indoor mean temperature was the highest; the minimum value happened in cloudy day, which was 10.8°C; while the maximum value happened in fine days, which was 13.6°C. The daily range was 2.8°C. During rainy days, the temperature change was all day long with daily range 1.1°C; At night, indoor temperature gradually dropped.

#### 2. Relative humidity of indoor and outdoor air

Figure 4 is the test result of relative humidity of indoor and outdoor air. It can be seen from the figure that the average value of outdoor relative humidity was 83.8%. At 15:30, of the 8th day, the relative humidity was 41.9%; afterwards, the humidity gradually rose; the 9th day was a rainy day, the average humidity was the highest. For all the tested houses, the low-to-high sequence of indoor mean relative humidity was: R2 (dry-type house), R3 (masonry house), R1 (earth house), which respectively were 75.4%, 77.7%, 80.4%; the tendency of relative humidity change of all houses were as follows: it was fine in the 8th day, and the lowest humidity happened during 14:30 to 16:30. When night fell, and it rained in the 9th day, the humidity gradually rose.

#### 3.2 Environmental adaptability of new and old palisade components

According to test result, the high-to-low sequence of the mean value of base room temperature was

Figure 4. Indoor and outdoor air relative humidity.

R3 (masonry house), R2 (dry-type house) and R1 (earth house); and the high-to-low sequence of the relative humidity was R1 (earth house), R3 (masonry house) and R2 (dry-type house). It can be seen that the thermal performance of brick house and dry-type house is better than earth house, which reflects the adaptability of new materials to the complicated natural environment in Nu-River basin. Although from the perspective of long-term development, concrete material certainly will be replaced by more ecological environmental protection material. However, its current utilization is in line with the reality.

#### 4 PROBLEMS EXISTING IN CURRENT MASONRY DWELLING HOUSES

Cinder bricks are processed and made of industrial waste, which are provided with good performance of energy conservation, soil saving, environmental protection, thermal insulation, heat preservation and sound insulation, so that they are environmental friendly and new type building materials that can replace fired clay bricks. The manufacturing technique of slag hollow bricks is as following: waste slag lime parget, stirring digestion grinding, green brick molding steam curing finished products [4]. Since 1990s, this product has been developed rapidly. Currently, it has been widely applied in eastern coastal regions and western regions in China. Since the implementation of “closing hill-sides to facilitate afforestation” policy in Nu-River basin, the government has funded the promotion of this product in the vast mountainous areas. For its application in house construction in mountainous areas, it is provided with following advantages: ① at present, its replacement of wood reduces the load of forest resources. ② it utilizes industrial waste as the aggregate, which reduces environmental pollution. ③ it can be processed within a small scale nearby, which is free of space limits and reduces energy consumption during transportation process. ④ it is convenient for manual handling. In Nu-River basin, the mountains are high and slopes are abrupt, resulting in inconvenient transportation. Small-scale building blocks can be transported by tractors, handcarts, while it is inconvenient for larger wagons. At present, hollow bricks have the following problems: ① the strength is low due to low material density. ② The level of manufacturing technique is low, resulting in rough surface and broken corners (Fig. 5). Above-mentioned problems can be solved by improving the level of manufacturing technique.

The overall economic level of this region is low, and it is the extreme poverty region in China. Due to limitations of economy and a lack of related

Figure 5. Slag hollow bricks made in Nu-River basin.

Figure 6. Concrete box houses.

technical guidance and masonry dwelling, houses develop fast with the feature of low technology, which results in a large number of problems: the constructional column in the brick-concrete structure lacks steel ties, leading to hidden danger in seismic fortification; the spatial composition is rigid, incomplete, and not in line with the climate; the scene of buildings is stereotyped, and even disgusting. In a word, the newly built dwelling houses fail to improve people's housing quality, and even are far less comfortable than traditional dwelling houses (Fig. 6). In the condition that economy bearing capacity is limited, it is the research objective of this thesis to provide comfortable and pleasant living environment for national minorities.

## 5 OPTIMIZED DESIGN RESEARCH ON MASONRY HOUSES IN NU-RIVER BASIN

In order to facilitate the development of regional architecture and change the architectural image of newly built masonry dwelling houses in less developed areas and the dwelling level, the author explores the approaches to application of this material mainly from the perspective of aesthetic value of concrete hollow bricks and the climatic adaptation of mountainous environment.

### 1. Architectural decoration

Parts of the newly built dwelling houses are constructed on the basis of previous old houses. The traditional Muleng, girders and other components dismantled from the old houses are applicable for reuse for new dwelling houses. The mixed use of new and old material has two construction ways: ① the ground floor utilizes concrete hollow bricks, and the top utilizes traditional materials. In such way, the top room can be used in summer; and the ground room can be used in winter. ② The kitchen and bedrooms utilize concrete hollow bricks, which are fireproof and thermal insulation. Function rooms, such as living room, storeroom and bathroom, utilize the enclosure of traditional woods. On one hand, the mixed use of new and old materials saves building materials, on the other hand, it reflects the regional characteristics of traditional dwelling houses.

Besides, the most common materials are unified gray bricks. Color hollow bricks can be produced so as to satisfy the demands of architectural ornament of multiracial dwelling houses in mixed dwelling regions. Figure 7 shows the ornaments on the eave walls and plinth of the building scheme for new dwelling houses of the Nu nationality in Gongshan area.

### 2. Form expression

In the construction of new dwelling houses, architects should respect the living customs of the minority, and introduce new functional space for living, such as living room, dining room, and bathroom, so that dwelling buildings that combine the

Figure 7. Color concrete used for architectural decoration.

Figure 8. Gongshan area dwelling houses scheme.

traditional and the modern and reflect national features can be designed. In such way, the form expression of new architecture will certainly be enhanced, and the visual performance of new dwelling houses can be strengthened. Figure 8 shows the dwelling houses scheme in Gongshan area, which reflects the humanized design philosophy. (Designed by the author)

### 3. Building construction

The building space of traditional dwelling houses in Nu-River basin, no matter it's dry-type house or bamboo split house, is full of gaps and holes, like ventilating bamboo cages, so that it can adapt to the wet climate. The eave wall top, gable, and the wall body of newly built dwelling houses take advantages of the characteristics of hollow bricks and the wall body with holes in the masonry. Its unique building mechanism reflects the excellent likeness with traditional dwelling houses.

### 4. Structure safety

At present, masonry dwelling houses in Nu-River basin mainly have one or two floors, which mostly utilize brick-concrete structure. The buildings lack technical support, and the constructional column is

not provided with reinforcement. Besides, there are no steel ties between constructional columns and wall body. The consequence cannot be imagined once earthquake happens. The newly built dwelling houses should enhance the brick concrete of reinforcing bars and the composite bearing structure of frame. On one hand, it improves the earthquake resistance of houses, on the other hand, it provides technical guarantee for the scale enlargement of dwelling houses (increase of floors).

## ACKNOWLEDGMENTS

The research described in this paper was supported by science and technology talents fund of Xi'an University Of Architecture And Technology (RC1302) & National Natural Science Foundation of China (No. 51408470, 51221865).

**ABSTRACT:** Based on the Landsat TM Images in 1985, 1995, 2000, 2005, and 2014, spatial and temporal dynamic variation of landscape pattern for 30 years in Chuanjiang River Basin was analyzed to obtain its characteristics and to transfer features in space and time by software platform of ENVI5.1, ArcGIS10.1 (ArcView) and FRAGSTAT4.2. The results showed that: (1) there were conspicuous differences between characteristics of the landscape components, with the area ratio of grassland and forest landscape lower relatively; (2) as a whole, the landscape structure of the research basin was simple, the diversity was low, the fragmentation degree had an increase trend, and the vulnerability was high; (3) the distribution of different landscape gravity centers reflected the certain zonality in different periods. The movement of the gravity center of the built-up landscape was the most significant in a single landscape type, which was closely related to frequent and intense human activities; and (4) a typical landscape type and the comprehensive landscape dynamic changes shows the significant changes of landscape on different time scales from several angles, and the consistency with the landscape gravity center migration significance.

**Keywords:** landscape analysis; spatio-temporal dynamic variations; transfer model; Chuanjiang basin

## 1 INTRODUCTION

A river basin is a complete natural geographical unit, with its landscape pattern formed by superposition of natural and human's activities, and at the same time, the evolution of watershed landscape pattern restricts the occurrence and development of the natural processes directly, such as hydrological processes, biological processes, and also ensures the ecological safety of river basin as well as guarantees the production and living activities of human-beings (Fu B.J. et al., 2001, Wu J.G., 2000, Xiao D.N. & Li X.Z., 1997). It is the key measure to watershed comprehensive management that analyzing the dynamic changes of landscape pattern and then formulating reasonable landscape control countermeasures, with basins being treated as the research scale, based on the theory of landscape ecology and watershed ecology (Zhao J.Z., 1990, Robert T.W. & William D.S., 1999, Verbrug PH, et al., 1999).

Chuanjiang River Basin refers to the upper reaches of the Yangtze River from Yibin to Chongqing. The basin is the transition zone from mountain area to the low hills in general, with complex geomorphology and topography, severe rocky desertification, sharp contradiction between human and land, and quick urbanization development.

(Da F.Q., 2001, McIntyre, S. & Lavorel, S., 2007). Under the influence of strength human activity and nature, its ecological environment is quite vulnerable. Supported by RS and GIS, together with the software of FRAGSTAT4.1 (grid mode), the variation changes of landscape pattern and composition for 30 years in Chuanjiang River Basin were analyzed. It will provide a scientific reference to adjust landscape structure in the upper Yangtze River, enhance the utilization efficiency of land and natural resources, promote the western economic development, and improve environment quality in the upper Yangtze River. On the other hand, it explores integrated analysis for landscape dynamic changes.

## 2 OVERVIEW OF STUDY AREA

Chuanjiang River Basin, located in the southwest of China, between 102°49'E–109°15'E and 26°15'N–31°41'N, covering a total area of 164,000 km<sup>2</sup>, occupies the border region of four provinces/municipality, including Sichuan, Chongqing, Yunnan and Guizhou. It is also the core economic zone of the upper Yangtze River and an important region of the West China Development Drive. The research area is the southern margin

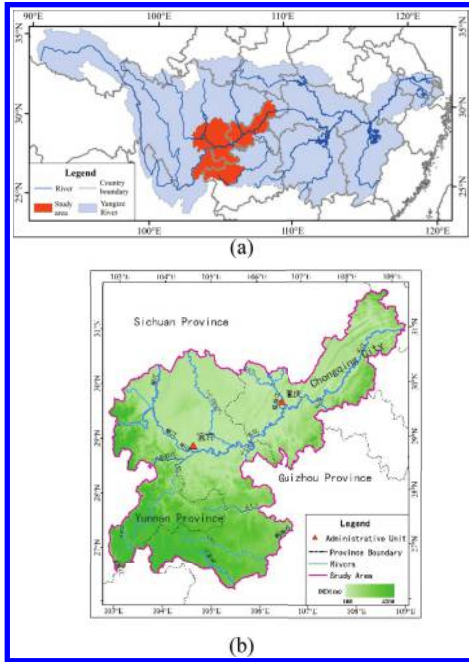

Figure 1. The location of study area in the Yangtze River basin and drainage map with DEM (Digital Elevation Model).

part of the Sichuan Basin, the transition zone from the hilly to the mountainous, with gentle hill terrain along the river sides. The main stream length is 969.6 km, including the main tributaries of Minjiang River, Jialing River, Wujiang River, Tuojiang River, and Jinsha River (as shown in Fig. 1).

It has a moist, subtropical monsoon climate. The annual average temperature is 15.4°C and the maximum and the minimum temperature are 18.9°C and 7.4°C respectively. The annual average rainfall is 1040.1 mm, while the annual maximum and minimum precipitation are 1371 mm and 779 mm, respectively. Soil types and distribution are diverse in the study basin, with the main soil type including paddy soils, purplish soils, yellow earths, limestone soils etc. The main plant types in the river basin are cultivated vegetation, shrubs, brushes, coniferous forest, broadleaf forest, meadows, and coniferous broad-leaved mixed forest.

### 3 DATA AND METHODS

#### 3.1 Data sources

Landscape information source is based on the Landsat TM data in 1985, 1995, 2000, 2005, and 2014 in Chuanjiang River Basin, composed by

4th, 3rd, 2nd (GRB) bands, corresponding to 30 m ground resolution ratio and 6–10 month phase.

#### 3.2 Data processing

##### 3.2.1 Landscape classification

Based on the data processing platform of ENVI5.1 and ArcGIS10.1, according to the *Current land use classification ISBN: GB/T 21010-2007*, promulgated by Ministry of land and resources of the People's Republic of China, combined with the practical situation of river basin, the landscape of research area was divided into 6 landscapes: agriculture landscape, forest landscape, grassland landscape, waterbody landscape, built-up landscape, and desert landscape.

##### 3.2.2 Characteristics evaluation system of landscape pattern

There are many indexes to evaluate the landscape pattern. Considering the specific characteristics of Chuanjiang River Basin, this study selected the indexes as follows to reveal the characteristics of the watershed landscape spatial structure: the number of patches, patch density, landscape shape index, Simpson-landscape diversity index, landscape fractal dimension, and fragmentation (Wu J.G., 2000, Fu B.J., et al., 2001). The combination of ArcView and Fragstat4.2 software platform was used to rasterize the landscape data and to calculate the corresponding parameters.

##### 3.2.3 Spatial variation and landscape types transfer model

In order to quantify the watershed landscape type spatial change trends, a gravity center model (Yan D.H., 2004), a single dynamic model, and a systematic dynamic model were integrated to (Wang X.L. and Bao Y.H., 1998) carry out the analysis study.

#### 1. The gravity center model

$$\left\{ \begin{array}{l} \bar{x}_j = \frac{\sum_{i=1}^n M_i x_i}{\sum_{i=1}^n M_i} \\ \bar{y}_j = \frac{\sum_{i=1}^n M_i y_i}{\sum_{i=1}^n M_i} \end{array} \right. \quad (1)$$

where  $\bar{x}_j$  or  $\bar{y}_j$  = the longitude or latitude coordinates for landscape category “j”;  $M_i$  = the area ( $km^2$ ) for landscape patch “i”;  $x_i$  or  $y_i$  = the longitude or latitude coordinates for landscape patch “i”; and  $n$  = the number of landscape patches in the basin. Latitude and longitude

coordinates of landscape patches mass center are calculated through Arcinfo 9.3 platform.

2. The single dynamic model

$$K_i = \frac{U_b - U_a}{U_a} \times \frac{1}{T} \times 100\% \quad (2)$$

where  $K_i$  = the annual variable rate of landscape category “ $i$ ” in river basin;  $U_a$  or  $U_b$  = the amount of the certain landscape category in early and late periods, separately; and  $T$  = the time length. If  $T$  is set as a year,  $K_i$  would be the annual variable rate of landscape in the river basin.

3. The systematic dynamic model

$$LC = \frac{\sum_{i=1}^n \Delta LU_{i-j}}{2 \sum_{i=1}^n LU_i} \times \frac{1}{T} \times 100\% \quad (3)$$

where  $LC$  = the integrated dynamic;  $LU_{i-j}$  = the area of landscape category “ $i$ ” from the start of monitoring;  $\Delta LU_{i-j}$  = the absolute value of landscape area that landscape category “ $i$ ” transfers to landscape category “ $j$ ” during the period; and  $T$  is the time of monitoring. If  $T$  is set as a year,  $LC$  would be the annual variable rate of landscape in the river basin.

4 RESULTS AND DISCUSSION

4.1 Overview of the landscapes composition in Chuanjiang River Basin

As for the landscape composition in Chuanjiang River Basin, the agricultural landscape occupied the dominant position, accounting for about 53 percent from 1985 to 2014, followed by the forest landscape and grassland landscape, whose distribution ratio are nearly 33 percent and 11 percent, respectively. However, the distribution of water landscape, built-up landscape, and desert landscape are relatively lower (as shown in Table 1). In terms of spatial distribution of landscape, the northern region is dominated by the agricultural landscape, while the southern region and basin boundary are the main areas of the cross landscape of forest and grassland, and the built-up landscape is concentrated in the North-East flat areas near waterbody and is likely to spread outside (as shown in Fig. 2).

4.2 Landscape pattern dynamic change characteristics

It is assumed that there are different structure characteristics of different landscapes and landscape index could be used to describe the landscape

Table 1. Landscapes composition and percentage of the landscape categories in Chuanjiang River Basin from 1985 to 2014.

In 2014	86385	54611.16	18047.63	2113.84	3058.53	57.66

\*\* : L-Disversity is the landscape diversity index, L-Shape Index is the landscape shape index, and L-Fractal is landscape fractal dimension.

of landscape patches significantly increasing in 2014. It could be proved that landscape fragmentation degree showed a wave-like curve: down-up-down-up, and the increase trend sustained until 2014. Generally, the patch density became larger; the landscape fragmentation also became larger. So the patch density could reveal the degree of the landscape fragmentation. In addition, the landscape fractal dimension index appeared at a high-low-high-low curve, fluctuating change such that taking landscape edge effect into account, the landscape fractal dimension index reduced. This will negatively affect the stability of the watershed landscape, and, to some extent, it will also increase the fragility of the landscape. Seen from the diversity index, it maintained between 0.5921 and 0.601 showing a weak increasing trend and the landscape complexity and stability were low.

### 4.3 Different landscapes spatial migration and temporal dynamic evolution

#### 4.3.1 Landscape gravity centers and migration

The landscape spatial and temporal change processes in Chuanjiang River Basin could be analyzed by the gravity center migration model: the gravity centers migration of all kinds of landscape types reflects the regional landscape spatial change pattern, and the direction, distance related with regional natural conditions could mirror the trend of the land use/coverage's gravity center migration qualitatively (Wang H. & Wang C.M., 2003).

In the Figure 3 and Table 3, gravity centers spatial characteristics of various landscape types have obvious spatial aggregation and difference, which means that the location of these gravity centers obey a certain zonal distribution pattern. Except gravity center of grassland landscape concentrating in the south of the Yangtze River, gravity centers of other landscape types are scattered in the north valley basin of Yangtze River evenly. From north to south, the landscape gravity centers of waterbody landscape, desert landscape, agriculture landscape, forest landscape, and grassland landscape were

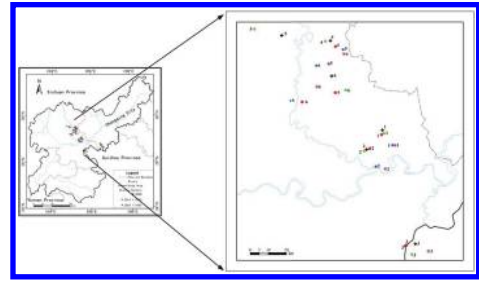

Figure 3. Gravity distribution of different landscape types in the Chuanjiang River Basin.

\*\*\*: The numbers 1, 2, 3, 4, 5, 6 present the gravity center position of the agriculture landscape, forest landscape, grassland landscape, waterbody landscape, built-up landscape and desert landscape, respectively.

Table 3. Gravity centers coordinates of landscape unit: degree.

Landscape Types	Agriculture Landscape	Forest Landscape	Grassland Landscape	Waterbody Landscape	Built-up Landscape	Desert Landscape
In 1985	105.50E, 29.07N	105.39E, 28.98N	105.66E, 28.47N	105.17E, 29.52N	104.76E, 29.58N	105.29E, 29.28N
In 1995	105.57E, 29.01N	105.51E, 28.89N	105.75E, 28.48N	105.28E, 29.46N	105.19E, 29.41N	105.12E, 29.30N
In 2000	105.49E, 29.08N	105.40E, 28.99N	105.68E, 28.52N	105.20E, 29.52N	104.91E, 29.55N	105.21E, 29.35N
In 2005	105.55E, 29.01N	105.46E, 28.90N	105.62E, 28.51N	105.12E, 29.40N	105.27E, 29.48N	104.97E, 29.23N
In 2014	105.49E, 29.06N	105.42E, 28.99N	105.63E, 28.51N	105.23E, 29.49N	105.23E, 29.27N	105.04E, 29.22N

located in order. The grassland landscape gravity center was around the boundary of the basin, while the gravity centers of agriculture and forest landscape mainly distributed in region 1 and 2 and the rest of others concentrated in area 4, 5, and 6.

As shown in Figure 4 and Table 4, in terms of gravity center's migration distance, from 1985 to 2014, was examined to be the most significant for agriculture landscape, followed by desert landscape and grassland landscape. The movement of gravity center of waterbody landscape was slight and that of and forest and agricultural landscape was not remarkable. In terms of orientation of migration of gravity centers, there was no obvious change law about different landscape types gravity centers migration direction in different the research period. The landscape spatial migration pattern could reflect, to a certain extent, the gravity centers migration significance.

The gravitational center of agricultural landscape moved to the northeast by a relatively far distance: moving to northeast from 1985 to 1995 by 39.73 m, to northwest from 1995 to 2000 by 27.47 km, to southeast from 2000 to 2005 by 23.90 km, to southwest from 2005 to 2014 by 23.90 km, and,

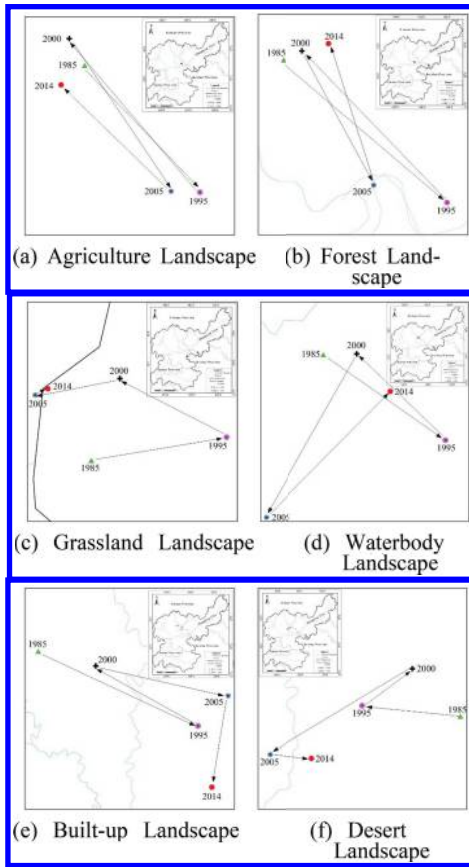

Figure 4. Different landscape types shift variation.

Table 4. Landscape Gravity Centers and Their Migration UNIT: m.

Landscape Types	Agriculture Landscape	Forest Landscape	Grassland Landscape	Waterbody Landscape	Built-up Landscape	Desert Landscape
1985 to 1995	9615.82 ES	16465.18 ES	10157.39 EN	11237.17 ES	39729.84 ES	15521.26 WN

1985 to 2014	1723.45 WN	3803.57 EN	5793.32 WN	5593.32 WN	53083.03 ES	24818.42 WS

\*\*\*\*: The unit of number is meters, and the capital letter monogram is shift directions.

generally, migrating to southeast from 1985 to 2014 by 53.08 km. Compared with other migration orientation, the relatively significant south-eastward migration showed that, in this direction, urbanizing speed is faster. In contrary, the desert landscape gravity center migrated to northwest.

And the range of agricultural and forest landscapes migration were small implying that they were more stable than other landscape types.

In addition, the correlation within the gravity center migration of different landscape types in Chuanjiang River Basin and between the regional economic, population growth, urbanization and other driving factors of migration will be further analyzed in the later research.

#### 4.3.2 Landscape dynamic changes

According to dynamic changes in different periods of all landscapes and integrated landscape dynamic changes (as shown in Table 5), regional landscape pattern changes in Chuanjiang River Basin were analyzed: the proportion of build-up landscape rise up to 44.62%, by 12.87% in period of 1995–2000 and 29.78% from 2000 to 2014, reflecting the significant urbanization speed. Agriculture landscape increased by 0.32% and forest landscape decreased by 0.31% during 1985–2014. Urbanization accelerated, at the same time, forest landscape were construct which influenced the agricultural landscape, like cultivated land, while the grassland landscape and desert landscape both changed in different degree.

The integrated landscape migration rate of Chuanjiang River Basin were 0.45%, 0.39%, 0.23%, 0.39% in 1985–1995, 1995–2000, 2000–2005 and 2005–2014, separately, which means that there were 0.45 km<sup>2</sup>, 0.39 km<sup>2</sup>, 0.23 km<sup>2</sup> and 0.34 km<sup>2</sup> of every 100 km<sup>2</sup> landscape area had changed. With the economic and social development, land use in the Chuanjiang River Basin was affected by various interferences in nearly 30 years, thus the area of each landscape significantly changed. Especially in the early 20th century, the population growth has accelerated, the contradiction between human and land sharpened and land use was faced with great pressure due to the advancement of urbanization (Shu R.Q., He T.R. & Ban B.R., 2013).

Table 5. Dynamic migration of landscape types of Chuanjiang River Basin from 1985 to 2014 UNIT: %.

Types	K <sub>i</sub>				
	1985 to 1995	1995 to 2000	2000 to 2005	2005 to 2014	1985 to 2014
1	-0.14	0.11	0.02	-0.3	-0.32
2	0.54	-0.46	0.25	-0.01	0.31
3	-0.6	0.21	<u>-0.72</u>	-0.8	-1.86
4	-1.02	<u>1.19</u>	0.26	<u>2.93</u>	<u>3.36</u>
5	<u>-3.78</u>	<b>12.87</b>	-0.52	<b>29.78</b>	<b>44.62</b>
6	<b>4.37</b>	-1.82	-2.88	1.13	0.03
LC	<b>0.45</b>	<b>0.39</b>	<b>0.23</b>	<b>0.34</b>	<b>0.99</b>

\*\*\*\*\*: The number of 1, 2, etc. presents the different landscape respectively, namely the agriculture landscape, forest landscape, grassland landscape, waterbody landscape, built-up landscape and desert landscape. The bold is the maximum and underline presents the minimum in the column, and the bold italic is the value of the LC.

## 5 CONCLUSIONS

1. The composition of landscape was obviously different, with the percentages of forest landscape and grassland landscape being relatively lower.
2. The overall landscape pattern is simple, landscape diversity is low, and the increase trend of landscape fragmentation sustained and then aggrandizes the fragility of the landscape. So land use resources utilization should be adjusted to improve the integrity and diversity of watershed landscape and to enhance the anti-interference of landscape itself.
3. Gravity center distribution of different landscape types has particular zonal distribution patterns in different periods. Gravity center migration of a typical landscape type is significant, especially the agriculture and desert landscape, which indicates that the spatial changes of agriculture and desert landscape are largest under the influence of natural force and human activities.
4. A typical landscape type and the comprehensive landscape dynamic changes shows the significant changes of landscape on different time scales from several angles, and the consistency with the landscape gravity center migration significance. The most significant change is built-up landscape for it bears the population and urbanization. The integrated landscape dynamic rate of Chuanjiang River Basin was 0.99% during 1985–2014, which means there are 0.99 km<sup>2</sup> of landscape areas per 100 km<sup>2</sup> have changed.

**ABSTRACT:** Green building is the core topic of human habitat construction. A comprehensive index of NO<sub>x</sub> pollutant was proposed to evaluate the effect of motor vehicle emissions on green buildings. The evaluation index was extracted from the regulatory requirements of Urban Residential Area Planning Design standard (GB50180-93) and Ambient Air Quality Standard (GB3095-2012). The effect of local meteorological wind field on the comprehensive index was considered. The component transport (species transport) model was adopted to simulate the pollutant distribution of motor vehicle emissions. The air quality of the urban community was evaluated under the condition of typical wind of different seasons. The weight of each season was determined by analytic hierarchy process method. The result showed that the proposed comprehensive index was favorable to evaluate the air quality of green buildings.

**Keywords:** air quality; green buildings; motor vehicle emissions; urban community

## 1 INTRODUCTION

Currently, motor vehicle emissions are considered as a major source of urban ambient air pollution. NO<sub>x</sub> is the main substance near the surface atmospheric which forms photochemical smog. Furthermore, NO<sub>x</sub> delivery leads to regional acid rain, eutrophication and other large-scale pollution.

The study of motor vehicle emissions began in the mid 20th century in Europe and America. (Zhang et al., 2013) estimated on- and near-road NO<sub>2</sub> concentrations and the health risks for freeway and arterial scenarios attributable to traffic for different traffic volumes during rush hour periods. (Madalozzo et al., 2014) investigated numerically the wind flow and pollutant dispersion with a two-dimensional street canyon model by considering three different aspect ratios and four different wall heating configurations. (Tang et al., 2014) investigated the effects of real-time road condition on each vehicle's speed, acceleration, headway, fuel consumption, CO, CH and NO<sub>x</sub> under uniform flow with a car-following model.

The wind effects are not fully considered in the existing evaluation methods to achieve a comprehensive evaluation of motor vehicle emissions of complex buildings, especially in windy areas. In this paper, a comprehensive evaluation index is proposed by considering the frequency of local

wind speed and direction of different seasons. The outdoor motor vehicle emissions diffusion was simulated by CFD and the weight of each season was determined by the analytic hierarchy process (AHP). The results showed that the proposed comprehensive index is favorable to evaluate the quality of atmospheric environment in windy cities.

## 2 MATHEMATICAL MODEL

Air flow around buildings is a low speed incompressible turbulent flow. The widely used RNG  $k-\epsilon$  model was introduced to consider the effects of turbulence and the control equations are the same as those in the reference (Chen et al., 2011). The average inlet air velocity is as following (Liu et al., 2011):

$$\frac{U(z)}{U_0} = \left(\frac{z}{z_0}\right)^{0.25} \quad (1)$$

where  $U(z)$  and  $U_0$  is air velocity at the height of  $z$ ; and the reference height of  $z_0 = 10$  m.

At the outlet boundary, the air velocity is assumed to be fully developed. The non-slip wall boundary is applied to the ground and walls of buildings.

Pollutant convection-diffusion equation:

$$\frac{\partial C}{\partial t} + \frac{\partial(u_i C)}{\partial x_i} = \frac{\partial}{\partial x_i} \left( \frac{V_i}{S_c} \frac{\partial C}{\partial x_i} \right) + S \quad (2)$$

where,  $C$  is concentration of pollutant;  $S_c$  is Schmidt number; and  $S$  is source term of pollutant.

The vehicle pollution was assumed as a line source located in the center of the street and the flow field in the street is not affected by the presence of pollutant. Emission source intensity of motor vehicle was determined by:

$$Q = NE/3600 \quad (3)$$

where  $Q$  = vehicle emission source intensity on the road,  $g/(km \cdot s)$ ;  $N$  = road traffic discharge, vehicle/h; and  $E$  = integrated emission factor of NOx,  $g/km/vehicle$ .

Refer to the literature,  $N$  is 2175 vehicle/h (Ye et al., 2007),  $E$  is 4.4  $g/km/vehicle$  (Liu et al., 2008) in the study area. The emission source was supposed to be at the height of 0.4 m in order to simulate the emission of vehicles.

### 3 MODEL ESTABLISHMENT AND SIMULATION WIND CONDITIONS

The community of the present approach is located in the centre of Tianjin city. The height

NNW	9.9	6.6	7.5

\*The wind velocity refers to the wind speed at the height of 10 m.

of computational domain is 5 times of that of the tallest building of the community, which is about 250 meters. Horizontal length and width of the computational domain is taken as the center of the surrounding streets. Since the wind field far above the buildings is affected weakly by them, the computational domain is divided into two zones by the mid-height of the domain. Dense unstructured grids are used in the lower zone, while sparse structured grids are used in the upper zone. After grid independence is checked, two million grids are suitable to the present simulation. The control equations are discretized by finite volume method with second order upwind scheme. Pressure-velocity coupling is realized by the SIMPLEC algorithm.

According to meteorology wind rose of Tianjin (Lu et al., 2013), the selected typical scenes of Tianjin meteorology were shown in Table 1.

### 4 REQUIREMENTS AND EVALUATION INDEX

According to the Urban Residential Area Planning Design standard (GB50180-93) and Ambient Air Quality Standard (GB3095-2012), the air quality of residential area is the secondary level, where the average concentration of NOx is less than 100  $\mu g/m^3$  ( $2.173 \times 10^{-9}$   $kmol/m^3$ ) in 24 hours. Based on the above requirements, one evaluation index called as Standard Area Ratio of Characteristic Pollutant Concentration Limit (SARCL) was proposed. It is the area ratio of the pedestrian area with pollutant concentration above 100  $\mu g/m^3$  to that of outdoor at 1.5 m height.

The outdoor comprehensive index of motor vehicle emissions of a season is calculated as follows:

$$R_K = 100 \sum_{j=1}^M P_j f_j \quad (4)$$

Table 2. Assessment standards of effect of motor vehicle emissions on outdoor air quality.

Outdoor air quality	Assessment standards				
	Poor	General	Good	Better	Very good
R	<60	60-80	80-90	90-95	95-100

Table 3. Weight of typical season.

Typical season	Winter	Summer	Spring and autumn
Weight	0.25	0.25	0.5

where,  $R_k$  is the outdoor comprehensive index of motor vehicle emissions of a season. Large  $R_k$  means good outdoor air quality.  $M$  is the number of typical wind cases.  $f_j$  is the wind frequency of  $j$ th typical wind of the season and  $P_j$  is the value of index (SARCL) at  $j$ th typical wind. For the present case,  $M=16$  is for all seasons.

Considering the season of winter, summer, spring and autumn, the outdoor comprehensive index of motor vehicle emissions for a whole year is calculated as:

$$R = \sum_{k=1}^3 W_k R_k \quad (5)$$

AHP method (Li et al., 2012) was adopted to determine index weight. Assuming the equal weight for all seasons, the weight of typical seasons was shown in Table 3.

## 5 NUMERICAL RESULTS AND DISCUSSION

Figure 1a showed the concentration distribution of NOx on the plane  $z = 1.5$  m under the typical 2.2 m/s

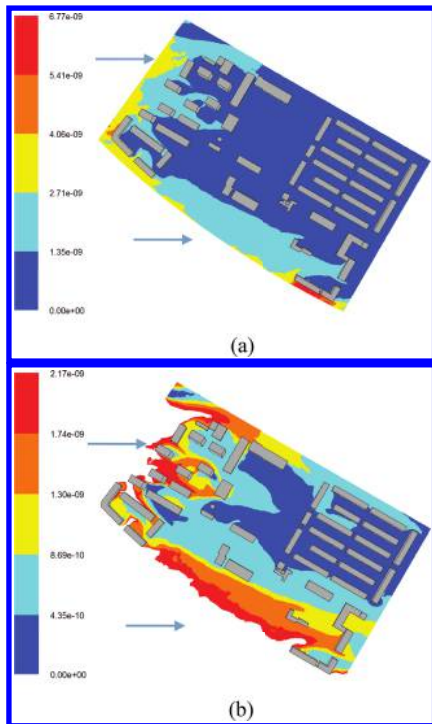

Figure 1. Concentration contours of NOx (kmol/m<sup>3</sup>) at the height  $z = 1.5$  m under the typical 2.2 m/s W wind in summer.

W wind in summer. The maximum concentration is  $6.77 \times e^{-09}$  kmol/m<sup>3</sup>. High concentration of NOx is mainly near the inlets. Figure 1b shows the NOx concentration distribution that meets the requirement of Ambient Air Quality standard. Because the street is the generation place of pollutants, high concentration of pollutants is close to the inlet. At this case, SARCL is 93.8%. The areas not satisfying the standard requirements should be improved by appropriate measures, such as rearranging the buildings to reduce NOx concentration.

Figure 2a showed the NOx concentration distribution on the plane  $z = 1.5$  m under the typical 4.1 m/s S wind in winter. The maximum concentration is  $7.47 \times e^{-09}$  kmol/m<sup>3</sup>. High concentration of NOx is in the region of the inlets mainly. Areas with eddies are poorly ventilated and they are easy to accumulate high pollutant concentration. Figure 2b showed the NOx concentration distribution that meets the requirement of Ambient Air Quality standard. For this case, SARCL is 85.7%.

Similarly, the outdoor NOx diffusion of motor vehicle emissions of different wind directions in all seasons was simulated and the results of SARCL are shown in Table 4.

The outdoor air quality of the studied community of winter, summer and spring and autumn is

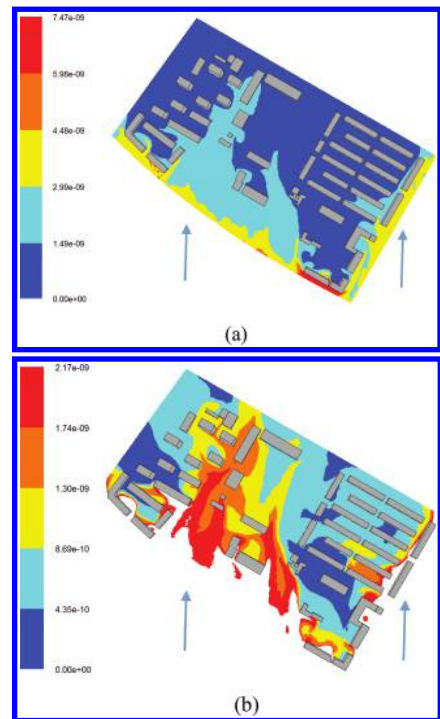

Figure 2. Contours of molar concentration of NOx (kmol/m<sup>3</sup>) at height  $z = 1.5$  m under the typical 4.1 m/s S wind in winter.

Table 4. The value of evaluation index of all seasons.

Typical season	Typical simulated scenes		
	Winter	Summer	Spring and autumn
Wind velocity (m/s)	4.1	2.2	2.2
Wind direction	$P_1$ (%)		
N	82.7	85	83.2
NNE	80.5	82.7	81
NE	84.4	86.6	85.5
ENE	82.1	83.6	82.8
E	84.8	87.5	86.7
ESE	87.4	87	85.9
SE	87.9	89.9	87.9
SSE	87.1	88.5	87.9
S	85.7	89.9	88.1
SSW	89.7	94.2	93.6
SW	92.7	93.1	93
WSW	92.5	93.8	93.1
W	91.9	93.8	93.4
WNW	91.5	93.4	92.8
NW	91	93.8	92.7
NNW	85.7	90.1	88.9

86.96, 89.76 and 89.93, which is all corresponding to the grade of good, respectively. The outdoor air environmental quality of the studied community in the whole year is 89.1, which is also in the grade of good.

## 6 CONCLUSIONS

The outdoor NO<sub>x</sub> concentration of motor vehicle emissions of a community in central Tianjin city were simulated by considering typical local winds. The outdoor comprehensive index of motor vehicle emissions was proposed by considering the standard for Urban Residential Area Planning Design standard (GB50180-93) and Ambient Air Quality Standard (GB3095-2012).

The results indicated that the outdoor air quality of the studied community in all seasons and the whole year is in the grade of good. Obvious eddies and low wind zones were found between the buildings in the seasons of spring, summer and autumn. The windward sides of buildings need to be reduced for small wind obstruction and eddies.

The high concentration of pollutant near the inlet boundary was found to exceed the Ambient Air Quality Standard of China. The areas should be improved through reasonable measures, such as rearrangement buildings.

## The old town of Wubu the forgotten stone castle

X. Liang

*College of Architecture and Civil Engineering, Taiyuan University of Technology, China*

**ABSTRACT:** In a class trip, we happened to get acquainted with a centenarian at the west of the Yellow River—the Old Town of Wubu. The Old Town of Wubu awed us greatly with its vigorous and majestic momentum, and profound historical values are embedded in its dilapidated appearance that went through ages. Rammed earth walls, cave dwellings built with bricks as well as streets and roads built under the principle of “adjusting measures to local conditions” all show the wisdom and effort of ancient Chinese people. However, with transportation streamlines moving to the south, the Old Town of Wubu gradually lost its geographic advantages and was abandoned, leaving a “ghost town” standing in the rubble. How should the historical values of Wubu be re-evaluated? In addition, what should be done to protect the Old Town of Wubu?

**Keywords:** old town; current situation; brick and stone masonry structure; protection

### 1 LOCATION ANALYSIS

The Old Town of Wubu, also called the Stone Town of Wubu, is located at the mountain peak on the west bank of the Yellow River. Only 2.5 kilometers to the north of the Town of Songjiachuan, Wubu County, the Old Town of Wubu is the best-remained ancient town with a history of more than a thousand year at northwest China. Located at the east border of Yellow River Plateau and the west side of the mid-stream of the Yellow River, Wubu is an important transportation hub at the road connecting Shanxi and Shaanxi. The Yellow River at its east and the natural moat to its west provide natural covers for defense; meanwhile the town connects with the bank on the south and the mountain to the north by a state road and a strategic passage. Located on

the natural barrier of the Yellow River—the Stone Mountain, the Old Town of Wubu was known as “Bronze Wubu” at ancient times. It is shown in [Figure 1](#) that Wubu is situated on the key gateway of Lvliang Mountain Range. As early as the Spring and Autumn Period, this position was an important checkpoint between the State of Qin and the State of Jin, playing an indispensable role in the aspect of strategic defense. However, nowadays as the important traffic road moving to the new County of Wubu, the Old Town of Wubu lost its geographical advantages and was gradually abandoned.

### 2 A VISIT TO THE OLD TOWN OF WUBU

An accidental occasion brought us to the sleeping old town with a history of more than thousands of years. The destination of our class trip was Lvliang County of Shanxi Province. Originally, we were planning to end our trip at the Town of Qikou, Liulin County, hoping to make the view of the magnificent ferry of the Yellow River the highlight of the whole trip. We did not have the intention of traveling across the Yellow River. However, while passing by the Village of Jundu, we were deeply attracted by the hundreds-meter Yellow River Bridge. Impulsively, we went across the trembling Bridge and arrived at Wubu County across the river.

Exploring the Old Town of Wubu, we found a dilapidated yet exquisite Taoist temple. After traveling along the winding mountain road for dozens of Li, we encountered with fragments of the city wall. The stone town cast a touch of ancient

Figure 1.

style to us. About 300 meters away from the wall, an abandoned building was standing quietly, as if it was a housekeeper welcoming guests from afar. Since it must have been abandoned for a rather long period of time, the building appeared very humble. Entering the only yard of the building, we identified the grand hall in the middle with two blurred stone tablets at the east and west side. The yard was covered with barbed wild grass, and brick rubble and broken tiles scattered around. Picking up a piece randomly, I identified the engraved “dragon scale” on it. It might be a piece from the dragon engraving on the stone pillar. The head of the engraved dragon was missing, maybe it was picked home as a collection. While pitying about the pillar, we also found that the structure of the grand hall was rather completely remained. The outline of the hall was in the shape of a cubic with a flat top, and the inside was a traditional structure of a stone cave. The plaque above the door was engraved with characters “Yu Xu Gong (Temple of Yu Xu)”, from which one can tell that the construction was an abandoned Taoist Temple. The statue of Celestial Yuxu had already disappeared, yet the mark of its base can still be found on the floor. Soft color wall paintings can be seen from the wall and the ceiling, yet they were all blurry under the power of weathering. Thus, contents of the paintings were difficult to tell. Later I also failed to find relevant resources regarding this temple from the internet. We could only tell from the degree of the weathering that the temple was constructed at the same period with the old town of Wubu. Passing this dilapidated yet meaningful Taoist temple, we finally entered the Old Town of Wubu.

Ancient city wall, the weather-beaten stone guardian. The ancient wall of the old town was weathered seriously, standing now with a dilapidated overall structure and grass growing at the crack of stones. The mark of bomb and fire reminded us of the cruel situation during the period of the Anti-Japanese War. It seems that this ancient city had encountered with not only the weather beaten of time, but also the damage brought by the invader. Nowadays it is still sitting quietly and strongly at there, waiting for its visitors. The gate tower above the wall had collapsed yet the gate was still firm. The character “Ying En” can be seen from the stone plaque over the gate. I reckoned that the gate used to be an abustle place, yet with the development of time, it was neglected by people. The two characters presented a feeling of loneliness. Quietly standing under the gate and gazing it, we were overwhelmed with complicated feelings. Climbing onto the wall and walking to the eastern part of it, we looked at the view down from a height. Through the crenel we can see the Yellow River stretching dozens of li with a magnificent momentum. The eastern side of

the wall was better retained. I reckoned the reason was that the eastern part was next to the cliff that was able to prevent the town from the attack of enemies. The advantageous geographical location retained its appearance, leaving valuable materials for researches at later times. At the connection point of southern and eastern wall, there was a three-story masonry-timber structured hexagonal building. An awe-inspiring statue of Kuixing was standing on the top floor. With its red face, bushy beard, red calligraphy brush in his hand and wood bowl on his foot, the statue as if was intimidating enemies from dozens of li to stay away from the town. Walking along the wall to the south gate, we saw a well-structured barbican with a complete and magnificent Temple Of Guan Yu in it. There were three masonry-timber structured grand halls in the Temple, and the statue of Guangong was also remained thus we can identify the function of the temple. Constructing a barbican at this side indicating that the spot was of strategic importance. Although the town does not contain strategic function nowadays, the solid structure and the marks remained from wars still prove its heroic position in people’s mind.

Visiting the dwellings in the old town and feeling the mingling of history and present. Stepping down the city wall and feeling reluctant to leave, we realized that the city wall only contained assistive functions to the old town and cannot represent the folk culture and customs of the town. Thus we decided to enter the town and visit our real destination: the residential area. The roads and streets in the old town were built under the principle of adjusting measures to local conditions. Houses were built alongside the mountain without an obvious axis. Stone cave was the major construction form of the residential building group. Brick caves and wood houses lined alongside the winding and narrow road. Different kinds of constructions echoed each other and formed a harmonious picture, presenting an exquisite beauty that was rarely seen in northern China and bringing pleasant feelings to passersby.

A depiction of major characteristics of the dwellings in the old town—taking an abandoned house as an example. The appearance of the abandoned house is shown as in [Figure 2](#). Just like major construction groups in northern China, the house was a quadrangle dwelling. Unlike usual quadrangle dwellings, houses around the yard were all stone caves. From the decayed window and doorframes as well as knee-high grass, one can tell that this house had been abandoned for years. The time of its construction was also very difficult to tell. The four rooms on the main side were caves built with square stones, the cliffs on two sides supported the outer wall of the caves,

Figure 2.

Figure 3.

bearing side thrusts from the caves and making them stand firmly. Thus after being abandoned for years, the caves can still standing steadily as new. Exquisite decorations made by bricks were placed on the tiles at the top of the cave, telling people that the original host may be a rich and influential family. Other constructions at the old town were similar to this. Most of them were quadrangle dwellings, yet with less structured orders. Thus this house can be analyzed as a typical residential construction in the Old Town of Wubu.

### 3 ANALYSIS ON THE HISTORICAL VALUE OF THE OLD TOWN OF WUBU

Analysis on the geographical location of Wubu: why was the city such a firm fortress? From the geographical location of Wubu as well as relevant documents, one can see that as early as the Spring and Autumn Period and Warring States Period, Wubu was an important strategic point as well as

a business checkpoint. Thus the town had a very high demand for its defensive function. The reason why ancient people built the Town of Wubu as a firm stone fortress was more or less related to its important geographical location. As two important counties at the border of the State of Qin and the State of Jin, Yulin and Lishi, with Jundu and Wubu as their frontier towns, stood opposite to each other on the two banks of the Yellow River. The Old Town of Wubu, located on the hill to the west of the ferry, offered a clear view of dozens of Li. Naturally the view of the town of Jundu can be seen from the gate tower of Wubu. The Yellow River that stretches dozens of Li on the borderline between the State of Jin and the State of Qin played the role of a natural barrier, in addition, Wubu, the stone fortress at the peak of the hill, enhanced the degree of protection. Casting their eyes on each other, the two States never dared to step forward. This kind of strategic confrontation that formed since very long time ago, on the contrary played a decisive role for promoting the “alliance between the State of Qin and the State of Jin”. Hundreds of years later, with the eastward expansion of the State of Qin, China is gradually unified. Yet the strategic significance of Wubu still remained. After being unified, ancient China had experienced long-standing conflicts with nomads from the north, while the middle and lower reaches of the Yellow River became the major area suffered from the conflicts. The County of Yulin thus became the northern gateway of the capital city (near today’s City of Xi’an). If the county of Yulin once was occupied by the invaders, other cities and counties of the ancient China will be easily invaded. Thus the significance of the old town of Wubu in guarding the country became more obvious. With the changes of many dynasties and the expansion of the territory of China, the old town of Wubu, once a border city, gradually became an inland city. With the changing of its geographical meaning, the old town of Wubu entered its transformation period. The major function of it changed from defense to trade, meanwhile the residents moved gradually from the hill to the field by the river. Due to the disadvantage of traffic inconvenience, the stone city of Wubu was neglected by people and was downgraded to a county. During the years of Anti-Japanese War, residents moved back to the stone fortress due to special historical reasons, and Wubu for another time became an important military post of the anti-Japanese revolutionary base area. During this period, the town of Wubu suffered from Japanese Army’s artillery attack. The wall of the town was seriously damaged, yet the town survived from the war and was not occupied by Japanese Army. After liberation, the old town of Wubu was again seriously destroyed in

Cultural Revolution. Residents for another time demolished their houses and moved to the field by the river, leaving only four to five households living at the old town. Thus Wubu became an abandoned town at present. And we could only catch a glimpse of this building group that contains a history of more than thousands of years by accident.

#### 4 SUGGESTIONS ON THE PROTECTION AND PROMOTION OF THE OLD TOWN OF WUBU

What should be done to protect historical living fossils like the Old Town of Wubu? My suggestions are as follows. It is expected that readers of this article can gain certain inspirations from my suggestions and realize the significance of the protection of regional culture.

##### 4.1 *Traffic*

Smooth mountain roads should be paved to connect the Old Town of Wubu with the outside world so that people will not refuse to live there due to traffic inconvenience. This is the most important measure that should be conducted. The biggest disadvantage of Wubu is that rough and rugged roads seriously affect people's daily traveling. Transforming and optimizing traffic conditions as well as setting striking road signs can not only make local people willing to live in the Old Town of Wubu, but also allow more travelers passing by to notice its existence.

##### 4.2 *Reasonable planning*

The original constructions of the Old Town of Wubu should be retained; meanwhile residential areas should be designed and built around the old town. The dilapidated appearance of the Old Town of Wubu can still reflect the style of its historic beauty. Thus rebuilding or repairing ancient constructions should not be the only target of our effort, since only rebuilding or repairing may lead to further damages to historical relics. Building new

residential areas around the original old town cannot only protect the historical and cultural relics to the largest extent; the economy of the old town can also be driven by the development of the new residential area. Indeed the two accomplishments can be achieved by conducting this one measure.

##### 4.3 *Cultural education*

Cultural education to local residents should be further enhanced thus to make people realize the significance of protecting cultural relics. Through holding festival activities at the Old Town of Wubu, the County Government has conducted cultural education and publicity to local residents. Efforts have been made to promote the idea of "Be Proud of Old Town of Wubu" and lead people to spontaneously protect cultural and historical relics. Experts studying local cultural relics were also trained and supported to conduct researches, make surveys and write books on the old town, thus to promote to the largest extent the Old Town of Wubu.

##### 4.4 *Advertising*

More advertising publicity should be conducted to push forward the development of Old Town of Wubu as a tourist spot. Travel routes should be set in the Old Town of Wubu and business commercials should be shot thus to further promote the fame of the old town in Shaanxi Province or even larger area and attract more tourists. These measures can not only drive the business development of the surrounding areas, but also make local residents focus more on the protection and repair of cultural and historical relics.

# Inspiration of evaluation criteria of international historic site to China heritage protection system

X.Y. Zhao & J. Gao

College of Architecture and Civil Engineering, Taiyuan University of Technology, Taiyuan, Shanxi, China

**ABSTRACT:** The essay takes the evaluation criteria of historic sites as the clue to illustrate the means of expressions of historic sites under the different state contexts; makes comparison and analysis on the evaluation criteria of national historic sites of United Nations and China, Japan, Britain, and America; and offers some suggestions to the deficiency of China evaluation criteria.

**Keywords:** historic site; comparative study; historic conservation; evaluation criteria

## 1 THE REFLECTION OF THE DEFINITION OF HISTORIC SITE UNDER DIFFERENT STATE CONTEXTS

With the development of world cultural heritage protection movement, when the historic protection develops from the historic relic protection to the integrality protection of historic and cultural environment protection, an extremely important definition emerges out of demand and opportunity. “Historic District/Historic Site” refers to those the areas with urban historic features, landscape and image which can reflect social life and cultural diversity in the aspects of natural environment, artificial environment, and humanistic environment, and it is the witness of urban history. [1] In China, when publishing the second batches of famous historic cultural cities in 1986, the definition of historic site was officially proposed the definition of historic site—“it refers to the sites with rich relics which can completely and really reflect the traditional scene or national and local features in certain historic period, and it is the area of certain scale existing more cultural relics and historic sites, and modern historic relics and historic building.”

Different countries make use of different means of expression of historic site. The essay makes simple comparison on the names in China, Japan, Britain, and America (Fig. 1).

## 2 EVALUATION CRITERIA OF HISTORIC SITE OF UNITED NATIONS AND BRITAIN, AMERICA, JAPAN, AND CHINA

The protection way for cultural heritage in world-wide scale can be divided into appointment system, listed system, and mixture of appointment system and listed system. [2] Most of countries in Europe and America adopt listed system or mixture of appointment system and listed system. In 1996, Japan also added the heritage listed system in the evaluation criteria while it retained the heritage appointment system by revising the heritage protection law—*Protection Law of Cultural Properties*.

### 2.1 Evaluation criteria of “outstanding universal value” of world cultural heritage

As the only criteria for listing *World Heritage Lists* that was formulated by World Heritage Committee, Outstanding Universal Value (shorten for OUV in the following) mainly emphasizes that the cultural and natural value or some value of heritage is rare. Since the Operational Guidelines of *World Cultural and Natural Heritage Convention* were issued in 1977, it is revised nearly every year. In the current 2005-version *Operational Guidelines*, the OUV definition of world heritage is illustrated as: “OUV means the cultural/historic meaning. It is so special

Historic District/ Historic Area	China	Famous Historic and Cultural City, Historic and Cultural Block, Historic Feature Zone
	Japan	Cultural Properties, Traditional Building Conservation Area
	Britain	Listed Building/conservation Area
	America	Historic Area

Figure 1. Relevant definitions of historic site.

that it exceeds the national boundaries, which is of common significance to all mankind's contemporary and future generations. Therefore, protecting these heritages permanently has the greatest importance for international society which is as a whole."

Assessing 10 criteria of OUV, first six criteria are used to measure cultural heritage, covering all the definitions of historic sites mentioned in the essay: [3]

- i. *represent a masterpiece of human creative genius;*
- ii. *exhibit an important interchange of human values, over a span of time or within a cultural area of the world, on developments in architecture or technology, monumental arts, town-planning or landscape design;*
- iii. *bear a unique or at least exceptional testimony to a cultural tradition or to a civilization which is living or which has disappeared;*
- iv. *be an outstanding example of a type of building, architectural or technological ensemble or landscape which illustrates (a) significant stage(s) in human history;*
- v. *be an outstanding example of a traditional human settlement, land-use, or sea-use which is representative of a culture (or cultures), or human interaction with the environment especially when it irreversible change;*
- vi. *be directly or tangibly associated with events or living traditions, with ideas, or with beliefs, with artistic and literary works of outstanding universal significance. (The Committee considers that this criterion should preferably be used in conjunction with other criteria).*

## 2.2 Criteria of listed heritage in Britain, America, and Japan

I. The conception of listed protection for historic site in Britain appeared in *Law of Urban Planning* in 1944. The definition of listed architecture was given by the law, but the revised *Law of Urban Planning* in 1947 was the law to officially establish the criteria framework. The *Planning (Listed Building and Conservation Areas)* in 1990 gave the definition of listed building and conservation areas: "it refers to the architecture with special architectural art value or historic value whose features and appearance are worth conserving." The listed process of building and listed conservation areas is: first, the experts of architectural history go to the site to investigate the candidate architecture; then the architecture which was assessed to reach the listed criteria should be listed in "tentative list" to

vend; and the suggestions of local government, protection communities, and ordinary citizens should be heard. If there is no objection, the notification will be sent to local government after the official identification of DNH, and then the local government notifies the owner or user of architecture.

The main criteria and objects for selection of Listed Building and Conservation Areas include: [4]

1. *The building which has special value in the aspects of building type, building art, planning and design, or the display of social and economic development history, such as industrial building, train station, school, hospital, theater, city hall, poorhouse, and prison and so on;*
  2. *The master work of technological reform or exquisite workmanship, such as cast iron, pre-cast technology, and the early building with concrete technology;*
  3. *The building which is related to important historic events and important historic figures;*
  4. *The building with the complete architectural complex, especially with the examples of urban regulations, such as square, townhouse, and typical village and so on.*
- II. America formulated *The National Historic Preservation Act* as early as October 1966. The national listed system of Historic Places could be regarded as the footstone of historic and environmental protection system in America, which is one of the important means of The National Historic Preservation Act to protect historic environment. The listed criteria for the national historic places are: it has important meaning in the aspects of American history, building, archeology, engineering technology, and culture; it has the complete area, relic, building, structure, and object in the aspects of site, design, environment, material, craft, emotion, and association; it has a history of over 50 years and complies with the following conditions: [5]
1. *It is associated with important historic events;*
  2. *It has relation to the life of outstanding figures in the history;*
  3. *It should be the work which reflects the unique characteristic of some type, some period, or some construction method, the representative work of masters, the work with high art value, or the ordinary work with group value;*
  4. *The prehistoric or historic important information may be found or has been found in it.*

III. The heritage protection and assessment in Japan is dominated by the appointment system, being assisted by the listed system. Compared with the listed system, the content and procedure of the appointment system is more detailed and strict. While the listed system is more flexible, whose feature is regarding culture as the “resource” to continue to give development space for it and the necessary protection should be done as well. The *Protection Law of Cultural Properties* issued in 1950 is the fundamental law of historic protection in Japan. In June 1996, Japanese Congress passed the new round of revise of *Protection Law of Cultural Properties*. Influenced by similar systems in various countries of West Europe, Japan also introduced the listed system into laws. In Japan, the listed system can be regarded as a report and declaration and record system. If the owner or user wants to be listed, they can apply to the local public group; local public group can also recommend to the state to be listed.

The listed criteria for cultural properties are: it should be the building, which has a history of more than 50 years and it should comply with one of the three following conditions: [6]

1. *It may be the landscape with land historic meaning;*
2. *It should be the example of modeling art;*
3. *It should be the one which is hard to reappear or to be rebuilt.*

### 2.3 Evaluation criteria of Chinese historic site

Conforming to the trend of international protection movement, the historic and cultural heritage protection work in China keeps up with the trend of international protection movement, and experiences the protection process from “point” to “surface”—namely the protection concentrating on cultural building and architectural complex gradually develops into the protection of historic site concentrating on historic area, which gradually establishes the protection system of famous historic and cultural cities and the protection system of scenic spots.

The declaration conditions for the famous historic and cultural cities and towns and villages in China: the cities, town, and villages which comply with the following conditions can be declared as the famous historic and cultural cities, towns, and villages: [7]

1. *It has rich cultural relics;*
2. *There are many concentrated historic buildings;*
3. *It should keep the traditional layout and historic style;*

4. *It was the political center, economic center, cultural center, traffic center, or important military area in the history, or the place where the important historic events happened once; or its traditional industry and important projects in the history had important influence on the development of local area, or the place which could reflect the cultural features and national features of local buildings.*

## 3 THE COMPARISON AND ANALYSIS ON THE EVALUATION CRITERIA OF HISTORIC SITE OF UNITED NATIONS AND BRITAIN, AMERICA, JAPAN, AND CHINA

In summary, by analyzing and comparing the evaluation criteria of historic site of United Nations and Britain, America, Japan, and China, the essay finds that:

- I. In the World Heritage List of the United Nations, the evaluation criteria of OUV are more detailed and comprehensive, which can summarize the evaluation criteria of historic site of China, Japan, Britain, and America from different perspectives without anything uncovered. Moreover, it describes from the more bigger perspective with more flexible description. For example, the content about “building, technology, relic art, urban planning, or landscape design” mentioned in the second criterion of OUV, which cover comprehensive and concrete fields, while other countries only simply describe them by the relevant definitions of “important events”.
- II. In the similar content of criteria of different countries, the value of cultural heritage in historic site is especially emphasized rather than only limited to the definite object of cultural heritage itself in the criteria for the assessment of OUV in the *World Heritage List* of the United Nations. “Spirit” (first criterion), “value” (second criterion), and “witness of civilization or culture” (third criterion) appear multiple times in the criteria. By making comparison, it can be found that the descriptions of the criteria in other countries are static and monotonous, which only focus on the cultural heritage itself and don’t explore the deeper historic value and cultural value.
- III. It is remarkable that it can be found in the comparison that the criteria of Japan, China, Britain, and America are reflected in the first four criteria of OUV, while there is almost no relevant illustration about the fifth and the sixth criteria of OUV in the criteria of

these countries. However, the fifth and the sixth criteria emphasize the relation between “human and environment,” is emphasized in the fifth and the sixth criteria, which is the core of assessment of OUV. The fifth and the sixth criteria take the abstract “culture” and “belief” as the assessment requirement directly. It shows that historic and cultural value is attached more importance, but these content and ways are not mentioned in the criteria of other countries.

#### 4 THE INSPIRATION OF THE EVALUATION CRITERIA OF INTERNATIONAL HISTORIC SITE TO CHINA HERITAGE PROTECTION SYSTEM

By making comparison, there are following inspirations to China heritage protection system:

1. The declaration requirement for famous historic city, town, and village is too closed and static in China.

It can be seen from the comparison from third criterion of OUV in Figure 2 and the similar criterion (1) and criterion (3) of China that now Chinese assessment of historic site only focuses on the description of quality and style of current situation of building, which doesn't consider the historic information, scientific value, art value, and emotional value of building. The assessment only focuses on the stage of horizontal comparison, whose measurement standards only fix on relic quantity, wholeness of building and architectural complex, and relic age. These criteria are too stiff and closed, and the delimitation for protection range and construction control zone can only keep the protection in the state of isolated, static, and negative state. For the protection of historic site, it is not only reflected on the expansion of protected object, but also is reflected on the understanding of material value of historic environmental protection, the understanding and assessment of spiritual value and cultural value of historic environment.

2. China should strengthen the assessment of cultural value of heritage

Except for having precious value in the aspect of material space environment, the deep humanistic value of historic site should also be paid more attention. The real value of historic site and historic environment is not the building or structure itself; it is the outcome of culture and spirit, which creates and carries one or more historic atmosphere(s) with historic value, art

OUV	Country	Content
i. represent a masterpiece of human creative genius;	China	None
	Japan	2. being the model of modeling art
	America	3. It shows the works with unique characteristic in some type, some period, or some construction method, or the works of masters, or the works with high art value, or the ordinary works with group value;
	Britain	None
ii. exhibit an important interchange of human values, over a span of time or within a cultural area of the world, on developments in architecture or technology, monumental arts, town-planning or landscape design;	China	4. It was the political center, economic center, cultural center, traffic center, or important military area in the history, or the place where the important historic events happened once; or its traditional industry and important projects in the history had important influence on the development of local area, or the place which could reflect the cultural features and national features of local buildings.
	Japan	None
	America	1. has association with important historic events; 2. has relation with the life of outstanding figures in the history;
	Britain	1. The building which has special value in the aspects of building type, building art, planning and design, or social and economic development history, such as industrial building, train station, school, hospital, theater, city hall, poorhouse, and prison and so on; The representative buildings of technological reform or exquisite workmanship, such as the building in the early period made of cast iron, precast technology, and concrete technology; 3. The building which has association with important historic events and important historic figures;
iii. bear a unique or at least exceptional testimony to a cultural tradition or to a civilization which is living or which has disappeared;	China	1. With rich relics; 3. It keeps the traditional layout and historic style;
	Japan	1. It is hard to reappear.
	America	1. Prehistoric or historic important information has been found and maybe found.
	Britain	None
iv. be an outstanding example of a type of building, architectural or technological	China	2. There are many concentrative historic buildings;
	Japan	1. It is helpful to shape the historic landscape of land;
	America	None
	Britain	4. The building with the complete architectural complex, especially
ensemble or landscape which illustrates (a) significant stage(s) in human history;		with the examples of urban regulations, such as square, townhouse, and typical village and so on.

Figure 2. Similarities of evaluation criteria of various countries.

value, and cultural value at the same time. They not only witness the environmental change of this region for a long time, but also record the change of culture, thought and concept, and lifestyle in different periods. They reemerge the history and the mutual reform of human and nature at any time. Thus, in the formulation of China heritage protection system the attention to the humanistic value in historic site and historic block must be drawn more..

3. Suggest for bringing in cultural listed system in China

The emergence of new cultural heritage system doesn't mean to deny or replace the original cultural system, but also bring new conception with available value in China protection system to supplement and improve the deficiency. For the current system in China, the formulation of it is mainly from the standing point of state to strictly select and "designate" the one which is important, prominent, and with special value in cultural heritages, and then some necessary limits are added to their owners with the coerciveness more or less. The advantage of listed system lies in that it not only expands the range of heritage relic and protects some modern building and industrial relics, but also the sustainable protection can be deployed on these objects on the purpose of development and a new flexible protection system will be established, which is the trend of world heritage protection.

4. Strengthen the promotion and improvement of laws and regulations

It can be found in Figure 3 that the protection awareness of historic site in Britain, America,

and some European and American countries is formed earlier than that of the United Nations and Asian countries. Britain established the framework of current listed system in *Law of Urban Planning* in 1947, while American enacted *The National Historic Protection Act* issued in October 1966 which became the foot-stone of protection of historic site in America. However, from the perspective of assessment content, the evaluation criteria of OUV of the United Nations are more detailed and comprehensive, because the criteria for the assessment of cultural heritage will be revised every year in United Nations. The revise of the criteria is the constant illustration of the definition of "OUV" in *Convention*. The OUV is endowed by people, which is relative and changeable.

It can be seen that the value of historic site is dynamic and changeable. In the formulation of China heritage protection system, the international vision and acute perspective for international heritage protection trend should be possessed, and the mutual promotion and improvement of laws and regulations should be paid attention.

Item	Name	Starting	Latest Revise

# The application of modular building in post-disaster reconstruction of the countryside

X.S. Wang & Q. Zhao

*College of Architecture and Civil Engineering, Taiyuan University of Technology, Taiyuan, Shanxi, China*

**ABSTRACT:** This paper, contraposes the particularity of post-disaster reconstruction of the countryside and puts forward the application of modular building in the post-disaster reconstruction of country. Then we sort out the concept, summarize the application of modular building, and explore the application of modular building in post-disaster reconstruction of countryside. In the end, we analyze an actual case. This research is expected to reduce the difficulty of post-disaster reconstruction in the vast rural areas of China.

**Keywords:** modular building; post-disaster reconstruction; countryside; application

## 1 INTRODUCTION

Earthquake disasters are very severe in China, with has features of great magnitude, high frequency, wide distribution, and shallow source. In recent years, earthquakes have happened often in China: an earthquake measuring 8.0 on the Richter Scale struck Wenchuan and Beichuan in Sichuan in 2008; another measuring 7.1 occurred in Yushu county of Tibetan Autonomous Prefecture of Yushu in Qinghai in 2010; in 2011, an earthquake measuring 5.8 on struck Yingjiang of Yunnan; another measuring 7.0 happened in Lushan county of Ya'an city in Sichuan in 2013; earthquake quake measuring 6.6 happened in the boundary between Min county and Zhang county of Dingxi city in Gansu in 2013; another measuring 6.5 happened in Ludian county of Shaotong city in Yunnan in 2014; and an earthquake measuring 5.0 Richter Scale happened in Jinkou river area of Leshan city in Sichuan in 2015.

The epicenters of these earthquakes are generally located in rural areas. There was no earthquake resistance measure or fortification measure for the residences in rural areas, so the earthquakes brought a lot of losses to these areas especially. Modular buildings have multiple values, so applying the modular buildings to the post-disaster reconstruction in rural areas is helpful to reduce the difficulties.

## 2 INTRODUCTION TO MODULAR BUILDING

### 2.1 Definition

Modular building is the building which is designed, produced, and constructed modularly

by complying with the module definition and by combining the features of modeling, function, and science and technology. The module feature for the modular building is very obvious. A series of basic modules with relatively independent and standard structures and functions are designed and produced by analyzing the modeling, structure, function, crafts, and technology and so on. These basic modules can be wall unit, door and window unit, stair unit, balcony unit, bathroom unit, kitchen unit, and bedroom unit, which shape the architectural industrial products that meet individual consumer's demand and meet the demand of market by selecting and combining the modules.

### 2.2 The development situation in rural areas

The study on modular building is late in China with slower development. There is less study on modular building in the aspect of residences in rural areas.

As China is increasingly focusing on residences in rural areas, China has also opened up studies on application of modular buildings to rural residences. For example, the 11th Five-Year topic—Modular Technology and Software Development of Design for Residence Building in Rural Areas proposed by Ministry of Science and Technology that Beijing Jintumu Software Technology Co., Ltd has completed the study on Jinzhong area, Lijiang area, and Huizhou area, but there are some rural buildings with national and traditional features to be studied, such as the CHouse CAD three-dimensional software system designed for rural residence building. These research results lay a solid foundation for the application of modular building in rural areas.

### 3 THE APPLICATION VALUE OF MODULAR BUILDING IN THE PROCESS OF POST-DISASTER RECONSTRUCTION IN RURAL AREAS

#### 3.1 *Improve the earthquake-resistance function of rural residence*

Most rural residences are self-built houses, whose earthquake-resistance quality doesn't reach the national or local relevant standards. Rural areas tend to be harder hit by earthquakes. The good earthquake-resistance function of modular building can improve the earthquake-resistance function of the residences in post-disaster reconstruction and reduce the loss that earthquake brings to rural areas.

#### 3.2 *Speed up post-disaster reconstruction and make reasonable reconstruction plan*

The technological level and construction efficiency of rural residence building are lower. Especially under the special situation of post-disaster reconstruction, the traditional construction way and technology cannot meet the urgency of post-disaster reconstruction in rural areas. The efficient way of production and construction modular building can speed up the post-disaster reconstruction in rural areas and play the consoling role of building. Furthermore, as the production efficiency of modular building is fixed, it is beneficial to the post-disaster reconstruction, providing the reliable data support and reference frame for making scientific plan of post-disaster reconstruction work.

#### 3.3 *Raise the usage ration of resources*

The main material for modular building is steel, so the retrievability of whole materials of buildings should be higher than that of ordinary buildings. Only in this, can it save resources. The materials for wall and floor slab are light, which can reduce the column load and therefore reduce the basic construction cost. Under some conditions, the disaster relief funds can be used directly to buy the modular building that is needed in rural areas, so the cycle chain of disaster relief funds will be reduced to raise the usage ratio of funds and to avoid the uncertain factors to some degree.

#### 3.4 *Improve the post-disaster rural environment effectively*

The ecological environment of post-disaster rural areas is destroyed severely, which becomes very weak. Thus, post-disaster reconstruction should be focused on the scientific, environmentally-friendly, and sustainable construction. Compared with the traditional building mode of rural residence, the

production and construction mode of modular building is more environmentally friendly and scientific, which can improve the rural environment after disaster effectively.

#### 3.5 *Motivate people to attend and diversify the building space types*

The functions of modular building are better than that of the residences built by peasants with their limited knowledge and experience. Moreover, due to its special universal system, the non-professional construction staff are able to design and construct residences with some professional knowledge. Local residents can make use of spare time to select the modules that they need and assemble their own residence, which is nearer the individual's special demand than that of the residence designed by professional staff with a shorter time, and exerts the enthusiasm of the people in disaster areas in the post-disaster reconstruction.

#### 3.6 *Raise the energy-conserving and environment-friendly index of residences*

Modular building combines the advanced production technology for low-carbon and energy-saving residences in developed countries. Compared with the traditional building, modular building can save over 47% of energy and reduce 51% of carbon emission, whose energy-saving index has reached 65% of the energy-saving compulsory standard of heating of buildings in the third stage and is developing to the four-step energy-saving requirement.

#### 3.7 *Be helpful to promote residence industrialization*

Residence industrialization began late in China and it is developing slowly. At present, although there are some residence production enterprises, they don't promote residence industrialization remarkably due to the limit of their own technological ability and other factors. Some buildings can be designed and produced like products, if modular building is released.

### 4 THE APPLICATION OF MODULAR BUILDING IN THE PROCESS OF POST-DISASTER RECONSTRUCTION IN RURAL AREAS

#### 4.1 *Special post-disaster situation in rural areas*

Rural residence construction is always a problem that is ignored and needs to be solved. It is very

severe especially in the process of post-disaster reconstruction in rural areas.

#### 4.1.1 Multiple types and strong regional features of rural residence

Rural residences are different features in different regions. For example, the building forms and space structures are different among Hui-style buildings in Huizhou area, quadrangle dwellings in Beijing, and residences in Jinzhong and so on. Thus, it adds the difficulty to the fast, ordered, and scientific post-disaster reconstruction in rural areas. However, modular building can meet the demand of space structure of different residences to the maximum degree due to its flexible and changeable spatial organizational ways.

#### 4.1.2 Complicated and changeable post-disaster environment in rural areas

Rural areas spread all over China, whose environment is different, such as collapsed loess regions with the continental monsoon climate, and saline areas with the temperate continental climate and so on. Due to the complicated and changeable environmental conditions, and the destruction of earthquake, it adds the difficulty of post-disaster reconstruction in rural areas. Owing to the special physical and structural functions, modular buildings can adapt to the complicated environment.

#### 4.2 The application analysis of modular building in post-disaster reconstruction in rural areas

Rural residence building spaces have strong regional features, so the post-disaster reconstruction in rural areas must be combined with local regional environmental conditions. The flexible and changeable spatial assemble forms of modular building are suitable to the regional features of post-disaster rural areas, so the post-disaster reconstruction will be more reasonable and scientific.

According to modular thinking, post-disaster reconstruction work can be divided into the combination of organic space of architectural complex and the spatial structure of single building unit. According to demand, it can be further divided. Finally, various modules can be combined organically. With the help of the effective leading and feedback system of organic space and unit space, both sides can be combined reasonably (Fig. 1). The difficulty in post-disaster reconstruction in rural areas can be reduced by simply facing the complicated situation and stably changing the same.

##### 4.2.1 The combination modes of organic space

The regional feature of organic space is obvious, which emphasizes the organic integration with the

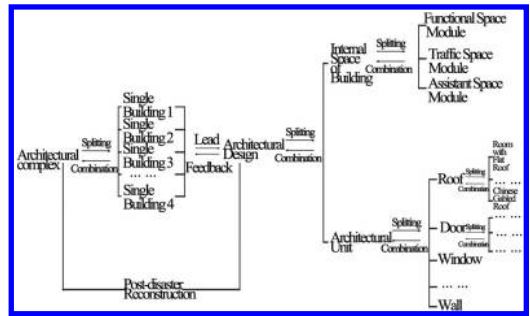

Figure 1. Diagram of construction principle for modular building space.

surrounding environment. It can reflect the modern sense at the same time of keeping the original geomorphic features, thereby improving the quality of environment of post-disaster reconstruction in rural areas. The organic space design of modular architectural complex mainly refers to combine several single building unit modules into a harmonious and complete organic space of architectural complexes, whose forms are as shown in Figure 2. Various single building unit space modules need to respond and connect with each other, so the internal space and external space can be interweaved, harmonious, and uniform, whose basic combination modes are as shown in Figure 3.

The interaction and flexibility of building modules can make architectural complexes combine properly with the special environment to adapt to the complicated and changeable environment in rural areas. For example, the courtyard combination can combine with the forms of “three outsider courtyards and five insider courtyards” and “broking two courtyards with three courtyards” in Jinzhong area of Shanxi; it can also combine with the single courtyard or multiple courtyards in Beijing; it can freely combine with the topographic form of Shanxi to shape the form of architecture complex that is suitable to the local features. This comprehensive combination can combine with the complicated environment to shape the architectural form in harmony with regional culture.

##### 4.2.2 The structural form of unit space

Comparatively speaking any relatively independent single building in the organic space can be called the unit space. The inferior modules of the unit space of single building can be divided into the architectural internal space module and architectural unit module.

###### 4.2.2.1 Architectural internal space module

Architectural internal space module can be divided into functional space module, traffic space module,

Figure 2. Diagram of combination patterns of building modules.

Figure 3. Diagram of combination modes of building modules.

and assistant space module. The distribution of functional module plans divides the reasonable internal space, whose space structure forms are as shown in Figure 4. Its flexible and reasonable space division can meet the different demands of residents in post-disaster rural areas to building internal space.

**Series combination:** Various functional space modules punch through. It is usually suitable for the situation of functional space modules with strong continuity or without independent separation. For example, the series combination can be used in kitchen or dining room.

**Parallel combination:** It is the combination which connects various functional spaces by traffic space module and assistant space module. This combination form makes various space modules relatively independent to reduce the disturbance with each other. For example, the parallel combination can be used between master bedroom and guest bedroom to reduce the disturbance.

**Blended combination:** It flexibly uses series combination and parallel combination so that the architectural internal space can be combined reasonably and scientifically in accordance with the demand of architectural space. It can be used in the complicated space to divide the functional divisions reasonably.

#### 4.2.2.2 Architectural unit module

Architectural unit modules can be divided into wall, door and window, balcony, stair, and some decorative units with local features to divide the inferior modules in accordance with color, material, and scale, such as the grill, suspended ceiling, and doors in different sizes and different qualities. These architectural unit modules can be combined flexibly to shape multiple-form architectural styles

Figure 4. Diagram of structure forms of architectural internal space.

to meet the style demands with different regional features in rural areas.

The division of modules should consider reducing the dependence on each other to make modules have independent functional features, and make modules be divided, combined, and repeated with good interchangeability. For the series standards of the modulus of module size, Chinese Coordinate and Uniform Standard of Architectural Modulus can be referred, whose basic value is 100 mm and whose symbol is M—1 M = 100 mm. The multiple of basic modulus is the modulus size of modular building. For example, the architectural unit module should adopt the horizontal basic modulus number sequence from 1 M to 20 M and adopt the horizontal expansion modulus number sequences of 3 M, 6 M, 12 M, 15 M, 30 M, and 60 M to be the modulus sizes of architectural internal space module.

## 5 MODULAR BUILDING CASES

The demonstration project of the building of vacation room on the mountain developed by Yi De construction consulting (Shanghai) Co., Ltd. is not located in Ba'nán area of Chongqing in Chongqing. The building includes two single houses, whose floor area is 80 square meters and construction area is 160 square meters. The house includes two families which are connected by the stairs. The living room is in the middle of each house. The bedroom with bathroom or the dining room with kitchen is on both sides, which can be allocated flexibly in accordance with user's demand.

The modular system of light steel is used in the project, which has high intensity and good earthquake-resistance function. It can resist earthquakes measuring 8.0 on the Richter Scale. Its deadweight is lighter than that of the traditional buildings, which can reduce 60% of deadweight. The thermal conductivities for outer wall and roof are 0.26–0.45 (W/m<sup>2</sup>·K) and 0.3 (W/m<sup>2</sup>·K), respectively; the fire endurance could reach 1–2 hours; the sound insulation requirement is ≥45 db. Dry process is adopted during the construction without wet operation, which can save 90% of water. There is

Figure 5. Plane Graph of the Building.

Figure 6. Exterior appearance of the building.

less operation on the construction field, which has less destructive influence on the surrounding environment. Compared with the traditional concrete construction mode on the field, it can reduce 50.9% of carbon emission. The construction is fast with a shorter construction cycle. It only takes 10 days for the whole project. Compared with the traditional construction mode, its construction cycle can reduce 30%–50%. The accurate quantization of industrial production can realize the minimum error of budget and final accounts. The project reaches the centimeter error of construction on the field and the millimeter error of manufacture in plant, whose quality can be improved and the cost can be controlled effectively. The main steel structure can be recycled. Owing to the industrial production and high-accuracy control, the loss of raw materials is less than 3%. It can save 75% of energy in the whole lifecycle from production, construction, to utility.

## 6 CONCLUSION

Now, a complete modular building system that is suitable for rural areas has not been shaped in China, which adds the difficulty of applying modular building in the post-disaster reconstruction in rural areas. However, with the development of standardization, serialization, supporting, and universalization of architectural units in China, the architectural products can be produced in plants with modular construction. Meanwhile, due to the development of information technology, the connection between all industries is more convenient and fast, which is helpful to gradually establish a set of complete and reasonable modular building systems in China which is suitable for different regions, different residents, and different cultural features. When the earthquake disaster happens in rural areas, the reconstruction work can be organized and started rapidly in accordance with the stocked relevant information of building and construction, and residents can return to the original life rapidly. The booming development of modular building will help the post-disaster reconstruction work in China start smoothly, and meanwhile will bring a new industry updating and huge reform in architecture industry, logistics industry, building material industry, and construction industry and so on.

# Analysis of development trend of country parks in China

L.N. Li & J. Gao

*College of Architecture and Civil Engineering, Taiyuan University of Technology, Taiyuan, Shanxi, China*

**ABSTRACT:** Based on the need for rapid development of the construction of country parks in China in recent years, as well as 389 research literatures on country parks through retrieval from CNKI (China National Knowledge Infrastructure) in 30 years from 1984 to 2014, this paper has classified statistics of these documents from four aspects, such as the year of publication, sources of database, research point of view, and research methods. It has summarized the progress, results, and trend of related theoretical researches at home and has analyzed the characteristics of the current research in order to provide references for the construction and study of country parks in the future.

**Keywords:** country park; literature; statistical analysis; development trend

## 1 INTRODUCTION

In the rapid process of urbanization, as environmental issues are increasingly projecting, building ecological and livable cities have become widespread concerns. Construction of country parks aim to create ecological and livable cities so as to enhance the quality of urban and rural residents. Country parks belong to a mosaic in the city's overall level or a large plaque, and its mosaic and distribution pattern is repeatable to some degree. Being an important part of an urban green space system, country parks not only protect the fine natural resources at the junction of urban and rural areas, but also can restore the resource conditions that have been destroyed. With important ecological functions, it serves to improve the ecological environment, blocking the city's infinite sprawl. In addition, with the accelerated pace of urban life and magnified work pressure, the demand for pleasure and leisure has been growing. City Park has been unable to meet the needs of residents, and country parks in peri-urban areas have favorable ecological environment and superior geographical advantages, and have become a crucial option of weekend getaways for urban residents. Based on these reasons, there is a rapid development in construction of country parks in various regions of China in recent years. Practice in the development of country park is far ahead of the theoretical development of the construction of country parks, resulting in the great blindness in the construction of country parks. Thus, further improvement and perfection is needed in all aspects.

There is a total of 389 research literatures containing "country park" included in CNKI in 30 years from 1984 to 2014 through retrieval. This paper has conducted statistics of these documents from four aspects, such as the year of publication, sources of database, research point of view, and research methods to make analysis of the progress, results, and trends of current research on country park in the hope of playing a guiding role in research and construction of country parks.

## 2 AN INCREASING TREND OF RESEARCH ON COUNTRY PARKS

By statistical analysis of the year of publishing research literatures on country park, in 1984, Chinese scholars began to conduct research on the country parks, with less number of research papers from 1984 to 2005, for at this time, the research on the country park is still in the initial stage of exploration, developing slowly. From 2006 to 2009, the number of research papers began to increase, the overall showed a rising trend, and the study of country parks became the hot spot. Thus at this time, the study on country parks in our country has begun to develop. From 2010 to 2014, the number of research papers tended to change smoothly, with small differences in research papers each year. Thus at this time, the research on country parks in our country has entered into a relatively stable period of development (See Fig. 1).

Figure 1. Change in number of research literature on country parks from 1984–2014.

### 3 A RISING TREND OF ACADEMIC DEPTH AND INNOVATION OF RESEARCH ON COUNTRY PARK

By statistical analysis of the source database of research literatures on country parks, the original source database of research literatures on country parks has low academic value, while as research progresses, the academic value of source database has begun to increase, especially in the high academic value in China Doctoral Thesis Full-text Database (See Table 1).

The number of research literatures from China Academic Journals Full-text Database, Proceedings Papers of Chinese Meetings Full-text Database, and China’s Major Newspapers Full-text Database shows an overall upward trend, while the proportion displays an overall downward trend. There is less number of research literatures from Featured Journal and Proceedings Papers of International Conferences Full-text Database, and the proportion is on a declining curve. There is an upward trend in the number of articles from China Outstanding Master’s Thesis Full-text Database as a whole, while the proportion shows the overall upward trend. Research literatures from China Academic Journal Series Full-text Database and China Doctoral Thesis Full-text Database have just appeared in recent years with very few research papers. In 2005, the literature on support of research funds has begun to arise in the study of country parks in our country, and the number of literatures on funds support has shown an overall upward trend (See Fig. 2).

Overall, academic depth and innovation of research literature on country parks in our country has been on the rise, and the type of database

Table 1. Starting year of different sources of databases of research literatures on country parks.

Starting Year	Database source of research literatures on country park
1984	Featured Journal
1996	China Academic Journals Full-text Database Proceedings Papers of Chinese Meetings Full-text Database
1999	Proceedings Papers of International Conferences Full-text Database
2003	China’s Major Newspapers Full-text Database
2006	China Outstanding Master’s Thesis Full-text Database
2010	China Academic Journal Series Full-text Database
2011	China Doctoral Thesis Full-text Database

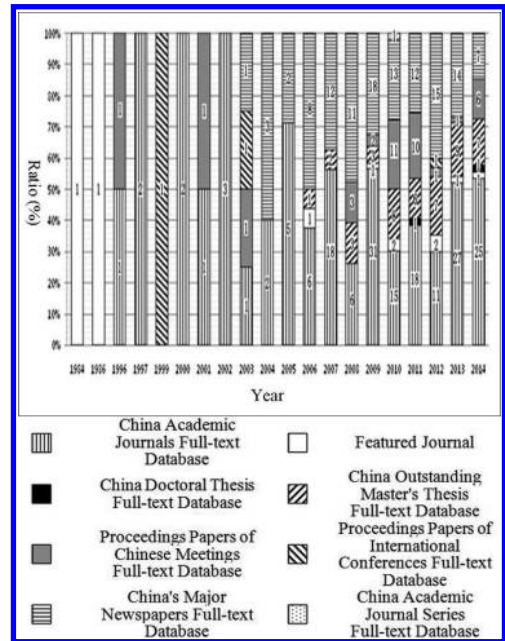

Figure 2. Change in source of database of research literature on country park from 1984–2014.

sources of research literature has gradually increased.

### 4 TRANSFORMATION FROM A SINGLE DISCIPLINE TO INTERDISCIPLINE FROM THE PERSPECTIVE OF RESEARCH ON COUNTRY PARKS

By statistical analysis of the perspective of research literature on country parks, with the

development of the research, the angle of research literature on country parks has begun to increase, gradually involving all aspects of them (See Table 2).

The overall number of articles each year is firstly increased and then decreases from two research perspectives of country park management and description of the construction and development in various regions, and the proportion shows an overall downward trend. The overall number of research papers each year shows a rising trend from two research perspectives of country park planning and design, and vegetation landscape, and the proportion shows a steady rise after decline as a whole. There are less number of research papers each year from two research perspectives of relation between country park and city as well as ecological protection and ecological benefits, and the proportion first decreased and then stabilized. There is a less number of research papers each year from three research perspectives of tourists' behavior and experience in country park, concluding thoughts and review and construction, and the proportion shows a steady trend as a whole. There are a less number of research papers each year from the research perspective of tourism development in country parks, and the proportion shows a declined trend as a whole. The overall number of articles each year first increased

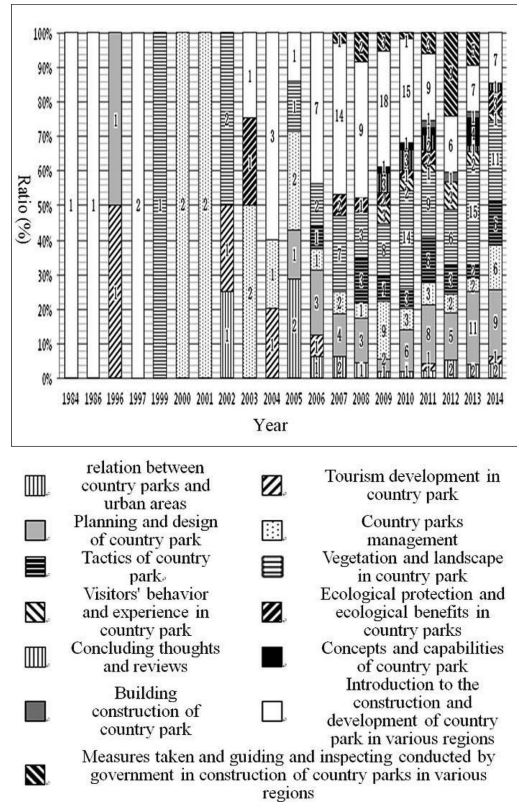

Table 2. Starting year of different research perspectives of research literatures on country parks.

Starting Year	Research perspective of research literature on country park
1984	Introduction to the construction and development of country park in various regions
1996	Tourism development in country park and planning and design of country park
1999	Vegetation and landscape in country park
2000	Country parks management
2002	Relation between country parks and urban areas
2003	Ecological protection and ecological benefits in country parks
2006	Research on tactics of country park
2007	Measures taken and guiding and inspecting conducted by government in construction of country parks in various regions
2009	Concepts and capabilities of country park, concluding thoughts and reviews and visitors' behavior and experience in country park
2011	Building construction of country park

Figure 3. Change in research perspective of research literature on country park from 1984–2014.

and then decreased from the research perspective of measures taken and guiding and inspecting conducted by government in construction of country parks in various regions, and the proportion firstly increased and then decreased. The overall number of research papers each year shows a rising trend from the research perspective of tactics of country park, and the proportion shows a steady trend as a whole. There are a less number of research papers each year from the research perspective of concepts and capabilities of country parks, and the proportion shows a rising trend as a whole (See Fig. 3).

Overall, the research angles are gradually transformed from introduction to construction of country parks in various regions, country parks management, tourism development, vegetation and landscape, and planning and design to research perspective of relation between country parks and urban areas, ecological protection and ecological benefits of country parks, strategy, tourists' behavior and experience, the concept and function and so on.

## 5 STATISTICAL ANALYSIS OF RESEARCH METHODS IN NEARLY 30 YEARS

With the development of the study, the method adopted in research literature on country parks has gradually enriched, and the use of a variety of methods can promote research and development of country parks (See Table 3).

Using frequency of descriptive research and mathematical method first increased and then declined as a whole, and the proportion shows an overall downward trend. Using frequency of case study and qualitative analysis firstly increased

and then declined as a whole, and the proportion firstly increased and then declined as a whole, and gradually stabilized. Using frequency of survey method firstly increased and then declined as a whole, and the proportion shows an overall steady trend after decline. Using frequency of literature research shows an overall upward trend, while the proportion shows an overall downward trend. Using frequency of quantitative analysis method shows an overall upward trend, while the proportion shows a steady trend as a whole. Using frequency of simulation, systematic science, experience summarizing, interdisciplinary research method adopted each year is less, and the proportion shows a steady trend as a whole (See Fig. 4).

Overall, the research methods are transformed from descriptive study, case study, qualitative analysis, mathematical method, investigation method and others gradually to quantitative method, systems research, interdisciplinary research, and simulation and so on.

Table 3. Starting year of different research methods of research literatures on country parks.

Starting Year	Research methods in research literatures on country park
1984	Descriptive research method
1996	Case study, qualitative analysis, literature study
1999	Mathematical method
2000	Investigation method
2006	Quantitative analysis
2007	Experience summarizing
2008	Systematic scientific method
2009	Interdisciplinary research and simulation

## 6 CONCLUSIONS

Since the initial research on country parks in 1980s in China, there has been faster research and development of country parks, and especially in the 21st century, considerable achievements have been made in the related theories and the number of applied research literatures. But currently, the theoretical system of research on country park is imperfect, requiring further development and improvement. The discussion on the above research and summary is as follows.

### 6.1 Future development trend of country parks

Chinese scholars have been increasingly concerned with country parks, the number of research literatures on country park shows a rising trend as a whole, and research on country park has become a hotspot, and it can be predicted that in the next period of time, research on country parks will continue to be the hot issue studied by domestic departments of construction and planning.

### 6.2 The theoretical system of country park research is still not perfect

Although academic depth and innovation of research literature on country parks in our country continues to rise, the theoretical system of domestic research is inadequate. Firstly, the authoritative standard of defining country parks has not formed yet. Secondly, there are still less points of innovation in domestic research. Thus, the theoretical system according with China's reality fails to be formed.

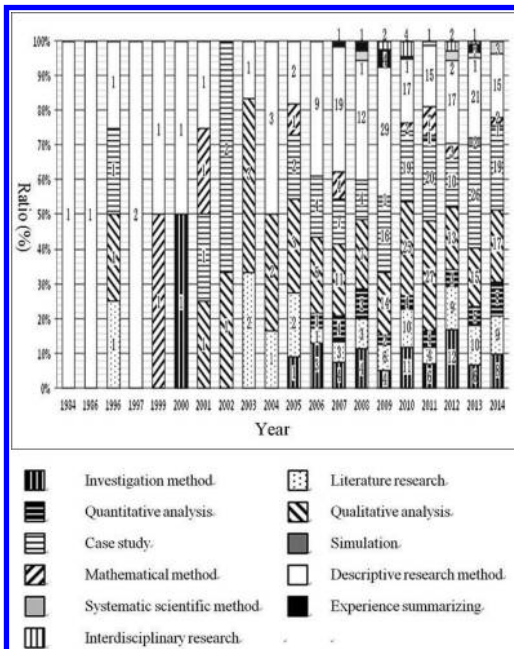

Figure 4. Change in research methods adopted in research literature on country park from 1984–2014.

### 6.3 *Forecast of future country park research perspectives*

Although research on the country parks in our country has already begun to be involved in the relationship between country park and city, ecological protection and ecological benefits of country parks, tourists' behavior, and experience in country parks, it is still in the exploratory stage, with shallow research findings. Nevertheless, the ecological function and recreation function is the most important function of country parks, and in order to give full play to the function, the study on the ecological function of country parks and recreationists' demand is essential, and for country parks as an important part of the urban greening systems, the research on the relationship between country park and city helps to curb unlimited sprawl of urban "overspreading" style so as to achieve the sound development of relationship between country park and urban space. Therefore, the relationship between country park and city, ecological protection and ecological benefits of country park, visitors' behavior and experience in country park should become a crucial perspective of research on country parks in the future.

### 6.4 *Forecast of future country park research methods*

As for research methods of country park, although a number of methods has begun to be adopted, such as quantitative method, systematic

approach, interdisciplinary research, simulation and others, the using frequency is less, and quantitative method and simulation can make more scientific and precise analysis of country parks to forecast the growing trend of country parks. Systematic approach can make the question and conclusion of research on country park become more systematic and clear, and interdisciplinary research method can conduct a comprehensive study of country parks through mutual reference and penetration of a variety of research methods so as to attain the reuse and innovation of knowledge and technology. Therefore, quantitative method, systematic approach, interdisciplinary research, and simulation should become significant methods of research on country parks in the future.

# The analysis of urban underground space based on environmental comfort

YanPing Gong

College of Civil and Architecture Engineering, Shandong University of Science and Technology, Qingdao, Shandong, China

**ABSTRACT:** The 21st century has witnessed the constant development of urban underground space. In this paper, combined with the current situation and problems of urban underground space, on the basis of underground works, we discuss the method of environmental design and planning of urban underground space from the points of environmental comfort and artistic views. We discuss the better way to create a comfortable urban underground space environment to improve the level of people's satisfaction in urban underground space.

**Keywords:** environmental comfort; urban underground space; environmental planning; artistic quality; overall planning

## 1 THE STATUS OF URBAN UNDERGROUND SPACE DEVELOPMENT

### 1.1 *The embryonic stage*

Began in the 1960s, China started to construct urban underground projects in large-scale and most of the projects were civil air defense projects. After decades of effort, it has achieved remarkable results in guaranteeing national defense security and become an important part of urban underground space. However, since its function is relatively simple, the civil air defense construction can only be regarded as the initial stage of urban underground space utilization.

### 1.2 *The rapid development stage*

Since the mid of 1980s, with urban redevelopment, the number of underground space projects has continued growing and the type has become increasingly rich. It has built a number of projects, like Shanghai People's Square underground mall, Beijing Xidan underground mall and so on. Meanwhile, underground transportation facilities have also been well developed in many Chinese cities, such as Guangzhou and Tianjin. Qingdao, Harbin, Chongqing. Other cities are also actively being constructed their own underground transportation system.

### 1.3 *Future development stage*

From the air defense projects to underground commercial street, people have accumulated a wealth

of experience on the utilization of urban underground space. With the further development and utilization of urban underground space, people's functional requirements are gradually transformed into the pursuit of "people-oriented" environmental comfort. To achieve the comfortable relationship between people and the environment has become the new trend of underground space development. "Comfort" is the assumption that people will strive to achieve and ultimately reach the "most comfortable environment". Based on the relationship of people's needs, behavior, and environment, people should design underground space from the point of environmental comfort, to realize the coordinated development between urban underground space and over-ground space, to gradually construct three-dimensional integrated future urban space in the future.

## 2 THE PROBLEMS OF URBAN UNDERGROUND SPACE DEVELOPMENT

Throughout the current development of urban underground space in recent years, the main problems are in the following aspects.

### 2.1 *The lacks of coordination and integration on city's 3D space*

Three-dimensional space of the city means the city's upper ground, ground, and underground space. At present, China's comprehensive and multi-functional

urban underground space design is still on embryonic stage. It lacks the coordination between the underground and ground projects. It also lacks the combination of various subsystems and overall planning of the future development. The lacks of 3D space integration effectiveness directly lead to a predicament: the underground space is relatively in a large number, but still can not effectively solve the traffic problems of the city and the city center's ground contradiction is still not eased.

## 2.2 *The lack of advance planning*

Whether it is from the perspective of engineering technology, or from the point of urban space reasonable hierarchical planning and sustainable development, urban underground space hierarchical planning and construction should have been given priority in spatial planning and construction. Because China's underground space development started late, most of urban underground space construction lags behind the over-ground projects. It not only results the waste of underground space resources, but also causes increased construction costs.

In some areas, large-scale underground space development causes a shortage of underground space resources. Municipal pipeline, subways, underpasses and other different facilities emerge contradictions in the underground space occupation. Constructors often meet such situation: When they plan to bury pipelines; they find there are already a completed underground works, so that the pipelines have to change their routes. Some areas even spend a lot of energy to move the completed shallow underground pipelines to utilize deeper space.

## 2.3 *Poor environment and low comfort of underground space*

With the development and utilization of underground space, many shortages of underground space environment have been concerned. Insufficient natural light, inadequate ventilation, humidity, and other physical characteristics are not conducive to people health. At the same time, the poor artistic environment and unclear signpost also cause psychological damage to people. For instance, people will feel anxious, nervous, fear in underground space. From this perspective, underground space environment cannot meet peoples' basic needs and is not suitable for long-term residence.

### 2.3.1 *Factors influencing physical health*

#### 1. Insufficient natural light

Since the underground space is relatively a closed environment, it deeply relies on artificial

lighting. Compared to natural light, artificial light does not have bactericidal function and cannot prevent diseases and other bad effects from human body.

#### 2. Inadequate ventilation

Windowless underground structure is often difficult to achieve natural ventilation resulting in lack of fresh air. It causes people in the underground environment feel shortness of breath.

#### 3. High humidity

In the underground space, when moist air contact with cold wall, it will be cooled and turned into water droplets gathering on the wall. This will lead to high humidity in underground environments, which will cause mold growth and rheumatic diseases.

### 2.3.2 *Factors influencing psychological health*

#### 1. Unclear sign system

Lack of clear indicating information, which fails to provide proper guidance to pedestrian, makes them easy to get lost in underground. Terminology and specifications are not standardized and unified. On some signposts, text, language and symbols do not use national norms, standard and international customary symbols, which are not conducive to people to understand. Labeled small amount of information, some signs only mention in some of the main streets and buildings, but there are still some important places that are not being mentioned. Perhaps, those unmentioned places are the real destinations of pedestrians.

Psychologist has proved that acknowledging and obtaining the environmental information is one of the basic biological needs of human. If you lose this precondition, people will not be able to establish contact with the surrounding environment. To identify their location in the environment is also an indispensable basic condition. A person who has no idea about his location in a chaotic space always tends to feel nervous and produce a sense of emotional instability. Unclear signposts make people easily lose sense of direction in underground space. Thereby it causes nervousness, anxiety, and fear.

#### 2. Low overall culture of art

At present, in China, overall artistic design for underground space is still in its infancy. Underground space usually designed by a single color. Single color in the underground space, where space lacks of natural light, makes people feel tedious. It may cause depression and other psychological disorders over time. Similar underground space artistic design in different place, which lacks of geographical and cultural characteristics, can not improve the city's image.

### 3 URBAN UNDERGROUND SPACE ENVIRONMENTAL PLANNING BASED ON THE ENVIRONMENTAL COMFORT

Through the expansion, urban underground space utilization meets the city's need for space that is essential to city's continued development. Ultimately, it should achieve the goal of "harmonious cities". Development and utilization of urban underground space involve several aspects, and environmental space design is one of the most important parts. Compared with over-ground space, underground space environment has significant differences mainly in the closed space, the lack of natural light, the poor air circulation etc. These will have certain influence on human physiology and psychology. So, for a long time, a social consensus has formed that underground environment is inferior to over-ground environment. Therefore, people's reaction towards underground environment, to some extent, determines the outcome of underground space utilization.

According to the characteristics of underground space and function principles of environmental adaptability, combined with the experience and technology of underground space environment development at home and abroad, the future urban underground space development should include the ventilation system of underground space, moisture-proof system, lighting system, and sign system.

#### 3.1 Ventilation systems of underground space

Ventilation design of urban underground space can be divided into two basic types: decentralized and centralized. Decentralized ventilation system mainly takes small independent ventilation skylights, patio and basement high side windows. Centralized ventilation system usually takes underground central courtyard, atrium, wind tunnel and other methods. Due to the large contact area between underground construction and soil, construction has strong energy storage and high thermal inertia. So, the temperature change is far less severe than over-ground buildings. According to the particularity of underground space, the local regional climate, geographical conditions, considering the use of features such as personnel-intensive, air permeability and equipment fever, we should make full use of ventilation shafts, high side windows, courtyards and light pipes underground, wind tunnel and other methods. Then the design of underground space ventilation system can better meet the ventilation requirements to create a comfortable and energy-efficient space.

#### 3.2 Underground space dehumidification system

Two factors led to the increased humidity in underground space: (1) Leakage: water enters inside through structural layer of underground space and by evaporation into the air, causing increased humidity; (2) Improper Ventilation: people use ventilation in rainy season, the high humidity outside leads air into the underground space, resulting in increased humidity.

To reduce the underground space air humidity, we must prevent two factors mentioned above and design specifically underground space dehumidification system: (1) Build seamless waterproof system: to prevent leak water into the underground space; (2) The reasonable control of ventilation: ventilate in the dry season with low temperatures to purge the humid air out of the underground space; (3) The use of mechanical or chemical dehumidification process: strengthen the underground space dehumidification to further reduce the water vapor in the air content.

#### 3.3 Underground space lighting system

A striking feature of most of today's underground space is the interior space with no natural light and no direct access to outside sight. Humans have depended on natural light to survive for generations. This feature of underground space could make people feel a big difference, psychologically and physiologically, between over-ground and underground. It may even cause adverse physiological consequences due to lack of sunlight. In underground construction, the use of traditional artificial illumination will consume a lot of power. The use of natural lighting can not only meet the requirements of saving energy, but also meets the people's psychological requirements for natural sunlight, sense of direction, sense of diurnal variation, seasonal climate and other perception. The research on directing sunlight into underground construction and forming diffuse natural light, which increases space openness, greatly reduces the negative effects of closed underground space. Therefore, the advanced design of underground space lighting system not only meets the physical needs of people, but also improves the underground construction environment in many ways.

#### 3.4 Underground space sign system

With the increasing size of urban underground space, underground space network becomes increasingly complex. So setting the underground space sign system is especially important. Sign system should be regarded as an important part of the underground space environmental design to design and layout. By accurate and effective sign system,

people, even in a strange underground public environment, can also rely on a sound signpost to their destination.

At present, compared with Japan, Canada and other countries' sound underground space sign system; China's underground system has some shortcomings, such as unclear direction, no-standard sign, less information on sign as well as uneasily recognizable sign. According to these existing problems, when we design underground space sign system: (1) Signs should maintain continuity; (2) Setting proper transition sign between underground and ground; (3) Signs should keep visibility under emergency condition; (4) Setting the map at appropriate place makes pedestrians have a macroscopic realization of underground environment.

#### 4 OVERALL ARTISTIC PLANNING OF UNDERGROUND SPACE ENVIRONMENT

Urban Underground Space Design should meet people's psychological needs, paying attention to environment art design, improving underground physical environment to attract people to use. It should create a good cultural atmosphere to eliminate closed underground space and cold environment, so that users could get spiritual enjoyment.

Combined with the environment art design principles of creating comfort, producing spaciousness, strengthening a sense of direction, and using the knowledge of human factors engineering, we re-create the underground space from color, lighting, decorative graphics, materials and other parts to build a comfortable aesthetically pleasing interior. When we carry out underground space overall artistic planning, we should uphold the people-centered concept in human factors engineering and fully consider the impact of color on mental and physical. Scientific color adjustment and lighting design, let's people work effectively in the comfortable underground space environment.

#### 5 CONCLUSIONS

With the constant urbanization process in China, we are confronted with the acute shortage of land. So, the development and utilization of urban underground space will get more and more attention. With the expansion of the underground space, the number of people living and working in the underground space is also growing rapidly. People requirements for underground environment on environment quality and comfort become increasingly high. Underground space environment

design and planning has become an important point of future underground space development. In modern underground space design, we should combine the traditional design studies with human factors engineering and other emerging cross-disciplinary to promote users experience and comfort. Furthermore, by the design of underground space based on environmental comfort, it can reverse people stereotype about underground space and improve people's production efficiency in underground space.

From the perspective of environmental comfort and artistic design, we research urban underground space in this article. Through analysis of its current situation of the underground space environment, we discuss the method to create a comfortable and attractive urban public space underground, mainly from the physiological factors, like ventilation, moisture, light; and from psychological factors, like sign system and overall artistic planning. In physiological factors, we should take appropriate measures, such as using natural light, improving natural ventilation, promoting dehumidification system, to make underground space as comfortable as over-ground with similar living conditions. To psychological factors, by improving underground sign system, it will enhance the user's sense of security and a sense of direction; By the use of color, lighting, decorative graphics, and other artistic elements, it creates a clever and vivid visual sense, which can ease human adverse feelings in underground space.

Interaction between environmental factors of urban underground space is an organic whole, so that we should consider rational allocation of these factors. Through above new design ideas, from the physical and psychological perspectives, meet the human needs of the urban underground public space, to achieve the comfortable and arts standard, so as to achieve modern urban underground space development goals.

# Post occupancy evaluation of urban public space environment: Take Yingze Park in Taiyuan as an example

X.R. Zhao & Q.F. Shi

*Architecture and Civil Engineering Institute, Taiyuan University of Technology, Taiyuan, Shanxi, China*

**ABSTRACT:** Taking the Yingze Park of Taiyuan as the object of study, the scientific observation and interview is used to plan the layout. Building monomer, facilities, function, and behavior levels are indicative of post occupancy evaluation environment for their research. On the basis of the combination of domestic and foreign outstanding cases, reasonable suggestions for improvement are put forward.

**Keywords:** environmental assessment after use; Yingze Park; index study

## 1 THE RELATIONSHIP BETWEEN ENVIRONMENTAL ASSESSMENT AND POST-EVALUATION

Building Environmental Evaluation is the value of the study built environment, namely, the relationship between the built environment and the subject need. In the development and practice of the discipline of architecture and the built environment evaluation, and it can promote to realize the value of building environment, to reflect the scientific theory of building design and management feedback, making theory to guide practice. The research into the environmental assessment is to make people correct their own behavior, and realize the environmental value of the greater sense. Post-Environmental Evaluation widely spreads. Mainly it includes two aspects, Pre-Design Evaluation and Post-Occupancy Evaluation.

Post-Occupancy Evaluation is the core content of building environmental evaluation. It emphasizes the comprehensive technology research in the building environment. Preiser (1988) in his book “post use evaluation,” the definition of POE is: “after the construction and use of a period of time, the construction of the strict evaluation process.”<sup>1</sup> Focusing on the architectural needs of the user, the success of the architectural design and the performance of the building after the completion of the building POE. All of this will provide the basis and foundation for future architectural design”. The POE intends the purpose of architectural design and the actual use for the construction of the actual benefits and performance standards which are compared, give feedback and for the future improvement of architectural designs that provides reliable basis.

American scholar Jan Jacob believes that the most dynamic place in the city is the city’s public activity space. Public space refers to by the city building, building materials, plant perpendicular to the interface and the road, water and sector level, using combination of elements of urban space. It is the important place for the exchange of material, energy and information between human and nature. It is also the important manifestation of the city image, and it is the “sitting room” and “window” of the city.

## 2 BACKGROUND AND PURPOSE OF THE RESEARCH

City Park is the recreation place for urban residents, and is the urban green infrastructure, but also the main public open space. More caring about users, understanding their needs and interests is the successful design of the park. Which is advocated “people-oriented” ideology today.

The main body of the evaluation of the building environment is the following five factors: users, developers, designers, government, business managers. The main body of the evaluation should be considered in the choice of the city public space after the use of the evaluation of its own characteristics. First, the use of the post-evaluation means that the user is the center of the evaluation of the subject. Second, the characteristics of public space in the city are still the main body of the evaluation. To some extent, the concept of the public is equivalent with the user. But on the other hand, users of the evaluation tend to have tacit, clear and stable, more subjective shortcomings, so this topic choice another evaluation subject, from the point of view

of a more professional designers. In the evaluation of the entire process, such as the construction of the evaluation factor set, beauty of form factors of the evaluation, for measuring, sorting environment physical properties and the user's behavior can give professional advice. Most of the results of the evaluation of data can make more accurate and comprehensive evaluation of the space environment. It also can lay the foundation for the evaluation from the user's angle. Anyway, according to the evaluation goal, the evaluation content, the integrity of the people and the environment of the system from the point of view, we all need to subject and object view of combination of evaluation main body wherein the user is still the core subject.

There are different classification methods for urban public space. The square is characterized by multi-function and comprehensive, which constitutes the public activity center of the public. The park is a pleasant place to enjoy, and relatively square, there is a certain circumference of nature. The street is a pedestrian system, which is closely related to urban public space. Such as the mall, commercial pedestrian street etc. Waterfront space is an important marginal in city, which plays an important role in the connection of city public space, and it is usually the main green space of city.

### 3 CASE INTRODUCTION

Total garden area is 63 hectares. The Yingze Lake area is 20 hectares, lake and Nanhu separated by Qikongqiao. Landscape park to plant landscaping, 39 million lines of the existing landscape plants, 130 varieties, 24 hectares of lawns, built square, decorated archway, the rockery, the peony garden, rose garden and so on. The core of the building is the park celebration, the floor assembly, a variety of cultural activities center.

### 4 OBSERVATION AND INTERVIEW ANALYSIS RESULTS

#### 4.1 *Research on landscape planning and analysis*

Built in the Park rockery in the northwest of the rolling hills, the aim is to reduce the impact of local climate on plant and ecological environment, and to stop the strong wind from northwest during winter. Water park layout is single, only the North Lake, South Lake and lake. Lake should be number one or two human activities and natural ecological integrated design, the park waters system interconnected add radiance and beauty to each other. This will be closer to nature and weaken the interference of artificial factors. The layout of the combination

should be used to increase the river course and flow through a good ecological resource chain. There are no independent green spaces for visitors and sun bathing, just some small forest. It sets a real public open space to visitors. Holiday night is the perfect place to launch a movie. Park within the majority of the elderly and no sports should be added, such as basketball courts, small football field, tennis courts, etc. To attract more young people to increase the vitality, the mini basketball and football field construction reference park along the Fen River Fen river. The lack of open theater or amphitheater Park, research noticed beside the park building at the heart of the Tripitaka floor has many of the elderly in next to rehearse the songs, the apparent lack of suitable for mass of public entertainment buildings. On the south side of the north gate of the musical fountain layout is reasonable, but designers will the north is between the north and the musical fountain increases the rockery, seriously blocked from the north gate to watch the musical fountain sight. (Figs. 1 and 2).

Figure 1. Yingze lake.

Figure 2. Public green space.

## 4.2 *Building environment analysis*

The harmonious charm and the landscape of the public space itself can bring people a wonderful visual to enjoy. Public space makes person produce upward, happy, yearning mood, physical and mental pleasure to achieve the purpose of relaxing, and to realize the beauty of artistic conception creation. An attractive public space belongs to own the special atmosphere, solemn, serene, dynamic and lively. In short, according to their own characteristics, it seems to create a bright spot to attract people.

North Gate imitation can not deeply reflect Taiyuan profound cultural heritage. Because it is not the history of the remains, just a taste of the construction of antique buildings is not the essence of its urban culture. Personally, the design fails, and the construction fee is expensive and can not get the effect. The core building of the park is the relocation of the Taigu County, and there are 800 years of history, which is a non local architecture can not reflect the historical and cultural heritage of Taiyuan. The park of the antique building is similar to more, the Summer Palace garden. However, the Summer Palace is the imperial garden built during the Qing Dynasty, and it is the legacy of the world heritage.

Park design techniques should not be confined to the use of Chinese classical garden gardening practices, combining Chinese and Western design can reflect the inclusive flowing. Artificial factors within the park lose its natural beauty, such as the construction of the large number of antique buildings which doesn't make any sense, and it should be more than the construction of a number of life elements. At the edge of the lake, with artificial stone and marble railing, the structures of human and nature of isolation shall dismantle these structures, and it will narrow the distance between man and nature. Some of the platform design, based on the platform of some arbor below placed some of the tables and chairs; some of the park scattered selling snacks trolley flooding seriously damaging the natural landscape. We should stop and design some small buildings, and checkered shaft uniform network layout, increase convenience; grassland and roads separated by a fence will let man and nature produced the distance. In a word, we should respect all life forms with the basic features, not easily change them, the artificial factors to blend natural factors.

Scale is one of the major elements of the design, the width of public space (D) and the height of adjacent building (H) ratio (D/H) of human psychology and the vitality of the space, which has a great impact. Japanese scholars Yoshinobu ashihara said "when  $D/H > 1$ , with the increase of the

ratio will be formed gradually away from the sense; more than 2 are produced when the broad sense; when  $D/H < 1$ , with the ratio of reduced generated close to the feeling; when the  $D/H = 1$ , height and width between existence with a balanced sense." If the adjacent building height 2 times more than the width of the square, it will produce the empty feeling, a sense of separation, no polymerization; on the contrary, if the width of the square building is less than the height, between buildings interfere too strong and too close, which makes people have a sense of depression.

Therefore, different scales and proportion of space has different atmosphere and vitality, in the design we should adjust measures to local conditions, create a pleasant interesting city public environment space. Urban public space within the facility image compared to "furniture city", and how to make "furniture city" rational and humanized. It will give a person with the cold feeling of material; and people will have the features of local pool depth should not be too deep, lest children stay at the edge of the water, playing accidents.

Entertainment facilities are dilapidated, so it needs to update, a torrent of children's recreational facilities such as a roller coaster. The lack of food and Rest Area, and we should build the lake construction of dining and leisure development and a platform of waterscape construction, such as the introduction of food street restaurants, coffee hall introduction part bars, and other leisure and entertainment. To increase the vitality and popularity of Yingze park, we shall set up a number of irregular and can reflect the nature of the material paving in the park; playground and park should be separated, because of the large Happy Valley old amusement park will be built after the playground should be replaced, so the new children's learning and entertainment facilities, some of the characteristics of the park; small Ferris wheel is not to enhance the landscape effect. We should build a large skyscraper wheel to increase the charm of the city. Such as the eyes of the domestic Tianjin etc. Will park tour bus replacement for European style carriage can be some of the highlights of the artificial factors weakened, better integrated into the natural. Park Lake local can add some landscape corridor rich vertical design. At the edge of the lake, it could be some interesting design plant pieces.

## 5 DEADLINE

The real value of the park is primarily reflected in the pleasure of providing the public with the harmonious coexistence of nature. Then, it is the

important part of the city to increase the vigor of the city, such as the Central Park in New York, Paris La Villette Park. In addition to provide leisure and recreation for the public, these two parks also become a place of exchange visitors everywhere. Tourists come here to rest, enjoy the city characteristics, to talk with local residents, to understand the different customs. They are attractive, parks, and it's still a place for a city in the living room, a city resident in order to display its own features and entertain the guests. So now the Yingze park is not likely to become a landmark and an impor-

tant part of Taiyuan, and it is impossible to make foreign tourists, if the park's planning and architecture can not reflect the Taiyuan historical and cultural heritage as a more vibrant park.

# Influence of the Chinese traditional Feng-shui theory on the layout of contemporary residential space

B. Wang & T. Li

*College of Architecture and Civil Engineering, Taiyuan University of Technology, Taiyuan, Shanxi, China*

**ABSTRACT:** The Oriental attaches importance to feng-shui, feng-shui is the Chinese people's pursuit of an important yardstick of the ideal living environment. But the object of feng-shui research is how people can get along with the environment better, and the core idea and the contemporary design idea have many consistent place. We should study the essence of feng-shui theory, and apply it to the modern design, establish the harmonious coexistence between man and nature of the ecological environment, build and integrate the system of interior design concept.

**Keywords:** chinese traditional culture; feng-shui theory; interior space design

## 1 INTRODUCTION

Feng-shui is an important part of Chinese traditional culture, and it is also a unique cultural manifestation of Chinese millennium culture heritage. The concept of "Feng-shui" first appeared in Guo Pu's "Zang jing" of the Jin Dynasty: "The Tibetan people gathered together to produce" "qi, and the ancients used it to make it effective, so is called feng-shui." The ancient Chinese Feng-shui theory is based on the Chinese traditional philosophy, which has the unique Chinese traditional culture mark. The pursuit of "harmony" realm of thought in western modern space environment of train of thought is such that it coincides with the embodiment.

## 2 THE THOUGHT OF FENG-SHUI IN THE CONTEMPORARY HOUSING SPACE PATTERN

With the rapid development of residential buildings, and the influence of social benefits, the residential buildings may have all kinds of improper places in the design. People tend to be in fixed location based residential choice, and then the choice of residential living space may exist in all kinds of unreasonable places, which requires designers to space transformation to meet the housing needs of the people.

### 2.1 *Physiological and psychological aspects*

In the feng-shui theory, the essence parts are "Jing" "Qi" and "Shen". Qi is a very important concept in

Chinese traditional culture, and it is also the core of Feng-shui theory. As the "Qi" is divided into auspicious and inauspicious. If it can gather "Ji Qi" it is good. While the scattered "Ji Qi" is fierce. When we live in houses, ventilation can product "Ji Qi", but the air circulation can not. It is easy to lead to physical weakness, then it is not belong to the "auspicious gas, and it need to spread out", is commonly known as the "Drafty", the people also do not have good effect. The theory is actually related to the physiological characteristics, discusses how to better to ensure people's health. And feng-shui also discusses some Interior design. Feng-shui is through the "Qi" and "form" of the dialectical relationship between the use of, feng-shui is the essence of the Chinese people for thousands of years are summarized and the survival experience, are based on Chinese people physiological and psychological needs and summed up the rule of thumb.

### 2.2 *The inheritance of context*

As a part of Chinese traditional culture, feng-shui has been deeply rooted in the hearts of every Chinese people, and it is the ancient Chinese context. This is similar to the historical development of the West. Roots of western culture in ancient Egypt, the construction of the pyramid can be seen, the pyramid construction group construction is to ensure that the dead Pharaoh can continue to enjoy the superior environment and rebirth. In fact, this is the ancient Egyptian "Fengshui". The essence and inheritance of Chinese Fengshui is similar. Regardless of the theory of the East and the West are by the ancient life experience accumulated and

inherited the rule of thumb, but Chinese feng-shui theory, theory have its own unique theoretical system, and few people use western scientific methods to test and analyze. “feng-shui theory,” is often cast a mysterious color, mistaken for the superstitious said, in fact, many parts of the feng-shui theory, are based on Chinese ancient and unique cultural heritage of a sense of identity, which is one kind of each country’s unique cultural heritage, and not simply to science two words to explain.

### 3 THE APPLICATION OF FENG-SHUI THEORY IN THE PATTERN OF RESIDENTIAL SPACE

In the traditional architectural composition of China, a large number of balanced symmetry is applied, and the plane and facade of the axis are emphasized. feng-shui believes that the founder of the building plane, the symmetrical symmetry of the trapezoid, the complete lack of environmental patterns are auspicious manifestations. Such as housing of too high to low, building shape of clutter, the door two door width different will is considered unlucky.

Residential space is a whole space, which due to the different functions and separated into different space, every space through different furniture display, decorative furnishings and camp to create a different atmosphere of space and function space. When the Fengshui theory is applied to the study of residential, in fact, is according to feng-shui “Jing, Qi, Shen” concepts to improve residential place that does not accord with people’s living habits and psychological, making it more in line with the requirements of the people living. While the living rooms are closely related with the behavior of the people, bedroom, kitchen, bathroom and other parts, the following is a feng-shui point of view to analysis. (Figs. 1 and 2)

#### 3.1 Living room

In Feng-shui theory, living room as a space point eye “is a key to residential” with the wind to get together “Qi”, we must see the sun, and if hall bright room is dark, parlor, families get together and the main space of living room, the sunshine will give people a psychological comfort.

Doors and windows of the hedge in feng-shui is taboo, by the gate of wealth not through the loop is through the window out, is not conducive to the fortunes of the aggregation. Feng-shui will have this kind of view, because windows and doors hedge causes air to flow without blocking, easily to cause “Drafty”. This is not good for health; therefore need to set up between the living room and the

Figure 1. The case of a feng-shui unfavourable.

Figure 2. The case of a feng-shui unfavourable.

door entrance to change a gas flow path. Second, to meet the privacy requirements to prevent the living room “Porch” is in the traditional local style dwelling houses in “Zhaobi” evolution. It discusses the traditional geom-antic omen contains simple life experience and in real life used, indicating that traditional geom-antic omen in some elaboration is the scientific truth, just need us to use modern ideas to interpret it.

Sofa is the important furniture of the living room, so it has a very important position. The best sofa places against the wall, and feng-shui is known as the “patron”. It will make people have the feeling of stability in psychology. Sofa and tea table is usually a combination, and it should also be unified

and harmonious. In the theory, low for the water, the higher the sofa for the mountain. The tea table is shorter for the water, there are mountains and water to produce a good feng-shui effect and this belongs to the context of the heritage of feng-shui.

### 3.2 *Bedroom*

Bedroom is a very important area of residential space, people have 1/3 of the time in sleep, so the bedroom feng-shui is closely related to the physical health of people.

Master bedroom should be located in the “possession of the wind to get together gas range, in the South or East, and it is the most ideal because of the South and east of the sun can be sufficient irradiation range, people have the sun would” Jing, Qi, Shen, and as a place to rest and sleep, must be placed on a sunny range. While the bedrooms area should not be too large, is not satisfied that the “Qi”, and from the psychological point of view, the bedroom is too crowded to open, it gives a person a kind of insecurity. Yangxin Hall of the Imperial Palace in Beijing is the emperor’s bedroom area only about ten square meters, which also shows the ancient architectural design and feng-shui theory is closely related to, until now still with our lives is closely related to. And feng-shui study said the bedroom door is unfavorable be opposite the bathroom or kitchen door is on the physiological aspects, the fumes from the kitchen and bathroom filthy gas will flow into the bedroom and detrimental to human health.

Placing bed, feng-shui school also has a lot of exposition, “bed to avoid pressure beam” “bed back door” and “straight to avoid door” “bed bogey there after the gap” are the ancients summary of experience living and modern also prove a lot of content and western psychology is consistent. Therefore, when we go to decorate the bedroom space, we can learn from the theory of feng-shui to avoid some inappropriate places.

### 3.3 *Kitchen*

Traditional geom-antic omen that the kitchen is housing the main, like one of the five internal organs of the body organs, it is the key to a healthy family, saying it is “people with food,” said and the location of the kitchen should according to the Yin Yang and the five elements theory to arrange. And Yin Yang and the five elements theory is geom-antic learn important part tradition for thousands of years, rooted in the hearts of the Chinese people, so in the kitchen space arrangement, consider feng-shui theory requirements and taboo, which is the cultural heritage of the embodiment.

From the viewpoint of feng-shui theory, the kitchen is unfavorable to the south, the south is fire, kitchen also belongs to fire is disadvantageous to the home, in the modern scientific point of view. South is not conducive to food preservation. At the same time, the kitchen door is not right is the door to see the stove, it means omen. The kitchen is also not the toilet, bacteria and filth can damage health.

Kitchen stove and water is too close to avoid the two water clip a fire, such as stove caught between the dishes and washing machine, two water grams of a fire, the family will health and harmful. At the same time, the kitchen is very sacred, the kitchen god, this washing dirty clothes, will affect the luck. These claims in the science of place, if the stove and sink and so too close, water easily splashed on the stove, causing rust, dirty water if splashed into the pot, health effects.

### 3.4 *Bathroom*

In feng-shui theory, bathroom is called the “run-off” and “water” is residential to drainage, in relation to a family’s wealth and health. Bathrooms should not be opened in residential center, heart center is like room, and central pollution is not only unsightly and stench easily convection to the other room and health adverse. And the central is soil, toilet placed in the central will occur the soil grams of water, these feng-shui in the taboo are in line with our contemporary scientific truth.

Residential space not only includes the above four parts, but feng-shui theory is broad and profound, and it is not only the part of the point of view, but from the above analysis of the feng-shui in the residential space of several large. The overall core can be attributed to the “Jing, Qi, Shen” connotation, whether from the point of view of human physiological habit the “Qi” of the paper, or from the psychological habit of “Jing, Shen” is discussed, and some inherent in our traditional cultural heritage in cognitive habits, which constitutes a complete residential feng-shui theory. Therefore, there are many traditional geom-antic and modern science with content, only limited to the level of the expression of the ancients, so it will appear to discuss the too profound to be understood, with a sense of mystery, and we need the scientific theory of composition of traditional residential feng-shui inherit and applied into the scientific design method.

## 4 SUMMARY

The essence of Feng-shui theory is the environmental assessment system of ancient China. Although its interpretation system and operating system with ambiguity, coupled with the interpretation of

ancient occult things on the inside, it will give the human one kind of mystical and mysterious feeling, which will lead to being misunderstood as superstition. But the pursuit of “harmony”, the “Jing, Qi, Shen” as the core of the theory of discourse, passing the overall concept and natural humanism thought, it is modern residential environment evaluation system can reference and inspired.

The inheritance of feng-shui has its own rationality and scientific nature, and it inevitably mixed with many superstitious elements during the course of inheritance. This mainly reflects in three aspects: one is the feng-shui of ancient architectural environment of site selection and design experience summary is has certain practical and scientific; second is the ritual of the art of geomancy, assimilated by Confucian metaphysics; three is to theology based superstition thought origins. Feng-shui is

not superstition. On the contrary, “Residential of Feng-shui” is suitable for building practical component, and the essence is a summary of ancient building experience. We should learn to inherit and develop it.

# Research on strategy of ecological security assessment in Beijing urban space

X.Y. Ma, L. Feng & W.L. Zhang

*School of Landscape Architecture, Beijing University of Agriculture, Beijing, China*  
*Beijing Rural Landscape Planning and Design Engineering Technology Center, Beijing, China*  
*Beijing Laboratory of Urban and Rural Ecological Environment, Beijing, China*

**ABSTRACT:** Urban green space provides resources for human and maintains ecological diversity, which plays a major role within the ecological security system. Thus, the ecological security of urban green land is the crucial barrier and foundation of the regional ecological security. Scientific and objective assessment of urban green land ecological security could provide a reference for the establishment, maintenance, management of a guaranteed ecological security system, as well as related laws and regulations. This article in the first place systematically summarized the scope and progress of existing research on ecological security assessment of urban green space. At last it discussed the developmental opportunities of the ecological security of urban green space in Beijing particularly, and put forward its assessment strategy.

**Keywords:** urban green space; ecological security assessment; ecological security of Beijing urban green space

## 1 INTRODUCTION

Ecological security refers to the environment security status which is able to sustain the development of society, economy and nature, as well as safeguarding the social ecological safety, economic safety and natural environment safety. At the beginning of 2000, China announced in its “national ecological environment protection program”, the first clear target of national ecological environmental security. It presents the overall ecology protection strategy called “protection first, prevention first, protection and prevention combined”, which opened the prologue of ecological security research in China. While urban green area able to provide resources for human meanwhile maintains ecological diversity, which acts as the main component within the construction of the entire ecological security, and the important guarantee of regional ecological security.

## 2 RESEARCH SCOPE OF ECOLOGICAL SECURITY OF URBAN GREEN SPACE

Ecological security assessment refers to a series of methods and specifications, which are about: 1. Analyzing, predicting and assessing the regional ecological security values of waters, atmosphere, forest, mineral, animal and plant species; 2. Putting forward the countermeasures and measures to prevent or reduce the ecological risks; 3. Tracing and monitoring the ecological risks. While the research scope of ecological security assessment on urban green land is relatively wider, which mainly researching on urban green land resources as the core of all kinds of green space. Within this research scope, at present scholars at home and abroad has done a lot of research work on “other green space” among the urban green space types (emphasizing on key scenic areas and nature reserves, forest park, wetland, etc.) The study found that with the exception of some well-preserved local area enjoying high-quality natural ecological environment (room use, etc., 2007; Zhang Pin etc., 2013), the overall situation of China’s urban green land ecological security is below average.

According to Urban Green Space Classification Standard, urban green space is divided into five categories, in which the fifth class type of “other green space” refers to the urban ecological environment

2. Beijing Laboratory of Urban and Rural Ecological Environment Project (PXM2015\_014207\_000014).

quality, the residents' leisure life, the urban landscape and biodiversity conservation has a direct effect of green space. It includes scenic area, water conservation, country parks, nature reserves, forest park, scenic forest land, urban greening belt, parks, wetlands, green space reclaimed from landfill etc. They mostly have large area and intense influence on the ecological environment of the city. At present, research on urban green land ecological security assessment mainly concentrated in the scenic areas and nature reserves, forest park, wetlands and other green space types.

### 2.1 *Research on ecological security assessment of scenic spot and nature reserves*

Ecological security assessment of scenic spot and nature reserves is an important part of the assessment of overall urban green space. Researches show that, one of world cultural and natural heritage, the Wuyi Mountain has ecological footprint which is 1.503 hm<sup>2</sup>/person, ecological carrying capacity of 4.1476 hm<sup>2</sup>/person, ecological occupying rate being 0.3015, ecological occupying rate of grassland being 11.535 and that of water area being 5.386. These data indicate that Mount Wuyi is in a relatively safe condition as a whole, while its grassland and water area are still in unsecured situation (Tan Dehua etc, 2009). Moreover, from 1986–2009 the ecological security degree of Mount Wuyi Scenery District showed an increasing trend (You Weibin etc, 2011). In year 2004, the tourism ecological footprint per capita of Jiuzhaigou was 0.105190274 hm<sup>2</sup>, with local resident's humanism ecological footprint being 0.994925 hm<sup>2</sup>.

That the coefficient of ecological security was between 1.093158–1.159388, a safe stage for sustainable development. However, there were some main factors influencing the jiuzhaigou ecological security, such as increasing tourist amount and tourism market radius, along with the change of residents' consumption patterns and residents' strong dependence on the natural environment resources (Zhang Jinhe, 2008). When it comes to Mount Qilian Nature Reserve, its ecological security index is 0.5146, which is a very "unsafe" condition (Tang Feifei, 2013).

### 2.2 *Research on ecological security assessment of forest parks*

Research on ecological security assessment of forest parks indicates that the ecological security index of Beijing Jiufeng National Forest Park in 2007 was 0.8421, a relatively high standard (Mi Feng etc., 2010). Wang Chaohui (2012) systematically studied the ecological security assessment of mountain-type forest parks through scoping into 7 mountain-type

forest parks in Wenzhou, among which are 5 national forest parks and 2 provincial ones. His research found that the ecological security condition of these parks was misogynistic, that except the flower rock national forest park being "safe" condition, the other parks suffered various safety risks. Security indexes of humanistic environment of most parks are in unsafe levels. Similar unsafe stage is the indexes environmental pressures such as: water supply and demand balance; prevention and control of forest diseases and insect pests; and the prevention and control of geological disasters. Reversely the conservation levels on water, air, sound and soil environmental quality are considerably high. In particular, study on Zhangjiajie National Forest Park found that its indexes are in "unsafe" stage on the following aspects: visitors receive strength; the strength of local residents growth; water supply and demand balance; meteorology; the prevention and control of geological disasters; surface water environment quality; the protection of animals; the strength of waste-water treatment, development of the education system; development of the legal guarantee system. The threatening factors to its ecological security are mainly made of unreasonable tourism behavior, environmental pollution resulted from weak ecological consciousness of residents and tourism practitioners, environmental capacity pressure of golden tourist line, disturbance to the forest park ecosystem made by adjacent tourism development, imperfection of the ecological education, monitoring and guarantee system.

### 2.3 *Research on ecological security assessment of wetlands*

In recent years, domestic scholars in the area of wetland ecological security assessment have done a lot of work. The study on Guizhou Liupan-shui Ming-Lake National Wetland Park indicated that the parks' connection degree of pressure and response is 0.9315 and 0.6529 respectively, which is unsafe stage. Connection degree of condition elements, a relatively safe stage. Its comprehensive ecological safety connection degree is 0.6726, within the unsafe level (Qin Qu etc., 2014). The study on Zhejiang Leqingwan Wetland showed that 9.66% of the wetland in Leqingwan was at risk, 7.14% being unhealthy, 46.54% being sub-healthy, 27.08% being safe and only 9.58% being healthy. According to the maximum membership principle, the wetland in Leqingwan area could be defined as a specialty (Songguoli etc. 2011). Another study was on China's current highest-elevation paludification meadows wetland—the Dabao Mountain Wetland in Yunnan Province. It shows that at current the ecological security assessment of Dabao Mountain Wetland is in an ordinary, with most of ecological

function not exerted. However, some particular ecological pressure indexes have exceeded the bearing capacity of the ecosystem (Gao Xingguo etc. 2013). More over, a study on wetlands of different phases in tumen river basin of Jilin province indicates that in 1976 and 1990 the value of ecological security was 0.650 and 0.620 respectively, which suggested that the wetland ecosystem was in a safe condition. While in 2000 and 2010 the value was 0.536 and 0.454, which implied that the ecosystem has been an alerting states, that certain arrangements should be made to protect it (Zhu Hongwei etc., 2014).

### 3 MODELS AND SYSTEMS OF ECOLOGICAL SECURITY ASSESSMENT OF URBAN GREEN SPACE

#### 3.1 *The assessment models*

Among the core of the research on urban green space ecological security are the indicator system, evaluation methodology and the evaluation standard (safety criterion). The establishment of the conceptual model could clearly illustrate the relationship between social activities, economic development and ecological process. Therefore the method structuring indicator system through conceptual model is widely applied (Wei Bing etc., 2009).

It is best to first retype the first words manually and then to paste the correct text behind. When the new file contains all the text, the old tags in the text should be replaced by the new Balkema tags (see section 3). Before doing this apply automatic formatting (AutoFormat in Format menu).

##### 3.1.1 *The P-S-R model*

The P-S-R Model is named for the Pressure-State-Response (Allen et al., 1996 Tong, 2000; Wolfslehner et al., 2008) model raised by the United Nations agency for economic cooperation development and the OECD. This model reflects the interactive relationship between human and environment. In this model one particular type of issue can be described by three indicators that are in different but interrelated types.: Pressure refers to the load caused by human activities to the system; the State refers to characterization of environmental quality, natural resources and the status of the ecosystem; the Response refers to humans' corresponding measures when facing humanity environmental problem. This model is widely applied in the ecological security assessment at home and abroad. The R-S-P model has clearer cause-and-effect relationship than other models, that it classifies environmental indicators starting from the interaction of human and environmental systems. Thus having strong systemic

and maneuverability. However, this model singularly regards human activities as pressure without considering natural pressure, resulting from the lack of natural indicators (Liu Zhancai, 2008).

##### 3.1.2 *The D-S-R model*

The D-S-R Model refers to the Driving Force-State-Response Model raised by the UN Department for Policy Coordination and Sustainable Development (DPCSD, 1996). The Driving Force is describing the natural disasters and human activities to ecological system pressure; The State refers to the ecosystem's structure and function, also the reflection that natural ecosystems provides services and resources to human; The Response indicates the operating capability to deal with the ecological environment problem and maintenance/improve the ecosystems' security status.

##### 3.1.3 *The D-P-S-I-R model*

The European Environment Committee combined and improved the former two models, then came up with the Driving Forces-Pressure-State-Influence-Response Model (Smeets et al., 1999; Spangenberg et al., 2009). In another word, it insert into the former P-S-P model with the D (Driving Forces), which describes human economic activities and natural disasters, and the I (influence), which illustrate the impact on human or ecosystem by the change of state. The D-P-S-I-R model can remedy the limitation of the P-S-P model and interpret clear logical relations while offering solutions, as a result preferred by many scholars.

##### 3.1.4 *Other models*

Based on the study on the cons and pros of all the above models, Corvalan and fellows further developed the DPSIR model and raised the Driving Force-Pressure-State-Exposure-Effect-Answer DPSEEA model Waheed et al., 2009. This model introduced the Effect-Answer indicators from risk evaluation and regard pollution exposure as a independent part, emphasizing its pressure on the ecosystem (Zuo An, 2004). Zhang Zhiguang (2013) proposed FES-PSIR model. His model is based on the symbiosis of Ecology and industry, structurally analyzing the compounding system which ecological security (FES) concerns. It also contrastively analyzes the studies on P-S-R, D-S-R, D-P-S-I-R models by domestic and international scholars. Specific to the ecological security issue of urban green space, it establishes the Pressure-State-Influence-Response model.

#### 3.2 *Indicator systems*

The indicator system of ecological security assessment of urban green space requires for

comprehensive evaluation on related issues through multi-layer indicator system, whose contents involve ecological, economic and social factors comprehensively reflecting the compound system of society-economy-ecology. The system usually consists of 3 layers which are the target layer, criterion layer and indicator layer. The target level reflects the comprehensive ecological security situation; the criterion layer is composed of the main factors of ecological security which can be further divided; The indicator layer is on the most basic level of the system which is made up of measurable indicators. The specific measures have clear ecological economic significance there for they are convenient for analyzing the cause of ecological security problems. However, in order to get the synthesizing value, the method mentioned above need the nondimensionalization action to each index, which may result that the synthesized value lost its ecological economic significance and becoming difficult to understand and use. Never the less, when it comes to setting the index weight, the above method suffers the problem of being subjective.

Zhang Zhi-guang (2013) developed the FES-PSIR structured model which is made up of the social and economic pressures (FES-P) subsystem, resources and environment condition (FES-s) subsystem, ecological impact (FES-I) subsystem and human response (FES-R) subsystem. Social and economic pressures (FES-P) subsystem contains the development of social economy and forestry industry demands for forest resources and the ecological environment destruction and so on pressure; Resources and environment condition (FES-s) subsystem, include forest resources, quality, coverage, distribution, type, structure, and the concentration of greenhouse gases, and other state; Ecological impact (FES-I) subsystem, including forest ecosystem health and vitality, ecosystem productivity, ten-fold increase forest, the forest disasters incidence, biological diversity, soil erosion, air quality, climate warming effect; Human response (FES-R) subsystem, improve the ecological status of human input, artificial afforestation, industrial circular economy, science and technology support, integration, legal policy guarantee, ecological civilization consciousness, crisis response mechanism response. Wang Chaohui (2012) type of mountain forest park, population pressure, ecological safety evaluation and study of land and resources pressure, pressure natural disasters, the quality of environmental factors, ecological factors, quality of science and technology input, intellectual support and legal support, community involvement, and visitors safety as the main factors of ecological security, 21 indicators to determine type of mountain forest park, ecological security evaluation index system, including visitor reception, local

residents growth strength, strength, construction land use intensity, water supply and demand balance, forest fire prevention and control, forest diseases and insect pests prevention and control, meteorology, the prevention and control of geological disasters such as, atmospheric environmental quality, surface water environment quality and acoustic environment quality, soil environment quality, plant protection, the protection of animals, landscape resources protection, exhaust gas treatment strength, the strength of wastewater treatment, waste management strength, the perfect degree of the education system, the perfect degree of the legal guarantee system, and community economic development and the management level and visitors safety protection, etc. On the basis of wetland edge soils, plants, aquatic plants and water quality of four features a total of 13 indicators, Spencer (1998) conducted the assessment for the health status of the Murray Darling basin in the southeast Australia permanent floodplain wetland. While Zhao Zhenhe (2005) assessed the health of lake wetland ecosystem, choosing lake ecological structure index (including the biomass of phytoplankton, zooplankton, and the ratio of the two) and lake ecosystem indicators (including quality and structure can quality) as evaluation index.

#### 4 ECOLOGICAL SECURITY OF BEIJING URBAN GREEN SPACE TEXT AND INDENTING

Urban green space is the main part of the regional ecological civilization construction, but also the important guarantee of regional ecological security. Under the background of serious deterioration of Beijing's ecological environment as well as great development of urban ecological civilization, it has been more and more significant to study and conduct urban green space ecological security assessment.

##### 4.1 *Development opportunities of Beijing urban green space for ecological security*

Rapid urbanization and expansion resulted worsening ecological environment in cities, along with the "city disease" such as severe air pollution and water shortages. In his three time's visit of Beijing, our General Secretary emphasized on the strategic positioning to a foothold in the capital city Beijing, accelerate the construction of ecological environment construction, the international first-class harmony and livable city. The "twelfth five-year" is a crucial period for Beijing to develop into a globally recognized livable city. The impression of urban forest is important city, is an important symbol of degree reflect the livable city, and expand the city

livable space, and promote social harmony and stability, enhance people happiness is important carrier and rely on, so the construction of urban forest is Beijing livable environment construction, urban and rural ecological network construction of main job.

Urban forest is capable of dust noise reduction, reduce the concentration of PM<sub>2.5</sub>, emissions increase sinks, conserving soil and water, water conservation, reason fully functional and structural stability directly affect the Beijing urban ecological security. Build reasonable planning and complete functions and benefits of urban forest ecosystem, to ensure ecological security in the capital, improve the ecological environment of the city and meet the demand of residents ecological, world urban construction with Chinese characteristics, the construction of “humanistic Beijing, science and technology Beijing, green Beijing” has important strategic significance. In 2009 Beijing seventh landscaping resources census results show that the city forest area of 658900 hectares, including plain area in the city forest area of 14.41 hectares, the forest coverage of 14.85%. Plain area of forest land accounts for only 15.8% of the city’s forest area. Forest area accounted for 87.14% of forest land area in the plain area. By 2010, the total area of 1.047 million hectares of forest land in the city, 63.8% of the total land area, the forest coverage rate was 37%, 53% green area of forest, mountainous forest, trees afforestation rate reached 50.97%, 71.35% respectively. “Beijing 2013–2017 clean air action plan is put forward, to strengthen the construction of afforestation and beautify, increase forest resources, improve the quality of forest construction, in the plain area, after the end of 2016 millions of acres of afforestation project, by 2017, the city green greening rate of more than 60%. A few days ago, Beijing one million mu of plain afforestation task has been completed ahead of schedule, puts forward nine project of Beijing gardens green bureau points out that in 2020 years ago, the land use is given priority to with horticulture in Beijing, to add 380000 mu of plain afforestation, 100000 mu of high efficient orchard construction, renovation, 100000 mu of inefficient orchard. Beijing, therefore, the existing total forest and gradually perfect the forest network construction for the development of Beijing urban green land ecological security provides a new opportunity and challenge.

#### 4.2 *Strategy of Beijing urban green space ecological security assessment*

##### 4.2.1 *Choose reasonable method for the urban green space ecological security assessment*

Urban green land ecological security assessment makes more use of ecological security evaluation method or its improved version. At present the

study of urban green land ecological security evaluation method is still in its infancy. Beijing urban green land ecological security evaluation methods should be considered the particularity of Beijing urban environment, the characteristics of Beijing forest layout, the structure and function of urban forest in Beijing and Beijing composite factors such as social and economic development needs, choose the suitable Beijing urban green land ecological security evaluation method.

##### 4.2.2 *Construct scientific system for the urban green space ecological security assessment*

The establishment of sustainable management of Beijing urban green land ecological security evaluation system will involve a lot of natural elements such as vegetation, soil, hydrology, and also including forest structure, function such as ecological indicators, as well as social, economic, human pressure, and many other factors. Therefore in the process of the construction of evaluation system should be selected as little as possible, easy to control and operation of indicators to reflect the characteristics of Beijing urban green space ecology system, in order to increase urban green land ecological safety observation index of practicability, avoid too much evaluation index will make the ecological security problem is more complicated, or incomplete information index, the evaluation index system covering the phenomenon of overlap between information or indicators, in order to increase the difficulty of the actual evaluation work.

##### 4.2.3 *Conduct objective and accurate assessment for urban green space ecological security*

The ultimate goal of urban green land ecological security research is the guarantee of urban green land ecological security, maintenance and management research, urban green land ecological security evaluation, prediction and early warning research, is to establish a comprehensive security system, formulate scientific and reasonable ecological security maintenance and management measures, action, and lay the foundation and basis by the relevant laws and regulations. Therefore, should be objective and accurate in Beijing urban green land ecological security evaluation.

## 5 CONCLUSION

As environmental pollution and ecological environment have seriously affected and threatened human survival and social development, ecological environment issues has risen to ecological security issues. Ecological security is the guarantee of the ecological—economic—social system and sustainable development. Ecological security assessment is

of great significance for regional urban green space system. For urban green space ecological security assessment, the main challenge is how to combine various characteristics of the urban environment to build the evaluation index system. There for, ecological security assessment of Beijing urban green space should be combined with the demand of city development and functional needs, should choose the urban green land ecological security evaluation method, should build urban green land ecological security evaluation system on scientific approaches, should conduct accurate and convenient evaluation. It should also provide the basis for the establishment, maintenance and management of the system, as well as related laws and regulations.

## Study on types of rural landscape

Yuan Liu

*The school of Landscape Architecture, Beijing University of Agriculture, Beijing, China*  
*Beijing Rural Landscape Planning and Design Engineering Technology Center, Beijing, China*  
*Beijing Laboratory of Urban and Rural Ecological Environment, Beijing, China*

**ABSTRACT:** Rural landscape is different from urban landscape. The purposes of studying on types of rural landscape are to strengthen types of landscape with rural characteristics and highlight unique style of rural landscape in the planning designs of rural landscape in the future. Types of rural landscape can be classified into natural landscape and human landscape, which include material and immaterial attribute, and not one of them can be dispensed with. Starting with material and immaterial attribute, the article makes a further classification.

**Keywords:** rural landscape; material attribute; immaterial attribute; nature; humanity

### 1 SUMMARY OF RURAL LANDSCAPE

#### 1.1 *Landscape*

In China, the word “landscape” is not a vocabulary and concept that has existed from time immemorial. It is a newly rising field in twentieth century, and its concept meaning is different from the Chinese traditional garden and landscape architecture. Landscape is more of a visual vocabulary, which refers to people’s feeling toward the environment’s external characteristics. As a concept in the sense of visual aesthetics, “landscape” is similar to the word “scenery” (Fengjing) and “view” (Jingzhi) in Chinese. From the perspective of subjects, it has more applications and correlations in and with geography, ecology, architecture, etc. In geography, as a scientific terminology, landscape refers to terrain scene within one geographic unit. In ecology, landscape is an ecological system and ecological resource. In architecture, landscape is a design consideration and scenery type.

#### 1.2 *Rural landscape*

The concept “rural landscape” derives from the concept “landscape.” Based on landscape, rural landscape places restriction to the region. It is a type of landscape that taking the countryside as its study objects. With the development of China, people begin to recognize landscape with new requirements, and are in the hope of improving their living environments. More and more people

are involved in the studying and constructing of urban landscapes, hoping to establish perfect homelands. However, in fact, China is a large agricultural country. Agriculture is always the root of the people’s livelihood, since ancient times and farmers are major productive forces in China. Agricultural lands make up the largest portion of the land-use type in China. From the development point of view, agriculture is the root of China’s development. With respect to the industry of landscape planning designs, the key is the development of urban landscapes and the basis is the development of rural landscapes. China put forward the strategy of new rural development, and formulates guidelines of industry re-feeding agriculture, city supporting village and giving more taking less and loosening control, and clarifies the fundamental requirements of simultaneously carrying out modernization of agriculture in the process of developing in-depth industrialization and urbanization, and quickens formation of new pattern of urban-rural integration, which all in all provide with new development and research thoughts for the industry of landscape planning designs.

Rural landscape is a type of regional landscape. However, the defining of region is becoming more and more difficult with the continuous developing in depth of city and countryside integration. For the present, a relatively common approach is to define urban and rural region from the local administrative domination area and land usage. To differ urban from rural region from landscape viewpoint, the differences among types of landscape can basically be made from visual points, which are possibly fixed feelings toward the differences between city and countryside in people’s mind. For example,

---

Foundation item: Beijing Higher Education Young Elite Teacher Project (YETP1719)

one can distinguish one place as city or countryside at a glance from its environment. Now, such distinguishing is becoming more and more difficult due to the continuous integration between city and countryside, and thus, the differences of landscapes between them have narrowed gradually. People in cities have constantly explored methods of naturalization, and in countryside have gradually changed life-style with human landscapes being more and more urbanized. The purposes of studying on types of rural landscape are to strengthen types of landscape with rural characteristics and highlight unique style of rural landscape in the planning designs of rural landscape in the future.

## 2 OVERALL CLASSIFICATION OF RURAL LANDSCAPE

Different subjects have different emphasizes toward rural landscape. Aesthetically, rural landscape conveys pure, clean and rural natural scenery, and unsophisticated cultural customs. Geographically, rural landscape is different from urban landscape from the regional attribute. Ecologically, rural landscape has more abundant natural qualities and biological diversities. I think that those points of view emphasize particularly on the natural qualities of rural landscape. In fact, besides natural scenery, characteristic historic cultures, folk traditions, and folk customs also make up unique style of rural landscape. They cover a wide range of contents, and it is necessary to categorize them, which establish the foundation to certain extent for the planning designs of rural landscape.

### 2.1 Principles of classification

While study on classification of countryside is made, both variety and uniqueness of rural landscapes should be taken into consideration, based on which principles as below should also be mainly considered:

#### 1. Integral principle

Integrity, but not certain individual condition, should be taken into comprehensive consideration in classifying types of rural landscape. For instance, the influences of many factors such as climate, soil, landform, vegetation, hydrology, human activities, etc. toward rural landscapes should be comprehensively considered. Natural and human factors are especially not to be neglected. The classification of rural landscape would be incomplete without taking integral principle into consideration.

#### 2. Characteristic principle

Among the overall factors, each factor has different functions in different landscape types of

different levels. In certain sub classification, the dominant factor that affects the formation transformation of rural landscape should be highlighted and the essence of problem should be taken so as to scientifically and effectively make more precise classification toward rural landscape.

#### 3. Scale principle

In the overall classification of rural landscape, not only the contents should be solved, but also classifying scale should be considered. In fact, it has much relativity with the concept of rural landscape. Due to the lack of unified definition concerning the concept of rural landscape as yet at home and abroad, scholars have different understandings toward it, and thus, there is no unified standard for the scale of landscape studies. Basically, the study of concept of rural landscape determines the grasp of landscape scale. The article simply defines the concept of rural landscape as: the region that outside the urban built-up area with abundant natural and human attributes. Based on the concept, the overall classification of rural landscape is a region type classification of large scale.

#### 4. Level principle

Gradually, progressive level principle of classification should be noticed when region type classification of large scale is made. Scale should be gradually reduced and classification of large scale should be refined to divide types of small scale, so as rich and varied types of rural landscape can be reflected comprehensively and in detail.

### 2.2 Overall classification of rural landscape

In the classification of large scale, rural landscape can generally be classified into natural landscape and human landscape (see Table 1). Natural landscape refers to true type of landscape formed by original material ecology in the nature, which has been affected and reformed by humankind only to a small extent. Human landscape refers to the landscape with regional characteristics in the countryside,

Table 1. Overall classification of rural landscape.

Number	Overall classification of rural landscape	Examples
1	Natural landscape	Such as: woodland, grassland, water area, farmland, etc.
2	Human landscape	Such as: folk traditions and folk customs, religion, garden, architecture and music, etc.

which has been affected and reformed by humankind to a relatively large extent, and based on humanistic background, human landscape has certain atmospheres such as culture, tradition, history, living habit, appreciation of the beauty (includes religious faith), etc. From the meaning of the word "human" we can make out that: (1) the principal part of human landscape is human's creative thought and subjectively transformative capacity; (2) landscape perception created from human's wisdom has historical and cultural attributes, and in contrast to the nature, it has a higher spiritual and cultural meaning.

With respect to the visibility of landscape, overall rural landscape can be classified into material and immaterial attribute. In general division of landscape types, visibility is always taken as standard of division of landscape, and immaterial attributes influencing characteristics of landscape are often neglected. In human landscape, more immaterial attributes are especially included, in which new meanings are given to the human landscape from human's wisdoms and creations. Therefore, the superposition of nature and human landscape with material and immaterial attribute in general classification is stated as in the Figure 1.

Figure 1. Classification and attribute division of rural landscape.

### 3 CLASSIFICATION OF MATERIAL ATTRIBUTE

#### 3.1 Standard of classification

Taking China's current land use classification (PRC National Standard GB/T21010-2007) as the standard of classification, rural landscape can be further classified into natural landscape, semi-natural landscape, and artificial landscape. In accordance with the standard, with generalizing and improving the classification, the article proposes classification of material attribute concerning rural landscape in Table 2 as below.

#### 3.2 Classification declaration

In the classification of material attribute, natural landscape mainly includes types of landscape in rural region naturally formed such as natural woodland landscape, natural grassland landscape, etc. In semi-natural landscape, artificial woodland landscape, artificial grassland landscape, and artificial water area landscape are the major three landscapes that should be necessarily explained. Though being artificially built, but they are similar to natural landscape so as to be called semi-natural landscape, but not artificial landscape. So are farmland, orchard, tea garden, etc. Semi-natural landscape both has landscape of natural scenery and human landscape. Artificial landscape mainly includes types of landscape influencing human's life to a relatively large

Table 2. Classification of material attribute concerning rural landscape.

Number	Classification of material attribute	Concrete contents
1	Natural landscape	Natural woodland landscape, natural grassland landscape, natural water area landscape, natural mudflat landscape, glacier and snow cover landscape, saline-alkali soil landscape, wetland landscape, sand, bare land, etc.
2	Semi-natural landscape	Artificial woodland landscape, farmland landscape, garden landscape, artificial grassland landscape, artificial water area landscape, etc.
3	Artificial landscape	Settlement landscape, road landscape, engineering facilities landscape, etc.

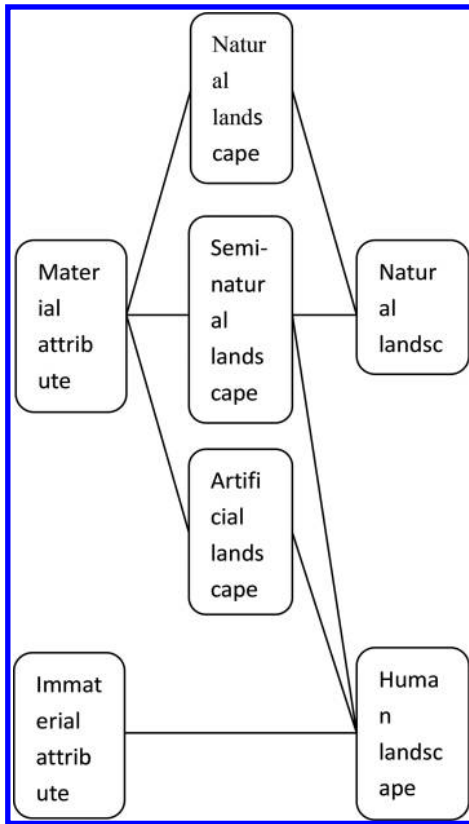

Figure 2. Correlations between each type of rural landscape.

extent, such as rural settlement, road landscape, engineering facilities landscape, etc. The overall classification of natural and human landscape stated in the last section can be seen in Figure 2.

#### 4 CLASSIFICATION OF IMMATERIAL ATTRIBUTE

Immaterial attribute is quite different from material attribute. It refers to the immaterial attribute of cultural and artistic value. It has implicit characteristics of landscape with various forms.

Combined with Chinese cultural characteristics, it includes folk literatures, folk customs, traditional medicines, traditional manual skills, folk arts, acrobatics and athletics, Chinese folk art forms, traditional dramas, folk dances, folk music, etc.

Immaterial cultural landscape is of an indispensable part in rural landscape, which is the display and inheritance of rural historical and cultural characteristics. Its various cultural expressions bring about meanings and features to rural landscapes. It is also an important part that should be necessarily noticed in planning designs of landscape.

#### 5 CONCLUSION

The article has made an explanation toward classification methods and types of rural landscape, and finally reached to some basic classification systems. Diversity and uniqueness of rural landscapes are determined by region. More detailed summarizations and analyses of types of rural landscape would be made in accordance with different regions in the future.

**ABSTRACT:** With the intensification of the building energy consumption problem and the general sub-health status that the current working group faces, create a low-carbon, efficient and livable working space has become the development goals of the green office buildings. Green technologies as the important way to achieve this goal, how to optimize the integration of active and passive technologies combine with the regional climate characteristics to seek the best balance between the energy use and environmental quality becomes the key point for green office building design. This paper takes the management committee office building in a scenic area of Wuhan city as an example, made a comprehensive analysis of its design objectives, design principles and the specific green design strategies, and in order to provide some useful reference for the future of green building design, in view of the current green building development, puts forward some relevant suggestions from the aspects of architectural design strategy formulation and green technology selection around the essence of green building design.

**Keywords:** numerical model; office building; green design

## 1 INTRODUCTION

As an important place in people's daily work activities, the functional attributes which office building carries should not only provide the necessary space itself, but also to meet the spiritual needs of the office staff. With the intensification of the building energy consumption problem and the general sub-health status that the current working group faces, creates a low-carbon, efficient, and livable working space has become the development goals of the green office buildings. Green technologies as the important way to achieve this goal, how to optimize the integration of active and passive technologies combine with the regional climate characteristics to seek the best balance between the energy use and environmental quality becomes the key point for green office building design.

The main principles that the green office building design should follow include:

### 1. Adjust Measures to Local Conditions

Create a native, low carbon green high quality construction and has the era characteristics that according to the climatic conditions, regional characteristics, resource conditions where the

project locates, eliminate the negative impact brought by the "portability Copy."

### 2. Passive Priority and Active Optimization

Building design should first pay attention to the design itself, allow natural acting by using the rational design means to optimize the layout of the building, interior space and detail design, and give priority to use the passive technology of natural ventilation, natural lighting, high insulation external retaining system, and vertical greening to reduce energy consumption. Then, consider using active technologies as supplement to improve efficiency.

### 3. Optimizing Integration with Ultra Technologies

Avoid focusing on the technology itself, but focus on the suitability, interoperability, economic rationality, and energy efficiency of the technologies when making the choice of technology strategies.

## 2 MATERIALS AND METHODS

The office building located within a well-known scenic spot in Wuhan City, the planned total land area is 10438 m<sup>2</sup>, with a total construction area

of 5760 m<sup>2</sup>. This project site has a very beautiful landscape environment. Its base surface is close to the mountains in the north, Liangzi Lake in the south, and region development plot in the east and west. Based on the need of this study, this paper select the main building orientation and distribution, outside micro-climate, natural lighting, and natural ventilation as the four elements, by use the computer simulation software of Phoenics and Ecotect to make analysis and comparison between the multiple design scenarios, and then take optimize and adjust measures according to the simulation results to get the most ideal design scenario.

According to the Evaluation Standard for Green Office Building, these four elements corresponding to the entry requirements were:

1. Building orientation and distribution  
Wind speed of the pedestrian area around the building at the 1.5 m height should be less than 5 m/s, the site should not appear vortex and dead space, Wind velocity amplification coefficient should be less than 2.
2. Outdoor environment  
Landscape design should choose a suitable local climatic and soil conditions of local, using a complex layer containing shrubs, grasses. etc, and the planting area should have sufficient overburden depth and good drainage.
3. Natural Lighting  
More than 75% of the main function space's daylight factor to meet the requirements of "Standard for Daylighting Design of Building" GB/T 50033-2013.
4. Natural Ventilation  
Architectural design and structural design should have induced flow measures to promote natural ventilation.

### 3 RESULTS AND DISCUSSION

#### 3.1 Building orientation and distribution

Good natural ventilation and sunlight effect are the factors that should be considered in the phase of planning and construction layout. In consideration of there has no affectable surrounding buildings, only take the natural ventilation as the primary factor in this project planning and building layout considerations.

Northeast wind direction perennial dominant wind direction of Wuhan, according to this feature, in order to reduce the impact of cold air infiltration in winter, and get a better natural ventilation effect in summer, the building layout finally select the toward that close to the south. Since the building height and space changes in the organizational relationship will bring a different effect of

indoor and outdoor ventilation, using simulation software of Phoenics to make analysis and comparison between the multiple programs, and take a corresponding adjustment according to the simulation results.

In the optimized layout pattern, the maximum wind speed around the building is less than 5 m/s in both the summer and winter, wind speed amplification factor is less than 2, the wind pressure between the windward and leeward side o is greater than 1.5 Pa, and the site around the construction site has no swirl and dead ends (Figs. 1–4), the overall natural ventilation condition is good, and meet the comfort requirements of pedestrian.

#### 3.2 Outdoor environment

There has an outward Green Square in the south of the main entrance area of the office building, and

Figure 1. Outdoor pressure contours in summer.

Figure 2. Outdoor wind velocity contours in summer.

Figure 3. Outdoor pressure contours in winter.

Figure 4. Outdoor wind velocity contours in winter.

with the combination of the space which enclosed by the building body design an inward-looking garden in the north, thereby forming a north-south landscape visual corridor through the building, at the same time, set up a sunken garden green space by using of terrain elevation in the west of the site, thus makes the most functional space have good visual accessibility combined with the design of glass walls and French window design.

In addition to the function of beautify, the more important function of outdoor environment is to improve the micro-climate of the office building. For this reason, the project pays special attention to greening in the aspect of outdoor environment creation. And using the simulation software of Ecotect to simulate the photosynthetic effective

Figure 5. Photosynthetic effective radiation analysis.

radiation of the field around the building prior to the landscape design, which provide the basis for plant configuration. According to the simulation results (Fig. 5), combine with the habits of plants, in the area where the solar radiation is less than 3 MJ/m<sup>2</sup>d planted hi shade plants, in the area where the solar radiation is between the 3 MJ/m<sup>2</sup>d and 6 MJ/m<sup>2</sup>d planted neutral plants, and in the area that larger than 6 MJ/m<sup>2</sup>d planted heliophilous plants. And through the multi-layer green means, by planting local native trees and shrubs to reduce the noise, block cold wind in winter, adjust the solar radiation according to the season change. in addition, by setting the landscape pool, sunken lawn forming organisms climate buffer zone, thus to play the role of water conservation, and regulating outdoor air temperature and humidity.

### 3.3 Natural lighting

Compared with other public buildings, the service time of office buildings is mainly in the daytime, each room of the office has designed the glazed facades to reduce lighting energy consumption. In the south side space of the office blocks, the interior design carries forward the open architecture features, emphasizes open space and clarity skillfully, the continuous glass facade not only can make the interior office staff enjoy the full sun, but also Join together the indoor and outdoor environments effectively, creating a pleasant work environment; In the multi-purpose hall block, through setting an inner courtyard to introduce external light and air into the reception lounge space.

For larger spaces, such as employee dining area, just rely on the limited one-sided lighting cannot fully meet the indoor lighting demand, by extending outwardly 1.5 meters wide of the second floor flat with the stainless steel bottom pane to let outside natural light enter into deeper indoor space throughout reflecting, which greatly improves the effects of indoor lighting. Meanwhile, the overhanging floor settings also played a role in shade.

According to the natural lighting simulation results, interior lighting coefficient of 75% indoor space are above 3.0% (Tables 1–2; Figs. 6–7), meet the requirements of “Standard for daylighting design of building.”

### 3.4 Natural ventilation

Besides setting large windows that can be opened on the exterior walls, the office building also design an inner courtyard to increase natural ventilation. In the layout stage, by using the simulation software of Phoenics to analyze the indoor natural ventilation effect, so as to provide the basis to develop the most reasonable design program.

The indoor air environment simulation results of summer shows that the indoor space has a good

natural ventilation effect: the wind speed is within 0.2–1.0 m/s range in most indoor areas, the indoor air pressure on both sides is more than 1.5 Pa, and the air age is relatively small (Fig. 8).

## 4 CONCLUSIONS

This study is a useful attempt to the design philosophy of “Optimize Passive and Priority Active” in the green office buildings, by the means of reasonable building orientation and distribution, efficient building envelope design and natural lighting, ventilation, etc, giving full play to the role of passive energy-saving. Meanwhile, use suitable active technologies as supplementary to achieve.

The goal of enhancing the practical performance, energy performance and environmental performance, its investment is not high, but it made a good effect, providing a reference t for future green building design.

In terms of design strategy formulation, nowadays, with the rapid development of green building and under the guidance of energy-saving policy, more and more designers are introducing green

concept in the office building design. However, due to lack the awareness of the essence of green building, there has been emerging some problems that one-sided pursuit of “high input, high-quality,” blindly take the expected energy savings effect in the use of green technology, while ignoring the phenomenon of architectural design itself, which resulting in economic investment of the buildings is much greater than the social and environmental effects it produces, and contrary to the original intention of green buildings. At the beginning green building design, should according to the actual situation of the site conditions and natural resources, excavating the energy-saving potential of architectural detail designs, so as to reduce building energy consumption from the source.

In terms of green technology selection, the key point is to focus on suitability, combine the actual situation of the project with the technology’s practicality and efficiency, avoiding piling up the technologies blindly, and selectively learn and use local traditional technology to achieve implementation technology of human ascension. In addition, the choice making of green technology should consider the economical efficiency, optimize and integrate the active and passive technologies to

improve environmental quality of buildings based on a reasonable cost.

# Research on rural greenway suitable for Beijing

L. Feng & X.Y. Ma

*School of Landscape Architecture, Beijing University of Agriculture, Beijing, China*  
*Beijing Rural Landscape Planning and Design Engineering Technology Center, Beijing, China*  
*Beijing Laboratory of Urban and Rural Ecological Environment, Beijing, China*

**ABSTRACT:** This article first defined Beijing's rural greenway areas, took two successful examples of the Baili Landscape Painting Gallery and the Shen tang yu Landscape Road to draw four main appropriate types of greenways for Beijing countryside, which are riverfront type greenway, valley type greenway, cultural heritage type greenway, and natural ecological type greenway. Then it gives more details on the characteristics of each type of greenway. The authors proposed valley type greenway initially.

**Keywords:** landscape architecture, rural greenway types, beijing, valley type greenway

## 1 INTRODUCTION

The concept of greenway originated in the 19th-century in America. The world's first park system, Boston Park System, was planned by Olmsted, and was the first greenway ever built in its true meaning in America. In the 1950s, the idea of greenway was more about theoretical research and practice. Today, the concept of greenway has developed into a more comprehensive meaning, the *E-way* (environmental way, ecological way, entertainment way, educational way, esthetic way, economic way, exit way, etc.). The *E-way* has various functions such as ecological protection, recreational, popular science education, aesthetic ethic experience, and safety evacuation. (Liu, 2012).

The greenway experienced few courses. It went from park system, to open space, and then to greenway. The study subject also changed, from city to city-and-town combined. (Flink, C.H. Searns, R.M., 1993) (Little, C.E., 1990).

When we see the greenway system of the Pearl River Delta, we know that greenway construction has been developing very quickly in China. (Sun, Pan, 2011) (He, etc., 2010) In 2013, Beijing Municipal Government Executive Council adopted the *Beijing Municipal Greenway Construction Overall Plan* to determine Beijing's municipal greenway, the "three-ring, three-wing, multi-gallery." The plan has an objective to construct 1000-km municipal

greenways within 5 years, connect more than 200 parks, scenic spots, and historical and cultural sites.

The present article divides the greenway into three parts based on different zones: municipal greenway, suburban greenway, and rural greenway. At present, Beijing's construction planning is concentrated in urban and suburban zones and form a chronic-system post. There are few researches on rural greenway. Yet, the rural zone of Beijing is not only the ecological zone of the city, but it also provides natural landscape to the whole city, as well as recreational opportunities and precious historical and cultural heritage. Therefore, conducting a research on rural greenway has a great and important value for the municipal greenway system. In his research about Beijing's suburban greenway, Qin (2014), based on the set-up of the greenway separation between Beijing five ring roads and six ring roads, defined the suburban zone as the zone between the five ring and the six ring. The present article took the above classification method to fix the scope of the research, determined as the zone outside Beijing six ring roads. The article cards about the Baili Landscape Painting Gallery and the Shentangyu Natural Scenic Area to put forward the main Beijing municipal greenways to give a general view on the future planning and construction of rural greenways.

## 2 GREENWAY-RELATED CONCEPTS

There are lots of definitions about greenway. Little defines "greenway" as a kind of linear open space, generally a natural corridor (such as rivers, valleys, and mountains) or a common roadway which has been converted into a recreational way (such as canal, water channel, scenic trail and abandoned

2. Beijing Laboratory of Urban and Rural Ecological Environment Project (PXM2015\_014207\_000014).

railway, etc.), or any natural and scenic roads for bicycle and pedestrian. (Little C.E., 1990) But Bertie Ahern is stressing out the comprehensiveness of greenway. He believes that greenway is a land network built through meticulous planning, design and management, and that this network has various functions including ecological, recreational, cultural, aesthetical, as well as many other functions. These functions can all be found in the land network.

The greenway proposed by Bertie Ahern includes 5 meanings: first, greenway has a linear contour; second, greenway must have connectivity; third, greenway has versatility; fourth, greenway has multiple functions; fifth, greenway must satisfy the requirements of the sustainable development, but most important, greenway planning is an important supplement of nonlinear landscape architecture greenway planning. Greenways connect the other non-linear landscape architecture system to form an integral body aiming to protect the landscape ecology. (Ahern J., 1995).

### 3 CASE STUDIES ON BEIJING RURAL GREENWAY

Although the concept of greenways has been heard from abroad only these recent years, Beijing rural zone has already few successful cases about roads complying with the greenway design concept. Let's take the Baili Landscape Painting Gallery of Yanqing and the Shentangyu Natural Scenic Area of Beijing as examples and give more details.

#### 3.1 *Baili landscape painting gallery*

The Beijing Yanqing Baili Landscape Painting Gallery is located in Qianjiadian Town, in the northeast of Yanqing County, and is the core zone of Yanqing Ecological Conservation Development Area. There are 56km main waterfront roads connecting 6 scenic spots, Guihuamuqun, Wulong Canyon, Dishuihu Scenic Area, Chaoyang Temple, Longwang Temple, and Guandi Temple, and numerous geological science and natural landscape such as Kunlun mountains, Shujian peak, marine deposits remains, Caimuguo aleolithic ruins, Wenchang monument, Datan natural reserve, Qianmiao Sunflower Sea, Wanmiao huangqin tea plantation, and Yanshan Painting Academy.

Thanks to the ecological resources, landscape and cultural resources of Baili Landscape Painting Gallery, since their integration, the tourism industry of Qianjiadian Town has boosted and increased the farmers' income. Plus, the recreational activities in the gallery are done in cycles, and the majority of accommodations are farmhouses. This system limits the over-exploitation and development of resorts and lands in the area. Therefore, not only the scenic spot provides to Beijing citizens

a tourism greenway rich in natural and cultural landscapes, but as a waterfront greenway, it also protects the habitat of wildlife, reduces the damages due to flood, and safe keeps water quality and groundwater level.

Having great cycling roadway, Bali Landscape Painting Gallery was named one of the "Ten Best Cycling Route of Beijing" in 2007.

The Bali Landscape Painting Gallery was not meant to be a greenway. But, the site possesses the 5 characteristics given by Ahern: has linear contour, connect many natural scenic spots and cultural landscapes, has various functions (tourism, recreation, education, and protection of historical heritage), contribute to the economic development of surrounding countryside, and satisfy the requirements of the sustainable development.

The waterfront ecological corridor links each part of the valley together to form an ecological network. Bali Landscape Painting Gallery awoke the local tourism resources and its construction is appropriate from the local geographical position point of view, forming a rural green land with strong local characteristic, a very successful rural greenway in Beijing.

#### 3.2 *Shentangyu natural scenic area*

The Shentangyu Natural Scenic Area is located in the Yanqi Valley in Buyegu. The total length from Buyegu Tourism Service Zone to the Shentangyu Natural Scenic Area is 7.558 km; it is Beijing's longest pedestrian plan road alongside cliffs with mountains and waters. The plank road and the roadway in the valley zone are parallel. The natural scenic area crosses fourteen sites, Chuangulanxiu, Taigongchuidiao, Linkongtingquan, Shanyedenghuai, etc., worth seeing, with mountain roads, appropriate for climbing. The place is just simple and natural, near mountains and waters. Shentangyu Natural Scenic Area is at the foot of a hill and beside a stream, a beautiful roadway for sightseeing, recreation, and fitness.

Shentangyu Natural Scenic Area adopts the following measures to reduce the contact between humans coming for recreation in the area and the wild animals living in the site: decrease the width of the greenway so to reduce the interference of wild animals; the greenway must keep distance with the river from vertical and horizontal levels to stay far away from wild animals' habitat; humans' sightseeing, education, experiential activities are all done from far away or from an observation space; reduce the environmental impact by using natural and impermeable materials.

### 4 BUILDING BEIJING RURAL GREENWAY PLANNING SYSTEM

Based on the specific ecological characteristics in Beijing and by combining Beijing's rural

topography, cultural characteristics and road network, the present article divides Beijing's rural greenways mainly into 4 types: riverfront type greenway, valley type greenway, cultural heritage type greenway, and natural ecological greenway.

#### 4.1 *Riverfront type greenway*

For many greenways, the most important landscape is the water landscape. The riverfront type greenway is the most important and the most used greenway. Main rivers in Beijing belong to the Hai River Drainage System, such as Yongding River, Chaobai River and Juma River, and to Ji River Drainage System such as Ju River. Most of the river basins are in the countryside, the source of water of Beijing city, and the lifeline of Beijing ecology and residents' life. The establishment of a waterfront type greenway has a very significant importance to the whole city of Beijing and to its ecological network. The ecological values of waterfront greenways are: provide ecological corridor to migratory species, use vegetation along the river to filter pollutants, reduce stream pollution, mitigate air pollution, regulate local climate. Since the waterfront greenways shall connect the city, the suburbs and the countryside, they run through the northwest of Beijing in the mountain areas, the city in the center and the southwest plain area to form an important ecological corridor. The greenways are the keys to connecting the city's ecological system with the forest ecosystem, garden ecosystem, and wetland eco-systems.

From the point of view of the importance of the ecological use of the waterfront greenways, the author thinks that the primary objective of Beijing's rural waterfront greenway must be ecological protection.

To protect wild animals, numbers of visitors in the site have been limited, and this is one of the important protective measure set. On the other hand, the design of greenway planning shall have close relation with river training work, ecological recovery, the city's drainage management. And when necessary, build a buffer at the appropriate point. The width of the greenway shall be determined based on the status of the area. As well, when needed, give all efforts to recover the natural vegetation, so that humans and cars stay far from the river edges. If there is really a need to approach the water, the plank road must be the first choice in order to avoid the complication of natural terrain and environment impact.

#### 4.2 *Valley type greenway*

Beijing has 7 counties in mountainous areas (Fangshan, Mentougou, Changping, Pingyong, Huaiyi, Miyun County, and Yanqing County), 83 villages and towns in mountainous and half-mountainous areas, a bit more than 1600 villages

committees, a total acreage of 1.04 km<sup>2</sup>, 62% of Beijing total area. Beside Wenyu River, the four drainage systems, the Daqing River, Yongding River, Chaobai River, and Liyun River all are in mountainous areas with large drainage area. The many stream tributaries form lots of valleys. In recent years, Beijing started to develop the valley economy. With valley economy as unit, Beijing began to build greenways to connect each industrial node together, develop the valley with the surrounding areas and plains, set a general plan for city and towns to promote and enrich the industry and provide more functions. (Chen etc., 2012) The boundaries of the valley are not administrative borders; they are mostly connecting most of the villages in the mountainous areas and coincide with main line of communications (Zhang, etc., 2009). At present, Beijing's valleys follow a model of economic development with Beijing mountains areas' local characteristics and a pattern of space network. Based on this pattern, the communication network within the valley economy and the surrounding lands are categorized into the rural greenways. All these contribute to the rational development and use of rural lands, to water protection, to recreational activities and also to increase the income from economic growth.

Since most of the valley greenways disperse the main river streams of Beijing city, valley greenways are mostly for ecological protection, and then for recreational and education of the people. Today, the development of valleys in Beijing has already benefit the city, significantly boosted the development of the rural economy. However, it has also led to some environmental problems. Taking Yebohai in Huairou as an example, it is located on reservoir of the upstream of Huairou river basin, one of the key valley constructions in Huairou district. Following the increase of the number of tourists, rainbow trout farms have been expanding. According to the Environmental Protection Administration test, these farms have already caused a certain degree of contamination on the water quality of the Huairou reservoir. (Shi, 2014) In the meantime, lots of resorts and hotels have been developed and entered the area, causing a great environmental burden. Thus, there is an urgent need to introduce more about the concept of greenways, strictly control the land development and limit the public recreational activities in the valley to protect the rural ecological environment. This has a great significance for the healthy development of Beijing.

#### 4.3 *Cultural heritage type greenway*

Beijing is a world famous historical and cultural city, one of the most ancient capitals. The city has large number cultural resources such as numerous cultural heritage protection units, historical and cultural route, and historical river drainage systems.

Rural greenways that connect historical and cultural heritage can form a green network for heritage protection and let people experience in real the memories of history and tradition, witness history and revisit ancient villages, buildings, ruins, tombs, modern building, historical, and cultural neighborhoods. Besides all, there are lots of historical and cultural routes in Beijing, such as Beijing-Hangzhou Grand Canal, the Royal Road of the Ming and Qing Dynasties, Jingxi Ancient Roads. They often connect with historical and cultural heritage points, have great value. They are important resources for the construction of Cultural Heritage-type Greenway.

#### 4.4 Natural ecological greenway

Beijing's natural ecological greenway is mostly landscape fragmentations due to road construction or mining work combined together and transformed into greenway, a space with greenery connected with wildlife habitats. Natural ecological greenway helps keep alive and healthy the diverse living beings in an area and reduce the facilities destroying the wildlife region within the area; it is a different kind of connecting network ecological corridor.

Beijing's natural ecological corridors are mainly along the western part of Taihang mountains and the northern side of Yanshan mountains, forming a linear space, building connections between natural reserves, forest parks and scenic areas, and provide migration corridors to living being. Simultaneously, implementing greening strategy contributes to reducing the uncertainty of the lands' situation and stopping the exploitation in the western mountainous areas, therefore would achieve the ecological protection, the safety of land and water quality and the survival of living beings in the area. (Wang, 2012).

This kind of natural ecological greenway mainly focuses on the requirements of biodiversity; therefore, the people in charge of the related planning shall have close relationship with wildlife experts to implement the related project. It is necessary to identify the wild animals within the area, the location of the habitats and the breeding-sites, as well as the animal tracks and migratory routes of the animals. The strategic points for wildlife conversation include knowing the animal tracks and migratory routes, the corridor interchanges, the intersection point of the animal biological corridor and the urban road, at least basic information related to the ground and the wildlife in the area. Then based on these key notes, arrange an ecological restoration, set up animal routes. (Yu, 2009).

## 5 CONCLUSION

The construction of rural greenways in Beijing must suit Beijing's geographical position, fully

respect the existing road network, forest network, water network, take into account ecology, landscape science, economy and other field techniques, and reflect multi-functionality and connectivity of the greenway. (Jack Ahern etc., 2011).

Greenways can help protect the countryside's environment since greenways protect natural ridges, rivers and nature, and human and cultural resources, therefore can project the countryside, prevent the countryside to rapidly become a city. Greenways are important supporting planning to protect farmland and open spaces. All the characteristics of greenways combined are protective measures. The whole system forms the rural greenway network, a significant key point for Beijing ecological safety.

**ABSTRACT:** The present study is concentrated on evaluating the climate adaptive capability of alkaline soil dwelling by means of comparing the thermal performances between alkaline soil dwelling and brick house. The analysis results show that, for alkaline soil dwelling, the values of thermal resistance  $R_0$ , thermal inertia index data  $D$ , reduction coefficient of thermal wave transferring  $V_0$ , and thermal transferring delaying time  $\xi_0$  are much bigger than current brick house. Therefore, regarding climate adaptive capability, traditional alkaline soil dwelling is much better than brick house.

**Keywords:** alkaline soil dwelling; thermal resistance; thermal inertia index data; reduction coefficient of thermal wave transferring; thermal transferring delaying time

## 1 INTRODUCTION

Alkaline soil is widely distributed in the western of northeast plain. In west Jilin province, alkaline soil are mainly distributed in the Baicheng, Tongyu, Daan, etc., that most of them are alkaline soil swamp without any plant growth. The local climate belongs semi-arid continental monsoon climate with long and cold winter and short and cool summer. The typical city of this area is Baicheng city with annual average temperature 5 °C, average annual

Figure 1. Average daily temperature change curves of Baicheng city.

Figure 2. Passive design strategy chart of Baicheng city.

rainfall 398.4 mm, annul sunshine 2919.4 hours and abundant solar energy resources. Average daily temperature change curves and passive design strategy of Baicheng city are shown in Figures 1 and 2.

In order to adapting alkaline land and harsh climate in northeast China, cultivation farmers created a unique residential—alkaline soil dwelling, which is made of local alkaline soil and based on the perspective of nature and aesthetic, adjusting measures to local conditions. There is sparse population in the

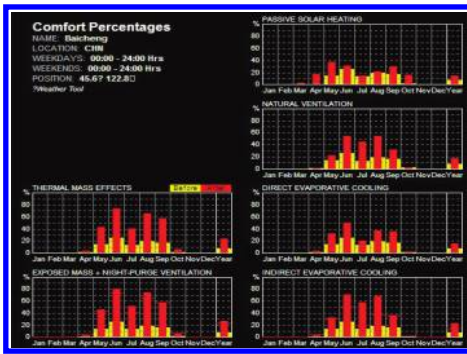

Figure 3. Effect of different passive designs strategies of Baicheng city.

Figure 4. Elevation, cross-section, and plan of typical alkaline soil dwelling.

Figure 5. Typical alkaline soil dwelling.

local area, so local people used to choose shadow embrace sunny area to build houses. Village layouts are usually opening matrix or spread-point distribution. Courtyard layout is usually opening and spacious. Local buildings possess some uniform features—small, compact, sunny exposure, and attached worm room. All of these measures reflect the typical climates adaptability and ecological characteristics. Elevation, cross-section, and plan of typical alkaline soil dwelling are shown in Figure 4 and typical alkaline soil dwelling is shown in Figure 5.

## 2 MATERIAL AND STRUCTURE OF ENVELOPE

Owing to severe natural environment of alkaline soil area such as scarce wood resources, sandy climate, and low temperatures, the envelope and roof of local buildings are usually structured by wood and enclosed by mixture of alkaline soil, sorghum stem, and Chinese wild rye. Alkali soil is grey, very fine particles, no sticky, no hygroscopicity, fine waterproof performance and cheap material. Grasses are widely used for wall, roof, kang mat, and shade curtains because of their properties of wide distribution, diversity species, good flexibility, local materials, and economy.

Rammed soil wall, also known as “cross wall”, is built by ramming alkaline soil incorporation of bits of cathayense. While constructing, well-mixed alkaline soil is filled in the timber formwork. Every 2 meters wall is regarded as one construction segment. Finally, 700 mm bottom width, 500 mm top width, and 600 mm thick wall has been finished. Adobe wall is made of adobe with 440 mm thick gable and 360 mm thick eaves wall. As adobe wall is difficult to avoid the gap space easy to leak wind, rammed soil wall has better thermal protection capability than adobe wall.

There are two types of roof for alkaline dwellings: flat roof and arch roof with slightly curve. Alkaline roof constructing approach is (Fig. 4): first, resting beams on the top of the wall or column and purlins on beams; second, paving 100 mm thick tile baling reed or sorghum stalk; third, paving 100 mm thick chinensis; fourth, and claying 200 mm thick strawed alkaline mud; and finally, compacting 30 mm thick alkaline mud 2 ~ 3 layers. This approach can extend the building life more than one hundred years, even if the beams damaged, roof still will not fall. Exterior wall and roof of typical alkaline soil dwelling are shown in Figure 6.

Figure 6. Exterior wall and roof of typical alkaline soil dwelling.

### 3 THERMAL PERFORMANCE ANALYSIS OF ENVELOPE

#### 3.1 Thermal performance analysis of exterior wall

Two types of exterior wall have been calculated: 600 mm thick rammed earth wall and 440 mm thick adobe wall. Thermal physical properties calculation results are shown in Tables 1 and 2.

Thermal physical properties calculation for two kinds of normal brick wall with 240 mm thick and 370 mm thick have also been carried out. Calculation results are shown in Tables 3 and 4.

Insulation performance: the thermal transfer resistance of rammed earth wall, adobe wall, 240 mm thick normal wall and 370 mm thick normal wall is 1.06 m<sup>2</sup>·K/W, 0.98 m<sup>2</sup>·K/W, 0.57 m<sup>2</sup>·K/W, 0.77 m<sup>2</sup>·K/W respectively. The external walls' thermal insulation performance of alkaline soil dwelling is much better than normal brick wall house. As a result, in winter, the external walls' of alkaline soil dwelling can more effectively reducing heat energy outflow.

Thermal inertia performance: the thermal inertia of rammed earth wall, adobe wall, 240 mm

$S_i$ (m <sup>2</sup> ·K/W)	10.75	8.49	10.75
$D_i$	0.247	4.908	0.247
$R_0$ (m <sup>2</sup> ·K/W)	0.77		
$\Sigma D$	5.40		
$V_0$	59.80		
$\xi_0$ (hour)	17.97		

thick normal wall and 370 mm thick normal wall is 7.86, 6.44, 3.68, 5.40 respectively. The results show that the external walls' of alkaline soil dwelling can more effectively reducing temperature fluctuations.

In summer daytime, the surface temperature of external walls rise by means of absorbing heat from outdoor environment. The peak surface temperature is reached at afternoon. Under the action of thermal inertia, heat storage performance and delay performance, the heat flux, heat flux amplitude and temperature amplitude will reduce greatly, so the peak value of inner surface temperature will be delayed to the early morning. At that time, cooling indoor conditions can be achieved by opening the doors and windows to increase ventilation.

In winter daytime, the external walls absorb and save a large amount of solar heat radiation. When the outside temperature plunge to the lowest at night, under the action of thermal inertia, heat storage performance and delay performance, the heat accumulated in external walls during the daytime radiation from outside can heat the indoor environment at night. Strong thermal inertia of alkaline soil dwelling can keep the wall

$R_0$ (m <sup>2</sup> ·K/W)	0.26		
$\Sigma D$	1.60		
$V_0$	4.10		
$\xi_0$ (hour)	8.34		

surface temperature at a higher level whole day in winter.

From the above analysis results, thick heavy envelope of alkaline soil dwelling can effectively reduce indoor outdoor heat transfer, and reduce the indoor temperature fluctuation.

### 3.2 Thermal characteristics analysis of roof

The roof of alkaline soil dwelling is consisted of 200 mm thick clay layer, 100 mm thick chinensis layer and 100 mm sorghum stalk layer. The roof configuration layers of brick house are 30 mm waterproof mortar, 100 mm RC slab, and 20 mm thick plaster. Calculation results are shown in Tables 5 and 6.

To the calculation results, for alkaline soil dwelling, the values of four thermal physical properties are significantly larger than brick house. Therefore, the roof of alkaline soil dwelling can also provide ideal thermal stability and thermal comfort.

In general, by means of its own thermal property of the soil, the thermal transmission speed for wall and roof of alkaline soil dwelling is very slow. As a result, this type of envelope

Table 7. Thermal property comparison of wall between alkaline soil dwelling and energy-saving code.

	Code	Alkaline soil dwellings	Brick house
$R_i$ (m <sup>2</sup> ·K/W)	2.5	4.32	0.26
Percentage	–	172%	10%

Table 8. Thermal property comparison of roof between alkaline soil dwelling and energy-saving code.

	Code	Alkaline soil dwellings	Brick house
$R_i$ (m <sup>2</sup> ·K/W)	1.67	1.06	0.57
Percentage	–	63%	34%

structure can easily adjust the temperature fluctuation and create a pleasant internal thermal environment.

## 4 THERMAL PROPERTY COMPARISON BETWEEN ALKALINE SOIL DWELLING AND ENERGY-SAVING CODE

The comparison results of thermal property between alkaline soil dwelling and energy-saving code are shown in Tables 7 and 8. The results shows that the thermal resistance of envelope of alkaline soil dwelling is very close to the demand of energy-saving code and is much better than brick house. Although thermal resistance of external wall still have to meet the code, it is also better than brick house. In the process of old residential renovation and new residential construction, improvement the thermal property of envelopes will greatly promote indoor comfort property, reduce the cost of renovation and reduce the waste of resource.

## 5 CONCLUSION

In the process of old residential renovation and new residential construction, masses of house in rural area mindlessly aping city building to build brick house. These brick houses look capacious and bright; therefore, their thermal properties are much worse than traditional alkaline soil dwelling. In present study, the climates adaptive capability of traditional alkaline soil dwelling has been evaluated. The comparisons to different thermal physical properties such as thermal resistance  $R_0$ , thermal inertia index data  $D$ , reduction coefficient of thermal wave transferring  $V_0$  and thermal transferring delaying time  $\xi_0$  have been performed between alkaline soil dwelling and brick house. Comparing result shows that the alkaline soil

dwelling has much better thermal properties than brick house. As a result, this type of residential house type can easily adjust the temperature difference and create a pleasant internal thermal environment.

School of Architecture, Xi'an University of Architecture and Technology, Xi'an, China

Qiwei Zhang

Construction Management Department, Shaanxi Xixian New Area Development Group, China

**ABSTRACT:** Based on architecture form, construction methods, structure selection, and material application research, this study is concentrated on evaluating the climate adaptive capability of Jilin Alkaline dwelling by means of statistics, calculation and comparison, and the computer simulation method. The analysis results show that Jilin Alkaline dwelling have good climate adaptability and ecological superiority characteristic, which is worth promoting.

**Keywords:** Jilin Alkaline dwelling; climate adaptation; shape coefficient; hybrid wall frame; fork wall

## 1 INTRODUCTION

The production of traditional houses are masses of working people in the long-term production and life practice, according to their own requirements, combining with local climate conditions, geographical environment, customs and habits, with wisdom and skills to create products. Various forms of traditional local-style dwelling houses everywhere reflect the harmony of man and nature, and give us a large number of valuable experience.

Alkali soil in the western of northeast China plain distribute wide, there into Jixi alkaline are

mainly distributed in west Baicheng and Tongyu, Jilin province. In the local, there is alkali swamp land without any plant growth. In order to adapt to the local alkaline land and harsh climate, local people created a unique northeast shape alkaline dwelling, a kind of civil house with soil wall and soil flat.

Baicheng, Tongyu, and Dan'an locate in the sub temperate zone with a sub-humid continental monsoon climate. There are long cold winter and short cool summer. Baicheng is located in the northwest of Jilin Province, altitude of 155.3 m. Average daily temperature change curves and Passive design strategy of Baicheng city are shown in Figure 1.

Figure 1. Average daily temperature change curves of Baicheng city.

## 2 CLIMATES ADAPTABILITY AND ECOLOGICAL CHARACTERISTICS OF ARCHITECTURAL FORM

### 2.1 Settlement location—shadow embrace sunny

West Jilin alkali soil area is sparsely populated area. Local people building used to choose shadow embrace sunny area to build houses. Experimental data show that, in the mountain area, the total temperature of sunny side is about 10 °C higher than shadow side due to more sunlight temperature which effectively improve the comprehensive outdoor temperature in winter and create more comfortable indoor thermal environment.

## 2.2 Village layout—opening matrix or spread-point distribution

In sparsely populated northeast area, local people choose open flat field to build independent building whereas forming matrix distribution in city and spread-point distribution in countryside. Both layouts can provide large spacing between each building that winter sunshine can maximum project on the window or outside wall without shade in order to meet the demands of directly winter heat gain for the building. Typical village layout is shown in Figure 2.

## 2.3 Courtyard layout—open and spacious

The courtyard of alkaline dwellings is unique spacious courtyard patten in northeast zone. In each building, foreyard is used for producing and living and backyard is used for food storage. Surrounding 1.5 meters high low alkaline walls are built around the building. Open up channels have been created between houses and walls for the convenience of food conveying; therefore, the separate form between houses and walls have been developed (Fig. 3).

The width-to-depth ratio of Binary compound space is 0.8 ~ 1.9 in northeast zone and 0.3 ~ 1.0 in Shaanxi province, thus courtyard scale is large more than warm temperate region. The reason is that in cold weather northeast zone, the use of open broad courtyard layout to avoid block building by each other, the south walls and windows can get more sunshine in winter, thus more winter sunlight and indoor heat gain be carried out. At the same time, computer CFD compound wind

Figure 2. Typical village layout.

Figure 3. Typical courtyard layout.

environment simulation results show that even the opening courtyard will not increase the winter air volume and wind speed.

## 2.4 Building shape features—small, compact, and sunny exposure

The statistical results of 9 representative farmhouse in the Qing Shan Bao Village, Baicheng, Jilin province show, room depth is about 5.46 m, width is about 3.02 m, clear height is about 2.37 m, building shape coefficient average is about 1.04, and window wall area ratio of south direction is about 18%. First, large depth and square layout of Alkaline dwellings can effectively reduce shape coefficient and surface heat dissipation area. Second, large south area can get more winter solar radiation heat gain. The calculation results show that, in alkaline dwellings, south interface absorption of sunlight heat radiant in winter is greater than its heat lost.

## 2.5 Plain layout—compact and attached warm room

Alkaline dwellings usually include three or five rooms. For example, in a three-room dwelling, the kitchen with tanks and stove is located at center of house. (Fig. 4). Heaven is around pass through chamber of fire resistance. The warm room, equipped with small heaven in order to warm cloths in winter is located at back part. Warm room isolated cold air from north wall and gateway together with stove in kitchen. Bed room is located on the right sides and left side of the main room. One straight heatable brick bed with flue directly going through outside is set up in each bed room. Elevation, cross-section and plan of typical alkaline soil dwelling are shown in Figure 3.

Figure 4. Elevation, cross-section and plan of typical alkaline soil dwelling.

### 3 CLIMATES ADAPTABILITY AND ECOLOGICAL CHARACTERISTICS OF ENVELOPE COMPONENTS

#### 3.1 Wall

There are two types of wall shape: rammed soil wall and adobe wall. Rammed soil wall, also known as “cross wall”, is built by ramming alkaline soil incorporation of bits of cathayense. While constructing, well-mixed alkaline soil is filled in the timber formwork. Every 2 meters wall is regarded as one construction segment. Finally, 700 mm bottom width, 500 mm top width, and 600 mm thick wall has been finished. Adobe wall is made of adobe with 440 mm thick gable and 360 mm thick eaves wall. As adobe wall is difficult to avoid the gap space easy to leak wind, rammed soil wall has better thermal protection capability than adobe wall.

#### 3.2 Roof

There are two types of roof for alkaline dwellings: flat roof and arch roof with slightly curve. Alkaline roof constructing approach is shown in Figure 4: first, resting beams on the top of the wall or column and purlins on beams; second, paving 100 mm thick tile baling reed or sorghum stalk; third, paving 100 mm thick chinensis; fourth, and claying 200 mm thick strawed alkaline mud; and finally, compacting 30 mm thick alkaline mud 2 ~ 3 layers. This approach can extend the building life by more than one hundred years, and even if the beams damaged, the roof will not fall.

Owing to its good thermal inertia property, envelope structure of alkaline dwellings possess slow heat absorption and dissipation characteristics, which can effectively reduce the heat transfer between indoor and outdoor, avoid indoor temperature fluctuation, and adjust the temperature difference between day and night naturally, so as to create a pleasant indoor thermal environment.

Figure 5. Alkaline soil wall.

Figure 6. Roof of alkaline soil dwelling.

Figure 7. Roof construction detail.

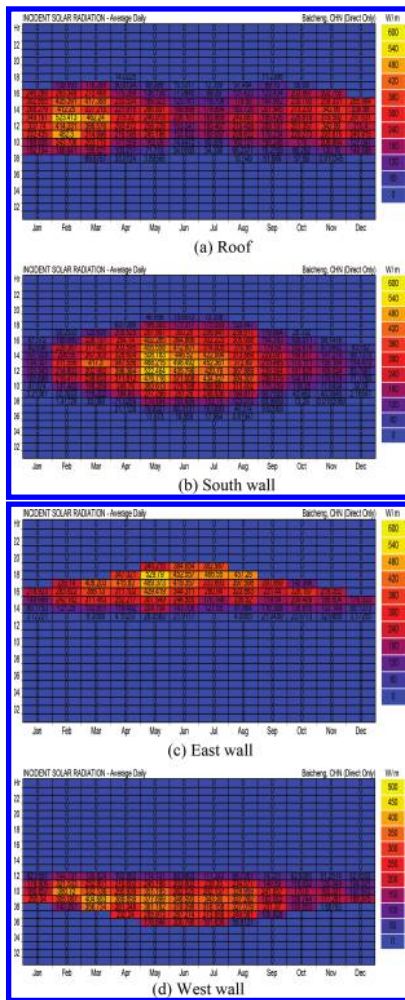

Figure 8. South wall surface of the sun direct radiation.

### 3.3 Window

There are removable window consisting of two fans on the north and south wall of back room. The upper fan can be lifted by the iron hook or with short stick for ventilation. The lower fan can be removed at any time. Outside of the window can be pasted with paper, such as most common Korea paper, a paper tubed oil, or brine-processed special paper in order to effectively prevent the rain and snow wet paper leading to the loss.

Considering the local climate differences, different demands of accepting and rejecting direct solar radiation, almost all traditional dwellings, use overhanging length of eaves to control window shadow. Calculation results of relationship between casting light depth and eave overhanging length are shown in Figure 9.

Figure 9. Incidence sunshine analysis.

South eaves are over hanged at 420 mm. The incident angle of the sunlight is low in winter, so the sunlight can completely enter indoor at noon (home invasion depth of 5082.16 mm). The incident angle of the sunlight is high in the summer; the sunlight can only enter on windowsill at noon (home invasion depth of 190.61 mm). At the same time, south roof on the entrance can guide snow away from the foot of the wall, so as to secure and extend the durability of wall. In summer, weather is not so hot, so east-west side of the house need not shade. In winter, maximum sunlight can heat the wall; simultaneously, high heat storage of wall body can also improve indoor comfort level.

## 4 CONCLUSION

Alkaline dwellings have many ecological characteristics such as land resource saving vertical village distribution, functional plain layout, local material use, simple construction method, economic, as well as many climate adaptabilities that modern ordinary residential housing do not possess. Therefore, we should focus on improving the structure node and the construction technology of traditional alkaline dwellings, taking full advantage of local resources, developing built technology, and carrying forward the traditional local-style dwelling houses into modern residential buildings.

## Plant configuration discussion of urban riparian park in the loess plateau region: Setting Taiyuan Fenhe Park as an example

J.Y. He & J. Gao

*College of Architecture and Civil Engineering, Taiyuan University of Technology, Taiyuan, Shanxi, China*

**ABSTRACT:** Urban riparian park is a characteristic element in urban green space system. It not only assumes the function of urban ecological corridor, but also becomes the bridges in the urban green space network system as its strip shape, waterfront location. Setting Taiyuan Fenhe Park as an example, this paper expounds the concept and characteristics of urban riparian park, explaining the principles of plant configuration. Then, the paper discussed the existing problems of fen river park in Taiyuan, seeking for the ecological plant configuration mode of the urban riparian park of the loess plateau region.

**Keywords:** urban riparian park; the loess plateau region; plant configuration; ecological

### 1 CONCEPT OF RIPARIAN PARK AND SIGNIFICANCE OF PLANT CONFIGURATION

According to the "Urban Green Space Classification Standard" (CJJ/T85-2002), riparian park the park green space in the five urban green space types, at the same time belongs to belt-shaped park, one of the five park green space types. Riparian park is the essence of green space system, usually combined with city water system. And it bears the function of urban ecological corridor. As the land conditions affect the width, the riparian park shape is long and narrow. It is through the landscape node with waterfront greening.

Throughout history, rivers not only provide water to the city and constitute transportation, so that the humans can thrive, creating civilization, but also are closely related to the urban ecological plaque architecture, which has profound significance to the attenuation of the urban heat island and flooding, composition of landscape diversity, and the protection of species diversity. Plants grown thereon, ornamental characteristics, species composition, and community structure have largely determined the quality and its exertion of ecological role in waterfront landscape, affecting the quality and level of urban waterfront landscape and the ecological development of the city. Hence, to create a scientific and rational waterfront plant landscape with urban characteristics is of great significance to conservation of biodiversity in urban waterfront, and to create a harmonious and green living environment. Currently, researches on plant configuration in urban riparian parks are mostly

developed at the macro level using the theory of urban planning, and there are few studies at the micro-level suited to local conditions conducted in the local waterfront plant landscape. Part of them is limited to theory of plant gardening in city park, failed to closely integrated with the specific characteristics of the waterfront environment. Taking Fenhe Park in Taiyuan as an example, this article has made analysis of its plant configuration guidelines and existing problems in order to seek more scientific and suitable way of ecological plant configuration.

### 2 CURRENT SITUATION OF FENHE PARK IN TAIYUAN AND THE FUNCTIONAL CHARACTERISTICS OF URBAN RIPARIAN PARKS

Taiyuan is located in the central of Shanxi. Its east, west, north three sides are surrounded by mountains, besides its middle and southern parts are plains of the valley. Its average elevation is about 800 m. Its average annual rainfall is 442 mm and its annual average temperature is 9.5 °C. The coldest month in Taiyuan is January, the average temperature is 6.8 °C, and the hottest month in Taiyuan is July, the average temperature is 23.5 °C; Frost-free period is 116 d to 165 d. The soil in Taiyuan is slightly alkaline or alkaline, and the brown soil is the main kind [1]. The climate in Taiyuan is north temperate zone continental climate. Taiyuan has rich plant resources, ancient origin, and many single species. Existing greening tree species has 235 species, belonging to 61 families, [2].

Taiyuan Fenhe park laid on both sides of fen river, which place is flat, and with more than 18 kilometers long. The green space of the first issue is 1.3 million square meters, contains 24000 plants and shrubs which belongs to 183 species, and 820000 square meters of lawn, more than 10000 Outdoor perennial root flowers. The park formed an one hundred meters wide, 6 km long green ecological corridor. Launched in 2014, the third phase extends to the north and the south, throughout the city.

In comparison between urban riparian parks and other types of green areas, the two have both general feature and its individual features. General feature includes: recreation, disaster prevention, landscaping, sound ecology, and spiritual culture. Individual features: 1. banding form. 2. Waterfront area. 3. Strong openness. 4. Significant effect of corridor. Role of corridor in urban riparian parks is reflected in the form. First, its linear band is a natural form of corridor; second, in promoting the flow of urban air, it has become airy corridor of the city, while it allows the spread of natural plants more convenient and the ecology more diverse, with quite obvious ecological corridor role. 5. Network connectivity. In the network of urban green space system, the linear and banding urban riparian parks have function of network connection. It can connect green points and green surface distributed in different sections of the city by the extension of linear band, so as to weave the city's green network structure [3].

### 3 THE DESIGN PRINCIPLES OF PLANT CONFIGURATION IN URBAN RIPARIAN PARKS OF LOESS PLATEAU

#### 3.1 *Follow the systematic principle from a macro perspective of the whole region*

Systematic principle refers that in plant configuration of urban riparian parks, the system theory is regarded as the principle, and the urban riparian parks, taken as constituent elements of the entire city green large system, and other forms of urban green spaces are interrelated and interact on each other to form a unified system of urban green space. Plant configuration in urban riparian parks is required to comply with two ways, namely, the coordination with urban master planning and overall urban environment.

Fen River Park runs through the city in belts, and is connected to the city expressway, thus it shall obey the overall urban planning, regulating various types of urban land-use in strict accordance with the overall urban planning, to achieve coordinated and balanced urban development.

#### 3.2 *Follow ecological principle from the micro perspective of city parks*

The natural environment of each region is the most basic guarantee to maintain the city's ecological functions as a whole. During the planting design in urban riparian parks, the ecological environment of the urban riparian parks should be given high priority and strict protection. According to the principles of ecology, natural ecological landscape is simulated in terms of configuration of biological populations and communities, as well as settings of topography, geomorphology and river waters to manually create a living environment adapted to its evolution for biological species and community, so as to make artificial landscape "naturalized, so that the application of the method of ecological greening in "approx-natural" community" can be promoted. The application of the method of ecological greening in "approx-natural" community" refers to regard the potential natural vegetation and community succession in ecology as basic theory to select suitable native plants [4].

Natural plant communities in waterfront of Fenhe Park are located at the boundary of two ecosystems of waters and land, ecologically called ecotone. Its flow and exchange of material and energy is very frequent, with quite high biodiversity and environment productivity, and its natural vegetation is characterized by the community form of abound species and complex structure.

#### 3.3 *Follow humanized principle from perspective of visitors' feelings*

From the view of visitors, the core of the design is to focus on humanized site design. People have the nature to be close to nature and water. Accordingly, in the configuration of plants and on the basis of meeting safety specifications, we shall do our best to imitate nature and increase accessibility. "Design with Nature" is put forward by the designer McHarg, and its essence is to design landscape with the environmental studies and other related disciplines theory as a guide, and its purpose is by introducing natural environment, to ecologically create woods, lawns, streams, etc.[5].

Fenhe Park has open Structure, should be using good color and formation to well-integrated surrounding buildings into the environment, which enables visitors to feel more natural. Waterfront plants have a complex structure, multiple levels and rich types, so that it can take advantage of scale, the degree of enclosure, to combine with the road and architectural pieces. And it can be divided into primary and subordinate fields, public and private spaces, which improves the possibility for people to choose and meet diverse needs.

#### 4 DISCUSSION ON THE EXISTING PROBLEMS IN FENHE PARK AND RECOMMENDATIONS FOR THE PLANT CONFIGURATION IN URBAN RIPARIAN PARKS OF LOESS PLATEAU

Plants have become the main material of landscape planning and design and construction, for they can not only improve the ecological environment which humans rely for existence, but also can create a beautiful space of realm, playing a very important role in construction of garden space [6]. There still exist several aspects that need to be further improved in Fenhe Park in Taiyuan at present, such as the lack of systematicness and stability in plant community structure, landscape heterogeneity to be enhanced, insufficient plant community level, inadequate considerations for storm water management, and the enjoyment of tour. Hence, plant configuration can be improved from the following aspects:

- a. Ecological community structure of natural river shoreline shall be simulated, with emphasis on matching species with the site, and specialized in native trees. Choice of varieties should be in line with various demands of the landscape and ecology, focusing on maintaining structural stability. Final-period management shall be strengthened to avoid ecological imbalance caused by excessive inundation of aquatic and wetland plants. For instance, some floating plants should be planted in a small pool of water, or their growth ranges are delineated with a fence to prevent water eutrophication caused by the large accumulation of plant residues, resulting in secondary pollution of aquatic and wetland plants.
- b. Landscape heterogeneity should be increased to emphasize the landscape character and to promote the circulation of natural objects, thereby framing urban habitat corridor. Elements of natural vegetation should be introduced to ecologically sensitive areas in the waterfront, including the proper construction of ecological protection areas of the waterfront, as well as the establishment of a variety of wildlife habitats, and division of the specific scope of protection.
- c. In addition to focusing on ornamental requirements, also combined with the vertical design of terrain, typical landscape features (such as estuaries, beaches, wetlands, etc.) formed in natural process of forming drainage are simulated to create terrain environment suitable for waterfront plants. With naturalization and diversity of plant as the guiding principle, configuration of aquatic, near-water, terrestrial plants shall be conducted according to the natural distribution and characteristics of the system of waterfront

- waters and land areas, to reflect the characteristics of natural evolution, creating a continuous waterfront green band. In addition to choice of conventional ornamental trees, we must also focus on nurturing water-resistant plants or aquatic plants locally, paying attention to the complex vegetation communities of waterfront.
- d. In allusion to the rainy summer in Loess Plateau, from the angle of urban stormwater management, the urban sponge technology is used to reduce hardening of plant and to increase permeable paving. For the catchment area with serious pollution, vegetation buffer zones are increased for pretreatment of rainwater runoff. In area of water purification in rainwater wetland, according to water depth, different types and levels of aquatic organisms are planted. Vegetation buffer zones should be increased, and the flow velocity of overland runoff is retarded through action of vegetation interception and soil infiltration. Also, part of pollutants in runoff are removed, slope of forest buffers generally being 2% to 6%, the width not less than 2m. The function of waterfront plants absorbing harmful substances can also be fully used, applied to be self-purification of water in the design, so as to improve environmental quality.
  - e. Multifaceted features such as space and appreciation requirements shall be considered focusing on topographical fluctuation and slope and change of bent and straight, so that the plant configuration and the natural environment can be in harmony with ecological environment, with balanced effects of short-term and long-term landscape. It is appropriate to employ the combination of tree, shrub, flower, grass, and rattan, integrated with evergreen and deciduous trees. Spaces are separated by trees, shrubbery mass, and greenbelt, equipped with a certain depth of field, then to reach a large space after passing by several winding small spaces. In configurations with different focuses, one or most multiple ornamental trees are utilized to implement vast clump planting or mass planting, so that each locality can exhibit different characteristics. The effects of landscape construction are taken into account from the many aspects, such as use of color, texture matching, seasonal changes, and so on. For instance, emulational rustic landscape is simulated to introduce the nature by the side of residents, so that the landscape can be more accessible.

#### 5 EXPECTATIONS

The plant configuration of Urban riparian park is a major issue in ecology, behavior psychology,

economics, botany, aesthetics, literature, and other related theories, the issue is difficult to explain clearly, nor can it be realized only by the personal thinking and the subjective desire of landscape architects. This article discusses the plant configuration of Loess Plateau Urban riparian park of China from the perspective of theoretical research, emphasizes the systematic, ecological, humanization three principles, and through the analysis of the current situation of Taiyuan Fenhe Park, proposes some suggestions of the waterfront landscape plant configuration, in order to provide helpful reference to the plant configuration of the Loess Plateau Urban riparian park in the future.

# Analysis of traditional architectural heritage protection strategy: Taking Jiajiazhuang historical and cultural district in Xiaoyi as an example

Da Zhang & Yuanping Liu

*Departments of Architecture, Taiyuan University of Technology, Shanxi, China*

**ABSTRACT:** The traditional settlement is the carrier of people's living, and the basic cell of China's social structure and urban development. The vast basin of the Yellow River has a unique and abundant geographical feature, which is a unique and abundant traditional settlement of the protection of many well-preserved villages. This paper takes the protection of the old city dwelling houses in Xiaoyi as an example, and discusses the Protection Countermeasures of the traditional residential buildings.

**Keywords:** historical and cultural county; protection plan; heritage protection

## 1 INTRODUCTION

As the historical remains of the settlement and residential space, the traditional dwelling house is the main building form of the settlement building, and is the main place for people to live and live. With the further development of the society and the continuous improvement of the economic level, the protection of historical buildings is increasingly concerned about the whole society. This paper will address this issue in Xiaoyi, Jiajiazhuang historical and cultural district, as an example and discusses the protection planning countermeasures.

## 2 THE BASIC SITUATION OF JIAJIAZHUANG

Jiajiazhuang is located in the east of Lvliang Mountain in Xiaoyi City, Shanxi Province. It is situated in the northwest corner of West Bank of Fenhe River, in the northwest corner of Jinzhong basin. Traditional block is an important part of Chinese architectural heritage, and its abundant resources are left to state, which is a history and can be called the Chinese cultural treasures.

Jiajiazhuang has a long history, according to "Xiaoyi County Records", in the Neolithic period, the unearthed Lanwenyi red sand pottery in Xiaoyi region belongs to Jiajiazhuang' second level terrace unearthed relics of Yangshao culture. There were two families in Jiajiazhuang whose names are Jia and Li first, gradually formed a settlement, then other families moved in. Because of Jia's large population and earlier immigration,

it is called Jiajiazhuang. The historical district of Jiajiazhuang is composed of two regions of Shangjie and Houjie. In the past, Jiajiazhuang village in Shangjie, largely regarded Sanhuang Temple as its center, and had Dongdao Street, Xitou Street and Miao Street. Miao Street, a total length of less than 500 meters, is the north-south, Dizang Temple to the south, central temple of Sanhuang. The Shangjie is from Jinhuanyi Courtyard in the west, south to Xiao River, east on the Bandao Road, north next to the Houjie Street. With the development of history, Jiajiazhuang's residents continue to expand, people of insight who were from outside gradually moved to settle down, and the formation of Jiajiazhuang, completing Jiajiazhuang historical and cultural blocks from then on.

## 3 HISTORICAL RELICS

Jiajiazhuang historical cultural district has a long history and rich cultural heritage, and its ancient architectural structures are most well preserved. Houjie Street high lies to the west of the village, lower east side, district court seat in southern and in northern built in accordance with the East-West ramp, through hundreds of years, it still retains its original pattern and historical style. These local characteristics of ancient buildings, concentrated reflects the building layout of Ming and Qing dynasties. They are the layout of rigorous, magnificent, exquisite workmanship, full-featured architectural style and level. The history of the settlement building orderly has a strong sense of unity.

### 3.1 *Defensive architecture*

The long-term complex and unstable social environment makes the defense consciousness as a psychological accumulation, directly affecting the settlement pattern of Jiajiazhuang. There is no danger according to the flat land of the village optional site, so the construction of the settlement has a strong sense of Fortress form, which mainly depends on the artificial defense construction. In history, Jiajiazhuang had East gate, West gate, South Gate, and North gate, these four Fort gates combined with high build castle walls, combining linear fortification and defense nodes, and forming a solid defense system. This level of fortification reality defense operation is a typical Jiajiazhuang defense mode.

### 3.2 *Temples and other public buildings*

The typical public buildings in historical and cultural blocks is a temple in Jiajiazhuang. The present temples Sanhuang Temple in the north of Xiao Fen Road, Xiao Fen avenue to the south of the Guanyu Temple, and Dizang Temple. These public buildings are the concentrated reflection of the emotional needs of the villagers' religion and social intercourse.

### 3.3 *Streets*

Road system is contact settlements within and outside the transport hub. It is the basic skeleton of the settlement, and it is divided into different functional areas and the basis of defining the village spatial axis, which plays a pivotal decisive role on the overall layout. Jiajiazhuang village is located in the plain area, the village streets using chessboard layout of traditional. In all, the road system of the village can be divided into three levels, namely main streets, secondary streets, and alleys.

## 4 PROTECTION PLAN

### 4.1 *The strategies of protection plan*

According to the status of Jiajiazhuang historical and cultural blocks of historical and cultural relics, the planning and the "overall protection with emphasis on the protection of the combination, supplemented by the key historical information moderate repair" countermeasures. Jiajiazhuang's protection of historical and cultural blocks planning blocks as a whole and protection of historical and cultural relics of moderate repair is composed of two parts.

A. The historical and cultural protected area of Jiajiazhuang consists of three parts of protected areas, construction control area, and

environmental coordinated area. The protection plan for different protection areas determines the contents of the protection and protection measures.

B. We must moderately repair the parts of the historic block, and analyze the important material and cultural relics that constitute the block, and analyze the status of the material culture remains and the historical form.

### 4.2 *The content of protection plan*

A. On the basis of Jiajiazhuang's natural environment, history and culture, the overall planning, traditional style, space form of in-depth research and analysis, this study summarizes the value characteristics, clear protection, and utilization of some important contents.

B. According to the current situation of distribution of Jiajiazhuang's cultural relics, historic buildings, historic street, in conservation planning regulation protection area, a construction control area, construction of secondary control area, environmental coordination area four degrees of protection and the scope of protection, and then put forward protection requirement, construction control index, environment coordination.

C. According to the present situation of Jiajiazhuang buildings and environment, they will be divided into the protection, the preservation, the renovation, and the renewal of four categories. To protect the classic construction, structures, including mapping, images, text descriptions and protection of the archives and the listing of the public, were proposed for the repair, maintenance, and other measures. The maintenance and improvement of the reserved classic construction are put forward. For the improvement of the construction and structures of the remediation, the improvement and the renovation are proposed; also for the construction of the renewal classic construction, structures, respectively, a targeted renovation, remediation, removal, and other measures.

D. In accordance with the principle of overall protection plan, it concludes Jiajiazhuang's historical and cultural paths and internal historical environment and the surrounding natural environment the protection and remediation requirements.

E. According to the Ming and Qing Dynasties of the office, county annals and witness the oral history, and the textual research of archaeological researchers identified, Jiajiazhuang's historical and cultural blocks for repairing improves Jiajiazhuang's Traditional Pattern and historical style.

F. Under the condition of keeping the traditional pattern and historical style, Jiajiazhuang's historical

and cultural blocks of infrastructure and environmental of comprehensive planning, puts forward the concrete improvement measures.

G. We need to put forward the protection plan implementation measures and suggestion, formulate the protection management method, establish the protection fund raising mechanism, encourage the public participation protection, and so on.

## 5 ANCIENT ARCHITECTURAL HERITAGE PROTECTION MEASURES

In any country or time, architecture cannot exist in isolation. It is hard to understand the ancient architecture without studying the relevant factors. In the same way, the protection of architectural heritage cannot be isolated from other human cultural heritage, even nearly a hundred years of heritage protection movement is no exception. I believe the future of the construction heritage protection, from the following aspects, to expand further.

### 5.1 *The study of the ancient architecture as sociology and cultural anthropology*

The building was built by human. There are different societies, different ethnic groups, in thinking about a problem, although they are common human cognition; but, there are also inevitable differences. Now, the research methods of sociology and cultural anthropology in the world are very mature. We want to study the important living beings of the history of human development—architectural heritage, and can learn from the sociological method. Nowadays, certain primitive tribes of social life phenomenon can also serve as our reference to live fossil. The results of sociological research in the past century are also available for us.

### 5.2 *The relationship between ancient architecture and family, private ownership and state*

For example, documents related to the rites of Ming Dynasty provisions in Nanjing, if you catch the time conflict of visiting Xiaoling Tomb and Confucian Temple, Xiaoling Tomb will visit first. For example, during the reign of Zhu Yuanzhang, Xiaoling engineering has been repeatedly visited. The responsible person must be simple and firm.

### 5.3 *The study on the aesthetic of ancient architectural heritage*

To examine our architectural aesthetics study in addition to the aesthetic vision of our time, we also need to put ourselves from the point of view of the past to examine. For example, Xiao He

created Weiyang Palace for Liu Bang to live, Liu Bang looked with a big temper. Xiao He said a “The non magnificent no heavy prestige” explanation, Liu Bang would no longer say anything. This is the performance of people’s aesthetic in the Qin and Han Dynasties. Sima Guang in Song Dynasty disagreed with this. He thought that Xiao could not say that. Because at that time the world be kept constantly on the run. As the party was responsible for logistics, he was better than anyone who was clear. This is the aesthetic view of the opposition in the background of “Wang Anshi reform” in the Northern Song Dynasty.

### 5.4 *The study on the economic of ancient architectural heritage*

Why did Tang Wuzong want to destroy Buddha? Because his father emperor Wenzong early to he calculated “In ancient times, three people eat need a person cultivated land, now with soldiers and monk is five people dining needs a person farming, which will bring people’s dislike of Buddhism.” The history of China on the rise and fall of Buddhism, not the emperors did not know Buddhism had value, but because in the development of Buddhism in the head, economic forces strongly endanger the national economy and the people’s livelihood situation, had to pain determination.

## 6 CONCLUSION

We protect the historical and cultural heritage of a town, and we are not to limit the involvement of the new towns and the environment. In principle, in addition to the heritage architecture, the other parts can be a new creation, but we must have the idea that people build cities in a city. Its goal is “On the one hand, we should ensure to architectural history and culture heritage protection for the continuity of the basis of urban texture, on the other hand, we should ensure the coordination of the modern urban texture, in consideration of the quality of architecture, urban and landscape.”

# Study on the application of iron tailings for the improvement of saline-sodic soil

A.L. Shao

*Mining Company of Anshan Iron and Steel Group Corporation, Anshan, China*

**ABSTRACT:** A new soil amendment was prepared in this study, which was comprised of iron tailings (65%), active slag (20%), acid fertilizer (12%) and other additives (3%). Through comprehensive utilization, the iron tailings can be reused. The pH, salinity, density, porosity and permeability velocity of the soil from the test fields were detected. The results showed that the pH value of the soil decreased from 9.30 to 6.95, and the salinity decreased from 0.42% to 0.25% in one year. The density of the soil was lower by 7.80% than before improvement, while porosity and permeability velocity were higher by 9.35% and 72.73%, respectively. The new soil amendment could effectively resolve the problems of soil secondary salinization and re-alkali. The improvement of the saline-sodic soil by using this soil amendment has not only ecological, environmental and social benefits, but also economic benefits.

**Keywords:** iron tailings; saline-sodic soil; soil amendment; salinity

## 1 INTRODUCTION

With the unprecedented rate of mining and mineral processing over the last decade, there has been an increasing level of concern worldwide about the fate of tailings. An estimated above 10 billion tons of tailings have been discharged in China. The proportion of iron tailings as a solid waste is growing faster. The storage of iron tailings not only covers huge land and pollutes the environment, but also gives rise to security risks. At the same time, iron tailings as secondary resources have been of great importance worldwide. At present, there are several ways of utilization of iron ore tailings, which are as follows: useful metal recycling, producing building materials directly, filling goaf and using as a soil modifier and magnetization fertilizer.

The improvement of saline-sodic soil has a great significance at this stage of China's population growth and reduction of arable land. The traditional methods for improving saline-sodic soil include the physical method, the chemical method and the biological method.

A new high-efficient amendment for improving the saline-sodic soil was studied. The amendment was composed of iron tailings and organic matters. It is a new method to realize the resource utilization. In the laboratory research foundation, the new technique of saline-sodic soil improvement was carried out on industrial tests and obtained success.

## 2 MATERIALS AND METHODS

The iron tailings of magnetic separation were used in this study. Soil amendment was comprised of iron tailings (65%), active slag (20%), acid fertilizer (12%) and other additives (3%), such as starter cultures, precipitants, and humic acid. The saline-sodic soil was taken from Baicheng Town of Jilin Province. The weight of the soil was 150.89 kg and the volume of the water was 60.49 L. The soil was soaked in the water for about 3 days.

Soil amendment was mixed in the saline-sodic soil. The experiment was conducted at 8°C. Various indicators of the soil were tested every 5 days, such as pH value, Cation Exchange Capacity (CEC), Exchangeable Sodium Percentage (ESP), and contents of  $K^+$ ,  $Na^+$ ,  $Ca^{2+}$ , and  $Mg^{2+}$ .

The industrial tests were undertaken on two fields in Jilin Province, named as A and B. The fields A and B were 23 hectares and 3.1 hectares, respectively. The tests were divided into the following several stages: the capital construction of the paddy field, salinity regulation, dynamic test of soil parameters, and result analysis.

## 3 RESULTS AND DISCUSSION

### 3.1 *Iron tailings analysis*

In order to verify the feasibility of magnetic separation iron tailings used as soil amendment, its composition and particle size distribution

were determined. Table 1 presents the chemical composition (%) of the iron tailings. Table 2 presents the particle size distribution of the iron tailings. The results indicated that the iron tailings selected in this study did not contain any substance that was poisonous or noxious to crops. The content of SiO<sub>2</sub> was 76.10% in the chemical composition of the iron tailings. It could be instead of the sand mixed with soil. In addition, the particle size of the iron tailings met the requirements. Therefore, the magnetic separation iron tailings could be used for the improvement of the saline-sodic soil.

### 3.2 Laboratory analysis of the soil

The saline-sodic soil is distributed mainly over the Northeast China, and the soil parent materials were made of clayey or sandy sediments, which have the characteristics of poor permeability and strong capillarity. The improvement of the saline-sodic soil is a problem in the world. How to

Table 1. Chemical composition of the iron tailings.

Element	Fe	Fe <sub>3</sub> O <sub>4</sub>	SiO <sub>2</sub>	CaO
Content (%)	11.31	4.8	76.1	0.28
Element	Al <sub>2</sub> O <sub>3</sub>	MgO	P	MnO <sub>2</sub>
Content (%)	0.43	0.32	0.037	0.12

effectively control soil secondary salinization and re-alkali is the key to solving the problem. According to the survey, the phenomenon of secondary salinization and re-alkali often occurred after planting in paddy for about 2 months, and the pH value returned to the baseline level, i.e. before improvement.

Table 3 presents the variation of the soluble salt contents and the properties of the soil after improving. As can be seen from Table 3, the pH value of the soil decreased from 10.58 to 6.93 within 15 days by adding the composite soil amendment. The concentration of Na<sup>+</sup> decreased from 6511.45 mg/kg to 3566.15 mg/kg, with a decline of 45.23% in 15 days. The concentration of K<sup>+</sup> decreased about 37.25%. Meanwhile, the concentration of Mg<sup>2+</sup> increased from 10.90 mg/kg to 131.65 mg/kg, and the concentration of Ca<sup>2+</sup> increased about 39.09%. With the decreasing pH value, the concentrations of HCO<sub>3</sub><sup>-</sup>, Cl<sup>-</sup>, SO<sub>4</sub><sup>2-</sup>, and CO<sub>3</sub><sup>2-</sup> decreased about 75.69%, 69.67%, 40.67%, and 50.29%, respectively. The Cation Exchange Capacity (CEC) changed from 92.91 mold/100 g to 165.65 mold/100 g. It indicated that the fertilizer preservation ability of the soil is enhanced after improvement. At the same time, the Exchangeable Sodium Percentage (ESP) and salinity of the soil were lower than before improvement. Thus, it can be seen that the soil amendment has a pronounced effect on the improvement of the saline-sodic soil.

Table 2. Particle size distribution of the iron tailings.

Particle size range (mm)	-0.01	0.01-0.02	0.02-0.03	0.03-0.043	0.043-0.06
Particle size (mm)	39.25	5.28	10.83	12.03	11.02
Particle size range (mm)	0.06-0.076	0.076-0.10	0.10-0.0154	+0.154	/
Particle size (mm)	5.00	12.75	3.43	0.41	/

Table 3. The soluble salt contents and the properties of the soil after improving.

No.	S-1	S-2	S-3	S-4
Time (day)	0	5	10	15
pH	10.58	8.43	7.02	6.93
K <sup>+</sup> (mg/kg)	136.12	112.52	95.13	85.41
Na <sup>+</sup> (mg/kg)	6511.45	5859.45	4020.91	3566.15
Ca <sup>2+</sup> (mg/kg)	2217.10	2685.18	2950.18	3083.82
Mg <sup>2+</sup> (mg/kg)	10.90	67.36	112.83	131.65
HCO <sub>3</sub> <sup>-</sup> (mg/kg)	3494.47	3075.96	2401.94	849.60
Cl <sup>-</sup> (mg/kg)	303.46	296.46	286.62	92.03
SO <sub>4</sub> <sup>2-</sup> (mg/kg)	43.20	42.58	41.21	25.63
CO <sub>3</sub> <sup>2-</sup> (mg/kg)	1.75	1.70	1.62	0.87
CEC (mold/100 g)	92.91	117.32	137.58	165.65
ESP (%)	57.81	44.10	46.30	28.60
Salinity (%)	2.13	1.95	1.65	1.12

Because the fine particles in the iron tailings have a porous structure, which could control the concentration of  $\text{Na}_2\text{CO}_3$  and  $\text{NaHCO}_3$ , the iron tailings had a good performance in controlling the soil secondary salinization and re-alkali. In addition, the elements Fe, Si, Mg and S in the iron tailings were essential for crop growth.

In addition, unformed activated carbon was contained in the active slag, which had good adsorption and filtration properties for metal ions. The addition of the acid fertilizer had a clear effect on salt absorbing, and ensured that the crops can be protected from salt damage. The pH value was adjusted to the acidic conditions by adding the other additives, which was beneficial to crops.

The new soil amendment, which was composed of the iron tailings, active slag, acid fertilizer and other additives, could effectively resolve the problems of soil secondary salinization and re-alkali. Through comprehensive utilization, the iron tailings can be reused. This soil amendment used in the saline-sodic soil has not only ecological, environmental and social benefits, but also economic benefits.

### 3.3 Analysis of the test fields

The test fields were leveled first, and then ploughed 20 cm deep. The height difference between the parcels was in the range of 10–15 cm, and the height difference in one parcel was not beyond 2 cm. After leveling, the ditches were constructed.

Iron tailings about 550 t were transported from Anshan tailings ponds to the test fields in May 2013. Active slag, acid fertilizer and livestock manures were also carried to the test fields. After mixing the raw materials at certain proportions, the soil amendments were obtained. According to the plan, the amendments were scattered in the fields and then irrigated. Water was changed every 5 days. After repeating twice, the fields were harrowed, which made the amendments to function.

Table 4 presents the salinity (%) of the test fields. In field A, the salinity of the soil decreased from 2.53% to 0.65% in 2 months. The salinity of the soil in field B decreased from 0.42% to 0.25%. The results show that the soil amendments could significantly reduce the salinity of the fields. It turned the strongly salinized soil into the middle salinized soil, and turned the middle salinized soil into the mild salinized soil. The control of soil secondary salinization and re-alkali was proved to be successful. The improvement of the strongly saline-sodic soil was feasible.

Table 5 presents the pH value of the test fields. Rice could grow normally in this condition. Because of the heavy rains, the data of field A from August to September were missed, but the pH value of field

Table 4. The salinity of the test fields (%).

Data	Test fields	
	A	B
1 Jun	2.53	0.42
16 Jun	1.20	0.25
1 Jul	0.95	0.26
16 Jul	0.75	0.27
31 Jul	0.65	0.25
15 Aug	—*	0.24
31 Aug	—*	0.26
14 Sep	—*	0.26
29 Sep	—*	0.25

\*The field A was flooded because of the heavy rains, and the test was forced to be terminated.

Table 5. The pH value of the test fields.

Data	Test fields	
	A	B
1 Jun	10.27	9.30
16 Jun	8.12	7.52
1 Jul	8.05	7.41
16 Jul	8.06	7.50
31 Jul	8.03	7.31
15 Aug	—*	7.45
31 Aug	—*	7.38
14 Sep	—*	7.10
29 Sep	—*	6.95

\*The field A was flooded because of the heavy rains, and the test was forced to be terminated.

A decreased from 10.27 to 8.03 in about 2 months. The pH value of field B was decreased from 9.30 to 6.95. The change in the pH value was slow, but stable. It indicated that the pH value decreased by adding the soil amendments.

Table 6 presents the properties of the soils before and after using the soil amendment. The addition of the soil amendments played an important role in the improvement of the soils, which decreased the density and significantly increased the porosity and permeability velocity. The density of field B decreased by 7.80%, its porosity increased by 9.35% and its permeability velocity increased by about 72.73%. The trends were beneficial to the growth of rice.

The fields, where the rice cannot grow earlier, became the rice cultivable areas after improvement. In field B, for example, the production of rice was 6800 kg/ha before improvement, and the production reached up to 9300 kg/ha after improvement.

Table 6. The density, porosity and the permeability velocity of the soils.

Test fields	Density (g/cm <sup>3</sup> )	Porosity (%)	Permeability velocity (mm/min)
<i>A</i>			
Before the improvement	1.48	42.19	0.08
After the improvement	1.38	46.10	0.12
<i>B</i>			
Before the improvement	1.41	45.01	0.11
After the improvement	1.30	49.22	0.19

The improvement of the saline-sodic soil by the soil amendment showed a significant effect. It was also technically feasible and economically affordable.

#### 4 CONCLUSIONS

A high-efficient soil amendment was obtained, which comprised iron tailings, active slag, acid fertilizer and other additives. It decreased the pH value of the saline-sodic soil and solved the problem of secondary salinization and re-alkali. The results showed that the pH value of the soil decreased from 9.30 to 6.95, and the salinity decreased from 0.42% to 0.25% in one year. The density of the soil was lower by 7.80% than before improvement, while porosity and permeability velocity were higher by 9.35% and 72.73 than before improvement. The addition of the soil amendment played an important role in the improvement of the soil, which decreased the density and significantly increased the porosity and permeability velocity.

The improvement of the saline-sodic soil by using iron tailings not only restored the soil function, but also reduced the environmental pollution. It has an important significance to the work of ecological environmental protection and mining sustainable development of mining areas.

# The general solution of the Sturm–Liouville equation in heat conduction problems

F.B. Lu, Y.Z. Fu & S.Y. Su

*Institute of Urban Construction, Wuhan University of Science and Technology, China*

**ABSTRACT:** In this paper, the method of variable separation is applied to solve the thermal problem, which leads to the Sturm–Liouville problem, also known as the SL problem. Using the solution of Ref. [2] on the SL problem, it then combines own reasoning calculation and gives a more general solution to the SL problem. It considers the orthogonal characteristic functions including weight function, and draws the corresponding coefficient expressions of primary function. Finally, through an example, it shows the solution of the SL equation.

**Keywords:** variable separation; SL problem; orthogonality; primary function

## 1 INTRODUCTION

Unsteady heat conduction and more than one-dimensional partial differential equation of heat conduction problem cannot be solved by the direct integration. Variable separation is one of the methods for solving such partial differential equations. In addition, after the adoption of variable separation, the solution can be written in the form of  $\theta = \sum \theta_n$ , that is, the real variable separation is actually a series expansion of the mathematical problem, which involves the eigenvalue and eigenfunction issue, also known as the Sturm–Liouville problem (SL problems).

## 2 VARIABLE PREPARATION METHOD TO SOLVE THERMAL PROBLEMS

For the one-dimensional unsteady heat conduction problem, suppose there is an endless planumural, then the thickness is  $2\delta$ , the initial temperature is  $t_0$ , the two sides are cooled by the fluid, in which temperature is  $t_f$  and the heat transfer coefficient is  $h$  (see Fig. 1).

The mathematical description is as follows:

$$\begin{cases} \frac{\partial t}{\partial \tau} = a \frac{\partial^2 t}{\partial x^2} \\ \tau = 0 & t = t_0 \\ x = 0 & \frac{\partial t}{\partial x} = 0 \\ x = \delta & -\lambda \frac{\partial t}{\partial x} = h(t - t_f) \end{cases} \quad (1)$$

Figure 1. Schematic diagram of heat conduction.

Suppose that  $\theta = t - t_f$ , then (1) can be transformed as follows:

$$\begin{cases} \frac{\partial \theta}{\partial \tau} = a \frac{\partial^2 \theta}{\partial x^2} \\ \tau = 0 & \theta = \theta_0 = t_0 - t_f \\ x = 0 & \frac{\partial \theta}{\partial x} = 0 \\ x = \delta & -\lambda \frac{\partial \theta}{\partial x} = h\theta \end{cases} \quad (2)$$

In order to use the method of integral transform to handle the form of differential equations, suppose that  $\theta(x, \tau) = X(x) \cdot T(\tau)$ , and substitute this

formula into differential equation (2), and then through variable separation<sup>[1]</sup>, we can obtain the following equation:

$$\frac{T'}{aT} = \frac{X''}{X} = \mu \quad (3)$$

From Solution (3), we can obtain the expression of  $X(x)$  and  $T(\tau)$ , respectively, and substitute in the corresponding boundary conditions, and the expression of  $\theta(x, \tau)$  can be obtained. The variable separation method is successful because the solution can be written as follows:

$$\theta = \sum \theta_n = \sum A_n X_n \quad (4)$$

It means that the solution of heat condition equation  $\theta$  can be developed into a series based on  $X_n$ . If it really can, then  $\theta$  already becomes the solution of the problem. Therefore, the essence of variable separation is a series expansion of mathematical problems. The details of this problem include why written series, why can write the series, and the series should take the number of items. This is the famous eigenvalue and eigen function problem.

### 3 SERIES OF ORTHOGONAL FUNCTIONS TO ARBITRARY FUNCTION-BASED SERIES EXPANSION

In mathematics, the eigenvalue and eigenfunction problem were known as the Sturm–Liouville problem, referred to as the SL problem. The following questions deal with the matter of ordinary differential equations:

$$\frac{d}{dx} \left[ p(x) \frac{du}{dx} \right] + [q(x) + \lambda s(x)]u = 0 \quad (5)$$

$$\begin{cases} c_1 u(a) + c_2 u'(a) = 0 \\ d_1 u(b) + d_2 u'(b) = 0 \end{cases} \quad (6)$$

Equation (5) is called the SL equation, Equation (6) corresponds to the boundary conditions of the third boundary condition, also known as the SL boundary condition problem, or SL problems overall.

According to Ref. [2], the orthogonality of the characteristic function series can be proved from the equation and the boundary conditions of the SL problem directly. The solution is as follows:

Suppose that the eigenvalue  $\lambda_m$  and  $\lambda_n$  correspond to the characteristic function of  $u_m(x)$  and  $u_n$ , then:

$$p u_m'' + p' u_m' + (q + \lambda_m s) u_m = 0$$

$$p u_n'' + p' u_n' + (q + \lambda_n s) u_n = 0$$

Multiplying the left-style by  $u_n$  and the right formula by  $u_m$ , the left-style subtracts the right, which is as follows:

$$p(u_m'' u_n - u_n'' u_m) + p'(u_m' u_n - u_n' u_m) + s u_m u_n (\lambda_m - \lambda_n) = 0$$

The type integral between  $[a, b]$  is as follows:

$$\begin{aligned} & \frac{s(\lambda_m - \lambda_n)}{p} \int_a^b u_m u_n dx \\ &= \int_a^b \left[ \frac{d^2 u_m}{dx^2} u_n - \frac{d^2 u_n}{dx^2} u_m \right] dx = \left[ u_n u_m' - u_m u_n' \right]_a^b \\ &= \left[ u_n(b) u_m'(b) - u_m(b) u_n'(b) \right] \\ & \quad - \left[ u_n(a) u_m'(a) - u_m(a) u_n'(a) \right] \end{aligned} \quad (7)$$

Contrast boundary conditions can prove that (7) is equal to 0. For example, the first term, at the boundary conditions of  $x = b$ , is as follows:

$$\lambda u_n'(b) + h u_n(b) = 0$$

$$\lambda u_m'(b) + h u_m(b) = 0$$

Multiplying  $u_m$  by the left-style and  $u_n$  by the right-style, and then subtracting two of them, we obtain

$$\begin{aligned} & \lambda u_n'(b) + u_m(b) + h u_n(b) u_m(b) - \lambda u_m'(b) - h u_m(b) u_n(b) \\ &= \lambda \left[ u_n'(b) u_m(b) - u_m'(b) u_n(b) \right] \\ & \quad + h \left[ u_n(b) u_m(b) - u_m(b) u_n(b) \right] = 0 \end{aligned}$$

As this second term is 0, the first term is also 0. Similarly, we demonstrate that the second term of (7) is also 0.

Therefore, when  $\lambda_m \neq \lambda_n$ ,  $\int_a^b u_m u_n dx = 0$ , i.e. the function  $u_m$  and  $u_n$  are orthogonal.

From the above solution, we can see Ref. [2], the authors regard the function of  $s$  and  $p$ , respectively, as a constant function to solve this SL problem, is one-sided. In fact,  $s$  and  $p$  are the function of  $x$ , namely  $s(x)$  and  $p(x)$ . For  $s(x)$  and  $p(x)$ , at the corresponding different eigenvalue  $\lambda_m$  and  $\lambda_n$  of characteristic function  $u_m(x)$  and  $u_n(x)$  orthogonal under certain conditions, i.e., the general solution. It can be proved as follows.

Suppose that eigenvalues  $\lambda_m$  and  $\lambda_n$  are characteristic function corresponding to  $u_m(x)$  and  $u_n(x)$ , which in turn is satisfied as follows:

$$\frac{d}{dx} \left[ p(x) u_m' \right] + [q(x) + \lambda_m s(x)] u_m(x) = 0 \quad (8)$$

$$\frac{d}{dx} \left[ p(x) u_n' \right] + [q(x) + \lambda_n s(x)] u_n(x) = 0 \quad (9)$$

Multiplying (8) by  $u_n$  and multiplying (9) by  $u_m$ , and subtracting two of them, we obtain

$$u_n \frac{d}{dx} [p(x)u'_m] - u_m \frac{d}{dx} [p(x)u'_n] + (\lambda_m - \lambda_n)s(x)u_m(x)u_n(x) = 0 \quad (10)$$

Substitute (10) integral in  $[a, b]$ :

$$\int_a^b \left\{ u_n(x) \frac{d}{dx} [p(x)u'_m(x)] - u_m(x) \frac{d}{dx} [p(x)u'_n(x)] \right\} dx + (\lambda_m - \lambda_n) \int_a^b s(x)u_m(x)u_n(x) dx = 0 \quad (11)$$

For (11):

$$\begin{aligned} & \int_a^b \left\{ u_n(x) \frac{d}{dx} [p(x)u'_m(x)] - u_m(x) \frac{d}{dx} [p(x)u'_n(x)] \right\} dx \\ &= \int_a^b u_n(x) d[p(x)u'_m(x)] - \int_a^b u_m(x) d[p(x)u'_n(x)] \\ &= [p(x)u_n(x)u'_m(x)]_a^b - \int_a^b p(x)u'_n(x)u'_m(x) dx \\ &\quad - [p(x)u_m(x)u'_n(x)]_a^b + \int_a^b p(x)u'_n(x)u'_m(x) dx \\ &= [p(x)u_n(x)u'_m(x)]_a^b - [p(x)u_m(x)u'_n(x)]_a^b \\ &= [p(x)u_n(x)u'_m(x) - p(x)u_m(x)u'_n(x)]_{x=b} \\ &\quad - [p(x)u_n(x)u'_m(x) - p(x)u_m(x)u'_n(x)]_{x=a} \end{aligned} \quad (12)$$

For formula (12), contrasting the boundary conditions, this term is equal to 0. For the first term, at the boundary conditions of  $x = b$ , it is as follows:

$$\lambda u'_n(b) + hu_n(b) = 0$$

$$\lambda u'_m(b) + hu_m(b) = 0$$

Multiplying  $p(b)u_m(b)$  by the left formula, and  $p(b)u_n(b)$  by the right formula, and then subtracting the two equations, we obtain

$$\begin{aligned} & p(b)u_m(b) [\lambda u'_n(b) + hu_n(b)] \\ & - p(b)u_n(b) [\lambda u'_m(b) + hu_m(b)] \\ &= \lambda p(b) [u_m(b)u'_n(b) - u_n(b)u'_m(b)] \\ &= \lambda [p(x)u_n(x)u'_m(x) - p(x)u_m(x)u'_n(x)]_{x=b} = 0 \end{aligned}$$

Similarly, we prove that the second term of (12) is also equal to 0.

So

$$\int_a^b \left\{ u_n(x) \frac{d}{dx} [p(x)u'_m(x)] - u_m(x) \frac{d}{dx} [p(x)u'_n(x)] \right\} dx = 0$$

Therefore,  $(\lambda_m - \lambda_n) \int_a^b s(x)u_m(x)u_n(x) dx = 0$ .

So, when  $\lambda_m \neq \lambda_n$ , corresponding to different eigenvalues  $\lambda_m$  and  $\lambda_n$  characteristic functions  $u_m(x)$  and  $u_n(x)$  in the interval  $[a, b]$  with weight function on  $s(x)$  orthogonal, i.e.  $\int_a^b s(x)u_m(x)u_n(x) dx = 0$ . Arbitrary function can be expanded based on  $u_n(x)$ :

$$f(x) = \sum_{n=0}^{\infty} A_n u_n(x) \quad (13)$$

where  $A_n$  is the  $n$ th coefficient, which is associated with  $n$ .

Here, we use the nature of the orthogonal function to solve the coefficient  $A_n$ , calculated as follows:

For (13), multiplying both sides by  $s(x)u_m(x)$ , and integrating in  $[a, b]$ , we obtain

$$\begin{aligned} & \int_a^b f(x)s(x)u_m(x) dx \\ &= \int_a^b \sum_{n=0}^{\infty} A_n u_n(x)s(x)u_m(x) dx \end{aligned}$$

When  $m \neq n$ ,  $\int_a^b s(x)u_m(x)u_n(x) dx = 0$

So,  $\int_a^b f(x)s(x)u_n(x) dx = A_n \int_a^b s(x)u_n^2(x) dx$

$$\text{So, } A_n = \frac{\int_a^b f(x)s(x)u_n(x) dx}{\int_a^b s(x)u_n^2(x) dx}$$

That is, arbitrary function can be expanded based on:  $u_n(x)$ :  $f(x) = \sum_{n=0}^{\infty} A_n u_n(x)$ , where

$$A_n = \frac{\int_a^b f(x)s(x)u_n(x) dx}{\int_a^b s(x)u_n^2(x) dx}$$

#### 4 ILLUSTRATION OF THE SL ISSUE

As shown in the example of [Figure 1](#), to solve the  $x$  is a SL problem, variable separation is used in one-dimensional unsteady heat conduction problem of convection boundary conditions, at this point:  $p(x) = 1$ ,  $q(x) = 0$ ,  $s(x) = 1$ ,  $\lambda = -\varepsilon^2$ . So, the SL equation is a differential equation of 2nd-order, linear, homogeneous, constant coefficients. See the concrete solution on Ref. [2].

For (5), take the derivative of the 2nd derivative  $p(x)$  and get the 1st derivative  $p'(x)$ , namely all of them are function of  $x$ , and the SL equation is a differential equation of 2nd-order, linear,

homogeneous, variable coefficients. Although the  $\lambda$  of the SL equation can get its values according to the requirement of the boundary conditions,  $q(x) + \lambda s(x)$  can still express arbitrary functions. This is the reason that  $q(x)$  exists in the SL equation.

For example, the temperature distribution of spherical: to get the solution of harmonic function  $u$  within a radius of 1, which makes it meet the sphere of  $u|_{r=1} = \cos^2 \theta$ . The question boils down to solve the following problem:

$$\begin{cases} \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial u}{\partial r} \right) + \frac{1}{r^2 \sin \theta} \frac{\partial}{\partial \theta} \left( \sin \theta \frac{\partial u}{\partial \theta} \right) = 0, & 0 < r < 1 \\ u|_{r=1} = \cos^2 \theta \end{cases} \quad (14)$$

Using variable separation, suppose  $u(r, \theta) = R(r)\Theta(\theta)$  and substitute it in (14), we get

$$\frac{r^2 R'' + 2rR'}{R} = -\frac{\Theta'' + \cot \theta \Theta'}{\Theta} = \lambda \quad (15)$$

So, (15) can turn into

$$r^2 R'' + 2rR' - \lambda R = 0 \quad (16)$$

$$\Theta''(\theta) + \cot \theta \Theta'(\theta) + \lambda \Theta(\theta) = 0 \quad (17)$$

Solution function (17), in the boundary conditions on  $[0, \pi]$

$$\Theta_n(\theta) = P_n(\cos \theta)$$

However, (16) is the SL equation, namely a differential equation of 2nd-order, linear, homogeneous, variable coefficients. The general solution is:

$$R_n(r) = C_1 r^n + C_2 r^{-(n+1)}$$

To make  $u$  bounded,  $R_n(r)$  must also be in bounded, so  $C_2 = 0$ , namely  $R_n(r) = C_n r^n$ .

So the solution of original problem is

$$u(r, \theta) = \sum_{n=0}^{\infty} C_n r^n P_n(\cos \theta) \quad (18)$$

The solution of the coefficient is (18), thus the problem of the solution is obtained.

## 5 CONCLUSIONS

By inference calculations for the SL problem, when  $\lambda_m \neq \lambda_n$ , different eigenvalues  $\lambda_m$  and  $\lambda_n$  corresponding to the characteristic function  $u_m(x)$  and  $u_n(x)$  in the interval  $[a, b]$  with the weight function  $s(x)$  orthogonal, i.e.,  $\int_a^b s(x) u_m(x) u_n(x) dx = 0$ . Arbitrary function can be expanded based on  $u_n(x)$  as follows:

$$f(x) = \sum_{n=0}^{\infty} A_n u_n(x)$$

where  $A_n$  is the  $n$ th coefficient, which is associated with  $n$ , with

$$A_n = \frac{\int_a^b f(x) s(x) u_n(x) dx}{\int_a^b s(x) u_n^2(x) dx}$$

## Solar Decathlon—entries of Tongji University

Li Yang & Feng Qian

*Key Laboratory of Ecology and Energy Saving Study of Dense Habitat (Tongji University), College of Architecture and Urban Planning, Ministry of Education, Tongji University, Shanghai, P.R. China*

**ABSTRACT:** International Solar Decathlon (Solar Decathlon, SD) was launched, and hosted by the United States Department of Energy, for universities globally that have an interest in participating in solar building technology competitions. With the technology and originality of the world's top research and design team, goals of the solar energy and energy savings are combined closely with architectural design. This incorporates new methods of design and building to run a fully functional, comfortable, livable, and sustainable solar house. During the competition, solar power alone must provide the energy needed for the solar house. The competition will comprehensively assess each of the entries based on various aspects, including the energy conservation, architectural and environmental physics regulation, and quality of the produced solar energy. The competition determines the final ranking through ten key aspects; therefore it is called a “decathlon” competition.

**Keywords:** Solar Decathlon; building energy consumption; Tongji University works

### 1 SOLAR DECATHLON IN CHINA

#### 1.1 *Solar Decathlon introduced to China*

On January 18, 2011, China National Energy Bureau, Peking University, and The U.S. Department of Energy signed a cooperation agreement called the, “Solar Decathlon Memorandum of Understanding” in Washington, D.C. It introduced the world's highest level of solar application in China. On October 10, 2014, the competition's global launch ceremony in China was held.

The Solar Decathlon in China is the first Sino-US Energy Cooperation Program and included a U.S. visit by Chairman Hu Jintao.

The competition in China was jointly organized by China National Energy Bureau and the United States Department of Energy, contracted by Peking University.

Currently, energy use has become increasingly important and a topic of international affairs. The goal is to reduce and end dependence on high-emission energy resources. It has become an urgent issue of the people, asking the government to provide alternatives to the current unsustainable and contaminating options. The goal of the Solar Decathlon in China is to solidify attention on the promotion of the new energy technology and encourage social responsibility for energy conservation.

#### 1.2 *Influences of the Solar Decathlon in China*

The solar powered building will be an important direction of development for the future in our country, being that the total size of building stock is 44 billion square meters, with two billion new square meters per year. This development is where there exists huge building energy consumption and ecological problems. Participating in the competition not only relates to innovations in domestic construction, but also works to improve public consciousness, both of which are critical for a change in current consumption.

#### 1.3 *Five objective of introduction of Solar Decathlon in China*

**Education:** The application of renewable energy in construction and the important role that new energy plays in future life, college students are motivated to participate in this challenge, in order to put the technological innovations to practical use.

**Public awareness:** as an international competition, the Solar Decathlon has attracted research teams from around the world to participate and is also open to audiences around the world. The entries are lined up for the competition, using realistic living conditions to directly reflect the energy saving technology and the reduction of environmental impact. This method allows for the

public and judges to directly see and understand renewable energy sources, the implementation of the latest energy-saving technology and the individual designs, which encourages awareness of consumption and importance of sustainable development.

**Promote new solar technology market process:** By showing the entry designs for this competition, interest and public understanding of solar energy can be greatly improved. For the entries, the design teams innovatively use industrial construction and solar technologies closely, which integrates the two with architecture design. These innovative technologies include solar photovoltaic technology (independent/micro network technology and network systems), solar thermal cooling, and indoor physical environment of intelligent control.

**Conservation and utilization of water resources:** The application of new technologies and materials, as well as household appliances, solar energy technology research and integration, involve a number of new water-efficient technologies.

**Promotion of solar residential outcomes:** Present a living pattern that contains comfort, appeal and functionality, which satisfies the sustainable development and creates profitable market potential for the future.

## 2 CHINA'S ATTENTION TO THE SOLAR DECATHLON

On January 19, 2011, Chairman Hu Jintao signed the first Sino-US Energy Cooperation Program called, "Solar Decathlon" in China, with the state visit. Hu Jintao met with the U.S. President, Barak Obama, at the White House, specifically to meet regarding the matter. The two leaders showed a high degree of attention and support for the competition. Dozens of Chinese and foreign media such as Economy, China Daily, China Youth Daily, People's Daily, Xinhua, Sina, Sohu, Netease, the White House press, the financial community, HC, Xinmin, Qianlong, the International Energy Network, the China Energy Information Network, reported that "Peking University will host the international Solar Decathlon".

## 3 TEN STANDARD'S OF THE COMPETITION

The competition requirements include the global universities participating to design and construct solar, energy-saving homes that's energy usage can solely be supplied by solar power equipment.

The competition selected 10 aspects of solar power use and efficiency, and through professional

analysis, the final ranking score is determined. The comprehensive assessment is of each entry's energy-saving technology, building physics, environmental regulation and the ability of energy efficiency. This solar power competition is called a "decathlon" competition because of the ten indicators of the assessment. The Solar Decathlon is also called, "solar session of the Olympic Games" due to the introduction of solar technology.

## 4 ENTRY PROCESS

The organizing committee will send the invitation to the universities world-wide. After review, the top 20 University entries are selected for the Solar Decathlon competition finals. Competition requires each participating University to design and construct a 60 square meters to 92 square meters solar energy powered house. The final step of the competition is to move entries to designated locations (successive games were held at the National Mall in Washington America) after assembling construction. After comprehensive evaluations, the entries will be displayed to the public.

Every solar building that participates should meet the daily requirements of a household. This includes use of a complete set of household appliances, furniture and other basic living facilities, such as TV, refrigerator, cooking stove, dishwasher, washing machine and computer. In the competition evaluation period of one week, the organizers will cut off the outside water, and electricity supply. The solar buildings should not only meet the energy consumption, indoor temperature, humidity and comfortable environment that 3 to 6 participating students need to live, but also supply enough energy for dinners for 8, when students invite other international students into the buildings.

## 5 CASE ANALYSIS—TONGJI UNIVERSITY

### 5.1 *China 2010: Solar Bamboo House*

In June 17, 2010, an entry, "Solar Bamboo House", by the team from Tongji University, was submitted for the "Solar Decathlon" for a period of ten days in the Spanish capital Madrid, at the Manzanares River East Bank. The "Solar Bamboo House", with an area of 74 square meters, was a green ecological house. The external facade of the house was composed of bamboo. Indoor flooring, wall decoration, and furniture were also mostly made up with the bamboo as well. A solar photovoltaic system was used in the bamboo house, completing the "solar power" requirement of the competition. The bamboo house used the original ecological architectural style of southern China. The anti-sky

roof structure of classical Chinese architecture was adopted, to maximize power generation efficiency of the photovoltaic panels and ensure ventilation. The Bamboo House integrates a number of energy-saving technologies and systems, including passive and active energy-saving technology in order to achieve an efficient use and management of energy and hydropower required by normal life inside the house. The high-performance vacuum insulation panels, or VIPs, were installed inside the Bamboo House, and phase change materials were applied on the interior wall to maintain the indoor temperature. The wall's interlayer of the phase change material adjusts the room temperature by storing heat and coolness from the day and night. The highest level of vacuum insulation and hollow triple glazing were adopted in the design of the windows, which helps heat insulation performance 4 times that of the ordinary window. The roof of the Bamboo House was covered with solar photovoltaic modules, with cooling and heat recovery equipments set up on the back. These equipments could not only recycle heat, but also ensure the high efficiency of power generation.

### 5.2 2011: Sunshine container house

In the Solar Decathlon held in late September in Washington, the entry from Tongji University was

Figure 1. "Solar Bamboo House"  
(Source: [http://info.bamboo.cn/detail\\_26026\\_1.html](http://info.bamboo.cn/detail_26026_1.html)).

Figure 2. "Y type container"  
(Source: <http://blog.ifeng.com/article/14194380.html>).

a "Y type container". It was composed of 6 shipping containers, from Shanghai's port, that are convenient for movement, economical and comfortable in size. The Sunshine Container House was built to be a Y-shaped structure composed of 3 containers, and the intersection angle of two adjacent containers was 120 degrees, providing a greater perspective. A container was hollowed out as the room, which could be divided into two small rooms by clapboard. In order to connect the indoor and outdoor, the wall can be folded. The terrace is not only useful to have social activities, but it also can collect and store rainwater. The rainwater was then used after filtration. Large windows and glass doors out from the platform allowed light into the house, making it a modern, fully functioning apartment. The "Y type container" was able to become two small bedrooms using clapboard at night, while in the day the bed could be folded up and pushed into the cupboard. A triangle bench was used to be assembled into many different forms of furniture.

### 5.3 2012: Para Eco-House

In 2012, the Solar Decathlon competition was held in Madrid, Spain. Tongji University participated in the competition with a solar house named "Para Eco-House". The entry combined indoor and outdoor architectural spaces with ecological technology. "Para Eco-House" was covered with a diamond mesh that interleaved with the body of the house and stretched across roof supporting the solar photovoltaic power generation tracking system on the roof. The three-dimensional greenery hanging down on the west side of the house was embedded into a thin-film photovoltaic module. It combines solar energy, ventilation and shading as a whole, constituting a gray outdoor space that adjusted the outdoor microclimate. The tacit understanding of construction technology was shown in the use of the solar energy. The parametric method was integrated in the logical language

of architectural design. The integration of passive and active energy saving technology was achieved in the ecological strategy.

This entry made full use of the competition site conditions and many ecological technologies, such as a mono crystal line silicon PV system installed on the roof of Eco-House that could automatically track solar elevation angle, thin film photovoltaic system with good and weak light, high efficient solar flat plate collectors cooperated with the house, PVT system, water source heat pump air-conditioning system that used diurnal temperature to save and release heat, drip irrigation system that recycled water and made wastewater treatment, outdoor spray evaporative cooling system, building shade system, patio hot-pressing ventilation system, VIP high-performance insulation, heat and moisture individually controlled air-conditioning systems, intelligent home energy information system and LED lighting.

## 6 CONCLUSIONS

The Solar Decathlon provides a platform for students to understand the application and impact of sustainability and energy saving technology. It allows them to participate directly against competition from around the world and teaches skills to become global leaders. Through the publicity of the competition and displays of functional living in solar buildings, it provides an opportunity to improve the understanding of solar technology and energy-saving products for the public, and also raises awareness of reducing consumption to allow for environmental protection. Furthermore, the regional development of strategic emerging industries is promoted. Solar Decathlon competitions around the world are a great platform to drive governments, universities, businesses and non-profit organizations to communicate and cooperate to achieve future sustainable goals.

# The ecological restoration of building landfill and garbage landfill

J.N. Yang, H.Y. Li & L.Y. Lv

*College of Environmental Science and Engineering, Nankai University, Tianjin, China*

**ABSTRACT:** The study on the ecological restoration of landfills has gradually become a hotspot in recent years. The ecological restoration project of garbage landfill in Tangshan South Lake and of building landfill in Tianjin Nancuiping has been proved to be successful. Taking the two successful experiences as examples, we describe the technologies and processes of ecological restoration of the two types of landfills systematically, in order to provide reference for the ecological restoration of other landfills.

**Keywords:** building landfill; garbage landfill; ecological restoration

## 1 INTRODUCTION

A lot of wastes are generated in the process of industrialization and urbanization, which mainly includes industrial waste and city garbage [Yang & Wang 2010]. The three main techniques are landfill, waste incineration, and recycling [Li & Ju 2005]. Landfill is an important component of the solid waste treatment system because of its obvious advantages, such as small investment, high yield and convenient operation [Huang 2003]. However, landfills take up large areas of land in order to meet the capacity and service time. At the same time, landfills affect the surrounding water environment, soil environment, atmospheric environment and ecological system. What's more, landfills can produce acute and chronic damage to surrounding residents, causing a series of diseases. How to control environment pollutions and renovate the ecological environment of landfills is a urgent and outstanding problems in the field of environmental protection [Peng et al. 2002].

Ecological restoration of landfills can bring many benefits. On the one hand, it will reduce the pressure on the ecological environment. On the other hand, it can restore the use value of land. There are three types of land that a landfill site can reform: agricultural land, forest land and land for public entertainment [Yang 2009]. Agricultural land is an ideal landscape that can bring economic benefits and is easily accepted by local residents. However, its restoration project costs are high, and the high management cost is also a problem. Forest land meets the guidelines of urban planning and construction, and it has the potential value of tourism development and business development. Nevertheless, adapting to the use of urban residents is different for forest land. Comparatively, land for

public entertainment meets the requirement of urbanization more than others. It can provide large areas for public activity. It can meet other purposes including nature protection and forestry development at the same time, achieving double harvest of ecological benefits and social benefits. Many practices have been reported abroad. La Vallde'n Joan Park was a typical waste landfill field in valley before ecological engineering [Battle 2006]. Byxbee Park in George Hargreaves built in 1991 was built at a landfill with 18 meters high [Wang & Lin 2002]. Fresh Kills Park, which is about three times the size of Central Park in New York, was the Fresh Kills Landfill before ecological engineering [Yu & Ding 2006]. Korea built golf courses and World Cup Park in the landfill sites [Chen et al. 2013]. Seattle Gasworks Park set up in the landfill site, which was piled with trash and scrap [Chen et al. 2013]. The above examples are successful ecological restoration of landfills.

For garbage landfills, the effects of landfill gas on plant growth should not be neglected, and landfill leachate is good to plant growth because it has higher amounts of organic components [Li & Ju 2005]. However, building landfills are different, kinds of pollutants and concentration of landfill leachate are less, and there is scarcely any landfill gas in a building landfill [Yuan et al. 2006]. Based on the differences between building landfill and garbage landfill, the method of ecological restoration of the two types of landfill is different. In this paper, we take the garbage landfill in Tangshan South Lake and the building landfill in Tianjin Nancuiping as examples, the technologies and processes of ecological restoration of the two types of landfills are described systematically, and thus hope to provide reference for ecological restoration of the two types of landfills.

## 2 GARBAGE LANDFILL IN TANGSHAN SOUTH LAKE

### 2.1 *Background*

Tangshan South Lake landfill was located in the south suburb of Tangshan, covering an area of 9.8 hm<sup>2</sup>. The total landfilled mass was 4.5 million tons, forming a garbage mountain about 50 meters high. The garbage mountain damaged the appearance or environment of Tangshan. What's more, landfills produced acute and chronic damage to the surrounding residents, causing a series of diseases [Zhou 2012]. The ecological recovery project of Tangshan South Lake landfill was completed in April 2009, with 110,400 trees and shrubs planted. The whole mountain greening area achieved 130 thousand square meters after the project [Wang & Li 2009]. The garbage mountain that was once avoided by everyone in the past has now turned into a "phoenix platform", which is the symbol landscape of the South Lake area.

### 2.2 *Recovery process*

#### 2.2.1 *Leachate control system*

Before the recovery, we changed the shape of the garbage mountain with 1:3 slopes. Then, we laid a blind ditch of 2360 meters length along the retaining wall back to collect leachate. Landfill leachate is a kind of liquid containing a high concentration of suspended substances and a high concentration of organic and inorganic compounds. Landfill leachate is produced from soluble substances, rainwater and surface water percolating through the waste. It is formed by the biochemical and chemical degradation processes of the waste [Liu et al. 2006]. The leachate backfilling area was laid 11 double row tubes. Then, leachate was transported to adjust the pool for disposal. There were 35 leachate junction wells in the leachate control system.

#### 2.2.2 *Landfill gas control system*

Organic matter in landfills could be degraded by facultative and specificity of microorganisms, producing landfill gas. Landfill gas contains a lot of CH<sub>4</sub> and CO<sub>2</sub> and other trace elements. If a large amount of landfill gas accumulated within the soil, the growth of vegetation will be affected seriously and even results in an explosion. There were 24 wells for gas collection at the top of the slope and at the 28 meter-elevated platform. We laid blind ditches at other areas to collect horizontal gas. The landfill gas was then funneled to a torch burning furnace for combustion.

#### 2.2.3 *Surface covering*

According to the design, we laid geotechnical cloth, geomembrane, composite geotechnical grid

and geosynthetic at the garbage mountain that shaped according to order from top to bottom and side to bottom. We covered with clay of 30 centimeters thickness, and then with compact clay by a large crawler machine in order to prevent rain-water infiltration. We also covered planting soil of 50 centimeters thickness to provide a good growing environment for the subsequent recovery of vegetation. When the waste rots, it will emit flammable gases and make the soil alkali-affected, leading to difficulty in vegetation survival, so soil amelioration is necessary. We added organic manure and peat soil to the planting soil, resulting in three planting soils for every one organic manure and every one peat soil. Then, we stirred them well and covered them. The soil disposed was rich in N, P, K and other nutrients, and air permeability and water permeability were also good, which are characteristics that are beneficial to the plant growth.

#### 2.2.4 *Vegetation recovery*

A total of 57 kinds of plant species, which were tolerant to drought, poor soil and strong wind, were selected, including 6 species of evergreen trees, 10 species of deciduous trees, 24 species of shrubs and 17 species of ground covers and flowers. We planted these plants with a dense mixture. Considering the land use of landfill after restoration, we planted pioneer plants, constructive plants and auxiliary fertilizer plants with rational coordination to speed up the formation of a stable plant community. Planting trees with grass and shrubs is good to the formation of the plant community. According to the different slopes of the mountain, we selected adaptive species to shape and adjust the slope. The engineering measures can help the formation of the terrain to a certain extent, while the plants planted on the mountain can shape the natural terrain. Plants can guide the mountain runoff in the right direction and form a good microclimate in some part of the area.

## 3 BUILDING LANDFILL IN TIANJIN NANCUIPING

### 3.1 *Background*

Nancuiping Park is located in the south-west of Tianjin, adjacent to the water park. It was a building landfill before the ecological recovery project, which piled up waste including project dregs, mass concrete and harmless industrial waste, totaling 3.2 million cubic meters. Nancuiping Park is the product of ecological restoration of the building landfill. There have been more than 6 thousand tourists per day and about 90 delegates per year who visit the Nancuiping Park since it opened

in 2009. Nancuijing Park has become a bright business card of Tianjin [Chen et al. 2013].

### 3.2 Recovery process

#### 3.2.1 Earthwork

Earthworks included cleaning mud, digging lakes, transporting muck, shaping mountain and covering planting soil. The original topography is fish pond, with the thickness of the mud layer being 7 to 9 meters, which affected the project of piling up hill. So all the silt particles were removed and filled by muck layered to ensure the stability of the mountain.

#### 3.2.2 Covering soil and greening

We covered the planting soil with a thickness of 1.2 to 1.5 meters after the formation of the mountain. The planting soil covered is about 190 thousand cubic meters, and the green area is about 210 thousand square meters. The ground is mainly covered with the ryegrass (*Lolium perenne*), with all slopes covered with the buffalograss (*Buchloedactyloides*) as well as with the wild *Zoysia* (*Zoysia japonica*). Native tree species were mainly planted at the park based on the climate and environment in Tianjin.

#### 3.2.3 Irrigation system

Every plant was equipped with an automatic water-saving irrigation equipment, which was an internationally leading one and adjusted to local conditions. The use of the automatic irrigation equipment compared with artificial water-saving fuel consumed electricity by 60% and water saved by 60%, so labor costs was lowered and irrigation efficiency was improved. Precise irrigation was good to the formation of wet microclimate, which improved the survival rate of plants greatly.

#### 3.2.4 Ecological landscape design

The government of the city of Tianjin carried out a new round of comprehensive environmental control in 2008, and Nancuijing Park was in the list. According to the principle of layout optimization, space connection and function improvement, the park was divided into two parts, which were further subdivided into six landscapes. The six landscapes include the lotus area, big lake area and tortuous channel area in the lake landscape, and grass area, trees area and flowers area in the mountain landscape.

The lake landscape has a changeable waterfront space by making the space open or closed. Both the mirror of water and the twists and turns of the river were included. In a word, the lake landscape's style ranged widely. Accessibility, hydrophilicity, and security were emphasized in the details of the treatment. For example, the revetment of

high straight rubble was replaced by low natural stone and hydrophilic terraced revetment. We set the shallow water in nearshore, and planted a large number of local hygrophilous plants in the shallow water, forming a wetland landscape with distinctive local characteristics. The wetland vegetables played an important role in softening the rigid retaining wall and guaranteeing the safety of tourists. The mountain landscape emphasized the diversity of the plant landscape. The large areas of landscape forest are the main component of the mountain landscape. We planted trees with grass and shrubs. Evergreen trees and deciduous trees were planted in a mixed pattern, which formed a stratified plant community. According to the difference in terrain and orientation at different positions of the mountain, we selected different accent plants, forming a series of characteristic plant landscapes, which included flowering shrubbery, colorized shrubbery, evergreen coniferous forest and gentle slope lawn.

## 4 CONCLUSION

The ecological restoration of a landfill provides a long-term strategy based on the natural evolution and the plant's life cycle. It uses ecological engineering that is mainly based on the interaction between the plant and the soil and the microorganism to deal with waste and to improve the soil. The ultimate aim is to restore and build a virtuous circle ecological environment that is close to the natural environment [Wang & Li 2009]. In this paper, we have taken the garbage landfill in Tangshan South Lake and the building landfill in Tianjin Nancuijing as examples, and the technologies and processes of ecological restoration of the two types of landfills have been described systematically. The following points can be used for reference.

Special attention should be paid to landfill gas control and landfill leachate control. In the process of ecological restoration of garbage landfill in Tangshan South Lake, special research on landfill leachate contamination and landfill gas was carried out. We laid pipelines to collect and transport leachate and landfill gas, and also built leachate equalization basins to treat leachate together. The landfill gas was funneled to a torch-burning furnace for combustion. Measures were also taken to control leachate and gas in the process of ecological restoration of building landfill in Tianjin Nancuijing.

Special attention should also be paid to the land subsidence caused by the degradation of waste, whether in building landfill or in garbage landfill. Some measures were taken to maintain the stability of the mountain for the garbage landfill in Tangshan South Lake, changing the shape of the

garbage mountain with 1:3 slopes and building security platform and retaining wall were included. For the building landfill in Tianjin Nancuiping, all the silt particles were removed and filled by muck layered to ensure the stability of the mountain.

Plants growing in landfills will face many serious environmental stresses, which include landfill gas, landfill leachate and high temperature, drought and poor environment of the final layer. So, it is important to select tolerant species. There were some species selected to be planted in the two types of landfill because of their characteristics of drought resistance, shallow root and stain resistance.

# The key technologies of ecological restoration of sanitary landfill

J.N. Yang, H.Y. Li & L.Y. Lv

College of Environmental Science and Engineering, Nankai University, Tianjin, China

**ABSTRACT:** With the growing urbanization, the city rubbish is also growing, and consequently its effect on the environment and the ecological restoration of sanitary landfill have become major social problems. There are many different practices at home and abroad. In this paper, with the clue of process, we commented on the key technologies of ecological restoration of sanitary landfill, hoping to provide reference for ecological restoration of sanitary landfill.

**Keywords:** sanitary landfill; ecological restoration; key technologies

## 1 INTRODUCTION

Urban domestic waste is solid waste produced by people's daily life activities, turning out with the city and soaring emissions in the process of urbanization, and currently our cities are facing the predicament of being surrounded by waste [Yang & Wang 2010]. According to information statistics, the annual per-capita output of urban waste extends to 440 kilograms. In 2010, the amount of urban waste was reported to be 3.52 billion tons in China, ranking the first in the world, and is growing 8% to 10% per year. The four main techniques for the disposal of rubbish include landfill, waste incineration, high-temperature composting and recycling. Landfill becomes an important component of the solid waste treatment system because of its obvious advantages, such as small investment, high yield and convenient operation [Li 2005, Liu 2007]. It has been found that nearly 95% of the world's urban domestic waste is buried [Wang 2011]. On the other hand, landfills also lead to many problems. They take up large areas of land in order to meet the capacity and service time. At the same time, landfills affect the surrounding water environment, soil environment, atmospheric environment and ecological system. What's more, landfills will produce acute and chronic damage to the surrounding residents, causing a series of diseases [Zhou 2012]. How to control environment pollutions and recover the ecologic environment of landfills is an urgent and outstanding problems in the field of environmental protection at home and abroad with people's continuous improvement of environmental awareness [Cao 2010, Kwon & Gary 2010, Mutasem et al. 1997, Zhao et al. 2012]. In this paper, with the clue of process, we commented on the key technologies of ecological restoration

of sanitary landfill, hoping to provide future reference for ecological restoration of sanitary landfill.

## 2 POLLUTION CONTROL

### 2.1 Landfill leachate control

Landfill leachate is a kind of liquid containing a high concentration of suspended substances and a high concentration of organic and inorganic compounds. Landfill leachate is produced from soluble substances, rainwater and surface water percolating through the waste. It is formed by the biochemical and chemical degradation processes of the waste [Liu et al. 2006]. In order to prevent the vertical infiltration of leachate, anti-leakage lining is necessary. There are many materials for the impermeable layer. It can be a single clay layer with the permeability coefficient of less than  $10^{-7}$  cm/s and the thickness of at least 1 meter. It also can be a composite liner, which is made by laying an elastic anti-seepage film on the clay layer [Cui 2005]. Generally, we need to lay a blind ditch or a perforated pipe to collect and guide leachate. The pipe's slope to the sump or sewage adjust the pool with more than 40-percent slopes. The main methods to dispose leachate both at home and abroad include dispose leachate and urban wastewater together (outside field), separately *in situ* dispose, and pre-dispose-merged dispose (both inside and outside landfills). It is better to combine the leachate dispose with urban sewage treatment. We can discharge leachate into a sewer system after the *in situ* dispose, and then introduce leachate to municipal sewage treatment plants.

## 2.2 Landfill gas control

Organic matter in landfills could be degraded by facultative and specificity of microorganisms, producing landfill gas. Landfill gas contains a lot of CH<sub>4</sub> and CO<sub>2</sub> and other trace elements. If a large amount of landfill gases accumulated within the soil, the growth of vegetation will be affected seriously and even result in an explosion. So, it is necessary to collect and dispose landfill gas for the safety of landfill and the smooth progress of vegetation restoration. There are two methods to collect landfill gas: sealing method and air-permeable method [Cheng 2009]. Sealing method is the method with no permeability barrier and gas only passes through the top cover, or use the wall to prevent air from flowing. The bottom or the side wall of the landfill with a thickness of 0.5–1.2 meters can be made with compacted clay holding certain moisture, in order to prevent air that escapes from the bottom or side wall. We can also use a thin film made of synthetic materials to cover the bottom or side wall in order to prevent air and protect the groundwater from polluting. Air-permeable method is a method that uses the pebble channel or the groove filling pebble to guide and collect landfill gas. We can set ventilation tubes at the top of the garbage and set branch pipes within the shallow gravel channel, and then connect the branch pipes with vertical ventilation tubes. We can also arrange access shafts evenly in the site, so that the access shafts will both collect vertical landfill leachate and permit a free passage of air. Landfill gas is a kind of precious energy. Only rational utilization can make the landfill gas contribute to humans. The following are the main utilization ways of landfill gas control: electricity generation, used as a civil gas, used for a compressed natural gas and used as a boiler fuel [Gong 2006].

## 2.3 Surface covering

Surface covering for ecological restoration in landfills is a technology that includes both the selection of proper covering materials and the design of effective and reasonable cover thickness and shape. It tends to meet the goals of preventing the escape of landfill gas and decreasing the concentration of landfill leachate. Using surface covering, we can construct an artificial ecosystem, which is mainly vegetation, and make the recovered land for other uses [Peng et al. 2002]. Landfill covering layers can be mainly divided into two parts. One is for ecological restoration, the other is for drainage and seepage control, which is made up of drainage layer, venting layer, seepage control layer (protective layer is included) and base layer. The ecological restoration part includes

nutritive layer and vegetable layer. It can beautify the surroundings and reduce soil erosion, which is good to collect and guide surface runoff. Drainage layer is made up of sand or soil materials with a larger permeability coefficient (generally more than 10<sup>-4</sup> cm/s). It can collect rainwater and avoid the anti-seepage layer in direct contact with the ecological restoration part, which can protect the anti-seepage layer by preventing plant roots from intruding into the anti-seepage layer [Chen 2013]. The anti-seepage layer material usually includes a high-density polyethylene film, geosynthetic clay liner and clay. It can keep rain from penetrating into the rubbish material, and also prevent the landfill gas diffusion through soil porosity. Base layer has the effect of support and stability on the whole cover. Its cover material include soil, gravel, and even some hard solid waste, such as construction waste. The surface covering materials of a city landfill in the ecological restoration project mainly depend on both input costs and output benefits of ecological restoration; at the same time, the surface covering materials vary between the landfill site and the restoration project.

# 3 VEGETATION RESTORATION

## 3.1 Soil amelioration

During the rotting of waste, flammable gases are emitted and make the soil alkali-affected, leading to difficulty in vegetation survival, so soil amelioration is necessary. For soil amelioration, green manure or organic fertilizer is mainly used to increase organic matter content and improve the soil's physical and chemical characteristics. In the place where landfill gas is relatively small, a significant negative correlation was observed between the content of mineral nitrogen and the quality of dry matter of vegetation. It proves that it is necessary to apply nitrogen fertilizer in landfill. Organic substances can stimulate the growth of plants obviously, so some compost is useful [Chang 2008]. Loosening the final soil appropriately improves the soil's physical characteristics because the final soil compressed by the device frequently during construction restricts the growth of plant roots severely. In the process of ecological restoration of garbage landfill in Tangshan South Lake, we added organic manure and peat soil to the planting soil, resulting in three planting soils for every one organic manure and every one peat soil. Then, we stirred them well and covered them. The soil disposed was rich in N, P, K and other nutrients, and air permeability and water permeability were also good, which are the characteristics that are beneficial to the plant growth [Li 2010]. In the

process of ecological restoration of garbage landfill in Wenzhou Yangfushan, nitrogen fertilizer and compost fertilizer were applied to improve soil fertility, and humus soil sieved out from the garbage was also used. At the same time, loosening the final soil appropriately also had a positive effect on the improvement of soil fertility [Han et al. 2008].

### 3.2 *Vegetable selection*

Plants growing in landfill will face many serious environmental stresses, which include landfill gas, landfill leachate and high temperature, drought and poor environment of the final layer. So, it is important to select tolerant species. The basic principle of selecting plants is that the species must be able to endure the stress from landfill gas and landfill leachate and have a stronger tolerance to drought. There are two main different ways of selecting suitable species. One way is to select through the planting experiment. Guo et al carried out a planting experiment at Dongtan Lake landfill, Jiaozhou Bay, Qingdao, Shandong, screening several plants that have good resistance [Guo et al. 1994]. The other way is to select through vegetation investigation in landfill. Ji et al investigated the vegetation of a landfill site in Shenyang closed for 2 years, recommending six plant species that were suitable for ecological restoration of landfill [Ji 2005]. Summarizing different plant species planted in different landfills reported by different researchers is helpful to select suitable plant species for the ecological restoration of landfill. However, the selected species cannot always be employed universally, because there are many differences in the background of landfill. We must combine only with the particular local case.

### 3.3 *Vegetation reconstruction process*

At the beginning of vegetation reconstruction, we can plant some herbs, because herbs have developed roots that can improve the soil and create conditions for the growth of other plants including trees and bushes. After that, we should plant some trees that grow slowly, are small, have shallow roots and are not susceptible to pests to improve the single herb plant landscape. Trees can also accelerate soil improvement. At the same time, trees can create better conditions for the growth of other plants because they can intercept rain water and reduce leachate through absorption and transpiration. In the middle and the development phase, combined with ecological planning and development planning, we need to plant trees with grass and shrubs on a large scale according to the different functional regionalization and green design.

## 4 ENVIRONMENTAL MONITORING

The process of ecological restoration of landfill is long term and dynamic, so environmental monitoring must be done on a continuous basis during the end-to-end process [Han et al. 2013]. The main inspection factors include landfill gas, leachate and plants. In the process of ecological restoration of Shenzhen Guoqiao landfill, we laid many monitoring wells from upstream to downstream. The samples were taken regularly to monitor the migration of landfill gas and leachate, guaranteeing the minimum pollution to the environment after closure [Guo & Zheng 2004]. The vegetation system established at the initial stage is always unstable, so it is necessary to monitor the plant growth. A scientific way of maintenance is very important. We need to adjust the species composition and community structure of green vegetation constantly. At the same time, we should cultivate the plants' power of self-renewal.

## 5 CONCLUSION

In this paper, with the clue of process, we commented on the key technologies of ecological restoration of sanitary landfill systematically from two aspects, namely pollution control and vegetation restoration, hoping to provide reference for ecological restoration of sanitary landfill. At the beginning of ecological restoration, a scientific and reasonable planning and design is necessary, and we need to attach importance to pollution control and utilization of rehabilitation land. It is better to determine the ultimate way of land use in the future before the construction or close of landfill. We should study the critical factors for ecological restoration of sanitary landfill, such as landfill stability, harmful gases and leachate, the nature of the final soil and the selection of plant species. During and after ecological restoration, environmental monitoring must be done on a continuous basis. During ecological restoration, environmental monitoring can help managers and decision-makers to know the degree to which the ecosystem is restored and whether ecological restoration is effective or not. Environmental monitoring after ecological restoration is important for the evaluation of the ecological recovery technique.

# Experimental verification and pair-group analysis study of passive space design strategies

Junjie Li & Yehao Song

*School of Architecture, Tsinghua University, Beijing, P.R. China*

*State Key Laboratory of Subtropical Building Science, South China University of Technology, P.R. China*

Qingguo Wang

*China Design and Research Group, China*

**ABSTRACT:** Passive design has widely been identified as one of the most economical and effective strategies for reducing energy demand. However, the employment of passive design strategies is often based primarily on experience that often lack long-term effective validation data to prove or disprove their effectiveness. This research is based on the physical surveillance, and has adopted physical environment fieldwork test and data analysis methods to evaluate the effectiveness of passive space design strategies and their influence on the main body spaces. The two selected experiment platforms shared various commonalities such as climate environment, layout, structure, designers, construction time, etc., which offered numerous opportunities for parallel comparisons. Therefore, this research adopted a pair-group analysis method to isolate and analyze a single variable through one-year monitoring of one typical passive spaces (a sunlight space) to verify the effectiveness. The experiment tested several physical parameters such as temperature, humidity, wind speed, CO<sub>2</sub> concentration index in winter, summer and trans-seasons, and analyzed the impacts of the passive space on the entire building. This test research also incorporates the results of the quantified data regarding the impact levels of the passive spaces and summarizes its advantages and disadvantages, and provides suggestions regarding possible improvements. The research results indicate that passive space design strategies need to balance the entire year's climate characteristics, and consider matching technologies with technical strategies that approach design problems from both the environment and the human comfort perspectives.

**Keywords:** passive design; building space; pair-group analysis; field work test

## 1 INTRODUCTION

The lack of quantitative research on passive strategies was one of the bottlenecks faced by this present study [1–3]. Current evaluations of sustainable building designs only consider whether or not they are involved in environmental factors, use the regulating function of passive space, or employ new types of thermal insulation materials or construction details. Consequently, the existing body of research is insufficient, and needs to provide answers to questions such as: how might these designs be optimized by the use of technology-based strategies? To what extent might such strategies provide further optimization? And, how should architects go about such optimizations? With the majority of scholarly attention being focused on sustainable concepts and green buildings in recent years, building design needs to proceed beyond the fuzzy qualitative research stage and on to the precise quantitative research stage [4–5].

## 2 EXPERIMENTAL PLATFORM

### 2.1 Platform 1: O-house at Tsinghua University

The O-house is an experimental building designed by a Tsinghua University research team; it took three years to design, construct, and monitor. It is a net-zero house that relies completely on solar energy to supply its energy consumption [6]. To achieve net-zero energy consumption, works on the inflow and outflow of energy were both necessary. A ground floor plan plays an important role in the reduction of a building's energy dissipation. In a building functioning as a house, spaces that are the most often used and user-related should be optimized for physical comfort as much as possible. The O-house is based on a principle of passive priority. The most cardinal and comfort-demanding space is at its very center, and three layers of space encircle this core. The micro-environment transitions from outside layer to inner layer. (as shown in Fig. 1).

Figure 1. Passive strategy for three layers of spaces.

Figure 2. Plan of Waterfowl Pavilion.

## 2.2 Platform 2: Waterfowl Pavilion in Beijing Zoo

The Waterfowl Pavilion is located inside of the Beijing Zoo which has a superior natural environment, and vegetation coverage of more than 90% [7]. On the south side of the site, there is a large wetland area used as a bird habitat. To avoid destroying the building’s ecological status and to provide a natural and livable environment for the birds, this project aims to build a net-zero energy demonstration building that intricately combines green and low carbon concepts. There are two domain spaces in the Waterfowl Pavilion, each based on a different design target. One is an open space used as a bird habitat. To better coordinate with the natural environment and ensure that the birds’ living space allows for sufficient sunshine, the birdhouse is located on the southernmost point of the building. The second domain space is related to people’s needs, rather than birds’ needs. This space includes an exhibition hall, meeting rooms, service rooms, etc. Therefore, after considering the relationship between the building’s shape factors and functional organization, the building envelope was formed into two layers of nested spaces [8] (as shown in Fig. 2).

## 2.3 Platform 1 vs. platform 2

The two experimental platforms’ building information is compared below (as shown in Table 1). The two buildings were built during the same time

Table 1. Building information comparison between the two experimental platforms.

	O-house	Waterfowl Pavilion

	Dec 2013 –Jan 2014	Apr–May 2014	June–July 2014	Dec 2014 –Jan 2015
	Winter	Trans-season	Summer	Winter
Platform one	Air temperature	PMV, air temperature and humidity, wind speed, black ball radiation temperature	PMV, air temperature and humidity, wind speed, black ball radiation temperature, lighting	PMV, air temperature and humidity, wind speed, black ball radiation temperature, lighting
Platform two	Air temperature	Air temperature	Air temperature and humidity, CO2 concentration, lighting, wind speed	Air temperature and humidity, CO2 concentration, lighting, wind speed

period, designed by the same design group, adopted the same building structures, and are located in the same climate zone and almost identical surrounding environments. Moreover, they have the same topological relationships and spatial layouts that the core spaces are surrounded by functional space to the east, north, and west sides, in response to climate factors. Both of the two core spaces are large and without division. Both buildings' southern sides have large areas of glazing provided by the same manufacturer, and the window-to-wall ratios of the two are 0.6 and 0.52, respectively. One of space design differences between the two buildings is platform one (the O-house) has an extra layer of openable sunspace in the southern façade.

### 3 FIELDWORK TEST SCHEME

The two selected experiment platforms had various commonalities such as climate environment, layout, structure, designers, construction time, etc., which offered the possibility of parallel comparisons. Therefore, this research adopted a pair-group analysis method to make a comparison of the two the topic of this research. In order to test the effectiveness of passive space in different climate conditions over the course of an entire year, the test period had four separate phases. Together, the four phases lasted more than one year, from December of 2013 to January of 2015. (as shown in Table 2). To minimize the interference of other factors, the two buildings were not left open to active system equipment such as the air conditioning system, lighting, and other electrical equipment.

### 4 RESEARCH RESULTS AND ANALYSIS

The test points were located at the east and west doors in the southern façades of the two buildings,

Figure 3. Test temperature curve for platforms 1 and 2 in winter.

the sunspace of the O-house, and outdoors. The outermost layer of sunspace in the O-house was dark thin-film solar PV shutters were closed but not sealed during the test period. It was expected at the design stage that the sunspace would serve as a buffer, preheating the indoor spaces in cold winters and providing shading to reduce the indoor temperature during hot summers.

The test results indicated that there was a substantial gap between the actual test results after the building was constructed and the designer's subjective judgment during the design stage. The curve of the winter test results (as shown in Fig. 3) indicates that the sunspace was greatly influenced by outdoor temperature fluctuations. The mean temperature in the sunspace was just 0.9°C higher than the outdoor temperature during the winter test period, and the indoor temperature was only 1.6°C higher than the outdoor space. Conversely, in the Waterfowl Pavilion, the mean indoor and outdoor temperature differences reached 7.2°C and over 16°C between 12:00 pm and 5:00 pm (as shown in Table 3). The sunspace in the O-house experienced only a slightly greater preheating effect than it would have without the addition of this passive space. The reason for this very different result

Table 3. Average temperature in winter test results (unit: °C).

	Winter				Summer			
	$\bar{T}_{outdoor}$	$\bar{T}_{indoor}$	$\bar{T}_{sunspace}$	$\bar{T}_d$	$\bar{T}_{outdoor}$	$\bar{T}_{indoor}$	$\bar{T}_{sunspace}$	$\bar{T}_d$
P1	1.9	3.5	2.8	1.6	24.7	27.5	25.9	2.8
P2	1.9	9.1	—	7.2	27.9	28.9	—	1

between the built performance and the first design concept is that although the designer had a basic understanding of the sunspace’s preheating function in winter, in practice, due to the vertical layout demands of the photovoltaic panels on the southern facade, the solar spectrum of infrared light was resisted by the dark glazing blinds and generally did not penetrate into the sunspace. Moreover, air leakage and the lack of an up-and-down ventilation device in the PV blind panels were other factors worsening the cold air resistance and pre-heated warm air exchange.

The curve of the summer test results (as shown in Fig. 4) indicate that the temperature in the sunspace fluctuated greatly with the outdoor temperature. Although the highest temperature appeared in the outdoor space, the mean temperature in the sunspace was 1.2 °C higher than that of the outdoor space. The test results indicate that the thermal environment in the sunspace did not benefit from the envelope itself because the unsealed shading blinds on the southern façade offset the heat between the shading’s cooling and the solar radiation’s penetration. With a real-time thermal exchange in and out of the sunspace, the temperature remained almost the same. However, the test data obtained on the 5th of June showed that the sunspace provided a good shading effect to the interior space. The highest temperature occurred at 12:26 pm and reached 38.8°C. The temperature in the sunspace was 36.6°C, while the indoor temperature on both sides of the gate was only 29.2 °C and 29.9 °C, respectively, nearly 10 °C lower than the outside air temperature. The highest indoor temperature occurred at 5:00 pm, thus, the indoor temperature peak obviously lagged behind the outside air temperature. The indoor temperature stayed within a stable range for a long time, and had smaller swings than the outdoor variations.

Comparing these results to the temperature test curve of the Waterfowl Pavilion (as shown in Fig. 4), it can be seen that 90% of the stable temperature in summer conditions was a benefit provided by the passive strategy of the south side sunspace in the O-house. The indoor south side temperature curve in summer was almost synchronous with the outdoor space in the Waterfowl Pavilion, regardless of whether the openings were closed, the indoor and

Figure 4. Test temperature curve for platforms 1 and 2 in summer.

outdoor temperature changes were nearly simultaneous. On the one hand, these results demonstrate that with southern façades with similar window-to-wall ratios, the buffer and shading functions of the sunspace had a significant effect, reaching to a 10°C temperature difference between the indoors and outdoors. On the other hand, these results demonstrate that a large glazing area on the southern façade without shading can significantly increase indoor temperatures and cooling loads in summer weather conditions, even in a cold northern climate zone such as in China.

## 5 CONCLUSION

The research results yielded quantified data regarding the impact levels of the passive spaces, and allowed researchers to summarize their advantages and disadvantages and provide some possible improvements. The test results indicated the following conclusions with regards to sunspaces:

1. Don't just “pick up” passive strategies. Different from what was expected from the initial design concept, the passive strategy of using a sunspace in winter may have no effect on the cold air buffer and preheating effect in cases where there are issues of inappropriate glazing color, glazing air tightness, or ventilation measures between the sunspace and the interior space. Therefore, with regards to winter weather

conditions, a sunspace should not only be considered an easy “pick up” of one kind of passive strategy, but rather designers should strive to create cooperation within the design between the sunspace and the main space.

2. Maximize advantages. The O-house is an example of how the solar radiation can be blocked by an unsealed dark blind on the southern façade, in order to maintain better ventilation inside of the sunspace. The indoor temperature benefited from this design that the temperature was 10°C lower than it was in the outside space during the test period. The dual function of shading and providing natural ventilation in the buffer zone maximized these advantages during summer weather conditions.
3. Weigh the pros and cons. considering the climate conditions that occur throughout year, a designer should weigh the pros and cons regarding pursuing a preheating effect in the winter or shading and ventilation effects in the summer. Such decisions do not have to be either/or, but precise research and designs are required to achieve a “win-win” effect.
4. Pay attention to shading in the summer. Even in cold climates such as those experienced in northern China, large areas of south-facing glazed façades without shading devices may result in a sharp increase in the building’s cooling load in summer weather conditions. In addition, a well-designed buffer zone could perform significantly better than simple shading devices with regards to creating a shading effect.

# Research into the measurement detection and line optimization of the carbon capture ability of Italian poplars

Zhiguo Wang

*School of Physics and Electronic and Electrical Engineering, Huaiyin Normal University, Huaian, China*

Qing Liu

*School of Liberal Arts, Huaiyin Normal University, Huaian, China*

**ABSTRACT:** Carbon storage can offset more CO<sub>2</sub> emission, creating a broader space for Chinese economic development. By dynamically predicting the carbon sink function of such trees as Italian poplars, we can acquire a reference basis for working out the plan of industrial production and emission reduction. It is one of the important contents and the easiest approaches for China to develop low-carbon economy. This thesis introduces the development process and research tendency for the measurement detection and line optimization of the carbon capture ability of Italian poplars, and explores the measurement detection and line optimization measures and implementation paths of the carbon capture ability of Italian poplars, which can help to boost the construction of ecological civilization, enhance industrial level and achieve the concerted promotion of social and economic benefits.

**Keywords:** carbon capture; forestry carbon sink; measurement detection; line optimization

## 1 INTRODUCTION

Nowadays, people advocate developing low-carbon economy, which means the highly-efficient utilization of energy as well as the development and utilization of clean energy in essence. Low-carbon economy chiefly includes: saving energy, reducing emission; promoting the rate of energy utilization<sup>[1]</sup>; developing clean energy including renewable energy, nuclear energy and hydrogen energy; improving the structure of energy consumption; achieving the control of carbon emission; reducing the emission of CO<sub>2</sub> and its impact by building ecological carbon sink and developing the technology of carbon capture and utilization. Therefore, developing low-carbon economy requires the strong support of the technological innovation of energy-saving and emission reduction, clean energy and carbon capture and utilization.

## 2 RESEARCH BACKGROUND AND ACTUALITY OF THE MEASUREMENT DETECTION AND LINE OPTIMIZATION OF THE CARBON CAPTURE ABILITY OF ITALIAN POLARS

### 2.1 Research background

Carbon sink refers to the process of absorbing CO<sub>2</sub> in the air, chiefly referring to the ability of forests,

wetlands and oceans to absorb and store CO<sub>2</sub><sup>[2]</sup>. Ecological carbon sink refers to the ecological system which can effectively absorb CO<sub>2</sub>. Ecological carbon sink chiefly includes the ecological system of forests, wetlands and oceans. At present, the collection of CO<sub>2</sub> contains two aspects: the construction of ecological carbon sink and the technology of CO<sub>2</sub> capture. Since the global carbon programme was started in 2001, many countries worldwide have been dedicating themselves to relevant researches. With the clean development mechanism of Kyoto Protocol<sup>[3]</sup>, China has already set up several pilot projects, and has signed a contract of carbon emission reduction with a dozen developed countries worldwide. The pilot projects that have been carried out in China include: Inner Mongolian Carbon Sink Pilot Project, Guangxi Pilot Project<sup>[4]</sup>, Sichuan and Yunnan Carbon Sink Project, Zhejiang Carbon Sink Pilot Project and Beijing Carbon Sink Project.

### 2.2 Research actuality

The rapid development of carbon sink trade requires people to put forward the measurement methods of artificial forest carbon sink. So far, scholars worldwide have already carried out intensive research into the measurement methods of forest carbon sink, and have put forward the following two methods: 1) the method of counting

the existing biomass which reflects the cumulative amount of carbon which is closely related to biomass; 2) the method of measuring the CO<sub>2</sub> flux of forests by using microclimate theory and technology, and then converting the amount of CO<sub>2</sub> into the storage of carbon. With the second method, a lot of achievements have been made overseas. So far, over 150 observation stations have already been set up. This method is applied to measure the flux of water vapor, and has been expanded to the research into the flux of CO<sub>2</sub> since the 1980s. Scientists of Euroflux Laboratory have applied the method of eddy correlation to intensively study the change of CO<sub>2</sub> fluxes of European forests at different latitudes. Malhi et al applied the method of eddy correlation to study the seasonal change model of tropical, temperate and northern forests, with the research findings being: tropical forests manifest net carbon sink all the year round, while forests in the high latitude area manifest sink in the growth season and manifest source in winter. China started later in this regard. In 2002, Chinese Academy of Sciences officially started the project of observing the carbon fluxes of Chinese terrestrial ecosystem. So far, 4 CO<sub>2</sub> flux fixed position observation stations of typical forest ecosystems in Changbai Mountain, Qianyan Sandbar, Dinghu Mountain and Xishuangbanna respectively.

### 3 RESEARCH CONTENT OF THE MEASUREMENT DETECTION AND LINE OPTIMIZATION OF THE CARBON CAPTURE ABILITY OF ITALIAN POPLARS

#### 3.1 *The main content of research and development*

The implementation content of this project is the system development of the measurement detection and line optimization of the carbon capture ability of Italian poplar. The system consists of: a central control machine and a large-screen display system; a sound and wind velocity meter, an infrared CO<sub>2</sub> analysis meter, a data recording and data comparison device, a conduit system; wireless sensor nodes and a relay base station, etc.;

The demonstration system of development has the following functions: capable of automatically increasing/decreasing the measurement frequency of each test point according to the external environment and the expert system. When the carbon-absorbing ability of Italian poplars is in a stable state and within a safety scope in spring and summer, the frequency of measurement is reduced. When the weather variation and wind velocity are in an unstable state and at a critical point of safety scope, the frequency of measurement is increased.

Relevant parameters are adjusted dynamically according to the situation of measurements; wireless sensors are networked and relay nodes are set up according to the distribution of monitoring sites, and data transmission free from distance limitation is carried out.

#### 3.2 *Key technological problems to be solved emphatically during project implementation*

3.2.1. The substitution scheme of energy (wind) measurement. The project summarizes empirical data and weather and other factors while combining the fuzzy algorithm method and expert system to substitute the three-dimensional ultrasonic anemoscope, which is the key technological problem to be solved in the project.

3.2.2. The problem of the dynamic networking of wireless sensors. Considering that the woodlands of carbon sink measurement are independent of one another, each woodland of Italian poplars is different from others, and Italian poplars have different carbon capture abilities in different seasons, the dynamic networking of wireless sensors is also one of the key technological problems.

3.2.3. The maintenance-free problem of the monitoring system. For large-sized woodlands, the around-the-clock continuous work of CO<sub>2</sub> concentration analyzer needs to consume a lot of electric energy. The around-the-clock continuous data transmission and receipt of sensor nodes need also to consume a lot of electric energy. The maintenance-free power supply carried by wireless sensor nodes has also become a key problem to be solved.

### 4 MAJOR RESEARCH METHODS

#### 4.1 *The overall technological line of this project*

The design of the overall scheme → the design of various modules → system integrated manufacturing → equipment debugging → system operation.

#### 4.2 *Module design*

##### 4.2.1 *The design of wireless sensor network nodes*

At present, against different applications, the structures of sensor nodes are almost the same, chiefly including the collection unit, the processing unit, the transmission unit and the power supply unit, just as shown in [Figure 1](#).

Against the demand of measurement of CO<sub>2</sub> concentration and the characteristics of wireless sensor network, this project will focus on studying and developing the new-type wireless sensor nodes

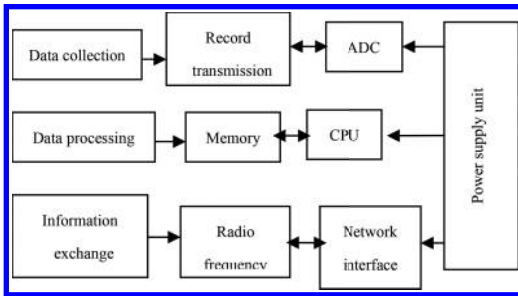

Figure 1. The structure chart of wireless sensor network nodes.

based on ZigBee technology. These nodes shall be designed separately and hierarchically in a modularized way, consisting of the front-end sensor collection module, the signal processing module, the radio frequency transceiver module and the power supply module.

1. The front-end sensor collection unit.

The selection of sensors: The system sensors shall be selected on the principle of high reliability, low cost, simple interface and convenient line connection, and the equipment with a high-cost performance shall be selected according to the situation and the actual project demand.

2. The processor unit: According to the characteristics of wireless sensor nodes: low energy consumption, complete functions, high integration and large memory capacity, embedded microprocessor is adopted. This system is expected to use the MSP430 series processors of TI Company and compile signal processing and corresponding decision-making management software.

3. Communication unit: In the wireless transceiver chips, both the TR1000 of RFM Company and the CC1000 of Chipcon Company are ideal choices of low power consumption. However, considering the conflict-free frequency band, node safety, performance and other factors, the CC2420 wireless transceiver chips of Chipcon Company will be used in the system design because they work on general ISM frequency band, carry their own hardware encryption mechanism and conform to the ZigBee technology designed exclusively for wireless sensor network.

4. Power supply unit: Power supply unit supplies power to various circuits of the system. According to the actual requirement of field monitoring, this project is expected to use storage battery for power supply, and can consider adding a solar panel if necessary.

4.2.2 The design of monitoring system

The monitoring system is used to exert management over nodes, process incoming data, automatically generate database statements, carry out intelligent management according to prepared operation procedures, and deliver the results of system processing to a large screen for display.

4.2.3 The design of relay node communication system

The designed communication system is used to complete the wireless communication between relay nodes and central control machine. Zigbee communication protocol, communication frequency band of 2.4 GHz and band width of 8 MHz will be adopted.

5 INNOVATIVE POINTS OF THE PROJECT

5.1 The wireless monitoring technology and system integration of the carbon capture ability of Italian poplars

In connection with the demand of parameter monitoring of Italian poplar woodlands and the characteristics of wireless sensor network, the wireless monitoring network is used for real-time perception of carbon-capture information and processing of Italian poplar, and transmission of results to the central server. The server uses the method of signal processing and the expert system for integrated decision-making, and commands the processing of relevant data. All the sensors used in the network work intermittently according to requirement, capable of effectively saving limited electric energy resources. The utilization of wireless sensors is characterized by no cable wiring, low expense and no network maintenance.

5.2 Energy (wind) measurement monitoring technology

The high price of three-dimensional ultrasonic wind velocity meter has become a problem for the detection application of Italian poplar carbon sink ability. The project summarizes empirical data and weather and other factors while combining the fuzzy algorithm method and expert system to substitute the three-dimensional ultrasonic anemoscope.

5.3 The dynamic networking of wireless sensors

Considering that the woodlands of carbon sink measurement are independent of one another, each woodland of Italian poplars is different from others, and Italian poplars have different carbon capture abilities in different seasons, the sensors

in the wireless sensor monitoring network work in a state of dynamic changes. The central control machine can issue relevant instructions according to weather and other factors, so as to carry out the optimization of monitoring network.

## 6 CONCLUSION

Since the Forestry Property Exchange was established, China has successively set up carbon sink exchange centers in such cities as Beijing, Shanghai and Tianjin. The measurement detection and line optimization system of carbon capture ability of Italian poplars enjoys a broad development space and a brilliant industrialized prospect. China boasts a huge potential of carbon emission reduction, and the property of forest carbon sink and the compensation and marketing of ecological service have already become a development trend. Carrying out research into carbon sink projects can play a very important role in enabling China to take an active part in international cooperation and become familiar with the trading rules of international carbon market. Developing forestry carbon sink and establishing and perfecting the long-term mechanism of forest ecology compensation can help to save energy, reduce emission,

optimize energy structure and improve ecological environment. Furthermore, it also plays an important role in enriching farmers and boosting the construction of new rural areas.

# Analysis of current situation after restoration in the Tianjin Lingang ecological wetland park

N. Zhao & H.Y. Li

*College of Environmental Science and Engineering, Nankai University, China*

J. Hu & J.W. Hou & T. Wen

*Tianjin Lingang Industrial Zone Construction Development Co. Ltd., China*

**ABSTRACT:** Ecological restoration and landscape construction of urban wetlands are gradually becoming a research hotspot at home and abroad. In China, urban wetland reconstruction projects have achieved remarkable results. Tianjin Lingang ecological wetland park is a typical urban wetland park, which was constructed on artificial reclamation land. Earlier, the park was deserted salinity tidal flats; however, by the water system design, plant configuration, ecological reconstruction, engineering measures, it became a multifunction park integrating water landscape and ecological restoration. After ecological restoration, the biodiversity level of Tianjin Lingang ecological wetland park increased significantly, reaching up to 149 kinds of plants, belonging to 56 families and 113 genera. Plants were widely distributed in the habitat types of forests, grassland, lawn, flower border, and near water's edge belt. The construction of the vegetation ecosystem was achieved not only through bringing in varieties of cultivated plants, but also by keeping a certain percentage of the wild native species in some sections. The case of Tianjin Lingang ecological wetland park provides an important theoretical guidance and application reference for the similar ecological restoration in the future.

**Keywords:** Lingang ecological wetland park, plant species, habitat types, status analysis

## 1 INTRODUCTION

In 2000, London wetland park nearby the Thames River was opened, which provided a successful model for urban wetland protection and development [1]. With the speeding up of urbanization, urban wetland ecological restoration and landscape construction are gradually becoming a research hotspot at home and abroad [2]. In our country, urban wetland ecological restoration has made a breakthrough. The construction of Xixi wetland park [3], Chongming wetland park [4], Dongying wetland park and Dongtan wetland park has provided a strong reference for the urban wetland park construction.

In the perspective of landscape ecology, urban wetland park is a wetland landscape, which is constructed on the urban artificial landscape matrix and composed of wetland corridor and wetland patches [5]. Wetland park has important roles in adjusting the balance of atmosphere carbon and oxygen as well as reducing the greenhouse effect [6], and it has a very high ecological value. As an ecological park that was constructed on salinity tidal flats, the ecological benefit of Tianjin Lingang

ecological wetland park will directly affect the Tianjin's urban ecological environment. As one of the successful cases in the city wetland ecological restoration, Tianjin Lingang ecological wetland park provides an important theoretical guidance and application reference for similar ecological restoration cases in the future.

## 2 RESTORATION METHOD

### 2.1 Sample area introduction

Tianjin Lingang ecological wetland park is located in the Tianjin Binhai Lingang industrial zone, whose total area is about  $6.3 \times 10^5$  square meters, and it was constructed on artificial reclamation land. The park is located in a typical muddy tidal flat in the Bohai bay. Owing to the long-term development of the coastal zone area, it has accumulated a fair degree of pollution. Through kinds of ecological restoration measures and landscape construction measures, such as water system design, plant configuration measures, salt exclusion engineering design, ecological reconstruction engineering, hard landscape design, and landscape sketch design, it

became a multifunction park integrating water landscape and ecological restoration. Meanwhile, by using the combination of undercurrent wetland technology and surface current wetland technology, its sewage purification treatment function has realized the local wastewater zero discharge in part of the Lingang economic zone. It became a park that possessed the ability of sewage water treatment as well as the landscape effect. The entirety shape of the park is like a butterfly, which mainly includes three big scenic spots, namely undercurrent wetland, regulating lake, the main body of the landscape area.

## 2.2 Field investigation

After the ecological restoration in Lingang ecological wetland park, the vegetation was investigated in this paper in July 2014. The optimal size of samples used for plant community surveys is as follows: the idiomatic sample size of the arbor layer is 10 m × 10 m; the idiomatic sample size of the shrub layer is 5 m × 5 m; and the idiomatic sample size of the herb layer is 1 m × 1 m. According to the different geographical locations, habitats, climate zones, investigation objects (arbor, shrub, herb) and the ecological system types, it has a flexible choice in setting the sample area and samples, but it must abide by the principle of typical sampling, integrity and representative, and the sample area cannot be less than the minimum area of community. For community samples, the longitude, latitude and elevation, and the types, quantity, and height of the dominant species are recorded.

## 2.3 Data analysis

The survey data were analyzed and entered in Excel software.

# 3 RESULTS AND ANALYSIS

## 3.1 Plant species richness

Lingang ecological wetland park has a high level of endemic species: a total of 149 plant species were found in the survey, and these kinds of plants belong to 56 families and 113 genera. As shown in Figure 1, the number of species contained in specific families is as follows: the majority is *Rosaceae*, which contains 24 species (accounting for 16.11% of the total species), the second is *Leguminosae* (13 species, accounting for 8.72% of the total species), *Gramineae* (12 species, accounting for 8.05% of the total species), *Compositae* (8 species, accounting for 5.37% of the total species), *Salicaceae*, *Oleaceae* and *Chenopodiaceae*

Figure 1. The number of species contained in the families.

(all 6 species, accounting for 4.03% of the total species), respectively. The majority of the above-mentioned families contain the species accounting for 50.34% of the total species, and the rest are less than 6 species.

## 3.2 The habitat types of plants

Tianjin Lingang ecological wetland park has really made lots of efforts in the aspect of building wetland parks, except for bring in lots of aquatic or hydrophilous plants, such as *Schoenoplectus tabernaemontani*, *Pontederia cordata*, *Canna glauca* and *Lythrum salicaria*. Also, the considerable quantity of aquatic, hydrophilous wild herbs in the water area and near water's edge belt, such as *Scirpus planiculmis*, *Rorippa islandica*, *Eclipta prostrata* and *Ceratophyllum demersum* is retained.

After investigation, the habitat types of Lingang ecological wetland park mainly included forest, grassland, lawn, flowers border, water area, or near water's edge belt. According to the survey, the distribution of the plants varies in the habitat types based on their different ecological habits, which is shown in Figure 2. The plants of Lingang ecological wetland park are mostly distributed in forest/grassland: first, the plant species that are mainly distributed in this kind of habitat reach up to 80 species (accounting for 53.69% of the total species); second, the plants that are mainly distributed in water area or near water's edge belt reach up to 30 species (accounting for 20.81% of the total species). The plant species used to create flower border reach up to 30 species (accounting for 20.13% of the total species). The rest of the plant species that are obligatorily distributed in canopy frame, palings and lawn are few, i.e. reaching up to only 8 species (accounting for 5.37% of the total species).

Figure 2. The habitat types of plants.

#### 4 CONCLUSION

After ecological restoration, Tianjin Lingang ecological wetland park was significantly improved in biodiversity level: a total of 149 plant species were found in the survey, and these kinds of plants belonged to 56 families and 113 genera. Lingang ecological wetland park had really made lots of efforts in the aspect of building wetland parks. After investigation, the habitat types of Lingang ecological wetland park mainly included forest, grassland, lawn, flowers border, water area, or near

water's edge belt. The plants in the Lingang ecological wetland park were distributed in the habitat types of forest and grassland.

# The analysis of Lingang Wetland Park's eco-efficiency

Y.Y. Wan & H.Y. Li

*College of Environmental Science and Engineering, Nankai University, Tianjin, China*

J. Hu, J.W. Hou & T. Wen

*Tianjin Lingang Industrial Zone Construction Development Co. Ltd., Tianjin, China*

**ABSTRACT:** Wetland park has a huge environmental adjustment function, eco-efficiency and high ecological value. Earlier, the Tianjin Lingang Ecological Wetland Park was deserted saline-alkali tidal flats, which was built on artificial reclamation land. During the construction of the park, by the methods of ecological reconstruction, and vegetation restoration measures, it has become a multi-function park that is completed integrated with hydrophilic landscape and ecological restoration. Wetland's wastewater treatment capacity has reached the partial zero emissions. After restoration, the Tianjin Lingang Ecological Wetland Park's eco-efficiency improved significantly. After investigation, at the initial stage of the wetland park, its total biomass was 11.61 t/hm<sup>2</sup>, with a relatively small amount of biomass. The post real-time monitoring should be strengthened. Lingang Wetland park plant carbon reserves were 1607.2245 tons with a net carbon reserve calculation. This study will be carried out for the future similar ecological restoration project to provide important theoretical guidance and application of reference.

**Keywords:** Lingang Ecological Wetland Park; carbon fixation; oxygen release; biomass; ecological benefits

## 1 INTRODUCTION

In 2000, the wetland park opened in London on the Bank of the River Thames, for the protection and development of urban wetlands, has provided a successful model. With the accelerated process of urbanization, urban wetland ecological restoration and landscape has gradually become the hot spots at home and abroad. Regulating function of wetland park has huge environmental and ecological benefits, which also had core effects on the protection of biodiversity, the maintenance of fresh water resources, regulating climate, and the degradation of pollutants, providing production as well as living resources.

Utilization of urban wetland resources is under the premise of protecting wetlands, on the rational development and utilization of urban wetland resources. Lingang Wetland Park acts as a ecological park that possesses a high ecological value and was established in saline-alkali tidal flats. It plays a significant role in adjusting the balance of carbon and oxygen in the atmosphere and exerts a big influence on reducing the greenhouse effect. The park's ecological benefits will take a direct impact on the city itself, and will also provide a theoretical guidance and application reference for subsequent ecological restoration cases as a very successful example.

## 2 MATERIALS AND METHODS

### 2.1 *Sample and introduction*

Lingang Wetland Park is located in the Binhai New District of Tianjin, Tianjin Lingang Industrial Zone where is the South of the estuary of the Haihe River shoals area, and built with a total area of about 630,000 square meters on the reclaimed land. The typical park is located in the Bohai Bay muddy tidal flat, which had accumulated a considerable degree of pollution due to the long-term development of the coastal zone. Typical ecological recovery measures, such as water system design, plant configuration measures, salt-removing engineering, ecological reconstruction engineering, hardscaping design, landscape sketches design and the landscape create measures, have been used to build a multi-function park integrated with hydrophilic landscape and ecological restoration. Combined with the undercurrent technology and table flow technology of wetland, its sewage purification processing function achieved partial sewage zero emissions, and the park gives consideration to the function of sewage processing and also brings about landscape effects. The overall shape of the park looks like a butterfly, and there are three main major scenery plots in it, namely Subsurface Flow Constructed Wetlands, Adjusting Lake and Main Landscape.

## 2.2 Field investigation

Vegetation surveys were carried out after the ecological restoration of Lingang Wetland Park July 2014. The optimal quadrat size for community investigations is as follows.

Arbor stratum used the qadrat size of 10 m × 10 m, the fruticose stratum of 5 m × 5 m and the herb layer of 1 m × 1 m. As for community plots, the data of the community's longitude, latitude and elevation, and within the community's species are recorded, especially the dominant species, number and height.

## 3 CALCULATION METHOD

### 3.1 Method of calculating the biomass of arbor

#### 3.1.1 Method of logging

This method includes the clear-cutting method, the average method and size selection.

#### 3.1.2 The biomass

The biomass of the individual tree model is as follows:

$$W = aD^b \quad (1)$$

$$W = a(D^2H)^b \quad (2)$$

where  $W$  is the biomass;  $D$  is the Diameter at Breast Height (DBH); and  $H$  is the height of the tree; and  $a$ ,  $b$  are the estimate parameters.

### 3.2 Fruticose biomass calculation method

Implementing the quantification dispose on each factor effect plant volume, the dependent variable  $y$  relies on the independent variable  $x$ , reading the specific value when  $x$  acts as number indicators (e.g. diameter, tree height, crown diameter and stand age) and qualitative indicators (e.g. growth situation, and stand density), and these quantification indicators of factor and classes are collectively known as category (Ck), which are graded using expectations on its seeking derivatives.

### 3.3 Data analysis

The survey analysis and collation of data were processed and analyzed by Excel software.

### 3.4 Conclusions

Conclusions should state concisely the most important propositions of the paper as well as the author's views of the practical implications of the results.

## 4 RESULTS AND ANALYSIS

### 4.1 Calculated results of Lingang Wetland vegetation biomass

#### 4.1.1 Estimation of arbor biomass

Biomass can be divided into arbor biomass and non-tree biomass two parts, and arbor biomass was calculated according to the formulas of 'lumber timber volume's fast calculation table:

$$V = 5.7468552 \times 10^{-5} D^{1.9155590} H^{0.92659720} \quad (3)$$

where  $V$  is the volume ( $m^3$ );  $D$  is the diameter at breast height (cm); and  $H$  is the height (m).

Single-tree volume calculation was used in 58 species of trees in the Lingang wetland park, resulting in a total volume of 306.40  $m^3$ . This was in accordance with the individual tree biomass model law, by the empirical formula for calculation. Arbor totaled 41382 trees, and total arbor biomass was calculated as 307.61 t. The specific results are summarized in Table 1.

#### 4.1.2 Non-tree biomass estimation

Biomass estimation of non-arbor's part (shrubs, hedges, flower) increased with plant age. Plant parameters (diameter, height and crown width) and biomass changes were very small, so they were calculated with the direct empirical value. The specific results are summarized in Table 2.

#### 4.1.3 Lingang Wetland Park total biomass

①. Biomass:

$$\begin{aligned} B &= B(\text{arbor}) + B(\text{others}) \\ &= 306.40 + 444.05 + 72.02 + 198.29 + 0.78 \\ &= 1021.54 \text{ t} \end{aligned}$$

Table 1. Empirical formula.

Species	Formula
The paulownia	$lgw = 0.8925lgD^2H - 1.2409$
Koelreuteria Paniculata	$lgw = 0.915 + 0.1 D^2H$
Black locust	$lgw = 0.253 (D^2H)^{0.646}$
Acer mono	$lgw = 0.714 + 0.0295 D^2H$
Ginkgo biloba	$lgw = 0.09 D^2H - 0.684$
Poplar	$lgw = 0.13513 (D^2H)^{0.802003}$

Table 2. Biomass estimation of non-tree's part.

Type	Total number	Average individual biomass (Kg)	Total biomass (t)
Deciduous shrub	120994	3.67	444.05
Hedgerow	122063	0.59	72.02
Perennial flowers	271624	0.73	198.29
Chinese rose	7091	0.11	0.78

Table 3. Tianjin Lingang Wetland carbon reserves.

Type	Total number/10 <sup>5</sup>	Average individual biomass/kg	Total biomass/t	Carbon content	Individual carbon reserves/kg	Carbon reserves/t
Aiphyllium	0.072	69.72	50.1984	0.51	35.5572	25.6012
Deciduous trees	3.1297	85.88	2687.786	0.48	41.2224	1290.1373
Deciduous shrub	10.1239	3.67	371.5471	0.49	1.7983	182.0581
Hedgerow	9.4834	0.59	55.9521	0.51	0.3009	28.5356
Perennial flowers	25.1811	0.73	183.8220	0.44	0.3212	80.8817
Chinese rose	0.6748	0.11	0.7423	0.48	0.0528	0.3567

Biomass per unit area:

$$B = [B(\text{arbor}) + B(\text{others})]/S \\ = (306.40 + 444.05 + 72.02 + 198.29 + 0.78)/88 \\ = 11.61 \text{ t/hm}^2$$

Or

② Biomass:

$$B = B(\text{arbor}) + B(\text{others}) \\ = 307.61 + 444.05 + 72.02 + 198.29 + 0.78 \\ = 1022.75 \text{ t}$$

Biomass per unit area:

$$B = [B(\text{arbor}) + B(\text{others})]/S \\ = (37.61 + 444.05 + 72.02 + 198.29 \\ + 0.78)/88 \text{ hm}^2 \\ = 11.62 \text{ t/hm}^2$$

By the two estimate methods of arbor biomass, slight differences were found between the results, which can be ignored basically. The total biomass is small to some extent. The possible reasons for this are as follows. a. Neglect the part from the park's aquatic plant biomass. b. Large errors were caused due to the calculation by using the empirical formula. c. Wetland park itself at the initial period after building and plants at the young stand age so that the biomass was little small to some extent, especially the arbor.

#### 4.1.4 Net carbon reserves calculation

Garden plants biomass and types of plants average carbon content, Tianjin Lingang calculated net carbon storage in wetland park gardens plant taxonomy (Table 3) can be calculated by the following formula:

$$C_i = N_i \times W_i \times C F_i + 10^6 \quad (4)$$

where  $C_i$  ( $10^5$  t) is the type  $i$  of the net carbon reserves;  $N_i$  is the general investigation number of type  $i$  plant;  $W_i$  (g) is the plant individual biomass of type  $i$ ;  $C F_i$  is the average rate of carbon of type  $i$  plant; and  $10^{-6}$  is the unit conversion factor ( $1 \text{ g} = 10^{-6} \text{ t}$ ).

Characteristics of carbon content are given in Table 3. The plant carbon rate ranging between 0.4 and 0.6 is basically stable, with all less than 0.6 and the total average being 0.485; aiphyllium, hedgerow color blocks displays more than 0.50, while the smaller carbon content results from perennial flower.

The reason may be due to evergreen trees' dense material caused by slow growing.

Many studies have proved that little differences in the carbon content of the plant exist and its value is usually between 0.45 and 0.55 in different regions. The IPCC recommends using the average carbon content of 0.5 (2006, National Greenhouse Gas Inventories). The results of this study further validates the conclusions of previous research. Meanwhile, it also supplements the local region parameters with respect to the carbon content of plant communities in Tianjin wetlands.

## 5 CONCLUSION

After investigation, the Lingang ecological wetland park's total biomass was found to be  $11.61 \text{ t/hm}^2$ ; this overall value was a small to some extent. Plant carbon rate ranging between 0.4 and 0.6 is basically stable, and plant carbon reserves were 1607.2245 tons. After restoration, the Tianjin Lingang Ecological Wetland Park's eco-efficiency improved significantly, and subsequent real-time monitoring should be strengthened as well.

# A study on the influence of space expansion in the urban fringe area in megalopolis on urban land used for carbon source and sink: A case of Shanghai

M.L. Qin, J. Zhao, H. Li, J. Ya & Y. Tang

*College of Civil Engineering and Architecture, Guangxi University, Nanning, China*

**ABSTRACT:** Urban fringe area has three characteristics, namely spatial transformation acceleration, urban and rural land boundary fuzziness and carbon sink function sensitivity. To explore the particularity of the urban fringe space expansion on land used for carbon source and sink in megalopolis, the research uses the GIS to have a quantitative analysis of the land used for carbon source and sink fringe areas in Shanghai from the year 1990 to 2013. It is found that the land used for carbon sink in the fringe areas of Shanghai is mainly composed of cultivated land. And in the process of expansion, most cultivated land is transformed into the land used for carbon source, and a part of it is replaced by the garden land; the area of the woodland first falls and then rises. The important ways for megalopolis to realize low carbon include adjusting population distribution, controlling urban development pattern, regulating energy structure, developing sustainable energy sources, protecting carbon sink land, and improving carbon sequestration capacity. In the end, it is found that problems such as land structure confusion and excessively fast erosion of carbon sink land are quite significant in megalopolis.

**Keywords:** megalopolis; fringe area; land used for carbon source and sink; space structure; expansion pattern

## 1 INTRODUCTION

The expansion process in urban fringe areas is a centrifugal and extensional urbanized space process<sup>[1,2]</sup>. In this process, problems such as wasting of land resources, land structure confusion, carbon source land's continuous erosion of carbon sink land and serious ecological damage are becoming increasingly prominent. Such problems are even more remarkable in megalopolis where the rate of urbanization is higher and the transformation of carbon source land is faster. Megalopolis has an early urbanization process, a more complete and complex urban system network, and a wide radiating area in the inner city area, so the transformation process of carbon source land is undoubtedly irreversible. The space expansion in the fringe areas of megalopolis on the land used for carbon source and sink is of its own particularity.

The acceleration of the land transformation process in the fringe areas of megalopolis is one of the most significant features of used land for carbon source and sink. Serious waste of cultivated land resource, low utilization efficiency and unreasonable space structure all lead to the fact that the land used for carbon sink is excessively occupied by land used for carbon source, causing a serious

carbon sequestration capacity<sup>[3]</sup>. In the study of the transformation of fringe areas in megalopolis, overseas scholars have mainly focused on the research of regional land-use and land-cover change (LUCC)<sup>[4-6]</sup>. Because the landscape pattern in the fringe areas of megalopolis has significant features of locality and accumulation<sup>[7]</sup>, the acute change of landscape pattern has accelerated the transformation from traditional agricultural land to industrial land or other non-agricultural land<sup>[6]</sup>. For example, Wu Yanfang<sup>[4]</sup> performed a quantitative analysis of the dynamic change of land utilization in Pinggu District of Beijing from 1993 to 2008, and it was found that within 15 years, the area of the cultivated land in Pinggu District decreased sharply, the area of garden land increased greatly, and urban and rural construction areas increased year by year. Taking Shunyi District of Beijing as an example, Li Can<sup>[8]</sup> carried out an analysis from the perspective of the influence of land utilization and cover on the regional landscape fragmentation pattern and its spatial heterogeneity, and explored the action mechanism of the landscape pattern in the fringe areas of metropolis. The fuzziness of urban and rural land boundaries is another feature. The boundary of the fringe areas in metropolis is more difficult to recognize. The

drastic expansion in urban fringe areas drives the process of urban and regional integration. The urban fringe area breaks the single space expansion scope of suburbanization and becomes the core regional space of urbanization, leading to a fuzzier boundary between urban and rural land utilization. From the research on Fanyu District of Guangzhou, Li Kaiyu<sup>[10]</sup> found that metropolis adopted the method of “withdraw county (city) and set up district” to expand the interior of the city, which leads to the continuous expansion of the urban fringe area. With the top-down expansion in the city and the bottom-up spreading in villages and towns, the dualistic development means is more significant in the fringe areas of metropolis. Fan Lingyun<sup>[9]</sup> found that the fringe area of Guangzhou is influenced by the central city area and the peripheral subcenter, and urban and rural development interweaves with each other and different land plaque intersections within the district are more complex. Land utilization and cover caused by human activities has become the second largest source of the increase in carbon content in the atmosphere, whose effect is only second to the burning of fossil fuels<sup>[11]</sup>. The rapid process of urbanization and industrialization in metropolis leads to the drastic shrink of agricultural land, and the rapid expansion of urban residential land strongly influences regional carbon sink and emission. Shan Fuzheng<sup>[12]</sup> conducted a research on the land utilization and carbon emission of Zhangjiang High-tech Park, and found that the agricultural land similar to the cultivated land decreased dramatically, which brought the negative effect of continuously declining carbon sequestration capacity. In 2009, the carbon sequestration volume reduced by 85.1% compared with that in 2000, while the carbon emission volume is 3037.7 times more than that in 2000. The park is faced with a serious carbon deficit.

The space expansion in urban fringe areas results in drastic changes of land utilization structure as well as a serious unbalance of the carbon cycle, which is more significant in metropolis where transformation of land used for carbon source is quicker. So far, research on the space expansion in fringe areas of metropolis has mainly focused on the change of land utilization and cover from the perspective of regional landscape pattern, while only a few have focused on different space expansion patterns in fringe areas to study the change of land used for carbon source and sink, and there is a lack of quantitative and qualitative studies on land used for carbon source and sink. In this article, taking fringe areas of Shanghai as an example, we study the influence of space expansion in fringe areas on land used for carbon source and sink.

## 2 SPACE EXPANSION PATTERNS

### 2.1 *Finger type*

Finger type usually occurs in the starting stage or initial stage of a city's rapid development period. It relies on the city's traffic lines and expands outwards in a certain axis direction in a linear pattern. Relying on traffic lines, fringe areas' outward development is of rapid driving effect, so the expansion speed of finger type is usually very fast and has a high-efficient driving effect on the regional construction of surrounding areas. That is to say, finger-type expansion can quickly transform the land for carbon sink into land for carbon source. Generally, the transformed land used for carbon sink is cultivated land or garden land, and because of the action of road planning, its invasion of forest is relatively less. The scope of the transformed carbon sink land mainly centers on the surroundings of the traffic line, so relatively, its scope is not quite large but the expansion speed is relatively fast. Meanwhile, the transformation degree in the fringe area is not complete, and there exists a large amount of scattered land for carbon sink, most of which is unconstruction area, having little erosion on land for carbon sink.

### 2.2 *Satellite type*

Satellite-type expansion usually occurs in the middle stage of a city's rapid development period, when the city's development has formed a large scale and the expansion in urban fringe areas chooses to rely on original towns to generate development by leaps and bounds or select a new place to build in order to obtain a better living environment. Not relying on the major city to develop, the city's planning and implementing efficiency is relatively low. Relatively speaking, the satellite-type expansion pattern has a slower speed of transforming carbon sink land, but simultaneously relatively complete. The satellite-type fringe areas relying on original towns present a slow circle-layer shape, and the carbon sink land transformed into carbon source land is mostly the original cultivated land surrounding the villages and towns, whose scale is relatively small. Because of the urban planning and site selection, the newly built satellite town is relatively large, and the carbon skin land within the area has a complex constitution. However, if the two can be better planned and regulated, it will do little damage to the ecological structure of carbon sink land.

### 2.3 *Group type*

Group type occurs in the middle stage or later stage, when the city's development had begun

to take shape and the expansion in fringe areas manifests as the newly planned development area or industrial area. The expansion in urban fringe areas presents a planned and regular form, and the city is able to largely control the scope and function of the expansion in the fringe areas and control the expansion speed and the degree of carbon sink land transformation. However, the group-type expansion will encroach a large area of carbon sink land, whose constitution will be more complex. The transformation speed of cultivated land and garden land into carbon source land is the fastest. Meanwhile, a large area of forest will be transformed into construction land. Without control and planning, the group expansion will do great damage to the ecological structure of fringe areas. At the same time, the group-type expansion pattern has a slower speed of transforming carbon sink land, but simultaneously more complete.

#### 2.4 Spreading type

Spreading type usually occurs in the initial stage or later stage of a city's rapid development, which manifests as the unordered and uncontrolled expansion in fringe areas. The spreading is formed artificially and spontaneously, whose expansion is of significant blindness and randomness. It is formed because of a lack of planning management in the initial stage and because of uncontrolled rapid development in the later stage. The area of a single spreading is relatively small and fast, which has little erosion on carbon sink land. However, because spreading is of highest occurrence probability, its influencing scope is the largest. The carbon sink land eroded by spreading is mainly cultivated land and unconstruction area, and because of a lack of unified planning, its transformation degree is relatively low and it is easy to form repeated demolition and construction.

#### 2.5 Wheel type

Wheel type occurs in the later stage of a city's development, which usually relies on the city's circuits to expand outwards, with a significant circle-layer feature. Because of the construction of urban traffic circle lines as well as its dependency on the development of the main city, the expansion speed in fringe areas of wheel type is generally slow, and at the same time, the surrounding directions present the characteristic of unbalanced transformation degree. The influencing scope of wheel-type expansion is relatively wide, which mainly centers on the surroundings of traffic circuits, whose periphery is generally surrounded by forest and the transformed carbon sink land is usually cultivated land or garden land. Relatively, wheel-type expansion also has

high erosion on carbon sink land, the transformation degree is relatively high and the reserved carbon sink land within the circle is relatively small. Without proper control, it may cause a series of "overspreading" problems in urban development, causing great damage to the ecological structure of carbon sink land.

#### 2.6 Filling type

Filling occurs in any stage of urban development. Filling refers to self-improvement and supplement of infrastructure or complete district in fringe areas or core areas. Filling has a fast speed in transforming carbon sink land into carbon source land, but the area is relatively small and scattered. Generally speaking, the transformed carbon sink land is the unconstruction land or urban green land in the city. The transformation of filling is complete, but its erosion on carbon sink land is small.

### 3 AN EXAMPLE OF THE FRINGE AREA IN SHANGHAI

#### 3.1 Definition method of the fringe areas

The study chooses the remote-sensing image of American Landsat TM in the mid-1990s, covering China as the data source, and has a supervised classification of the land in the fringe area in 1990, 2000, 2006 and 2013 (from September to December). After that, remote-sensing image screen digital technology as well as man-machine interaction numerical analysis is adopted to have a manual visual interpretation, directing the extraction of the inner margin and outer edge of the fringe area of Shanghai from ArcGIS. Based on the interpretation of Shanghai's core district in 1990, at the end of every time period later, a new urban form is formed until the information of urban core districts and fringe areas in different periods is abstracted. The sketched boundary can be directly input into the GIS, and statistics of the area will be done in ArcInfo so as to obtain the area of core area and fringe areas of Shanghai as well as the occupation information of carbon sink land in the expansion process. The spatial form of the fringe area of Shanghai in 1990, 2000, 2006 and 2013 is shown in [Figure 1](#).

#### 3.2 An analysis of the influence of different expansion patterns formed in different stages on land used for carbon source and sinks

Taking the year of 1990, 2000, 2006 and 2013 as the research timings, this paper studies on the change in the features of land used for carbon source and

Figure 1. Urban fringe areas form of Shanghai City during the four periods of time from 1990 to 2013.

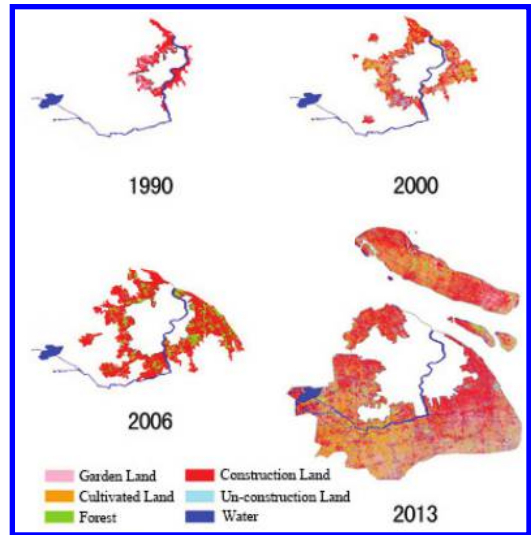

Figure 2. Land used for carbon source and sink distribution in the urban fringe areas of Shanghai City during the four periods of time from 1990 to 2013.

sink in the fringe areas of Shanghai to discuss the changing rules of expansion patterns in different stages. The distribution and data of the land used for carbon source and sink in the urban fringe areas during the four periods of time are shown in Figure 2 and Table 1.

1. **1990–2000: this is a rapid development stage. The expansion pattern in urban areas centers on wheel type and satellite type and the land used for carbon sink is mainly cultivated land.**

In 1990, the urban form of Shanghai was relatively divergent and fragmented, and the expansion pattern in urban fringe areas was mainly spreading type. In the 1990s, Shanghai was already developed well enough, and it was originally one of the Chinese metropolises. At that time, the city needed rapid development, and there was not a proper unified planning and management. As a result, the city was still continuously spreading outwards and it was out of control as a whole. At that time, the total area of the core district was 24663.21 ha, and the total area of the fringe area was 40710.66 ha, in which the carbon source land was 28143.3 ha and the carbon sink land was 12567.36 ha, with the proportion of 2:1. Most of the carbon sink land was cultivated land, which was 7573.67 ha, accounting for 60.26%; unconstruction area was in the second place, which was 3244.22 ha in total, accounting for 25.81%; forest was in the third place, which was 324.77 ha, accounting for 2.59%; the rest was garden land, which was 117.14 ha, accounting for 0.93%.

After the year 1990 and 2000, the city entered a rapid development stage. The major feature

of expansion in urban core district was river-crossing, while the major feature of expansion in fringe areas was the emergence of the satellite town, whose expansion patterns were mainly wheel type and satellite type. At that time, the development of the city was under control, and the city started to use total planning to carry out construction. By 2000, the total area of the core district was 51925.04 ha and the total area of fringe areas was 75029.33 ha. Within the fringe area, the total area of land used for carbon source was 28523.76 ha, and that of land used for carbon sink was 46505.57 ha, with a proportion of 1:1.6. The proportion of land used for carbon sink increased. Among the land used for carbon sink in fringe areas, cultivated land still accounted for the most, which was 20566.51 ha, accounting for 44.22%; garden area was in the second place, which was 10350.54 ha, accounting for 22.27%; unconstruction land was in the third place, which was 8871.85 ha, accounting for 19.08%; forest was in the last place, which was 6414.99 ha, accounting for 13.76%.

Altogether, from 1990 to 2000, the growth rate of carbon source land in the fringe areas of Shanghai City was 1.35%; 270.05% for carbon sink land; 171.55% for cultivated land; 1875.24% for forest, experiencing a large amount of growth; 8736.04% for garden land and 173.47% for un-construction land.

2. **2000–2006: this is a rapid development stage, when the expansion pattern of fringe areas**

Table 1. Situation of constitution of lands used for carbon source and sink in the fringe areas of Nanning City at the four periods of time from 1990 to 2013 (unit: hm<sup>2</sup>).

Land for carbon source and sink	Year			
	1990	2000	2006	2013
<i>Land for carbon sink</i>				
Water	1307.56	301.68	857.56	14466.49
Forest	324.77	6414.99	14967.23	18232.26
Garden land	117.14	10350.54	21579.62	84724.57
Cultivated land	7573.67	20566.51	23232.12	119030.8
Unconstruction land	3244.22	8871.85	5664.02	84541.66
Total	12567.36	46505.57	64611.52	320995.7
<i>Land for carbon source</i>				
Construction land	28143.3	28523.76	41060.93	106805.6
Total	40710.66	75029.33	107361.45	427801.40

**centers on finger type and the land used for carbon sink is mainly cultivated land.**

From 2000 to 2006, the city entered a rapid development stage, the fringe areas expanded continuously and the original fringe area was quickly transformed into the core district, and the urban form became divergent and incomplete. At that time, the major expansion pattern was finger type and the fringe area presented the tendency of connecting to the original satellite town outwards along the road. Until 2006, the total area of the core district of Shanghai was 81943.77 ha, and the total area of fringe area was 107361.48 ha. In the fringe area, land for carbon source was 41060.93 ha and land for carbon sink was 66300.55 ha, maintaining the proportion of 1:1.6. Among the land used for carbon sink, the majority was still cultivated land, accounting for 23232.12 ha, 35.04% of the total; garden land was still in the second place, which was 21579.62 ha in total, accounting for 32.55%; forest was in the third place, which was 14967.23 ha, and accounting for 22.57%; unconstruction area was in the last place, which was 5664.02 ha, accounting for 8.54%.

Altogether, from 2000 to 2006, the growth rate of carbon source land in fringe areas of Shanghai was 43.95%; 42.56% for carbon sink land; 12.96% for cultivated land; 133.32% for forest, 108.49% for garden land and -36.16% for un-construction land, experiencing a fall.

**3. 2006–2013: this is a stage of stable development, when the expansion model of fringe areas centers on wheel type and group type and the land used for carbon sink is mainly cultivated land.**

From 2006 to 2013, Shanghai entered a stage of stable development, and the urban construction was under a unified planning and management with a strong control force. The land of

the city was mostly constructed in the form of group development and the edge of the core district became smooth and square. Until 2013, the core district of the city expanded rapidly, constantly filling the gap with the fringe area, whose total area reached 153655.1 ha. The edge of the fringe area gradually expanded to the city's whole area under administration, the shape tended to be regular, and the inner edge constantly approached the outer edge, whose total area was 427801.37 ha. The expansion models were wheel type and group type. The total area of land for carbon source in fringe areas was 106805.59 ha and the area of land for carbon sink was 320995.78 ha, with a proportion of 1:3, in which the land for carbon sink rose a little. Among the land for carbon sink, cultivated land was the most, which was 119030.8 ha, accounting for 37.08%; garden land was in the second place, which was 84724.57 ha, accounting for 26.93%; unconstruction land was in the third place, which was 84541.66 ha, accounting for 26.33%; forest was in the last place, which was 18232.26 ha, accounting for 5.68%.

Altogether, from 2006 to 2013, the growth rate of carbon source land in fringe areas of Shanghai was 160.11%, experiencing a significant increase in this stage; 384.15% for carbon sink land; 412.35% for cultivated land; 21.81% for forest, experiencing stagnation; 292.61% for garden land and 1392.61% for unconstruction land, experiencing a large increase.

**4 SUGGESTIONS OF FRINGE AREAS IN METROPOLIS BASED ON LOW-CARBON DEVELOPMENT**

The development of metropolis is becoming complete, the urbanization rate is basically up to 70%, and

the transformation from urban sink land to carbon source land has entered a plateau. In going through the process of thrilling and divergence expression as well as large-scale and high-density carbon sink land transformation, the problem of carbon deficit in metropolis is becoming more significant. Therefore, aiming at the characteristic of expansion in the fringe areas of metropolis, it is the only way for metropolis to face low-carbon development by adjusting population distribution, controlling urban development pattern, regulating energy structure and developing sustainable energy sources.

1. Adjusting population arrangement and controlling urban development pattern. The strong radioactivity of the center of metropolis makes the expansion pattern of the fringe area present the significant feature of satellite type, and the peripheral villages, towns and counties become the hinterland for the development of the central city. Because of the complete infrastructure, public facilities and mature function of residence and working, the satellite town in the fringe areas of the metropolis differs from the traditional "dormitory town", which is the major feature distinguishing the development pattern in the fringe areas of metropolis from that in the middle and small cities. In order to relieve the excessively centralized pressure and energy consumption, the metropolis should inevitably carry out population distributing, while the mature satellite towns in the fringe areas thus become the best direction for population distributing of the central city and the gathering of the rural population. Therefore, in the urban development pattern of metropolis, it has become an irresistible trend to establish the development zone for cities and towns, guide urban-rural integration development, control the self-development scale of the central city and lead population and industries in the central city to the satellite town. Therefore, it is necessary to establish a complete "central city-satellite city" system for metropolis, define the industrial orientation of the satellite town, establish ecological industrial parks, promote circular economy and cleaner production, improve energy efficiency, and reduce carbon. Meanwhile, it is also needed to further develop the tertiary industry, transform the industrial city into a metropolis supported by tertiary industry, and reduce its dependence and consumption of energy and industry.
2. Regulating energy structure and developing sustainable energy. There is no doubt that metropolis consumes a large amount of energy. In China, fossil energy accounts for the majority in urban function, and most of it is coal and petrol. In cities, carbon emission

is mostly caused by fossil fuel. Thus, it is unavoidable for metropolis to carry out energy structure adjustment while guaranteeing its development. In future development, the metropolis should try to take natural gas as the main fuel, reduce the consumption of primary energy, develop the research and usage of sustainable energy such as wind energy and solar energy, and increase energy use efficiency, and reduce carbon emission. What's more, the carbon emission caused by a large number of vehicles in metropolis is also difficult to ignore. Therefore, it is essential to control the carbon emission of vehicles, encourage cars, buses and taxis to use hybrid power energy, increase filters of automobile exhaust, and control carbon emission of automobile exhaust. Furthermore, the city should further enhance the coverage and transport capacity of urban mass transit so as to reduce people's dependence on vehicles. In the fringe areas of metropolis, a binary interweaved mixed situation is formed in land used for carbon source, and taking towns and villages as extension, the city constantly permeably encroaches the land for carbon sink surrounding towns and villages. As a result, a large area of land for carbon sink centering on cultivated land is transformed into land for carbon source. In public administration, the metropolis should strengthen its control over towns and villages, strictly plan the development land of towns and villages, strictly designate that cultivated land and garden land do not allow being encroached, change the residential model of residents in towns and villages, advocate centralized residence, and strictly prohibit the encroachment of cultivated land.

3. Protecting land used for carbon sink and increasing carbon sequestration capacity. The metropolis has entered the stage of balance in urban development, when it should start to pay attention to the cultivation and development of land used for carbon sink such as forest. So, it is important to build large-scale forest, water conservation forest and protection forest, strengthen the greening of river banks and roads, and protect the wetland resources. Native trees and subtropical broad-leaf species should be selected. Meanwhile, it is also necessary to promote the community development and expansion of forest, maintain the self-renewal ability of communities, increase tree age, improve the carbon sequestration capacity of forest, increase the carbon sequestration capacity of soil, conserve and fertilize in a scientific and reasonable way, and reduce the carbon wastage rate of soil.

## 5 CONCLUSION

The metropolis is of a large economic aggregate and population scale, so it is still considered as a large carbon source. The metropolis is still in the process of developing continuously, strengthening scale and rapidly developing economy. In the process within a period of time, because of the loss in early development, metropolis is still facing a large carbon deficit. The land for carbon source is still at a level of continuous expansion, but the expansion rate has slowed down to some extent. The change of the land structure for carbon source and sink in the fringe areas of metropolis is a typical process. In the initial stage of urban development, and that is, a slow expansion period, the expansion of land for carbon source and sink in the fringe areas of the city, is basically within the controlled scope, the form is relatively structured and the expansion model mainly centers on the wheel type. Once it enters the stage of rapid expansion, the city turns to the state of uncontrolled exploitation and spreading, whose form is spreading type and the expansion model centers on finger type with a significant feature of divergence. Once it enters the stage of stable and rapid development, with unified planning and construction, the development of the city is again under control, the form tends to completeness and the expansion model centers on spreading type. In the expansion process of the fringe area, although there are lots of construction land within the fringe area, the construction is not perfect and the total construction level is relatively low, so the land for carbon sink has been in the majority. However, with the increasing perfect of land utilization and continuous decrease of land for carbon sink in the core district, the land used for carbon sink in fringe areas is gradually replaced by land for carbon source. The land for carbon sink in fringe areas is mostly cultivated land, garden land is in the second place, and the proportion of forest is inconstant. To reduce the carbon deficit in metropolis, we should first get down to the land used for carbon source and sink. Increasing the carbon sequestration capacity is the development direction for the metropolis in the future.

# The study on the characteristics of the spatial structure of carbon source and carbon sink in megalopolis: Shanghai as a case

Menglin Qin, Hang Li, Jing Zhao & Jing Ya

*College of Civil Engineering and Architecture, Guangxi University, Nanning, China*

**ABSTRACT:** Compared with other areas, there are highest density and most destructive interruptions in metropolis. With the expansion of the city and the high speed of the urbanization, the metropolitan areas have become the ones where characteristic and varieties of field are changing most dramatically. These changes have directly influenced the carbon fluxes in one area, even the whole world. So, analysis of the spatial characteristics of the carbon source and carbon sink in the metropolis is a crucial premise to reintegrate and plan on the whole area. Based on the orientation that Shanghai is a global metropolis, this paper regards Shanghai as the study area. With the help of the techniques of the RS and GIS, this paper analyzes the distribution of various kinds of lands from 1990 to 2013 in Shanghai, and puts forward some suggestions about the balance between the carbon source and carbon sink, in order to set a foundation for the low-carbon urban planning.

**Keywords:** land-use for carbon source and sink; spatial structure; low-carbonization; Shanghai

## 1 INTRODUCTION

Developing low-carbon city is one of the most important strategies of global climate change, while increasing the carbon sequestration capacity of urban carbon stock is the core of developing low-carbon city. Metropolitan area, the most sensitive area of balancing carbon source and carbon sink in various global habitats, is the concentration with the largest carbon flux gap. So, studies on the spatial structure of carbon source and carbon sink in the metropolitan area and exploration of the core characteristics of its change can provide a theoretical basis for the low-carbon planning and design of carbon source and carbon sink in metropolitan areas, which is realistically significant to the development of low-carbon cities. At present, research on the changes in the spatial structures of city carbon source and carbon sink is focused on land use and the land cover change, especially for the development of “International Geosphere and Biosphere Plan” in 1995 and “International Human Dimension of Global Environmental Change Program (IHDP)”<sup>[1]</sup> as well as the abundant scientific results achieved after “Land Use and Cover Change Plan (LUCC)” was raised jointly<sup>[2]</sup>. Taking advantage of the GIS and RS technologies and the multi-period remote-sensing image and detailed data of land use, characteristics, patterns and impetus of the changes in the spatial structure of land use and land cover have been studied

from the dimensions of urban fringe, city field and districts, which has achieved systematic research results at the urbanization level, cultivated area change, efficiency of farmland conversion and the driving factor of cultivated land conversion<sup>[3-4]</sup>. In terms of ecological environmental influences, relevant studies have shown that the changes in urban land use and land cover could bring relevant environmental changes under the combined action of multiple factors, and urbanization could make the surface runoff of the expanded area increase at various degrees<sup>[5]</sup>, and that the expansion of different administrative units has different influences on the varieties of the soils in the process of urbanization, making the general environmental quality decrease, especially heavy metal pollution<sup>[6]</sup>. Meanwhile, it has also been shown that the changes in land use resulting from urbanization also generate negative effects on vegetation ecological functions and flood discharging capacity.

The aforementioned literature is about the study on the characteristics, patterns and dynamic mechanism of the changes of land use and land cover. However, spatial arrangement in the metropolis is rarely studied from the aspect of land use balance of carbon source and carbon sink in China. This paper attempts to study the land use of carbon source and sink in Shanghai as the entry point with the aim to obtain the core characteristic of spatial change in the land use of carbon source and carbon sink in metropolitan areas.

## 2 DEFINITIONS OF RELEVANT CONCEPTS

### 2.1 Carbon source and carbon sink

United Nations Framework Convention on Climate Change (UNFCCC) gives specific definitions to source and sink. Source refers to the process or activity with the possibilities of discharging greenhouse gases and aerosols to the atmosphere or with the possibilities of discharging greenhouse gases and aerosols to the atmosphere, while sink refers to any process, activity or mechanism of removing greenhouse gases from the atmosphere. Referring to the definitions, carbon source refers to the process or activity of discharging CO<sub>2</sub> to the atmosphere, while carbon sink refers to the process, activity or mechanism of removing CO<sub>2</sub> from the atmosphere.

### 2.2 Land use of carbon source and carbon sink

The defined scope of carbon source and carbon sink corresponds to the town and country land of Urban Land Classifications and Standards for Land Planning for Construction, i.e. various land covers, including carbon source land and carbon sink land. Carbon source land includes urban construction land and regional transportation land, while carbon sink includes water area, cultivated land, garden plot, forest land, grassplot, greenbelt and unused land. Judging whether a land is for carbon source or carbon sink depends mainly on the size of the flux of CO<sub>2</sub> of the land cover and soil

of certain land within a rather long period ( e.g. the time span of this study is from 1990 to 2013). If the flux is positive, the land is carbon source land, whereas if the flux is negative, the land is carbon sink land. Though harvest of crops could make the carbon enter the next cycle, taking the capacity of fixing carbon of soil into consideration, it could be regarded as the carbon sink land, and meanwhile, water region with weak carbon sink capacity is regarded as carbon sink land.

### 2.3 Relevant research index

#### 1. Increasing and decreasing the speed of carbon sink (S, unit: hectare/year)

Increasing and decreasing the speed of carbon sink refers to the land areas increased or decreased within a year, which could be represented by the formula as follows:  $S = (CS_t - CS_0) / \text{year}$ , where CS<sub>0</sub> refers to the area of one type of land in the earlier stage, while CS<sub>t</sub> refers to the area of one type of land in the later stage. When (CS<sub>t</sub> - CS<sub>0</sub>) is a positive value, S is the increasing speed of carbon sink land. When (CS<sub>t</sub> - CS<sub>0</sub>) is a negative value, S refers to the decreasing speed of carbon sink land. The larger the absolute value is, the faster the increasing or decreasing speed is, and the larger the influence on the carbon source and carbon sink land of the city is.

#### 2. Cover intensity of carbon sink land (R, unit:%)

Cover intensity of carbon sink land refers to the percentage of the carbon sink land (CS) in the total carbon source and carbon sink land (CES), the expression of which is given

Table 1. Classification of land types.

Name	Types of land use	CO <sub>2</sub> flux	Carbon source or sink
Forest land	Forest land, shrubland, other forest land	-	Carbon sink land
Garden plot	Garden plot, tea garden, other garden plot	-	Carbon sink land
Cultivated land	Paddy field, irrigable land, dry land	-	Carbon sink land
Grassland garden	Natural grassplot, tame pasture, other grassplot	-	Carbon sink land
Unutilized land	Idle land, saline-alkali soil, wetland, sand, bare land, mud flat, grass land not used for animal husbandry, as well as facility farm-oriented land and ridge of the field	-	Carbon sink land
Water area	Rivers, lakes, reservoirs, ponds, channels, glacier and perpetual snows	-	Carbon sink land
Construction land	Various lands not included greenbelts in urban and rural residents, as well as municipal utilities, including buildings and facilities land	+	Carbon source land
Transportation land	Roads, railroads, airport, ports and lands for inside and outside transportation as well as squares and parking lots	+	Carbon source land

as follows:  $P = CS/CES*100$ . It represents the overall coverage of carbon sink land. The larger it is, the more beneficial it is to the balance of urban carbon source and carbon sink.

### 3. Increasing and decreasing the range of carbon sink land (I, unit:%)

Increasing and decreasing the range of carbon sink land refers to the ratio between the increased or decreased carbon sink land and the area of the carbon source and carbon sink land, the expression of which is given as follows:  $S = (CS_t - CS_0) / CES * 100$ . When  $(CS_t - CS_0)$  is a positive value, it means the carbon sink land is increasing and when the  $(CS_t - CS_0)$  is a negative value, it means the carbon sink land is decreasing. The variable P expresses the relations between the increased or decreased carbon sink land and the overall carbon source and carbon sink land. The larger the absolute value is, the larger the influence of its increasing and decreasing on the balance of the carbon source and carbon sink land of the city.

## 3 ANALYSIS OF SPATIAL STRUCTURE CHANGES OF CARBON SOURCE AND CARBON SINK LAND

### 3.1 Survey region and research method

#### 3.1.1 Survey region

Shanghai is located at N31°14' and E121°29'. It is at the front edge of the Yangtze River, bordering Jiangsu in the west, the Hangzhou Bay in the south and the entrance of the Yangtze River in the north. It is one of the cities with the most developed economy in China and first-tier cities. In 2013, its population in the downtown was about 24,151,500, with per capita GDP of 73,297 yuan and urbanization rate of 89%. It is the center of economic and financial activities in China. Therefore, it is selected as the representative of the megalopolis cities in this study. Based on the requirement of the study and the availability of the data, the survey region is the administrative region of Shanghai City, with the east-west width of 100 km, the south-north length of 120 km and the total area of 6410.03 km<sup>2</sup>.

#### 3.1.2 Research method

This study takes the TM image as the information source to extract the information of carbon source and carbon sink land. The spatial data used in the research region are from Shanghai remote-sensing images of the same season (September to December) of 1990, 2000, 2006 and 2013, the resolution ratio of which is 30 m. Supervised classification is adopted to extract the distributed data of carbon source and carbon sink land at

different times with Erdas. Through interpretation and analysis, the spatial interpretation chart and the structural data of carbon source and carbon sink land at the four periods of time are shown in Figure 1 and Table 2. Since there are few grassplots in Shanghai, they are ignored in this study.

### 3.2 Feature analysis of spatial structure changes

Continuous decrease in carbon sink land is one of the core characteristics of spatial structure changes in rural-urban areas, so the cover intensity of carbon sink land (S), increasing or decreasing speed of carbon sink (R) and change in the ratio of carbon sink land (I) are used to conduct the feature analysis of the spatial structure changes of carbon source and carbon sink land. Their results are summarized in Table 2.

#### 3.2.1 Intensity analysis of carbon sink land increase and decrease (S)

The increasing and decreasing rates during 1990 to 2000, 2001 to 2006 and 2007 to 2013 were, respectively, -4543.14 ha<sup>2</sup>/year, -17549.26 ha<sup>2</sup>/year and -4227.51 ha<sup>2</sup>/year. In other words, the increasing rate of carbon sink land during 1990 to 2000 was retained at about 45 square kilometers; since 2001, the decrease in carbon sink land reached its climax, with an annual decrease of about 175 square kilometers, and from 2006 to 2013,

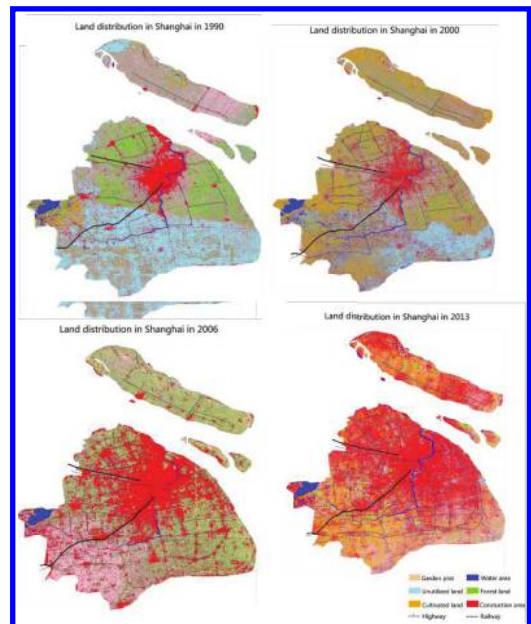

Figure 1. Spatial distribution of lands used for carbon emission and sequestration at the four periods of time from 1990 to 2013.

Table 2. Index analysis of carbon sinks land change.

Analysis index	Periods		
	1990–2000	2001–2006	2006–2013
Increasing and decreasing speed (S, ha <sup>2</sup> /year)	–4543.14	–17549.26	–4227.51
Cover intensity (R, %)	85.44–78.35	78.35–61.92	61.92–57.30
Alternative range index (I, %)	–7.09	–16.43	–4.62

the speed slowed down, with the annual speed decreasing to 42 square kilometers. On the whole, the increase and decrease in carbon sink land were imbalanced, decreasing about 1,053 square kilometers from 2001 to 2006 and about 296 square kilometers from 2007 to 2013.

### 3.2.2 Analysis of carbon sink land cover intensity (R)

With three periods of time, the average carbon sink coverage intensity during 1990 to 2000 (end of the last century) was 81.9%. During 2001 to 2006 (the beginning of this century) was 70.14% and during 2007 to 2013 (the first 10 years of this century), it was 59.1%. The carbon sink land coverage intensity in 1990, 2000, 2006 and 2013 were, respectively, 85.44%, 78.35%, 61.92% and 57.30%.

From the end of the last century until the beginning of this century, as the pioneer of the reform and opening-up, Shanghai was in the period of fast expansion, growth and development, with its carbon sink land decreasing from 85.44% to 78.35%, lowering by 7.09%. During this period, not only Shanghai developed rapidly, but also the towns and villages in the suburbs of Shanghai put into the upsurge of urbanization, especially the city outskirts such as Pudong and Minhang districts<sup>[8]</sup>. Implementing “Pudong reform and opening-up policy”, the Jinqiao development zone, the Lujiazui development zone, the Waigaoqiao development zone and the Pudong international airport were constructed one after another, covering much cultivated lands. Urban construction land including industrial parks of all levels grew continuously like mushrooms after the rain. Pushed by urbanization, traffic construction was also designed and constructed, for example, Luoqing harbor district of Port of Shanghai, metro line 2 at phase I and the road to the Pudong international airport<sup>[9]</sup>.

During 2000 to 2006, urbanization in Shanghai developed dramatically. The downtown, the suburbs and the outskirts advanced urbanization, with the development of Fengxian, Qingpu and Songjiang being the fastest. Meanwhile, the carbon sink land decreased sharply from 78.35% to 61.92%, decreasing by 16.43%, while the carbon

source land cover increased continuously. Limitation of the scope of administrative regions and guarantees of basic farmland also became the bottleneck to further development of the city.

From 2006 to 2013, urbanization of Shanghai transformed from the pattern focused on quantity to the pattern focused on quality, with the changes of various lands becoming steady, which revealed the process of the metropolis growing towards maturity after a certain increase. The spatial structure of the land use in the city tended to be stable, with its average carbon sink land coverage intensity decreasing from 61.92% to 57.30%, lowering altogether by 4.62%.

From 1990 to 2000, the carbon sink land decreased sharply. However, from 2006 to 2013, the change of carbon sink land was small. Because during this period, urbanization of Shanghai changed from quantitative promotion to interior organic renewal. Nevertheless, the carbon sink coverage intensity continued to decrease during the study, dropping from 85.44% in 1990 to 57.30% in 2013, lowering altogether by 28.14%. These 23 years had witnessed the period when Shanghai developed the fastest.

### 3.2.3 Analysis of increasing and decreasing range of carbon sink land (I)

The increasing and decreasing intensities of carbon sink land during the periods from 1990 to 2000, 2001 to 2006 and 2007 to 2013 were, respectively, –7.09%, –16.43% and –4.62%, i.e. The increasing and decreasing intensities of carbon sink land during 1990 to 2000 were small. The increasing and decreasing intensities during 2001 to 2006 were with a large fluctuation, while during 2007 to 2013, they reached their climax. Generally speaking, compared with the total amount of carbon source and carbon sink land, the increasing and decreasing scopes were not large, but from the balance of carbon source and carbon sink, the carbon source had surpassed far the carbon sink. On the one hand, it was because the carbon sink land was decreasing and, on the other hand, urbanization discharged a great amount of greenhouse gases. Therefore, the core reason of carbon imbalance

was the development of urban industry, but not the decrease in carbon sink capacity. Since the existing metropolis is still at the stage of expansion, which means the invaded carbon sink land could not be restored within a short time, it is a problem that must be dealt with for metropolis development to guarantee the quantity of the existing carbon sink land and to increase the carbon reserve of unit area carbon sink land.

## 4 SUGGESTIONS AND LIMITATIONS

### 4.1 *Ensuring the compact growth of Shanghai at different dimensions*

The urban construction land of Shanghai increased from 72843.39 ha in 1990 to 242477.16 ha in 2013, at the speed of 68.80% per year. If it could be said that the previous urbanization of Shanghai used the land development bonus in return for urban development, this kind of development would severely limit the development of the limited lands. Compact development is the most efficient and sustainable way to use limited spatial resources and land resources. The key of the compact growth is to coordinate the relations between growth points and the even aspects at different dimensions, and to guarantee the fast growth of various dimensions within the limited space. Macroscopically, the question is how to coordinate the whole Yangtze River Delta with central Shanghai as well as how to coordinate Shanghai and Hangzhou and Ningbo. In the medium aspect, Shanghai, as the growth point, shall coordinate the relations between the central city and the peripheral clusters and even new towns (including Chengqiao, Lingang New City and Jinshan New City). Microscopically, it is to coordinate the relations between the residential centers and various residential districts.

### 4.2 *Controlling and adjusting to combine Shanghai greenbelts and soil features*

The forest land of Shanghai decreased from 87288.53 ha in 1990 to 21622.58 ha in 2013, at the speed of 6.26% per year, and the cultivated land of Shanghai decreased from 202842.75 ha in 1990 to 126008.44 ha in 2013, at the speed of 6.26% per year. Based on the survey of the actual conditions of Shanghai and analyzing relevant documents, it has been found that the forests of Shanghai were basically man-made forest, with a high cultivation index and young age, which is less than the average national level, so it is with a high carbon sequestration potential. It is suggested to increase the rotation of the woods so as to guarantee full exertion of carbon reserve capacity. Though the quantity of cultivated lands is continuing to decrease, it

is undeniable that it is the indispensable land of Shanghai, and its carbon sequestration capacity could not be ignored. Under the premise of ensuring basic supply of fruits and vegetables, it is suggested to adjust the farming system from the original triple cropping to double cropping per year, to lower the resolving speed of organic carbon and to promote the reservation of soil organic carbon.

### 4.3 *Establishing the joint controlling system*

Keeping the balance of metropolis carbon source and carbon sink is actually a part of constructing a low-carbon city, which could be defined as “the city with low-carbon economy as its development pattern and direction, whose citizens take low-carbon life as the philosophy and characteristic and the governmental management layer regard low-carbon society as their construction specimen and blueprint”. This definition differentiates the traditional management pattern relying purely on the government and stresses on the participation of government organizations, commercial enterprises and non-profit organizations and the public. Its goal is to educate the common people with harmonious and win-win strategies and to guide the enterprise with the market. Joint control of the carbon source and carbon sink balance can be completed through “the government issuing policies, the enterprises investing the capitals and the public participating”.

### 4.4 *Insufficiencies of the study*

There are also some limitations of this study, which are as follows. 1. The resolution of the satellite remote-sensing pictures was low in the supervised classification and limited auxiliary materials, which caused some errors in the supervised classification; 2. To simplify the classification and based on the actual conditions of Shanghai, the areas of grass-plots and greenbelts were not calculated; 3. More years should be calculated as the statistic periods to ensure the accuracy of the conclusion. Based on these shortcomings, the patterns and dynamic mechanism of spatial structures will be researched further so as to obtain a relevant theoretical basis for the low-carbon spatial planning and design.

# The environmental factor evaluations on the recycling models of WHA reverse logistics

Yuanyuan Liu & Tianjun Hu

*School of Traffic and Transportation, Beijing Jiaotong University, Beijing, China*

Fangfang Xie

*Beijing Sustainable Development Center, Beijing, China*

**ABSTRACT:** This study first sets forth some basic theory of the WHA (Waste Household Appliances) reverse logistics and three recycling models of the WHA reverse logistics, namely simple recycling mode, individual workshops processing mode and diversified recycling mode. Based on the three modes, we then calculate the environmental impact and resource consumption load for the three recycling models using life cycle assessment from the aspect of environmental load and resource utilization. Finally, we provide some suggestions about building the reverse WHA logistics system in China and promoting diversified recycling modes according to the above analysis.

**Keywords:** WHA reverse logistics; life cycle assessment

## 1 INTRODUCTION

With the development of economy and improvement of technology, the lifecycle of household appliances has been shortening, and the appliances have been upgraded quickly. China is entering the peak period of scrapped appliances. The revolved heavy metals from the WHA could have a large influence on the environment and person's health if the metals cannot be handled correctly, and thus people are paying more attention to the recycling of WHA. WHA reverse logistics is the process of planning, implementing and controlling of logistics activities from the point of consumption to the point of origin. The logistics activities include recycling, detecting, taking apart, abstracting, regeneration and final treatment<sup>[1]</sup>. There are many benefits to build the WHA reverse logistics: it could lower the cost of logistics, the abandoned goods can be recycled and reused effectively, and it also could effectively control the harm caused to the environment<sup>[2]</sup>. This paper analyzes the impact degree of three recycling modes on the resource and environment to explore suitable management methods and recycling technology for reducing energy consumption and environmental pressure. It has an important reference significance for building recycling modes of WHA and WHA reverse logistics system, and regulating the treatment technology of WHA.

## 2 THE RECYCLING MODES OF THE WHA REVERSE LOGISTICS

### 2.1 *Simple recycling mode*

This recycling mode has two characteristics: single method of collection and small number. Generally, it only takes apart the main elements using manual sorting, the residues are usually thrown out directly or buried under the ground, and heavy metals dissolved from the WHA have a large impact on the environment.

### 2.2 *Individual workshops processing mode*

In this recycling mode, individual handicraftsman bought a great deal of WHA from the domestic and abroad to extract the valuable materials through manual workshop, acid leaching and open-burning. However, the final handling method has a great deal of impact on the environment.

### 2.3 *Diversified recycling mode*

In this mode, collected appliances from factories, commodities and individuals are handled through disassembly and metallurgical technology to reclaim valuable units. The recycling residues are handled by burning and burying. Nevertheless, it is not suitable for small factories because of high cost of investment and handling.

### 3 THE EVALUATION OF ENVIRONMENTAL FACTORS ABOUT THE RECYCLING MODES OF THE WHA REVERSE LOGISTICS

#### 3.1 The analysis of environment factor about recycling modes of the WHA reverse logistics

This paper holds that the environmental factors refer to the factors that have an influence on environmental quality and resource consumption in the process of collecting, taking apart, abstracting and final handling. It includes environmental pollution factor and resource consumption factor. The former contains the environmental pollution factor in the WHA recycling process and the electronic wastes environmental pollution factor. The latter contains resource consumption factors in the WHA recycling process and the electronic wastes resource factor<sup>[3]</sup>.

#### 3.2 Life cycle assessment

LCA is defined by the ISO as a tool to evaluate and solve the environmental problems from the whole life cycle of products: the acquirement of materials, producing, using and recycling<sup>[4]</sup>.

It involves four steps. The first phase of LCA is defining goals and scopes to determine the purpose of the study, system boundaries and selection of suitable functional units. The second phase is Life Cycle Inventory (LCI), which is the process of data collection of all relevant inputs and outputs in the life cycle of product. The third phase is the Life Cycle Impact Assessment (LCIA), which evaluates potential environmental impacts and estimates resource consumption. The last phase is the interpretation, which identifies some significant issues, gets conclusions, explains the limitations and provides recommendations<sup>[5]</sup>.

#### 3.3 The LCA of recycling modes of the WHA logistics

##### 3.3.1 The goals and scopes of assessment

The goal is to analyze the resource utility and environmental pollution of the three recycling modes, and evaluate the impacts of the three recycling modes on the environment.

We identify that the scope is from recycling, sorting, dismantling and final disposal. Not including the transportation process. Resource consumption is mainly considered as the non-renewable mineral resources in this paper. Energy consumption is mainly considered as electricity, coal and oil. And pollution emissions are mainly considered as wasted gas, wasted water and wasted solid.

##### 3.3.2 LCI

LCI is the analysis about the energy, material utility and environmental pollution of WHA. It includes three types: data collection, calculating and analyzing of the results.

Data collection includes input of all resources and energy, the output of production and pollution emissions. We suppose that all WHA have the same parameters, and the electricity is all from fire coal in the process of recycling and handling, and the efficiency of energy transferring is 30%<sup>[6]</sup>.

##### 3.3.3 The evaluation of environmental impacts

Impact assessment is the main stage of LCA. It evaluates the index by transferring the data from LCI to comparable index. It includes data classification, characterization and quantification.

From the goal of assessment, we divide the data into two types: resources consumption and environmental pollution. The former includes non-renewable resource consumption and renewable resource consumption. The latter includes global warming, acidification, eutrophication and ecotoxicity. Then, we describe each type of pollutants with the method of reference. CO<sub>2</sub> is the reference of global warming; SO<sub>2</sub> is the reference of acidification. The effect equivalence of reference is 1, and the others can be achieved by comparing with the contribution of reference to the environmental impact, as shown in Table 1.

The environmental impact potential could be obtained by using Equation (1):

$$EP(j) = \sum EP(j)_i = \sum [Q(j)_i \times EF(j)_i] \quad (1)$$

where  $EP(j)$  is the potential value of the product system to type- $j$  of the environment effect;  $EP(j)_i$  is the potential contribution for pollution category  $i$  to impact  $j$ ;  $Q(j)_i$  is the release of emission  $i$ ,  $EF(j)_i$  is the effect equivalent factor for pollution  $i$  to effect  $j$ .

We set the normalization data to compare their contribution to the environment. It can be obtained by using Equation (2):

$$NEP(j) = EP(j) \frac{1}{Te \cdot ER(j)_{90}} = \frac{EP(j)_{pro}}{ER(j)_{90}} \quad (2)$$

where  $NEP(j)$  is the standard value of environment for type  $j$ ;  $Te$  is the time of product service;  $ER(j)_{90}$  is the reference of the environmental effect;  $ER(j)_{pro}$  is the present potential value of environment for type  $j$ .

The standardized resource potential value can be obtained by using Equation (3):

$$NRC(j) = RC(j) \frac{1}{Tr \cdot RR(j)_{90}} = \frac{RC(j)_{pro}}{RR(j)_{90}} \quad (3)$$

Table 1. The effect equivalence of environmental impacts.

Types	Emissions	The equivalent value
Global warming (gCO <sub>2</sub> eq./g)	CO <sub>2</sub>	1
	CH <sub>4</sub>	25
	N <sub>2</sub> O	320
	CO	2
	NMHC	3
	3,4-Benzo pyrene	3
Acidification (gSO <sub>2</sub> eq./g)	Chlor.HC	3300
	SO <sub>2</sub>	1
	NO <sub>x</sub>	0.7
	HF	1.60
	H <sub>2</sub> S	1.88
	HCl	0.88
Photochemical ozone (gC <sub>2</sub> H <sub>4</sub> eq./g)	NH <sub>3</sub>	1.88
	VOC	0.5
	CO	0.03
Eutrophication (gNO <sub>3</sub> eq./g)	CH <sub>4</sub>	0.007
	NO <sub>x</sub>	1.35
	NH <sub>3</sub>	3.64
Eco-toxicity (gEFm <sup>3</sup> soil eq./g)	COD	0.23
	Cadmium	1.8
	Chromium	0.01
	Copper	0.02
	Lead	0.01
	Mercury	5.3
	Nickel	0.05
	Zinc	0.005

where  $NRC(j)$  is the standard value of resource consumption for type  $j$ ;  $Tr$  is the time of using product;  $RR(j)_{90}$  is the reference of resource consumption;  $RC(j)_{pro}$  is the present potential value of resource consumption for type  $j$ .

The resource weighting factors can be obtained by using Equation (4):

$$WR(j) = RR(j)_{90} / RES(PEj)_{90} \quad (4)$$

where  $RES(PEj)_{90}$  is the per capita reserves in 1990.

The environmental weighting factors can be obtained by using Equation (5):

$$WP(j) = ER(j)_{90} / ER(j)_{T2000} \quad (5)$$

where  $ER(j)_{T2000}$  is the per capita level of environmental impact for type  $j$  in 2000.

$WR(j)$  and  $WP(j)$  reflect the amount of occupied average resource and environmental space, which can be compared with different potential values.

Resource depletion factor index can be obtained by using Equation (6), the unit of which is  $PE_{WCnEast90}$ :

$$RDI = \sum WR(j) = \sum \frac{RC(j)_{pro}}{RES(PEj)_{90}} \quad (6)$$

Environmental effect load can be obtained by using Equation (7):

$$EIL = \sum WP(j) = \sum \frac{EP(j)_{pro}}{RE(j)_{T2000}} \sum \frac{\sum [Q(j)_i \times EF(j)_i]}{ER(j)_{T2000}} \quad (7)$$

Resource depletion coefficient reflects the share of product resource consumption in the whole resource, reflecting the scarcity of resources; it also reflects the pressure on the natural environment. Through the data classification, characterization, quantification, we explore environmental factors of a more suitable mode to meet the environmental impact standards.

### 3.4 Case analysis

Guiyu is the largest rubbish processing factory, which is closely monitored because of the severe electronic pollution. This paper evaluates the carrying capacity of resource and environment by taking waste plastic boxes and printed circuit boards in Guiyu as the research object, and explores the suitable recycling technology to give some reference for improving recycling technology in Guiyu.

#### 3.4.1 Simple recycling mode

These modes only dismantle components and bury the wastes, and have no energy consumption, and so the scope of evaluation is resource consumption and pollutant emissions.

The resource input is metals, such as iron, copper and aluminum. Through normalization and weighing, we obtain a potential value of the metal consumption and resource depletion coefficient, as given in Table 2.

From Table 2, we can obtain the resource depletion coefficient as 22345.31. The consumption of copper has the biggest pressure on the resource system.

The pollution emissions are mainly produced by solid waste stacking or release of heavy metals. The results are summarized in Table 3.

From Table 3, we can obtain the carrying capacity of environment as 55.55, which indicates that the heavy metal pollutants that are released directly will cause pressure on the environment.

#### 3.4.2 Individual workshop processing mode

The recycling processes of waste plastic and printed circuit board include four steps: welding,

Table 2. Normalization and weighting of resource consumption.

Type of resource	Iron	Copper	Aluminum
Consumption (kg/a)	$2.05 \times 10^6$	$1.3 \times 10^6$	$0.63 \times 10^6$
The reference of standardization ER [kg/(per capita a)]	103	1.7	3.4
Standardized value	19920.91	764705.88	185294.12
Period (a)	120	36	200
Weighted value	166.01	21241.83	946.47
Resource depletion coefficient	22354.31		

Table 3. The potential value of pollution emission.

Pollution	Emissions (kg/a)	Effect of equivalence factor EF(gw)	Impact potential value EP(gw)
Eco-toxicity		(gEFm <sup>3</sup> soil eq./g)	(kgEFm <sup>3</sup> soil eq./a)
Cadmium	143.66	1.8	258.59
Chromium	293.91	0.01	2.94
Copper	483360	0.02	9667.20
Lead	8481.06	0.01	84.81
Mercury	7.22	5.3	38.27
Nickel	1091.38	0.05	54.57
Zinc	13500.16	0.005	67.50
PE90	—	—	56.55

pickling, burning and mechanical crushing. The scope of evaluation is resource consumption and environmental emission.

We can get the energy consumption list converting the power consumption into coal consumption according to “the Chinese Energy Statistical Year-book” and “People’s Republic of China Environmental Protection Industry Standard”.

The resource input is mainly iron, copper or aluminum. We can obtain the recycling rate of common resource from the “Industrial Pollution and Emission Index Manual”, and then get the results by calculating, as given in Table 4.

From Table 4, we can obtain the resource depletion coefficient as 442.21. The recycling rate of copper is highest; however, consumption of copper has the largest pressure on the resource system. Thus, we should pay more attention to improve the recycling rate of copper and reduce the consumption of copper deposits.

The pollution emissions include waste gas, waste water and heavy metals. Through normalization and weighting, we can obtain the results, as summarized in Table 5.

From Table 5, we can see that the global warming has the largest effect on the environment; the carrying capacity of the environment is 5838005.35.

### 3.4.3 Diversified recycling mode

This mode usually adopts the way of centralized processing, and the scope of the evaluation focuses on the evaluation of energy recovery and discharge of pollutants. Through calculating, we can obtain the results, as given in Table 6.

We can get the results by characterization and normalization and weighting, as given in Table 7.

From Table 7, we can see that the potential value of acidification and eutrophication decreases obviously, and the environmental effect load is 627753.41. The results indicate that this mode realizes the optimization compared with the individual workshop processing mode.

## 3.5 The comparison of resource and environment load for the three modes

To further understand the positive effect on the environment with the centralized processing mode, we compare the resource and environment load of the three modes.

### 3.5.1 The comparison of resource load

From Table 8, we can get the following results: the centralized processing mode can save 98.67% of coal and can slow the shortage condition of supplying electric, and the diversified recycling mode

Table 4. Normalization and weighting of recourse consumption.

Types of resource	Coal	Iron	Copper	Aluminum
Consumption (kg/a)	$5.26 \times 10^6$	$1.94 \times 10^6$	$0.02 \times 10^6$	$0.03 \times 10^6$
Reference [kg/(per capita a)]	574	103	1.7	3.4
Standardized value	91.6	19730.66	7590.13	13282.73
Period (a)	170	120	36	200
Weighted value	0.54	164.42	210.84	66.41
Resource depletion coefficient	442.21			

Table 5. The standardized and weighted analysis of pollution emissions.

Type	Global warming	Acidification	Eutrophication	Eco-toxicity
Potential value EP	$6.58 \times 10^9$	$1.35 \times 10^8$	$2.09 \times 10^8$	961.56
Standardized reference	8700	36	62	358
Standard value	$0.75 \times 10^6$	$3.75 \times 10^6$	$3.38 \times 10^6$	2.69
Weight factor	0.83	0.73	0.73	1.99
Weighted value	$6.28 \times 10^5$	$2.74 \times 10^6$	$2.47 \times 10^6$	5.35
Environmental effects load	5838005.35			

Table 6. The list of resource consumption and reusing.

Energy	Coal (kg/a)	Recycling power (KWh/t)	Coal Consumption (kg/a)
Mechanical grinding	$0.38 \times 10^6$	–	–
Welding components	$0.03 \times 10^6$	–	–
Burning	$0.15 \times 10^6$	6.75	–
Total Consumption	$1.01 \times 10^6$	6.75	$0.07 \times 10^6$

Table 7. The normalization and weighting of environmental impacts.

Type	Global warming	Acidification	Eutrophication	Eco-toxicity
Potential value EP	$6.58 \times 10^9$	245.28	100.33	13.14
Standardized reference	8700	36	62	358
Standard value	$0.75 \times 10^6$	6.81	1.62	0.037
Weight factor	0.83	0.73	0.73	1.99
Weighted value	$6.28 \times 10^5$	1.18	1.18	0.073
Environmental effects load	627753.41			

can recycle resource through the advance technology, equipment and reasonable management.

### 3.5.2 The comparison of carrying capacity of environment

The carrying capacity of the environment of the simple recycling model is from heavy metals. The environmental impact load of individual workshops processing pattern can be divided into the new environment impact load and environmental

impact load caused by heavy metals. The environmental impact load of the heavy metals is lower than the simple recycling mode because of recycling of some heavy metals. However, the air pollutants and water pollutants generated by dismantling account for 89% in the individual workshop processing. Diversified recycling mode adopts advanced technology and uniform management to reduce environment pollution from acid leaching, and it effectively reduces metal emissions.

Table 8. The analysis of resource load.

Resource and energy consumption (kg/a)	Coal	Iron	Copper	Aluminum
Simple recycling mode	–	$2.05 \times 10^6$	$1.03 \times 10^6$	$0.63 \times 10^6$
Individual workshop processing	$5.26 \times 10^6$	$1.94 \times 10^6$	$0.02 \times 10^6$	$0.03 \times 10^6$
Centralized processing mode	$0.07 \times 10^6$	–	–	–

Table 9. The comparison of environment load.

Pollution emission (kg/a)	Simple recycling mode	Individual workshop mode	Centralized processing mode
<i>Atmosphere</i>			
CO <sub>2</sub>	–	$6.58 \times 10^9$	$6.58 \times 10^9$
SO <sub>2</sub>	–	$1.98 \times 10^7$	197.81
HCl	–	$6 \times 10^4$	0
NO <sub>x</sub>	–	$1.55 \times 10^8$	67.82
<i>Water</i>			
COD	–	38.16	38.16
HCl	–	$1.94 \times 10^6$	0
<i>Ecotype</i>			
Cadmium	143.66	143.52	0.4
Chromium	293.91	293.62	89.04
Copper	483360	25440	128.47
Lead	8481.06	8077.2	156.88
Mercury	7.22	7.21	0.51
Nickel	1091.38	606.32	71.11
Zinc	13500.16	8437.6	234.47

The recycling rate of metals can reach up to 70%, and all the indices meet the national standards.

#### 4 CONCLUSION AND ADVICES

From the above analysis, we can draw the following conclusions: in the aspect of resource consumption, the resource depletion coefficient of the simple recycling mode is 22354.31, and it is 442.21 in individual workshop processing; the coal consumption in the centralized processing mode is  $0.07 \times 10^6$ , which saves 98.7% of coal comparing with individual processing. In the aspect of environment factors, the environment load of the simple recycling mode is 56.55, the load of individual mode is 5838005.35, and the load of centralized processing mode is 627753.41. By comprehensively considering the resource consumption and environment load, it can be found that the centralized processing mode is superior to the individual treatment mode and simple mode. Therefore, the diversified recovery and centralized processing mode is the development direction based on building the WHA reverse logistics system. There are some

advices for the building WHA reverse logistics system.

1. Pay attention to the construction of the WHA reverse logistics system. The investment and cost of the diversity recycling mode is high, which is suitable for large-scale manufacturers, so that it should be guided by government, and the special finance funds at all levels of government should promote enterprise and private capital investments in the field as soon as possible, and further promote its industrialization development.
2. Push the concept of green design of home appliances. Instead of passively recycling home appliances, it is better to reduce initiatively its environmental harm, and we can adopt the green design method to solve the problem of environmental pollution and resource recycling WHA reverse logistics.
3. Establish suitable recycling policy regulations of WHA. At present, China is in the home appliances scrapped peak, so it is especially important to reasonably handle the WHA. The regulations clear the responsibility of each side, and enhance operability; the policy can prevent the emergence of improper recycling for the pursuit of economic growth.

# Practice of interprovincial public transport in Beijing–Tianjin–Hebei region

Y.Y. Mai & X.N. Sun

*China Academy of Transportation Sciences, Beijing, China*

**ABSTRACT:** This paper first analyzes the interprovincial public transport demand in Beijing–Tianjin–Hebei region on the basis of studying the development status and problems of road passenger transport in this region, and then summarizes the influencing factors of public transport operation organization, finally puts forward public transport transformation mechanism mode and route operation mode and studies the public transport operation management policies.

**Keywords:** Beijing–Tianjin–Hebei region; interprovincial public transport; practice

## 1 INTRODUCTION

### 1.1 *Research background*

With the acceleration of urban and rural passenger transport integration, the voice of the masses for enjoying equal travel services has been increasingly stronger. To deeply implement the strategic deployment of the Party Central Committee and State Council on Beijing–Tianjin–Hebei synergetic development and adapt to the new situation and requirements of Beijing–Tianjin–Hebei traffic integration development, the Ministry of Transport proposed the implementation of pilot reform of urban and rural passenger transport integration in Beijing, Tianjin, and Hebei in the program of deepening pilot transportation reform comprehensively. Under this background, the exploration on new development mode of public transport in interprovincial adjacent areas will promote the realization of policy coordination, resource sharing, reasonable layout, smooth connection and integrated service of road passenger transport in Beijing, Tianjin, and Hebei and provide powerful support for synergetic development of Beijing, Tianjin, and Hebei and the establishment of interlinked comprehensive transportation network.

### 1.2 *Determination of the study scope*

Areas within the scope of 200 km radius with Beijing and Tianjin as two cores are defined as main adjacent areas, including Beijing, Tianjin, Tangshan, Langfang, Baoding, Zhangjiakou, Chengde, and Cangzhou. Areas within the scope of 200–300 km radius are defined as secondary adjacent areas, including Shijiazhuang, Qinhuangdao, and Xingtai.

## 2 DEVELOPMENT STATUS AND PROBLEMS

### 2.1 *Operation of existing routes*

#### 2.1.1 *Interprovincial passenger transport routes*

According to incomplete statistics, there are over 900 road passenger transport routes and over 2200 operating regular buses among these three provinces. Currently, the public transport of Beijing has covered 14 counties of Hebei Province with 26 operating routes, over 800 operating vehicles and a daily number of passengers originating from 300,000 person-time. It has supported integration development of areas around the capital in Hebei Province with Beijing. However, due to different financial subsidies among administrative divisions, the margin of preference of interprovincial buses is different in Beijing and Hebei. For some buses with sixty percent discount for cardholders in Beijing, the margin of preference is changed or canceled after they drive away from the provincial boundary. Due to the low ticket price of interprovincial buses driven from Beijing, Beijing buses have been resisted by local public transport companies in Hebei for several times.

#### 2.1.2 *Operation of intercity public transport*

The opening of intercity public transport is an inevitable trend of Beijing–Tianjin–Hebei integration development, which will drive the development and utilization of Beijing–Tianjin–Hebei suburbs effectively and can provide powerful support for the circulation of production factors among Beijing, Tianjin, and Hebei.

According to incomplete statistics, there are over 40 bus routes in Beijing leading to various places

in Hebei. Residents in the urban area of Langfang, Dachang, Xianghe, Gu'an, Zhuozhou, Huailai, Xinglong, and Luanping can take the bus to Beijing in the local place. Intercity public transportation plays an important role in the exchange of Beijing, Tianjin, and Hebei.

### 2.1.3 *Operation of intercity rail*

Currently, the process of traffic integration in Beijing, Tianjin, and Hebei is accelerated obviously and an intercity railway network covering Beijing, Tianjin and Hebei is spreading densely. Besides Beijing–Tianjin intercity railway and Tianjin–Qinhuangdao passenger special line built and opened to traffic, Beijing–Chengde passenger special line, Beijing–Zhangjiakou intercity railway, Beijing–Hengshui passenger special line and Beijing–Tangshan intercity railway have entered the stage of planning, exploration or environmental assessment.

## 2.2 *Existing problems*

Currently, road transport in Beijing, Tianjin and Hebei has a good overall development level. However, due to different development strategies and emphases in these three provinces, many uncoordinated phenomena exist. One the one hand, regional policies and legal systems are incomplete. Various regions often start from local interests and intervene in market activities with administrative order, thus influencing the rational allocation of transportation resources. On the other hand, competent authorities go their own way in the planning of transportation system and cross-departmental, trans-regional, and multi-level transportation planning coordination mechanism is lacking. Therefore, problems such as local protection and inadequate resource sharing are caused. It is difficult to meet the development demand of economic integration in Beijing, Tianjin, and Hebei. The following problems exist currently.

### 2.2.1 *Non-smooth transport corridor and interlinked level of infrastructure to be improved*

Currently, many parts of fast highway corridor among provinces (districts and cities) in the area are not interlinked. There are many dead end highways and bottleneck roads between Hebei and Beijing and Tianjin.

### 2.2.2 *Slow overall progress of integration*

The extension of public transport causes conflicts in operation and intergovernment coordination has a great difficulty. The extension of urban public transportation in Langfang and Zhangjiakou around the capital to 14 counties in Beijing is a typical example. It has caused impact on operators of road passenger transport in the same route.

Therefore, they resist it and even stop the traffic and exchange blows, thus seriously influencing traffic safety and the travel of the masses. The government should balance interest subjects and provide public transportation service for the public.

### 2.2.3 *Management mode to be further specified*

The opening of public transport in interprovincial adjacent areas aims at facilitating the travel of the masses and improving the quality of passenger transport service. The operation mode of interprovincial passenger transport route is reformed and adjusted appropriately with the use of operation service pattern of urban public transportation for reference. It belongs to interprovincial road passenger transport and should be managed according to interprovincial passenger transport.

### 2.2.4 *Construction of supporting system to be strengthened*

There are insufficient system, standard and specification with respect to the route length, vehicle standard, safety supervision, site setting, service quality assessment, and management of operation market in the operation of intercity passenger transport route of public transport, which cannot provide basic support for the operation of public transport.

## 3 PUBLIC TRANSPORT DEMAND

### 3.1 *Interprovincial passenger travel demand*

With the acceleration of integration process in Beijing, Tianjin, and Hebei and constant deepening of regional cooperation, an integration pattern of support of regional central city and joint development of hinterland has gradually formed. Transprovincial commuter flow in the region will increase rapidly and passenger travel structure and purpose will change. Therefore, it is imperative to establish a traffic system dominated by public transport.

Traditional long-distance road passenger transport mode is operating in Beijing–Tianjin–Hebei region. Its in adaptation to the increasing commuter flow demand becomes prominent gradually. Therefore, it is necessary to transform the way of route planning, site setting, vehicle disposition, and bus run arrangement for public transport so as to adapt to new features of interprovincial passenger flow in the synergetic development process of Beijing, Tianjin, and Hebei.

### 3.2 *Relevant policies, regulations, and standards demand*

It is an urgent need to issue a unified management method in Beijing, Tianjin, and Hebei and

standardize the opening condition, route selection, site setting, vehicle condition, ticket pricing, and operation subject in the transformation of road passenger transport for public transport so as to provide guarantee for promoting the transformation of road passenger transport of main passages for public transport in Beijing–Tianjin–Hebei interprovincial adjacent areas.

It is an urgent need to discuss and issue a policy of fiscal subsidies for the transformation of road passenger transport for public transport in Beijing, Tianjin, and Hebei. Ticket pricing and the establishment of ticket system in the transformation of road passenger transport for public transport in Beijing, Tianjin, and Hebei involve various interests of different travelers, passenger transport enterprises and government sector. Due to its social publicity, governments of these three regions should discuss and issue appropriate fiscal subsidies to maintain the sustainability of its operation.

It is an urgent need to establish a unified service standard for the transformation of road passenger transport for public transport in Beijing, Tianjin, and Hebei. Currently, there is a great urban-rural gap in these regions and a great gap between Beijing and Tianjin and Hebei in the level of transportation service. To guarantee the consistency of regional transportation service provision after the transformation of road passenger transport for public transport, it is urgent to establish a unified service standard.

## 4 TRANSPORT OPERATION MANAGEMENT

### 4.1 *Influencing factors*

#### 4.1.1 *Passenger flow characteristics*

Interprovincial passenger flow is characterized by large passenger flow volume in the morning and evening, great seasonal variation of passenger flow volume and its great variation in festivals and holidays. It is required to fully consider the unbalance of passenger flow in time and space and the possibility of future rapid increase during the organization of operation.

#### 4.1.2 *Network layout structure*

Net layout structure not only plays a decisive role in organization means of specific routes, but also is the foundation of space organization form of routes. Many route organization forms are available for a net structure with complete layout. Generally, multiple organization forms are combined.

#### 4.1.3 *Urban layout structure and pattern*

Urban layout structure and pattern features directly influence the planning of route and further influence the organization arrangement of route. Different geographic properties have restrictions

on route planning, transport capacity, and vehicle choice. Therefore, geographic features, industrial distribution, and development and resource distribution in the region should be considered in terms of route organization arrangement.

#### 4.1.4 *Transport benefit and cost*

Public transport enterprises of interprovincial road passenger transport should conduct comprehensive analysis and feasibility evaluation on the operation efficiency of the route, reduce transportation costs, and improve the profitability of route and service quality through efficient operation organization management and show coordinated development of fairness and efficiency.

### 4.2 *Mechanism mode*

#### 4.2.1 *Selection standard of passenger transport route for public transportation*

Interprovincial road passenger transport route meeting the following conditions can be transformed for public transportation:

1. A large number of passengers traveling back and forth along the route, large passenger flow volume and daily average passenger capacity more than 1000 person-time in principle;
2. Route operation distance within 100 km in principle;
3. Good road condition. Roads pass the inspection of the police and traffic administration and meet requirements of vehicle meeting and loading and unloading of passengers in public transportation operation.
4. Repetition rate of urban public transportation routes not more than 50%.

#### 4.2.2 *Examination and approval method for passenger transport route for public transport*

It is required to accelerate the improvement of periodical coordination and joint examination and approval mechanism for the operation of interprovincial passenger transport for public transport and implement “one examination and approval for one route” so as to provide convenience for the input of transport capacity and ensure the opening and operation of mature routes as soon as possible.

#### 4.2.3 *Report of passenger transport route for public transport*

It is required to report the opening situation of interprovincial passenger transport routes to the competent department annually and list routes for public transportation separately.

### 4.3 *Route operation mode*

Passenger flow and regional urbanization level are judgment standards for determining the operation

mode of intercity road passenger transport for public transport-complete public transport mode and incomplete public transport mode. Whole-process public transport operation mode should be adopted in urbanized areas with the formation of intercity urban traffic corridor in adjacent areas and connection.

The same passenger transport route should be operated by the same operation subject in corporatization form. Affiliation or contract operation is prohibited. Routes parallel to direct passenger transport route should be operated by the same operation subject or with joint-stock partnership in corporatization form.

#### 4.4 Operation management policies

##### 4.4.1 Establishment of coordinated management mechanism

It is required to establish a daily coordinated management organization composed of Beijing Transport and Communications Committee, Tianjin Transport and Communications Committee and Hebei Department of Transportation, hold coordinated working conference periodically, establish Beijing-Tianjin-Hebei joint conference system, conduct consultative management over the preparation of integration development plan of road passenger transport in Beijing-Tianjin-Hebei region, the establishment of relevant standards, specifications and fiscal guarantee system, examination of interprovincial passenger transport routes for public transport, credit rating of transport enterprises and emergency disposal, and report the opening situation of interprovincial passenger transport routes to the competent department annually.

##### 4.4.2 Connection of regulations, standards and policies

1. Organize the preparation of integration development planning of road passenger transport in Beijing-Tianjin-Hebei adjacent areas positively

It is required to break geographic segmentation according to the principle of “rapid connection and convenience for transfer”, conduct unified planning, construction and management of road passenger transport network and public infrastructure such as station, urban and rural road and bus stop along the route and realize coordinated development of “road, station and transport”; adhere to the dominant role of transformation of existing routes and the helping role of opening of new routes, study and establish the development plan and annual plan of passenger transport routes for public transport in adjacent areas and make them public.

2. Improve relevant service standards on the transformation of road passenger transport route for public transport

It is required to establish and improve passenger transport service quality specification and quality assessment system, strengthen urban-rural passenger transport service quality assessment, use assessment results as the basis of various capital subsidies, link up with tendering and bidding of passenger transport route and enterprise development support policies, supervise and urge enterprises’ standardized management, cooperate with relevant departments to accelerate the improvement of standards and specifications on the route length, vehicle standard, site setting and service quality assessment in the operation of passenger transport route for public transport, and provide basic support for the standardization of public transport service of passenger transport route.

3. Study and establish fiscal guarantee system

The competent department of transportation should cooperate with other departments positively to study and establish low ticket price policies for road passenger transport and propose a preliminary scheme for ticket system and ticket price according to the compensation of public fiscal subsidies so as to improve the attraction of public transport. It is required to determine ticket price management policies according to Road Transport Price Control Regulations and Rules of Freight Rate of Buses jointly issued by the Ministry of Transportation and National Development and Reform Commission and implement cost pricing and the same price for the same route; implement specific ticket price optimization policies according to local fiscal subsidies; establish price evaluation system, strengthen effective supervision on financial management of enterprises engaged in road transport, conduct periodical dynamic monitoring on route cost and benefits and provide basis for scientific pricing of the government.

4. Strengthen integration and informatization management level of public transport regions

It is required to build a road passenger transport information management command center integrating transport management and control decision centers, propose the framework of public transport information system, strengthen information collection, storage, search and transmission functions, guarantee accurate, and rapid transmission of orders and implement “one-card” positively.

5. Attach great importance to safety and green production

It is required to make technical standard examination of vehicles strict. Operating vehicles

should be supplied with satellite positioning vehicle terminal and video surveillance equipment meeting the standard. It is required to further specify safety supervision responsibilities, implement supervision responsibilities of safety source of road transport management organization, supervise and urge relevant operators to strengthen the management over vehicles, drivers, and attendants, implement responsibilities of the subject of safety production in enterprises and improve the ability of emergency disposal in public transport of interprovincial passenger transport.

#### 4.4.3 Resource sharing mechanism

1. Make reasonable use of existing routes, site, and vehicle resources

Make reasonable use of existing routes and site resources; consider the demand for public transport of passenger transport in areas with large passenger flow volume such as important towns and villages, important industrial belt and tourist attractions based on existing routes and sites; form rational division of work and easy transfer with urban public transport, road passenger transport and rail transport in terms of site setting; increase the proportion of nonstop and one transfer in the total amount of travel of the public, reduce the average times of transfer, plan passenger transport, and public transport network structure rationally, and meanwhile select appropriate vehicles based on existing road operating vehicles and buses according to road conditions and passenger source.

2. Establish information sharing platform  
Promote intelligent dispatching system and IC system positively, expand the system module

of public transport service information search of passenger transport positively based on the existing information platform, exert the role of scientific and technological means in the supervision on operation and analysis on the operation of industrial economy, and constantly improve the industrial service quality.

## 5 CONCLUSIONS

In allusion to new situation and new problems of Beijing–Tianjin–Hebei integration development, for the development of Beijing–Tianjin–Hebei road passenger transport, it is required to promote the reform of public transport operation in road passenger transport routes in adjacent areas positively based on the new situation, promote the integration of urban and rural passenger transport into regional traffic integration system, establish a safety and green intercity road passenger transport service system with equal service and efficient information through constant deepening of transformation work and support the integration construction of Beijing, Tianjin, and Hebei comprehensively.

# Research on adsorption of methyl orange by magnetic activated carbon prepared by Eucalyptuses

Jia Liu, Hua Zhang, Liudan Luo, Haiyi Huang & Wen Chen

*Guangxi Scientific Experiment Center of Mining, Metallurgy and Environment, Guilin University of Technology, Guilin, China*

*College of Environmental Science and Engineering, Guilin University of Technology, Guilin, China*

**ABSTRACT:** Eucalyptuses are the mass agricultural plant in Guangxi province. The sawdust of eucalyptuses were used as the raw materials for the magnetic activated carbon, then analyzed for the adsorption of single factor such as amount of magnetic activated carbon by Eucalyptuses, adsorption time, and initial concentration of methyl orange solution and then gave the fitting and analysis by dynamic model and isothermal model.

**Keywords:** magnetic activated carbon by Eucalyptuses; adsorption removal; Methyl Orange (MO); kinetics model; isotherm

## 1 INTRODUCTION

Eucalyptuses are the mass agricultural plant in Guangxi province. The area of eucalyptuses in the autonomous region has reached to more than 180 million hm<sup>2</sup>, which comprises nearly one-fourth of all planted commercial forest's area in autonomous region. Eucalyptus production accounts for two-thirds of the all region's timber production with the largest area and the highest total output in China. Gross output of eucalyptuses utilized in wood processing, pulping, and paper-making is nearly 64 billion yuan. With the continuous reduction of mineral resource such as oil and coal, more attention is paid to exploitation of biological resource (Zhonglei Meng, Junji Li, Kang Sun, 2012). Activated carbon is a carbon-based adsorption material which has high surface area and abundant pore structures with its preparation technology having been fully developed. Now the major breakthrough of researching and preparation is the selection of new materials. Using the sawdust of eucalyptuses as the raw materials for the activated carbon can effectively reduce environment pollution, and it is an effective way to dispose of agriculture wastes. The sawdust of eucalyptuses are the high-quality raw materials for the activated carbon due to its low mass fraction (Xinping Xie, Zhonglei Meng, Jianchun Jiang, 2013).

## 2 MATERIAL AND METHODS

### 2.1 Materials and reagents

The stock solution (1000 mg/L) of MO was prepared by dissolving 1 g of solid dye in 1 L double ultrapure water and the working concentrations daily were prepared by its suitable dilution. Chemicals were methyl orange, K<sub>2</sub>CO<sub>3</sub>, and FeCl<sub>3</sub> (all were analytical reagent).

### 2.2 Preparation of activated carbon

In this research, the branch of eucalyptuses, popular in Guangxi province, was used. The raw material for the magnetic activated carbon was obtained after it was cleaned, dried and sawed into block. The eucalyptuses were dried at 400°C for 40 min, crushed and passed through a 60-mesh screen. Eucalyptuses carbon was mixed with K<sub>2</sub>CO<sub>3</sub> and FeCl<sub>3</sub> at the mass ratio of 1.5:1:1, then mixed with deionized water, which was shaken for 7 hours using a thermostat shaker bath at 25°C. After having been filtered and dried at 110°C for 8 h–12 h, the samples were placed in a muffle furnace and activated at 800°C for 80 min. The products were cooled to room temperature and washed with deionized water until the pH of the washing solution reached 7. The activated sample were dried in an oven at 110°C for 8–12 h, then passed through a 100 mesh screen, and the magnetic activated

carbon by eucalyptuses were obtained (Xiaolei Liu, 2012).

### 2.3 Methods

Experiments were studied by single factor experiments, Kinetic experiments and Isothermal experiments. Then after filtration with filter paper, the concentrations were analyzed by UV–VIS spectrophotometry whose wavelength of determination was 465 nm, the eucalyptus magnetic adsorbent on adsorption capacity of dye wastewater and the removal rate were calculated as shown in figures.

## 3 RESULTS AND DISCUSSION

### 3.1 Effect of initial concentration

Each 0.1000 g activated carbon was placed into 7 beakers all with 50 ml methyl orange solution whose initial concentrations were 100, 200, 300, 400, 500, 600, and 700 mg/L, respectively. Then stirred for 2 h in a water bath at 25°C. Result is shown in Figure 1.

Figure 1 shows the removal rate at the methyl orange solution of different concentration values. The initial (horizontal) part of the curve represents the methyl orange aqueous solution, which is almost adsorbed completely. Then, the curves gradually fell with increased concentration values of methyl orange solution and finally stabilized just around 58%.

### 3.2 Effect of time

A fixed amount of activated carbon (0.1000 g) and 50 ml of methyl orange solution were placed into a dozen 100 ml centrifuge tubes successively, which were shaken for 3, 6, 9, 12, 18, 30, 45, 60, 75, 90,

120, and 180 min, respectively, using a thermostated shaker bath at 25°C. Result is shown in Figure 2.

Experimental results show that the removal rate of the methyl orange as simulated dye wastewater through activated carbon increased with increased adsorption time. When adsorption lasted over 30 min, the increase in the removal rate has slowed. The removal rate remains unchanged basically after 75 min. It is chiefly because the methyl orange solution was adsorbed completely. So we choose 75 min as the adsorption time in further experiments (Yuanyuan Sun, 2014).

### 3.3 Effect of dosage

Weigh accurately 0.025, 0.5, 0.75, 0.1, 0.125, and 0.15 g of activated carbon in six 100 ml centrifuge tubes with 50 ml of methyl orange solution, respectively, then shake them for 2 h using a thermostated shaker bath at 20°C. Result is shown in Figure 3.

Figure 2. Effect of time on adsorption of MO.

Figure 1. Effect of the initial concentration of MO solution on adsorption of MO.

Figure 3. Effect of amount of magnetic activated carbon by Eucalyptuses on adsorption of MO.

Experimental results show that the removal rate of the methyl orange as simulated dye wastewater through activated carbon increased with increased quantity of activated carbon. When its quality has gone over 0.125 g, the increase in the removal rate has slowed and becomes horizontal gradually due to the methyl orange solution being adsorbed completely. So we choose activated carbon quality of 0.125 g in further experiments (Keqi Tian, 2010).

#### 4 KINETIC EXPERIMENTS

Three groups of 50 ml of methyl orange solution with certain concentration whose pH values are 2 were placed into seven 100 ml centrifuge tubes successively, and weighed 0.1 g of activated carbon in each group. Then shake them using a thermostated shaker bath at 25°C. Put them into the colorimetric tube after filtration with filter paper and oscillation by controlling the different oscillation time. The absorbances were analyzed using a UV-visible spectrophotometer at an appropriate wavelength, then compared the dates with a standard curve of dye concentration absorbance to determine the quality of the remaining dye concentration. The amount of adsorption at time t q were calculated by:

$$q = \frac{(C_0 - C_1) V}{m} \quad (1)$$

where  $C_0$  and  $C_1$  are the dye concentration at the beginning and at time t, respectively, and  $m/V$  is the dose of dried carbon ( $1 \text{ gL}^{-1}$ ).

In order to better describe the behavior of activated carbon adsorption kinetics on the methyl orange as simulated dye wastewater, fitting process is conducted on the date in Figure 4 through pseudo-second-order kinetic models.

Figure 4. Pseudo-second-order kinetic equation curve fitting.

Pseudo-second-order kinetic equation:

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{t}{q_e} \quad (2)$$

where  $q_e$  and  $q_t$  are the amount of adsorption at the equilibrium and at time t (mg/g), respectively,  $k_2$  is adsorption rate constants of pseudo-second-order ( $\text{g}/(\text{mg} \cdot \text{min})$ ) (Yude Liu, 2012).

Figure 4. shows that under different concentration conditions, liner correlations are more than 0.99, respectively. Correlation is obvious. Kinetic parameters obtained by calculation are shown in Table 1.

##### 4.1 Isothermal experiments

Three groups of 50 ml of methyl orange solution with 100, 200, 300, 400, 500, 600, and 700 mg/L concentration values, respectively, were placed into seven 100 ml centrifuge tubes successively, and weighed 0.075, 0.1, and 0.125 g of activated carbon in each group, respectively. Then shake them using a thermostated shaker bath for 3 h at 25°C. Put them into the colorimetric tube after filtration with filter paper and oscillation by controlling the same oscillation time. The absorbance is analyzed using a UV-visible spectrophotometer at an appropriate wavelength, then find the corresponding equilibrium concentration. The eucalyptus magnetic adsorbent on adsorption capacity of dye wastewater and the removal rate were calculated.

Fitting process is conducted on the  $C_e - q_e$  date under the different amounts of magnetic activated carbon by Eucalyptuses according to the Langmuir adsorption isotherm (3) and Freundlich adsorption isotherm (4). Fitting results shown in Figures 5 and 6, and adsorption isotherm parameters and correlation coefficient are shown in Table 2.

$$q_e = \frac{q_m K_L C_e}{1 + K_L C_e} \quad (3)$$

where  $K_L$  and  $q_m$  are Langmuir adsorption constants whose name are affinity of adsorbent toward

Table 1. Pseudo-second-order kinetic parameters for the removal of MO.

Pseudo-second-order kinetic parameters				
Concentration (mg/L)	$k_2$ (g/(mg · min))	$q_e$ (mg/g)	$R^2$	$q_e$ (exp) (mg/g)
300 mg/L	0.00581	149.25	0.99992	148.71
400 mg/L	0.01383	185.19	0.99947	184.34
500 mg/L	0.01228	217.86	0.99898	215.79

Figure 5. Langmuir plots for adsorption of MO by magnetic activated carbon by Eucalyptuses.

Figure 6. Freundlich adsorption of MO by magnetic activated carbon by Eucalyptuses.

Table 2. Isotherm parameters for MO adsorption onto the magnetic activated carbon by Eucalyptuses.

Langmuir isotherm constants			
Dosage (g)	$K_L/(L/mg)$	$q_m/(mg/g)$	$R^2$
0.075	1.2363	201.2072	0.99628
0.1	0.8409	207.9002	0.99655
0.125	0.8843	176.6784	0.98773
Freundlich isotherm constants			
Dosage (g)	$K_f/(mg/g \cdot (l/mg)^{1/n})$	n	$R^2$
0.075	97.1542	7.0507	0.82966
0.1	89.2436	6.0764	0.71128
0.125	76.9242	6.5129	0.61268

adsorbent and monolayer adsorption capacity, respectively;  $C_e$  is the dye concentration at the equilibrium (mg/L), and  $q_e$  is the adsorption amount.

$$\ln q_e = \ln K_f + \frac{1}{n} \ln C_e \quad (4)$$

where the  $K_f$  is Freundlich adsorption constant; the  $n$  is the constant which is used to judge the degree of difficulty in adsorption. Adsorption is more easily conducted when  $1 < n < 10$  (You Zhou, 2012).

It can be seen from Figure 5 and Table 2 that the dosages of magnetic activated carbon by Eucalyptuses are 0.075, 0.1, and 0.15 g, the correlation coefficients are 0.99628, 0.99655, and 0.98773, respectively, which means the correlation is high. As shown in Figure 6, a plot of  $\ln q_e$  against  $\ln C_e$  gave a fitted curve, and generates Freundlich constants from the plot of sorption date in Table 2 reveals that under different dosages of magnetic activated carbon by Eucalyptuses,  $n \geq 1$ , which means it belongs to the preferential adsorption.

## 5 SUMMARY

In our study, we used magnetic activated carbon by Eucalyptuses as adsorbent and methyl orange simulated wastewater as adsorption object to analyze the potential of this kind of wastewater treatment. We discussed the effect of amount of magnetic activated carbon by Eucalyptuses, adsorption time and initial concentration of methyl orange solution on adsorption of methyl orange and drew the conclusion that the most suitable condition for such adsorption are: initial concentration of methyl orange solution is 100 mg/L, the adsorption time is 75 min, and adsorbent dosage is 0.125 g. Kinetic studies of MO were performed based on pseudo-second-order model. The adsorption experimental result was analyzed through the Langmuir and Freundlich isotherm model. Eucalyptuses are the mass agricultural plant in Guangxi province. It's reasonable and economical that use it to convert into activated carbon to remove of the MO from wastewater instead of commercial activated carbon.

# Dynamic distribution and balance technique of energy-saving ventilation system

K. Zhang & J.L. Wang

Harbin Engineering University, Harbin, China

**ABSTRACT:** Different from the traditional hydraulic calculation, it constructed the coupled equations of air volume and the pressure through calculating friction factor and operating point of fan and on the basis of various norms. Then it translated the program into machine language using a high level programming language C++. By employing a dynamic relaxation factor  $k$ , it realized the intelligent iterative computation. It also did a dynamic analysis on the ventilation system, including the influence of various parameters on the dynamic distribution and balance of the system. Finally several proposals are offered to improve the independence of the ventilation system. The research method and dynamic technique applied in this paper would help engineers to analyze and solve problems in the design, and optimize the ventilation system.

**Keywords:** ventilation system; air supply; pressure; dynamic distribution and balance

## 1 INTRODUCTION

The chief aim of the traditional hydraulic calculation is twofold. The first issue is to obtain the pipe diameter and resistance according to the request of flow distribution, and find the fan performance curve, finally determine the fan and its power consumption (design calculation). The second is to determine the pipe diameter according to the defined power equipment (checking calculation) (Valiantzas, 1998, Janssens, 2003). While the work in this paper is neither the design calculation nor the checking calculation, it will focus on the dynamic distribution and balance of a given ventilation system which contains four different terminals. As is well known, a complex coupled relationship between the pipe accessory local resistance factor and the air distribution in the hydraulic calculation exists. The local resistance factors will change with the air volume fluctuating, which will again cause the variation of the air distribution, it is a process of dynamic equilibrium. In the circulation, once the relaxation factor is inappropriate, it may lead to a divergence, so a dynamic relaxation factor  $k$  is applied (Otter, 1965, Küttler, 2008). And a high level programming language C++ is applied to translate the program into machine language.

## 2 ORIGINAL CONDITION

As shown in the [Figure 1](#), the ventilation system includes four different terminals: F1, F2, F3, and F4. The computational flow diagram is

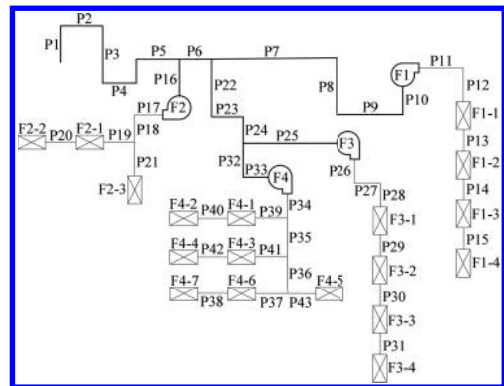

Figure 1. Ventilation system.

shown in [Figure 2](#), in which  $k$  is the dynamic relaxation factor. In the ventilation system, each fan is in charge of the resistance of its own branch. Four fans operate following their own performance curves  $Q = f(P)$ , and simultaneously they exert influence on each other. A new pipe air volume appears with the variation of pressure, and the new air volume will lead to a new pressure. The iterative process will be continued until some criterion for convergence is met.

For the original operational condition in steady-state, four fans run simultaneously, the pressure and air volume as well as the error with normal operating condition for each fan is shown in [Table 1](#). All the errors are less than 5%, which indicates that selection of four fans is appropriate.

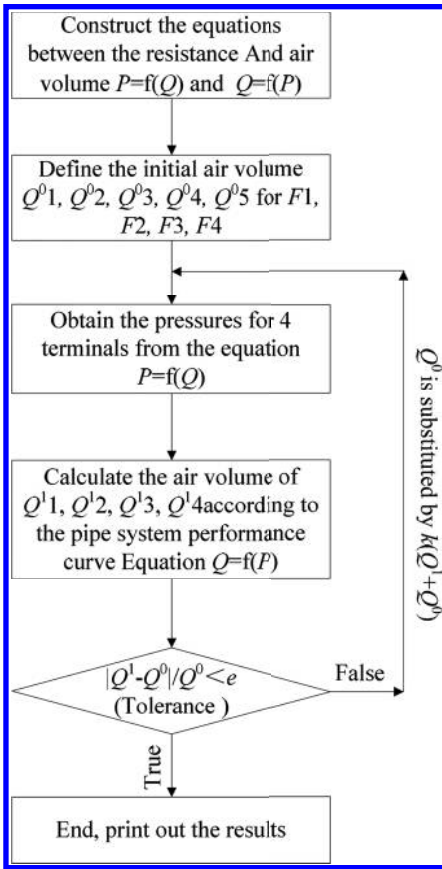

Figure 2. Computational flow diagram.

Table 1. Pressures and air volumes for four fans.

Fans	RP (Pa)	AP (Pa)	Error (%)	RA (m <sup>3</sup> /h)	AA (m <sup>3</sup> /h)	Error (%)
F1	700	697	-0.4	1100	1104	0.0
F2	700	688	-1.7	1100	1131	2.7
F3	4000	3892	-2.7	1000	1016	1.6
F4	1600	1678	4.9	2500	2524	1.0

RP means rated pressure, AP means actual pressure, and RA means rated air volume, AA means actual air volume.

### 3 INTERACTION AMONG DIFFERENT TERMINALS

For the given ventilation system, when parts of the terminals are turned off, the total air volume past the principal pipes will decrease with the reduction of system pressure, which will be bound to produce an effect on the rest terminals. The variation of pressures and air volumes for four fans are

shown in the Figure 3 when turning off different terminals.

It indicates that the pressure for operational user goes on a decrease while other terminals are turned off, while the air volume will increase. And a relative wider fluctuation of air volume is detected than that of pressure. The more terminals are turned off, the greater impact is exerted on the operating user. The result of the fluctuation is that the system operates in off-design performance. The sequence of sensitive degrees for four fans is F1 > F2 > F4 > F3. F1 is the most sensitive while the impact on F3 is minimal, which is due to the resistance of F1 branch,

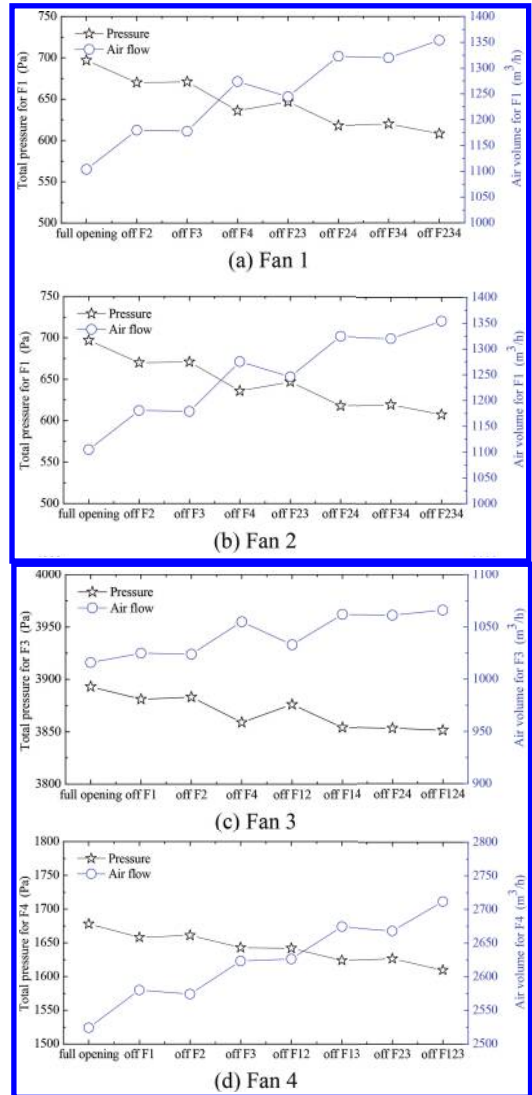

Figure 3. The pressures and air volumes of four fans with turning off different terminals.

which is the least, and it shares the most principal pipes with the other three fans. Relatively speaking, the principal pipes will exert more impacts on it when the other branches experience variations. On the contrary F3 shares the least principal pipes, so it becomes into a high independence of branch. In addition, the variation of four fans also shows that the operational state of F4 exerts the great impact

on the other terminals. For the design air volume of F4 is largest, and its operational state will produce a drastic impact on principal pipes.

#### 4 IMPACT OF PRINCIPAL PIPES ON THE VENTILATION SYSTEM

According to the analysis above, the operational state of terminals will exert impact on the other users, which is mainly because the principal pipes transfer the impact among different terminals. In order to research the impact of principal pipe size on the ventilation system, it compares five groups of different principal pipe sizes. The design case is labeled as Case 0, the diameter for each principal pipe with the increment of 0.1 m is labeled as Case 1 and increment of 0.25 m labeled as Case 2, with the decrement of 0.1 m is labeled as Case 3 and decrement of 0.25 m labeled as Case 4. The air volume fluctuation for four fans with different principal pipe sizes is shown in the Figure 4.

The ventilation system stability of the dynamic performance is degraded with the variation of the principal pipe size, both increment and decrement, namely the impact of the operational state will be enlarged. And the greater the change of the pipe the greater the impact is, which indicates that the original design size has been the optimal condition, so changing the size of the principal pipe can not improve the stability of the ventilation system. Once deviated from the design condition the ventilation system will run in fall-back state. It adequately demonstrates the importance of the jobs in design and model selection.

#### 5 MEASURES OF REDUCING THE MUTUAL EFFECTS AMONG DIFFERENT TERMINALS

In order to improve the independence of the terminals, several measures are recommended. Firstly it should reduce the resistance of the principal pipe, such as reducing the number of elbow and tee reducer-body, or increase the terminal resistance. Reducing the number and the length of the principal pipe is another effective approach. Further more adding an automatic control system to execute real-time monitoring and adjustment will be helpful to improve the independence of the ventilation system and to ensure the ventilation system to work well.

For a series branch like F1, the selection of the pipe diameter is particularly important. If all the pipe diameters are equal to each other, it is bound to cause their air volume to be divided unequally as shown in Figure 5(a). For the constant diameter

Figure 4. The air volume fluctuations of four fans with different principal pipe sizes.

Figure 5. Air volume and velocity for F1 branch.

pipe, the air volume will gradually reduce from the beginning of the branch to the end, coupled with the decrease of dynamic pressure and increase of the static pressure. As a result of the change, the orifice velocity as well as the air volume will increase gradually. In Figure 5(a) the velocity of orifice F1-4 is 6.2 m/s, which is far more than the design value.

In order to improve the uniformity of the air volume, the pipes in the branch are adjusted into convergent pipes. And the modified result of F1 branch is shown in Figure 5(b). In the new state of balance, the air volumes and the velocities of four orifices are more or less the same. Reduction of the velocity will lessen the noise in room and improve the thermal comfort of the human body.

With the help of different measures, the independence of terminal will be improved, and stability of the dynamic performance in ventilation system will be strengthened.

## 6 CONCLUSIONS

For an enormous ventilation system, there will be strong mutual influence among the different terminals. It is important to find the correlation degree and take measures to make sure each fan is working in the optimal state in design stage for the ventilation system designers, which avoids waste of time and money from unreasonable airflow program.

This paper applies C++ to compile the program, and finds out the source of mutual influence. The measures advertized in paper will be helpful and improve the efficiency of each fan with minimum energy consumption.

# Application of energy-saving technology of outer wall

Zhi Neng Tong

Jiangxi Science and Technology Normal University, Nanchang, China

**ABSTRACT:** Building energy saving is a hot spot in the construction domain. It is an important sign of the construction technology progress. This paper introduces the wall energy-saving technology application, to speed up the wall thermal insulation energy-saving technology, to create a more comfortable living environment that plays a positive role in promoting energy conservation. The construction of energy-efficient buildings needs to be discussed.

**Keywords:** heat preservation; building energy saving; energy saving technology

## 1 INTRODUCTION

Building energy saving is a new hot spot in the construction field, and it is an important symbol of the technological progress of the construction industry and a key problem of implementing the national sustainable development strategy. Building energy conservation is a big problem concerning the survival of the human environment; its strategic goal is not only to save the limited resources for the benefit of future generations, but also to improve the environment polluted by energy consumption, make human survival space cleaner, more comfortable. The development of building energy efficiency not only can bring great economic benefit and social benefit, but also develop the level of construction technology, effectively promoting the development of the construction industry as a whole.

In the building, the external wall of the structure consumes the most external heat. Therefore, the development of wall energy-saving is the main content of building energy saving technology; the development of exterior insulation technology and energy saving material is the main mode of building energy saving. Wall energy conservation and insulation measures are basically three major categories: external wall insulation, insulation, and exterior insulation.

1. Exterior wall: Internal heat preservation technology, namely in the building space interior wall additional heat preservation material is used in order to achieve the energy conservation goal. But within the external wall insulation exist the following problems: first, thermal efficiency is too low. Some parts of the wall, such as T-shaped wall, and ring beams are difficult to handle. They form a “bridge”, so that the heat preservation performance will be reduced; second thermal insulation layer for the

occupants, decorations adding hanging amenities cause great trouble, with quality issues and their repair and maintenance will cause great distress to tenants; three, insulation occupies indoor space and reduces user area.

2. Sandwich insulation technology, that is, the use of layered treatment measures, the formation of wall—thermal insulation material—wall system, on the external wall to achieve the purpose of energy saving. However, due to the complex production method, the problem of “cold bridge” in the building cannot be solved effectively, and the practice of sandwich insulation is therefore replaced by the practice of wall insulation.
3. Exterior insulation technology, that is, using additional insulation material on the outside of the wall for energy-saving purposes. Exterior insulation technology is currently vigorously promoting a building energy-saving technology. External wall thermal insulation and exterior wall insulation were compared across reasonable structure of energy-saving technology, the use of the same size, the same performance of thermal insulation material. We found that with thermal insulation, the thermal energy-saving effect is better. Exterior insulation technology is not only suitable for the energy saving of the new building, but also for the existing building. External thermal insulation material coated on the outside of the main structure, can effectively protect the construction to the main structure, prolong the service life of the building; can effectively reduce the thermal bridge of building structure, increase the construction of effective use of space; and while the building envelope insulation leads to condensation on the indoor side of the wall producing mildew, external thermal insulation eliminates this phenomenon and improves the indoor living environment of comfort.

## 2 EXTERIOR WALL INSULATION TECHNOLOGY

### 2.1 *Inside wall insulation technology*

Exterior wall internal insulation construction, is inside the outer wall structure of the insulation layer. Internal heat preservation construction is fast, easy in operation and can guarantee the construction progress. The internal heat preservation application time is long, the technology is mature, and the construction technology and the inspection standard are perfect.

The insulation technology: reinforced gypsum composite polystyrene insulation board, polymer mortar composite polystyrene insulation board, reinforced cement composite polystyrene insulation panels, interior wall stickers polystyrene board cast plaster and plastering polyphenyl granule thermal insulation slurry and anti crack mortar is pressed into the mesh. But the heat will be of more use to the area occupied by the “bridge” problem which is difficult to resolve, as it prone to cracking, but it also affects the speed of construction, residents of the second decoration, and wall hanging and fixed objects also easy to damage the insulation structure. The irrationality of internal insulation in the technology decides that it must be replaced by external heat preservation.

### 2.2 *Exterior wall insulation technology*

Exterior insulation is a kind of building heat preservation technology, which is vigorously promoted at present. Thermal insulation compared with the insulation, the technology is reasonable because of its obvious advantages, the use of the same size, the same size and performance of insulation material, thermal insulation than the thermal effect. External insulation technology applies not only to new construction projects, but also applies to the transformation of old buildings, applicable to a wide range, high technology content. External insulation on the outside of the main structure protects the main structure and extends the building's life; effectively reduces the thermal bridge of building structure, does not affect the use of indoor space; and at the same time eliminates condensation and improves living comfort.

There are several main external insulation technologies of the external wall.

#### 2.2.1 *Exterior wall external insulation*

External thermal insulation material rock (ore) cotton, glass cotton blanket, polystyrene foam board (hereinafter referred to as the polystyrene board, EPS, XPS), ceramsite concrete polyphenyl composite imitation stone decoration thermal

insulation board, wire mesh frame sandwich wallboard. The polystyrene board has excellent physical properties and is cheap in cost. It has been widely used in the external wall insulation plug-in technology worldwide. Plug-in technology is the use of adhesive mortar or special fixed pieces which will heat preservation material, hanging on the wall. Then the anticrack mortar is cast along with the pressure glass fiber mesh cloth to form a protective layer. Finally, the decorative surface is added. There is a practice using special fasteners that will not be easily absorbent and the insulation board is fixed on the wall. Then the aluminum, natural stone, and color glass plug in the keel of the pre production direct the formation of surface decoration. This plug-in external insulation installation is time-consuming, construction is difficult, and the construction takes the lead time limit for the construction, the main body after the main acceptance can carry out the construction. In the high-rise construction, it is not easy to get security personnel.

#### 2.2.2 *Insulation polystyrene board and wall once pouring molding*

The technology is in concrete frame—shear wall system with polyphenyl board is built in the architectural template, in the outside of the wall to be cast and pouring concrete, concrete and polystyrene board in a casting for composite wall. This technology solves the main problem of external insulation, for its obvious advantage. Because the main body of the external wall and the insulation layer of a survival, ergonomics, greatly shorten the time limit. In the pouring of concrete to pay attention to uniform, continuous casting, otherwise cause of polystyrene board in after stripping appear deformation and dislocation stubble and effects after construction procedures because of the influence of lateral pressure of concrete.

The built-in polystyrene board can be a double wire mesh or a single wire mesh. Double steel mesh polystyrene board and concrete connection, mainly rely on the medial wire frame and the lateral wall reinforcement phase of banding. Concrete and polystyrene board adhesion and its combination has good performance and a high degree of safety. Single steel mesh polystyrene board and concrete connection, rely mainly on concrete and polyphenyl plate adhesion and oblique in reinforced, L shaped steel and concrete wall anchoring force, combined with the performance is also good. Compared to the double wire mesh, single wire mesh technology saves man hours and material because of the cancellation of the inner steel wire mesh and installing insulation in front of the lateral plate plastering.

### 2.2.3 *Polystyrene particulate insulation mortar external wall insulation*

The waste polystyrene plastic (EPS) was processed into 0.5~4 mm particles, as the lightweight aggregate to prepare the insulation mortar. The technology contains heat preservation layer, anti cracking protective layer and impervious protective layer. This method is currently being widely recognized by the exterior wall insulation technology.

The construction technology is simple, can reduce labor intensity, improve work efficiency; is not affected by differences in the quality of structure, in defective wall construction metope does not need repairing and leveling, and directly using insulation slurry, Zhaobu can avoid other insulation construction technology for fall off phenomenon and leveling plaster that is too thick. And the technology to solve the external wall thermal insulation, engineering conditions by the use of the interface layer is easy for debonding the empty drum, surface layer is easy to crack problems caused by, so as to realize the external wall thermal insulation technology, which is an important breakthrough. Compared to the other external insulation, the cost of the same insulation effect can be reduced, and the construction cost can be reduced.

In addition, energy-saving insulation wall and the wall is made into a sandwich layer, the perlite, sawdust, mineral wool, glass wool, polystyrene foam, polyurethane foam (foam) filled in the inter-layer, the insulating layer is formed.

## 3 HEAT PRESERVATION AND ENERGY SAVING MATERIAL PROPERTIES

Energy saving material belongs to heat preservation and insulation material. Heat insulation material is used in building envelope or thermal equipment, impedance heat transfer of material or material composite material, including heat preservation material, as well as cold material. The significance of the insulation material, on the one hand, is to meet the thermal environment of building space or thermal equipment and on the other hand is to save energy. For residential heating air-conditioning, by using the insulation material, can be based on the existing energy 50%~80%. Therefore, some countries will heat insulation material as the fifth energy after coal, oil, gas, nuclear energy.

Exterior wall heat preservation mainly depends on the insulation material, as the building envelope and the application of the effective insulation material is the effective measure to ensure the building energy conservation.

### 3.1 *Performance of heat insulation material*

Adiabatic is to maximize the impedance of the heat transfer, so the insulation material must

have a large thermal resistance and small thermal conductivity.

From the perspective of the composition of the material, the thermal conductivity of organic polymer is smaller than that of the inorganic materials; non metal thermal conductivity is smaller than that of the metal material; gaseous material coefficient of thermal conductivity is less than that of the liquid substance, liquid matter less than solid. Therefore, in the case of the conditions, should try to use the organic polymer materials or amorphous inorganic materials, which for the insulation is favorable.

From the material structure, when the apparent density of the material is reduced, the porosity is increased, and the porosity of the material is closed. The thermal conductivity of the material is relatively small. For foamed plastics, the best apparent density of the insulation material is 16~40 kg/m<sup>3</sup>.

Due to the presence of porosity, material in the humid environment inevitably to suction. Therefore, when the humidity increases, material balance moisture content increases, and the thermal conductivity of the material also increases. So as heat preservation material, the moisture content of material should be as low as possible, if inevitable, carry on hydrophobic treatment or waterproof material cover with waterproof material.

In addition, heat insulation material must also resist a certain impact load, and has the same mechanical strength as the environment. The bonding performance is good, but also has a small shrinkage rate and the environment to adapt to the durability.

### 3.2 *Commonly used heat insulation material*

For building external insulation energy-saving materials mainly include: polystyrene foam board, rock wool board, glass wool felt, and ultra light polystyrene particles insulation slurry. All of the above materials have a common feature that there are a lot of sealing holes in the material, their apparent density is small, this is also because the heat preservation and heat insulation material are essential.

Rock wool and glass wool is sometimes referred to as mineral wool, which belongs to the field of inorganic materials. Rock wool is not burning, is low in price, has a certain effect on sound insulation, and at the same time it can also meet the insulation performance. But the rock wool quality varies greatly, good in insulation performance and low in density, the tensile strength is low, and the durability is poor.

Polystyrene foamed plastics are made of polystyrene resin as the main raw material and has

many closed microporous materials through foaming agent. Because of its apparent density, small thermal conductivity, low water absorption, good noise, high mechanical strength, and high dimensional accuracy, uniform structure, its occupancy is high in the external wall heat preservation.

Rigid polyurethane foam has a very superior thermal insulation, and its low thermal conductivity is compared with other materials.

Also, its unique obturator structure gives it a more superior water vapor performance because it does not need additional insulation moisture-proof, simplifying the construction procedure, and reducing the project cost. But because of its high price and flammability, its uses are limited.

#### 4 CONCLUSION

Using building energy conservation of building maintenance structure of high levels of insulation, is the main building energy-saving measures, the external wall insulation system with heat preservation function is the key technology of building and energy saving. This technique can effectively solve the temperature difference in summer and winter caused by the loss of energy, indoor and outdoor, in our country.

At present, the development of the external wall insulation technology is very fast, and is the key to energy saving work. The development of exterior insulation technology and energy saving material is inseparable, building energy saving must be based on the premise of developing new energy saving

material, and must have enough heat preservation and heat insulation material for the foundation. The development of energy saving material must be combined with the insulation technology of exterior wall to really play its function. In the field of architecture, if the beginning of the design has a thermal insulation energy-saving ideas, from the perspective of the life cycle of the architecture, heat preservation energy-saving concepts will perforate from the beginning to the end, make the building have good ventilation, vertical integration of sunshade structure, good effect of heat insulation envelope, and reasonable equipment system. These measures of building insulation energy saving will play a positive role, thus truly achieving energy-saving buildings.

## Advanced treatment of rainwater by $H_2O_2/UV$ process

Zheng Li, Weipeng Chen, Jun Li & Siyang Yue

Suzhou Industrial Park Design and Research Institute Co. Ltd., Suzhou, China

**ABSTRACT:** Organic pollutants in rainwater is a challenge for rainwater recycling currently. This study investigated efficiency of  $H_2O_2/UV$  process in removing two selected target aromatic compounds, phenol and para-Chlorobenzoic Acid (pCBA), in rainwater collected from a typical eastern metropolis with many chemical industries. The process showed high efficiency on phenol and pCBA removal, which both followed pseudo-first-order kinetics. Higher phenol removal efficiency was observed over pCBA, but effective TOC removal would require higher UV intensity or longer irradiation. The  $H_2O_2/UV$  process was compared with  $S_2O_8^{2-}/UV$  process in terms of pCBA removal efficiency, and thus was assessed for the practical application in rainwater treatment. The  $H_2O_2/UV$  process was advantageous as there was no introduction of secondary pollutants, and therefore, it is recommended to remove aromatic pollutants prior to recycling rainwater to guarantee biological and chemical safety.

**Keywords:** aromatic compounds; advanced oxidation processes; hydrogen peroxide; UV; rainwater

### 1 INTRODUCTION

Arising from the climate change and water pollution caused by anthropogenic activities, less and less fresh water on land and under ground is available, and more and more areas all over the world has been undergoing water crisis (Bohannon 2006, Carpenter et al. 2011, Fischer & Knutti 2015, Schwarzenbach et al. 2010). While it is necessary to treat the wastewater to keep aqueous environment clean, it is indeed an urgent task to explore more or even new water resources, in addition to the rapid development of water treatment technologies for full utilization of wastewater water, alkaline water such as sea water, and even polluted water (Carpenter et al. 2011, Simons et al. 2015). Generally, rainwater or storm water accounts for the most of origins of fresh water in rivers and lakes and under ground. Thus, rainwater harvesting in urban sites such as buildings and artificial turf is one of the feasible approaches, and may serve as a new but important fresh water resource for many cities (Blocken et al. 2013, Naddeo et al. 2013, Vieira et al. 2014, Ward et al. 2012a, Ward et al. 2012b).

One of the formidable problems for rainwater harvesting and reuse lies in its pollution, which is mostly caused by the pollutants in atmosphere released from industrial factories, traffic, etc., depending on the area locations and also type of rainwater reuse. There are many studies reporting the composition of rainwater over the world (Huston et al. 2009, Niu et al. 2014, Xiao et al. 2013). Inorganic ions, such as  $NO_3^-$ ,  $NO_2^-$ ,  $NH_4^+$ ,

sulfate,  $Na^+$ ,  $K^+$ ,  $Ca^{2+}$ ,  $Mg^{2+}$ , and  $Fe^{2+}/Fe^{3+}$  are usually present in the rainwater, besides the micro and macro particles and microbes. However, the occurrence of toxic pollutants, including heavy metals like Hg, and especially organics originating from the chemical industry and exhaust from traffic, inevitably inhibit the direct utilization of rainwater. For example, toxic aromatics like benzene and nitrated phenols, which are generated via the radical oxidation of aromatics followed by attack by and substitution of nitrogen-containing radicals (e.g.  $NO_2\cdot$  and  $NO_3\cdot$ ), exist in rainwater in many areas (Harrison et al. 2005). Most of those toxic organic pollutants are volatile, and their presence in rainwater may thus potentially cause risk during the utilization of rainwater polluted by them. So it is indeed necessary to remove those organic pollutants in the rainwater prior to its effective utilization to guarantee the water safety.

Actually, thanks to the efforts from scientists all over the world, various methods, such as coagulation, membrane filtration, adsorption by activated carbon and other adsorbents, biodegradation, oxidation, and chlorine and UV disinfection have been developed to treat water to comply with different guidelines or standards for water utilization. When these methods are applied in the rainwater treatment specific considerations should be taken individually, according to the chemical compositions of rainwater and the utilization purpose. Membrane filtration seems to be the most feasible method by removing not only particles, but also even the ions by reverse osmosis, and the treated

rainwater should be drinkable. However, high cost of membrane material and process maintenance, the membrane fouling, and intensive energy requirement limit its wide application currently (Elimelech & Phillip 2011). Activated carbon adsorption has been widely used in drinking water treatment plants, though it could only remove hydrophobic organics, leaving the hydrophilic pollutants, ions, and pathogenic virus, and bacterial in the water. Furthermore, the adsorption capacity of activated carbon is limited, and high cost of changing activated carbon indeed hinders its wide application. As for rainwater, it is usually case-specific, such as rain period, intensity, amount, water quality, and the purpose of its utilization.

Advanced Oxidation Processes (AOPs) has raised a great attention for its ability to efficiently remove aromatics and even to totally mineralize organic carbon, attributed to the powerful oxidizing species hydroxyl radical,  $\text{HO}\cdot$  (Heeb et al. 2014). In addition, the pathogenic virus and bacterial are also efficiently killed during the oxidation. Ozone is one of the most used oxidants, but it is restricted by the formation of toxic byproducts in the presence of bromide, and very low efficiency under acidic conditions for the lack of initiators such as  $\text{HO}^-$  (Liu et al. 2013). Most of the rainwater is acidic due to the pollution by  $\text{SO}_2$ ,  $\text{NO}_2$ , etc., so  $\text{H}_2\text{O}_2/\text{UV}$  process, an efficient and clean process, may be a good alternative to the conventional processes (Crittenden et al. 1999). It not only can remove almost all the organic pollutants, but also avoids the formation of toxic byproducts such as bromate. Furthermore, UV can also very efficiently kill the virus and bacterial simultaneously. In addition, this process is feasible in practical application, with simple installation, easy management, safe application, good adaption, and relatively low costs.

Therefore, the aim of this study was to investigate the efficiency of  $\text{H}_2\text{O}_2/\text{UV}$  process in rainwater treatment, and to evaluate the feasibility in practical application. Two typical aromatic compounds, phenol and p-Chlorobenzoic Acid (pCBA), were selected as the target compounds to assess the efficiency of the  $\text{H}_2\text{O}_2/\text{UV}$  process.

## 2 MATERIALS AND METHODS

### 2.1 Materials

Phenol, pCBA, and potassium persulfate were of ACS reagent grade and were purchased from Sigma-Aldrich. Phosphoric acid and methanol of HPLC grade were supplied by Tedia. Hydrogen peroxide and other reagents used were of analytical-reagent grade and purchased from Sinopharm Chemical Reagent Co., Ltd. All the chemicals were used as

received without further purification. All solutions were prepared in  $18.2 \text{ M}\Omega\cdot\text{cm}^{-1}$  Milli-Q-water produced by a Milli-Q Biocel water system.

### 2.2 Procedures

All the photochemical experiments were performed in a cylindrical photoreactor (2.0 L solution, 2.0 cm path length). A low-pressure mercury UV lamp (Heraeus, GPH436T5 L/4, 21 W, 254 nm) was centered in the cylindrical vessel axially along the length of the reactor. Temperature was controlled at  $25 \pm 0.5^\circ\text{C}$ . UV lamp was ignited at least 15 min to reach a stable output prior to the experiments. Reactions started by the addition of  $\text{H}_2\text{O}_2$ . Samples were withdrawn at predetermined time intervals and quenched using excessive sodium thiosulfate. All experiments were repeated independently at least two times, and average values along with a standard deviation are provided. Rainwater samples were collected from a rainfall event in a metropolis located in the east of China, in May, 2014. The samples were filtered using 0.45 mm cellulose membrane filter and were stored at  $4^\circ\text{C}$  prior to use.

### 2.3 Analytical methods

The concentrations of phenol and pCBA were determined by high performance liquid chromatography (Waters 2695 HPLC) equipped with a 2489 UV Detector and an autosampler, using a Waters symmetry C18 column (4.6 mm  $\times$  150 mm, 5  $\mu\text{m}$ ) and C18 guard column for separation. An eluent of phosphate buffer (pH 3) and methanol (40:60, v/v%) was used at a flow rate of 1.0. The concentration of phenol was quantified at 280 nm, while pCBA at 234 nm. The pH value was measured by a pH meter (PB-10, Satorious). The absorption was carried out on a Varian Cary 300 spectrometer. The cations and anions were analyzed on a Dionex ICS-3000 ion chromatograph. Total Organic Carbon (TOC) and Total Nitrogen (TN) were analyzed by a TOC analyzer (TOCL, Shimadzu). Other metals were analyzed by Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES, PerkinElmer). Other analysis was carried out according to the standard methods (Association et al. 2012).

## 3 RESULTS AND DISCUSSIONS

The location, where the rainwater was collected, had lots of various chemical industry, including petrochemical industries, agrichemical producers, electronics manufacturers, and electroplating factories. The air was heavily polluted by the release of exhaust and drainage of wastewater. The rainwater quality were as follows: suspend solid  $12.1 \pm 0.1 \text{ mg/L}$ , COD  $82.5 \pm 3.3 \text{ mg/L}$ , pH

5.1 ± 0.1, TOC 12.3 ± 0.2 mg/L, UV254 0.081 ± 0.001 cm<sup>-1</sup>, NH<sub>3</sub>-N 1.67 ± 0.064 mg/L, NO<sub>2</sub>-N 0.100 ± 0.003 mg/L, NO<sub>3</sub>-N 3.23 ± 0.09 mg/L, TP 0.141 ± 0.004 mg/L, Cl<sup>-</sup> 0.89 ± 0.02 mg/L, SO<sub>4</sub><sup>2-</sup> 23.5 ± 1.0 mg/L, Fe 0.152 ± 0.001 mg/L, and Hg 2.0 ± 0.1 μg/L, respectively. It is noted that about 0.02 μM total phenol was also determined, indicating the pollution of aromatics in the rainwater.

### 3.1 Degradation of phenol

Figure 1 shows the phenol degradation in H<sub>2</sub>O<sub>2</sub>/UV process. Phenol underwent significant direct photolysis, because it possesses strong absorption at 254 nm, and after excitation by UV the C–C or H–O bonds break and ring opens in the presence of oxygen (Wu et al. 2001). Compared with the direct photolysis, much rapid indirect photolysis of phenol was observed in the H<sub>2</sub>O<sub>2</sub>/UV process, and complete removal was obtained within 7 min, using 1.0 mM H<sub>2</sub>O<sub>2</sub>.

More quantitative details are shown Figure 2, which indicates the degradation kinetics of phenol in the H<sub>2</sub>O<sub>2</sub>/UV process. Both direct photolysis and indirect photolysis of phenol in H<sub>2</sub>O<sub>2</sub>/UV process followed pseudo-first-order kinetics. The comparison between the two cases shows that 1.0 mM H<sub>2</sub>O<sub>2</sub> could enhance the phenol degradation by at least an order of magnitude, suggesting the very high efficiency of such process in removing phenols.

The mechanism of degradation of phenols in H<sub>2</sub>O<sub>2</sub>/UV processes has been systematically studied and compiled before (Crittenden et al. 1999). Briefly, a powerfully oxidizing species, hydroxyl radical (HO•), is generated during the photolysis of H<sub>2</sub>O<sub>2</sub> in Equation 1, with a quantum yield of about 1.0 at 254 nm (Crittenden et al. 1999). Phenol is attacked by HO• via electron transfer, hydrogen abstraction, and electrophilic substitution pathways, producing organic radicals

Figure 1. Phenol degradation in UV and H<sub>2</sub>O<sub>2</sub>/UV processes. Conditions: [Phenol]<sub>0</sub> = 10 μM, [H<sub>2</sub>O<sub>2</sub>]<sub>0</sub> = 1.0 mM, pH 5.1 without adjustment by buffer, 25 °C.

Figure 2. Degradation kinetics of phenol in UV and H<sub>2</sub>O<sub>2</sub>/UV processes. Conditions: [Phenol]<sub>0</sub> = 10 μM, [H<sub>2</sub>O<sub>2</sub>]<sub>0</sub> = 1.0 mM, pH 5.1 without adjustment by buffer, 25 °C.

(Equation 2), which are subsequently oxidized by oxygen and transformed to alcohols, aldehydes, ketones, organic acids, etc. (Equation 3).

### 3.2 Degradation of pCBA

pCBA is much more recalcitrant than phenol studied above, and is usually selected as the HO• probe. The degradation of pCBA in rainwater by H<sub>2</sub>O<sub>2</sub>/UV process was studied in order to evaluate the availability of HO• by target compounds (Rosenfeldt & Linden 2007). Figure 3 shows the degradation of pCBA in H<sub>2</sub>O<sub>2</sub>/UV process. pCBA shows slower direct photolysis than phenol in Figure 1. H<sub>2</sub>O<sub>2</sub> markedly accelerated the degradation of pCBA in the system, and complete removal was observed within 7 min.

Figure 4 shows the degradation kinetics of pCBA in H<sub>2</sub>O<sub>2</sub>/UV process. As degradation of phenol in Figure 2, the direct photolysis and indirect photolysis of pCBA also obeyed well the pseudo-first-order kinetics. The indirect photolysis resulting from the HO• oxidation shows much higher rate than direct photolysis by UV by at least 20 times higher. The degradation kinetics in Figure 2 and Figure 4 indicate the higher efficiency on phenol removal than pCBA removal, possibly attributed to the higher rapid capture of HO• by phenol than that by pCBA and, thus, the less impact of competition of byproducts for HO• (Buxton et al. 1988). Furthermore, the high content of TOC (~12.3 mg/L) in rainwater also competed for HO• significantly, resulting in the less availability of HO• by the target pollutants.

Figure 3. Degradation of pCBA in UV and  $H_2O_2/UV$  processes. Conditions:  $[pCBA]_0 = 10 \mu M$ ,  $[H_2O_2]_0 = 1.0 mM$ , pH 5.1 without adjustment by buffer,  $25^\circ C$ .

Figure 4. Degradation kinetics of pCBA in UV and  $H_2O_2/UV$  processes. Conditions:  $[pCBA]_0 = 10 \mu M$ ,  $[H_2O_2]_0 = 1.0 mM$ , pH 5.1 without adjustment by buffer,  $25^\circ C$ .

### 3.3 Efficiency comparison

Because of the acidity of the rainwater, ozone should not be feasible in such water matrix. In order to assess the efficiency of  $H_2O_2/UV$  process in removing organic pollutants, comparison with an emerging AOPs, persulfate/UV, was performed. Figure 5 shows the pCBA degradation in the two processes. It seems that  $S_2O_8^{2-}/UV$  process shows higher efficiency than  $H_2O_2/UV$  process, and complete removal of pCBA was obtained within 4 min. According to the degradation kinetics of pCBA in Figure 4 and Figure 5, it is obvious that the  $S_2O_8^{2-}/UV$  process shows about 1.7 times higher efficiency than  $H_2O_2/UV$  process. This may be caused by the higher selectivity of sulfate radical,  $SO_4^{\cdot-}$ , than  $HO^{\cdot}$ . The latter is generally regarded to be non-selective towards organics (Buxton et al. 1988). Nonetheless, the  $S_2O_8^{2-}/UV$  process introduces a high amount

Figure 5. Comparison of pCBA degradation between  $H_2O_2/UV$  and  $S_2O_8^{2-}/UV$  processes. Inset: degradation kinetics of pCBA in  $S_2O_8^{2-}/UV$  process. Conditions:  $[pCBA]_0 = 10 \mu M$ ,  $[H_2O_2]_0 = 1.0 mM$ ,  $[S_2O_8^{2-}]_0 = 1.0 mM$ , pH 5.1 without adjustment by buffer,  $25^\circ C$ .

Figure 6. TOC removal in the  $H_2O_2/UV$  process. Conditions:  $[H_2O_2]_0 = 1.0 mM$ , pH 5.1 without adjustment by buffer,  $25^\circ C$ .

of sulfate, and thus, is not recommended to apply in rainwater treatment. In comparison,  $H_2O_2/UV$  process has the advantage that the final product is  $H_2O$ , without introducing secondary pollution such as sulfate in the  $S_2O_8^{2-}/UV$  process.

### 3.4 TOC removal efficiency

The rainwater collected in a district having many chemical industries was polluted by organic chemicals, as indicated by the high TOC content. The TOC in rainwater usually leads to the growth of algae and microbes, resulting in the subsequent biological contamination and thus the limitation of rainwater reuse. Although efficient removal of phenol (Fig. 1) and pCBA (Fig. 3) was obtained by the  $H_2O_2/UV$  process, much lower efficiency was observed on the TOC removal, as shown in Figure 6. Under the given conditions, only about 9% of TOC was removed. It is explained by the low

generation of HO•, which determines the removal of TOC. As reported (Xiao et al. 2015), obvious TOC would be obtained by higher UV dose by improving UV intensity or longer irradiation time.

However, as UV kills almost all the microbes and algae in the rainwater, there will be little proliferation of bacterial, virus, algae, etc. if the treated rainwater is stored correctly. Furthermore, because almost all of the toxic pollutants in rainwater are aromatic, while they can be efficiently removed by the H<sub>2</sub>O<sub>2</sub>/UV process, the safety of rainwater reuse can be consequently guaranteed. For reuse in other stricter fields such as drinking water, further treatment is required.

#### 4 CONCLUSIONS

The H<sub>2</sub>O<sub>2</sub>/UV process showed high efficiency on removal of phenol and even recalcitrant pCBA in the rainwater, which was polluted by organic contaminants and inorganic ions. Both the degradation of phenol and pCBA followed the pseudo-first-order kinetics, while higher efficiency on phenol removal was obtained over pCBA, due to its higher reaction rate constant with HO• than that of pCBA. Efficient TOC removal required higher UV intensity or longer irradiation. The H<sub>2</sub>O<sub>2</sub>/UV process was compared with the S<sub>2</sub>O<sub>8</sub><sup>2-</sup>/UV process in terms of pCBA removal efficiency, and the latter showed about 1.7 times higher efficiency. Nonetheless, the H<sub>2</sub>O<sub>2</sub>/UV process was still advantageous over the S<sub>2</sub>O<sub>8</sub><sup>2-</sup>/UV process on no introduction of secondary pollution. Therefore, the H<sub>2</sub>O<sub>2</sub>/UV could be used to efficiently remove the aromatic pollutants in rainwater to guarantee the safety of the rainwater reuse.

## Effects of ozone and drought on fluorescence physiology of three seedling types in China

Xiaoli Hou & Xue Li

College of Forestry and Landscape Architecture, South China Agricultural University, Guangzhou, China

**ABSTRACT:** Seedlings of *Michelia macclurei*, *Cinnamomum camphora*, and *Rhodolcia championii* were treated with ozone fumigation and drought treatment, and their chlorophyll fluorescence parameters were determined. The results showed that with increasing treatment time, minimal initial fluorescence ( $F_0$ ) of the three seedling types continuously increased or followed by a decrease; *PSII* maximum photochemical efficiency ( $F_v/F_m$ ) of *M. macclurei* under drought stress and *R. championii* under all treatments decreased, whereas it remained stable in *M. macclurei* treated with ozone stress and zone-drought intercross stress, and in *C. camphora* treated with all treatments. Except for *C. camphora* under ozone stress, *PSII* actual quantum efficiency ( $Y(II)$ ) of the three seedling types decreased. Non-photochemical quenching (*NPQ*) of *M. macclurei* under single stress and *R. championii* under all treatments decreased, whereas it remained stable in *M. macclurei* treated with zone-drought intercross stress and in *C. camphora* treated with all treatments. Principal component analysis indicated that resistance abilities of ozone, drought, and ozone-drought intercross stresses for the three seedling types decreased in the order of *C. camphora* seedlings > *M. macclurei* seedlings > *R. championii* seedlings.

**Keywords:** ozone stress; drought stress; chlorophyll fluorescence parameters; seedling

### 1 INTRODUCTION

Ozone is a kind of toxic gaseous pollutant to plants (Zhang et al. 2010). In recent decades, due to the extensive use of fossil fuels, the concentration of nitrogen oxides and volatile organic compounds in the atmosphere increased sharply, resulting in  $O_3$  concentration to rise in the surface layer (Vingarzan et al. 2004). High concentrations of ozone can increase stomatal resistance of plants, change absorbing light energy and structure distribution of *PSII* antenna pigment (Keller et al. 2007), inhibit photosynthetic electron transport (Vandermeiren et al. 2005), reduce photochemical efficiency, and affect the chlorophyll fluorescence parameters (Luo et al. 2012). Ozone can also change the composition of plant thylakoid membrane, resulting in changes in chlorophyll fluorescence yield (Lie et al. 2014). Drought stress is the most common form of plant adversity (Li et al. 2007), which can disrupt the chloroplast photosynthetic mechanism II (*PSII* system) and photosynthetic electron transport of leaves (Zhou et al. 2004, Zhang et al. 2011a), lead to photosynthetic organ damage and chlorophyll content decrease (Li et al. 2008, Yang et al. 2007), and inhibit plant photosynthesis. In the process of photosynthetic response to environmental stress, *PSII* plays an important role (Wei et al. 2012). The

application of chlorophyll fluorescence kinetics to study plant resistance to environmental stress will contribute to screening tree species with strong ozone and drought resistance.

*Michelia macclurei*, *Cinnamomum camphora* and *Rhodolcia championii* are three important tree species for garden greening in south China. Although there were some few studies on photosynthetic physiology of these species (Yu et al. 2011, Zhang et al. 2011b, Guo et al. 2013), we still know little about response of chlorophyll fluorescence parameters of these species to ozone stress or drought stress. This study is aimed at providing the reference for screening tree species with strong ozone and drought resistance.

### 2 MATERIALS AND METHODS

**Experimental material.** One-year-old seedlings of *M. macclurei*, *C. camphora* and *R. championii* were individually planted into nutrition bags (12 cm diameter and 10 cm height). The seedlings growth status was shown in Table 1.

Fumigation test equipment was Open-Top Chamber (OTC) with hexagonal cross-section, glass wall and a diameter of 3 m and a height of 2.4 m, which was located in Yuejinbei Nursery in

Table 1. Growth status of three seedling types.

Tree species	DBH (mm)	Height (cm)	Crown width (cm)
<i>M. macclurei</i>	4.50 ± 0.18	32.97 ± 0.89	14.77 ± 0.64
<i>C. camphora</i>	4.16 ± 0.18	38.96 ± 1.12	13.55 ± 0.97
<i>R. championii</i>	3.15 ± 0.18	32.97 ± 0.95	12.67 ± 0.48

Notice: The data is “average + standard error” in the table.

South China Agricultural University of China. Ozone was provided by CFY5 oxygen manufacture equipment and COM-AD-01 ozone generator (ranges of 0–1 ppm, resolution of 0.001 ppm), and its concentration was detected by GT901-03 portable ozone detector continuously.

**Test method.** Two ozone treatments were designed in two OTCs: E40 (non-filtered air, ozone concentration is about 40 ppb), E150 (elevated ozone at 150 ppb). Each chamber was designed two moisture gradient: control (the relative water content of soil was 75–80%), drought treatment (the relative water content of soil was 40–45%). As a result, three treatments were designed as follows: E40+D (Drought stress), E150 (Ozone stress) and E150 + D (Ozone and drought stress). Ventilation and air system could meet the gas exchange more than one time per min in the chambers, which kept almost consistent in temperature, humidity and CO<sub>2</sub> concentration between the chamber and outside chamber. Aeration time in chambers was 9:00–17:00 every day. The fumigation test lasted for 30 days. At the beginning of experiment, the 15th day and 30th day (the end of experiment), chlorophyll fluorescence parameters were separately measured.

**Determination method for index.** The determination methods of fluorescence parameters were as follows: individuals of three seedling types with similar growth were selected, and three leaves of each seedling were marked among the third to eighth functional leaves. OS-IP pulse modulation fluorometer was used to determine the leaves from 9:00 to 11:00 in the morning. The initial fluorescence yield ( $F_0$ ), maximal fluorescence yield ( $F_m$ ), steady state fluorescence ( $F'$ ), maximum fluorescence in light adapted state ( $F_m'$ ) were measured and variable fluorescence [ $(F_v) = F_m - F_0$ ], the *PSII* maximum photochemical efficiency ( $F_v/F_m$ ), *PSII* actual photosynthetic efficiency [ $Y(II) = (F_m' - F')/F_m'$ ], Non-photochemical quenching ( $NPQ = F_m'/F_m - 1$ ) were calculated.

**Data analysis.** All statistical analyses were used Excel 2010 and the Statistical Analysis System (SAS 9.0). After each index was standardized using range method, principal component analysis was used to analyze the data and the scores of

ozone resistance and drought resistance of each tree species in treatments E40+D, E150, E150 + D were calculated.

### 3 RESULTS

**The changes of minimal initial fluorescence ( $F_0$ ) under ozone and drought stress.** With increasing ozone and drought stress time, the  $F_0$  of *M. macclurei* had a significant increase ( $P < 0.05$ ) followed by a stable status in Treatments E40 + D and E150 + D, while it had an undulation followed by a significant increase ( $P < 0.05$ ) in Treatment E150 (Fig. 1). The  $F_0$  of *C. camphora* had a significant increase followed by a significant decrease in Treatments E40 + D and E150 + D ( $P < 0.05$ ), while it had a continuous increase in Treatment E40. The  $F_0$  of *R. championii* had a continuous increase in Treatments E40 + D and E150, while it had a significant increase followed by a significant decrease in Treatment E150 + D ( $P < 0.05$ ).

**The changes of *PSII* maximum photochemical efficiency ( $F_v/F_m$ ) under ozone and drought stress.** With increasing ozone and drought stress time, the  $F_v/F_m$  of *M. macclurei* had an undulation followed by a significant decrease ( $P < 0.05$ ) in Treatment E40 + D, while it kept stable in Treatments E150 and E150 + D (Fig. 2). The  $F_v/F_m$  of *C. camphora* was stable in each treatment. The  $F_v/F_m$  of *R. championii* decreased significantly ( $P < 0.05$ ) and then stabilized in Treatment E40+D; it had an undulation followed by a significant decrease ( $P < 0.05$ ) in Treatment E150 and a continuous significant decrease in Treatment E150 + D ( $P < 0.05$ ).

**The changes of *PSII* actual quantum efficiency ( $Y(II)$ ) under ozone and drought stress.** With increasing ozone and drought stress time, the  $Y(II)$  of *C. camphora* had a slight decrease followed by a significant increase in Treatment E150 ( $P < 0.05$ ), whereas its other treatments and that of *M. macclurei* and *R. championii* in all treatments tended to decrease (Fig. 3).

**The changes of non-photochemical quenching ( $NPQ$ ) under ozone and drought stress.** With increasing ozone and drought stress time, the  $NPQ$  of *M. macclurei* had an undulation followed by a significant decrease ( $P < 0.05$ ) in Treatment E40 + D, decreased significantly ( $P < 0.05$ ), and then was stable in Treatment E150 and kept stable in Treatment E150 + D (Fig. 4). The  $NPQ$  of *C. camphora* kept stable in all Treatments. The  $NPQ$  of *R. championii* decreased significantly in Treatments E40 + D and E150 ( $P < 0.05$ ), and decreased significantly ( $P < 0.05$ ) and then kept stable in Treatments E150 + D.

**Principal component analysis of the ability to resistance ozone and drought of three seedling types**

Figure 1. The change of minimal initial fluorescence under O<sub>3</sub> stress and drought stress. Significant differences between treatments were indicated by different letters above bars, P < 0.05.

Figure 2. The change of PSII maximum photochemical efficiency ( $F_v/F_m$ ) under O<sub>3</sub> stress and drought stress.

Figure 3. The change of PSII active quantum efficiency under O<sub>3</sub> stress and drought.

Figure 4. The change of non-photochemical quenching under O<sub>3</sub> stress and drought stress.

Table 2. Comprehensive assessment values and orders of drought resistance of the four seedling types.

Testing indexes	E40 + D		E150		E150 + D	
	Score	Rank	Score	Rank	Score	Rank
<i>C. camphora</i>	1.183	1	0.985	1	1.491	1
<i>M. macclurei</i>	0.665	2	0.864	2	0.549	2
<i>R. championii</i>	0.595	3	0.779	3	0.526	3

by using. In this study, principal component analysis was used to evaluate the resistance ability to ozone and drought of the three seedling types. The calculating score decreased in the order of *C. camphora* seedlings > *M. macclurei* seedlings > *R. championii* seedlings in Treatments E150, E40 + D and E150 + D, indicating that the resistance abilities of the three seedling types to ozone, drought or intercross stresses decreased in the order of *C. camphora* seedlings > *M. macclurei* seedlings > *R. championii* seedlings (Table 2).

#### 4 DISCUSSION AND CONCLUSION

A series of changes of chlorophyll fluorescence parameters will occur under environmental stress, because the initial injured part of photosynthesis is closely related with photosynthetic system II (*PSII*) (Li et al. 2009).  $F_0$  is fluorescence yield when *PSII* reaction center is open, and its size is related to the structure state of *PSII* reaction and the chlorophyll concentration (Chong et al. 2010, Lu et al. 1994). The non-photochemical energy dissipation of *PSII* antenna pigment often leads to the decrease of  $F_0$ , and the destruction or reversible inactivation of *PSII* reaction center causes the increase of  $F_0$  (Yang et al. 2013). With increasing ozone and drought stress time, the  $F_0$  of *M. macclurei* and *R. championii* in Treatment E150 + D, and the  $F_0$  of *C. camphora* in Treatments E40 + D and E150 + D had a significant increase and then a decrease. The reason might be that the reversible inactivation of *PSII* reaction center occurred in the seedling types in ozone stress or drought stress 15 d after the experiment, and the regulating mechanism of photoprotection was launched to reduce the destruction from strong light 30 d after the experiment (Chong et al. 2010, Zhang et al. 2010). However, the  $F_0$  of *M. macclurei* and *R. championii* under single stress, and the  $F_0$  of *C. camphora* under ozone stress increased significantly, indicating that their *PSII* reaction center may not be seriously damaged (Qian et al. 2011).

$F_v/F_m$  is the *PSII* maximum photochemical efficiency under dark adaptation and reflects the efficiency and utilization ability of capturing excitation

energy of *PSII* reaction center, and  $F_v/F_m$  decrease is an important manifestations of photoinhibition (Wang et al. 2009). Most OCT test indicated  $F_v/F_m$  decrease under environment stress was due to  $F_m$  decrease and  $F_0$  increase, the stress can destroy or inhibit the activity of *PSII* reaction center (Flowers et al. 2007). In this study, the  $F_v/F_m$  decrease of *M. macclurei* under drought stress and *R. championii* in each treatment indicated that the activity of *PSII* reaction center was injured or inhibited, but the transfer rate of photosynthetic electron chain recovered in a certain degree through adaptive adjustment, so that it maintained basic physiological functions such as normal dark reaction (Qian et al. 2011). The  $F_v/F_m$  of *M. macclurei* under ozone stress and intercross stress, *C. camphora* in each treatment had no significant change, indicating that the activity of *PSII* reaction center of leaves under ozone stress or drought stress was not damaged (Sun et al. 2009), so that the photoinhibition of seedlings was not obvious.

The actual photosynthetic efficiency ( $Y(II)$ ) reflects actual original light-trapping efficiency when *PSII* reaction center is partly closed, and the consumption ratio of photochemical reaction energy (Park et al. 1995, Govidjee. 2002).  $Y(II)$  decrease indicates that the decrease of actual original light-trapping efficiency and the ability of releasing oxygen, and plant photosynthesis is blocked. Except for *C. camphora* under ozone stress, the  $Y(II)$  of other treatments of all seedlings decreased, indicating that the ability of electron transport of *PSII* decreased, the whole process of photosynthetic electron transport was blocked, as a result, the proportion of converting light energy into chemical energy decreased (Wang et al. 2012). The  $Y(II)$  of *C. camphora* under ozone stress decreased and then increased, indicating that decrease of the actual photosynthetic efficiency was reversible (Liang et al. 2010).

Non-photochemical quenching (*NPQ*) reflects the heat dissipation ability after natural pigment of *PSII* reaction center absorbs excessive light energy and the damage degree of, being a self-protection mechanism of photosynthetic apparatus (Yu et al. 2011). The *NPQ* of *M. macclurei* in Treatments E40 + D and E150 and that of

*C. camphora* in Treatments E40 + D and E150 decreased significantly, and had no significant change in Treatment E150 + D, which might be drought can increase *NPQ* value, namely, relieving ozone stress damage to the efficiency of capturing excitation energy (Showman 1991). The *NPQ* of *C. camphora* in each treatment kept stable, indicating that these species had a steady heat dissipation function. The *NPQ* decrease of *R. championii* in each treatment indicated that heat dissipation was lesser, which is favorable for the absorption light energy entering into electronic transfer system and carbon fixation (Zong et al. 2010).

Principal component analysis indicated that resistance abilities of ozone, drought, and ozone-drought intercross stresses for the three seedling types decreased in the order of *C. camphora* seedlings > *M. macclurei* seedlings > *R. championii* seedlings. The three seedling types have a certain ability to resist ozone or drought by starting adjustment mechanism of photoprotection under ozone stress and drought stress.

# Study on Shenyang region PM 2.5 concentration variation characteristic based on GIS

Hua Ding, Lishuang Sun & Xin Wang

*Institute of Transportation, Shenyang Jianzhu University, Liaoning, China*

**ABSTRACT:** PM 2.5 is a kind of fine particulate matter air pollution and the main source of air pollution. In the last decade, PM 2.5 pollution has grown rapidly in major cities of China that seriously damaged the urban economic development and health of residents. This paper has studied temporal and spatial variation characteristics of PM 2.5 concentration and factors of PM 2.5 concentration variation by collecting monitoring data from eleven monitoring stations of Shenyang city for five months, combining electronic map of Shenyang city and adopting GIS techniques and statistical analysis methods. The research findings of this paper would provide great help for Shenyang city's atmospheric fine particulate matter pollution treatment and reliable data support for Shenyang city's air quality improvement and ecological environment preservation.

**Keywords:** PM 2.5; pollution; ArcGIS

## 1 INTRODUCTION

Atmospheric suspended particulate matter was one of the causes of severe air pollution of most Chinese cities and also the primary pollutant of urban air quality that has a strong impact on virtuous cycle of urban climate. Suspended particulate matter referred to solid particles and droplets with diameter of 0–100  $\mu\text{m}$  suspended in air, including PM 10 (particle size range of 0–10  $\mu\text{m}$ ) and PM 2.5 (particle size range of 0–10  $\mu\text{m}$ ). Haze was a general expression of excess level of suspended particulate matter in the atmosphere that has become a new meteorological and environmental disaster phenomenon. Since the beginning of the year 2013, major cities of China have endured persistent haze weather especially cities in surrounding area with Beijing as the center becoming one of the most serious affected area. Due to its regional characteristics and industrial characteristics, Shenyang has experienced serious haze weather repeatedly during recent years, many of which even triggered orange alert. Among toxic substance in haze, PM 2.5 contained the strongest toxicity and the rapid growth of PM 2.5 has been considered to be the “Culprit” of haze weather because its particles were small enough to be directly inhaled into the lungs that may trigger various severe respiratory diseases and may severely impair the health of citizens.

Taking severe haze polluted Shenyang area as research area, collecting 5-month PM 2.5

concentration monitoring data from 11 monitoring stations located in urban and suburbs of Shenyang, and utilizing powerful analysis capabilities of ArcGIS software, our research has studied the temporal and spatial variation characteristic of PM 2.5 concentration in Shenyang area by vertical and horizontal analysis on monitoring data and statistical analysis technique utilization. Combining electronic maps and meteorological data of Shenyang area, our research has analyzed the PM 2.5 concentration variation factors of Shenyang area and provided advice and decision support of great reference value for environmental protection in the region.

## 2 RESEARCH METHOD

### 2.1 Establishment of database

Located in south of the northeast region of China, Shenyang has served as the comprehensive hub connecting northeast China to regions of Yangtze River Delta, Pearl River Delta and Beijing-Tianjin-Hebei. Shenyang covered total area of more than 13,000 square kilometers with 3,495 square kilometers urban area. The urban terrain tilted from northeast to southwest and from both sides to the center, the highest elevation of the city was 65 m and the minimum was 36 m above sea level. Shenyang was densely populated by resident population of 8 million resulting in congested traffic. Within a radius of 150 km of the city, there were

seven large-scale industrial and commercial cities as steel base—Anshan, coal base—Fushun, chemical fiber—Liaoyang, coal and iron base—Benxi, petroleum production base—Panjin, coal and grain base—Tieling, and electric power base—Fuxin. The four-month heating supply period in winter, which consumed large amount of coal has intensified the degradation of air quality in Shenyang. For example, in the beginning of 2014, due to urban heat supplying, air quality degradation was intensified resulting in persistent haze weather and the highest PM 2.5 monitoring index among large-scale cities and also severely affected urban development and health and lives of citizens.

Shenyang, as one of the 113 key environmental protection cities throughout our country, adopted automatic monitoring system in municipal environment air quality monitoring. Currently, there were 11 national environment air quality automatic monitoring spot (National Monitoring Spot), namely, Ermao, Taiyuan Street, Xiaoheyan, Wenyi Road, Beiling, Artillery Academy, Zhangshi, Neusoft, Liaoning University, Hunnan II, and Huishan. These National Monitoring Spots were all certified by Ministry of Environmental Protection and their spot setting and monitoring method were in accordance with national regulations. In this research, we collected PM 2.5 concentration data released by 11 monitoring stations over 5 months from Dec. 1, 2013 to Apr. 26, 2014 on daily basis at four time points of 7:00, 12:00, 17:00, and 20:00 and tabulated the data in form of excel and then imported it into ArcGIS platform and completed the establishment of attribution database.

Establishment of figure database mainly were based on utilization of 1:5000 Shenyang electronic map of the year 2008 and completed by importing grid electronic map into ArcGIS software and then implementing hierarchical vector quantization toward ground features. In addition to 11 monitoring stations scattergram, factors that affecting PM 2.5 concentration, such as map layers of residential areas, factories and mines, vegetation were also included.

## 2.2 Research method

Thematic map is a convenient method for us to achieve various professional study findings. It would highlight one or multiple elements on the basis of normal maps. GIF thematic map function was a product of combination of two powerful functions of GIS platform, namely, charting and analytic statistics which may directly demonstrate and dig out the characteristics of elements making itself an essential tool for data analytic statistics. This paper has analyzed the PM 2.5 variation law of Shenyang city on both daily and monthly basis, pollution level of each monitoring spot, and variation law during the 5 months of each monitoring spot by establishing attributes and graphic database and charting various thematic maps, including pie chart, histogram, line chart assisted by ARCGIS10 comprehensive GIS platform developed by ERSI. The thematic maps in ArCGIS with the features of simple processing and abundant expression forms could directly present the data analytic statistics achievements.

Inverse Distance Weighting was based on the similarity of interpolation area internal sample points to estimate the cell value by calculating weighted average of adjacent area sample points, and then interpolation got a surface. As there were only 11 monitoring stations in Shenyang, in order to do continuous spatial analysis, most regions in Shenyang needed to adopt inverse distance linear interpolation method to do interpolation, PM 2.5 concentration affected weight in the interpolation spot was in inverse proportion with the distance of the monitoring station. In this paper, linear interpolation has been applied to do interpolation of PM 2.5 concentration in each region in accordance with their distance to the 11 monitoring stations, and the calculation results has been demonstrated by rendering, which provide very good guidance in analyzing the pollution situation of the whole Shenyang City.

For better analysis on the influence of temperature, humidity, wind on PM 2.5, SPSS software has been applied in correlation calculation to get relevant parameters of influence factor and PM 2.5. SPSS (Statistical Package for Social Science) is

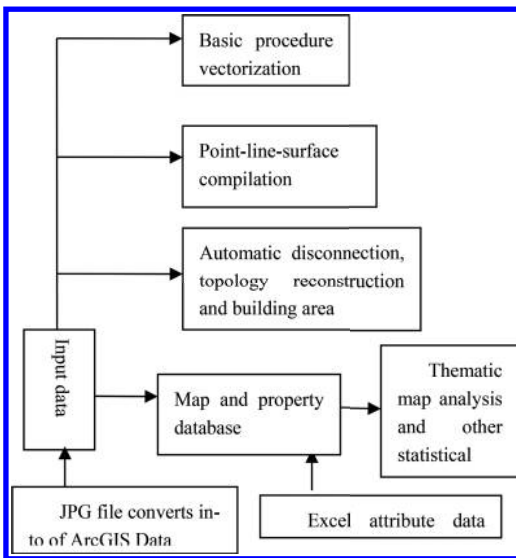

Figure 1. Database establishment procedure diagram.

one of the current popular statistical analysis software with advantages, such as simple to operate, efficient, and accurate in data correlation analysis. SPSS analyzed the closeness between PM 2.5 and factors, such as temperature variation, humidity, and nearby sewage plants, and gave out specific values. By correlation analysis, PM 2.5 pollution could be predicted and prevented to some extent.

### 3 RESULTS AND ANALYSIS

In China, PM 2.5 concentration was classified into 6 grades: excellent (0~35 ug/m<sup>3</sup>), good (35~75 ug/m<sup>3</sup>), mild pollution, (75~115 ug/m<sup>3</sup>), moderate level pollution (115~150 ug/m<sup>3</sup>), heavy pollution, and severe pollution (250~350 ug/m<sup>3</sup>). And PM 2.5 concentration in Shenyang was classified in accordance with aforementioned grades.

#### 3.1 PM 2.5 concentration variation characteristics

PM 2.5 concentration statistics were gathered 4 times during 2013.12~2014.4, 5 months in total, and got excessive rates of each monitoring station by classification (above moderate pollution level): Huishan 40.8%, Hunnan II 50%, Neusoft 52.3%, Zhangshi 56.2%, Artillery Academy 13.1%, Beiling 50%, Wenyi Road 46.9%, Xiaoheyuan 49.9%, Taiyuan Street 57.8%, and Ermao 54.8%, Liaoning University 49.2%. Thus, it can be seen that PM 2.5 in Taiyuan Street was most serious; Zhangshi was second serious; Artillery Academy was the one with lowest pollution. Besides data statistics and analysis of each monitoring station, in order to know rules of PM 2.5 concentration variation with time better, we also analyzed the daily and monthly PM 2.5 variation by gathering PM 2.5 concentration statistics of 7:00, 12:00, 17:00, and 20:00 everyday during the 5 months, and concluded PM 2.5 concentration variation with time in a day by histogram: PM 2.5 concentration kept declining during 7:00~17:00 and after 20:00, had a trend to pick up. This indicated that there was a minimum value during 17:00~20:00 and a maximum value during 20:00~7:00. Therefore, it was better for Shenyang residents to hang out or exercise in the afternoon or evening as during that time PM 2.5 concentration was low. We have formed line chart with monitoring month as independent variable, and PM 2.5 average monthly concentration of the 11 monitoring points as dependent variables, and reached a conclusion that from Dec. 2013 to Apr. 2014, PM 2.5 concentration of each monitoring point has been decreasing every month generally. Thus, it can be seen that PM 2.5 pollution was serious in winter and gradually became better with the arrival of spring.

Inverse distance weighting has been applied to get spatial distribution pattern of PM 2.5 concentration. Taking PM 2.5 concentration of each monitoring point in May as cardinality, reciprocal value of distance between each point and observation station as weight, drawing up the PM 2.5 spatial distribution map of Shenyang by interpolation, Shenyang PM 2.5 concentration distribution could be seen from the map, and PM 2.5 concentration in Zhangshi neighborhood was high and that in Artillery Academy was low.

#### 3.2 Influence factor analysis

PM 2.5 concentration was influenced by temperature and relative humidity, through SPSS software based on weather data and PM 2.5 concentration record during 5 months, we got the conclusion that relative coefficient of temperature and relative humidity to Shenyang PM 2.5 concentration was 0.18 and 0.481 respectively, and the influence of temperature on PM 2.5 concentration was much larger than the relative humidity. In a certain extent, PM 2.5 concentration was also affected by adjacent residential communities, the number and types of factory and traffic conditions, and it was greatly affected by coal-fired pollution for Shenyang residents in winter, winter was high-incidence season for haze in Shenyang.

### 4 PHOTOGRAPHS AND FIGURES

By analyzing PM 2.5 concentration data of 11 monitoring stations in Shenyang, we found that PM 2.5 concentration varied considerably among the monitoring stations, due to lots of traffic pollution and factories in urban district, PM 2.5 concentration of monitoring stations in Taiyuan Street, Beiling and Hunnan II were seriously over-standard, while Artillery Academy, located in rural area close to Arboretum and Qipan Mountain Scenic Zone, its PM 2.5 concentration seldom over-standard. From spatial perspective, PM 2.5 pollution in Tiexi, Yuhong, and Heping were most serious due to high population density, especially Tiexi, who has the largest number of population and factories and the most serious traffic jam, was the most polluted area in December and January to March during the winter heating supply period, while Dadong, Dongling, and Shenbei, who have high greening degree, low population density and scattered factories, were slightly polluted. From an overall perspective, PM 2.5 pollution in Shenyang was very serious, especially, in winter central heating period and it would become better with the arrival of spring. Peak concentration of PM 2.5 was in morning everyday, and then gradually declined,

after 20:00 started to pick up again. Therefore, it was not appropriate to do morning exercise in winter in Shenyang.

**ABSTRACT:** The main basis for thallium emission standard of industrial wastewater includes factory production technology, wastewater treatment technology, and the characteristics of local water ecological environment. This article discusses the research method of industrial wastewater thallium emission standard by using the thallium wastewater treatment technology and the local ecological environment characteristics. As for thallium wastewater treatment technology, the most practical processing method is precipitation, while biological method is the most prospect method. The local water ecological environment characteristics mainly include the present situation of the water ecological environment, water quality management, the law of water quality change and other aspects. According to the characteristics, ecological environment present situation survey should include the dry season, normal season and wet season. Hydrological survey should focus on the changes in hydrology, sediment, and river channel; Water quality survey focus on conventional, characteristics and the bottom sediment parameters; The objective of water quality management, executes the local “Surface Water Environmental Function Zoning”. As the water environmental health concept study becomes more perfect, the water environment functional zoning will develop to the water ecological environment functional zoning. WASP7 is chosen as the model to study the water quality change laws and the parameter of the model can be confirmed by theoretical method, empirical method, experimental method, and model correction method.

**Keywords:** thallium; emission standard; river basin

### 1 INTRODUCTION

Thallium is a typical toxic element which has lasting harm. Related studies have shown that thallium toxicity for mammals is higher than other heavy metals, much higher for plants. Thallium is a typically rare scattered elements in the earth's crust, coming to the environment with the exploitation of mineral resources. Because of the highly disperse in ore deposit and difficulty in industrial recycling, thallium pollution problem was overlooked all the time before. Along with the rapid population growth, the rapid development of economy and science technology, exploitation of resources is at an unprecedented scale and intensity which makes thallium pollution problem gradually revealed. Thallium contained in sulfide mine water can be dozens of times or even hundreds of times higher than the environmental background value and when it is serious, it can be tens of thousands of times. The thallium contained in tailings of Kellogg' Pb-Zn-Cu-Ag mine

fields which mixed with surface water has a high content up to 110 µg/L; Two rivers near nonferrous metal mineralization zone in New Brunswick contains thallium up to 80 µg/L. In Yunnan province, South China As-Tl Mine contains thallium from 2.91 to 13.0 µg/L in ore pit water. Beijiang river in Guangdong Province has been polluted in 2005, the thallium in Beijiang river is hundreds of times higher than the background value and the pollution accident in 2010, the wastewater from Shaoguan Smelter contains thallium as high as 600 ~ 700 µg/L, thousands of times higher than environmental background. These events also lead downstream to stopping supply water for several days.

The harm of the thallium in water caused the attention of USEPA. It has formulated 0.002 mg/L is the safety valve of thallium in the drinking water in 1993, the long term secure value is 0.0005 mg/L. This standard is more strict than many other harmful element, such as the 0.05 mg/L of As, 0.005 mg/L of Cd and 0.05 mg/L of Pb. Russia has a more

strict safety standards at present, thallium in drinking water must contained less than 0.0001 mg/L. China has begun to focus on thallium toxic materials and the ministry of construction has set up the standard of thallium in urban supply water in 2006, it is 0.0001 mg/L. Hunan Province has published “The Emission Standard Of Thallium In Industrial Wastewater Of Hunan Province”(DB43968-2014) on November 27, 2014 and implemented on January 1, 2015. The standard set 0.005 mg/L as the limit value of thallium emission. However, the study of thallium emission standards is still very weak.

Drinking water sources protection is the most important in the national water environment protection policy. So the establish of river basin’ thallium emission standard and regulate of the factory emission is no time to delay.

According to the basis for emission standard, thallium in wastewater emission standards is related to the factory production technology, wastewater treatment technology and local water environment features. The advanced nature of industrial process is closely related to the characteristics of different businesses. The following study is mainly from thallium wastewater treatment technology and the local ecological environment features to confirm the determination of thallium in wastewater emission standard.

## 2 RESEARCH OF THALLIUM REMOVAL METHOD IN WASTEWATER

At present, thallium pollution control technology mainly include adsorption, ion exchange, membrane separation, chemical precipitation, carrier activated absorption method, biological or composites adsorption method, etc. These methods are shown in Table 1.

According to the Table 1, adsorption and ion exchange methods have a particularly high removal rate, but they cost high; Membrane separation process also has a very high removal rate, but the membranes need to update every few years; Biological or composites adsorption method has a great prospect, but it still needs more tests; Precipitation is low cost and widely used at present, but the removal rate is low, but through the optimization this method also has great prospect.

## 3 ECOLOGICAL ENVIRONMENT CHARACTERISTICS OF LOCAL WATER

Local water ecological environment characteristics mainly include the present situation of the ecological water environment, water quality management and the law of water quality change and other aspects. These aspects are important basis to determine the wastewater emission standard.

### 3.1 Present situation survey of ecological environment

Reference to the “Technical Guidelines For Environment Impact Appraisal—Surface Water Environment”, present situation survey of ecological environment mainly includes hydrology survey and water quality survey. We choose Beijiang in Guangdong Province as an example to decide which parameters should include during the survey.

#### 1. Hydrology survey

The hydrological character of Beijiang river is: an even distribution of rainfall in a year and great seasonal changes in water level, sediment concentration. Sediment transport mainly concentrated in April to August, these five months accounted 84 percent of sediment transport in a year.

Table 1. The main removal method of thallium and its effect analysis.

Current method	Material	Removal rate	Advantages and disadvantages
Adsorption	Activated alumina	Set pH to 4.5, removal rate nearly 100%	High removal rate but the cost is high
	Activated carbon	Removal rate is 96%–99%	High removal rate but high cost
Ion exchange	NaCl solutions	Effluent water quality of Tl <sup>+</sup> is less than 2 μg/L	Less selective of thallium
Membrane separation	Membrane	High effluent water quality	High effluent water quality but high cost
Precipitation	Offscum of pyrite contains Fe <sup>3+</sup> and Mn <sup>2+</sup>	Removal rate is between 69% to 81%,	Medium removal rate but cost free
Biological material	Sawdust	Removal rate is 98%	Fast and low cost
	Nut shell	Removal rate is 96.5%	Low cost
	Tea waste slag	Removal rate is 98.4%	

According to the characteristics of the Beiji-jiang river' hydrology has a great seasonal change, hydrological survey of Beiji-jiang river mainly include: the divide of wet season, normal season, dry season, the change of riverbed shape: the situation of river bend, cross section (flood plain changes, etc.), vertical section (slope), roughness; The change of watercourse' hydrological features: water level, water depth, the river width, flow, velocity, sediment concentration, sediment transport, and water level—flow relations, water—sediment relations.

2. Water quality survey: According to Beiji-jiang river' hydrology features, features of pollution sources (Fankou lead-zinc Mine, Shaoguan Smelter and Dabosan Mine, etc.) all belong to the non-ferrous metal smelting. The water quality survey of Beiji-jiang river mainly include: General parameters: pH, temperature, suspended solids, dissolved oxygen, potassium permanganate index and BOD5, five days kjeldahl nitrogen or non-ionic ammonia, sulfide, fluoride, petroleum, phenol, cyanide, arsenic, mercury, hexavalent chromium, phosphorus, etc.; Characteristic parameters: thallium, copper, zinc, lead, cadmium, etc.; Bottom sediments (including aquatic organisms) parameters: the amount and type of planktonic animals and plants, algae, benthic invertebrates, the consist of aquatic community structure. Bottom materials are accumulative particular pollutants which related to the water quality of drainage. The survey period includes dry, normal, wet seasons. In addition, the water quality of the pollution sources and the particular pollutants should added to the survey.

### 3.2 The object of water quality management—water environment functional zoning

According to the local “Surface Water Environmental Function Zoning”, we can determine the position of the pollution sources. As the water environmental health concept study becomes more

perfect, the water environment functional zoning will develop to the water ecological environment functional zoning.

### 3.3 Research of the law of thallium—water quality

Using the law of water quality change (always express by a mathematical model) is an important method to determine the emission standard, based on the present situation of water quality, water quality management, reflex the water quality of the emission sources by using a model.

1. The choice of model  
Water quality model using mathematical language to describe the mutual transformation relationships, the law of pollutants change in water environment and the influencing factors. At present, the river water quality simulation has two ways, one is to develop a specific water model for a specific river; the other way is use a water quality models which have successfully used before. Among them, the second way is the most commonly used. The water quality simulation models which have successfully used before are: WASP7, MIKE21, CE-QUAL-W2, SMS-SED2D, SMS-RMA4, HEC-RAS, HEC-HMS, QUAL2E, QUAL2K, etc. Table 2 lists the contrast of several main models.

According to Table 2: WASP7 is the most suitable water quality model in type, dimension and computing speed compared to other models. So WASP7 is chosen to be the water quality simulation model.

2. Model parameters and its determination method

WASP7 water quality model parameters include hydrodynamic and water quality (describe pollutant migration). Among them, the hydrodynamic parameters include: the convection velocity and diffusion coefficient in lengthways, crosswise and vertical; roughness coefficient and

Table 2. Contrast of several models.

Model	Dimension	Parameters	Calculation method	Calculation results
WASP7	3	DO, germ, Eutrophication, ss, toxic materials	Difference method	Low accuracy but fast
MIKE21	2	Flow, water level and velocity	Difference method	Low accuracy but fast
SMS-RMA4	2	Diffusion coefficient of pollutants	Finite element method	High accuracy but slow
QUAL2E	1	BOD, DO, T, NH3-N and others	Finite element method	High accuracy but slow
HEC-RAS	1	Flow, water level and velocity	Difference method	High accuracy but slow

hydraulics factors of flow, velocity and water depth. Water quality parameters include: coefficient of heavy metals adsorbed and desorbed by sediments, Coefficient of sediment release, coefficient of absorption and release by aquatic organisms. The parameters of the model can be confirmed by theoretical method, empirical method, experimental method and model correction method.

#### 4 CONCLUSION

Thallium is a typical toxic element which has lasting harm, but the study of thallium emission standards is still very weak. Thallium has severely the rivers in the recent years. So the establish of thallium emission standard is no time to delay.

Thallium in wastewater emission standards is related to the factory production technology, wastewater treatment technology, and local water environment features. This paper mainly discusses from the latter two features to confirm the determination of thallium in wastewater emission standard.

Thallium pollution control technology mainly includes adsorption, ion exchange, membrane separation, chemical precipitation, biological adsorption method. The most practical processing method is precipitation, while biological adsorption method is the most prospect method.

Local water ecological environment characteristics mainly include the present situation of the ecological water environment, water quality management, and the law of water quality change and other aspects. We choose Beijiang in Guangdong Province as an example to decide what parameters should be included during the survey. According to Beijiang river hydrology has a great seasonal change, hydrological survey of Beijiang river include wet season, normal season, and dry season. Hydrological survey focuses on hydrology, sediment and change of river channels; Water quality survey focus on general parameters, characteristic parameters and Bottom sediments parameters; As for the object of water quality management, executes the local "Surface Water Environmental Function Zoning", As the water environmental health concept study become more perfect, the water environment functional zoning will develop to the water ecological environment functional zoning. WASP7 is the most suitable water quality model in type, dimension and computing speed compared to other models. So WASP7 is chosen to be the water quality

simulation model. The parameters of the model can be confirmed by theoretical method, empirical method, experimental method, and model correction method.

# Limit of abandoning wind and sunshine rate research based on wind-photovoltaic-thermal coordinated dispatch model

Ran Li, Lei Dang & Zhe Dong

Department of Electrical Engineering, North China Electric Power University, Baoding, Hebei, China

**ABSTRACT:** Along with the increase of wind and photovoltaic capacity, due to the adverse effect on peak regulation and the probabilistic fluctuation, wind and sunshine power is often abandoned in practice when considering economic or security. However, it is necessary to limit it to avert the seriously abandoning wind and sunshine phenomenon. This paper aims to analyze this problem by establishing the relationship between reliability indices and up-down spinning reserve in order to calculate up-down spinning reserve. At the same time, the start-up and down, output power dispatch model is built and solved by Evolutionary Iteration Particle Swarm Optimization (EIPSO). Meanwhile, thermal power units are start-up and down in order. Second, economic dispatch result when abandoning wind and sunshine is compared with the result when not abandoning wind and sunshine, of which the outage cost is the main change.

**Keywords:** spinning reserve; coordinated dispatch; Evolutionary Iteration Particle Swarm Optimization (EIPSO); abandon wind and sunshine

## 1 INTRODUCTION

With the increase of capacity of wind power and solar power, their anti-peak shaving and fluctuation characteristics bring more difficulty to power dispatching, like more peak-valley differential caused by anti-peak shaving of wind power and more spinning reserve by solar power fluctuation. These will change the schedule of generator's start/stop and power output, which cause more power generation cost [Yang Dongfeng et al. 2014].

Wind/Solar/Thermal power combined scheduling model described in this article need to determine the upper spinning reserve when renewable energy is connected to power grid. Reference [Yuan Bo et al. 2013] correlated the spinning reserve to load-loss forecast. Risk value and conditional risk value are used to define the upper and lower spinning reserve in reference [Zhang Guoqiang et al. 2011]. Upper and lower spinning reserve is determined by upper and lower limit of wind power forecast [Yao Yao et al. 2011]. The error of wind power and solar power forecast is not considered in above literature, so reliability index of LOLP is adopted to define the spinning reserve limit in this article.

The simplified model of selective area includes many same type of generators. To ensure the uniqueness of the start/stop process solution, the start and stop sequence of same type of generators need to be numbered. Coordinate schedule model including wind-discard ratio and solar-discard ratio will be set up by using EIPSO algorithm.

## 2 MODEL ESTABLISHED

### 2.1 Economical and safe wind curtailment and PV curtailment

Economical wind curtailment aims to give up part of wind and PV power to reduce operation costs. Some elements including economical wind curtailment, wind curtailment rate, the biggest limit constraint are added to the scheduling model, after that, the value of economical wind curtailment and PV curtailment will be calculated.

Safe wind curtailment and PV curtailment aims to give up part of beyond planning power and wind power to reduce the demand of down planning reserve when the thermal power is short of cut capacity.

### 2.2 The relationship between up and down planning reserve and reliability index

The forecasting error probability distributions of wind and PV power and load are supposed to be based on normal distribution. And the prediction error percentages are  $\sigma_w$ ,  $\sigma_s$ ,  $\sigma_l$  respectively. The outputs at the moment  $h$  are  $P_{w,h}$ ,  $P_{s,h}$ ,  $P_{l,h}$ , so the total prediction error at the moment  $h$  is  $\sigma_{total,h}$ , and it can be showed as (1).

$$\sigma_{total,h} = \sqrt{(\sigma_w \times P_{w,h})^2 + (\sigma_s \times P_{s,h})^2 + (\sigma_l \times P_{l,h})^2} \quad (1)$$

Up and down planning reserve can be determined according to two parts. One is reserve demand considering prediction error when all units operate normally; the second is same to former but the units are out of service. This paper use LOLP and EENS to determine the value of up and down planning reserve. And the probability of unbalanced power caused by the lack of down planning reserve can be set no more than  $\alpha$ . So, using LOLP, EENS and  $\alpha$ , the value of up and down planning reserve in the model can be calculated [Ronan Doherty et al. 2005].

$$LOLP = \left( 1 - \Phi \left( \frac{P_{L,up,h}}{\sigma_{total,h}} \right) \right) \times \prod_{i=1}^{W,S,T} (1 - FOP_i) + \sum_{j=1}^{W,S,T} FOP_j \times \left( 1 - \Phi \left( \frac{P_{L,up,h} - P_j}{\sigma_{total,h}} \right) \right) \times \prod_{\substack{i=1 \\ i \neq j}}^{W,S,T} (1 - FOP_i) \quad (2)$$

$$EENS_{15} = \left( \int_{P_{E,up,h}}^{P_{w+s}} xP \left( \frac{x}{\sigma_{total,h}} \right) dx \times \prod_{i=1}^{W,S,T} (1 - FOP_i) + \sum_{j=1}^{W,S,T} FOP_j \times \int_{P_{E,up,h} - P_j}^{P_{w+s}} xP \left( \frac{x}{\sigma_{total,h}} \right) dx \times \prod_{\substack{i=1 \\ i \neq j}}^{W,S,T} (1 - FOP_i) \right) \times \frac{1}{4} \quad (3)$$

$$\alpha = \Phi \left( \frac{-P_{\alpha,down,h}}{\sigma_{total,h}} \right) \times \prod_{i=1}^{N_{W,S,T}} (1 - FOP_i) + \sum_{j=1}^{W,S,T} FOP_j \left( \Phi \left( \frac{-P_{\alpha,down,h} - P_j}{\sigma_{total,h}} \right) \times \prod_{\substack{i=1 \\ i \neq j}}^{W,S,T} (1 - FOP_i) \right) \quad (4)$$

where:  $N_{W,S,T}$  is the total number of units according to the rank of wind, PV and fire;  $FOP_i$  is the forced outage rate of the unit  $i$ ;  $P_j$  is the maximum power output of the unit  $j$ ;  $\Phi(x)$  is standard normal distribution function;  $P(x)$  is the probability density function of standard normal distribution.

This area can receive part of power through tie line from other area. So it can be thought that this area just need  $w(w < 1)$  times of up and down planning reserve. And the up and down planning reserve can be defined as following:

$$P_{up,h} = \max(\max(\omega \times (P_{L,up,h}, P_{E,up,h}), P_{maxG})) \quad (5)$$

$$P_{down,h} = \omega \times P_{\alpha,down,h} \quad (6)$$

where:  $P_{maxG}$  is minimum constraint value of up planning reserve in this isolated area, and its value can be set as the maximum output power of the biggest unit.

### 2.3 The determination of the objective function and constraint conditions

Objective function can be set as total generation cost, including unit start-up cost and the cost of fuel. Owing to serious environmental problem, the generation cost of wind and PV is nearing zero. Therefore, in the objective function formula (7),  $SU_{n,d} + SD_{n,d} + F(P_{n,d})$  are starting cost, cost of downtime and generating cost, respectively.

$$C_1 = \sum_{n=1}^{n_r} \sum_{h=1}^{24} (SU_{n,d} + SD_{n,d} + F(P_{n,d})) \quad (7)$$

$$SU_{n,d} = \begin{cases} 0 & U_n^d (1 - U_n^{d-1}) \leq 0 \\ d0_n (1 - e^{-T_{n,d}^{off}/d1_n}) + d2_n & U_n^d (1 - U_n^{d-1}) > 0 \end{cases} \quad (8)$$

$$SD_{n,d} = \begin{cases} 0 & U_n^{d-1} (1 - U_n^d) \leq 0 \\ d3_n & U_n^{d-1} (1 - U_n^d) > 0 \end{cases} \quad (9)$$

$$F(P_{n,d}) = A_n + B_n \times P_{n,d} + C_n \times P_{n,d}^2 \quad (10)$$

where:  $n_r$  is the total number of units;  $d0_n, d1_n, d2_n$  are the parameters of unit start-up cost;  $A_n, B_n, C_n$  are the parameters of fuel;  $U_n^d$  is the unit's state at the moment  $d$ , and 0 stands for closing, 1 stands for starting;  $P_{n,d}$  is the power in practice of unit  $n$  at the moment  $d$ .

Constraint conditions include unit start-up, unit's power, abandon the wind in economy, discard rate limit, climbing constraints power balance constraints and up-down planning reserve constraints.

#### 1. Unit start-up constraints

$$\sum_{s=h}^{h+T_{n,on}-1} U_n^s \geq T_{n,on} (U_n^h - U_n^{h-1}) \quad (11)$$

$$\sum_{s=h}^{h+T_{n,off}-1} (1 - U_n^s) \geq T_{n,off} (U_n^{h-1} - U_n^h) \quad (12)$$

where:  $T_{n,on}, T_{n,off}$  is the minimum time of start-up of unit  $n$ .

#### 2. Constraints of unit's power, efficiency to abandon the wind and discarding rate limit

$$P_n^{\min} \leq P_{n,d} \leq P_n^{\max} \quad (13)$$

$$\begin{aligned} 0 &\leq \omega_{w,d}\% \leq \omega_{eco,w}\% \\ 0 &\leq \omega_{s,d}\% \leq \omega_{eco,s}\% \end{aligned} \quad (14)$$

where:  $P_n^{\min}$ ,  $P_n^{\max}$  are the maximum and minimum power of unit  $n$ ;  $\omega_{w,d}\%$ ,  $\omega_{s,d}\%$  are the rates of abandoning wind and light in practice at the moment  $d$ , respectively.  $\omega_{eco,w}\%$ ,  $\omega_{eco,s}\%$  are the value of abandoning the wind and light in economic, respectively.

### 3. Climbing constraints

$$P_{n,d-1} - 15 \times P_{n,GD} \leq P_{n,d} \leq P_{n,d-1} + 15 \times P_{n,GU} \quad (15)$$

where:  $P_{n,GD}$ ,  $P_{n,GU}$  are the up and down climbing speed respectively.

### 4. Constraints of power balance

$$\begin{aligned} \sum_{n=1}^{n_r} P_{n,d} + (1 - \omega_{w,d}\%)W_{w,d} \\ + (1 - \omega_{s,d}\%)W_{s,d} - P_{lost,d} = L_d \end{aligned} \quad (16)$$

where:  $W_{w,d}$ ,  $W_{s,d}$  are the power of wind and PV at the moment  $d$  respectively;  $L_d$ ,  $P_{lost,d}$  are the load powers and power loss at the moment  $d$ , respectively.

### 5. Constraints of up and down planning reserve

$$\sum_{n=1}^{n_r} \min(P_n^{\max} - P_{n,d}, 15 \times P_{n,GU}) \geq P_{up,h} \quad (17)$$

$$\begin{aligned} \sum_{n=1}^{n_r} \min(P_{n,d} - P_n^{\min}, 15 \times P_{n,GD}) + W_{w,d} \\ \times \omega_{safe,w}\% + W_{s,d} \times \omega_{safe,s}\% \geq P_{down,h} \end{aligned} \quad (18)$$

where:  $\omega_{safe,w}\%$ ,  $\omega_{safe,s}\%$  are the values of safely abandoning wind and light at the moment  $d$ , respectively.

## 3 THE SOLVING PROCESS OF THE MODEL

In order to avoid dimension disaster, model solving process can be divided into two steps. The first step of the outer loop schedules for unit start-up, and the second step of the inner loop schedules for power. The time interval is 1h, and the EIPSO algorithm is used to solve this model. The model solve process is as follows:

1. The first step is to initialize the start up and down sequence of unit particles whose dimension is  $N \times D$ .  $N$  that represents the total units, and  $D$  represents the number of times. Then calculate the start and stop costs according to the formula (6)~(7), and verify the unit particles to meet the constraints of (9)~(10);

2. The second step is to initialize the output power for each unit particles whose dimension is  $N_{up,d} \times D$ .  $N_{up,d}$  and represents the total units for the moment  $d$ , and  $D$  represents the number of times. Then calculate the economic costs according to the formula (5), and verify the unit particles to meet the constraints of (11)~(14);
3. The third step is to add constraints as the form of penalty function to fitness value, and use EIPSO algorithm to solve the inner loop. This step is used to get optimal power corresponding to the start up and down sequence of unit particles;
4. The fourth step uses the EIPSO algorithm to solve the outer loop to obtain the optimal start-up and down sequence of particles;
5. The fifth step use the optimal start up and down sequence of unit particles and optimal output to calculate the thermal output, wind and PV abandon rate scheduling. The method is same as the second step.

## 4 EXAMPLES

This paper establish a mixed integer nonlinear programming model to solve a day-ahead generation scheduling problem and the data of the model selected from some wind-photovoltaic-thermal coordinated area. We assume that there are 10 units whose capacity is 300MW and the capacity of other 10 units 350MW. In addition, the total power of 20 wind farms is 2000MW, the power generated by photovoltaic power generation is 200MW. Characteristics of the units refer IEEE-RTS system and the research. Assuming that the line loss is 5%, the forced outage rate of 300MW, 350MW, wind turbines and photovoltaic panel is separately 7%, 8%, 4% and 4%, Take 2.18%, 9.32% and 19.57% as load, wind power and photovoltaic power's prediction error respectively. Select the data of wind power, photovoltaic power of which anti peak shaving and adulatory property is the most obvious as the research object from scheduling data. The initial state of thermal power units is assumed as unit 9 and 10 in 300MW, unit 5~10 in 350MW are open. Because unit can shut-down quickly,  $T_{on}$  and  $T_{off}$  separately take 1h and 6h.

Shown as Figure 1(a), in 300MW units, unit 3, 4, 7 open and close repeatedly as result of the short of capacity, and 9, 10 unit is always being open. While in 350MW units, unit 9 and 10 is always being open, and unit 5 opens and closes repeatedly because of the short of capacity. Figure 1(b) shows that the output of 350MW units are more than 300MW units, especially 350MW units provide mainly at load peak, that's because the costs of each MW fuel of 350MW unit is less than 300MW units.

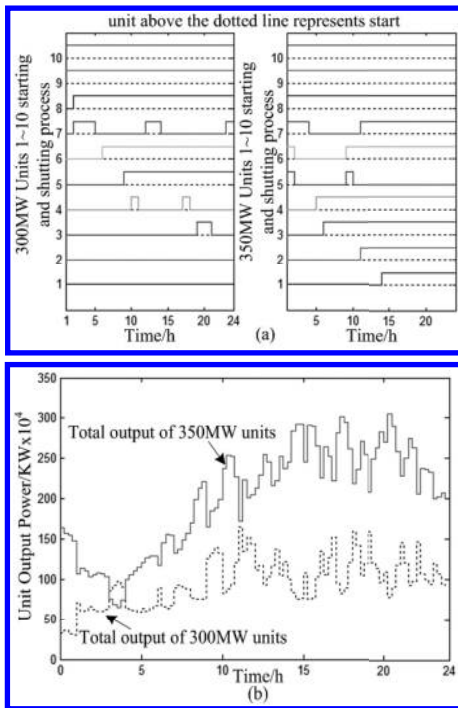

Figure 1. Units dispatch without abandoning wind and photovoltaic ((a) start-up and down, (b) output).

As shown in Figure 2(a), spinning reserve shortage occurred under the cause of the unit start-stop occurred in 1 ~ 10 times, and 18 ~ 21 times, 1 ~ 10 times lead to 7 unit of 300 MW and 350 MW unit 5 to unnecessary start-stop, 18 ~ 21 times the cause of 300 MW generating unit 3, 4 unnecessary start-stop. It's shown in Figure 2(b), the reserve capacity requirements calculated from traditional method are close to the reserve capacity requirements calculated from (1)-(4), when wind power and PV are not considered, therefore the rationality of the alternate calculation method was verified. When wind power and PV are included at the same time, the reason that the limit of spinning reserve rise at time 0~5 times is because wind power is more than PV, in order to prevent the power supply shortage caused by wind power less than its plan, it's necessary to increase the limit of spinning reserve. While, the increase of spinning reserve in 0~5 times is because of the high output of wind power, given the real output may be more than plan output, thermal power should rise the ability of cut to ensure security constraints.

Comparing Figure 1(a) and Figure 3(a), we can find that in Figure 1(a) the units on 300 MW start 9 times and the units on 350 MW start 7 times, and in Figure 3(a) the units on 300 MW start 7 times

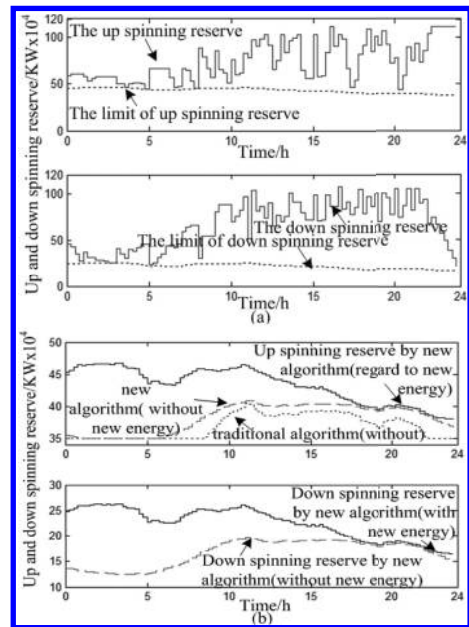

Figure 2. Values of up and down spinning reserve without abandoning wind and photovoltaic.

Figure 3. Units dispatch under the limit of abandoning wind and photovoltaic rate is 5% ((a) start-up and down, (b) output).

Figure 4. Power and percentage of abandoning wind and photovoltaic rate which is limited within 5%.

and the units on 350 MW start 7 times, that will reduce the start-up costs of two 300MW units. Besides, Figure 3(b) shows that 300 MW units output increase during to the process of an 300 MW unit off and on in the time of 16 to 18.

It's shown in Figure 4, the given-up wind power in used to decrease the influence on economy by the anti-peak shaving of wind power.

## 5 CONCLUSIONS

Comparing the schedule result at economy and safety wind/solar discard ratio, two types of wind/

solar discard ratios can be figured out to reduce the start/stop cost and thermal generation power cost. The limit will be taken into the daily-before schedule to ensure higher economy and restrict the quantity of wind/solar discard. Meanwhile, the calculation effort will be reduced because of setting of lower power of wind/solar power regulation compared with no lower power model.

Wei Hu

*College of Computer Science and Technology, Wuhan University of Science and Technology, China*

**ABSTRACT:** Contradiction between rapid development of economy and technology in deteriorating ecological environment is one of the important challenges in urbanization of China. By learning from foreign experience, this paper aims at the typical problems of the municipal solid waste management, and takes one of China's largest cities Wuhan for example. Using computer data processing technology, this paper explores how to realize intelligent control of the whole process of municipal solid waste, and to promote the sustainable development of urban human settlement environment. This whole process of municipal solid waste management strategies can provide useful references and inspiration for cities in China as well as other developing countries.

**Keywords:** municipal solid waste; intelligent control; management strategies; Wuhan

## 1 INTRODUCTION

With the acceleration of urbanization and the rapid development of economy, municipal solid waste management problems are getting more and more serious. Nowadays, China's strategy for municipal solid waste management and treatment focuses at the end. There are three main ways: composting, landfill, and incineration. However, composting technology can only operate well under microbial environment, and the processing period is too long; Fill method has the advantage of dealing with large capacity and high economic efficiency, but it still has a great negative impact on the groundwater environment; Incineration treatment belongs to the relatively high energy efficiency and resource utilization of the heat produced by the incineration, and occupies an area of small, but easy more pollution to the air environment. Therefore, it is easy to see that the above three ways have their advantages and disadvantages, need for municipal solid waste management problems in the process, then apply the appropriate measures.

## 2 MATERIALS AND METHODS

In this paper, we take Wuhan City, central China's largest city and a center of the city—as the object

of study. According to the statistics, 2010–2013, Wuhan municipal domestic waste output has increased significantly, from 2.2 million tons in 2010, rising to 2.6 million tons in 2013, with an average annual growth rate of 6.1% (Fig. 1). However, the city for waste treatment model and improvements haven't been made. Especially, in the old city and outside the third ring, feel free to dump garbage everywhere. In the course of delivery, garbage truck often sewage leaks, trash overflow, and so on.

Figure 1. Wuhan municipal solid waste outputs variation in 2010–2013. (data source from Wuhan Environmental Protection Bureau).

Wuhan, have seriously affected the health of cities and also reduce people's quality of life. In this case, information intelligence of the whole process of municipal solid waste is necessary to study. The effective management and monitoring of municipal solid waste not only save existing land resources, highly coordinated transportation, but also can make rational use of existing resources. In February 2011, the city proposed "intelligent city" construction concept. On this basis, promoting urban waste intelligent control strategy can help the whole process of Wuhan municipal solid waste recycling and promoting Wuhan achieved the purpose of building a harmonious and livable city, lead the smart city concept extends to every corner of society and people's livelihood.

The research methods are:

1. Based on current domestic solid waste problems and obstacles faced by the processing system of the whole process, from municipal solid waste processing, transport and processing, and find the optimal solution.
2. Introduction of current urban development promoted by the "intelligent city" concept, using the smart technology, to trash the whole process in real time, linkage, stability, and effectiveness.
3. Waste processing operations connected with the information management system of city, urban data.
4. Use the "3R" concept of municipal solid waste treatment technology and ultimately achieve waste minimization, recycling and harmless requirements.

### 3 WUHAN MUNICIPAL SOLID WASTE MANAGEMENT SYSTEM ANALYSIS

#### 3.1 *Waste separation and recovery system is not perfect*

Because the lack of residents' awareness of environmental protection and waste separation knowledge, the serious problem of the amount of municipal solid waste and miscellaneous. Wuhan construction of waste treatment facilities is still not on the agenda, without waste sorting waste for subsequent recovery of utilization and disposal of inconvenience, not only increases the workload of the operator, and also put forward higher requirements for waste disposal equipment. Eventually, lead to garbage recycling rate is very low, the waste of resources is not reduced.

#### 3.2 *Reduce waste treatment*

Waste reduction is in the waste produced in the process, suppress or avoid the eventual incineration

and land filling of waste, which is source of waste down, reduce the production of waste. As of right now, still follows the end of treatment of domestic waste treatment in Wuhan City pattern, garbage disposal problems piled up on the last incineration or landfill link. Municipal waste reduction, resource recovery, innocent sort of goals also requires long-term efforts to achieve.

#### 3.3 *Inadequate waste collection and transportation system*

Municipal domestic waste collection and transportation work is characterized by traffic, transport level involves more. However, transport of municipal solid waste, and no systematic layout of Wuhan, resulting in waste transportation energy consumption and low efficiency. In addition, part of junk jobs drivers of vehicles not required to route jobs, often reselling halfway through "wild waste" on urban health and environment hazards.

## 4 INTELLIGENT MANAGEMENT STRATEGIES FOR MUNICIPAL SOLID WASTE DISPOSAL

In order to solve the problems above, this paper argues that if municipal solid waste management system wants to achieve the most efficient and optimum condition, there must be a systematical innovation through the whole process of municipal solid waste disposal. Therefore, the municipal solid waste management will be divided into three stages: collection, delivery, and disposal. By combining the intelligent equipment and management system, our paper presents the following optimal solutions.

#### 4.1 *Real-name trash bags*

1. Because that residents' waste classification awareness is not so strong, and current situation of sanitation supervision is inadequate we will trash bags for the new design under the premise of vigorously promoting and popularizing knowledge of waste. The recorded information of urban residents of two-dimensional code combined with the garbage bag, forming a real-name system for garbage bags.
2. Real-name trash bags will be divided into four colors, each color corresponding to a kind of waste categories. It is mainly based on the traditional garbage bag attach the recorded holder of personal information and litter species information the QR code. By scanning the QR code, one of the trash doors can be opened. In addition, when random rubbish is found in garbage

bags, sanitation Inspector can quickly trace spam sources (Fig. 2).

#### 4.2 Solid waste intelligent storage devices

1. Intelligent storage devices for solid waste is a key equipment through the whole management process. For city waste bins sealed enough, often distributing odors and germs a lot of mosquito breeding conditions, we use QR code as rubbish bins open “key.” Once the rubbish is put in the specified bin, the door will shut. When collecting the garbage, our staffs only need to put their own QR code on scanned area, and the door can be opened.
2. To ensure the waste be divided at source, our intelligent waste storage device can be divided into four closed containers according to waste classification category, namely, recycling waste (green), and general waste (yellow), food waste (orange), and hazardous waste (red). Garbage bags are attached to the classified information by scanning the QR code; the door corresponds to the trash will open as quickly as possible.

#### 4.3 Intelligent supervision system

1. Hand out the real-name system garbage bags by the amount and time granted. Quantitative issue with community management institutions each month QR garbage bags, people working at home must do the garbage classification. When garbage processing, such as free classified waste, will be based on the cloud computing system data that can be recorded to the holder’s credit limit cuts. Once the credit falls below a certain value, it will be required for social work. In addition, QR code information will be updated once in every month, updated the original QR codes will not be available. Monthly, the rest of garbage bags are available to users receiving point’s redemption prizes. So that the people can consciously reduce solid waste and achieve the reduction of solid waste.
2. To collect the waste on the amount. Intelligent storage devices can store waste garbage weight monitoring in real time, all data will be input to the database. Once the weight reaches a preset value, it will send hint to the garbage station, and the waste dump position, sending the

Figure 2. Waste information management with real signature.

corresponding vehicle charge. Regularly collecting garbage at this stage of the process is better, so that it can deliver savings greater consumption of energy and improve efficiency.

#### 4.4 Municipal solid waste link

1. The overall handling of hazardous waste box we use, in transport box directly into the waste inside the vehicle. Refuse in the back compartment with two hazardous waste box for the card slot can be fixed for a fixed bin.
2. Installed in the vehicle GPS (Global Positioning System), real-time control of the vehicle location information to stop halfway dump “wild waste” phenomenon. Finally, the information storage systems install in a vehicle, and send information to a Terminal, so that garbage collection agencies keep track of vehicle information.
3. The garbage station, routes will be set in advance for each recycling site, refuse collection vehicles before delivery, vehicle information, operator information, departure time has a record, as judging the rationality of the transportation process basis as well as supervision of the operator (Fig. 3).

#### 4.5 Municipal solid waste processing

When the waste is transported to the landfill successfully, it is then unloaded by unified garbage disposal personnel to deal with. Each staff member’s information will also need to undergo a rigorous monitoring so that waste treatment sessions, determined for each question appear in charge (Fig. 4).

Complement the above procedure is needed innovation and implementing the enterprise

Figure 3. Waste transit information management model.

Figure 4. Waste disposal information management model.

system of waste disposal units. Process data via cloud computing meet no harm standards and then focused on the destruction, to achieve the waste harmless. In city life garbage full process management, completely using real networking technology, building dangerous waste regulatory real networking system, on life garbage in the dangerous waste of disposal process and the processing personnel, for real-time monitoring, for solid waste processing process of full of regulatory provides technology guarantees, achieved on dangerous waste from source to fill buried processing of full can tracing of monitoring, prompted solid waste management by traditional artificial management way to modern intelligent management way for change.

## 5 CONCLUSIONS

As the Development and improvement of science and technology information, municipal solid waste management brings out new opportunities and challenges. Through Global perspective on urban development, the paper studies combine the intelligent technology and waste management system, based on the consolidation of the waste management system operation. For whole city garbage disposal process running system, our paper hold wisdom city construction concept, on city life garbage management has optimized strategy: 1) through referencing both at home and abroad city garbage management experience, we proposed that garbage processing can adopt intelligent cloud computing technology. We expect the linkage is what our new management system has. 2) Starting

with whole intelligent management system equipment, we have systematic arrangements on municipal solid waste whole process. Through the garbage disposal and recycling, we expect to achieve stability of solid waste treatment and recycling. In Conclusion, smart city concept-based research on municipal solid waste management strategy is in line with the requirements of the times, The use of intelligent technologies is to address solid waste problems in contemporary cities, and to promote resource-saving and environment-friendly urban development with a positive effect.

# Experimental study of infiltration characteristics of outdoor particulate matter into the indoor

Zhiyong Li, Fan Zhang & Qianqian Shi

*School of Civil Engineering, North China University of Technology, Beijing, China*

**ABSTRACT:** This paper set up an experimental platform and tested the penetration rate of particles of different diameters penetrating the crack. The results show that the particle penetration rate through cracks is mainly influenced by the pressure difference between the ends of the crack and by the diameter of particles. The particle penetration rate through cracks goes bigger as the pressure gets larger, within the scope of the low penetration rate changing with pressure difference is more sensitive. Unlike pressure change, penetration rate turns smaller along with the increase of particle size.

**Keywords:** particulate matter; penetration rate; crack; haze

## 1 RAISE QUESTION

In 2014, haze phenomena occurred frequently in Beijing and other cities in China. The bad influence that haze has on people's lives cannot be sneezed at. In recent years, studies of epidemic diseases and other toxic symptoms indicate that human health is closely related to the degree of body's exposure to fine particulate matter in the air. Firstly, the fine particulate matter in the air can carry bacteria, carcinogens, and virus directly into the lungs, and lungs may get injured and infected. Secondly, outdoor fine particulate matter can carry inorganic composition and heavy metal accumulating toxins, which causes acute or chronic damage to human breathe system, immune system, and cardiovascular system. Studies show that the smaller of the particle size, the acid will be more apparent, namely the acids of PM 2.5 and PM 10 particles will significantly increase. Therefore, the air pollution caused by particulate matter has been closely connected with people's health and environmental quality. For the study of the relationship between the penetration rate and relevant variables, this paper set up an experiment device to test the characteristics of particles penetrating under different experimental conditions.

## 2 EXPERIMENT

### 2.1 *Experiment set-up*

As shown in [Figure 1](#), this experiment device mainly include: 1—entrance, 2—rectifying section, 3—first sampling segment, 4—crack structure,

5—last sampling segment. In the experiment, the air flow entered by the entrance, through the rectifying section, then flowed into the first sampling segment and is tested in it. Under the pressure difference, particulate matter in the first sampling segment flowed arriving in the last sampling segment to be tested. Finally, the air with particles would be exhausted from transition section by the fan. As shown in [Figure 1](#), 4—crack structure was made up of several vertically stacked glass (0.20 m (W) × 0.15 m (L) × 0.004 m (H)) in the test chamber. At the same time, the metal wires were clamped between the two adjacent pieces of glass to make a straight seam, which can connect the first sampling segment and the last sampling segment. This experiment designed two slits in all, as more airflow could pass under the same pressure difference, so as to strengthen the control of the fan and small pressure difference. With different diameters of the wire, the height of the straight crack will also change accordingly. This diameter of wire used in the experiment is 0.3 mm, 0.5 mm, and 1 mm. As the surface of sand paper is inlaid with sand grains uniformly, it can simulate the vast majority of roughness of construction material surface. Therefore, this experiment would use sand papers with different size of grains attaching onto the inner surface of the glass tablet to simulate different roughness of the material surface. The roughness of inner surface of glass tablet in the experiment is 0 μm, and the roughness of the sandpapers also used were 10.3 μm and 20.5 μm. YYT-2000 type micro manometer was used to measure the pressure difference between two sides of the crack structure. The difference of pressure

Figure 1. 1-entrance; 2-fence; 3-rectifying section; 4-first sampling segment; 5-crack structure; 6-last sampling segment; 7-transition section; 8-fan; 9-CLJ-03A type laser dust particle counter; 10-micro manometer gauge; 11-copper pipe joint; 12-hose; 13-upper tablet; 14-wire; 15-bottom tablet.

was gained by the fan exhausting the air from last sampling segment to make its pressure down. The positive side of micro manometer connected to the first sampling and negative side was connected to the last sampling segment. The micro manometer was filled with 99%-alcohol solution as the hydraulic fluid. When testing, slope  $K = 0.2$  was chosen to enhance the sensitivity, under which circumstances maximum range can reach 46 pa, and the error can be controlled to 0.5 pa. When the differential pressure changes, we can adjust the fan frequency to control the value of the pressure difference on both sides. CLJ-03A type laser dust particle counter extracts the air from the first sampling segment and the last sampling segment through a hose respectively. The particle counter could be used to measure quantity concentration of the particulate matter with different diameter.

## 2.2 Experiment procedure

Before the experiment was carried out, the glass surface should be cleaned first. The particles attached on the surface of sand papers should also be blown off. When installing crack structure, all other slits (including gaps between the glass plate and the outer wall and other contact gaps between glass tablets) would be sealed except the two cracks made by wire, to ensure that the air can only flow by the specific cracks. After the experiment device was installed, open the fan to make the actual differential pressure

between two ends of the crack is close to the experimental design value. Then open experimental apparatus and rotate the valve V to connect the first sampling segment with the particle counter.

Adjust the fan make the differential pressure between the two ends of the crack stable at the design pressure difference. Then use CLJ-03A laser dust particle counter to test quantity concentration of the particulate matter in the first sampling segment. Rotary valve V to connect the last sampling segment with the particle counter. Again, after the differential pressure between the two ends of the crack was stable, measure the quantity concentration in the last segment with the instrument. The CLJ-03A type laser dust particle counter can measure the concentration of particles in 0.3  $\mu\text{m}$ , 0.5  $\mu\text{m}$ , 1  $\mu\text{m}$ , 3  $\mu\text{m}$ , 5  $\mu\text{m}$ , and 10  $\mu\text{m}$  so on, which has 6 different sizes in all. Though other slits were soft sealed with sludge, there would be still a small amount of gas leak. This part of influence of the gas leak was treated as negligible on penetration ratio. Since the last sampling section is directly connected with the fan, the deposition rate of the particulate matter in the test chamber is negligible as well.

## 3 ANALYSIS

### 3.1 Effect by the height of the crack

As shown in Figures 2–3, the penetration rate has a relationship with the height of the gap, but

Figure 2. The curve of penetration rate with the change of the crack height; differential pressure is 2 pa and the roughness is 0  $\mu\text{m}$ .

Figure 3. The curve of penetration rate with the change of the crack height; differential pressure is 4 pa and the roughness is 0  $\mu\text{m}$ .

the penetration rate will not always decrease as the height increase and sometimes become more complicated.

### 3.2 Effect by the differential pressure

As shown in Figures 4–6, the value of I/O ratio of different particles becomes increasing with the increase of the differential pressure, and decreases with the pressure difference. Compared with the high pressure difference, the penetration rate is more sensitive in the low pressure difference range, namely the penetration rate within 2–4 pa is increased quickly.

### 3.3 Effect by the diameter of particles

As shown in Figures 7–9, under the same pressure, I/O ratio of particulate matter generally increases as the particle size becomes small. Because of which characteristics the penetration rate curve became scattered as the particle size becomes large at the same differential pressure. When the surface roughness is 0  $\mu\text{m}$ , the permeability of the particles is more regular. When the roughness of the surface is not 0, the infiltration law of the particles is slightly complex.

Figure 4. The curve of penetration rate with the change of the differential pressure; crack height is 0.5 mm and the roughness is 0  $\mu\text{m}$ .

Figure 5. The curve of penetration rate with the change of the differential pressure; crack height is 0.3 mm and the roughness is 10.3  $\mu\text{m}$ .

Figure 6. The curve of penetration rate with the change of the differential pressure; crack height is 0.3 mm and the roughness is 20.8  $\mu\text{m}$ .

Figure 7. The curve of penetration rate with the change of the particle size; crack height is 0.5 mm and the roughness is 0  $\mu\text{m}$ .

Figure 8. The curve of penetration rate with the change of the particle size; crack height is 0.3 mm and the roughness is 10.3  $\mu\text{m}$ .

Figure 9. The curve of penetration rate with the change of the particle size; crack height is 0.3 mm and the roughness is 20.8  $\mu\text{m}$ .

#### 4 CONCLUSION

In this paper, an experimental set-up is designed, which is aimed at the main relevant conditions such as the height of the crack, the roughness of the inner surface, the pressure difference between the two ends of the crack, and the diameter of the particle. The experiment cannot fully explain the influence of the roughness and the height of the crack on the penetration rate. But the

results show that even with the minimal pressure difference (such as 2 pa), the penetration rate is also different accordingly. The penetration rate is mainly influenced by the pressure difference and the diameter of the particles. When the pressure difference gets larger, the penetration rate generally goes upward; as the pressure difference decreases, the penetration rate is generally decreased. At the same time, the penetration rate was negatively correlated with the particle size, and as the particles size decreases, the penetration rate decrease as well. In the range of low pressure difference, the permeability of the particles is important for indoor pollutant control. To study the mechanism further of the penetration of particles, we need to study the theory further and get more experimental data.

# The prediction research of underground road pollutant distribution

Zhiyong Li, Qianqian Shi & Hao Zhang

*School of Civil Engineering, North China University of Technology, Beijing, China*

Chao Chen

*School of Civil Engineering, Beijing University of Technology, Beijing, China*

**ABSTRACT:** This paper has established the one-dimensional steady-state diffusion model of underground road pollutant, and applied the finite difference method to solve the model. The source term of equation about pollutant is the measured data, which is obtained by the current national standard motor vehicle emission factor data, combined with the traffic flow, the proportion of vehicles and vehicle speed, etc. Then we verified the model according to the measured data of Shanghai Yan'an east road tunnel. These studies have shown that the established model calculated values tallies with the actual measurement, when the calculated values and measured values of CO concentration within the maximum deviation, the application of the model can realize the prediction of the underground road pollutant concentration distribution.

**Keywords:** heating, ventilation and air conditioning engineering; urban underground roads; pollutants diffusion; intensity of sources

## 1 INTRODUCTION

As the city traffic is increasing, urban underground roads have become an important means to alleviate urban plane transportation. The underground roads with a high pollutant concentration which is difficult to spread, makes the problem of air pollution within road more serious (Gao, 2013). So the analysis and prediction of underground distribution of the pollutant on the road is of great significance to solve the problem of air quality in the underground road (Deng, 2012).

This paper has established the one-dimensional steady-state diffusion model of underground road pollutant. The source term of equation about pollutant is the measured data, which is obtained by the current national standard motor bike emission factor data, combined with the traffic flow, the proportion of vehicles and vehicle speed. The CO concentration is then verified according to the measured data of Shanghai Yan'an east road tunnel. Experimental research shows that the calculation of the CO pollutants concentration field in the tunnel by using model is close to measured values. This model can provide the reference for the safety of urban underground roads ventilation system and the formulation of energy saving operation.

## 2 THE MATHEMATICAL MODEL

In urban underground road, due to the road cross-sectional area scale is far less than the road longitudinal dimension, the pollutants diffusion equation can be considered to one-dimensional processing. Select road longitudinal as the x axis, establish one dimensional convection diffusion equation of underground road pollutant. We solved the problem by applying the finite difference method. The solution ideas as follows: setting up the pollutant diffusion dynamics model, determining the boundary conditions, calculating the pollutant source term S, and finally, inputting model parameters for underground road pollutant concentration field.

### 2.1 Convection diffusion equation

Underground road pollutant diffusion dynamics equation is:

$$u \frac{\partial C_i}{\partial x} = K_x \frac{\partial^2 C_i}{\partial x^2} + S_i(x) \quad (1)$$

This equation consists of three parts, on the left side of the equation is convection item, the first item on the right side is the diffusion item, and the second is the source term. Diffusion item using

central difference scheme and convection item using the first-order difference scheme.

The difference equation of equation (1):

$$u \frac{C_i - C_{i-1}}{\Delta x} = K_x \frac{C_{i+1} - 2C_i + C_{i-1}}{\Delta x^2} + S_i(x) \quad (2)$$

The equation using the first kind of boundary condition:

$$C(x)|_{x=0} = C_1 \quad (3)$$

where

$C_i$ —the  $i$  kind of pollutants mass concentration, mg/m<sup>3</sup>;

$u$ —the piston wind velocity of underground road, m/s;

$x$ —the distance of measuring location and the entrance to the road in underground road, m;

$K$ — $i$  kind of pollutant diffusion coefficient on the  $x$  axis, m<sup>2</sup>/s;

$S_i$ — $i$  kind of pollutant source term in underground road, mg/(m<sup>3</sup>·s);

$L$ —the distance from exit to the entrance in underground road, m; and

$C_1$ —the import pollutants concentration in underground road, mg/m<sup>3</sup>.

## 2.2 The calculation of source term

The source term of equation is mainly composed of motor vehicle exhaust emission in the process of moving parts within the road and pollutants introduced by ventilation shaft. Due to environmental pollutants in the atmosphere have a low pollutant concentration than what in underground road, the pollutants introduced by the ventilation shaft have a low pollutant concentration (Deng, 2004), which can be ignored. Therefore, the source item of equation is mainly caused by motor vehicle pollutants (Han, 2011). Motor vehicle emissions intensity calculated by using line source emission model, according to the type, motor vehicle can be divided into light vehicle, midsize cars, and heavy vehicles. For different kinds of pollutants, it is calculated respectively according to the current vehicle bicycle pollutant discharge factor limit. Line source emission model of intensity of the motor vehicle exhaust pollutant is as follows:

$$S_i = \frac{1}{3600A} \sum_{j=1}^n \alpha \lambda_{ij}(v) E_{ij} A_j \quad (4)$$

where

$S_i$ — $i$  kind of pollutant emission intensity in urban underground roads, mg/(m<sup>3</sup>·s);

$\alpha$ —altitude correction coefficient;

$v$ —motor vehicle average velocity, km/h;

$\lambda_{ij}(v)$ — $j$  kind of vehicle speed correction coefficient in  $i$  kind of pollutant discharge;

$E_{ij}$ — $j$  kind of single vehicle speed emission factor in  $i$  kind of pollutant discharge, mg/(m·veh);

$A$ —underground road cross section area, m<sup>2</sup>;

$A_j$ —underground road motor vehicle traffic capacity per hour, veh/h;

$i = 1, 2, 3$ , respectively, represent the carbon monoxide (CO), hydrocarbons (HC), and nitrogen oxide (NO<sub>x</sub>)

$j = 1, 2, 3$ , respectively, represent the light vehicle, midsize cars, heavy vehicles.

The calculation formula of  $\lambda_{ij}(v)$  for CO, NO<sub>x</sub> is:

$$\lambda_{ij}(v) = a_{ij} + b_{ij}v + c_{ij}v^2 \quad (5)$$

where  $a_{ij}$ ,  $b_{ij}$ , and  $c_{ij}$  as the regression coefficient, the value refers to the following Table 1 (Deng, 2001).

In Table 1, the light vehicle velocity  $v$  (km/h),  $20 \leq v \leq 110$ , when  $110 \leq v$ , for  $v = 110$ , heavy duty vehicle velocity  $v$  (km/h),  $20 \leq v \leq 90$ , when  $90 \leq v$ , for  $v = 90$ .

Because of the enforcement of the national III and IV phase motor vehicle emission standards on July 1, 2008 and November 1, 2009 in Shanghai, the measured date is August 2013, therefore, according to the actual road driving motor vehicle models, single motor vehicle pollutant emission factor  $E_{ij}$  should be determined by the standard of light vehicle emissions limits (GB 18352.3, 2005), light

### 3 EXPERIMENTAL VERIFICATION

Measured by Shanghai Yan'an east road tunnel, first, get the distribution data of pollutants along the access road, then validate the one-dimensional pollutants convection diffusion equation established before.

#### 3.1 The experiment method

##### 3.1.1 The underground road case

Yan'an East Road tunnel is at the center area of Shanghai, which is an important hub for east-west trunk road connecting downtown Yan'an Road and Pudong Avenue. This tunnel is a cross-river tunnel established to alleviate traffic problems in the Pudong Lu Jiazui financial district and the city center, which is the second cross-river tunnel in Shanghai. The tunnel start from Fujian Yan'an Road intersection, crossing the Huangpu River to the east to reach Lu Jiazui Road Yang Jiazhai intersection, its municipal environment is relatively complex. The water and land transportation are more complex of Yan'an East Road area, including crowded people, heavy traffic, and the dense buildings. The tunnel parameters are in Table 3.

##### 3.1.2 The experiment data acquisition

On August 21 to August 27, 2013, the project team measured tunnel traffic, CO concentration, the temperature in tunnel, and the piston wind speed of Shanghai Yan'an east road, without mechanical ventilation during measuring. The data acquisition test time is on August 21 to August 27, in morning

Table 3. Yan'an east road tunnel parameters.

Name of parameter	Unit	Parameter values	Remark
Tunnel length	m	2193	
Road	Each	2	Single tunnel
Cross-sectional area of the tunnel	m <sup>2</sup>	40.05	Single tunnel
Tunnel road grade	%	Two-way grade 3.0%	Maximum grade
Number of shaft	Hole	3	
Design of the driving speed	km/h	40–50	
The design flow	veh/h	2400	

and evening peak (early 7:00–9:00, late 17:30 pm—at 19:00) time. The air temperature measuring by using air quality tester in measurement instruments, precision of  $\pm 0.1^\circ\text{C}$ . The tunnel piston wind speed is measured by using hot wire anemometer at the entrance of tunnel, with an accuracy of  $\pm 0.01$  m/s. The CO concentration is measured by using infrared analyzer in each measurement point along the way, the accuracy of  $\pm 0.1$  ppm. Experimental instrument platform probe position is located in the middle bus lateral (leaned out the window of 1 m, 2 m high from ground, away from the tunnel on the right side wall 2 m), inside the bus along the road to road traffic, using radar to measure the average speed. Traffic count calculated by artificial method in the underground road entrance. According to the test data of the underground road motor vehicle model types and conditions, the surveyor could analyze the pollutant emission characteristics of road motor vehicle and selection main CO, NO<sub>x</sub> pollutants to measure distribution of the pollutant along the road of certain city, setting points along the longitudinal spacing and recording road pollutants concentration and traffic environmental data in different time.

#### 3.2 Calculated value compared with the measured values

Applied in this paper, the underground road pollutant diffusion model is established to analyze the pollutant concentration field, and also to compare the numerical results with experimental data. The result is present in Figures 2–5.

Figure 1. The measurement point position of Yan'an east road tunnel pollutants.

Figure 2. Yan'an east road tunnel in Pudong—Puxi, Aug. 23, 17:12.

Figure 3. Yan'an east road tunnel in Pudong—Puxi, Aug. 25, 15:34.

Figure 4. Yan'an east road tunnel in Pudong—Puxi, Aug. 21, 8:59.

Figure 5. Yan'an east road tunnel in Pudong—Puxi, Aug. 26, 16:53.

Figures 2–5 are the pollutants concentration comparison about calculation and measured values, in the process of model calculation, the convection item select the underground road average wind speed of that period. The figure shows that the pollutants concentration distribution values is a linear model, the reason is that source term of this model, calculated through single emission factor limitation, is a fixed value. The measured concentration is up to the national III and IV standard and conforms to the driving motor vehicle types. The CO concentration value has relative error from 2% to 138% compared with the IV standard calculated value in Figure 2 to Figure 5 mode, has

relative error of 28% with the III standards calculated value. The above data shows that motor vehicle emission characteristics are as per national III standards.

#### 4 CONCLUSION

This article established one dimensional convection diffusion model of underground road pollutants and applied the finite difference method to solve equation. The paper also measured the CO concentration distribution in Shanghai Yan'an east road tunnel and tested CO concentration distribution in different proportion of traffic flow, vehicles size, and motor vehicle speed. The comparison of the measured values and calculated values about CO shows that the model has a relatively high precision, which can be used to analyze the pollutants concentration in underground road. Due to the single vehicle emission factors limited for the fixed value in current national standard, however, the vehicle emissions factors in the process of actual driving is affected by speed, road slope, etc. So the source term in this article calculated by emissions limits, compared with the actual road conditions, has poor adaptability. Subsequent study will be done based on the changing rules of actual road source term.

**ABSTRACT:** It is quite important to flow in equilibrium for fluid in the parallel plates. If there are restriction orifices, the flow characteristic of fluid could be improved obviously; therefore, the fluid flows well-distributed and keeps its flux balanced. While the flux coefficient is measured by the experiment, the optimal orifice is discovered and designed. It shows that the diameter of orifice in experiment is 11.2% smaller than the calculated one in view of flux coefficient. The result could be for reference when the precision is not very high during engineering designs.

**Keywords:** parallel plate-exchanger; restriction orifice; flux coefficient

## 1 INTRODUCTION

At present, as far as known, there are many ways how to get high or low temperature in environment simulation. According to practical application, a temperature-control model that is stable as operating and low in cost is necessary to simulate the surrounding parameters such as its temperature and humidity<sup>[1]</sup>. Heat transferring on the surfaces of solid is not exigent at refrigerant, because its cooling medium is not mixed or contacted with that of the simulation environment. Consequently, the different substance or pollutant is not able to enter into controlled area<sup>[2]</sup>. To plate exchangers in a large space, there are two ways of heat transfer: convection at the boundary between fluid and solid; radiation at the solid surface. These do not only accelerate the cooling rate when temperature is lowering, but also keep the temperature of space balanced during temperature control stage. The way of plate heat-transfer is very popular to some small thermo technical products and some modest engineering projects. The above-mentioned applications are successful and fruitful<sup>[3]</sup>. Further, this study will be on fluid flow and cooling characteristic when many plate exchangers are parallel. It could give some references to apply plate configuration and integration to large scale engineering projects.

## 2 THEORETICAL MODEL ANALYSIS AND DESIGN CALCULATION

Many plates are parallel and made up a plate module; and many modules are parallel to make up a plate unit then. To some extent, the plate unit is basic to lower and control the temperature of environment. The effect of cooling and temperature control is influenced directly by the fluid flow and flux distribution when plates are connected parallel. Consequently, the research on the flow characteristic of medium indoors appears very important<sup>[4]</sup>. As far as engineering studies, it could discover some laws of fluid flow and heat transfer in parallel plates to analyze a sole module of plate. The distance between two plates is short and its loss of resistance could be ignored. So the parallel plates could be simplified as an integral plate that its length is enlarged. The model of whole plate is set up as [Figure 1](#). The fluid in the model is air.

As shown in [Figure 1](#), when the air enters into the whole plate, it need go through each branch way. That is to say, those two series of equations should be solved: one is about that is nearest to the entrance of main way for given air (also the exit of main way for return air); the other is about that is farthest. As to the farthest and nearest branch, there is friction restriction loss along the way, so their kinetic pressure and static pressure (such as  $P_1$  and  $P_n$ ) are different respectively. What is more,

Figure 1. Model of whole plates that are connected in parallel.

their air velocity (such as  $W_1$ , and  $W_n$ ) and flow flux are not equal. If the air flow and heat transfer are also optical in the whole plate, some appropriate restriction orifice should be designed at the entrance of branch ways<sup>[5]</sup>. Meanwhile, the diameter of restriction orifice should be calculated and analyzed to keep the air flow balanced in the whole plate exchanger.

Based on the design of one project, the theory analysis and calculation about plate exchanger are done. The given total of cooling air is 6.4 kg/s in this project, which is called as  $G$ . Around the walls of environment space, there are 4 units of plate, and each unit comprised 3 plate modules. Additionally, six plate exchangers are connected in parallel to make up a whole, and one plate consists of 15 branch tubes with extended surfaces. In summary, the plate modules is called as  $M$  and it is 12; the plates in a module is called as  $P$  and it is 6; the branch tubes is called as  $Z$  and it is 15.

### 2.1 Calculation on flow equations of whole-plate model

The air is distributed equally, then the flow rate at entrance of main tube for given air is:

$$Q_m = \frac{G}{M} = \frac{6.4}{12} = 0.53 \text{ kg/s}$$

The fluid velocity at entrance of main tube for given air

$$\omega_1 = \frac{4Q_m}{\rho\pi d_1^2} = \frac{4 * 0.53}{2.274 * 3.142 * 0.15^2} = 13.19 \text{ m/s}$$

When air goes along the main tube for given air, from its entrance to its end, the flow flux reduces step by step. The velocity of air became low gradually because the diameter of main tube

does not vary. The flow flux of branch tube in whole plate is:

$$q_m = \frac{G}{ZPM} = \frac{6.4}{15 * 6 * 12} = 0.006 \text{ kg/s}$$

The air velocity at entrance of the branch tube that is at the end of main tube for given air is same as that velocity at the end of main tube, and it is

$$\omega_n = \frac{4q_m}{\rho\pi d_1^2} = \frac{4 * 0.006}{2.274 * 3.142 * 0.15^2} = 0.15 \text{ m/s}$$

The stable velocity of air in branch tube is:

$$\omega_2 = \frac{4q_m}{\rho\pi d_2^2} = \frac{4 * 0.006}{2.274 * 3.142 * 0.019^2} = 9.31 \text{ m/s}$$

Additionally,  $d_1$  is the diameter of the main tube; and  $d_2$  is the diameter of the branch tube;  $\rho$  is the density of air.

### 2.2 Calculation on energy equations of whole-plate model

According to these two cross-sections from 1 to  $n$  in main tube for given air, the energy equation is

$$p_1 + \frac{\rho\omega_1^2}{2} = p_n + \frac{\rho\omega_n^2}{2} + p_{l,1-n}$$

The flow loss from cross-section 1 to  $n$  because of friction along the main tube is calculated as following.

The Reynolds number is

$$Re_1 = \frac{\rho_1 \bar{\omega}_{1-n} d_1}{\mu_1}$$

The coefficient of friction restriction is

$$\lambda_1 = \frac{64}{Re_1}$$

The flow loss along the main tube is:

$$\begin{aligned} p_{l,1-n} &= \lambda_1 \frac{l_1}{d_1} \frac{\rho_1}{2} \bar{\omega}_{1-n}^2 = \frac{32\mu_1 l_1}{d_1^2} \bar{\omega}_{1-n} \\ &= \frac{32 * 11.8 * 10^{-6} * 3 * 6 * (13.19 + 0.15)}{2 * 0.15^2} = 2.0 \text{ Pa} \end{aligned}$$

Because the loss is little, it can be ignored. The equation became as

$$p_1 + \frac{\rho\omega_1^2}{2} = p_n + \frac{\rho\omega_n^2}{2}$$

The difference of static pressure from cross-section 1 to  $n$  in main tube is

$$p_n - p_1 = \frac{\rho\omega_1^2}{2} - \frac{\rho\omega_n^2}{2} = \frac{2.274 * (13.19^2 - 0.15^2)}{2} = 198 \text{ Pa}$$

According to these two cross-sections from  $n'$  to  $1'$  in main tube for return air, the energy equation is

$$p'_n + \frac{\rho\omega_n^2}{2} = p'_1 + \frac{\rho\omega_1^2}{2} + p_{l,n'-1'}$$

The flow loss from cross-section  $n'$  to  $1'$  because of friction along the main tube is calculated as following:

$$p_{l,n'-1'} = \lambda_1 \frac{l_1}{d_1} \frac{\rho_1}{2} \omega_{n'-1'}^2 = \frac{32\mu_1 l_1}{d_1^2} \omega_{n'-1'} = \frac{32 * 11.8 * 10^{-6} * 3 * 6 * (13.19 + 9.31)}{2 * 0.15^2} = 3.4 \text{ Pa}$$

Likely, because the loss is little, it can be ignored. The equation became as

$$p'_n + \frac{\rho\omega_n^2}{2} = p'_1 + \frac{\rho\omega_1^2}{2}$$

The difference of static pressure from cross-section  $1'$  to  $n'$  in main tube is

$$p'_n - p'_1 = \frac{\rho\omega_1^2}{2} - \frac{\rho\omega_n^2}{2} = \frac{2.274 * (13.19^2 - 9.31^2)}{2} = 99 \text{ Pa}$$

To calculate the difference of static pressure from cross-section  $n$  to  $n'$  in the farthest branch tube, and that from cross-section 1 to  $1'$  in the nearest branch tube, then compare them:

$$(p_n - p'_n) - (p_1 - p'_1) = (p_n - p_1) - (p'_n - p'_1) = 99 \text{ Pa}$$

If the comparison between the two differences of static pressure is small and could be ignored while the local loss of restriction orifice is large, the whole module of parallel plates is thought ideal. That is to say, in each branch tube, there is same flow loss; so their flow flux is equal similarly. To design their comparison between the two differences is as small as about 5% of the local loss of restriction orifice<sup>[6]</sup>. Hence, the local loss of restriction orifice is

$$\Delta p = 2000 \text{ Pa}$$

According to the relation of flow flux and pressure difference in orifice flow, there is

$$q_m = \rho c_q A \sqrt{\frac{2\Delta p}{\rho}}$$

$c_q$  is defined as flux coefficient, and is measured by experiment.

The area of restriction orifice is

$$A = q_m / (c_q \sqrt{2\rho\Delta p})$$

The diameter of restriction orifice is

$$d = \sqrt{\frac{4A}{\pi}}$$

### 3 MEASURE OF FLUX COEFFICIENT BY EXPERIMENT

#### 3.1 Experiment installation and building

The installation is shown in Figure 2, which is composed of some tubes, one fan, one flow meter and one differential-pressure meter. There are several restriction orifices of different diameter in the main tube. Additionally, one branch tube is linked to one orifice. At entrance of each branch tube where the air is distributed in main tube for given air, there is a measure point for inlet pressure of orifice. After air flows steadily along the branch tube, there is another measure point for outlet pressure of orifice; and the distance (defined as  $L$ ) from orifice is about 5 times as long as the diameter of orifice. Meanwhile, the second point is for inlet pressure of the flow meter. The outlet pressure of flow meter is atmosphere pressure.

The parameter of installations for experiment and measure instruments is shown in Table 1.

#### 3.2 Experiment procedure

When the experiment starts, the differential pressure meter is placed rightly at first. Keep two liquid levels to be same in the tube of U type.

Figure 2. The experiment installation.

Table 1. Parameter of installations and instruments.

Name	Type	Technical parameter
Differential pressure meter	Tube of U	Water column; range: 0~5 kPa
Flow meter	Float	Range: 2.5~25 m <sup>3</sup> /h
Fan	Centrifugal	Range: 0~30 m <sup>3</sup> /h
Tubes for experiment	PV tube	Diameter: 150 mm, 19 mm

Next, link the entrance of flow flux meter and the outlet of branch tube, and keep the gravity center of the meter vertical.

Then, seal the rest restriction orifices and branch tubes; and open the valve at main tube.

At last, start the fan and control the valve to adjust the flow flux of air.

When the state is steady, write down the differential pressure and flow flux of the air going through a restriction orifice.

#### 4 DATA PROCESSING AND ANALYSIS

##### 4.1 Data processing

1. Revise the flow flux of air tested at experiment; revision coefficient  $\varepsilon$  is based on a formula of the flow flux meter.
2. Calculate the theoretical flow flux of air based on a formula following:  $q_{V,t} = A\sqrt{\frac{2\Delta p}{\rho}}$ .
3. Calculate the coefficient of flow flux  $c_q$ :  $c_q = \frac{q_v}{q_{v,t}}$ .

##### 4.2 Data analysis and discussion

1. Relation between pressure drop and orifice diameter

As shown in Figure 3, if the flow-flux of air going through a restriction orifice do not became, the pressure drop will increase while the orifice diameter become small. Take the flow-flux of 7.5 m<sup>3</sup>/h for example, the pressure drop increases from 500 Pa to nearly 7000 Pa when the orifice diameter became from 13.5 mm to 7 mm. On the other hand, keep the orifice diameter constant, the pressure drop rises while the flow-flux grows up. Take an orifice of 10 mm, for example, the pressure drop at the flow flux of 10 m<sup>3</sup>/h is 2000 Pa more than that of 5 m<sup>3</sup>/h. It is indicated that the pressure drop is affected more by the orifice diameter than the flow flux.

2. Relation between flow flux and orifice diameter
- As shown in Figure 4, if the pressure drop of air going through a restriction orifice do not

Figure 3. Trend of pressure drop with change of orifice diameter and flow flux.

Figure 4. Trend of flow flux with change of orifice diameter and pressure drop.

became, the flow flux will increase while the orifice diameter become big. Take the pressure drop of 2000 Pa for example, the flow-flux increases from 3.8 m<sup>3</sup>/h to nearly 20.8 m<sup>3</sup>/h when the orifice diameter became from 8 mm to 17 mm. It increases about 4.5 times. On the other hand, keep the orifice diameter constant, the flow flux rises while the pressure drop grows up. Take an orifice of 10 mm, for example, the flow flux at the pressure drop of 1000 Pa is 5 m<sup>3</sup>/h more than that of 3000 Pa. It is indicated that the flow flux is affected more by the orifice diameter than the pressure drop.

3. Relation between flux coefficient and orifice diameter

As these two conditions-flow flux and pressure drop are given, a diameter of restriction orifice could be achieved in Figures 3 and 4. Moreover, if the diameter of orifice and pressure drop

Figure 5. Trend of flux-coefficient with change of orifice diameter and pressure drop.

is given, the flux coefficient could be got from Figure 5.

As shown in Figure 5, if the pressure drop of air going through a restriction orifice do not became, the flux coefficient will also increase while the orifice diameter become big. Take the pressure drop of 2000 Pa, for example, the flux coefficient increases from 0.41 to nearly 0.71 when the orifice diameter became from 6 mm to 17 mm. It increases about 73.2%. On the other hand, keep the orifice diameter constant, the flux coefficient rises while the pressure drop grows up. Take an orifice of 10 mm, for example, the flux coefficient at the pressure drop of 1000 Pa is 0.07 higher than that of 3000 Pa. It is indicated that the flux coefficient is affected by the orifice diameter equally by the pressure drop.

## 5 CONCLUSIONS

The flow characteristic of air in the parallel plates with restriction orifice is analyzed theoretically,

and the optimal diameter is designed by flux coefficient based on experimental measure. The results are:

1. During the application of plate-exchangers configuration and integration, restriction orifices could keep fluid well-distributed and its flux balanced.
2. During the design of restriction orifice, the flux coefficient  $C_q$  is achieved by experiment measure. The optimal diameter of orifice is based on that  $c_q = 0.56$ .
3. Additionally, based on these two conditions-flow flux of air and its pressure drop, the diameter of orifice is 11.9 mm. To compare with that experimental diameter of 10.7 mm, it is 11.2% more. The result could be for reference when the precision is not very high during engineering designs.

# Health risk assessment of heavy metals in PM<sub>2.5</sub> of major and typical cities in China

Lingyue Lv, Hongyuan Li & Jianan Yang

*College of Environmental Science and Engineering, Nankai University, Tianjin, China*

**ABSTRACT:** This study selected typical cities in different regions of China, and based on the experimental results of heavy metal contents in PM<sub>2.5</sub> by different researchers, their health risks were evaluated. The health risk assessment results showed that the risk level of five kinds of heavy metals is Cr > Cd > Pb > Zn > Cu, and the risk through the respiratory route of exposed populations about Cd, Cu, Pb, and Zn is between  $3.10 \times 10^{-7}$ – $1.99 \times 10^{-11}$ , lower than the acceptable risk level  $1 \times 10^{-6}$ . Only the risk index of Cr is higher, and the risk of Cd and Cr was significantly higher than Cu, Pb, and Zn. In addition, five kinds of heavy metal elements had the largest influence on the health risks of adult males, followed by the adult women, and the health risks of the children were minimized.

**Keywords:** PM<sub>2.5</sub>; health risk assessment; heavy metal; exposure parameters

## 1 INTRODUCTION

With the rapid urbanization and industrialization process, the impact of human activities on the natural environment is growing. The environmental impacts of the city continue to gain weight, air dust, smoke, and other harmful gases are gradually increasing, and the atmospheric particulate matter pollution is worsening. In recent years, long-term and high intensity haze has tended to spread with a large range in our country, and PM<sub>2.5</sub> has become the primary pollutant in most cities in China. Therefore, the prevention of PM<sub>2.5</sub> pollution is currently in urgent need.

## 2 OVERVIEW OF PM<sub>2.5</sub> AND HEAVY METAL POLLUTION IN CHINA

In the monitored 74 cities of China in 2013, nearly 92% of the city's PM<sub>2.5</sub> concentration cannot reach the national standard, the PM<sub>2.5</sub> concentration of 32 cities was 2 times above the national standard, and the top 10 cities was nearly 3 times to the national standard. The statistics showed that the average annual concentration of China's northern cities was approximately 89.9 µg/m<sup>3</sup>, the southern cities were about 59.4 µg/m<sup>3</sup>, the eastern cities were about 70.6 µg/m<sup>3</sup>, and the central cities were approximately 76.6 µg/m<sup>3</sup>, west about 59.9 µg/m<sup>3</sup>. Thus, the serious air pollution was not only in developed areas of China, China's central and western provinces also had serious air pollution problem. PM<sub>2.5</sub> concentration of Xi'an, Zhengzhou, Wuhan, Chengdu, Urumqi, Hefei, Taiyuan, and other cities

in 2013 also reached twice more than the national standard. For the majority cities in China, especially Beijing, Tianjin, the Yangtze River Delta and Pearl River Delta, and other key areas, the air PM<sub>2.5</sub> concentration often exceeds the standard, and the haze usually appears (Cheng, 2013).

Monitoring results showed that the frequency of heavy PM<sub>2.5</sub> pollution weather was significantly increased in a number of cities and urban agglomerations in recent years, and the duration of pollution have extended. For example, the haze is of high frequency, long duration, and low visibility in the eastern part of China in January 2013, involving 17 provinces, which is quarter of the land area, and the affected population was about 600 million. Heavy haze pollution process occurred five times in Beijing, Tianjin a Hebei Region, and the most serious haze lasted five days, and PM<sub>2.5</sub> instantaneous concentration of some urban areas was near 1000 µg/m<sup>3</sup>. In December, the air quality index reached six serious pollution level in Jiangsu, Anhui, Henan, Zhejiang, Shanghai and other places. PM<sub>2.5</sub> concentration was seriously overweight in 13 provincial jurisdiction cities of Jiangsu Province, reaching heavy pollution or serious pollution. In February 2014, haze pollution occurred to 1.43 million square kilometers in the eastern part of China, accounting for 1/7 of the land area, lasting longer than 1 week, and heavy or severe pollution attacked Beijing, Tianjin and Hebei area again. The long duration and high concentration of PM<sub>2.5</sub> in this several air pollution had hit a historical record (Wang, 2014; Lu, 2015).

The source and composition of PM<sub>2.5</sub> is very complex. The chemical composition and

Table 1. Comparison of heavy metal contents in PM<sub>2.5</sub> in different cities (μg/m<sup>3</sup>).

composition ratio are not the same due to the natural environment, the economic development and industrial structure in different cities, but most are made from organic carbon, elemental carbon, heavy metal elements, and other organic and inorganic particles. Research results show that many harmful heavy metals and organic carcinogens are enriched in PM<sub>2.5</sub> because of the small particle size, large surface area, long residence time and transmission distance, and the harm to human health is the most prominent. In addition, PM<sub>2.5</sub> can reach the alveoli, damaging the human respiratory system and cardiovascular system, causing heart disease, bronchitis, asthma, lung cancer and a series of diseases, even increasing people's premature death risk (Guo, 2013). Therefore, the health risk evaluation of heavy metal in PM<sub>2.5</sub> has become very important, and the results may provide a scientific basis for the pollution control of PM<sub>2.5</sub>. The heavy metal contents of PM<sub>2.5</sub> in different cities of China are given in Table 1 (Du, 2012; Hu, 2013; Gan, 2011; Bao, 2010; Geng, 2012; Chen, 2013; Wang, 2010; Yalkunjan, 2010).

### 3 HEALTH RISK ASSESSMENT OF HEAVY METALS IN PM<sub>2.5</sub>

#### 3.1 Health risk assessment model

The main way of fine particulate matter PM<sub>2.5</sub> in the atmosphere into the body is breathing intake.

In this paper, the health risk assessment model recommended by the United States Environmental Protection Agency (USEPA) (USEPA, 2011) is adopted, and some parameters in the model have been modified based on the actual situation. This health risk assessment model is applicable to the health risk evaluation of different types of pollutants into the human body through a variety of channels, including the carcinogenic risk and the non-carcinogenic risk. Using the modified evaluation model, the health risk on the human body through the respiratory route of Cd, Cr, Cu, Pb, and Zn in atmosphere PM<sub>2.5</sub> in Chinese major cities (adult males, adult females, children) were evaluated. According to the research results of EPA Integrated Risk Information Database (IRIS) and IARC (IARC), the contaminants can be divided into carcinogenic and non-carcinogenic. In this study, Cd and Cr belong to the carcinogenic substances, Pb, Zn, and Cu is non-carcinogenic, and the health risk assessment model varies.

#### 3.2 Calculation of exposure dose rate

Non-carcinogenic substances usually used commonly daily exposure dose ADD, and carcinogen usually adopted the life-long daily exposure dose LADD.

$$ADD/LADD = (C \times IR \times ED)/(BW \times AT)$$

ADD: daily average exposure dose, mg·kg<sup>-1</sup>·d<sup>-1</sup>; LADD: lifetime average daily exposure dose, mg·kg<sup>-1</sup>·d<sup>-1</sup>; C: pollutant concentration, m<sup>3</sup>·d<sup>-1</sup>; IR: respiratory rate, m<sup>3</sup>·d<sup>-1</sup>; ED: duration of exposure, d; BW: body weight, kg; AT: average exposure time, d. Lack of basic data to support research on exposure parameters, we generally cited the exposure parameters of the United States in health risk assessment. Taking the differences between Chinese people physique (body weight) and Western populations into account, the weight in this article used the national average values in the 2010 National physique monitoring bulletin (State Sports General Administration, 2011): adult males (20–59 years), 69 kg; adult women (20–59 years), 57 kg; children (7–19 years), 44 kg. The exposure parameters into human body through the breath way is in Table 2.

#### 3.3 Carcinogenic risk assessment

The average annual excess risk of carcinogenic pollutant is calculated as:

$$R = [1 - \exp(-LADD \cdot SF)] / \text{Life}$$

R: the average annual excess risk, dimensionless; LADD: daily exposure dose of exposed population, (mg·kg<sup>-1</sup>·d<sup>-1</sup>); SF: cancer potency

Table 2. Exposure parameters into human body through the breath way [3–4].

Population	IR/(m <sup>3</sup> d <sup>-1</sup> )	BW/kg	ED/d
Adult male	15.2	69	30 × 365
Adult women	11.3	57	30 × 365
Children	8.7	44	18 × 365
Population	AT (carcinogenic)/d	AT (non-carcinogenic)/d	
Adult male	70 × 365	30 × 365	
Adult women	70 × 365	30 × 365	
Children	70 × 365	18 × 365	

Table 3. Exposure parameters of toxic heavy metals into the body by the respiratory route [5].

Element	Characteristic	SF (kg · d)/mg	RfD mg/(kg · d)	Source	Foundation
Cd	Carcinogenic	8.4	/	HEA	
Cr	Carcinogenic	56	/	HEA	
Pb	Non-carcinogenic	/	4.3E-4	HEA	NAAQS
Zn	Non-carcinogenic	/	1.0E-2	HEA	TLV
Cu	Non-carcinogenic	/	2.0E-3	HEA	TLV

Table 4. Health risk assessment of 5 heavy metals in PM<sub>2.5</sub> through breathing (adult males).

Element	Shenzhen	Xi'an	Zhengzhou	Chengdu
Cd (×10 <sup>-8</sup> )	1.13	31.0	10.8	6.07
Cr (×10 <sup>-8</sup> )	9.75	67.9	137	72.0
Pb (×10 <sup>-10</sup> )	3.38	23.6	9.12	11.6
Zn (×10 <sup>-11</sup> )	6.61	72.9	13.0	10.8
Cu (×10 <sup>-11</sup> )	2.22	/	3.02	4.04
Element	Shanghai	Urumqi	Hangzhou	Tianjin
Cd (×10 <sup>-8</sup> )	2.88	15.1	9.68	0.586
Cr (×10 <sup>-8</sup> )	268	471	81.4	128
Pb (×10 <sup>-10</sup> )	3.67	76.6	8.04	37.4

Zn (×10 <sup>-11</sup> )	7.66	11.7		
Cu (×10 <sup>-11</sup> )	6.77	5.02		

factor of carcinogenic chemicals, (kg · d<sup>-1</sup> · mg<sup>-1</sup>); the average life expectancy for each city using the latest average life expectancy, years.

### 3.4 Non-carcinogenic risk assessment

The average annual excess risk of non-carcinogenic pollutant is calculated as:

$$R = (ADD \cdot 10^{-6}) / (RfD \times \text{Life})$$

R: the average annual excess risk, dimensionless; ADD: daily exposure dose of exposed population, mg/(kg · d); RfD: reference dose, mg/(kg · d)<sup>-1</sup>; 10<sup>-6</sup> is the acceptable risk level corresponding to RfD; and the average life expectancy for each city using the latest average life expectancy, years.

Zn ( $\times 10^{-11}$ )	6.87	10.5		
Cu ( $\times 10^{-11}$ )	6.08	4.50		

#### 4 CONCLUSIONS AND OUTLOOK

The health risk assessment results showed that the risk level of five heavy metals is Cr > Cd > Pb > Zn > Cu. The cancer risk Cd and Cr was significantly higher than non-cancer risk of Cu, Pb, Zn, with a difference of 2–5 magnitudes, which has greater harm

to the human health. And the excess risk of Cd, Cu, Pb, and Zn through the respiratory route of exposed population is between  $3.10 \times 10^{-7}$ – $1.99 \times 10^{-11}$ , lower than the acceptable level of risk population  $1 \times 10^{-6}$ , only the risk index of Cr is higher.

The five heavy metal elements in atmospheric PM<sub>2.5</sub> had the largest health risks on the adult males,

followed by the adult women, and the health risks of children are minimized. Under normal circumstances, the elderly and children are more sensitive to  $PM_{2.5}$ , but the results of this study showed that the adult males had the greatest health risk. This may be related to the time length of people outdoors, and the adult males usually have longer outdoor activities, so the  $PM_{2.5}$  exposure is higher than other groups.

In this study, the risk evaluation of toxic heavy metals in the  $PM_{2.5}$  on human health still has many uncertainties. Firstly, a relatively small number of samples were chosen by the researchers subject to the conditions, so the resulting data is still relatively limited, which cannot fully reflect the concentration level of  $PM_{2.5}$  and their heavy metals in urban air environment, and it also indirectly affects the health risk level. In addition, the exposure time, the exposed population and other studies still have some uncertainties, which would have an impact on the assessment results. In addition, due to the current research related to the exposure parameters is still limited in China, lack of the underlying data of exposure parameters, not yet owning the exposure parameter database, although the exposure parameters of life expectancy and weight parameters were modified according to the actual situation in China, the respiratory rate, exposure duration and other parameters referred to the EPA's recommended value. Taking the differences between the different races and regions into account, the risk assessment calculations might have some errors.
