A prodrug of aprepitant, a substance P/neurokinin₁ (NK₁) receptor antagonist. Has little or no affinity for 5HT₃, dopamine, and corticosteroid receptors. Fosaprepitant is rapidly converted to aprepitant following IV administration. Aprepitant inhibits emesis induced by cytotoxic chemotherapeutic agents, such as cisplatin, via central actions. Crosses the blood-brain barrier and occupies brain NK₁ receptors. Augments the antiemetic activity of the 5HT₃-receptor antagonist ondansetron and the corticosteroid dexamethasone and inhibits both the acute and delayed phases of cisplatin-induced emesis. Highly protein bound. Undergoes extensive metabolism, primarily by CYP3A4 and to a lesser extent by CYP1A2 and CYP2C19. Eliminated primarily by metabolism; not renally excreted. Half-life is approximately 9 to 13 hours.

INDICATIONS AND USES

Given in combination with other antiemetics for the prevention of acute and delayed nausea and vomiting associated with initial and repeat courses of highly emetogenic cancer chemotherapy, including high-dose cisplatin. ■ In combination with other antiemetics for the prevention of nausea and vomiting associated with initial and repeat courses of moderately emetogenic cancer chemotherapy.

Limitation of use: Has not been studied for treatment of established nausea and vomiting. Chronic continuous administration is not recommended, and the drug interaction profile could change during chronic continuous use.

CONTRAINDICATIONS

Hypersensitivity to fosaprepitant, aprepitant, or any components of the product. ■ Concurrent use with pimozone (Orap) or cisapride (Propulsid); see [Drug Interactions](#).

PRECAUTIONS

A moderate inhibitor of CYP3A4 when administered as a 3-day antiemetic dosing regimen for CINV. Use with caution in patients receiving concomitant medications that are primarily metabolized through CYP3A4; see [Drug Interactions](#). ■ Use with caution in patients with severe hepatic insufficiency (Child-Pugh score >9); see [Dose Adjustments](#). ■ Hypersensitivity reactions have been observed; see [Monitor](#).

Monitor: Monitor for S/S of a hypersensitivity reaction during the infusion (e.g., anaphylaxis, dyspnea, erythema, flushing, hives, itching, rash). ■ Monitor IV site. See [Drug Interactions](#).

Patient Education: Read manufacturer-supplied patient package insert before starting therapy and with each subsequent 3-day regimen. ■ Discontinue use of fosaprepitant and promptly report S/S of a hypersensitivity reaction (e.g., difficulty breathing or swallowing, hives, itching, rash). ■ Efficacy of hormonal contraceptives may be reduced during and for 28 days following administration of the last dose of aprepitant; includes birth control pills, skin patches, implants, and certain IUDs. Alternative or backup methods of contraception should be used during treatment and for 1 month following the last dose of fosaprepitant or aprepitant. ■ Numerous drug interactions possible. A complete review of all prescription, non-prescription and herbal products is required prior to each dose. ■ Patients on chronic warfarin therapy should have their INR checked in the 2-week period, particularly at 7 to 10 days, following initiation of regimen.

Maternal/Child: Category B: should be used during pregnancy only if clearly needed. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response similar to that seen in younger patients, but greater sensitivity of some older individuals cannot be ruled out; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

When administered as a 3-day regimen, fosaprepitant or aprepitant is **a substrate, a moderate inhibitor, and an inducer of CYP3A4**. When administered as a single 150-mg dose, it is **a weak inhibitor of CYP3A4 and does not induce CYP3A4**. ■ It is **also an inducer of CYP2C9**. ■ Efficacy of **hormonal contraceptives** may be reduced during and for 28 days following administration of the last dose of fosaprepitant or aprepitant; see [Patient Education](#). ■ Patients on chronic **warfarin** therapy should be closely monitored in the 2-week period, particularly at 7 to 10 days following initiation of fosaprepitant or aprepitant. Coadministration may result in a clinically significant decrease in INR. ■ Concurrent use with **pimozone (Orap) or cisapride (Propulsid)** is **contraindicated**. Inhibition of CYP3A4 by fosaprepitant or aprepitant could result in elevated plasma concentrations of these medications, potentially causing serious or life-threatening reactions; see [Contraindications](#). ■ Aprepitant can increase plasma concentrations of **dexamethasone (Decadron)**

and methylprednisolone (Solu-Medrol). When given concurrently with fosaprepitant or aprepitant, reduce the dexamethasone and methylprednisolone PO doses by approximately 50% and the methylprednisolone IV dose by approximately 25%. (Dexamethasone doses listed in Usual Dose take drug interaction into account.) ■ **Chemotherapy agents** that are known to be metabolized by CYP3A4 include docetaxel (Taxotere), paclitaxel (Taxol), etoposide (VePesid), irinotecan (Camptosar), ifosfamide (Ifex), imatinib (Gleevec), vinorelbine (Navelbine), vinblastine, and vincristine. In clinical studies, fosaprepitant was commonly administered with etoposide, vinorelbine, paclitaxel, and docetaxel. Dose adjustments were not required. Coadministration of fosaprepitant or aprepitant with other chemotherapy agents metabolized by CYP3A4 should be done with caution and careful monitoring. ■ May increase plasma levels of **benzodiazepines** (e.g., alprazolam [Xanax], midazolam [Versed], triazolam [Halcion]). Monitor for sedation. ■ Aprepitant is a CYP2C9 inducer. Has been shown to induce metabolism of **CYP2C9 substrates** (e.g., phenytoin [Dilantin], tolbutamide, warfarin [Coumadin]), thus decreasing plasma concentrations. Monitor patients receiving CYP2C9 substrates as indicated (e.g., plasma drug concentrations, therapeutic effect/efficacy, blood sugar control). ■ Concurrent use with **CYP3A4 inhibitors** (e.g., clarithromycin [Biaxin], diltiazem [Cardizem], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], ritonavir [Norvir], troleandomycin [TAO]) may increase aprepitant or fosaprepitant plasma concentrations. Use caution. ■ Coadministration with **CYP3A4 inducers** (e.g., carbamazepine [Tegretol], phenytoin [Dilantin], rifampin [Rifadin]) may decrease fosaprepitant or aprepitant plasma concentrations and decrease efficacy. ■ Coadministration of **paroxetine** (Paxil) and aprepitant resulted in decreased plasma concentrations of both drugs. ■ Aprepitant is a moderate **inhibitor of CYP3A4**. Use with caution in patients receiving concomitant medications that are primarily metabolized through CYP3A4. ■ Has been given with **dolasetron** (Anzemet), **granisetron** (Kytril), and **ondansetron** (Zofran). Clinically significant drug interactions were not observed.

SIDE EFFECTS

The most common side effects reported include anorexia, asthenia, constipation, diarrhea, dyspepsia, eructation, fatigue, headache, hiccups, increased AST/ALT, and infusion site reactions (e.g., erythema, induration, pain, pruritus). Increased BP and infusion-site thrombophlebitis have also been reported. Many other side effects occurred in fewer than 1% of patients.

Post-Marketing: Hypersensitivity reactions (e.g., anaphylaxis, pruritus, rash, and urticaria), Stevens-Johnson syndrome, and toxic epidermal necrolysis have been reported.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. Discontinue fosaprepitant at the first sign of hypersensitivity. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Reinitiation of the infusion after a hypersensitivity reaction that occurs during the first use is not recommended. Fosaprepitant is not removed by hemodialysis.

FOSCARNET SODIUM **BBW**

(fos-KAR-net SO-dee-um)

Antiviral

Foscavir

pH 7.4

USUAL DOSE

Adequate hydration and specific testing required; see **Monitor**.

CMV retinitis: 90 mg/kg every 12 hours or 60 mg/kg every 8 hours for 14 to 21 days. Length of induction treatment based on clinical response. Begin a maintenance dose of 90 mg/kg/day the next day (Day 15 to 22). If retinitis progresses during the maintenance regimen, re-treat with the induction and maintenance regimens. Maintenance dose may be increased to 120 mg/kg/day in patients who show excellent tolerance to foscarnet or those who require early reinduction because of retinitis progression. Normal renal function required. For patients who have relapsed after induction and reinduction monotherapy with either foscarnet or ganciclovir, practitioners may consider combination therapy, which adds the alternate drug to the regimen. See the Clinical Trials section of the foscarnet sodium prescribing information.

Acyclovir-resistant HSV patients: 40 mg/kg every 8 or 12 hours for 2 to 3 weeks or until healed.

Acyclovir-resistant varicella-zoster infections in HIV-infected patients: CDC suggests 90 mg every 12 hours.

DOSE ADJUSTMENTS

Must be reduced and individualized according to patient's renal function. Safety and efficacy data for patients with baseline SCr greater than 2.8 mg/dL or measured 24-hour CrCl less than 50 mL/min are limited. Dose adjustment may be required during treatment even if patient had normal renal function initially. Specific calculation and testing required for both induction and maintenance dose; see the following charts.

Foscarnet Dose Adjustment Guide for Induction				
	Acyclovir-Resistant HSV		CMV Retinitis	
CrCl (mL/min/kg)	Dose of 40 mg/kg q 12 hr	Dose of 40 mg/kg q 8 hr	Dose of 60 mg/kg q 8 hr	Dose of 90 mg/kg q 12 hr
>1.4 mL/min/kg	40 mg/kg q 12 hr	40 mg/kg q 8 hr	60 mg/kg q 8 hr	90 mg/kg q 12 hr
>1-1.4 mL/min/kg	30 mg/kg q 12 hr	30 mg/kg q 8 hr	45 mg/kg q 8 hr	70 mg/kg q 12 hr
>0.8-1 mL/min/kg	20 mg/kg q 12 hr	35 mg/kg q 12 hr	50 mg/kg q 12 hr	50 mg/kg q 12 hr
>0.6-0.8 mL/min/kg	35 mg/kg q 24 hr	25 mg/kg q 12 hr	40 mg/kg q 12 hr	80 mg/kg q 24 hr
>0.5-0.6 mL/min/kg	25 mg/kg q 24 hr	40 mg/kg q 24 hr	60 mg/kg q 24 hr	60 mg/kg q 24 hr
≥0.4-0.5 mL/min/kg	20 mg/kg q 24 hr	35 mg/kg q 24 hr	50 mg/kg q 24 hr	50 mg/kg q 24 hr
<0.4 mL/min/kg	Not recommended	Not recommended	Not recommended	Not recommended

Foscarnet Dose Adjustment Guide for Maintenance in CMV Retinitis		
CrCl (mL/min/kg)	90 mg/kg/day (once daily)	120 mg/kg/day (once daily)
>1.4 mL/min/kg	90 mg/kg q 24 hr	120 mg/kg q 24 hr
>1-1.4 mL/min/kg	70 mg/kg q 24 hr	90 mg/kg q 24 hr
>0.8-1 mL/min/kg	50 mg/kg q 24 hr	65 mg/kg q 24 hr
>0.6-0.8 mL/min/kg	80 mg/kg q 48 hr	105 mg/kg q 48 hr
>0.5-0.6 mL/min/kg	60 mg/kg q 48 hr	80 mg/kg q 48 hr
≥0.4-0.5 mL/min/kg	50 mg/kg q 48 hr	65 mg/kg q 48 hr
<0.4 mL/min/kg	Not recommended	Not recommended

DILUTION

Calculate required dose. Remove any excess quantity of medication from the infusion bottle using aseptic technique. To avoid any possibility of overdose in either situation, only the calculated dose should be in the infusion bottle. Discard any excess before administration.

Central venous catheter: Standard 24-mg/mL solution may be given undiluted.

Peripheral vein: Each 1 mL of a calculated dose must be diluted with 1 mL of D5W or NS (yields a 12-mg/mL solution).

Storage: Store at CRT. Avoid excessive heat and freezing. Use only if vacuum is present and solution is clear and colorless. Use solution within 24 hours of entry into bottle.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Administer only with NS or D5W solutions; no other drug or supplement should be administered concurrently via the same catheter." Because of chelating properties, a precipitate can occur. Manufacturer specifically lists as **incompatible** with 30% dextrose, solutions containing calcium (e.g., LR, TPN), acyclovir (Zovirax), amphotericin B (conventional), diazepam (Valium), digoxin (Lanoxin), ***ganciclovir (Cytovene)***, leucovorin calcium, midazolam (Versed), pentamidine, phenytoin (Dilantin), prochlorperazine (Compazine), sulfamethoxazole/trimethoprim, vancomycin.

One source suggests the following **compatibilities**:

Additive: **Not recommended by manufacturer.** Potassium chloride (KCl).

Y-site: **Not recommended by manufacturer.** Aldesleukin (Proleukin), amikacin (Amikin), aminophylline, ampicillin, aztreonam (Azactam), cefazolin (Ancef), cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chloramphenicol (Chloromycetin), clindamycin (Cleocin), dexamethasone (Decadron), dopamine, doripenem (Doribax), erythromycin (Erythrocin), fluconazole (Diflucan), furosemide (Lasix), gentamicin, heparin, hydrocortisone sodium succinate (Solu-Cortef), hydro-morphone (Dilaudid), imipenem-cilastatin (Primaxin), lorazepam (Ativan), metoclopramide (Reglan), metronidazole (Flagyl IV), morphine, nafcillin (Nallpen), oxacillin (Bactocill), penicillin G potassium, ranitidine (Zantac), sulfamethoxazole/trimethoprim, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin.

RATE OF ADMINISTRATION

Infusion pump required to deliver accurate dose evenly distributed over specific time frame. Excessive plasma levels and toxicity (including hypocalcemia) will occur with too-rapid rate of infusion. Advisable to clear tubing with NS if possible before and after administration through Y-tube or three-way stopcock. Never exceed 1 mg/kg/min.

CMV retinitis: Induction doses: Each 60-mg/kg dose equally distributed over a minimum of 1 hour. Increase to 1½ to 2 hours for 90-mg/kg dose.

Maintenance dose: Each dose equally distributed over a minimum of 2 hours.

Acyclovir-resistant HSV: Each dose equally distributed over a minimum of 1 hour.

ACTIONS

An antiviral agent capable of inhibiting replication of all known herpesviruses, including cytomegalovirus (CMV), herpes simplex virus types 1 and 2 (HSV-1, HSV-2), and varicella-zoster virus (VZV [unlabeled]). Does not destroy existing viruses but stops them from reproducing and invading healthy cells. Also capable of chelating metal ions (e.g., calcium, magnesium). CMV strains resistant to ganciclovir and HSV strains resistant to acyclovir may be sensitive to foscarnet. Half-life ranges from 2 to 6 hours and increases markedly with renal impairment. Some penetration into bone and cerebrospinal fluid. Excreted unchanged in urine.

INDICATIONS AND USES

Treatment of CMV retinitis in patients with AIDS. Most frequently used in patients who do not tolerate or are resistant to ganciclovir. Combination therapy with ganciclovir is indicated for patients who have relapsed after monotherapy with either drug. ■ **Treatment of acyclovir-resistant mucocutaneous HSV infections in immunocompromised patients.**

Unlabeled uses: Treatment of varicella-zoster virus (VZV) infections suspected or known to be caused by acyclovir-resistant strains in immunocompromised patients.

CONTRAINDICATIONS

Hypersensitivity to foscarnet.

PRECAUTIONS

For IV use only. ■ Safety and efficacy of foscarnet have not been established for treatment of other CMV infections (e.g., pneumonitis, gastroenteritis), congenital or neonatal CMV disease, other HSV infections (e.g., retinitis, encephalitis), congenital or neonatal HSV disease, or CMV or HSV in nonimmunocompromised individuals. Use should be limited to treatment of conditions listed in Indications and Uses above. ■ May cause potentially life-threatening changes in renal function with cumulative exposure. Careful monitoring of renal function and dose adjustment is imperative. Changes can occur at any time, most likely during second week of therapy. Elevations in SCr are usually reversible following dose adjustment or discontinuation of therapy. ■ Confirm diagnosis of CMV retinitis by indirect ophthalmoscopy. Diagnosis may be supported by cultures of CMV from the throat and body fluids such as urine and blood; negative culture does not rule out CMV retinitis. ■ Use caution in patients with a history of impaired renal function, altered calcium or other electrolyte levels, neurologic or cardiac abnormalities, a low baseline absolute neutrophil count (ANC), and those receiving other drugs known to influence minerals and electrolytes; see [Drug/Lab Interactions](#). Has caused hyperphosphatemia, hypocalcemia, hypokalemia, hypomagnesemia, and hypophosphatemia, resulting in cardiac disturbances, seizures, and tetany. Seizures related to alterations in plasma minerals and electrolytes have been reported. ■ Resistance has been reported to develop. May be higher in patients treated for a prolonged period. Consider the possibility of resistance in patients who show poor clinical response or who experience persistent viral excretion during treatment. ■ Sensitivity testing for viral isolate is recommended before repeat treatment and/or to evaluate sensitivity versus development of resistance.

Monitor: Baseline 24-hour CrCl verified by creatinine index; baseline SCr, calcium, magnesium, potassium, phosphorus, and electrolytes required before treatment begins. Correct any deficiencies. ■ Repeat entire testing process 2 to 3 times a week during induction therapy and a minimum of every 1 to 2 weeks during maintenance therapy. Foscarnet dose must be adjusted as indicated by test results. More frequent testing may be indicated in specific patients. Supplementation of minerals and electrolytes may be required during treatment. ■ To minimize renal toxicity, hydration adequate to establish diuresis is recommended before and during treatment unless contraindicated. Give 750 to 1,000 mL NS or D5W before the first foscarnet infusion to establish diuresis. With subsequent infusions, give 750 to 1,000 mL concurrently with 90 to 120 mg/kg foscarnet and a minimum of

500 mL concurrently with 40 to 60 mg/kg. ■ Discontinue foscarnet if CrCl drops below 0.4 mL/min/kg or serum creatinine is greater than 2.8 mg/100 mL (1 dL). Monitor patient daily until resolution of renal impairment is ensured. Safety for use in these patients has not been studied. ■ Anemia may be severe enough to require transfusion. ■ Phlebitis or pain may occur at site of infusion; confirm patency of vein and use large veins to ensure adequate blood flow for rapid dilution and distribution. ■ See [Drug/Lab Interactions](#).

Patient Education: Not a cure. Retinitis may recur during maintenance or after treatment; regular ophthalmologic exams imperative. ■ Complete healing of HSV infections may occur, but most relapse. ■ Perioral tingling, numbness in the extremities or paresthesias indicate electrolyte abnormalities; report immediately. ■ Close monitoring of renal function and electrolyte balance during treatment is imperative. ■ Cases of male and female genital irritation/ulceration have been reported. Adequate hydration and increased personal hygiene may minimize some side effects. ■ Dose modification or discontinuation may be required for major side effects.

Maternal/Child: Category C: use only if clearly needed; has caused skeletal anomalies in animals. ■ Excreted in maternal milk of lactating rats at three times maternal blood concentrations; human data not available. ■ Safety for use in pediatric patients not established; deposited in teeth and bones, and deposition greater in young animals. Use only if benefits outweigh risks.

Elderly: Safety and effectiveness not established, however, foscarnet has been used in patients over 65 years of age. Side effects seen are similar to other age-groups. Consider age-related renal impairment in dose selection and monitor renal function; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Because of physical **incompatibilities**, foscarnet sodium and **ganciclovir sodium** must never be mixed. ■ Has caused hypocalcemia with parenteral **pentamidine**; deaths have been reported. ■ Capable of causing calcium or electrolyte disorders. Use particular caution when administering **any drug known to influence serum calcium concentrations, other minerals, or electrolytes** (e.g., hypocalcemic agents [gallium nitrate (Ganite)], diuretics [furosemide (Lasix), mannitol], adrenocortical steroids). ■ Elimination of foscarnet may be impaired and toxicity increased by **drugs that inhibit renal tubular secretion** (e.g., probenecid). ■ Avoid concomitant use with other **nephrotoxic drugs** (e.g., aminoglycosides [e.g., gentamicin], amphotericin B [conventional], cyclosporine [Sandimmune], pentamidine) unless benefits outweigh risks. ■ Use with **fluoroquinolones** (e.g., ciprofloxacin [Cipro]) may cause seizures; monitor patient carefully. ■ Abnormal renal function has been reported in patients receiving foscarnet and **ritonavir** (Norvir) or foscarnet and **ritonavir and saquinavir** (Invirase).

SIDE EFFECTS

Impaired renal function, alterations in plasma minerals and electrolytes, and seizures are major side effects and are dose limiting. Abnormal renal function, including acute renal failure, decreased CrCl, and increased SCr (27%); anemia (33%); bone marrow suppression (10%); diarrhea (30%); fatigue; fever (65%); headache (26%); hyperphosphatemia; hypocalcemia (perioral tingling, numbness in extremities, paresthesias, tetany); hypokalemia; hypomagnesemia; hypophosphatemia; irritation at injection site; irritation and ulcerations of penile and vaginal epithelium; nausea (47%); rigors; seizure (10%); vomiting (26%); and death (14%) have occurred. All deaths could not be directly related to foscarnet. Abdominal pain, anorexia, anxiety, asthenia, confusion, coughing, depression, dizziness, dyspnea, granulocytopenia, hypoesthesia, infection, involuntary muscle contractions, leukopenia, malaise, neuropathy, pain, rash, sweating, and vision abnormalities have occurred in 5% of patients. Numerous other side effects have occurred in less than 5% of patients.

ANTIDOTE

There is no specific antidote. Keep physician informed. Adequate hydration and careful monitoring will help reduce potential for renal impairment and may minimize other side effects. Elevations in SCr are usually reversible (within 1 week) with dose adjustment or discontinuation but have caused death. Discontinue foscarnet if CrCl falls below 0.4 mL/min/kg or SCr is greater than 2.8 mg/100 mL. Monitor daily until resolution of renal impairment is ensured. Discontinue foscarnet if perioral tingling, numbness in the extremities, or paresthesias occur during or after infusion; evaluate calcium and electrolyte levels (decrease in ionized serum calcium may not be reflected in total serum calcium); notify physician. Administration of foscarnet can be resumed following seizures or cardiac disturbances after treatment of underlying disease, electrolyte disturbance, or after dose adjustment. Overdose can occur with too-rapid rate of infusion. Hemodialysis and hydration may be useful in overdose. Treat anaphylaxis and resuscitate as indicated.

FOSPHENYTOIN SODIUM **BBW**

(FOS-fen-ih-toyn SO-dee-um)

Anticonvulsant
(hydantoin)

Cerebyx

pH 8.6 to 9

USUAL DOSE

1.5 mg of fosphenytoin sodium is equivalent to 1 mg phenytoin sodium and is referred to as 1 mg phenytoin sodium equivalents (PE). Fosphenytoin is always expressed as phenytoin sodium equivalents (PE). Fosphenytoin 15 to 20 mg PE/kg is equivalent to phenytoin 15 to 20 mg/kg, or a 1,000-mg PE dose of fosphenytoin is equivalent to a 1,000-mg dose of phenytoin.

Status epilepticus: Adult loading dose: 15 to 20 mg PE/kg. Full effect is not immediate; concomitant administration of an IV benzodiazepine (e.g., diazepam [Valium]) is usually necessary to control status epilepticus. If seizures are not controlled, consider other anticonvulsants and other measures as needed (e.g., barbiturates or anesthesia).

Maintenance dose: 4 to 6 mg PE/kg/24 hr in divided doses.

Another source adds: **Elderly loading dose:** 14 mg PE/kg. See all comments under Usual Dose. See [Elderly](#).

Nonemergent indications: Loading dose: 10 to 20 mg PE/kg. **Maintenance dose:** 4 to 6 mg PE/kg/24 hr in divided doses. **Substitute for oral phenytoin:** May be substituted at the same total daily dose (due to a 10% increase in bioavailability [IV/IM to oral], plasma levels with the IV/IM product may be increased slightly).

PEDIATRIC DOSE

Status epilepticus loading dose (unlabeled): 15 to 20 mg PE/kg at a rate of 3 mg PE/kg/min; do not exceed 150 mg PE/min.

Nonemergent loading dose: 10 to 20 mg PE/kg.

Maintenance dose: 4 to 6 mg PE/kg/24 hr initially; may be given as a single dose or divided into 2 doses. Safety for use in pediatric patients not established. Limited data available; no significant differences apparent to this date; see [Maternal/Child](#).

DOSE ADJUSTMENTS

Reduced doses may be required in the elderly (see [Usual Dose](#)), in impaired renal or hepatic function, or in patients with hypoalbuminemia. ■ See [Precautions](#), [Monitor](#), [Drug/Lab Interactions](#), and [Antidote](#).

DILUTION

Use only clear solutions. Should be diluted in D5W or NS to a concentration of 1.5 to 25 mg PE/mL. Supplied solution is 50 mg PE/mL. **Do not confuse the amount of drug to be given in PE with the concentration of the drug in the vial; serious errors have occurred.** Dilute each milliliter of fosphenytoin with 1 mL of diluent to equal 25 mg PE/mL. Dilute a 1,000-mg PE dose in 100 mL diluent to equal 10 mg PE/mL.

Storage: Keep refrigerated; do not store at room temperature for more than 48 hours.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following compatibilities:

Additive: Hetastarch in NS (Hespan), mannitol, potassium chloride (KCl).

Y-site: Lorazepam (Ativan), phenobarbital (Luminal).

RATE OF ADMINISTRATION

Each 100 to 150 mg PE or fraction thereof over a minimum of 1 minute. Do not exceed a rate of 150 mg PE/min. Risk of severe hypotension and cardiac arrhythmias increased. Slow or temporarily stop rate of infusion for burning, itching, numbness, or pain along injection site.

Pediatric rate: Manufacturer recommends 1 to 3 mg PE/kg/min for pediatric patients. Another source suggests a rate of 1.6 mg PE/kg/min.

ACTIONS

A water-soluble prodrug of phenytoin. Converts to phenytoin, phosphate, and formaldehyde within 15 minutes of IV/IM administration. An anticonvulsant, chemically related to barbiturates. Selectively stabilizes seizure threshold and depresses seizure activity in the motor cortex. Modulation of voltage-dependent sodium channels of neurons thought to be the primary cellular mechanism responsible for anticonvulsant activity. Also exerts a depressant effect on the myocardium by selectively elevating the excitability threshold of the cell, reducing the cell's response to stimuli. Peak levels of fosphenytoin are achieved by the end of an infusion, but conversion to therapeutic serum levels of phenytoin takes longer. The conversion half-life of fosphenytoin to phenytoin is approximately 15 minutes. Extensively bound to protein, fosphenytoin displaces phenytoin from protein binding sites and increases free phenytoin (dose and rate dependent). Phenytoin's half-life is 12 to 28.9 hours. It is metabolized in the liver by hepatic cytochrome P₄₅₀ enzymes (CYP2C9 and CYP2C19) and excreted in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment and control of generalized tonic-clonic status epilepticus. ■ Treatment or prophylaxis of seizures in neurosurgical patients. ■ Substitute for oral phenytoin when oral administration is not feasible or prompt increases in antiepileptic drug levels are needed. *Cerebix must not be given orally.*

CONTRAINDICATIONS

Hypersensitivity to fosphenytoin, any of its components, phenytoin, or other hydantoin. ■ Sinus bradycardia, sinoatrial block, second- and third-degree AV block, and Adams-Stokes syndrome. ■ Coadministration with delavirdine (Rescriptor).

PRECAUTIONS

Doses of fosphenytoin are expressed in terms of milligrams of phenytoin equivalents (mg/PE) to avoid the need to perform molecular weight-based adjustments when substituting fosphenytoin for phenytoin or vice versa; no adjustment required when substituting fosphenytoin or vice versa. Labeling of fosphenytoin has been updated by the manufacturer to reduce the incidence of dosing errors. To ensure accuracy, confirm actual dose, dilution, and amount of injection with pharmacist or another RN. ■ Advantages of fosphenytoin over present phenytoin products include solubility in IV solutions, improved infusion site tolerance, more rapid rate of injection, and well-tolerated IM option. ■ IV route indicated in emergency situations (e.g., status epilepticus). May be given IM in nonemergency situations. ■ Oral phenytoin is preferred in nonemergency situations because of the risks of cardiac and local toxicity associated with IV fosphenytoin. Adverse cardiovascular reactions have occurred during and after infusions and have been reported with infusion rates above the recommended rate as well as with infusion rates at or below the recommended rate. ■ Intended for short-term parenteral use (up to 5 days). ■ Transfer to oral phenytoin therapy as soon as feasible. ■ Abrupt withdrawal may cause increased seizure activity. Gradually reduce dose, discontinue, or substitute alternative antiepileptic agents. ■ Discontinue immediately for hypersensitivity reactions; with caution substitute a nonhydantoin anticonvulsant (e.g., valproate sodium [Depacon]). ■ May cause severe cardiovascular depression (e.g., bradycardia, various degrees of AV block; use extreme caution in elderly or seriously ill patients and in patients with hypotension or severe myocardial insufficiency. Risk of hypotension and cardiac arrhythmias increased by higher IV doses and/or rapid administration. ■ May exacerbate porphyria. ■ May cause acute phenytoin hepatotoxicity (e.g., elevated liver function tests, fever, jaundice, lymphadenopathy, skin eruptions). Discontinue immediately and substitute alternate anticonvulsant therapy. ■ Has caused lymphadenopathy and hemopoietic complications (e.g., agranulocytosis, granulocytopenia, leukopenia, thrombocytopenia, or pancytopenia with or without bone marrow suppression). If lymphadenopathy occurs with or without signs of serum sickness (e.g., fever, rash, hepatotoxicity), substitute alternate anticonvulsant ther-

apy. ■ Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS), also known as multi-organ hypersensitivity, has been reported. DRESS usually presents with fever, rash, and/or lymphadenopathy in association with other organ system involvement such as hepatitis, nephritis, hematologic abnormalities, myocarditis, or myositis. Eosinophilia is often present. Deaths have been reported. ■ Sensory disturbances, including severe burning, itching, and paresthesia, have been reported; more common with higher doses and/or rates. ■ Purple glove syndrome (edema, discoloration, and pain distal to the injection site) has occurred and may or may not be associated with extravasation. ■ Serious dermatologic reactions have been reported, including toxic epidermal necrolysis (TEN) and Stevens-Johnson syndrome (SJS). Usually occurs within 28 days but may occur later. ■ Use caution with low serum albumin levels, and adjust dose as indicated. Phenytoin is highly bound to serum protein, and a reduced albumin causes an increase in free drug availability and may increase toxicity. ■ Not effective for absence seizures; combined therapy required if both conditions present. ■ Inhibits insulin release and may increase serum glucose; monitoring indicated in diabetics. ■ May lower serum folate levels. ■ Psychotic symptoms and other behavioral changes have been reported with antiepileptic drugs and may include aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies. Some resolved without intervention. Others required dose reduction or discontinuation of the antiepileptic agent.

Monitor: Monitor ECG, BP, and respirations continuously during loading dose and for at least 10 to 20 minutes after infusion is complete. ■ Allow fosphenytoin time to convert to phenytoin; accurate serum levels are not available until 2 hours after the end of an IV infusion or 4 hours after IM injection. Narrow margin of error between therapeutic and toxic dose. Plasma levels above 10 mcg/mL usually control seizure activity. The acceptable range is 5 to 20 mcg/mL. Toxicity begins with nystagmus at levels exceeding 20 mcg/mL. ■ Observe for rash and discontinue if one appears. If rash is mild, fosphenytoin may be resumed when the rash has completely disappeared. If the mild rash occurs again or the initial rash is serious in nature (e.g., exfoliative, purpuric, bullous) or lupus erythematosus, Stevens-Johnson syndrome, or toxic epidermal necrolysis is suspected, discontinue fosphenytoin. Do not resume; consider alternative therapy. ■ Phosphate is produced as a metabolite; monitor in patients who require phosphate restriction (e.g., renal impairment). ■ Monitor closely patients who are gravely ill, have impaired liver function, or are elderly. May show early signs of toxicity. ■ Determine absolute patency of vein; avoid extravasation. Not as alkaline as phenytoin. ■ Observe patient closely for signs of CNS side effects; see [Precautions](#).

Patient Education: Report burning, itching, numbness, pain, or rash. ■ Consider birth control options; nonhormonal birth control recommended. ■ May cause alterations in mood (e.g., aggression, agitation, anger, anxiety, apathy, decreased ability to cope, depression, hostility, irritability, thoughts of suicide); report these changes promptly. ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry.

Maternal/Child: Category D: avoid pregnancy. Consider risk versus benefit. ■ An increase in seizure frequency may occur during pregnancy; if phenytoin is required, monitoring of plasma phenytoin levels may be helpful. ■ Newborns whose mothers received phenytoin during pregnancy may develop a life-threatening bleeding disorder that can be prevented by giving vitamin K to the mother before delivery and to the neonate after birth. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. ■ See [Patient Education](#).

Elderly: See [Dose Adjustments](#). ■ Sensitivity and/or toxicity may be increased because serum concentrations may be elevated due to reduced clearance, or low serum albumin may cause a decrease in protein binding and an increase in free phenytoin.

DRUG/LAB INTERACTIONS

No drugs are known to interfere with the conversion of fosphenytoin to phenytoin, although phosphatase activity may have an impact. ■ **Capable of innumerable catastrophic drug interactions; review of drug profile by pharmacist imperative.** In all situations, monitoring of phenytoin serum levels may be indicated. ■ Coadministration with **delavirdine** (Rescriptor) is contraindicated. Has the potential for loss of virologic response and possible resistance to delavirdine or to the class of non-nucleoside reverse transcriptase inhibitors. ■ Serum levels and toxicity of phenytoin may be increased by **alcohol (acute intake)**, **amiodarone** (Nexterone), **anti-epileptic agents** (e.g., felbamate [Felbatol], topiramate [Topamax], oxcarbazepine [Trileptal]), **azoles** (e.g., fluconazole [Diflucan], itraconazole [Sporanox], ketoconazole [Nizoral], voriconazole [VFEND]), **chloramphenicol**, **chlordiazepoxide** (Librium), **H₂ antagonists** (e.g., cimetidine [Tagamet]), **diazepam** (Valium), **disulfiram** (Antabuse), **estrogens**, **fluorouracil**, **fluoxetine** (Prozac), **fluvoxamine** (Luvox), **halothane**, **isoniazid** (INH), **methylphenidate** (Ritalin), **omeprazole** (Prilosec), **phenothiazines** (e.g., prochlorperazine [Compazine]), **salicylates** (aspirin), **sertraline** (Zoloft), **succinimides** (e.g., ethosuximide [Zarontin]), **sulfonamides** (e.g., sulfisoxazole), **tolbutamide**, **trazodone** (Deseryl), **and warfarin** (Coumadin). ■ Serum levels and effectiveness of phenytoin may be decreased by **carbamazepine** (Tegretol), **chronic alcohol abuse**, **cisplatin**, **nelfinavir** (Viracept), **reserpine**, **and ritonavir** (Norvir). ■ Serum levels of phenytoin may be increased or decreased by **phenobarbital** (Luminal), **valproate sodium** (Depacon), **valproic acid** (Depakene). Similarly, phenytoin may unpredictably affect the levels and efficacy of these drugs. ■ **Tricyclic antidepressants** (e.g., amitriptyline [Elavil], imipramine [Tofranil]) may precipitate seizures in susceptible patients. Dose adjustment of fosphenytoin may be indicated. ■ Phenytoin will inhibit the effects of **azoles** (e.g., fluconazole [Diflucan], itraconazole [Sporanox], ketoconazole [Nizoral], voriconazole [VFEND]), **corticosteroids**, **doxycycline**, **estrogens**, **furosemide** (Lasix), **irinotecan** (Camptosar), **oral contraceptives**, **paclitaxel** (Taxol), **paroxetine** (Paxil), **quinidine**, **rifampin** (Rifadin), **sertraline** (Zoloft), **teniposide** (Vumon), **theophylline**, **vitamin D**, **and warfarin** (Coumadin). Dose adjustment of these agents may be indicated. ■ Decreases plasma concentrations of **HIV antivirals** (e.g., amprenavir [Agenerase], efavirenz [Sustiva], lopinavir/ritonavir [Kaletra], indinavir [Crixivan], nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase]) **and anti-epileptic agents** (e.g., felbamate [Felbatol], oxcarbazepine [Trileptal], quetiapine [Seroquel], topiramate [Topamax]). Adjust doses of these agents as indicated. ■ May increase or decrease PT/INR responses when coadministered with **warfarin** (Coumadin). ■ Alters some **clinical laboratory tests** (e.g., may decrease T₄, increase glucose, alkaline phosphatase, and GGT may produce low results in dexamethasone or metyrapone tests).

SIDE EFFECTS

Transient ataxia, dizziness, headache, nystagmus, paresthesia, pruritus, and somnolence are the most common side effects; are dose and rate related; occur within several minutes of the start of the infusion; and usually resolve within 10 minutes of completion. Risks of side effects increased with upper-end doses given at upper-end rates. Coma, hyperreflexia, hypotension, lethargy, nausea, slurred speech, tremor, and vomiting are also signs of increased toxicity. Confusional states (e.g., delirium, encephalopathy, psychosis) and, rarely, irreversible cerebellar dysfunction can occur with high plasma concentrations. Fosphenytoin breaks down into formate and phosphate metabolites that may cause formate toxicity in overdose situations (hypocalcemia, metabolic acidosis, muscle spasms, paresthesia, and seizures). Psychotic symptoms, including aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies, have occurred with antiepileptic agents.

Major/overdose: Arrhythmias (e.g., bradycardia, cardiac arrest, heart block, tachycardia, ventricular fibrillation), coma, hyperreflexia, hypotension, lethargy, nausea, respiratory arrest, slurred speech, syncope, tonic seizures, tremor, and vomiting. Deaths have been reported.

Post-Marketing: Anaphylactoid reactions, including anaphylaxis.

ANTIDOTE

Notify physician of any side effects. Obtain serum plasma levels at first signs of toxicity; reduce dose. If symptoms persist or major side effects appear, discontinue fosphenytoin and notify physician. Treat symptomatically, maintain a patent airway, and resuscitate as necessary. Discontinue fosphenytoin at the first sign of a rash unless the rash is clearly not drug related. If TEN or SJS is suspected, do not rechallenge; consider alternate therapy. Evaluate for multi-organ hypersensitivity reactions (DRESS). Symptoms of bradycardia or heart block may be reversed with IV atropine. Epinephrine may also be useful. Cardiovascular toxicity, including hypotension or cardiac arrhythmias, may respond to a decrease in infusion rate. One source says hemodialysis may be helpful in overdose. Another source says hemodialysis, peritoneal dialysis, forced fluid diuresis, exchange transfusions, and plasmapheresis are ineffective. In overdose, measure ionized free calcium levels to guide treatment in phosphate toxicity.

FOSPROPOFOL DISODIUM

(FOS-proh-poh-fohl)

Sedative–hypnotic
Anesthetic
Anesthesia adjunct

Lusedra

pH 8.2 to 9

USUAL DOSE

Supplemental oxygen and continuous monitoring required; see **Monitor**. Dose must be individualized and titrated to desired level of sedation. Use the minimum dose required to facilitate the procedure. In clinical studies, fentanyl 50 mcg was administered as a premedication 5 minutes before the initial dose of fospropofol.

Standard dosing regimen for healthy adults under 65 years of age or those with mild systemic disease (ASA I or II): 6.5 mg/kg as an initial IV bolus. Follow with supplemental doses of 1.6 mg/kg (25% of initial dose) as an IV bolus as needed to achieve the desired level of sedation. Administer supplemental doses based on the patient’s level of sedation. Give supplemental doses only when patients can demonstrate purposeful movement in response to verbal or light tactile stimulation and not more frequently than every 4 minutes. Dose is limited by the lower and upper weight limits of 60 kg and 90 kg. Patients who weigh over 90 kg should be dosed as if they weigh 90 kg. **No initial dose should exceed 16.5 mL; no supplemental dose should exceed 4 mL.** Patients who weigh less than 60 kg should be dosed as if they weigh 60 kg. However, doses lower than those specified for the lower weight limit may be used to achieve lesser levels of sedation. See the following table for the standard dosing regimen described earlier.

Fospropofol Standard Dosing Regimen for Adults Under 65 Years of Age Who Are Healthy or Have Mild Systemic Disease (ASA I or II)*				
Weight (kg)	Initial Dose		Supplemental Dose (no more frequently than every 4 minutes)	
	mg	mL	mg	mL
≤60	385	11	105	3
61 to 63	402.5	11.5	105	3
64 to 65	420	12	105	3
66 to 68	437.5	12.5	105	3
69 to 71	455	13	105	3
72 to 74	472.5	13.5	122.5	3.5
75 to 76	490	14	122.5	3.5
77 to 79	507.5	14.5	122.5	3.5
80 to 82	525	15	140	4
83 to 84	542.5	15.5	140	4
85 to 87	560	16	140	4
88 to 89	577.5	16.5	140	4
≥90	577.5	16.5	140	4

***Note:** Doses in this table are rounded to the nearest half-milliliter volume to facilitate practical measurement; hence they may differ slightly from the dose recommended on the basis of mg/kg.

Modified dosing regimen for adults 65 years of age or older or those with severe systemic disease (ASA III or IV): Decrease initial and supplemental doses to 75% of the standard dosing regimen as listed in the following table.

Fospropofol Modified Dosing Regimen for Adults 65 Years of Age or Older or Those with Severe Systemic Disease (ASA III or IV)*				
Weight (kg)	Initial Dose		Supplemental Dose (no more frequently than every 4 minutes)	
	mg	mL	mg	mL
≤60	297.5	8.5	70	2
61 to 62	297.5	8.5	70	2
63 to 64	315	9	87.5	2.5
65 to 66	315	9	87.5	2.5
67 to 69	332.5	9.5	87.5	2.5
70 to 73	350	10	87.5	2.5
74 to 77	367.5	10.5	87.5	2.5
78 to 80	385	11	105	3
81 to 84	402.5	11.5	105	3
85 to 87	420	12	105	3
88 to 89	437.5	12.5	105	3
≥90	437.5	12.5	105	3

***Note:** Doses in this table are rounded to the nearest half-milliliter volume to facilitate practical measurement; hence they may differ slightly from the dose recommended on the basis of mg/kg.

DOSE ADJUSTMENTS

See **Usual Dose** for specific reduced doses required for adults 65 years of age or older or ASA risk III or IV patients. ■ Reduced doses are required in the presence of other CNS depressants; see **Drug/Lab Interactions**. ■ Reduced doses are not required based on race, gender, age, alkaline phosphatase concentrations, or mild to moderate renal impairment. ■ Has not been adequately studied in patients with a CrCl less than 30 mL/min or in patients with hepatic impairment.

DILUTION

Supplied as a ready-to-use solution containing 35 mg/mL of fospropofol (1,050 mg/30 mL vial). Intended for single use. Strict aseptic technique is imperative. Draw solution into a sterile syringe immediately after vial is opened. Discard any unused portion at the end of the procedure.

Filter: Not required. Information not available.

Storage: Store at CRT. Draw up into syringe immediately after opening vial and discard any unused solution at the end of the procedure.

COMPATIBILITY

Manufacturer states, “Do not mix with other drugs or fluids prior to administration. Is **not physically compatible** with midazolam or meperidine, and **compatibility** with other agents has not been adequately evaluated. Flush the infusion line with NS before and after administration.” Has been shown to be **compatible** with the following solutions: D5W, D5¹/₄NS, D5¹/₂NS, NS, LR, D5LR, ¹/₂NS, D5¹/₂NS, and 20 mEq KCl.

RATE OF ADMINISTRATION

Administer as a bolus injection.

ACTIONS

A sedative-hypnotic agent. A prodrug of propofol. Following injection, fospropofol is metabolized by alkaline phosphatases to propofol, which interacts with the GABA

(gamma-aminobutyric acid) receptors of the CNS, resulting in sedation. In clinical studies, peak plasma levels of propofol released from fospropofol were noted within 12 minutes. In patients undergoing a colonoscopy, the median time to sedation was 8 minutes (range 2 to 28 minutes), and the median time to Fully Alert following the procedure was 5 minutes (range 0 to 47 minutes). In patients undergoing a bronchoscopy, the median time to sedation was 4 minutes (range 2 to 22 minutes), and the median time to Fully Alert following the procedure was 5.5 minutes (range 0 to 6 minutes). Both fospropofol and its active metabolite propofol are highly protein bound, primarily to albumin. Propofol is further metabolized in the liver. The half-lives of fospropofol and propofol are approximately 0.8 and 2 hours, respectively. Propofol is excreted as metabolites in the urine.

INDICATIONS AND USES

To initiate and maintain monitored anesthesia care (MAC) sedation in adult patients undergoing diagnostic or therapeutic procedures.

CONTRAINDICATIONS

Manufacturer states, "None." See [Precautions](#).

PRECAUTIONS

Administered by persons trained in the administration of general anesthesia and not involved in the conduct of the diagnostic or therapeutic procedure. Patients should be continuously monitored, and facilities and supplies for responding to any medical emergency must be immediately available. ■ Respiratory depression, including the loss of spontaneous respirations, may occur. Supplemental oxygen is recommended for all patients. Hypoxemia may occur and has been seen in patients who retained the ability to respond purposefully. The risk of hypoxemia is reduced by appropriate positioning of the patient and the administration of supplemental oxygen. ■ Has not been studied for use in general anesthesia and is not recommended. Administration may inadvertently cause patients to become unresponsive or minimally responsive to vigorous tactile or painful stimulation. ■ May cause hypotension. Patients with compromised myocardial function, reduced vascular tone (e.g., sepsis), or reduced intravascular volume may be at an increased risk for hypotension. ■ Use with caution in patients with hepatic impairment or severe renal impairment (CrCl less than 30 mL/min). ■ Safety for continuous sedation has not been established and is not recommended. ■ See [Drug/Lab Interactions](#).

Monitor: Patients should be continuously monitored during sedation and through the recovery process with pulse oximetry, ECG, and frequent BP measurements for early signs of arrhythmia, hypotension, apnea, airway obstruction, and/or oxygen desaturation. Hypoxemia may be detected by pulse oximetry. ■ Assess patients for the ability to demonstrate a purposeful response while sedated. Patients who are unable to demonstrate a purposeful response may lose protective reflexes. Airway assistance maneuvers may be required. ■ Correct fluid volume deficiencies before administration.

Patient Education: Paresthesias and/or pruritus, usually manifested in the perineal region, are common side effects. Side effects are usually mild to moderate in intensity and of short duration. ■ Avoid alcohol or other CNS depressants (e.g., antihistamines, benzodiazepines) for 24 hours following the procedure. ■ Do not perform tasks that require mental alertness (e.g., driving, operating hazardous machinery, or signing legal documents) until the day after surgery or longer. All effects must have subsided.

Maternal/Child: Category B: use during pregnancy only if clearly needed. Use during labor and delivery, including cesarean section, is not recommended. It is not known if fospropofol crosses the placenta; however, propofol is known to cross the placenta, and as with other sedative-hypnotic agents, the administration of fospropofol may be associated with neonatal respiratory and cardiovascular depression. ■ Use during breast-feeding not recommended. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Patients 65 years of age or older should receive the modified dosing regimen; see [Usual Dose](#). Hypoxemia has been reported more frequently in the elderly.

DRUG/LAB INTERACTIONS

Potentiated by other medications that can depress cardiac or respiratory status (e.g., **narcotics** [e.g., morphine, meperidine (Demerol), fentanyl (Sublimaze)], **sedatives** [barbiturates, benzodiazepines (e.g., diazepam [Valium], midazolam [Versed])], chloral hydrate, droperidol [Inapsine]). ■ Has been administered with fentanyl, meperidine, midazolam, and morphine.

SIDE EFFECTS

The most commonly reported side effects are paresthesia (burning, stinging, tingling) and/or pruritus, usually manifested in the perineal region. The most serious side effects reported include hypotension, hypoxemia, loss of purposeful responsiveness, and respiratory depression. The most commonly reported reasons for discontinuation of therapy are cough and paresthesia. Other reported side effects include headache, nausea, procedural pain, and vomiting.

Overdose: (Secondary to accumulation of formate and phosphate metabolites) Anion-gap metabolic acidosis, hypocalcemia with paresthesia, muscle spasms, and seizures.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. A short-acting drug, a patent airway, and continuous controlled ventilation with oxygen until normal function is ensured should be adequate. Treat hypotension with IV fluid replacement, Trendelenburg position, or vasopressors (e.g., dopamine) as indicated. Resuscitate as necessary.

FUROSEMIDE **BBW**(fur-**OH**-seh-myd)

Diuretic (loop)

Lasix

pH 8 to 9.3

USUAL DOSE

Adjust dose and dose schedule to individual patient needs. Reserve parenteral therapy for emergent situations or for patients unable to take oral therapy. Switch to oral therapy as soon as practical.

Edema: 20 to 40 mg. May be repeated in 2 hours. If necessary, increase dosage by 20-mg increments (under close medical supervision and no sooner than 2 hours after previous dose) until desired diuresis is obtained. ACC/AHA 2009 guidelines for heart failure recommend a maximum single dose of 160 to 200 mg. If larger doses are required, may be given as an infusion at a rate not to exceed 4 mg/min. When high-dose parenteral therapy is elected for CHF, the ACC/AHA 2009 guidelines recommend a 40-mg IV loading dose followed by an infusion of 10 to 40 mg/hr. After the initial diuresis the minimum effective dose may be given once or twice every 24 hours as required for maintenance.

New-onset pulmonary edema: 40 mg. Dose may be increased to 80 mg after 1 hour if satisfactory response is not obtained. AHA guidelines recommend less than 0.5 mg/kg. Additional therapy (e.g., digoxin, oxygen) may be administered concurrently as needed.

Hypertensive crisis: AHA guidelines recommend 0.5 to 1 mg/kg over 1 to 2 minutes. If no response, increase dose to 2 mg/kg.

Acute pulmonary edema or post-cardiac arrest cerebral edema: AHA guidelines recommend 0.5 to 1 mg/kg over 1 to 2 minutes. If no response, increase dose to 2 mg/kg.

PEDIATRIC DOSE

See [Maternal/Child](#).

Diuretic: 1 mg/kg of body weight. After 2 hours increase by 1-mg/kg increments to effect desired response. Effective dose may be given every 6 to 12 hours. Another source suggests 0.5 to 2 mg/kg/dose every 6 to 12 hours. Do not exceed 6 mg/kg/dose.

NEONATAL DOSE

Diuretic: 0.5 to 1 mg/kg/dose every 8 to 24 hours. Maximum dose is 2 mg/kg/dose. Literature reports suggest that the maximum dose for premature infants should not exceed 1 mg/kg/day. See [Maternal/Child](#).

DOSE ADJUSTMENTS

Higher doses may be required in renal insufficiency and acute or chronic renal failure. ■ Reduced dose or extended intervals may be appropriate in the elderly. ■ Extend dosing intervals in neonates because half-life is prolonged. ■ See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted. May be given through Y-tube or three-way stopcock of infusion set. Not usually added to IV solutions, but large doses may be added to NS, LR, D5W, D5NS and given as an infusion. pH of solution must be over 5.5. Some sources recommend protecting diluted solutions from light to prevent photodegradation (minimized at pH 7).

Filters: One source found no significant drug loss when filtered through a 0.22-micron filter.

Storage: Store vials at CRT. Protect from light. If diluted for infusion, discard after 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Furosemide may precipitate at a pH below 7. Manufacturer states, "Acid solutions, including other parenteral medications (e.g., amrinone, ciprofloxacin, labetalol, milrinone)

must not be administered concurrently in the same infusion.” Additionally, “Furosemide should not be added to an IV line containing any of these acidic products.”

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), aminophylline, amiodarone (Nexterone), ampicillin, atropine, bumetanide, calcium gluconate, cefuroxime (Zinacef), dexamethasone (Decadron), digoxin (Lanoxin), epinephrine (Adrenalin), gentamicin, heparin, hydrocortisone sodium succinate (Solu-Cortef), lidocaine, mannitol (Osmitol), meropenem (Merrem IV), midazolam (Versed), morphine, nitroglycerin IV, potassium chloride (KCl), ranitidine (Zantac), sodium bicarbonate, theophylline, tobramycin, verapamil.

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), amiodarone (Nexterone), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), argatroban, aztreonam (Azactam), bivalirudin (Angiomax), bleomycin (Blenoxane), ceftipime (Maxipime), ceftaroline (Teflaro), ceftazidime (Fortaz), cisatracurium (Nimbex), cisplatin (Platinol), cladribine (Leustatin), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), epinephrine (Adrenalin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fentanyl (Sublimaze), fludarabine (Fludara), fluorouracil (5-FU), foscarnet (Foscavir), gallium nitrate (Ganite), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), indomethacin (Indocin IV), leucovorin calcium, linezolid (Zyvox), lorazepam (Ativan), melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), methotrexate, metoprolol (Lopressor), miconazole (Mycamine), mitomycin (Mutamycin), morphine, nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), oxaliplatin (Eloxatin), paclitaxel (Taxol), pantoprazole (Protonix IV), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), teniposide (Vumon), thiotepa, tirofiban (Aggrastat), tobramycin.

RATE OF ADMINISTRATION

IV injection: Each 40 mg or fraction thereof should be given over 1 to 2 minutes.

Infusion: Adults: 0.1 mg/kg/hr. **Pediatric patients:** 0.05 mg/kg/hr. Titrate to effect. High-dose therapy in an infusion should not exceed a rate of 4 mg/min.

ACTIONS

A potent loop diuretic, structurally related to sulfonamides. Onset of action is prompt, usually within 5 minutes. Duration of action and half-life are approximately 2 hours. Inhibits the reabsorption of sodium and chloride in the proximal and distal tubules and in the loop of Henle, causing increased excretion of water, sodium, chloride, magnesium, and calcium. Highly protein bound. Metabolized and excreted in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Parenteral therapy should be reserved for patients unable to take oral medications or for emergency clinical situations. ■ Edema associated with congestive heart failure, cirrhosis of the liver with ascites, and renal disease including the nephrotic syndrome. Particularly useful when an agent with a greater diuretic potential is required. ■ Adjunctive therapy in acute pulmonary edema. Indicated when rapid onset of diuresis is necessary (e.g., acute pulmonary edema).

CONTRAINDICATIONS

Anuria, hypersensitivity to furosemide.

PRECAUTIONS

A potent diuretic; may precipitate excessive diuresis with water and electrolyte depletion. Careful medical supervision is required. ■ Use caution and improve basic condition first in hepatic coma, electrolyte depletion, and advanced cirrhosis of the liver. ■ May be used concurrently with aldosterone antagonists (e.g., spironolactone [Aldactone]) for more effective diuresis and to prevent excessive potassium loss. ■ If increasing azotemia and oliguria develop during treatment of severe progressive renal disease, furosemide should be dis-

continued. ■ Use extreme caution in known sulfonamide sensitivity. ■ Risk of ototoxicity (tinnitus, reversible or irreversible hearing impairment and deafness) increases with higher doses, rapid injection, severe renal dysfunction, hypoproteinemia, or concurrent use with other ototoxic drugs; see [Drug/Lab Interactions](#). ■ May activate or exacerbate systemic lupus erythematosus. ■ Use caution in patients with severe symptoms of urinary retention (because of bladder emptying disorders, prostatic hypertrophy, urethral narrowing). May experience acute urinary retention related to increased production and retention of urine.

Monitor: Monitor BP frequently, especially during initial therapy. ■ May precipitate excessive diuresis with water and electrolyte depletion. Routine checks on electrolyte panel, CO₂, and BUN are necessary during therapy. Electrolyte replacement may be required. ■ May increase blood glucose and has precipitated diabetes mellitus. ■ Monitor for other S/S of fluid or electrolyte imbalance, which may include dryness of the mouth, drowsiness, lethargy, muscle cramps or fatigue, nausea or vomiting, oliguria, tachycardia, thirst, and weakness. ■ May lower serum calcium level; may cause tetany. ■ Hyperuricemia can occur. Rarely precipitates acute gout attack. ■ See [Drug/Lab Interactions](#).

Patient Education: Hypotension may cause dizziness; request assistance with ambulation. ■ Report cramps, dizziness, muscle weakness, or nausea promptly. ■ May cause a decrease in potassium levels and require a supplement. ■ Skin may become photosensitive; avoid unprotected exposure to sun. ■ Therapy for diabetes may require adjusting; monitoring of serum glucose required.

Maternal/Child: Category C: use during pregnancy only when clearly needed and benefits outweigh potential risks to fetus. Treatment during pregnancy requires monitoring of fetal growth because of the potential for higher fetal birth weights. ■ Use caution in breast-feeding; may inhibit lactation. ■ Safety for use in pediatric patients not established. ■ Prolonged use in premature infants may result in nephrocalcinosis and nephrolithiasis. Has also been observed in pediatric patients under 4 years of age who have been treated chronically with furosemide. ■ May increase risk of persistent patent ductus arteriosus in pre-term infants with respiratory distress syndrome. ■ Premature infants receiving doses exceeding 1 mg/kg/day may develop plasma levels that could be associated with toxicity, including ototoxicity. Hearing loss in neonates has been associated with the use of furosemide.

Elderly: Protein binding and clearance is decreased in the elderly. ■ Consider increased sensitivity to hypotensive and electrolyte effects. Dose selection should be cautious, starting at the lower end of the dosing range. ■ May be more susceptible to dehydration; observe carefully. ■ Avoid rapid contraction of plasma volume and hemoconcentration. May cause thromboembolic episodes (e.g., CVA, pulmonary emboli). ■ The initial diuretic effect in older patients is decreased relative to younger patients.

DRUG/LAB INTERACTIONS

Causes excessive potassium depletion with **corticosteroids**, **thiazide diuretics** (e.g., hydrochlorothiazide [HydroDIURIL]), **amphotericin B** (all formulations). ■ Potentiates **antihypertensive drugs** (e.g., angiotensin-converting enzyme [ACE] inhibitors [e.g., enalapril (Vasotec), enalaprilat (Vasotec IV), lisinopril (Zestril)], angiotensin II receptor blockers [e.g., losartan (Cozaar)], nitroglycerin, nitroprusside sodium); reduced dose of the antihypertensive agent or both drugs may be indicated. ■ May cause transient or permanent deafness with doses exceeding the usual or when given in conjunction with **other ototoxic drugs** (e.g., aminoglycosides [e.g., gentamicin], cisplatin). ■ **Amphotericin B** (all formulations) may increase potential for ototoxicity and nephrotoxicity; avoid concurrent use. ■ Nephrotoxicity increased by **other nephrotoxic agents** (e.g., aminoglycosides, cephalosporins [e.g., ciprofloxacin (Cipro)], cisplatin [Platinol], cyclosporine [Sandimmune], radiocontrast agents, vancomycin); avoid concurrent use. ■ May increase serum levels of **lithium** (may cause toxicity). ■ May cause cardiac arrhythmias with **amiodarone** (Nexterone) or **digoxin** (potassium depletion). ■ May enhance or inhibit actions of **nondepolarizing muscle relaxants** (e.g., atracurium [Tracrium]). ■ May potentiate the action

of **succinylcholine**. ■ Effects may be inhibited by **NSAIDs** (e.g., ibuprofen [Motrin]), or **probenecid**. ■ May cause profound diuresis and serious electrolyte abnormalities with **thiazide diuretics** (e.g., chlorothiazide [Diuril]) because of synergistic effects. ■ May be inhibited by **phenytoin** (Dilantin). ■ Do not use concomitantly with **ethacrynic acid** (Edecrin); risk of ototoxicity markedly increased. ■ **Salicylates** may decrease the diuretic effect of furosemide. ■ **Furosemide** may increase serum levels of salicylates, increasing the risk of toxicity. ■ May decrease arterial responsiveness to **norepinephrine**. Dose adjustment may be required. ■ May enhance adverse effects of **chloral hydrate**. Concomitant use not recommended. ■ **Methotrexate** and other drugs that undergo significant renal tubular secretion may decrease the effectiveness of furosemide. ■ Furosemide may decrease renal elimination of other drugs that undergo tubular secretion. High-dose treatment of both furosemide and these other drugs may result in elevated serum levels and may potentiate toxicity. ■ Concomitant use of **cyclosporine** and furosemide has been associated with increased risk of gouty arthritis secondary to furosemide-induced hyperuricemia and cyclosporine impairment of renal urate excretion. ■ See [Precautions](#).

SIDE EFFECTS

Usually occur in prolonged therapy, seriously ill patients, or following large doses.

Anemia, anorexia, blurring of vision, deafness (reversible), diarrhea, dizziness, elevated hepatic enzymes, eosinophilia, headache, hyperglycemia, hyperuricemia, hypokalemia, increases in serum cholesterol and triglyceride levels, leg cramps, lethargy, leukopenia, mental confusion, nausea, paresthesia, postural hypotension, pruritus, rash, tinnitus, urinary frequency, urticaria, vomiting, weakness.

Major: Anaphylactic shock, blood volume reduction, circulatory collapse, dehydration, excessive diuresis, hepatic encephalopathy in patients with hepatic insufficiency, hypokalemia, metabolic acidosis, Stevens-Johnson syndrome, toxic epidermal necrolysis, vascular thrombosis and embolism.

Overdose: Blood volume reduction, dehydration, electrolyte imbalances, hypochloremic alkalosis, and hypotension.

ANTIDOTE

If minor side effects are noted, discontinue the drug and notify the physician, who may treat the side effects symptomatically and continue the drug. If side effects are progressive or any major side effect occurs, discontinue the drug immediately and notify the physician. Treatment of major side effects is symptomatic and aggressive. Monitor serum electrolytes, carbon dioxide level, and BP frequently, and replace excessive fluid and electrolyte losses as needed. Hemodialysis does not accelerate furosemide elimination. Resuscitate as necessary.

GANCICLOVIR SODIUM **BBW**

(gan-SYE-kloh-veer SO-dee-um)

Antiviral

Cytovene IV

pH 9 to 11

USUAL DOSE

Adequate hydration and specific testing required; see [Monitor](#).

CMV retinitis: 5 mg/kg of body weight every 12 hours for 14 to 21 days. Begin a maintenance dose the next day (Day 15 to 22) of 5 mg/kg daily for 7 days each week or 6 mg/kg daily for 5 days each week. See [Precautions/Monitor](#). After IV induction and when retinitis is stable, Cytovene capsules may be used for maintenance therapy; see [Precautions](#). If retinitis progresses during the maintenance regimen, initiate the twice-daily program again. Do not exceed recommended dose or infusion rate. Larger doses or increased rates of infusion have resulted in increased toxicity. For patients who have relapsed after induction and reinduction monotherapy with either ganciclovir or foscarnet, practitioners may consider an unlabeled combination therapy, which adds the alternate drug to the regimen. Information on this combination regimen is available from Roche and in the Clinical Trials section of the foscarnet sodium prescribing information.

Prevention of CMV disease in transplant recipients: 5 mg/kg every 12 hours for 7 to 14 days. Follow with maintenance regimen as outlined in CMV retinitis. Length of treatment based on immunosuppression degree and duration; 3 to 4 months or longer is common. CMV disease may occur if treatment stopped prematurely.

Prevention of CMV disease in HIV-infected adolescents and adults (unlabeled): 5 to 6 mg/kg/dose for 5 to 7 days each week. Cytovene capsules may be used.

PEDIATRIC DOSE

Safety for use in pediatric patients under 12 years of age not established. ■ Use extreme caution; long-term carcinogenicity and reproductive toxicity are probable. Benefit must outweigh risks. See [Indications](#) and [Maternal/Child](#).

CMV retinitis in pediatric patients over 3 months of age (unlabeled): 2.5 mg/kg every 8 hours for 14 to 21 days followed by a maintenance dose of 6 to 6.5 mg/kg/day was used during clinical trials. When retinitis progressed, the adult dosing regimen for induction and maintenance was followed. Another source suggests the adult dose regimen listed in [Usual Dose](#).

Prevention of CMV disease in transplant recipients (unlabeled): Same as adults; see [Usual Dose](#).

Prevention of CMV disease in HIV-infected individuals (unlabeled): 5 mg/kg/dose IV daily.

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy. Assess renal function before administration to elderly patients and adjust dose appropriately; see [Elderly](#). ■ Withhold dose if absolute neutrophil count (ANC) less than 500 cells/mm³ or platelets less than 25,000 cells/mm³. ■ See [Drug/Lab Interactions](#). ■ With impaired renal function, reduce dose according to the following chart.

Ganciclovir Induction and Maintenance Dose Guidelines in Impaired Renal Function				
Creatinine Clearance (mL/min)	Ganciclovir IV Induction Dose (mg/kg)	Dosing Interval (hours)	Ganciclovir Maintenance Dose (mg/kg)	Dosing Interval (hours)
≥70	5 mg/kg	12 hours	5 mg/kg	24 hours
50-69	2.5 mg/kg	12 hours	2.5 mg/kg	24 hours
25-49	2.5 mg/kg	24 hours	1.25 mg/kg	24 hours
10-24	1.25 mg/kg	24 hours	0.625 mg/kg	24 hours
<10	1.25 mg/kg	3 times per week following hemodialysis	0.625 mg/kg	3 times per week following hemodialysis

DILUTION

Specific techniques required; see Precautions. Initially dissolve the 500-mg vial with 10 mL SWFI (50 mg/mL). Do not use bacteriostatic water containing parabens; will cause precipitation. Shake well to dissolve completely. Discard if particulate matter or discoloration observed. Withdraw desired dose and further dilute with NS, D5W, Ringer's, or LR to provide a concentration less than 10 mg/mL (70-kg adult at 5 mg/kg equals 350 mg; dissolved in 100 mL of solution equals 3.5 mg/mL).

Filters: Use not required by manufacturer; however, use of a filter would not have an adverse effect.

Storage: Store unopened vials below 40° C (104° F). Reconstituted solution in vial stable at CRT for 12 hours. Do not refrigerate. Solution fully diluted for administration must be refrigerated and used within 24 hours to reduce incidence of bacterial contamination. Stable for 14 days refrigerated at 5° C (41° F) if prepared in PVC bags and reconstituted with SWFI and further diluted with NS.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Because of physical **incompatibilities**, ganciclovir sodium and **foscarnet sodium** must never be mixed.

One source suggests the following **compatibilities**:

Y-site: Allopurinol (Aloprim), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), caspofungin (Cancidas), cisatracurium (Nimbex), docetaxel (Taxotere), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), etoposide phosphate (Etopophos), filgrastim (Neupogen), fluconazole (Diflucan), granisetron (Kytril), linezolid (Zyvox), melphalan (Alkeran), paclitaxel (Taxol), pemetrexed (Alimta), propofol (Diprivan), remifentanyl (Ultiva), teniposide (Vumon), thiopeta.

RATE OF ADMINISTRATION

A single dose must be administered at a constant rate over 1 hour as an infusion. Use of an infusion pump or microdrip (60 gtt/mL) recommended. **Do not give by rapid or bolus IV injection.** Excessive plasma levels and toxicity will occur with too-rapid rate of injection. Advisable to clear tubing with NS before and after administration through Y-tube or three-way stopcock.

ACTIONS

An antiviral agent that inhibits DNA synthesis and stops cytomegalovirus (CMV) from multiplying. Does not destroy existing viruses but stops them from reproducing and invading healthy cells. May allow a weakened immune system to defend the body against the CMV infection. May also be inhibitory against herpes simplex virus 1 and 2, Epstein-Barr virus, and varicella zoster virus, but clinical studies have not been done. Onset of action is prompt, and therapeutic levels are maintained for 3 to 6 hours with some drug remaining 11 hours after infusion. Widely distributed in tissues and body fluids. Half-life

is 2.6 to 4.4 hours. Crosses the placental barrier. Suspected to be secreted in breast milk. Approximately 90% excreted unchanged in urine in patients with normal renal function.

INDICATIONS AND USES

Treatment of CMV retinitis in immunocompromised individuals, including patients with AIDS. ■ CMV disease prevention in at-risk transplant patients. ■ Safety and effectiveness for use in congenital or neonatal CMV disease, treatment of established CMV disease other than retinitis, or non-immunocompromised individuals not established. Use should be limited to treatment of conditions listed above. ■ Now available as an ophthalmic surgical aid (intra-vitreous implant) to treat CMV retinitis. ■ Ganciclovir (Cytovene) capsules are used for prevention of CMV retinitis in at-risk patients with advanced HIV infection and in the prevention of CMV disease in solid-organ transplant recipients; see **Precautions**. Valganciclovir (Valcyte) is an oral drug recently approved for the treatment of CMV retinitis, and it is also being used for maintenance.

Unlabeled uses: Treatment of other CMV infections (e.g., gastroenteritis, hepatitis, pneumonitis) in immunocompromised patients. ■ Treatment of polyradiculopathy caused by CMV infections. ■ Combination therapy (ganciclovir and foscarnet) to treat progressive retinitis refractory to single therapy.

CONTRAINDICATIONS

Hypersensitivity to ganciclovir or acyclovir; patients with a neutrophil count less than 500 cells/mm³ or a platelet count less than 25,000 cells/mm³; patients receiving zidovudine (AZT, Retrovir), since both drugs cause granulocytopenia.

PRECAUTIONS

A nucleoside analog; follow guidelines for handling and disposal of cytotoxic agents. See Appendix A, p. 1251. ■ For IV use only; IM or SC administration will cause severe tissue irritation. ■ Hematologic toxicity (anemia, granulocytopenia, thrombocytopenia) common; see **Monitor**. ■ Use with caution in patients with pre-existing cytopenias or a history of cytopenic reactions to other drugs, chemicals, or irradiation. ■ Ganciclovir is not a cure for CMV infections. Maintenance therapy is almost always necessary to prevent relapse in patients with AIDS. ■ Resistance has been reported to develop. May be higher in patients treated for a prolonged period. ■ Cidofovir is also an agent for treatment of CMV retinitis. ■ Risk of a more rapid rate of disease progression is increased with oral ganciclovir. Use in maintenance recommended only if benefits of avoiding daily IV infusions outweigh risk.

Monitor: Confirm diagnosis of CMV retinitis by indirect ophthalmoscopy. Diagnosis may be supported by cultures of CMV (e.g., urine, blood, throat); negative culture does not rule out CMV retinitis. ■ Continue ophthalmologic exams during induction and maintenance treatment to monitor CMV status. ■ CBC with differential and platelet counts, SCr, and CrCl are required before treatment initiated. Monitor CBC and platelet counts frequently, especially in patients with previous leukopenia from ganciclovir or other nucleoside analogs or those with neutrophils less than 1,000 cells/mm³ at beginning of treatment and in patients undergoing hemodialysis. Withhold dose if absolute neutrophil count (ANC) less than 500 cells/mm³ or platelets less than 25,000 cells/mm³. Monitor SCr or CrCl every 2 weeks. ■ Maintain adequate hydration and urine flow before and during infusion. ■ Phlebitis or pain may occur at site of infusion; confirm patency of vein and use small needles and large veins to ensure adequate blood flow for rapid dilution and distribution. ■ Granulocytopenia usually occurs within 14 days but may occur at any time; recovery should begin within 3 to 7 days of discontinuing ganciclovir. ■ Consider the possibility of viral resistance if retinitis does not show significant improvement with treatment. ■ See **Drug/Lab Interactions**.

Patient Education: Must use effective birth control throughout treatment. Men should continue barrier contraception for at least 90 days. ■ Not a cure; retinitis may still progress. Frequent ophthalmoscopic examinations important. ■ Cooperation for close monitoring of blood cell counts is imperative to control side effects (e.g., anemia, neutropenia, thrombocytopenia). ■ Report any unexpected side effects promptly (e.g., chills, fever, unusual bleeding or bruising). ■ Patients with AIDS receiving zidovudine

(AZT, Retrovir) may not tolerate ganciclovir. ■ High frequency of impaired renal function increased with concomitant use of nephrotoxic agents (e.g., cyclosporine, amphotericin); high risk for transplant recipients.

Maternal/Child: Category C: avoid pregnancy. A potential carcinogen. Teratogenic and embryotoxic; has caused aspermatogenesis and will cause birth defects. Do not use during pregnancy unless risk is justified. May cause temporary or permanent infertility in men and women. ■ Discontinue nursing during treatment; minimum interval required before re-summing breast-feeding is unknown. ■ Use extreme caution in pediatric patients under 12 years of age. Long-term carcinogenicity and reproductive toxicity are probable. Benefit must outweigh risks.

Elderly: Dose selection should be cautious; see [Dose Adjustments](#). Monitor renal function during therapy and adjust dose as indicated.

DRUG/LAB INTERACTIONS

Because of physical **incompatibilities**, ganciclovir and **foscarnet** must never be mixed. ■ Additive toxicity may occur with concomitant use of **other drugs that inhibit replication of rapidly dividing cell populations** (e.g., dapsone, pentamidine, flucytosine [Ancobon], vincristine, vinblastine, doxorubicin [Adriamycin], amphotericin B [conventional], sulfamethoxazole/trimethoprim [Bactrim]). ■ May cause severe anemia and neutropenia with **zidovudine** (AZT, Retrovir). Combination used in patients with AIDS is rarely tolerated. ■ Concurrent treatment with **didanosine** (Videx) may cause increased didanosine levels. ■ May cause seizures with **imipenem-cilastatin** (Primaxin). ■ Potentiated by **probenecid and other drugs that may reduce renal clearance**; will increase toxicity. ■ Impaired renal function may be markedly increased with other **nephrotoxic agents** (e.g., cyclosporine, amphotericin B). ■ Concurrent or consecutive use with **other bone marrow suppressants** (e.g., antineoplastics, amphotericin B, zidovudine and/or radiation therapy) may produce additive bone marrow suppression. ■ Drug interaction studies with drugs commonly used in transplant recipients have not been conducted. ■ See [Contraindications](#).

SIDE EFFECTS

Anemia, leukopenia, and thrombocytopenia are most common and are generally reversible if treatment discontinued. Abdominal pain; anorexia; chills; diarrhea; fever; infection; nausea; neuropathy; pain, infection, and sepsis at injection site; phlebitis; pruritus; rash; retinal detachment; sepsis; sweating; and vomiting occur in some patients. Abnormal kidney function and/or failure, abnormal vision, alopecia, anxiety, arthralgia, asthenia, chest pain, confusion, constipation, cough, decreased CrCl, depression, dizziness, dry mouth, dry skin, dyspepsia, dyspnea, edema, eructation, headache, hypertension, increased ALT and AST, increased creatinine, insomnia, leg cramps, malaise, myalgia, myasthenia, pancytopenia, seizures, somnolence, stomatitis, taste perversion, tinnitus, tremor, and weight loss have occurred. Gastrointestinal perforation, multiple organ failure, pancreatitis, and sepsis have occurred and may be fatal. Numerous additional side effects may occur.

Overdose: Acute renal failure, hematuria, hepatitis, irreversible pancytopenia, persistent bone marrow suppression, and seizures have occurred.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Filgrastim (Neupogen) 1 to 10 mcg/kg/day has been used to maintain the neutrophil count. Discontinue drug if neutrophils fall below 500 cells/mm³ or platelets fall below 25,000 cells/mm³. Hydration and hemodialysis (up to 50% removal) are useful in overdose. Treat anaphylaxis and resuscitate as necessary.

GEMCITABINE HYDROCHLORIDE(jem-**SIGHT**-ah-been hy-droh-**KLOR**-eyed)**Antineoplastic
(miscellaneous)****Gemzar****pH 2.7 to 3.3****USUAL DOSE**

Pancreatic cancer: 1,000 mg/M² once each week for up to 7 weeks (or until toxicity necessitates reducing or holding a dose). Follow with a week of rest. In subsequent cycles, 1,000 mg/M² or appropriate reduced or increased dose once each week for 3 consecutive weeks. Follow with a week of rest.

Non-small-cell lung cancer (NSCLC): 1,000 mg/M² as an infusion on Days 1, 8, and 15 of each 28-day cycle. Given in combination with cisplatin (Platinol). Administer cisplatin 100 mg/M² IV on Day 1 after the infusion of gemcitabine. An alternate schedule is gemcitabine 1,250 mg/M² on Days 1 and 8 of each 21-day cycle. Administer cisplatin 100 mg/M² IV on Day 1 after the infusion of gemcitabine. See cisplatin monograph for administration and hydration guidelines.

Breast cancer: 1,250 mg/M² as an infusion on Days 1 and 8 of each 21-day cycle. Given in combination with paclitaxel (Taxol). On Day 1, administer paclitaxel 175 mg/M² as a 3-hour infusion before the gemcitabine infusion. Premedication required; see paclitaxel monograph.

Ovarian cancer: 1,000 mg/M² as an infusion on Days 1 and 8 of a 21-day cycle. Given in combination with carboplatin (Paraplatin). On Day 1, administer carboplatin at AUC 4 after gemcitabine administration.

Bladder cancer (unlabeled): 1,000 to 1,200 mg/M² once each week for 3 weeks. Follow with a week of rest.

Hodgkin's or non-Hodgkin's lymphoma (unlabeled): 1,000 to 1,250 mg/M² on Days 1, 8, and 15 of a 28-day cycle. Doses up to 1,500 mg/M² have been used.

DOSE ADJUSTMENTS

Clearance decreased in women and the elderly. May be less likely to progress to subsequent cycles; see **Precautions** and **Elderly**. ■ For pancreatic cancer, NSCLC and unlabeled uses reduce dose based on the degree of hematologic toxicity according to the following chart.

Gemcitabine Dose Reduction Guidelines			
Indicated for Dose Reduction in Pancreatic Cancer, NSCLC, and Unlabeled Uses			
Absolute Granulocyte Count (cells/mm ³)		Platelet Count (cells/mm ³)	% of Full Dose to Be Administered
≥1,000	and	≥100,000	100%
500-999	or	50,000-99,999	75%
<500	or	<50,000	Hold

Treatment of pancreatic cancer: Dose may be increased by 25% (to 1,250 mg/M²) in patients who complete an entire 7-week initial cycle or a subsequent 3-week cycle at a dose of 1,000 mg/M². Absolute granulocyte count nadir must exceed 1,500/mm³ and platelet nadir must exceed 100,000/mm³. Nonhematologic toxicity should not be greater than WHO Grade 1 (some examples are: able to eat, reasonable intake, no more than one emesis in 24 hours, asymptomatic heart and lungs, mild paresthesia). If this cycle is

tolerated, dose for the next cycle may be increased to 1,500 mg/M² providing the same criteria have been met (e.g., granulocyte nadir, platelet nadir, nonhematologic toxicity). **Treatment of NSCLC:** Treatment with gemcitabine and cisplatin should be held or decreased by 50% when Grade 3 or 4 nonhematologic toxicity occurs (except alopecia and nausea and vomiting). See cisplatin monograph for additional dose adjustment guidelines. **Treatment of breast cancer (combination with paclitaxel):** Reduce dose based on degree of hematologic toxicity seen on Day 8 according to the following chart.

Dose Reduction Guidelines for Gemcitabine in Combination with Paclitaxel Indicated for Dose Reduction in Breast Cancer			
Absolute Granulocyte Count (cells/mm ³)		Platelet Count (cells/mm ³)	% of Full Dose to Be Administered
≥ 1,200	and	> 75,000	100%
1,000-1,199	or	50,000-75,000	75%
700 to 999	and	≥ 50,000	50%
< 700	or	< 50,000	Hold

Treatment with gemcitabine and paclitaxel should be held or decreased by 50% when Grade 3 or 4 nonhematologic toxicity occurs. See paclitaxel monograph for additional dose adjustment guidelines.

Treatment of ovarian cancer in combination with carboplatin: Reduce dose based on the degree of hematologic toxicity that is seen on Day 8 according to the following chart.

Day 8 Dose Reduction Guidelines for Gemcitabine in Combination with Carboplatin Indicated for Dose Reduction in Ovarian Cancer			
Absolute Granulocyte Count (cells/mm ³)		Platelet Count (cells/mm ³)	% of Full Dose to Be Administered
≥ 1,500	and	≥ 100,000	100%
1,000-1,499	and/or	75,000-99,999	50%
< 1,000	and/or	< 75,000	Hold

Treatment with gemcitabine and carboplatin should be held or decreased by 50% when severe (Grade 3 or 4) nonhematologic toxicity (except nausea and vomiting) occurs. See carboplatin monograph for additional dose adjustment guidelines.

Dose adjustment for gemcitabine in combination with carboplatin for subsequent cycles is based on observed toxicity. In subsequent cycles, reduce the dose of gemcitabine to 800 mg/M² on Days 1 and 8 in case of any of the following hematologic toxicities:

- Absolute granulocyte count < 500 cells/mm³ for more than 5 days
- Absolute granulocyte count < 100 cells/mm³ for more than 3 days
- Febrile neutropenia
- Platelets < 25,000 cells/mm³
- Cycle delay of more than 1 week due to toxicity

If any of the previous toxicities recur after the initial dose reduction, administer gemcitabine 800 mg/M² only on Day 1 of subsequent cycles.

DILUTION

Specific techniques required; see Precautions. Each 200 mg must be reconstituted with 5 mL NS without preservatives (25 mL NS for 1 Gm). Yields 38 mg/mL. Shake to dis-

solve. Do not use less solution to reconstitute; dissolution will be incomplete. The appropriate dose **must** be further diluted with NS to concentrations as low as 0.1 mg/mL. 1,500 mg diluted in 250 mL yields 6 mg/mL. 750 mg in 100 mL yields 7.5 mg/mL.

Filters: Reconstituted solution may be filtered through a 0.22- or 0.45-micron pre-filter.

Storage: Store unopened vials at CRT. Reconstituted or diluted solutions are stable at CRT for 24 hours. Do not refrigerate in any form; may crystallize. Discard unused portion.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “**Compatibilities** with other drugs have not been studied. No **incompatibilities** observed with IV bottles or PVC bags and administration sets.”

One source suggests the following **compatibilities**:

Y-site: Amifostine (Ethylol), amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), aztreonam (Azactam), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), cefazolin (Ancef), cefotetan (Cefotan), cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cytarabine (ARA-C), dactinomycin (Cosmegen), daunorubicin (Cerubidine), dexamethasone (Decadron), dexrazoxane (Zinecard), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), etoposide (VePesid), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), ifosfamide (Ifex), leucovorin calcium, linezolid (Zyvox), lorazepam (Ativan), mannitol, meperidine (Demerol), mesna (Mesnex), metoclopramide (Reglan), metronidazole (Flagyl IV), mitoxantrone (Novantrone), morphine, nalbuphine, ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), palonosetron (Aloxi), potassium chloride (KCl), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, streptozocin (Zanosar), sulfamethoxazole/trimethoprim, teniposide (Vumon), thiotepa, ticarcillin/clavulanate (Timentin), tobramycin, topotecan (Hycamtin), vancomycin, vinblastine, vincristine, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 minutes. Do not extend infusion time beyond 60 minutes; will increase toxicity.

ACTIONS

A nucleoside analog with antineoplastic activity. Metabolized intracellularly to two active nucleosides. Cell phase specific, these nucleosides induce internucleosomal DNA fragmentation, primarily killing cells undergoing DNA synthesis (S-phase) and also blocking the progression of cells through the G₁/S-phase boundary. Very little is bound to plasma protein. Volume of distribution is increased by infusion length. Half-life is shorter (32 to 94 minutes) with a short infusion (less than 70 minutes), and longer (245 to 638 minutes) with a long infusion (more than 70 minutes). Half-life is slightly longer and rate of clearance is lower in women and in the elderly, resulting in higher concentrations for any given dose. Primarily excreted in urine.

INDICATIONS AND USES

First-line treatment for patients with nonresectable or metastatic cancer of the pancreas and for patients previously treated for cancer of the pancreas with fluorouracil. ■ First-line treatment in combination with cisplatin for the palliative treatment of locally advanced or metastatic non-small-cell lung cancer. ■ First-line treatment in combination

with paclitaxil for treatment of metastatic breast cancer after failure of previous anthracycline chemotherapy unless anthracyclines (e.g., doxorubicin [Adriamycin], idarubicin [Idamycin]) were clinically contraindicated. ■ Treatment in combination with carboplatin for patients with advanced ovarian cancer that has relapsed at least 6 months after completion of platinum-based therapy.

Unlabeled uses: Treatment of metastatic bladder cancer. ■ Treatment of relapsed or refractory testicular cancer. ■ Treatment of squamous cell cancer of the head and neck.

CONTRAINDICATIONS

Hypersensitivity to gemcitabine or any of its components.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be available. ■ For IV use only. May be administered on an outpatient basis. ■ Prolongation of the infusion time beyond 60 minutes and more frequent than weekly dosing have been shown to increase toxicity. ■ Clearance in women and the elderly is reduced; women, especially older women, were more likely not to proceed to a subsequent cycle and to experience Grade 3 or 4 neutropenia and thrombocytopenia. No age or gender dose adjustments recommended. ■ Use with caution in impaired renal or hepatic function. Clear dose recommendations are not available; data from clinical studies insufficient. ■ Hepatotoxicity, including liver failure and death, has been reported. Use in patients with concurrent liver metastases or a history of alcoholism, hepatitis, or liver cirrhosis may lead to exacerbation of the underlying hepatic insufficiency. ■ Hemolytic uremic syndrome (HUS) and/or renal toxicity, including renal failure leading to death or requiring dialysis, has been reported. ■ Gemcitabine is a potent radiosensitizer. Depending on the site being radiated, concurrent use with gemcitabine may cause severe, life-threatening esophagitis and pneumonitis. Data suggest that gemcitabine can be started after the acute effects of radiation have resolved or at least 1 week after radiation is completed. ■ Pulmonary toxicity has been reported. If gemcitabine-induced pneumonitis is confirmed or suspected, discontinue permanently. Dyspnea unrelated to underlying disease has been reported with gemcitabine therapy and has been occasionally accompanied by bronchospasm. ■ Use caution in patients who have had previous cytotoxic chemotherapy or radiation therapy.

Monitor: Monitor for bone marrow suppression; myelosuppression (e.g., anemia, leukopenia, and thrombocytopenia) is the dose-limiting toxicity. See [Dose Adjustments](#). ■ Obtain a CBC, including differential and platelet count, before each dose. ■ Obtain baseline renal function (e.g., SCr) and liver function tests (e.g., AST, ALT) and repeat periodically. ■ Monitor serum calcium, magnesium, potassium, and SCr during combination therapy with cisplatin. ■ Monitor vital signs. ■ Maintain adequate hydration. ■ Nausea and vomiting are frequent and were severe in 15% of patients; prophylactic administration of antiemetics will increase patient comfort. ■ Observe closely for S/S of infection. May cause fever in the absence of infection or prophylactic antibiotics may be indicated pending results of C/S in a febrile or nonfebrile patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Consider a diagnosis of HUS if anemia with evidence of microangiopathic hemolysis, elevation of bilirubin or LDH, reticulocytosis, severe thrombocytopenia, and/or evidence of renal failure (elevation of SCr or BUN) develops; discontinue gemcitabine. ■ Not a vesicant, but monitor injection site for inflammation and/or extravasation.

Patient Education: Nonhormonal birth control recommended. ■ See Appendix D, p. 1255. ■ Report any unusual or unexpected symptoms or side effects (e.g., shortness of breath, blood in stool or urine, S/S of infection, unusual bruising or bleeding) as soon as possible.

Maternal/Child: Category D: avoid pregnancy. May cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Small clinical studies have been performed with questionable results; see prescribing information.

Elderly: Clearance reduced in the elderly; hematologic toxicity requiring reduction, delay, or omission of subsequent doses is higher than in younger adults; however, incidence of nonhematologic toxicity is similar. Elderly men and women are more likely to experience grade 3 or 4 thrombocytopenia. Elderly women are also more likely to experience Grade 3 or 4 neutropenia. Usual dose adjustments based on toxicity are considered appropriate. Age-related impaired renal function may further reduce clearance and increase toxicity.

DRUG/LAB INTERACTIONS

Interaction of gemcitabine with other drugs has not been adequately studied. ■ Additive bone marrow suppression may occur with **radiation therapy, other bone marrow-suppressing agents** (e.g., amphotericin B [traditional and lipid], azathioprine [Imuran], chloramphenicol, melphelan [Alkeran]), and/or **immunosuppressants** (e.g., chlorambucil [Leukeran], cyclophosphamide [Cytosan], cyclosporine [Sandimmune], glucocorticoid corticosteroids [e.g., dexamethasone], muromonab-CD3 [Orthoclone], tacrolimus [Prograf]); dose reduction may be required. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents.

SIDE EFFECTS

Alopecia, anorexia, arrhythmias, arthralgia, bone marrow toxicity (e.g., anemia, leukopenia, neutropenia, thrombocytopenia), bone pain, bronchospasm, cerebrovascular accident, CHF, constipation, diarrhea, dyspnea, edema, elevated lab tests (e.g., BUN, creatinine, hematuria, proteinuria), fatigue, febrile neutropenia, fever, flu syndrome (e.g., anorexia, chills, cough, headache, myalgia, weakness), hemorrhage, hepatotoxicity, hypertension, increased liver function tests (e.g., ALT, AST, GGT, alkaline phosphatase, and bilirubin), infection, injection site reaction, myalgia, myocardial infarction, nausea

and vomiting, neuropathy (motor and sensory), pain, paresthesias, peripheral vasculitis and gangrene, pruritus, pulmonary effects (including pulmonary edema, pulmonary fibrosis, interstitial pneumonitis, ARDS, respiratory failure), radiation recall reactions, rash, severe skin reactions (e.g., desquamation and bullous skin eruptions), somnolence, stomatitis. Anaphylaxis and hemolytic uremic syndrome have been reported.

ANTIDOTE

Keep physician informed of all side effects. Symptomatic and supportive treatment is indicated. Reduce dose or withhold gemcitabine until myelosuppression improves to specific criteria; see [Dose Adjustments](#). If gemcitabine-induced pneumonitis or esophagitis is confirmed or suspected, discontinue permanently (in one study severe stomatitis and pharyngeal damage required patients to be fed by feeding tube for up to 12 months after receiving doses of 300 mg/M² [25% of the usual dose]). Anemia may require RBC transfusions. Other whole blood products (e.g., platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Most side effects are reversible with dose reduction or temporary withholding of gemcitabine. No known antidote for overdose. If hemolytic uremic syndrome occurs, discontinue gemcitabine; renal failure may not be reversible even with discontinuation of therapy and dialysis may be required. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine).

GENTAMICIN SULFATE **BBW**(jen-tah-**MY**-sin **SUL**-fayt)Antibacterial
(aminoglycoside)

pH 3 to 5.5

USUAL DOSE

3 mg/kg of body weight/24 hr equally divided into 3 doses (1 mg/kg every 8 hours). Up to 5 mg/kg/24 hr may be given if indicated. Reduce to usual dose as soon as feasible. Another source suggests 1 to 2.5 mg/kg/dose every 8 to 12 hours. A loading dose of 2 mg/kg is commonly used. **Dosage based on ideal body weight.** Studies suggest that a single daily dose of 4 to 7 mg/kg (instead of divided into 2 to 3 doses) may provide higher peak levels and enhance drug effectiveness while actually reducing or having no adverse effects on risk of toxicity. Various procedures for monitoring blood levels are in use. Some health facilities are monitoring with trough levels; others may draw levels at predetermined times and plot the concentration on nomograms. Depending on the protocol in place, doses or intervals may be adjusted. See [Precautions/Monitor](#).

Prevention of bacterial endocarditis in dental, respiratory tract, GI or GU tract surgery or instrumentation: 1.5 mg/kg 30 minutes before procedure. Do not exceed 80 mg. Repeat in 8 hours. Given concurrently with ampicillin, vancomycin, or amoxicillin.

Pelvic inflammatory disease: 2 mg/kg as an initial dose. Follow with 1.5 mg/kg every 8 hours for 4 days or 48 hours after patient improves. Given concurrently with clindamycin.

PEDIATRIC DOSE

See [Maternal/Child](#).

6 to 7.5 mg/kg of body weight/24 hr (2 to 2.5 mg/kg every 8 hours). A single daily dose is also being used in pediatric patients. See comments under [Usual Dose](#). 10 mg/mL product available for pediatric use.

Prevention of bacterial endocarditis in dental, respiratory tract, GI or GU tract surgery or instrumentation: 2 mg/kg. See [Adult Dose](#) for instructions.

NEONATAL DOSE

See [Maternal/Child](#).

2.5 mg/kg. Intervals adjusted based on age as follows:

0 to 7 days of age; less than 28 weeks' gestation: Every 24 hours.

28 to 34 weeks' gestation: Every 18 hours.

Over 34 weeks' gestation: Every 12 hours.

Over 7 days of age; less than 28 weeks' gestation: Every 18 hours.

28 to 34 weeks' gestation: Every 12 hours.

Over 34 weeks' gestation: Every 8 hours.

Another source suggests that higher doses (4 to 5 mg/kg/dose) at extended intervals (24 to 48 hours) may be used.

DOSE ADJUSTMENTS

Reduce daily dose commensurate with amount of renal impairment according to the following chart. Other protocols are in use; see literature. ■ Reduced dose or extended intervals may be indicated in elderly adults. ■ See [Monitor](#) and [Drug/Lab Interactions](#).

Gentamicin Dosing Guidelines for Impaired Renal Function (Dose at 8-Hour Intervals After the Initial Dose)		
Serum Creatinine (mg%)	Approximate Creatinine Clearance Rate (mL/min/1.73 M ²)	Percent of Usual Dose to Be Administered q 8 hr
<1	>100	100%
1.1-1.3	71-100	80%
1.4-1.6	56-70	65%
1.7-1.9	46-55	55%
2-2.2	41-45	50%
2.3-2.5	36-40	40%
2.6-3	31-35	35%
3.1-3.5	26-30	30%
3.6-4	21-25	25%
4.1-5.1	16-20	20%
5.2-6.6	11-15	15%
6.7-8	≤10	10%

The recommended dose at the end of each dialysis period is 1 to 1.7 mg/kg depending on the severity of the infection. 2 mg/kg may be administered to pediatric patients. The amount of gentamicin removed by dialysis may vary; however, an 8-hour dialysis session may reduce serum concentrations by 50%. Another source suggests the following dose guidelines for impaired renal function.

Conventional Gentamicin Dosing Guidelines for Impaired Renal Function	
Approximate Creatinine Clearance Rate (mL/min/1.73 M ²)	Administer Conventional Dose at the Following Intervals
>60 mL/min	Every 8 hours
40 to 60 mL/min	Every 12 hours
20 to 40 mL/min	Every 24 hours
<20 mL/min	Loading dose, then monitor levels

High-dose therapy: Interval may be extended (e.g., every 48 hours) in patients with moderate renal impairment (CrCl 30 to 59 mL/min) and/or adjusted based on serum level determinations.

DILUTION

Available premixed in several concentrations. Vials equal 10 or 40 mg/mL. Further dilute each single dose in 50 to 200 mL of IV NS or D5W. Decrease volume of diluent for pediatric patients. Commercially diluted solutions available.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not physically premix with other drugs; administer separately." Inactivated in solution with beta-lactam antibiotics (e.g., cephalosporins, penicillins) and

vancomycin. Do not mix in the same solution. Appropriate spacing required because of physical **incompatibilities**. See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

Additive: Not recommended by manufacturer. Atracurium (Tracrium), aztreonam (Azactam), bleomycin (Blenoxane), [cefotaxime \(Claforan\)](#), cefoxitin (Mefoxin), [ceftriaxone \(Rocephin\)](#), [cefuroxime \(Zinacef\)](#), ciprofloxacin (Cipro IV), [clindamycin \(Cleocin\)](#), [cytarabine \(ARA-C\)](#), [dextran 40](#), [dopamine](#), fluconazole (Diflucan), [furosemide \(Lasix\)](#), linezolid (Zyvox), mannitol (Osmitrol), meropenem (Merrem IV), metronidazole (Flagyl IV), midazolam (Versed), penicillin G sodium, ranitidine (Zantac), verapamil.

Y-site: Acyclovir (Zovirax), alprostadil, amifostine (Ethyol), amiodarone (Nexterone), [anidulafungin \(Eraxis\)](#), atracurium (Tracrium), aztreonam (Azactam), bivalirudin (Angiomax), [caspofungin \(Cancidas\)](#), cefepime (Maxipime), ceftazidime (Fortaz), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cyclophosphamide (Cytosan), cytarabine (ARA-C), daptomycin (Cubicin), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doripenem (Doribax), doxapram (Dopram), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), [filgrastim \(Neupogen\)](#), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), insulin (regular), labetalol, levofloxacin (Levaquin), linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), midazolam (Versed), milrinone (Primacor), morphine, multivitamins (M.V.I.), nicardipine (Cardene IV), ondansetron (Zofran), paclitaxel (Taxol), [palonosetron \(Aloxi\)](#), pancuronium, potassium chloride (KCl), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepa, tigecycline (Tygacil), vasopressin, vecuronium, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Each single dose, properly diluted, over 30 to 60 minutes, up to 2 hours in pediatric patients. Studies suggest bolus dosing (versus infusion over 30 minutes) may produce an earlier bactericidal effect, which is sustained. No dose, dilution, or rate recommendations are available at this time.

ACTIONS

Aminoglycoside antibiotic with neuromuscular blocking action. Bactericidal against specific gram-negative bacilli, including *Escherichia coli*, *Klebsiella*, *Proteus*, and *Pseudomonas*. Not effective for fungi or viral infections. Well distributed throughout all body fluids; serum and urine levels remain adequate for 6 to 12 hours. Usual half-life is 2 hours. Half-life prolonged in infants, postpartum females, fever, liver disease and ascites, spinal cord injury, cystic fibrosis, and the elderly; shorter in severe burns. Crosses placental barrier. Excreted through kidneys.

INDICATIONS AND USES

Treatment of serious infections of the GI (peritonitis), respiratory, and urinary tracts; CNS (meningitis); skin; bone; soft tissue (burns); septicemia; and bacterial neonatal sepsis. ■ Primarily used when penicillin and other less toxic antibiotics are ineffective or contraindicated. ■ Prevention of bacterial endocarditis in dental, respiratory tract, GI, or GU surgery or instrumentation. ■ Used concurrently with clindamycin to treat pelvic inflammatory disease. ■ Considered initial therapy after culture and sensitivity is drawn in suspected or confirmed gram-negative infections or other serious infections. ■ Treat suspected infection in the immunosuppressed patient. ■ May be used synergistically in gram-positive infections. ■ Used concurrently with penicillin for endocarditis and neonatal sepsis.

CONTRAINDICATIONS

Known gentamicin or aminoglycoside sensitivity, renal failure. Sulfite sensitivity may be a contraindication.

PRECAUTIONS

Sensitivity studies indicated to determine susceptibility of the causative organism to gentamicin. ■ Use extreme caution if therapy is required over 7 to 10 days. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ Use caution in infants, children, and the elderly. ■ Advanced age and dehydration may increase risk of toxicity. ■ May contain sulfites; use caution in patients with asthma. ■ Aminoglycosides are nephrotoxic; risk for nephrotoxicity is increased in patients with impaired renal function and in patients who receive high doses or prolonged therapy. ■ Use extreme caution in patients with end-stage renal disease. ■ Single daily dosing has been used effectively in abdominal, pelvic inflammatory, and GU infections in patients with normal renal function. Not recommended in bacteremia caused by *Pseudomonas aeruginosa*, endocarditis, meningitis, during pregnancy, or in patients less than 6 weeks postpartum. Limited data available for use in all other situations (e.g., burns, cystic fibrosis, elderly, pediatrics, renal impairment). ■ Potentially nephrotoxic, ototoxic, and neurotoxic. Risk of neurotoxicity (e.g., auditory and vestibular ototoxicity) is increased in patients with pre-existing renal damage or in normal renal function with prolonged use. Partial or total irreversible deafness may continue to develop after gentamicin discontinued. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with gentamicin.

Monitor: Narrow range between toxic and therapeutic levels. Periodically monitor peak and trough concentrations. Therapeutic level is between 4 and 8 mcg/mL. Avoid trough levels above 2 mcg/mL and prolonged peak levels above 12 mcg/mL; adjust dose as indicated. Risk of renal and eighth cranial nerve toxicity increased. Monitor frequently in patients with impaired renal function. ■ Watch for decrease in urine output and rising BUN and SCr. May require decreased dose. ■ Routine gentamicin serum levels and evaluation of hearing are recommended. ■ Closely monitor renal and eighth cranial nerve function, especially in patients with known or suspected reduced renal function at onset of therapy and in patients who develop signs of renal dysfunction during therapy. Monitor urine for decreased specific gravity, increased protein, and the presence of cells or casts. Serial audiograms are recommended, particularly in high-risk patients. ■ Maintain good hydration. ■ Monitor serum calcium, magnesium, sodium, and potassium; levels may decline. Depressed levels have caused mental confusion, paresthesia, positive Chvostek and Trousseau signs (provoked spasm of facial muscles and other muscles; occurs in tetany), and tetany in adults; muscle weakness and tetany in infants. ■ Closely monitor patients with impaired renal function for nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity, convulsions, muscle twitching, numbness, tingling); nephrotoxicity may be reversible. ■ In extended treatment, monitoring of serum levels, electrolytes, renal, auditory, and vestibular functions is recommended daily. ■ See [Drug/Lab Interactions](#).

Patient Education: Report promptly: dizziness, hearing loss, weakness, or any changes in balance. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Consider birth control options.

Maternal/Child: Category D: avoid pregnancy. Potential hazard to fetus. ■ Safety for use during breast-feeding not established; use extreme caution. ■ Peak concentrations are generally lower in infants and young children.

Elderly: Consider less toxic alternatives. Half-life prolonged. Longer intervals between doses may be more important than reduced doses. ■ Advanced age and dehydration may increase risk for toxicity. ■ Monitor renal function and drug levels carefully. Measurement of CrCl more useful than BUN or SCr to assess renal function. ■ See [Precautions](#).

DRUG/LAB INTERACTIONS

Inactivated in solution with **penicillins** but is synergistic when used in combination with **beta-lactam antibiotics** (e.g., sulbactam sodium, clavulanate potassium, cephalosporins, penicillins) and **vancomycin**. Do not mix in the same solution. Dose adjustment and appropriate spacing required because of physical **incompatibilities** and interactions. Synergism may be inconsistent; measure aminoglycoside levels. ■ Concurrent and/or sequential use topically or systemically with any other **neurotoxic or nephrotoxic agent** should be avoided (e.g.,

amikacin [Amikin], cephaloridine, cisplatin [Platinol], colistin [Coly-Mycin S], kanamycin, neomycin, polymyxin B, paromomycin [Humatin], streptomycin, tobramycin, vancomycin). ■ May have dangerous additive effects with **anesthetics** (e.g., enflurane), **other neuromuscular blocking antibiotics** (e.g., kanamycin, streptomycin), **beta-lactam antibiotics** (e.g., cephalosporins), **diuretics** (e.g., furosemide [Lasix]), **vancomycin**, and many others. ■ **Neuromuscular blocking muscle relaxants** (e.g., atracurium [Tracrium], succinylcholine) are potentiated by aminoglycosides. **Apnea can occur**. ■ Aminoglycosides are also potentiated by **anticholinesterases** (e.g., edrophonium), **antineoplastics** (e.g., nitrogen mustard, cisplatin). ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); bactericidal action may be impacted.

SIDE EFFECTS

Occur more frequently with impaired renal function, higher doses, or prolonged administration, in dehydrated or elderly patients, and in patients receiving other ototoxic or nephrotoxic drugs.

Anorexia, burning, dizziness, fever, headache, hypertension, hypotension, itching, lethargy, muscle twitching, nausea, numbness, rash, roaring in ears, seizures, tingling sensation, tinnitus, urticaria, vomiting, weight loss.

Major: Acute organic brain syndrome; blood dyscrasias; CDAD; convulsions; elevated bilirubin, BUN, SCr, AST, and ALT; hearing loss; laryngeal edema; neuromuscular blockade; oliguria; respiratory depression or arrest.

ANTIDOTE

Notify the physician of all side effects. If minor side effects persist or any major symptom appears, notify the physician; may require dose adjustment or discontinuation of gentamicin. Treatment is symptomatic. In overdose or toxic reactions, hemodialysis may be indicated. Rate of gentamicin removal is lower with peritoneal dialysis. Monitor fluid balance, CrCl, and plasma levels carefully. Complexation with ticarcillin may be as effective as hemodialysis. Consider exchange transfusion in the newborn. Calcium salts or neostigmine may reverse neuromuscular blockade. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Resuscitate as necessary.

GLUCAGON (rDNA ORIGIN)

(GLOO-kah-gon)

Antihypoglycemic
Diagnostic agent
Antidote

GlucaGen, Glucagon for Injection

pH 2.5 to 3.5

USUAL DOSE

Hypoglycemia in adults and pediatric patients weighing more than 20 kg (Glucagon [44 lbs]) to 25 kg (GlucaGen [55 lbs]): 1 mg. May be given IV, IM, or SC. Usually awakens an unconscious patient within 15 minutes. May be repeated in 20 minutes. For severe hypoglycemia or when patient fails to respond to glucagon, IV dextrose should be administered. Up to 2 mg of glucagon has been given as initial dose.

Diagnostic aid: stomach, duodenal bulb, duodenum, and small bowel: 0.2 to 0.5 mg IV or 1 mg IM before procedure begins. One source suggests 0.5 to 2 mg IV or 1 to 2 mg IM depending on the onset of action and duration of effect required for the specific examination. Upper range doses may be indicated during prolonged scan times (e.g., during an MRI [duration of action of glucagon is longer if given IM]). When diagnostic procedure is over, administer oral carbohydrates; see [Monitor](#).

Diagnostic aid: colon: 0.5 to 0.75 mg IV or 1 to 2 mg IM before procedure begins. When diagnostic procedure is over, administer oral carbohydrates; see [Monitor](#).

Management of cardiac effects of beta-blocker or calcium channel blocker overdose (unlabeled): 50 mcg/kg over 1 to 2 minutes. Doses up to 10 mg may be needed if the initial dose is ineffective. May be followed by an infusion of 2 to 5 mg/hr (up to a maximum of 10 mg/hr) diluted in D5W. Titrate to patient response. AHA guidelines recommend 3 to 10 mg slowly over 3 to 5 minutes, followed by an infusion of 3 to 5 mg/hr.

Treatment of foreign body obstruction in the esophagus (unlabeled): 0.5 to 2 mg IV. Repeat in 10 minutes if necessary.

PEDIATRIC DOSE

Hypoglycemia in infants and children weighing less than 20 kg (Glucagon [44 lbs]) to 25 kg (GlucaGen [55 lbs]): 20 to 30 mcg/kg or 0.5 mg. See comments under [Usual Dose](#). If the weight is unknown, use 0.5 mg for pediatric patients younger than 6 years of age and 1 mg for those 6 years of age and older.

DOSE ADJUSTMENTS

For uses other than hypoglycemia, lower-end doses may be indicated in the elderly; consider impaired organ function and concurrent disease or other drug therapy.

DILUTION

Dilute 1 unit (1 mg) with 1 mL SWFI (may be supplied). Shake vial gently until completely dissolved. Concentrations greater than 1 mg/mL are not recommended. Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set if a dextrose solution is infusing. A 2-mg dose may be diluted with an equal amount of SWFI.

Reverse effects of beta blockade: Reconstitute each 1 unit (1 mg) with 1 mL SWFI. For *continuous infusion* this reconstituted solution may be further diluted in D5W to deliver 1 to 5 mg/hr.

Storage: Use immediately after reconstitution. Discard any unused portion. Store *GlucaGen for injection* at CRT before reconstitution. Before reconstitution, *GlucaGen* may be stored at CRT for up to 24 months in original package to protect from light. Do not freeze.

COMPATIBILITY

May form a precipitate with saline solutions and solutions with a pH of 3 to 9.5. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Too-rapid rate of injection or doses over 1 mg may increase incidence of side effects (e.g., nausea and vomiting).

1 unit (1 mg) or fraction thereof over 1 minute.

ACTIONS

An antihypoglycemic agent and a gastrointestinal motility inhibitor. A polypeptide hormone identical to naturally occurring human glucagon produced by recombinant DNA technology. Induces liver glycogen breakdown, releasing glucose from the liver. Blood glucose is raised within 10 minutes. Glucagon acts only on liver glycogen; hepatic stores of glycogen are necessary for glucagon to produce an antihypoglycemic effect. Extrahepatic effect produces relaxation of the smooth muscle of the stomach, duodenum, small bowel, and colon, inhibiting GI motility. Maximal glucose concentrations are seen about ½ hour after administration. Onset of smooth muscle relaxation is less than 1 minute. Duration of antihypoglycemic effect is 60 to 90 minutes. Duration of smooth muscle relaxation is dose-dependent and ranges from 9 to 25 minutes. Has a half-life of 8 to 18 minutes. Degraded in the liver, kidney, and plasma. Does not cross the placental barrier.

INDICATIONS AND USES

Treatment of severe hypoglycemia (e.g., during insulin therapy in the management of diabetes mellitus). ■ As a diagnostic aid in the radiologic examination of the stomach, duodenum, small bowel, and colon when diminished intestinal motility would be advantageous.

Unlabeled uses: May be helpful in reversing adverse beta-blockade of beta-adrenergic blocking agents (e.g., propranolol) in overdose situations. ■ If conventional therapy is ineffective, may be helpful in reversing myocardial depression of calcium channel blockers (e.g., diltiazem [Cardizem]). ■ To decrease motility and aid in removing foreign bodies in the lower esophagus, including food boluses.

CONTRAINDICATIONS

Glucagon for injection: Known hypersensitivity to glucagon or its components, patients with known pheochromocytoma. **GlucaGen:** Known hypersensitivity to GlucaGen, lactose, or any of its components, patients with pheochromocytoma or insulinoma.

PRECAUTIONS

Easily absorbed IM or SC. ■ If glucagon and glucose do not awaken patient, coma is probably caused by a condition other than hypoglycemia. ■ Use caution in patients with a history suggestive of insulinoma, glucagonoma, and/or pheochromocytoma; secondary hypoglycemia may occur. Treat with adequate carbohydrate intake. ■ May cause the release of catecholamines in patients with pheochromocytoma. ■ Evaluation by a physician is recommended for all patients who experience severe hypoglycemia. ■ Use caution in patients with conditions that result in low levels of releasable glucose (e.g., adrenal insufficiency, chronic hypoglycemia, prolonged fasting, starvation). Will result in inadequate reversal of hypoglycemia. Treatment with dextrose is recommended. ■ Use caution; hypersensitivity reactions have occurred, usually in association with endoscopic examination during which other agents are administered (e.g., contrast media, local anesthetics). ■ As a smooth muscle relaxant, it is as effective as anticholinergic drugs and has fewer side effects. ■ When used to inhibit gastrointestinal motility, use caution in patients with known cardiac disease. ■ Hypotension has been reported for up to 2 hours after use as premedication for upper GI endoscopy procedures. ■ See [Drug/Lab Interactions](#).

Monitor: Should awaken patient in 5 to 20 minutes. Prolonged hypoglycemic reactions may result in severe cortical damage. ■ Repeat dose if necessary. Supplement with IV dextrose (50%) to precipitate awakening and avoid complications of cerebral hypoglycemia. ■ Use blood glucose measurements to monitor patient response. ■ Emesis on awakening is common. Prevent aspiration by turning patient face down. ■ Depletes glycogen stores, especially in children and adolescents; supplement with oral carbohydrates on awakening to prevent secondary hypoglycemia. ■ In the treatment of beta-adrenergic blocker toxicity, may be used with isoproterenol (Isuprel) or dobutamine if

indicated. Glucagon may decrease serum potassium levels; supplemental potassium may be indicated. ■ Monitor for S/S of hypersensitivity (e.g., dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria).

Patient Education: Eat some form of sugar if hypoglycemia recurs. ■ Report episodes of hypoglycemia and glucagon use at home. ■ Teach patient and family proper storage and preparation of glucagon from kits. Include signs of hypoglycemia and procedures to be followed after administration to an unconscious patient.

Maternal/Child: Category B: use during pregnancy only if clearly needed. Use caution during breast-feeding. Not absorbed through the GI tract; it would be unlikely to have any effect on the infant. ■ Does not cross the placental barrier. ■ Safety and effectiveness for treatment of hypoglycemia in pediatric patients has been demonstrated; however, safety and effectiveness for use in pediatric patients as a diagnostic aid has not been established.

Elderly: Cautious dosing may be indicated in the elderly; see [Dose Adjustments](#). ■ Differences in response compared to younger adults not identified. ■ If used to inhibit gastrointestinal motility, use caution in elderly patients with known cardiac disease.

DRUG/LAB INTERACTIONS

Beta-blockers (e.g., metoprolol [Lopressor], sotalol) may cause a temporary increase in BP and pulse; treatment may be required in patients with cardiac disease or pheochromocytoma. ■ Concurrent use with **indomethacin** (Indocin) may cause glucagon to lose its ability to raise blood glucose and may produce hypoglycemia. ■ Coadministration with **anticholinergic** agents (e.g., atropine) is not recommended due to increased GI side effects. ■ May increase the anticoagulant effects of **warfarin** (Coumadin). ■ **Insulin** reacts antagonistically toward glucagon; use caution when used as a diagnostic aid in patients with diabetes.

SIDE EFFECTS

Rare in recommended doses: hyperglycemia (excessive dosage), hypersensitivity reactions (e.g., anaphylaxis, dyspnea, hypotension, rash), hypotension, increased BP, increased HR, nausea, vomiting. Increases in BP and HR may be greater in patients taking beta-blockers.

Overdose: Nausea and vomiting, increase in BP and HR, inhibition of GI tract motility, hypokalemia.

ANTIDOTE

Nausea and vomiting are tolerable and do occur in hypoglycemia. Antiemetics are indicated when larger doses are given. Increased BP and HR may require treatment in patients with coronary heart disease or pheochromocytoma. Treat sudden increases in BP with phentolamine 5 to 10 mg IV. For any other side effects, discontinue the drug and notify the physician. Treat hypersensitivity reactions and resuscitate as necessary. Insulin administration may be indicated in acute overdose. Effects of dialysis unknown; unlikely to provide benefit because of the short half-life of glucagon and the nature of the symptoms of overdose.

GLUCARPIDASE

(gloo-KAR-pi-dase)

Antidote

Voraxaze

USUAL DOSE

50 units/kg as a single intravenous injection over 5 minutes.

PEDIATRIC DOSE

See Usual Dose.

DOSE ADJUSTMENTS

No dose adjustment is recommended in patients with renal impairment. ■ Has not been studied in patients with hepatic impairment.

DILUTION

Available in a vial containing 1,000 units of lyophilized powder. Reconstitute with 1 mL of NS to provide a solution containing 1,000 units/vial. Roll and tilt vial gently to mix. **Do not shake.** Solution should be clear and colorless. Withdraw calculated dose from vial for administration as a bolus injection.

Storage: Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Do not freeze. Do not use beyond expiration date on vial. Use reconstituted solution immediately or store under refrigeration for up to 4 hours. Discard any unused product.

COMPATIBILITY

Specific information not available. Consider specific use and potential for hypersensitivity reactions.

RATE OF ADMINISTRATION

Administer as an injection evenly distributed over 5 minutes. Flush IV line before and after administration.

ACTIONS

A carboxypeptidase enzyme produced by recombinant DNA technology. Hydrolyzes the carboxyl-terminal glutamate residue from folic acid and classic antifolates such as methotrexate. Converts methotrexate to its inactive metabolite, 4-deoxy-4-amino-N10-methylpteroic acid (DAMPA) and glutamate. Glucarpidase provides an alternate nonrenal pathway for methotrexate elimination in patients with renal dysfunction during high-dose methotrexate treatment. The desired end point of therapy is a rapid and sustained clinically important reduction (RSCIR) in methotrexate concentration, which is defined as attaining a plasma methotrexate concentration less than or equal to 1 $\mu\text{mol/L}$ at 15 minutes and sustaining it for up to 8 days after administration of glucarpidase. The likelihood of attaining a RSCIR correlates with the pre-glucarpidase methotrexate concentration. However, even patients with methotrexate concentrations greater than 50 $\mu\text{mol/L}$ were able to achieve greater than 95% reduction in methotrexate concentrations for up to 8 days following glucarpidase administration. Glucarpidase distribution is restricted to the plasma volume. Mean elimination half-life is 5.6 hours.

INDICATIONS AND USES

Treatment of toxic plasma methotrexate concentrations (greater than 1 $\mu\text{mol/L}$) in patients with delayed methotrexate clearance due to impaired renal function.

Limitation of use: Not indicated for use in patients who exhibit the expected clearance of methotrexate (plasma methotrexate concentrations within 2 standard deviations of the mean methotrexate excretion curve specific for the dose of methotrexate administered) or in patients with normal or mildly impaired renal function because of the potential risk of subtherapeutic exposure to methotrexate.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Serious hypersensitivity reactions, including anaphylaxis, have been reported. ■ Efficacy of a second dose of glucarpidase in patients with markedly elevated pre-glucarpidase methotrexate concentrations was not demonstrated in studies. ■ Continue hydration, alkalinization of the urine, and leucovorin rescue as indicated; see **Monitor** and methotrexate and leucovorin monographs. ■ A protein substance, it has the potential to produce immunogenicity. Anti-glucarpidase antibodies have been detected in a small number of patients treated with glucarpidase.

Monitor: Obtain baseline and periodic renal function tests (e.g., SCr and BUN). ■ Watch for early S/S of hypersensitivity or infusion reactions (e.g., chills, dyspnea, fever, flushing, headache, hives, itching, numbness, rash, throat tightness). ■ Monitor methotrexate concentrations. During the first 48 hours after glucarpidase administration, methotrexate concentrations can be reliably measured only by a chromatographic method. During this period, DAMPA (the inactive metabolite of methotrexate) interferes with the measurement of methotrexate concentration using immunoassays. ■ Continue to administer leucovorin after glucarpidase. Do not administer leucovorin within 2 hours before or after a dose of glucarpidase; see **Drug/Lab Interactions**. ■ For 48 hours after glucarpidase administration, determine the leucovorin dose based on the patient's pre-glucarpidase methotrexate concentration. Beyond 48 hours, administer leucovorin based on the measured methotrexate concentration. Continue therapy with leucovorin until the methotrexate concentration has been maintained below the leucovorin treatment threshold for a minimum of 3 days; see leucovorin monograph. Monitor for S/S of potential methotrexate toxicity (e.g., abdominal distress, chills, dizziness, fever, leukopenia, malaise, nausea, stomatitis, undue fatigue).

Patient Education: Promptly report any S/S of a hypersensitivity reaction or an infusion reaction (e.g., chills, feeling hot, fever, flushing, headache, hives, itching, numbness, rash, throat tightness or breathing problems, tingling). ■ Continued monitoring of methotrexate levels and renal status is imperative.

Maternal/Child: Category C: no human or animal data. Safety for use during pregnancy and breast-feeding not established. Use only if clearly needed. ■ Effectiveness in pediatric patients has been established in clinical studies. No overall differences in safety were observed between pediatric patients (age 1 month to 17 years of age) and adult patients.

Elderly: No overall differences in safety or effectiveness were observed between elderly patients and younger patients.

DRUG/LAB INTERACTIONS

Leucovorin is a substrate for glucarpidase. Do not administer leucovorin within 2 hours before or after a dose of glucarpidase. ■ Other potential exogenous substrates of glucarpidase include **reduced folates and folate antimetabolites**.

SIDE EFFECTS

The most commonly reported side effects included flushing, headache, hypotension, nausea, paraesthesia, and vomiting. Other reported adverse reactions included blurred vision, diarrhea, hypersensitivity reactions (including anaphylaxis), hypertension, rash, throat irritation or tightness, and tremor.

ANTIDOTE

Notify the physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated (airway, oxygen, IV fluids, antihistamines [e.g., diphenhydramine (Benadryl)], corticosteroids [e.g., hydrocortisone sodium succinate (Solu-Cortef)], epinephrine, pressor amines [e.g., dopamine]) and resuscitate as necessary.

GLYCOPYRROLATE

(GLYE-koh-pye-roh-layt)

Anticholinergic
Antidote

Robinul

pH 2 to 3

USUAL DOSE

Dose equivalents in mL are based on the 0.2 mg/mL concentration. Check vial for correct concentration.

Preanesthetic medication: 0.004 mg/kg (0.02 mL/kg) of body weight IM 30 to 60 minutes before anesthesia induction. Usually given at the same time as the preanesthetic narcotic and/or sedative.

Intraoperative medication: 0.1 mg (0.5 mL) IV. Repeat as needed at 2- to 3-minute intervals to counteract drug-induced or vagal traction reflexes and associated arrhythmias (e.g., bradycardia). Attempt to determine the etiology of arrhythmia and the procedures required to correct parasympathetic imbalance.

Reversal of neuromuscular blockade: 0.2 mg (1 mL) IV for each 1 mg of neostigmine or 5 mg of pyridostigmine (Regonol); to minimize the bradycardia and excessive secretions caused by these agents used to reverse the neuromuscular blockade of nondepolarizing muscle relaxants. May be administered simultaneously and may be mixed in the same syringe.

Peptic ulcer: 0.1 mg (0.5 mL) at 4-hour intervals 3 to 4 times/day. May be given IV or IM. Adjust frequency of administration based on patient response. Some may require only a single dose. If a more profound effect is required, dose may be increased to 0.2 mg (1 mL).

Respiratory antisecretory: 0.1 to 0.2 mg/dose (0.5 to 1 mL/dose) every 4 to 8 hours. Maximum dose suggested is 0.2 mg/dose or 0.8 mg/24 hr.

PEDIATRIC DOSE

See [Maternal/Child](#).

Preanesthetic medication: Same as Usual Dose. **Infants 1 month to 2 years of age:** May require up to 0.009 mg/kg (0.045 mL/kg) of body weight.

Intraoperative medication: Rarely needed in pediatric patients because of the long duration of action from the preanesthetic dose. If required, administer 0.004 mg/kg (0.02 mL/kg) of body weight IV. Do not exceed 0.1 mg (0.5 mL) in a single dose. Repeat as needed at 2- to 3-minute intervals to counteract drug-induced or vagal traction reflexes and associated arrhythmias (e.g., bradycardia). Attempt to determine the etiology of arrhythmia and the procedures required to correct parasympathetic imbalance.

Reversal of neuromuscular blockade: Same as Usual Dose.

Peptic ulcer: Not recommended for treatment of peptic ulcer in pediatric patients; see [Maternal/Child](#).

Respiratory antisecretory: 0.004 to 0.01 mg/kg/dose (0.02 to 0.05 mL/kg/dose) every 4 to 8 hours. Maximum dose suggested is 0.2 mg/dose or 0.8 mg/24 hr.

DOSE ADJUSTMENTS

Caution and lower-end dosing suggested for elderly patients based on potential for decreased organ function and concomitant disease or drug therapy. ■ Elimination prolonged in patients with renal failure. Dose adjustment not provided; see [Precautions](#). ■ See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted. Administer through Y-tube or three-way stopcock of infusion tubing containing D5 or D10 in water or saline, D5¹/₂NS, NS, or Ringer's. May be further diluted with D5 or D10 in water or saline.

Filters: No data available from manufacturer.

Storage: Store at CRT.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with lactated Ringer's and states, "Stability is questionable above a pH of 6. May form a precipitate or a gas with chloramphenicol (Chloromycetin), diazepam (Valium), dimenhydrinate, methohexitol (Brevital), pentazocine (Talwin), pentobarbital (Nembutal), sodium bicarbonate; do not combine in the same syringe." Dexamethasone (Decadron) will result in a pH above 6.

One source suggests the following **compatibilities**:

Y-site: Palonosetron (Aloxi), propofol (Diprivan).

RATE OF ADMINISTRATION

0.2 mg or fraction thereof over 1 to 2 minutes.

ACTIONS

A synthetic anticholinergic agent. It inhibits the action of acetylcholine. It reduces the volume and free acidity of gastric secretions and controls excessive pharyngeal, tracheal, and bronchial secretions. Antagonizes muscarinic symptoms (e.g., bronchorrhea, bronchospasm, bradycardia, and intestinal hypermotility) induced by cholinergic drugs. Onset of action is within 1 minute. Vagal blocking effects last 2 to 3 hours, and antisialagogic (inhibited saliva flow) effects last up to 7 hours. Metabolism has not been studied. Half-life is 0.7 to 0.96 hours. Excreted primarily in urine and to a small extent in bile. Does not effectively cross the blood-brain barrier. Crosses the placental barrier in very small amounts.

INDICATIONS AND USES

Adjunctive therapy in peptic ulcer. ■ Protection against the peripheral muscarinic effects (e.g., bradycardia and excessive secretions) of cholinergic agents such as neostigmine and pyridostigmine (Regonol) given to reverse the neuromuscular blockade due to nondepolarizing muscle relaxants (e.g., atracurium [Tracrium]). ■ Reduction of salivary, tracheobronchial, and pharyngeal secretions preoperatively. ■ Reduction of volume and free acidity of gastric secretions. ■ Other intraoperative uses controlled by the anesthesiologist (counteract drug-induced or vagal traction reflexes and associated arrhythmias, prevent aspiration pneumonitis).

CONTRAINDICATIONS

Known hypersensitivity to glycopyrrolate. May be contraindicated in patients with glaucoma, obstructive uropathy, obstructive disease of the GI tract, paralytic ileus, intestinal atony of the elderly or debilitated, unstable cardiovascular status in acute hemorrhage, severe ulcerative colitis, toxic megacolon, and myasthenia gravis, when used for treatment of peptic ulcer disease because of long duration of therapy. ■ Do not use in neonates.

PRECAUTIONS

Use IV only when immediate drug effect is essential. ■ Use extreme caution in autonomic neuropathy, asthma, glaucoma, pregnancy, breast-feeding, cardiac arrhythmias, congestive heart failure, coronary artery disease, hepatic or renal disease, hiatal hernia, hypertension, hyperthyroidism, incomplete intestinal obstruction (diarrhea may be an early symptom), ulcerative colitis, and prostatic hypertrophy. Anticholinergic drugs may aggravate these conditions. ■ Obtain cardiac history before administration of glycopyrrolate; may exacerbate pre-existing tachycardia. ■ Heat prostration can occur with the use of anticholinergic agents in the presence of fever or high environmental temperatures. Pediatric patients and the elderly are at increased risk.

Monitor: Urinary retention can be avoided if the patient voids just before each dose. ■ See [Drug/Lab Interactions](#).

Patient Education: Use caution if a task requires alertness; may cause blurred vision, dizziness, or drowsiness. ■ Report constipation, difficulty urinating, dry mouth, flushing, increased light sensitivity, or skin rash promptly. ■ Use caution during exercise or hot weather. Increased heat sensitivity may result in heatstroke.

Maternal/Child: Category B: safety for use in pregnancy not established. ■ It is not known whether this drug is secreted in breast milk; may suppress lactation; use caution. ■ Safety and effectiveness for use in pediatric patients under 16 years of age not established for management of peptic ulcer. ■ Dysrhythmias have been observed in pediatric patients. ■ Pediatric patients may have an increased response to anticholinergics and be at increased risk for side effects (e.g., paradoxical hyperexcitability). Infants and young children, patients with Down syndrome, and pediatric patients with spastic paralysis or brain damage are especially susceptible to this increased response. ■ **Contains benzyl alcohol; do not use in neonates;** see **Contraindications**.

Elderly: Differences in response compared to younger adults not observed. ■ Dosing should be cautious; see **Dose Adjustments**. ■ May produce excitement, agitation, confusion, or drowsiness in the elderly. ■ May precipitate undiagnosed glaucoma. ■ Risk of urinary retention and constipation increased. ■ May increase memory impairment.

DRUG/LAB INTERACTIONS

Potentiated by other drugs with **anticholinergic activity** (e.g., amantadine [Symmetrel], **antiparkinson drugs** [e.g., levodopa (Larodopa, Dopar)], **atropine**, **phenothiazines** [e.g., prochlorperazine (Compazine)], **tricyclic antidepressants** [e.g., amitriptyline (Elavil), imipramine (Tofranil)]). Reduced dose of either or both drugs may be indicated. ■ Concomitant administration with **KCl** in a wax matrix may increase the risk and severity of KCl-induced GI lesions (due to slower GI transit time). ■ May decrease antipsychotic effects of **phenothiazines**. Dose adjustment may be required. ■ Risk of ventricular arrhythmias increased when given in presence of **cyclopropane**. Risk is less than with atropine and when given in doses of 0.1 mg or less. ■ Potentiates **atenolol** (Tenormin) and **digoxin**.

SIDE EFFECTS

Anaphylaxis, anticholinergic psychosis, arrhythmias, blurred vision, cardiac arrest, confusion, constipation, decreased sweating, dizziness, drowsiness, dry mouth, headache, heat prostration, hypertension, hypotension, impotence, increased ocular tension, injection site reactions, insomnia, loss of taste, malignant hyperthermia, muscular weakness, nausea and vomiting, nervousness, palpitation, paralysis, photophobia, pruritus, respiratory arrest, seizures, suppression of lactation, tachycardia, urinary hesitancy and retention, urticaria, weakness.

Overdose: A curare-like action may occur (i.e., neuromuscular blockade leading to muscular weakness and possible paralysis).

ANTIDOTE

Notify physician of all side effects. May be treated symptomatically or drug may be discontinued. Treat hypotension with IV fluids and/or pressor agents (e.g., dopamine). Initiate artificial respiration if overdose with paralysis of respiratory muscles occurs. Neostigmine, in 0.25-mg increments, may be used to counteract peripheral anticholinergic effects. May repeat every 5 to 10 minutes to a maximum dose of 2.5 mg. Need for repetitive doses of neostigmine should be based on close monitoring of the decrease in HR and the return of bowel sounds. Physostigmine, in increments of 0.5 to 2 mg, may be used to counteract CNS effects. May repeat as needed to a maximum dose of 5 mg. Proportionately smaller doses should be used in pediatric patients. Resuscitate as necessary.

GRANISETRON HYDROCHLORIDE

(gran-**ISS**-eh-tron hy-droh-**KLOR**-eyed)

Antiemetic
(5-HT₃ receptor antagonist)

Kytril

pH 4 to 6

USUAL DOSE

Chemotherapy-induced nausea and vomiting (prophylaxis): A single dose of 10 mcg/kg of body weight as an injection or as an infusion. Begin within 30 minutes before giving emetogenic cancer chemotherapy (e.g., cisplatin, carboplatin) and only on the day(s) chemotherapy is given. Clinical trials used doses up to 40 mcg/kg with effects similar to the recommended 10-mcg/kg dose. Some studies question the effectiveness of a 10-mcg/kg dose. Repeat doses are frequently required to prevent nausea with chemotherapy. Oral granisetron is available.

Prevention and treatment of postoperative nausea and vomiting: 1 mg before induction of anesthesia, immediately before reversal of anesthesia, or postoperatively.

PEDIATRIC DOSE

Chemotherapy-induced nausea and vomiting (prophylaxis) in pediatric patients 2 to 16 years of age: Identical to adult dose. See *Maternal/Child*.

DOSE ADJUSTMENTS

No dose adjustment required for the elderly or in renal failure or impaired hepatic function.

DILUTION

Read label carefully. Available in two concentrations (0.1 mg/mL and 1 mg/mL). The 0.1-mg/mL vial contains no preservatives. The 1-mg/mL single-dose and multidose vials contain benzyl alcohol. Sterile technique imperative when withdrawing a single dose from the multidose vial; see *Storage*.

A single dose may be given undiluted by IV injection or further diluted to a total volume of 20 to 50 mL with NS or D5W and given as an infusion.

Storage: Store vials at CRT or below. Do not freeze; protect from light. Should be administered after dilution (preservative free) but is stable up to 24 hours at room temperature. Discard multidose vial within 30 days of initial penetration.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends not mixing in solution with other drugs as a general precaution.

One source suggests the following **compatibilities**:

Additive: **Not recommended by manufacturer.** Dexamethasone (Decadron), methylprednisolone (Solu-Medrol).

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), aminophylline, amphotericin B cholesteryl (Amphotec), ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefotetan (Cefotan), cefoxitin (Mefoxin), ceftaroline (Teflaro), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), cisplatin (Platinol), cladribine (Leustatin), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), daunorubicin (Cerubidine), dexamethasone (Decadron), dexmedetomidine (Precedex), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), etoposide (VePesid), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fil-

grastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gallium nitrate (Ganite), ganciclovir (Cytovene), gemcitabine (Gemzar), gentamicin, heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), leucovorin calcium, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, mechlorethamine (nitrogen mustard), melphalan (Alkeran), meperidine (Demerol), mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), mitomycin (Mutamycin), mitoxantrone (Novantrone), morphine, nalbuphine, oxaliplatin (Eloxatin), paclitaxel (Taxol), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), propofol (Diprivan), ranitidine (Zantac), sargramostim (Leukine), sodium bicarbonate, streptozocin (Zanosar), sulfamethoxazole/trimethoprim, teniposide (Vumon), thiotepa, ticarcillin/clavulanate (Timentin), tobramycin, topotecan (Hycamtin), vancomycin, vinblastine, vincristine, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

IV injection: A single dose over 30 seconds.

Intermittent infusion: A single dose equally distributed over 5 minutes.

ACTIONS

An antinauseant and antiemetic agent. A selective antagonist of specific serotonin (5-HT₃) receptors. Chemotherapeutic agents such as cisplatin increase the release of serotonin from specific cells in the GI tract, causing emesis. By antagonizing these receptors, chemotherapy-induced nausea and vomiting are prevented. Has little effect on BP, HR, ECG, plasma prolactin, or aldosterone concentrations. Moderately bound to protein (65%). Distributes freely between plasma and RBCs. Metabolized in the liver by hepatic cytochrome P₄₅₀ enzymes. Mean half-life is approximately 9 hours. Excreted in urine and feces.

INDICATIONS AND USES

Prevention of nausea and vomiting associated with initial and repeat courses of emetogenic cancer therapy, including high-dose cisplatin. Has been shown to be effective with most emetogenic antineoplastic agents. ■ Prevention and treatment of postoperative nausea and vomiting in adults.

Unlabeled uses: Prevention of nausea and vomiting associated with total body radiation or fractional abdominal radiation.

CONTRAINDICATIONS

Known hypersensitivity to granisetron.

PRECAUTIONS

Stool softeners or laxatives may be required to prevent constipation. ■ See **Drug/Lab Interactions**. ■ Hypersensitivity reactions have been reported. Use caution in patients who have exhibited hypersensitivity to other selective 5-HT₃ receptor antagonists. Cross-sensitivity has been reported between dolasetron (Anzemet) and other agents in this class (e.g., granisetron, ondansetron). ■ The use in patients following abdominal surgery or in patients with chemotherapy-induced nausea and vomiting may mask a progressive ileus and/or gastric distention. ■ Does not stimulate GI motility and should not be used instead of NG suction. ■ QT prolongation has been reported. Use with caution in patients with pre-existing arrhythmias, cardiac conduction disorders, or electrolyte abnormalities or in patients who are taking other medications that can prolong the QT interval; see **Drug/Lab Interactions**. ■ Not recommended if nausea and vomiting are not expected postoperatively unless nausea and vomiting must be avoided during the postoperative period.

Monitor: Ambulate slowly to avoid orthostatic hypotension. ■ Monitor for S/S of hypersensitivity (e.g., anaphylaxis, hypotension, shortness of breath, urticaria).

Patient Education: Request assistance for ambulation. ■ Report promptly if nausea persists for more than 10 minutes. ■ Maintain adequate hydration. ■ Stool softeners may be required to avoid constipation.

Maternal/Child: Category B: no evidence of impaired fertility or harm to fetus. Benzyl alcohol may cross the placenta; see **Dilution**. Use during pregnancy only if benefits justify risks. ■ Use caution if required during breast-feeding. ■ Safety and effectiveness for use in the treatment of chemotherapy-induced nausea and vomiting in pediatric patients under 2 years of age have not been established. ■ Not recommended for prevention and treatment of postoperative nausea and vomiting in pediatric patients due to a lack of efficacy and QT prolongation observed in a clinical trial.

Elderly: Response similar to other age-groups. ■ Clearance lower and half-life prolonged but has no clinical significance.

DRUG/LAB INTERACTIONS

Metabolism may be inhibited by **ketoconazole** (Nizoral). Clinical significance unknown. ■ Does not induce or inhibit the cytochrome P₄₅₀ drug metabolizing system, but definitive interaction studies have not been done. Its clearance and half-life may be affected by **inducers of these enzymes** such as anticonvulsants (e.g., carbamazepine [Tegretol], phenobarbital [Luminal], phenytoin [Dilantin]) or rifampin (Rifadin) or by **inhibitors of these enzymes** (e.g., cimetidine [Tagamet], calcium channel blockers [e.g., diltiazem (Cardizem), verapamil], antiviral agents [e.g., indinavir (Crixivan), ritonavir [Norvir], saquinavir [Invirase]). ■ Has been safely administered with **benzodiazepines** (e.g., lorazepam [Ativan], midazolam [Versed]), **neuroleptics** (e.g., chlordiazepoxide [Librium]), and **antiulcer drugs** (e.g., ranitidine [Zantac]) commonly prescribed with antiemetic treatment. ■ Does not appear to interact with emetogenic cancer chemotherapies. ■ Concurrent use with **drugs known to prolong the QT interval** (e.g., amiodarone [Nexterone], anti-histamines, azole antifungals [e.g., itraconazole (Sporanox)], disopyramide [Norpace], fluoroquinolones [e.g., levofloxacin (Levaquin)], ibutilide [Corvert], mexiletine, phenothiazines [e.g., thioridazine (Mellaril)], procainamide [Pronestyl], quinidine, and tricyclic antidepressants [e.g., amitriptyline (Elavil), imipramine (Tofranil)]) may result in clinical consequences.

SIDE EFFECTS

Asthenia (5%), constipation (3%), diarrhea (4%), headache (14%), somnolence (4%), and weakness (5%) occur most frequently. Hypersensitivity reactions, including anaphylaxis (rare), have occurred. Transient elevation of AST or ALT may occur. Other side effects include abdominal pain, anemia, anxiety, bradycardia, coughing, dizziness, dyspepsia, fever, hypertension, hypotension, infection, insomnia, leukocytosis, oliguria, pain. Other side effects have occurred in fewer than 2% of patients but could not be clearly associated with granisetron.

Post-Marketing: QT prolongation.

ANTIDOTE

Most side effects will be treated symptomatically. Keep physician informed as indicated. There is no specific antidote. Treat anaphylaxis and resuscitate as necessary.

HEMIN **BBW**

(HEE-men)

Porphyrin inhibitor

Panhematin**USUAL DOSE**

A single dose of 1 to 4 mg/kg of body weight/24 hr of hematin for 3 to 14 days. This dose could be repeated in 12 hours for severe cases. Never exceed a total dose of 6 mg/kg/24 hr. Length of treatment dependent on severity of symptoms and clinical response. See **Precautions**.

DILUTION

Each vial containing 313 mg of hemin must be diluted with 43 mL of SWFI (provides 301 mg of hematin). Shake well for 2 to 3 minutes to ensure dissolution. Each 1 mL contains 7 mg hematin. Each 0.14 mL contains 1 mg hematin. May be given directly from vial as an infusion or through Y-tube or three-way stopcock of infusion set.

Filters: Use of a 0.45-micron or smaller in-line filter recommended.

Storage: Store in refrigerator at 2° to 8° C. Contains no preservative, decomposes rapidly; discard unused solution.

COMPATIBILITY

Undergoes rapid chemical decomposition in solution. Manufacturer states, "No drug or chemical agent should be added unless its effect on the chemical and physical stability has been determined." Specific information not available; consult pharmacist.

RATE OF ADMINISTRATION

A single dose evenly distributed over 10 to 15 minutes.

ACTIONS

An iron-containing metalloporphyrin enzyme inhibitor extracted from RBCs. Inhibits rate of porphyria/heme biosynthesis in the liver and bone marrow by an unknown mechanism. Induces remission of symptoms only; not curative. Some excretion occurs in urine and feces.

INDICATIONS AND USES

To control symptoms of recurrent attacks of acute intermittent porphyria in selected patients (often related to the menstrual cycle in susceptible women).

CONTRAINDICATIONS

Hypersensitivity to hemin; porphyria cutanea tarda.

PRECAUTIONS

Confirm diagnosis of acute porphyria before use (positive Watson-Schwartz or Hoechst test). Administered by or under the supervision of a physician experienced in the treatment of porphyrias and in facilities equipped to monitor the patient and respond to any medical emergency. ■ Alternate therapy of 400 Gm glucose/24 hr for 1 to 2 days should be tried before use of hemin is initiated. ■ Give as early as possible with onset of attack to achieve the most benefit. ■ Must be given before irreversible neuronal damage of porphyria has begun. ■ See **Drug/Lab Interactions**.

Monitor: Use of a large arm vein or central venous catheter recommended to avoid phlebitis. ■ Effectiveness monitored by decrease in urine concentration of S-aminolevulinic acid (ALA), uroporphyrinogen (UPG), or porphobilinogen (PBG).

Maternal/Child: Category C: safety for use during pregnancy, breast-feeding, and in pediatric patients not established.

DRUG/LAB INTERACTIONS

Action inhibited by **estrogens, barbiturates, and steroid metabolites**. Avoid concurrent use. ■ Has mild anticoagulant effects. Avoid concurrent use with **anticoagulants** (e.g., heparin, warfarin [Coumadin]).

SIDE EFFECTS

Almost nonexistent with usual dosage and appropriate technique; fever, phlebitis. Reversible renal shutdown has been reported with excessive doses.

ANTIDOTE

Discontinue temporarily if known or questionable side effect appears and notify physician. Renal shutdown of overdose has responded to ethacrynic acid (Edecrin) and mannitol. Treat anaphylaxis (antihistamines, epinephrine, corticosteroids) and resuscitate as necessary.

HEPARIN SODIUM

Anticoagulant

(HEP-ah-rin SO-dee-um)

Hepalean[®], Heparin Lock-Flush, Heparin Sodium PF, Hep-Flush 10, Hep-Lock, Hep-Lock U/P

pH 5 to 7.5

USUAL DOSE

As of 2009 USP heparin has a new reference standard and a new test method for manufacturers to use in determining accurate potency. The adjustment in reference standard results in approximately a 10% reduction in the potency of heparin and makes it commensurate with the World Health Organization International Standard unit dose. In most situations this new reference standard will not require a dose adjustment; however, dose adjustments and more frequent monitoring may be indicated in selected clinical situations.

Intermittent injection: 10,000 units initially. Dosage is repeated every 4 to 6 hours and adjusted according to coagulation test results. Usually 5,000 to 10,000 units.

IV infusion: An initial bolus dose of 5,000 units is required. 20,000 to 40,000 units/24 hr in NS or other **compatible** infusion solution. Adjust dose according to coagulation test results.

Treatment of venous thromboembolism: American College of Chest Physicians recommend a bolus of 80 units/kg (maximum dose of 5,000 units) followed by a continuous infusion of 18 units/kg/hr (maximum rate of 1,300 units/hr).

Adjuvant therapy in treatment of AMI: AHA guidelines recommend an initial bolus dose of 60 units/kg of body weight (maximum dose 4,000 units). Follow with an infusion of 12 units/kg/hr. The initial maximum recommended infusion rate is 1,000 units/hr. Adjust to maintain aPTT at 1.5 to 2 times control. Other protocols are in use.

Adjuvant therapy during treatment with thrombolytic agents (e.g., alteplase, reteplase, streptokinase) and glycoprotein GPIIb/IIIa receptor antagonists (e.g., abciximab, eptifibatide, tirofiban): See individual monographs for suggested doses.

Open heart surgery: 150 to 400 units/kg of body weight during surgical procedure, depending on duration of procedure.

Disseminated intravascular coagulation: Use and dose of heparin is based on severity of DIC and underlying cause and extent of thrombosis. Several dosing regimens have been used; see literature.

Maintain patency of indwelling venipuncture devices used with a continuous infusion: 500 to 1,000 units to each 1,000 mL IV fluid.

Maintain patency of indwelling venipuncture devices (e.g., central venous line, heparin plugs) intended for intermittent use: 10 to 100 units. Dilute in a sufficient quantity of NS to fill the entire device (e.g., needle, catheter, or implanted port) and inject via injection hub. Use after each medication injection or every 8 to 24 hours. From 100 units up to 500 units may be required in central venous lines. Confirm patency by aspirating before each injection.

Continued

tion. Flush with SWFI or NS before and after any medication **incompatible** with heparin. Re-instill heparin after second flush. If additional medications are not needed, each single dose of heparin will prevent clotting within the lumen of indwelling venipuncture devices for up to 24 hours. Consult device manufacturer's instructions for specific requirements regarding its use.

Blood transfusion: 400 to 600 units/100 mL whole blood.

Converting to an oral anticoagulant: When converting from heparin to an oral anticoagulant (e.g., warfarin), begin the oral agent at the usual initial dose and determine PT at the usual intervals. To ensure continuous anticoagulation, continue full heparin therapy for several days after the PT has reached a therapeutic range. Once target PT/INR has been achieved and maintained for several days, heparin therapy can be discontinued without tapering.

PEDIATRIC DOSE

Read label carefully. Comes in many strengths. Confirm use of the correct strength. Fatal hemorrhages have occurred in pediatric patients, including neonates, as a result of medication errors in which heparin sodium injection vials have been confused with heparin-lock flush vials.

Do not use products containing benzyl alcohol in neonates or infants. Preservative-free solution is required for neonates and infants. See *Maternal/Child*.

Full-dose continuous IV infusion: A **loading dose** of 75 to 100 units/kg and a **maintenance dose** (to maintain an aPTT of approximately 60 to 85 seconds or a range corresponding to an anti-factor Xa level of 0.35 to 0.7 units/mL [for 5 to 10 days]) based on age as follows:

Infants less than 2 months: (Have the highest requirements) Average 28 units/kg/hr.

Infants 2 months to 1 year of age: 25 to 30 units/kg/hr.

Over 1 year of age: 18 to 20 units/kg/hr.

Older pediatric patients: May require less heparin, similar to the weight-adjusted dose in adults (18 units/kg/hr).

Another source suggests a **loading dose** of 50 units/kg followed by a **maintenance dose** of 25 units/kg/hr or up to 20,000 units/M² equally distributed over 24 hours. All doses should be adjusted to coagulation tests.

Disseminated intravascular coagulation: Use and dose of heparin is based on severity of DIC and underlying cause and extent of thrombosis. Several dosing regimens have been used; see literature.

Patency of indwelling venipuncture devices: See *Maternal/Child*. Safety and effectiveness of the 100-USP units/mL heparin lock flush solution for pediatric patients not established. Patency for peripheral devices (e.g., single- and double-lumen central catheters) is usually accomplished with 10 units/mL heparin solution in younger infants (e.g., less than 10 kg) and with 100 units/mL for older infants, children, and adults. Avoid approaching therapeutic unit/kg dose. Follow catheter manufacturer's guidelines. See all comments under similar section in *Usual Dose*.

DOSE ADJUSTMENTS

Reduction of initial dose indicated in low-birth-weight infants and may be indicated in patients 60 years of age and older (especially women). Dose is based on coagulation tests; see *Monitor*. ■ Increased dose may be required in smokers (half-life shortened and elimination rate increased).

DILUTION

May be given undiluted or diluted in any given amount of NS, dextrose, or Ringer's solution for infusion and given by IV injection, as an intermittent IV, or continuous IV infusion. **In all situations**, invert container a minimum of 6 times to ensure adequate mixing of heparin with solution. Available in several strengths for administration or dilution as well as in several premixed concentrations and volumes and in ADD-Vantage vials for use with ADD-Vantage infusion containers. Unit-dose heparin flush syringes are not for multiple use; discard unused portions.

Intermittent infusion: Usually diluted in 50 to 100 mL of NS.

Continuous infusion: Usually diluted in 1,000 mL of NS/24-hour dose.

Blood transfusion: Add 7,500 units heparin to 100 mL NS. Add 6 to 8 mL of this sterile solution to each 100 mL of whole blood.

Filters: No significant reduction in potency when 10,000 units diluted in D5W or NS was filtered through a 0.22-micron cellulose ester membrane filter.

Storage: Store at CRT. Do not freeze. Do not use if solution is discolored or contains a precipitate.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Several sources recommend not mixing or administering through the same IV line with other drugs until **compatibility** confirmed. To avoid precipitation with heparin, they also caution to flush with SWFI or NS before and after any acidic or **incompatible** medication or solution.

One source suggests the following **compatibilities**:

Additive: Aminophylline, amphotericin B (conventional), ampicillin, anti-thymocyte globulin (rabbit) (Thymoglobulin), ascorbic acid, bleomycin (Blenoxane), calcium gluconate, cefepime (Maxipime), ceftazidime (Fortaz), chloramphenicol (Chloromycetin), clindamycin (Cleocin), colistimethate (Coly-Mycin M), dimenhydrinate, dobutamine, dopamine, enalaprilat (Vasotec IV), esmolol (Brevibloc), fluconazole (Diflucan), flumazenil (Romazicon), furosemide (Lasix), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), isoproterenol (Isuprel), lidocaine, lincomycin (Lincocin), magnesium sulfate, meropenem (Merrem IV), methyl dopate, methylprednisolone (Solu-Medrol), mitomycin (Mutamycin), nafcillin (Nallpen), norepinephrine (Levophed), octreotide (Sandostatin), penicillin G potassium and sodium, potassium chloride, ranitidine (Zantac), sodium bicarbonate, vancomycin, verapamil.

Y-site: Acyclovir (Zovirax), aldesleukin (Proleukin), allpurinol (Aloprim), amifostine (Ethylol), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), anti-thymocyte globulin (rabbit), atracurium (Tracrium), atropine, aztreonam (Azactam), bivalirudin (Angiomax), bleomycin (Blenoxane), caffeine citrate, calcium gluconate, cefazolin (Ancef), cefotetan (Cefotan), ceftaroline (Teflaro), ceftazidime (Fortaz), ceftriaxone (Rocephin), chlorpromazine (Thorazine), cisatracurium (Nimbex), cisplatin (Platinol), cladribine (Leustatin), clindamycin (Cleocin), cyclophosphamide (Cytosan), dacarbazine (DTIC), daptomycin (Cubicin), dexamethasone (Decadron), dexmedetomidine (Precedex), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxapram (Dopram), doxorubicin liposomal (Doxil), droperidol (Inapsine), edrophonium (Enlon), enalaprilat (Vasotec IV), epinephrine (Adrenalin), ertapenem (Invanz), erythromycin (Erythrocin), esmolol (Brevibloc), estrogens, conjugated (Premarin), ethacrynic acid (Edecrin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), foscarnet (Foscavir), furosemide (Lasix), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hex-tend), hydralazine, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), insulin (regular), isoproterenol (Isuprel), labetalol, leucovorin calcium, lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), methotrexate, methyl dopate, methylergonovine (Methergine), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metoprolol (Lopressor), metronidazole (Flagyl IV), micafungin (Mycamine), midazolam (Versed), milrinone (Primacor), mitomycin (Mutamycin), morphine, nafcillin (Nallpen), neostigmine, nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), ondansetron (Zofran), oxacillin (Bactocill), oxaliplatin (Eloxatin), oxytocin (Pitocin), paclitaxel (Taxol), palonosetron (Aloxi), pancuronium, pemetrexed (Alimta), penicillin G potassium, pentazocine (Talwin), phytonadione (vitamin K₁), piperacillin/tazobactam (Zosyn), potassium chloride

(KCl), procainamide (Pronestyl), prochlorperazine (Compazine), promethazine (Phenergan), propofol (Diprivan), propranolol, quinidine gluconate, ranitidine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), sodium bicarbonate, succinylcholine, tacrolimus (Prograf), telavancin (Vibativ), theophylline, thiotepa, ticarcillin/clavulanate (Timentin), tigecycline (Tygacil), tirofiban (Aggrastat), vancomycin, vasopressin, vecuronium, vinblastine, vincristine, vinorelbine (Navelbine), warfarin (Coumadin), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

First 1,000 units or fraction thereof over 1 minute. After this test dose, any single injection (5,000 units or fraction thereof) may be given over 1 minute. A continuous IV infusion may be given over 4 to 24 hours, depending on specific dosage of heparin required, amount of heparin added, and amount of infusion fluid used as a diluent. Continuous IV infusion is the preferred method of administration. Use an infusion pump for accuracy.

ACTIONS

An anticoagulant with immediate and predictable effects on the blood. Inhibits reactions that lead to clotting of blood and the formation of fibrin clots. Heparin combines with other factors in the blood to inhibit the conversion of prothrombin to thrombin and fibrinogen to fibrin. Adhesiveness of platelets is reduced. Well-established clots are not dissolved, but growth is prevented and newer clots may be dissolved. Duration of action is short, about 4 to 6 hours. Average half-life is 30 to 180 minutes. The half-life of the anticoagulant effect of heparin is approximately 1.5 hours and does not increase with dose. The plasma half-life is prolonged by higher doses and in liver or kidney disease and shortened in patients with pulmonary embolism. Does not cross the placental barrier. Metabolic fate not fully determined. May be partially metabolized in the liver. Small amount excreted as unchanged drug in the urine.

INDICATIONS AND USES

Prevention and/or treatment of all types of thromboses and emboli including deep vein thrombosis (DVT), pulmonary emboli (PE), and embolization associated with atrial fibrillation (AF). ■ Treatment of disseminated intravascular coagulation (DIC). ■ Prevention of clotting in surgery of the heart or blood vessels, during blood transfusion, and hemodialysis. ■ Maintain patency of indwelling venipuncture devices (e.g., heparin-lock, needle, catheter, or implanted port) during prolonged IV infusion or for intermittent medication injection or vein access.

Unlabeled uses: Adjunct in treatment of coronary occlusion with acute myocardial infarction (MI). ■ Prevention of re-thrombosis or re-occlusion during MI after thrombolytic therapy (e.g., alteplase, reteplase, streptokinase). ■ Adjunct to use of glycoprotein GP IIb/IIIa receptor antagonists in percutaneous coronary intervention (PCI). ■ ST-elevation MI, as an adjunct to thrombolysis. ■ Unstable angina refractory to conventional treatment.

CONTRAINDICATIONS

Severe thrombocytopenia. ■ Patients receiving full-dose heparin unless blood coagulation tests can be performed at appropriate intervals. ■ Hypersensitivity to heparin unless required in a clearly life-threatening situation. ■ Uncontrolled bleeding except in DIC. ■ Do not administer heparin preparations preserved with benzyl alcohol to neonates, infants, pregnant women, or breast-feeding mothers.

PRECAUTIONS

Read label carefully. Comes in many strengths. Confirm use of the correct strength. Fatal hemorrhages have occurred in pediatric patients, including neonates, as a result of medication errors in which heparin sodium injection vials have been confused with heparin-lock flush vials.

■ Unit-to-milligram conversions are not consistent. ■ For IV or SC use only; avoid IM administration (may cause hematomas). ■ Derived from animal protein. ■ Use extreme caution in any disease state or clinical condition where risk of hemorrhage may be increased such as subacute bacterial endocarditis; severe hypertension; during or following spinal tap, spinal anesthesia, or major surgery (especially major surgery involving the

brain, spinal cord, or eye); hemophilia; thrombocytopenia; gastrointestinal ulcerative lesions; vascular purpuras; continuous tube drainage of the stomach or small intestine; menstruation; and severe liver disease with impaired hemostasis. ■ Resistance to heparin increased in cancer, fever, infections with thrombosing tendencies, MI, post-surgical patients, thrombophlebitis, and thrombosis. ■ Use caution if administering ACD-converted blood (variable). ■ May cause thrombocytopenia; monitor closely. ■ May develop heparin-induced thrombocytopenia (HIT, with or without thrombosis), an antibody-mediated reaction resulting from irreversible aggregation of platelets. HIT may progress to heparin-induced thrombocytopenia and thrombosis (HITT), which involves the development of venous and arterial thromboses. HIT and HITT may occur during heparin treatment or may be delayed for up to several weeks after heparin treatment is discontinued; see **Monitor**. ■ See **Elderly** for additional precautions. ■ Repeated flushing of an indwelling venipuncture device with heparin may result in a systemic anticoagulant effect. ■ Heparin-lock flush solution is intended for maintenance of patency of intravenous injection devices only and is not to be used for anticoagulant therapy. ■ See **Maternal/Child**.

Monitor: Whole blood clotting time (WBCT), activated coagulation time (ACT), or aPTT must be done before initial injection. Obtain a baseline platelet count. ■ During the early stages of treatment, coagulation tests are often done before each intermittent injection or every 4 hours with a continuous infusion. Usually repeated daily thereafter during IV therapy and more often if indicated (some sources recommend an aPTT every 6 hours). Depending on the test chosen the desired therapeutic level is approximately 1½ to 3 times greater than the control level (e.g., aPTT [1.5 to 2 times therapeutic level], WBCT [2.5 to 3 times control level]). Confirm desired control level with physician. Obtain test just before next dose due in intermittent injection. Notify the physician if aPTT, ACT, or WBCT is above therapeutic level. ■ Monitor platelet count periodically. Discontinue heparin if it falls below 100,000 or a thrombosis forms. May develop HIT (with or without thrombosis) or HITT (irreversible aggregation of platelets induced by heparin that may lead to severe thromboembolic complications [e.g., DVT; cerebral vein thrombosis, limb ischemia, mesenteric thrombosis, thrombus formation on a prosthetic cardiac valve, or renal artery thrombosis; skin necrosis; gangrene of the extremities that may lead to amputation; MI; pulmonary embolism; stroke; or death]). HIT and HITT may occur during heparin therapy or may be delayed. Evaluate patients for HIT and HITT if they present with thrombocytopenia or thrombosis after heparin is discontinued. Can occur up to several weeks after heparin is discontinued. ■ Also monitor hematocrit and occult blood in stool. ■ Hemorrhage can occur at any site and is the primary complication. Monitor closely. Consider the possibility of a hemorrhagic event with an unexplained fall in hematocrit, a fall in BP, or any other unexplained symptom. GI or urinary tract bleeding may indicate an underlying lesion. Certain hemorrhagic complications may be difficult to detect and can be very serious (e.g., adrenal [with resultant adrenal insufficiency], ovarian [corpus luteum], and retroperitoneal hemorrhage). ■ Use extensive precautionary methods to prevent bleeding if patient requires IM injection, arterial puncture, or venipuncture.

Patency of indwelling venipuncture devices: Obtain a baseline aPTT prior to insertion of an indwelling venipuncture device. Repeated heparin injections can alter aPTT. ■ To avoid precipitation, irrigate indwelling venipuncture devices with NS before and after injecting acidic or **incompatible** solutions. ■ Heparin and/or NS may interfere with blood samples drawn from these devices, especially if drawn on a frequent basis. Clear the heparin flush solution by aspirating and discarding a volume of solution equal to that of the indwelling venipuncture device before the desired blood sample is drawn.

Patient Education: Report all episodes of bleeding and apply local pressure if indicated. ■ Report tarry stools. ■ Compliance with all measures to minimize bleeding is very important (e.g., avoid use of razors, toothbrushes, other sharp items). ■ Use caution while moving to avoid excess bumping.

Maternal/Child: Category C: preferred anticoagulant in pregnancy but must be used with caution. Hemorrhage most likely to occur during the last trimester or postpartum. Has caused stillbirths and prematurity. ■ Not secreted in breast milk. ■ Some preparations may contain benzyl alcohol; do not use in neonates, infants, pregnant women, or breast-feeding mothers; see **Contraindications**. ■ Use to maintain patency of umbilical artery catheters has been associated with an increased risk of intraventricular hemorrhage in low-birth-weight infants. ■ Use heparin-lock flush with caution in infants with diseases with an increased risk of hemorrhage. The 100 units/mL concentration should not be used in neonates or infants who weigh less than 10 kg because of the risk of systemic anticoagulation. Use caution when using the 10 units/mL concentration in premature infants who weigh less than 1 kg and are receiving frequent flushes, because a therapeutic heparin dose may be given in a 24-hour period. Use minimal doses and preservative-free preparations, and monitor carefully. ■ See **Dose Adjustments** and **Precautions**.

Elderly: Higher plasma levels of heparin and longer aPTTs may occur in patients over 60 years of age. Higher incidence of bleeding in patients 60 years of age and older (especially women). Lower doses of heparin may be indicated; see **Dose Adjustments**.

DRUG/LAB INTERACTIONS

Nitroglycerin IV may cause a decrease in PTT with a subsequent rebound effect when nitroglycerin is discontinued. Monitor PTT carefully and adjust heparin dose as needed. ■ Increased risk of bleeding with **ACD-converted blood, adrenal cortical steroids** (especially chronic therapeutic use), **some cephalosporins** (e.g., cefotetan, moxalactam [Moxam]), **dextran, penicillins, platelet aggregation inhibitors** (e.g., dipyridamole [Persantine]), **glycoprotein GPIIb/IIIa receptor antagonists** (e.g., abciximab [ReoPro], eptifibatid [Integrilin]), **tirofiban (Aggrastat)**, **ticlopidine [Ticlid]**, **hydroxychloroquine** (Chloroquine), **NSAIDs** (e.g., ibuprofen [Motrin], indomethacin [Indocin], ketorolac [Toradol]), **plicamycin** (Mithracin), **salicylates** (e.g., aspirin), **other thrombolytic agents** (e.g., alteplase, streptokinase), **thyroid agents** (e.g., methimazole [Tapazole], propylthiouracil), **valproic acid** (Depakote), **or any drug that may cause hypothermia, thrombocytopenia, GI ulceration, or hemorrhage**. ■ Resistance to heparin anticoagulation may occur following administration of **streptokinase** as a systemic thrombolytic agent; adjust dose of heparin based on more frequent aPTTs. ■ Inhibited by **antihistamines, digoxin, nicotine, tetracyclines, and others**; may counteract anticoagulant action of heparin. ■ Potentiates **oral anticoagulants**. ■ See **Precautions/Monitor**. ■ Use caution when administered after **other anticoagulants**. Lab data may not provide an accurate baseline. ■ Numerous **lab values** (e.g., imaging studies, thyroid, AST, ALT, free fatty acid, triglycerides, cholesterol) may be altered. Notify lab of heparin use. Diagnostic results may not be attainable. See **Monitor**. ■ When heparin is given concomitantly with warfarin (Coumadin), the PT may be prolonged. Wait at least 5 hours after IV bolus heparin dose before drawing PT. If heparin is being administered as a continuous infusion, may draw PT at any time.

SIDE EFFECTS

Bruising, epistaxis, hematuria, hemorrhage, prolonged coagulation time (in excess of two to three times the control level), tarry stools or any other signs of bleeding, thrombocytopenia, HIT or HITT (platelet aggregation, clotting). Hypersensitivity reactions, including anaphylaxis, do occur. Vasospastic reactions resulting in a painful, ischemic, cyanotic limb may develop. Alopecia, arthralgias, chest pain, cutaneous necrosis, headache, hypertension, itching on the plantar surface of the feet, osteoporosis, priapism (painful penile erection), rebound hyperlipidemia, and suppressed aldosterone synthesis have been reported. Several studies have shown that moderately high doses of heparin can cause excessive internal bleeding that may lead to paralyzing or lethal strokes. Fewer side effects occur with controlled continuous IV infusion as compared to intermittent.

ANTIDOTE

Discontinue drug and notify physician of any side effects. Protamine sulfate is a heparin antagonist and specifically indicated in overdose or desired heparin reversal. Each milligram of protamine neutralizes approximately 100 units heparin. No more than 50 mg should be administered, very slowly, in any 10-minute period. Administration of pro-

tamine can cause severe hypotension and anaphylactoid reactions. Use with caution and have emergency equipment and medications readily available. If HIT (with or without thrombosis) is diagnosed or strongly suspected, discontinue all sources of heparin, including heparin flushes. Use an alternative anticoagulant. Whole blood transfusion may be indicated. If heparin-induced thrombocytopenia or white clot syndrome occurs, discontinue heparin and administer a non-heparin anticoagulant (e.g., argatroban [Acova], bivalirudin [Angiomax]) as an alternate form of anticoagulation. Follow-up with oral anticoagulation (e.g., warfarin [Coumadin]) may also be indicated. Avoid use of heparin for at least 3 to 6 months or for as long as the patient tests positive for HIT antibodies.

HEPATITIS B IMMUNE GLOBULIN INTRAVENOUS (HUMAN)

(hep-ah-TY-tiss ih-MUNE GLAW-byoo-lin IV)

HepaGam B

Immunizing agent
(passive)

pH 5.6

USUAL DOSE

(International units [IU])

Prevention of hepatitis B recurrence following liver transplantation: Administered by a set dosing regimen designed to attain serum levels of antibodies to hepatitis B surface antigen (anti-HBs) greater than 500 IU/L. Each dose should contain 20,000 IU calculated from the measured potency as stamped on the vial label. Administer the first dose of 20,000 IU concurrently with grafting of the transplanted liver (the anhepatic phase). Administer each subsequent dose of 20,000 IU as recommended in the following table.

Hepatitis B IGIV Dosing Regimen			
Anhepatic Phase	Week 1 Postoperative	Weeks 2-12 Postoperative	Month 4 Onwards
First dose of 20,000 IU	20,000 IU daily from Day 1 through Day 7; see Dose Adjustments	20,000 IU every 2 weeks from Day 14 (Week 2) through Week 12	20,000 IU monthly

DOSE ADJUSTMENTS

(International units [IU])

Increased doses may be required in patients who fail to reach anti-HBs levels of 500 IU/L within the first week after liver transplantation. Particularly susceptible to an extensive decrease of circulated anti-HBs are patients who have surgical bleeding or abdominal fluid drainage (greater than 500 mL) or those who undergo plasmapheresis. If the desired anti-HBs levels are not reached, increase the dosing regimen to a half-dose (10,000 IU [calculated from the measured potency as stamped on the vial label]) and administer IV every 6 hours until the target anti-HBs level is reached.

DILUTION

A ready-to-use liquid preparation; should be clear to opalescent. Multiple vials will be required. **Do not shake vials; avoid foaming.** Bring to room temperature before administration. Administer through a separate IV line using an IV administration set and an infusion pump.

Filters: No data available from manufacturer.

Storage: Store between 2° and 8° C (35.6° and 46.4° F). Do not freeze. Do not use after expiration date. Use within 6 hours of opening the vial, and discard partially used vials.

COMPATIBILITY

Manufacturer states, “Administer through a separate IV line using an IV administration set via infusion pump.”

RATE OF ADMINISTRATION

Set infusion pump rate at 2 mL/min. Decrease to 1 mL/min or slower for patient discomfort, infusion-related adverse events, or concern about the speed of infusion.

ACTIONS

A solvent/detergent-treated sterile solution of purified gamma globulin containing anti-HBs. Prepared from plasma donated by healthy, screened donors with high titers of anti-HBs. Purified by an anion-exchange column chromatography manufacturing method. It provides passive immunization for individuals exposed to the hepatitis B virus by binding to the surface antigen and reducing the rate of hepatitis B infection. Following liver transplantation, hepatitis B virus re-infection can occur immediately at the time of liver reperfusion due to a circulating virus or later from a virus retained in extrahepatic sites. Provides an immediate immune response to the hepatitis B virus. Mechanism of action is not known but may occur through several pathways (e.g., through blockage of a putative HBV receptor, neutralization of circulating virions through immune precipitation and immune complex formation, triggering of an antibody-dependent cell-mediated cytotoxicity response that results in target cell lysis, or binding to hepatocytes and interaction with HBsAg within cells). Clinical effectiveness is dependent on dose, length of administration, and viral replication status of the patient at the time of transplant. Bioavailability is complete and immediate and is distributed quickly between plasma and extravascular fluid. Immune globulins are metabolized by being broken down in the reticuloendothelial system. IM injection results in mean peak concentrations within 4 to 5 days of administration and an elimination half-life of 22 to 25 days. A slightly decreased half-life is expected following IV administration.

INDICATIONS AND USES

Prevention of hepatitis B recurrence following liver transplantation in HBsAg-positive liver transplant patients. Recommended for use in patients who have no or low levels of viral replication at the time of liver transplantation. ■ Used IM for post-exposure prophylaxis in the following settings: acute exposure to blood containing HBsAg, perinatal exposure of infants born to HBsAg-positive mothers, sexual exposure to HBsAg-positive persons, and household exposure to persons with acute HBV infection.

CONTRAINDICATIONS

History of anaphylactic or severe systemic reactions to human globulins. ■ Weigh benefits versus risk of hypersensitivity reactions in IgA-deficient individuals; see [Precautions](#).

PRECAUTIONS

Administer in a facility with adequate equipment and supplies to monitor the patient and respond to any medical emergency. ■ Hypersensitivity and/or infusion reactions may occur. ■ Individuals deficient in IgA may have the potential to develop IgA antibodies and have an anaphylactoid reaction. ■ Contains maltose, which can interfere with select blood glucose monitoring systems (those based on the glucose dehydrogenase pyrroloquinone [GDH-PQQ] method). May cause falsely elevated glucose readings, result in inappropriate insulin administration, and cause life-threatening hypoglycemia. In contrast, cases of true hypoglycemia may go untreated if the hypoglycemic state is masked by falsely elevated results. ■ Derived from human plasma. Despite screening and purification processes, may have the potential risk of transmitting infectious agents (e.g., viruses [e.g., HIV, hepatitis]) or the Creutzfeldt-Jacob disease agent. ■ Has not been evaluated in combination with antiviral therapy post-transplantation. ■ See [Patient Education](#) and [Drug/Lab Interactions](#).

Monitor: Hepatitis B IGIV is most effective in patients with no or low levels of HBV replication at the time of transplantation. Monitor serum HBsAg and levels of anti-HBs antibody regularly and pre-infusion to track treatment response and adjust dose when indicated. ■ Infusion reactions may occur; usually related to rate of infusion. Monitor closely during and following an infusion. ■ Use caution and observe diabetic patients closely; see [Precautions](#). Only glucose-specific testing systems can be used in patients receiving hepatitis IGIV. Review product information of the blood glucose testing system

to confirm that it can be used with maltose-containing parenteral products. ■ Monitor for S/S of a hypersensitivity reaction.

Patient Education: Regular monitoring of serum HBsAg and anti-HBs antibody levels imperative. ■ Vaccination with live virus vaccines should be deferred until approximately 3 months after administration of hepatitis B IGIV. Revaccination may be required if the previous vaccination occurred within 2 weeks of the initial hepatitis IGIV dose.

Maternal/Child: Category C: use during pregnancy only if clearly indicated. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly: Safety and effectiveness not established.

DRUG/LAB INTERACTIONS

May reduce the effectiveness of **live virus vaccines** (e.g., measles, mumps, rubella, varicella). Vaccination with live virus vaccines should be deferred until approximately 3 months after administration of hepatitis B IGIV. ■ Contains **maltose**, which can interfere with select blood glucose monitoring systems (those based on the glucose dehydrogenase pyrroloquinone [GDH-PQQ] method). May cause falsely elevated glucose readings. Use only glucose-specific testing systems in patients receiving hepatitis B IGIV. ■ Passively transferred antibodies may cause a misleading positive result in **serologic testing** (e.g., Coombs' test). ■ No data available on drug interactions with other medications.

SIDE EFFECTS

Arthralgia, chills, fever, headaches, hypersensitivity reactions, moderate or low back pain, nausea, and vomiting are the most common. Other reported side effects include agitation, amnesia, aphthous stomatitis, diarrhea, dyspepsia, edema, fatigue, gingival hyperplasia, hepatobiliary disease, hyperglycemia, hypertension, hypotension, infectious diarrhea, liver transplant rejection, nocturia, pleural effusion, pneumonia, presbyopia, pruritus, rash, sepsis, splenomegaly, tremors.

ANTIDOTE

Reduce rate of infusion for patient discomfort, infusion-related side effects, or other concerns. Discontinue the drug immediately for any signs of a hypersensitivity reaction. Notify the physician. Antihistamines (e.g., diphenhydramine [Benadryl]) or analgesic agents may be indicated for symptoms related to immune complex formation. Resume infusion at a slower rate if symptoms subside. Treat anaphylaxis immediately. Epinephrine, diphenhydramine (Benadryl), corticosteroids, and ventilation equipment must always be available.

HETASTARCH

(HET-ah-starch)

Plasma volume expander

Hespan, Hextend

pH 5.5 to 5.9

USUAL DOSE**HESPAN, HEXTEND**

Shock: Variable, depending on amount of fluid loss and resultant hemoconcentration. Age, weight, and clinical condition of the patient are also considered. Usually 500 to 1,000 mL. Total dose usually does not exceed 1,500 mL/24 hr or 20 mL/kg of body weight. Higher doses, usually in conjunction with blood and/or blood products, have been used in postoperative and trauma patients who have had severe blood loss.

HESPAN

Leukapheresis: 250 to 700 mL in continuous flow centrifugation procedures. Do not use Hextend for leukapheresis.

DOSE ADJUSTMENTS

In patients with a CrCl less than 10 mL/min, the initial dose remains as in Usual Dose; however, subsequent doses should be reduced by 20% to 50%.

DILUTION

HESPAN: Available as a 6% solution in 500-mL containers properly diluted in NS and ready for use. Calculated osmolarity is approximately 310 mOsm/L.

HEXTEND: Available as a 6% solution in 500 mL and 1,000 mL containers properly diluted in lactated electrolyte solution and ready for use. Lactated electrolyte solution contains dextrose, normal physiologic levels of calcium and sodium, and slightly lower than normal physiologic levels of potassium and magnesium.

Storage: Store at CRT. Avoid excessive heat. Do not freeze. Do not use if color is a turbid deep brown or a crystalline precipitate is visible. Discard unused portions.

COMPATIBILITY**(Underline Indicates Conflicting Compatibility Information)**

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

HESPAN

One source suggests the following **compatibilities:**

Additive: Enalaprilat (Vasotec IV), fosphenytoin (Cerebyx), oxacillin (Bactocill).

Y-site: Ampicillin, cefazolin (Ancef), diltiazem (Cardizem), doxycycline, enalaprilat (Vasotec IV), ertapenem (Invanz), nicardipine (Cardene IV).

HEXTEND

Safety and **compatibility** of other additives not established. Contains calcium; do not administer simultaneously through the same administration set as blood; coagulation likely.

One source suggests the following **compatibilities:**

Y-site: Alfentanil (Alfenta), amikacin (Amikin), aminophylline, amiodarone (Nexterone), ampicillin, ampicillin/sulbactam (Unasyn), atracurium (Tracrium), azithromycin (Zithromax), aztreonam (Azactam), bumetanide, butorphanol (Stadol), calcium gluconate, cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefotetan (Cefotan), cefoxitin (Mefoxin), ceftazidime (Fortaz), cefuroxime (Zinacef), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), clindamycin (Cleocin), dexamethasone (Decadron), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, dolasetron (Anzemet), dopamine, doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), ephedrine, epinephrine (Adrenalin), erythromycin (Erythrocin), esmolol (Brevibloc), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), furosemide (Lasix), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), isoproterenol (Isuprel), ketorolac (Toradol), labetalol, levofloxacin (Levaquin), lidocaine, lorazepam (Ativan), magnesium sulfate, mannitol, meperidine

(Demerol), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), midazolam (Versed), milrinone (Primacor), morphine, nalbuphine, nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), ondansetron (Zofran), palonosetron (Aloxi), pancuronium, phenylephrine (Neo-Synephrine), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), procainamide (Pronestyl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), rocuronium (Zemuron), succinylcholine, sufentanil (Sufenta), sulfamethoxazole/trimethoprim, theophylline, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vecuronium, verapamil.

RATE OF ADMINISTRATION

Variable, depending on indication, present blood volume, and patient response. Initial 500 mL may be given at rates approaching 20 mL/kg of body weight per hour. Reduce rate in burns or septic shock. If additional hydroxyethyl starch is required, reduce flow to lowest rate possible to maintain hemodynamic status. If pressure infusion is used (flexible containers), withdraw all air through medication port before infusing. If a pumping device is used for administration, discontinue pumping action before the container runs dry or air embolism may result.

Leukapheresis: Usually infused at a constant ratio to venous whole blood (i.e., 1:8).

ACTIONS

A synthetic polymer with properties similar to dextran. Approximates colloidal properties of human albumin. Provides hemodynamically significant plasma volume expansion in excess of the amount infused for about 24 hours. Permits retention of intravascular fluid until hetastarch is replaced by blood proteins. **Hextend** supports oncotic pressure and provides electrolytes. Its electrolyte content resembles that of normal plasma. **Hespan** increases erythrocyte sedimentation rate. Granulocyte collection by centrifuging becomes more efficient. Both are enzymatically degraded to molecules small enough to be excreted through the kidneys attached to glucose units.

INDICATIONS AND USES

HESPAN AND HEXTEND: Treatment of hypovolemia when plasma volume expansion is desired. An adjunct in treatment of shock due to burns, hemorrhage, sepsis, surgery, or trauma. ■ Used when whole blood or blood products are not available or when cross-matching of blood products cannot be accomplished quickly enough.

HESPAN: Adjunct in leukapheresis to improve harvesting and increase yield of granulocytes.

CONTRAINDICATIONS

Severe bleeding disorders, severe congestive heart failure, hypersensitivity to hetastarch, renal disease with oliguria or anuria not related to hypovolemia. **Hextend** contains lactate; not for use in leukapheresis or in the treatment of lactic acidosis.

PRECAUTIONS

HESPAN AND HEXTEND: For IV use only. ■ Not a substitute for whole blood or plasma proteins. ■ Use caution in heart disease, renal shutdown, congestive heart failure, pulmonary edema, and liver disease. ■ Does not interfere with blood typing or cross-matching. ■ Anaphylactic reactions have occurred, even after solutions containing hetastarch have been discontinued. Patients allergic to corn may also be allergic to hetastarch. ■ Use extreme caution in shock not accompanied by hypovolemia; volume overload may result. ■ Contains dextrose; use caution in patients with overt diabetes. ■ Administration of large volumes may transiently alter the coagulation mechanism due to hemodilution and a mild direct inhibitory action on factor VIII. Volumes greater than 25% of blood volume within 24 hours may cause significant hemodilution (decreased hematocrit and plasma proteins). Administration of packed RBCs, platelets, or fresh frozen plasma may be indicated. ■ When used over a period of days, hetastarch has been associated with coagulation abnormalities in conjunction with an acquired reversible von Willebrand's-like syndrome and/or factor VIII deficiency. If a severe factor VIII deficiency is identified, replacement therapy may be indicated. If coagulopathy develops, it may take days to resolve. ■ Not recommended for use as a cardiac bypass pump prime,

while the patient is undergoing cardiopulmonary bypass, or in the immediate period after the pump has been discontinued. Risk of coagulopathies and bleeding increased.

HEXTEND: Use extreme caution in patients with metabolic or respiratory alkalosis; contains lactate ions. Excessive lactate may result in metabolic alkalosis. ■ Contains electrolytes; sodium or potassium retention may occur. Use caution in patients receiving corticosteroids, and in renal or cardiac disease particularly in digitalized patients.

Monitor: Monitor HR, BP, central venous pressure, and urine output every 5 to 15 minutes for the first hour and hourly thereafter while indicated. ■ Maintain adequate hydration of patient with additional IV fluids. ■ Change IV tubing or flush with NS before imposing blood. ■ May reduce coagulability of the circulating blood. Observe patient for increased bleeding and/or circulatory overload. Risk increased with higher doses. ■ Hemoglobin, hematocrit, platelet count, acid-base balance, electrolyte, and serum protein evaluation are necessary during therapy. During leukapheresis also monitor leukocyte and platelet count, leukocyte differential, PT, and PTT. ■ Observe frequent donors carefully; may have a marked decline in platelet count and hemoglobin levels resulting from hemodilution by hetastarch and saline. Temporary declines in total protein, albumin, calcium, and fibrinogen may also be present.

Maternal/Child: Category C: not recommended for use in pregnancy, especially early pregnancy; benefit must justify the potential risk to the fetus. Embryocidal to rabbits. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established, but has been used. Increased prothrombin time noted in pediatric patients who received more than 20 mL/kg/24 hr.

Elderly: Differences in response between elderly and younger patients not identified. Risk of toxic reactions may be greater in patients with impaired renal function. Monitoring of renal function suggested in the elderly.

DRUG/LAB INTERACTIONS

Use with caution in patients receiving other drugs that affect coagulation (e.g., **anticoagulants** [e.g., argatroban (Acova), bivalirudin (Angiomax), heparin, warfarin (Coumadin)], **platelet aggregation inhibitors** [e.g., clopidogrel (Plavix), dipyridamole (Persantine), ticlopidine (Ticlid)], **glycoprotein GPIIb/IIIa receptor antagonists** [e.g., abciximab (ReoPro), eptifibatid (Integrilin), tirofiban (Aggrastat)], **plicamycin** [Mithracin], **valproic acid** [Depacon]). Close monitoring of aPTT and PT indicated. ■ May increase **indirect bilirubin** levels. Total bilirubin remained normal.

SIDE EFFECTS

Anemia and/or bleeding due to hemodilution and/or factor VIII deficiency, acquired von Willebrand's-like syndrome, and other coagulopathies, including DIC; chills; circulatory overload; congestive heart failure; elevated serum amylase; fever; headache; hypersensitivity reactions including anaphylaxis; increased urine specific gravity; intracranial bleeding; itching; metabolic acidosis; muscle pains; peripheral edema; pulmonary edema; submaxillary and parotid glandular enlargement; urticaria; and vomiting.

ANTIDOTE

Notify the physician of any side effect. Discontinue the drug immediately at the first sign of a hypersensitivity reaction, provided other means of sustaining the circulation are available. Antihistamines such as diphenhydramine (Benadryl) are helpful. Epinephrine (Adrenalin) may also be indicated. Not eliminated by dialysis. Many side effects can result in medical emergencies. Deaths from severe hypersensitivity reactions have occurred. Treat as indicated and resuscitate as necessary.

HYDRALAZINE HYDROCHLORIDE

(hy-**DRAL**-ah-zeen hy-droh-**KLOR**-eyed)

Antihypertensive
Vasodilator

pH 3.4 to 4

USUAL DOSE

10 to 40 mg. Begin with a low dose. Increase gradually as indicated. Repeat every 3 to 6 hours as necessary. Maximum dose is 300 to 400 mg/24 hr.

Eclampsia: 5 to 10 mg every 20 minutes. If no effect after a total dose of 20 mg, use another agent.

PEDIATRIC DOSE

See *Maternal/Child* (unlabeled).

0.1 to 0.5 mg/kg/dose every 4 to 6 hours. Initial dose should not exceed 20 mg. Maximum IV dose is 0.2 to 0.8 mg/kg/dose up to 40 mg. Another source suggests 0.1 to 0.2 mg/kg/dose (not to exceed 20 mg) every 4 to 6 hours as needed. Up to 1.7 to 3.5 mg/kg/day divided in 4 to 6 doses.

DOSE ADJUSTMENTS

Reduced dose may be required with advanced renal disease and in the elderly. ■ See *Drug/Lab Interactions*.

DILUTION

May be given undiluted. Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set. Color changes occur in most 10% dextrose solutions and after drawing through a metal filter. Use immediately after drawing up solution.

Filters: See *Dilution*.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Dobutamine.

Y-site: Caspofungin (Cancidas), heparin, hydrocortisone sodium succinate (Solu-Cortef), nitroglycerin IV, potassium chloride, verapamil.

RATE OF ADMINISTRATION

Adults: A single dose over 1 minute.

Pediatric patients: A single dose over 3 to 5 minutes.

ACTIONS

A potent antihypertensive drug. It lowers BP by direct relaxation of smooth muscle of arteries and arterioles. Peripheral vasodilation and decreased peripheral vascular resistance result. HR, cardiac output, and stroke volume are all increased. Renal blood flow increased in some cases, while cerebral blood flow maintained. Onset of action is 5 to 20 minutes. Average duration of action is 2 to 6 hours. Metabolized by the liver and excreted in urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Severe essential hypertension. ■ Vasodilation in cardiogenic shock. ■ Drug of choice for pregnancy-induced hypertension (eclampsia).

CONTRAINDICATIONS

Hypersensitivity to hydralazine, coronary artery disease, mitral valvular rheumatic heart disease.

PRECAUTIONS

IV use recommended only when the oral route is not feasible. ■ Rarely the drug of choice for hypertension unless used in combination (effectiveness increased and side effects decreased) with spironolactone (Aldactone), reserpine, guanethidine (Ismelin), and thiazide diuretics. ■ Tolerance is easily developed but subsides about 7 days after the drug is discontinued. ■ Use caution in advanced renal disease, cerebrovascular

accidents, congestive heart failure, coronary insufficiency, headache, increased intracranial pressure, and tachycardia. ■ Use in pregnancy should be limited to treatment of eclampsia.

Monitor: Check BP every 5 minutes until stabilized at the desired level. Check every 15 minutes thereafter throughout crisis. Average maximum decrease occurs in 10 to 80 minutes. ■ Withdraw drug gradually to avoid rebound hypertension.

Patient Education: Report chest pain, fatigue, fever, joint or muscle pain promptly.

Maternal/Child: Category C: can cause fetal abnormalities; see [Indications](#) and [Precautions](#). ■ Safety for use in pediatric patients not established. ■ May be used in breastfeeding women.

Elderly: Increased risk of hypotension. ■ Consider age-related renal impairment.

DRUG/LAB INTERACTIONS

Sometimes used with a **beta-adrenergic blocking drug** (e.g., propranolol) or **diuretics** (e.g., hydrochlorothiazide [Aldactazide]); use caution; may potentiate effects. ■ Potentiated by **anesthetics**, **MAO inhibitors** (e.g., selegiline [Eldepryl]), and **other antihypertensive agents**. ■ Inhibits **epinephrine**, **levarterenol** (Levophed). ■ Use with **diazoxide** can cause profound hypotension. ■ **NSAIDs** (e.g., ibuprofen [Motrin]) may decrease antihypertensive effect.

SIDE EFFECTS

May often be minimized by initiating therapy with a small dose and increasing the dose gradually.

Anxiety, depression, dry mouth, flushing, headache, nausea, numbness, palpitations, paresthesia, postural hypotension, tachycardia, tingling, unpleasant taste, vomiting.

Major: Angina, blood dyscrasias, chills, coronary insufficiency, delirium, dependent edema, fever, ileus, lupus erythematosus (simulated), myocardial ischemia and infarction, rheumatoid syndrome (simulated), toxic psychosis.

ANTIDOTE

If minor side effects occur, notify the physician, who will probably treat them symptomatically. Beta-adrenergic blocking agents (e.g., propranolol) will control tachycardia. Pyridoxine will relieve numbness, tingling, and paresthesia. Antihistamines, barbiturates, and salicylates may be required. Treat hypotension with a vasopressor that is least likely to precipitate cardiac arrhythmias. If side effects are progressive or any major side effects occur, discontinue the drug immediately and notify the physician. Treatment is symptomatic. Resuscitate as necessary. Occasionally methyl dopa (Aldomet) will be used as a substitute, since it is effective for the same indications but has fewer side effects.

HYDROCORTISONE SODIUM SUCCINATE

(hy-droh-KOR-tih-zohn SO-dee-um SUK-sih-nayt)

A-Hydrocort, Solu-Cortef

Hormone (corticosteroid)
Anti-inflammatory
Antiemetic

pH 7 to 8

USUAL DOSE

The IV route is usually used in an emergency situation or when oral dosing is not feasible. The lowest possible dose should be used to control condition. When reduction in dosage is possible, reduction should be gradual. Larger doses may be justified by patient condition. Repeat until adequate response, then decrease dose as indicated. Doses must be individualized and are not always reduced for pediatric patients. High dose treatment is utilized until patient condition stabilizes, usually no longer than 48 to 72 hours. Complications secondary to treatment with corticosteroids are dependent on the size of dose and duration of therapy.

Average dose range is 100 to 500 mg repeated as necessary every 2, 4, or 6 hours. For severe shock, doses up to 2 Gm or more every 2 to 10 hours have been given. Maximum dose is 8 Gm/24 hr. A minimum dose of no less than 25 mg/24 hr is recommended. Increased doses are indicated in patients undergoing corticosteroid therapy who are subjected to any unusual stressful situation (e.g., illness, surgery).

Other sources recommend:

Acute asthma: 1 to 2 mg/kg/dose every 6 hours for 24 hours. Follow with 0.5 to 1 mg/kg every 6 hours.

Anti-inflammatory or immunosuppressive: 15 to 240 mg every 12 hours.

Life-threatening shock: 50 mg/kg initially. Repeat in 4 hours and/or every 24 hours as needed *or*

0.5 to 2 Gm initially. Repeat every 2 to 6 hours as needed.

Adrenal insufficiency (acute): 100 mg as an IV bolus. Follow with 300 mg/day in divided doses every 8 hours or as a continuous infusion for 48 hours. Change to oral dosing when patient is stable.

Physiologic replacement: 20 to 30 mg/day (usually given PO).

PEDIATRIC DOSE

See *Maternal/Child*.

Average dose range in pediatric patients is 0.56 to 8 mg/kg/day in 3 to 4 divided doses (0.19 to 2.67 mg/kg every 8 hours or 0.14 to 2 mg/kg every 6 hours).

Other sources recommend:

Acute asthma: 1 to 2 mg/kg/dose every 6 hours for 24 hours; then 2 to 4 mg/kg/24 hr in equally divided doses every 6 hours (0.5 to 1 mg/kg every 6 hours). For status asthmaticus, another source suggests a **loading dose (optional)** of 4 to 8 mg/kg up to a maximum dose of 250 mg.

Maintenance dose: 8 mg/kg/24 hr in equally divided doses every 6 hours (2 mg/kg every 6 hours).

Anti-inflammatory: 1 to 5 mg/kg/24 hr, or 0.5 to 2.5 mg/kg every 12 hours, or 30 to 150 mg/M²/24 hr, or 15 to 75 mg/M² every 12 hours.

Adrenal insufficiency (acute): 1 to 2 mg/kg/dose bolus, then 25 to 150 mg/day in divided doses every 6 to 8 hours (8.33 to 50 mg every 8 hours or 6.25 to 37.5 mg every 6 hours) in infants and young children. In older children the bolus dose is the same, followed by 150 to 250 mg/day in divided doses every 6 to 8 hours (50 to 83.33 mg every 8 hours or 37.5 to 62.5 mg every 6 hours).

Physiologic replacement: 0.5 to 0.75 mg/kg/day given every 8 hours (usually given PO).

DOSE ADJUSTMENTS

Reduced dose may be required in the elderly. ■ See *Drug/Lab Interactions*.

DILUTION

Available in Act-O-Vials and Univials, which are reconstituted by removing the protective cap, turning the rubber stopper a quarter turn, and pressing down, allowing the diluent into the lower chamber. Agitate gently. Using sterile techniques, a needle can be easily inserted through the center of the rubber stopper to withdraw the solution. Also available in flip-top vials. For these other preparations, reconstitute each 250 mg or fraction thereof with 2 mL bacteriostatic water for injection. Agitate gently to mix solution. May be given by IV injection, or each 100 mg (250 mg, 500 mg, or more) may be further diluted in at least 100 mL (250 mL, 500 mL, or more) but not more than 1,000 mL of D5W, NS, or D5NS.

Storage: Store vials and solutions at RT (20° to 25° C [68° to 77° F]). Protect solution from light. Discard unused solutions after 3 days. If fluid restriction is necessary, 100 to 3,000 mg may be added in 50 mL of **compatible** solution. Resultant solution is stable for 4 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be diluted or mixed with other solutions."

One source suggests the following **compatibilities**:

Solution: Most commonly used IV solutions, fat emulsion 10% IV.

Additive: Amikacin (Amikin), aminophylline, amphotericin B (conventional), ampicillin, anti-thymocyte globulin (rabbit) (Thymoglobulin), calcium chloride, calcium gluconate, chloramphenicol (Chloromycetin), clindamycin (Cleocin), cytarabine (ARA-C), daunorubicin (Cerubidine), dimenhydrinate, diphenhydramine (Benadryl), dopamine, erythromycin (Erythrocin), furosemide (Lasix), heparin, lidocaine, magnesium sulfate, metronidazole (Flagyl IV), mitomycin (Mutamycin), mitoxantrone (Novantrone), norepinephrine (Levophed), penicillin G potassium and sodium, potassium chloride (KCl), vancomycin, verapamil.

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), aminophylline, amphotericin B cholesteryl (Amphotec), ampicillin, anidulafungin (Eraxis), anti-thymocyte globulin (rabbit) (Thymoglobulin), argatroban, atracurium (Tracrium), atropine, aztreonam (Azactam), bivalirudin (Angiomax), calcium gluconate, caspofungin (Cancidas), ceftaroline (Teflaro), chlorpromazine (Thorazine), cisatracurium (Nimbex), cladribine (Leustatin), cytarabine (ARA-C), dexamethasone (Decadron), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), droperidol (Inapsine), edrophonium (Enlon), enalaprilat (Vasotec IV), epinephrine (Adrenalin), esmolol (Brevibloc), estrogens, conjugated (Premarin), ethacrynic acid (Edecrin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), filgrastim (Neupogen), fludarabine (Fludara), fluorouracil (5-FU), foscarnet (Foscavir), furosemide (Lasix), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydralazine, isoproterenol (Isuprel), lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), methylergonovine (Methergine), morphine, neostigmine, nifedipine (Cardene IV), norepinephrine (Levophed), ondansetron (Zofran), oxacillin (Bactocill), oxaliplatin (Eloxatin), oxytocin (Pitocin), paclitaxel (Taxol), pancuronium, penicillin G potassium, pentazocine (Talwin), phytonadione (vitamin K₁), piperacillin/tazobactam (Zosyn), procainamide (Pronestyl), prochlorperazine (Compazine), promethazine (Phenergan), propofol (Diprivan), propranolol, remifentanyl (Ultiva), sodium bicarbonate, succinylcholine, tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiopeta, vecuronium, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Each 100 mg or fraction thereof over 30 seconds to 1 minute. Extend to 10 minutes for larger doses (500 mg or more). IV injection is usually the route of choice and eliminates the possibility of overloading the patient with IV fluids. At the discretion of the physi-

cian, a continuous infusion may be given, properly diluted over the specified time desired.

ACTIONS

Contains the principal hormone secreted by the adrenal cortex and has both glucocorticoid and mineralocorticoid properties. Has potent metabolic, anti-inflammatory, and innumerable other effects. Peak plasma levels achieved promptly. Metabolized in the liver and excreted as inactive metabolites in the urine. Elimination half-life is 1 to 2 hours. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Agents of choice for adrenocortical insufficiency; total, relative, and operative. ■ Agents of choice for acute exacerbation of disease for patients on steroid therapy. ■ Occasionally used for asthma or shock, but non-mineralocorticoid steroids are preferred (e.g., dexamethasone, methylprednisolone).

CONTRAINDICATIONS

Absolute contraindications except in life-threatening situations: Hypersensitivity to any product component, including sulfites; systemic fungal infections. ■ Administration of live or live-attenuated vaccines in patients receiving an immunosuppressive dose of corticosteroids.

Relative contraindications: Active or latent peptic ulcer, active or latent tuberculosis, chickenpox, diverticulitis, fresh intestinal anastomoses, measles, myasthenia gravis, ocular herpes simplex, pregnancy, thromboembolic tendencies, vaccinia.

PRECAUTIONS

To avoid relative adrenocortical insufficiency, do not stop therapy abruptly. Taper off. Patient is observed carefully, especially under stress, for up to 2 years. The exception is very short-term therapy. ■ Anaphylactoid reactions have occurred (incidence is rare). ■ Increased doses are indicated in patients undergoing corticosteroid therapy who are subjected to any unusual stressful situation (e.g., illness, surgery). ■ Should not be used for treatment of traumatic brain injury. May increase mortality. ■ Use with caution in patients who have had a recent MI. May be associated with left ventricular free wall rupture. ■ Kaposi's sarcoma has been reported in patients receiving corticosteroid therapy, most often for chronic conditions. Clinical improvement may occur if therapy is discontinued. ■ Use with caution in patients with CHF, hypertension, or renal insufficiency; see [Monitor](#). ■ Use with caution in patients with active or latent peptic ulcer disease, diverticulitis, fresh intestinal anastomoses, and nonspecific ulcerative colitis; may increase risk of perforation. Prophylactic antacids may prevent peptic ulcer complications. ■ May induce psychological side effects (e.g., euphoria, insomnia, mood swings, depression, psychosis) or may aggravate existing emotional instability or psychotic tendencies.

Monitor: Monitor electrolytes. May cause sodium retention and potassium and calcium excretion. Dietary salt restriction and potassium supplementation may be necessary. May cause hypertension secondary to fluid and electrolyte disturbances. ■ May increase susceptibility to infection, reactivate latent infectious diseases, or mask signs of infection. ■ Monitor blood glucose. May increase insulin needs in diabetes. ■ Administer before 9 AM to reduce suppression of individual's own adrenocortical activity. ■ Periodic ophthalmic exams may be necessary with prolonged treatment. ■ See [Drug/Lab Interactions](#).

Patient Education: Do not discontinue abruptly. ■ Advise all medical personnel of current or past corticosteroid use. ■ Report edema, tarry stools, or weight gain promptly. Anorexia, diarrhea, dizziness, fatigue, low blood sugar, nausea, weakness, weight loss, and vomiting may indicate adrenal insufficiency after dose reduction or discontinuing therapy; report any of these symptoms. ■ May mask signs of infection and/or decrease resistance. ■ Patients with diabetes may have an increased requirement for insulin or oral hypoglycemics. ■ Avoid immunization with live virus vaccines. ■ Carry ID stating steroid dependent if receiving prolonged therapy.

Maternal/Child: Category C: could produce fetal abnormalities. ■ Discontinue breastfeeding. ■ Observe newborn for hypoadrenalism if mother has received large doses. ■ Observe growth and development in long-term use in pediatric patients.

Elderly: Reduced muscle mass and plasma volume may require a reduced dose. ■ Monitor BP, blood glucose, and electrolytes carefully; increased risk of hypertension. ■ Higher risk of glucocorticoid-induced osteoporosis.

DRUG/LAB INTERACTIONS

Aminoglutethimide (Cytadren) may increase the metabolism of hydrocortisone, thereby decreasing therapeutic effects. Monitor carefully if concurrent use is necessary. ■ Metabolism increased and effects reduced by **hepatic enzyme-inducing agents** (e.g., alcohol, barbiturates [e.g., phenobarbital], hydantoin [e.g., phenytoin (Dilantin)], and rifampin [Rifadin]); dose adjustment may be required when adding or deleting from drug profile. ■ Risk of hypokalemia increased with **amphotericin B** or **potassium-depleting diuretics** (e.g., thiazides, furosemide, ethacrynic acid). Monitor potassium levels and cardiac function. Increased risk of **digoxin** toxicity secondary to hypokalemia. ■ May also decrease effectiveness of **potassium supplements**; monitor serum potassium. ■ **Diuretics** decrease sodium and fluid retention effects of corticosteroids; corticosteroids decrease sodium excretion and diuretic effects of diuretics. ■ May antagonize effects of **anticholinesterases** (e.g., neostigmine), **isoniazid (INH)**, **salicylates**, and **somatrem**; dose adjustments may be required. ■ Clearance decreased and effects increased with **estrogens, oral contraceptives, macrolide antibiotics** (e.g., azithromycin [Zithromax]), and **ketoconazole** (Nizoral). ■ May interact with **anticoagulants, nondepolarizing muscle relaxants** (e.g., atracurium [Tracrium]), or **theophyllines**; may inhibit or potentiate action. ■ Monitor patients receiving **insulin or thyroid hormones** carefully; dose adjustments of either or both agents may be required. ■ Increased activity of both **hydrocortisone and cyclosporine** may occur with concurrent use. Therapeutic use is beneficial for organ transplants; however, toxicity may also be increased, and convulsions have been reported. ■ Concurrent use with **aspirin or NSAIDs** (e.g., ibuprofen [Motrin], naproxen [Aleve, Naprosyn]) may increase the risk of GI side effects. ■ Administration of **live or live-attenuated vaccines** is contraindicated in patients receiving immunosuppressive dose of corticosteroids. Inactivated vaccines may be administered; however, the response to these vaccines cannot be predicted. ■ Altered **protein-binding capacity** will impact effectiveness of this drug. ■ **Corticosteroids** may suppress reactions to skin tests. ■ See [Dose Adjustments](#).

SIDE EFFECTS

Do occur but are usually reversible: alteration of glucose metabolism including hyperglycemia and glycosuria; Cushing's syndrome (e.g., moon face, fat pads); electrolyte and calcium imbalance; euphoria or other psychic disturbances; hypersensitivity reactions including anaphylaxis; increased BP; increased intracranial pressure; masking of infection; menstrual irregularities; perforation and hemorrhage from aggravation of peptic ulcer; protein catabolism with negative nitrogen balance; spontaneous fractures; sweating, headache, or weakness; thromboembolism; transitory burning or tingling; and many others.

ANTIDOTE

Notify the physician of any side effect. Will probably treat the side effect if necessary. Resuscitate as necessary for anaphylaxis and notify physician. Keep epinephrine immediately available.

HYDROMORPHONE HYDROCHLORIDE **BBW**

(hy-droh-MOR-fohn hy-droh-KLOR-eyed)

Opioid analgesic
(agonist)

Dilaudid, Dilaudid HP

pH 3.5 to 5.5, 4.5 to 6.5

USUAL DOSE

Individualize dose based on age; general condition and medical status; degree of opioid tolerance; daily dose, potency, and specifics of previous opioids prescribed; concurrent medications; type and severity of pain; risk factors for abuse or addiction (e.g., previous or current abuse problem, family history of abuse, history of mental illness or depression); balance between pain control and adverse reactions.

Dispense with caution; dosing errors due to confusion between different concentrations and between mg and mL could result in accidental overdose and death. Use the smallest effective dose with the least frequency that achieves acceptable analgesia and tolerable adverse events. Oral and IV doses and IV doses with doses of other opioids are **NOT** comparable; see prescribing information for conversions.

IV injection: Usual starting dose is 0.2 to 1 mg every 2 to 3 hours.

Infusion: Used postoperatively with a patient-controlled analgesic device (PCA) and in selected terminally ill cancer patients. One source suggests a concentration of 0.2 mg/mL, with a starting patient-controlled dose of 0.1 to 0.2 mg (range 0.05 to 0.4 mg) that can be activated at prescribed intervals. Must be administered through a controlled infusion device that may be patient activated. The initial loading dose, the continuous background infusion to provide a level of pain relief and maintain patency of the vein, additional patient-activated doses with specific time interval, additional health care professional–provided boluses with specific time interval, and the total dose allowed per hour must be determined by the physician specialist and individualized for each patient.

PEDIATRIC DOSE

Individualized on the basis of age and weight (unlabeled). One source suggests 0.015 mg/kg/dose every 4 to 6 hours as needed in pediatric patients; see [Contraindications](#) and [Maternal/Child](#).

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly and debilitated. Reduced initial doses may be indicated based on the potential for increased sensitivity, decreased organ function, and concomitant disease or drug therapy. ■ Depending on the degree of impairment, one-fourth to one-half the usual starting dose is recommended in patients with impaired renal or hepatic function. ■ Use lower initial doses in opiate-naïve patients. ■ Doses appropriate for the general population may cause serious respiratory depression in vulnerable patients. ■ Increase doses as required if analgesia is inadequate, tolerance develops, or pain severity increases. The first sign of tolerance is usually a reduced duration of effect. ■ Decrease dose if excessive side effects are observed early in the dosing interval. If this results in breakthrough pain at the end of the dosing interval, the dosing interval may be shortened. ■ See [Drug/Lab Interactions](#).

DILUTION

Available in more than one concentration (1 mg/mL, 2 mg/mL, and 4 mg/mL) and hydromorphone-HP (a high-potency [10 mg/mL]) formulation. Do not confuse hydromorphone-HP with standard formulations of hydromorphone or other opioids; overdose and death could result. Hydromorphone-HP is usually reserved for compounding in the pharmacy or for use in opioid-tolerant patients. Verify concentration to avoid overdose and/or death.

IV injection: May be given undiluted; further dilution with 5 mL NS to facilitate titration is appropriate. May give through Y-tube or three-way stopcock of infusion set.

Infusion: Each 0.1 to 1 mg is usually diluted in 1 mL NS to provide 0.1 to 1 mg/mL for use in a narcotic syringe infusor system. Dilaudid is available in 1-, 2-, or 4-mg/mL, clear ampules. Dilaudid-HP is available in 10-mg/mL amber ampules and as lyophilized powder that must be reconstituted with 25 mL SWFI for a concentration of 10 mg/mL. Generic hydromorphone is available in similar concentrations; check mg/mL carefully. Use concentrated preparations for larger doses. May be diluted in larger amounts of D5W, D5NS, D5 $\frac{1}{2}$ NS, or NS for infusion and given through a standard infusion pump (requires very close titration).

Storage: Store at CRT and protect from light and freezing. Stable for 24 hours at 25 C° (77° F), protected from light, in most common large-volume parenteral solutions.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following compatibilities:

Additive: Fluorouracil (5-FU), heparin, midazolam (Versed), ondansetron (Zofran), potassium chloride (KCl), promethazine (Phenergan), verapamil.

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), ampicillin, atropine, aztreonam (Azactam), bivalirudin (Angiomax), caspofungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), cefoxitin (Mefoxin), ceftazidime (Fortaz), cefuroxime (Zinacef), chloramphenicol (Chloromycetin), cisatracurium (Nimbex), cladribine (Leustatin), clindamycin (Cleocin), dexamethasone (Decadron), dexmedetomidine (Precedex), diazepam (Valium), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), doxycycline, epinephrine (Adrenalin), erythromycin (Erythrocin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), filgrastim (Neupogen), fludarabine (Fludara), foscarnet (Foscavir), furosemide (Lasix), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), 6% hydroxyethyl starch (Voluven), ketorolac (Toradol), labetalol, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), metoclopramide (Reglan), metronidazole (Flagyl IV), micafungin (Mycamine), midazolam (Versed), milrinone (Primacor), morphine, nafcillin (Nallpen), nicardipine (Cardene IV), nitroglycerin IV, norepinephrine (Levophed), ondansetron (Zofran), oxacillin (Bactocill), oxaliplatin (Eloxatin), paclitaxel (Taxol), palonosetron (Aloxi), pemetrexed (Alimta), penicillin G potassium, phenobarbital (Luminal), piperacillin/tazobactam (Zosyn), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sulfamethoxazole/trimethoprim, tacrolimus (Prograf), teniposide (Vumon), thiotepe, tobramycin, vancomycin, vecuronium, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Rapid IV administration increases the possibility of hypotension and respiratory depression.

IV injection: Administer a single dose over a minimum of 2 to 3 minutes. Frequently titrated according to symptom relief and respiratory rate.

Infusion: All parameters (outlined in Usual Dose) should be ordered by the physician. Any dose requiring a controlled infusion device requires accurate titration and close monitoring.

ACTIONS

A mu-opioid receptor agonist closely related to morphine. Precise mode of action unknown, but opioids are believed to combine with specific CNS opiate receptors. Pharmacologic effects include analgesia, anxiolysis, cough suppression, euphoria, and feelings of relaxation. Seven times more potent than morphine milligram for milligram. Produces respiratory depression by direct effect on brainstem respiratory centers and reduces the responsiveness to increases in carbon dioxide. Causes a reduction of motility in the GI tract. May produce hypotension due to either peripheral vasodilation, release of histamine, or both. Onset of action is prompt, and half-life is about 2.3 hours. Hydromor-

phone is metabolized in the liver and excreted in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Hydromorphone (1 mg/mL, 2 mg/mL, or 4 mg/mL): Management of pain in patients for whom an opioid analgesic is appropriate.

High-potency hydromorphone (10 mg/mL): Management of moderate-to-severe pain in opioid-tolerant patients who require larger than usual doses of opioids to provide adequate pain relief. Patients considered opioid-tolerant are those who are taking at least 60 mg oral morphine/day, 25 mcg transdermal fentanyl/hr, 30 mg oral oxycodone/day, 8 mg hydromorphone/day, 25 mg oral oxymorphone/day, or an equianalgesic dose of another opioid for 1 week or longer.

CONTRAINDICATIONS

Hypersensitivity to hydromorphone, any of its components, or sulfite-containing medications. ■ Acute or severe bronchial asthma, respiratory depression in the absence of resuscitation equipment or in unmonitored settings. ■ In patients with or at risk for developing GI obstruction, especially paralytic ileus. ■ Hydromorphone-HP is contraindicated in patients who are not opioid tolerant.

PRECAUTIONS

Hydromorphone-HP is for use in opioid-tolerant patients only. ■ Use of hydromorphone and hydromorphone-HP carries the risk of respiratory depression, abuse, and medication errors. Do not confuse hydromorphone-HP formulations with standard formulations of hydromorphone or with other opioids; overdose and death could result. ■ Schedule II opioid agonists, including hydromorphone, morphine, oxymorphone, oxycodone, fentanyl, and methadone, have the highest potential for abuse and a risk of producing fatal overdose due to respiratory depression. Alcohol, CNS depressants, and other opioids potentiate the respiratory depressant effects of hydromorphone, increasing the risk for respiratory depression that might result in death; see [Drug/Lab Interactions](#). ■ Use caution in elderly or debilitated patients and in patients with conditions accompanied by hypoxia or hypercapnia or upper airway obstruction. In these patients, even moderate therapeutic doses may dangerously decrease pulmonary ventilation. ■ Use with extreme caution in patients with COPD, cor pulmonale, a substantially decreased respiratory reserve, hypoxia, hypercapnia, or pre-existing respiratory depression. Usual therapeutic doses may decrease respiratory drive while simultaneously increasing airway resistance to the point of apnea. Consider using non-opioid analgesics, or administer under careful medical supervision at the lowest effective dose in these patients. ■ Use with alcohol and other CNS depressants increases the risk of respiratory depression, hypotension, or profound sedation and could result in coma or death; see [Drug/Lab Interactions](#). ■ Use with caution and reduce initial doses in elderly or debilitated patients; in patients with severe impairment of hepatic, pulmonary, or renal function; and in patients with myxedema or hypothyroidism, adrenocortical insufficiency (e.g., Addison's disease), CNS depression or coma, toxic psychoses, prostatic hypertrophy or urethral stricture, acute alcoholism, delirium tremens, or kyphoscoliosis associated with respiratory depression. ■ The respiratory depressant effects of hydromorphone promote carbon dioxide retention, resulting in increased intracranial pressure (ICP). This increase in ICP may be markedly exaggerated in the presence of head injury, intracranial lesions, or other conditions that predispose patients to ICP. The effects on pupillary response and consciousness can obscure the clinical course and neurologic signs of further pressure increases in patients with head injuries. ■ May cause severe hypotension in patients whose ability to maintain blood pressure is compromised by a depleted blood volume or a concurrent administration of drugs such as general anesthetics, phenothiazines, or other agents that compromise vasomotor tone; see [Drug/Lab Interactions](#). ■ Use with caution in patients in circulatory shock. Vasodilation caused by the drug may further reduce cardiac output and BP. ■ May produce orthostatic hypotension in ambulatory patients. ■ Avoid administration in patients with GI obstruction, especially paralytic ileus. Diminishes peristalsis and may prolong obstruction. ■ Symptoms of acute abdominal conditions may be masked. Use with caution in patients with biliary tract disease, including acute pancreatitis; may cause spasm of the sphincter of Oddi and diminish biliary and pancreatic secretions. ■ Cough

reflex may be suppressed. ■ Seizures and myoclonus have been reported in patients administered high parenteral doses. May also aggravate pre-existing seizures in patients with a convulsive disorder and may induce or aggravate seizures in some clinical settings. ■ Tolerance to hydromorphone gradually increases. ■ A Schedule II controlled substance. Physical dependence can develop but is not a factor in the presence of chronic cancer and non-cancer pain. Abuse poses a hazard of overdose and death. Use with caution in patients with alcoholism and other drug dependencies. ■ Some products may use a latex stopper and some may contain sulfites; may cause a hypersensitivity reaction in susceptible patients. ■ See [Maternal/Child](#).

Monitor: Oxygen, controlled respiratory equipment, and naloxone (Narcan) must be available. ■ Assess baseline pain, reassess after administration of hydromorphone, and adjust dose or interval as required. ■ Monitor vital signs and observe patient frequently to continuously based on dose administered. Keep patient supine; orthostatic hypotension and fainting may occur; less likely with continuous low doses, but observe closely during ambulation. ■ Uncontrolled pain causes sleep deprivation, decreases pain threshold, and increases pain. When pain is finally controlled, expect the patient to sleep more until recovery from sleep deprivation. ■ Laxatives with or without stool softeners will be required to avoid constipation and fecal impaction, especially with increased doses and extended use. Maintain adequate hydration.

Patient Education: Avoid alcohol or other CNS depressants (e.g., barbiturates, benzodiazepines [e.g., diazepam (Valium)]). ■ May cause blurred vision, drowsiness, or dizziness; use caution in tasks that require alertness. ■ Request assistance with ambulation. ■ May be habit forming. ■ Take only as directed. ■ Report unrelieved pain or unacceptable side effects promptly.

Maternal/Child: Category C: use during pregnancy only if the potential benefit justifies the risk to the fetus. ■ Use during labor and delivery may produce respiratory depression and a physiologic effect in neonates. May also prolong labor by reducing the strength, duration, and frequency of contractions. ■ Not recommended for use in breast-feeding mothers. ■ Infants born to mothers physically dependent on opioids will also be physically dependent and may exhibit respiratory difficulties and withdrawal symptoms (e.g., excessive crying, fever, hyperactive reflexes, increased respiratory rate, increased stools, sneezing, tremors, vomiting, yawning). ■ Safety and effectiveness for use in pediatric patients not established. ■ Pediatric patients may be more sensitive to effects (e.g., respiratory depression). ■ May cause paradoxical excitation.

Elderly: See [Dose Adjustments](#) and [Precautions](#). ■ May be more susceptible to effects (e.g., respiratory depression, urinary retention, constipation). ■ Lower doses may provide effective analgesia.

DRUG/LAB INTERACTIONS

Potentiated by **phenothiazines and other CNS depressants** such as opioid analgesics, alcohol, anticholinergics, antihistamines, barbiturates, centrally acting antiemetics, general anesthetics, hypnotics, sedatives, MAO inhibitors (e.g., selegiline [Eldepryl]), neuromuscular blocking agents (e.g., atracurium [Tracrium]), psychotropic agents (e.g., antidepressants, antianxiety agents), and skeletal muscle relaxants (e.g., cyclobenzaprine [Flexeril]). Side effects (e.g., CNS or respiratory depression, constipation, hypotension) may be additive. Reduced dosages of both drugs may be indicated. ■ Do not initiate treatment with hydromorphone within 14 days of use of a **MAO inhibitor**. ■ Administration of **agonist/antagonist analgesics** (e.g., butorphanol [Stadol], buprenorphine [Buprenex]) to an opiate-dependent patient receiving a pure opiate may precipitate withdrawal symptoms. ■ Concurrent use with **anticholinergics** (e.g., dimenhydrinate) or **drugs with anticholinergic activity** may cause urinary retention, severe constipation, and paralytic ileus. ■ Plasma **amylase and lipase determinations** may be unreliable for 24 hours following opioid administration.

SIDE EFFECTS

Most frequently occurring side effects include dizziness, dry mouth, dysphoria, euphoria, flushing, light-headedness, nausea, pruritus, sedation, sweating, and vomiting. Other side effects may include abnormal dreams; agitation; alteration of moods; anorexia; anti-diuretic effects; anxiety; arrhythmias (e.g., bradycardia, palpitations, tachycardia); biliary colic; blurred or impaired vision; bronchospasm; chills; depression; disorientation and hallucination; drug abuse, addiction, and dependence; GI effects (e.g., abdominal pain, constipation, diarrhea, ileus) and effects in sphincter of Oddi; headache; hypotension; increased intracranial pressure; injection site pain and urticaria; insomnia; laryngospasm; miosis; muscle rigidity; nervousness; nystagmus; paresthesia; rash; seizures; shock; taste alteration; tremor; urinary retention or hesitancy; weakness.

Overdose: Apnea, atypical snoring, bradycardia, cardiac arrest, circulatory collapse, cold and clammy skin, constricted pupils, hypotension (severe), partial or complete airway obstruction, respiratory depression or arrest, skeletal muscle flaccidity, somnolence progressing to stupor or coma, and death.

Post-Marketing: Anaphylactic reactions, confused state, convulsions, drowsiness, dyskinesia, dyspnea, erectile dysfunction, fatigue, increased hepatic enzymes, hyperalgesia, hypersensitivity reactions, injection site reactions, lethargy, myoclonus, oropharyngeal swelling, peripheral edema, and somnolence.

ANTIDOTE

Notify the physician of any side effect. If minor side effects progress or any major side effect occurs, including the onset of symptoms of overdose, discontinue the drug and notify the physician. Naloxone (Narcan) will reverse serious reactions. Naloxone use should be reserved for situations in which clinically significant respiratory or circulatory depression is present. Titrate naloxone dose carefully to avoid precipitating an acute abstinence syndrome or uncontrolled pain. The duration of action of hydromorphone may exceed the duration of action of naloxone. Monitor patient carefully. Repeat doses of naloxone may be required. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Treat anaphylaxis as indicated or resuscitate as necessary.

HYDROXOCOBALAMIN

(hy-DROX-oh-koh-BAL-ah-min)

Antidote

Cyanokit

pH 3.5 to 6

USUAL DOSE

Manufacturer provides a quick-use reference guide in carton to facilitate immediate administration. It covers reconstitution, mixing, infusion rate, common S/S of cyanide poisoning with or without smoke inhalation, **incompatibilities**, and alternate diluents.

Initial dose: 5 Gm administered by IV infusion over 15 minutes. Based on severity of poisoning and clinical response, a second 5-Gm dose may be administered for a total dose of 10 Gm.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established but has been used outside of the United States.

Initial dose (unlabeled): 70 mg/kg.

DOSE ADJUSTMENTS

No dose adjustments required in the elderly. ■ Potential need for dose adjustment in patients with impaired hepatic or renal function has not been studied.

DILUTION

Each kit contains one 5-Gm, 250-mL glass vial of lyophilized hydroxocobalamin, a sterile transfer spike, a sterile vented infusion tubing, a quick-use reference guide, and a package insert. The glass vial is marked with a fill line for diluent. Using a sterile spike, transfer 200 mL of NS diluent into the glass vial (to the fill line [25 mg/mL]). If NS is not available, LR or D5W may be used. **Do Not Shake!** Invert or rock vial for at least 60 seconds to mix. Solution should be clear and dark red. Attach infusion tubing and begin infusion of the first vial; see [Rate of Administration](#).

Filters: Specific information not available.

Storage: Store kit at CRT. See package insert for allowable storage temperatures for kit transport in extreme weather conditions. Reconstituted product may be held at a temperature not to exceed 40° C (104° F) for up to 6 hours. Do not freeze. Discard any unused portion after 6 hours.

COMPATIBILITY

Manufacturer lists as **incompatible** with ascorbic acid, blood products (whole blood, packed red cells, platelet concentrate, and/or fresh frozen plasma), diazepam (Valium), dobutamine, dopamine, fentanyl (Sublimaze), nitroglycerin IV, pentobarbital (Nembutal), propofol (Diprivan), sodium nitrite, sodium thiosulfate. Do not administer simultaneously through the same IV line. Use of a separate line on the opposing extremity is recommended.

RATE OF ADMINISTRATION

Each 5-Gm dose properly diluted and evenly distributed over 15 minutes. The rate of infusion for the second 5-Gm dose may range from 15 minutes (for a patient in extremis) to 2 hours based on patient condition.

ACTIONS

A high dose of cyanide can result in death within minutes by inhibiting the cells' ability to use oxygen (inhibition of cytochrome oxidase results in arrest of cellular respiration). Specifically, cyanide binds with a component of cytochrome oxidase (cytochrome a₃), prevents the cell from using oxygen, and forces anaerobic metabolism; this results in lactate production, cellular hypoxia, and metabolic acidosis. Each molecule of hydroxocobalamin can bind one cyanide ion to form cyanocobalamin (vitamin B₁₂) and reverse the toxic process. Cyanocobalamin is then excreted in urine.

INDICATIONS AND USES

Treatment of known or suspected cyanide poisoning. Administer without delay if clinical suspicion of cyanide poisoning is high. Symptoms of cyanide poisoning include chest tightness, confusion, dyspnea, headache, nausea. Signs of cyanide poisoning include altered mental status (e.g., confusion, disorientation), seizures or coma, mydriasis (excessive dilation of the pupil of the eye), abnormally rapid or deep breathing (early), abnormally slow breathing or apnea (late), hypertension (early), hypotension (late), cardiovascular collapse, vomiting, plasma lactate concentration equal to or greater than 8 mmol/L. Smoke inhalation victims with cyanide poisoning have usually been exposed to fire and smoke in an enclosed area and may present with soot around mouth, nose, and/or oropharynx; or an altered mental status. They may have a plasma lactate concentration equal to or greater than 10 mmol/L.

CONTRAINDICATIONS

Manufacturer states, “None”; see **Precautions**.

PRECAUTIONS

For IV use only. ■ In addition to treatment with hydroxocobalamin, immediate confirmation of airway patency, adequacy of oxygenation and hydration, cardiovascular support (may be hypotensive or hypertensive), and management of seizure activity is required. Decontamination measures may also be indicated. ■ Use caution in patients with known hypersensitivity to hydroxocobalamin or cyanocobalamin (vitamin B₁₂). Consider alternative treatments if available (e.g., sodium nitrite and sodium thiosulfate). ■ Collection of a pretreatment blood sample would be useful in confirming a diagnosis of cyanide poisoning but should not delay treatment. ■ May cause photosensitivity. ■ Use in patients with impaired hepatic or renal function has not been studied. ■ See **Drug/Lab Interactions**.

Monitor: Immediately confirm airway patency, adequacy of oxygenation, and adequate hydration. ■ If feasible, draw a pretreatment blood sample; see **Precautions**. ■ Monitor BP (may be hypotensive or hypertensive [BP equal to or greater than 180 mm Hg systolic or equal to or greater than 110 mm Hg diastolic has been reported with this treatment]). Hypertension may occur at the beginning of the infusion, is usually at a maximum by the end of the infusion, and should return to baseline within 4 hours. Note Compatibility if treatment is required. ■ Monitor for seizures. Note Compatibility if treatment is required. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, angioneurotic edema, chest tightness, dyspnea, edema, pruritus, rash, urticaria).

Patient Education: Skin redness may last up to 2 weeks. Avoid sun exposure while skin is red. ■ Urine redness may last up to 5 weeks. ■ An acne-like rash may appear 7 to 28 days after treatment. Has usually resolved without treatment. ■ Discontinue breast-feeding; talk with your physician to see when and if you can resume. ■ Report any side effect that is troublesome or doesn't go away.

Maternal/Child: Category C: has caused skeletal and visceral abnormalities in animal studies. Because cyanide readily crosses the placenta, maternal cyanide poisoning results in fetal cyanide poisoning that can be life threatening to the mother and fetus. Consider benefit versus risk before use in pregnancy and labor and delivery. ■ Discontinue breast-feeding until cleared with physician. ■ Safety and effectiveness for use in pediatric patients not established but has been used outside of the United States.

Elderly: Safety and effectiveness similar to that seen in younger adults.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ **Sodium nitrite and sodium thiosulfate** are also used to treat cyanide poisoning. They are **incompatible** with hydroxocobalamin and must be administered in a separate IV line if used concurrently. Safety of coadministration has not been established. ■ Because of its deep red color, hydroxocobalamin **interferes with numerous clinical laboratory tests**. Effects persist for varying lengths of time depending on test. See package insert for specifics. ■ Deep red color may cause hemodialysis machines to shut down (an erroneous detection of a “blood leak”). Consider before hemodialysis is initiated in patients treated with hydroxocobalamin.

SIDE EFFECTS

Most common side effects include chromaturia, decreased lymphocytes, erythema, headache, hypertension, injection site reactions, nausea, and rash. Hypersensitivity reactions and hypertension are the most serious side effects associated with hydroxocobalamin. Other reactions that may occur include abdominal discomfort, chest discomfort, diarrhea, dizziness, dry throat, dyspepsia, dysphagia, dyspnea, hematochezia (blood in stool), hot flashes, impaired memory, irritation, peripheral edema, pruritus, redness and swelling of the eyes, restlessness, throat tightness, urticaria, and vomiting.

ANTIDOTE

Keep physician informed of all side effects; will be treated symptomatically. Note Compatibility before treating hypertension or seizures; use an alternate IV line if indicated. Severe hypersensitivity reactions may require epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone), or bronchodilators (e.g., albuterol [Ventolin], theophylline). Data on overdose not available; manage symptomatically. Hemodialysis may be effective and is indicated for significant hydroxocobalamin toxicity. Cardiac and/or respiratory arrest may occur before treatment has an effect; resuscitate as indicated.

<p>6% HYDROXYETHYL STARCH 130/0.4 IN 0.9% SODIUM CHLORIDE INJECTION (hy-DROX-ee-eth-ihl starch)</p>	<p>Plasma volume substitute</p>
<p>Voluven</p>	<p>pH 4 to 5.5</p>

USUAL DOSE

Variable depending on patient’s blood loss, maintenance or restoration of hemodynamics, and hemodilution (dilution effect). Daily dose may be administered repetitively over several days. Titrate to individual colloid needs, hydration status, and hemodynamics.

Initial infusion: Administer initial 10 to 20 mL of infusion slowly. Observe patient continuously for S/S of a possible hypersensitivity reaction.

Daily dose: Up to 50 mL/kg of body weight per day (equivalent to 3 Gm hydroxyethyl starch and 7.7 mEq sodium/kg body weight). This dose is equivalent to 3500 mL for a 70-kg patient.

PEDIATRIC DOSE

See Usual Dose. Pediatric dose should be adjusted to the individual patient’s colloid needs, taking into account the patient’s underlying disease state and hemodynamic and hydration status. Doses used in clinical trials are listed in the following table.

Pediatric Dosing of 6% Hydroxyethyl Starch 130/0.4 in 0.9% Sodium Chloride in Clinical Trials		
Pediatric Age-Groups	Recommended Daily Dose	Mean Daily Dose ± SD* in Clinical Trials
<2 years	Up to 50 mL/kg body weight in all age-groups	16 ± 9 mL/kg body weight
2 to 12 years		36 ± 11 mL/kg body weight
>12 years		—

*SD, Standard deviation

DOSE ADJUSTMENTS

Use caution in patients with renal impairment and in the elderly. Volume status, infusion rate, and urine output should be closely monitored. Lower-end initial dosing may be appropriate. Titrate to effect.

DILUTION

Available as a 6% solution in a ready-to-use 500-mL flexible plastic intravenous solution container. Remove overwrap immediately before administration. See manufacturer instructions for use of free/flex IV container. Administer through a non-vented standard infusion set. Air inlet of infusion set must be closed.

Storage: Store at 15° to 25° C (59° to 77° F). Do not freeze. Use immediately after insertion of administration set. Manufacturer recommends changing administration set at least once every 24 hours. For single use only. Discard any unused portion.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states the safety and **compatibility** of additives have not been established.

One source suggests the following **compatibilities**:

Y-site: Ampicillin, calcium chloride, calcium gluconate, cefazolin (Ancef), ceftriaxone (Rocephin), ciprofloxacin (Cipro IV), clindamycin (Cleocin), dimenhydrinate, dobutamine, dopamine, esmolol (Brevibloc), fentanyl (Sublimaze), furosemide (Lasix), gentamicin, heparin, hydromorphone (Dilaudid), insulin, labetalol, levofloxacin (Levaquin), magnesium sulfate, meperidine (Demerol), methylprednisolone (Solu-Medrol), metronidazole (Flagyl IV), midazolam (Versed), morphine, moxifloxacin (Avelox), multivitamins (M.V.I.), nitroglycerin IV, norepinephrine (Levophed), octreotide (Sandostatin), potassium chloride, potassium phosphates, propofol (Diprivan), sodium bicarbonate, vasopressin.

RATE OF ADMINISTRATION

Variable depending on indication, present blood volume, and patient response. Initial 10 to 20 mL should be infused slowly, keeping the patient under close observation because of possible anaphylactoid reactions. Administer through a non-vented standard infusion set with air inlet of set closed. If pressure infusion is used, withdraw all air through medication port before infusing.

ACTIONS

A synthetic colloid for use in plasma volume replacement. Contains hydroxyethyl starch in a colloidal solution that expands plasma volume when administered intravenously. After isovolemic exchange of blood with 500 mL of Voluven in healthy volunteers, blood volume is maintained for at least 6 hours. Elimination half-life is 12 hours, and approximately 62% is excreted as hydroxyethyl starch molecules in urine within 72 hours.

INDICATIONS AND USES

Treatment and prophylaxis of hypovolemia in adults and children. It is not a substitute for red blood cells or coagulation factors in plasma.

CONTRAINDICATIONS

Known hypersensitivity to hydroxyethyl starch. ■ Fluid overload (e.g., pulmonary edema, congestive heart failure). ■ Renal failure with oliguria or anuria not related to hypovolemia. ■ Patients receiving dialysis. ■ Severe hypernatremia or severe hyperchloremia. ■ Intracranial bleeding.

PRECAUTIONS

For IV use only. ■ Not a substitute for red blood cells or coagulation factors in plasma. ■ Hypersensitivity reactions, including anaphylaxis, have been reported with solutions containing hydroxyethyl starch. ■ Use caution in patients with cardiac insufficiency, severe kidney or liver dysfunction, or severe bleeding disorders (e.g., severe cases of von Willebrand's disease). ■ In cases of severe dehydration, a crystalloid solution should be administered first. In general, sufficient fluid should be administered to avoid dehydration. ■ At high dosages, the dilutional effects may result in decreased levels of coagulation factors and other plasma proteins and a decrease in hematocrit.

Monitor: Monitor for S/S of hypersensitivity reactions (e.g., mild influenza-like symptoms, bradycardia, tachycardia, bronchospasm, hypotension, non-cardiac pulmonary edema, anaphylaxis); see Rate of Administration. ■ Clinical evaluation and periodic laboratory determinations are necessary to monitor fluid balance, electrolyte concentrations, kidney function, acid-base balance, and coagulation parameters during prolonged parenteral therapy or whenever the patient's condition warrants such evaluation. ■ Monitor BP, HR, and urine output. ■ Monitor fluid status and rate of administration closely, especially in patients with cardiac or renal insufficiency. ■ Monitor liver function and coagulation parameters in patients with severe liver disease or severe bleeding disorders. ■ Maintain adequate hydration of patient with additional IV fluids.

Maternal/Child: Category C: benefit must justify potential risk to the fetus. Embryocidal to rabbits. ■ Information on use during labor and delivery unknown. Use only if clearly needed. ■ Use caution during breast-feeding. ■ See Pediatric Dose.

Elderly: Differences in response between elderly and younger patients not identified, but greater sensitivity of some older individuals cannot be ruled out. Risk of adverse reactions may be greater in patients with impaired renal function. Monitoring of renal function suggested in the elderly.

DRUG/LAB INTERACTIONS

No interactions with other drugs or nutritional products are known. ■ Elevated serum amylase levels may be observed temporarily following administration. May interfere with diagnosis of pancreatitis. ■ Dilutional effects may result in decreased levels of coagulation factors and other plasma proteins and a decrease in hematocrit.

SIDE EFFECTS

Most common side effects include elevated serum amylase, hemodilution (resulting in dilution of blood components [e.g., coagulation factors and other plasma proteins, and in a decrease in hematocrit]), and pruritus. Anaphylactoid/hypersensitivity reactions and disturbances in blood coagulation beyond dilution effects have occurred rarely.

Overdose: May lead to overloading of circulatory system (e.g., pulmonary edema).

Post-Marketing: Anaphylactic/anaphylactoid/hypersensitivity reactions and hypotension/shock/circulatory collapse.

ANTIDOTE

Notify the physician of any side effect. Discontinue the drug immediately at the first sign of a hypersensitivity reaction and treat reaction as indicated. Antihistamines (diphenhydramine [Benadryl]) and epinephrine (Adrenalin) may be indicated. Discontinue infusion immediately in the event of circulatory overload. A diuretic (furosemide [Lasix]) may be administered if necessary. Treat side effects as indicated and resuscitate as necessary.

IBANDRONATE SODIUM

(i-BAN-dro-nate SO-dee-um)

Bone resorption inhibitor
Bisphosphonate

Boniva

USUAL DOSE

3 mg as an IV injection over 15 to 30 seconds every 3 months. Supplemental calcium and vitamin D may be required. See [Precautions](#). Do not administer more frequently than every 3 months; if a dose is missed, administer it as soon as it can be rescheduled, and schedule the next injection for 3 months from that date.

DOSE ADJUSTMENTS

No dose adjustment is indicated based on age, gender, or impaired hepatic function. ■ No dose adjustment is indicated for impaired kidney function in patients with a CrCl equal to or greater than 30 mL/min; see [Contraindications](#).

DILUTION

May be given undiluted. Available in a prefilled syringe with a 25-gauge needle and a needle-stick protection device. Administer only with the provided 25-gauge needle.

Storage: Store at CRT. Syringes are for single use only; discard unused drug.

COMPATIBILITY

Manufacturer states, "Must not be mixed with calcium-containing solutions or other intravenously administered drugs."

RATE OF ADMINISTRATION

A single dose as an IV injection over 15 to 30 seconds.

ACTIONS

A nitrogen-containing bisphosphonate. Action is based on its affinity for hydroxyapatite, which is part of the mineral matrix of bone. Ibandronate inhibits osteoclast activity and reduces bone resorption and turnover. In postmenopausal women with osteoporosis, it increases bone mineral density and reduces the incidence of vertebral fractures. Either rapidly binds to bone (40% to 50% of a dose) or is excreted unchanged in urine (50% to 60%). No evidence that it is metabolized in humans. Terminal half-life is dose dependent and ranged from 4.6 to 25.5 hours in studies in which 2 and 4 mg of ibandronate were administered. Renal clearance is related to CrCl. Patients with a CrCl less than 30 mL/min have a more than twofold increase in exposure (AUC) than do patients with a CrCl greater than 80 mL/min.

INDICATIONS AND USES

Treatment of osteoporosis in postmenopausal women.

Limitation of use: Safety and effectiveness based on clinical data of 1-year duration; optimal duration of use has not been determined. Re-evaluate on a periodic basis. Consider discontinuing ibandronate after 3 to 5 years of use in patients at low risk for fracture, and re-evaluate risk for fracture periodically in patients who discontinue ibandronate.

CONTRAINDICATIONS

Hypersensitivity to ibandronate or its excipients, uncorrected hypocalcemia, severe impaired renal function (CrCl less than 30 mL/min or SCr greater than 2.3 mg/dL).

PRECAUTIONS

For IV injection only. Confirm patency of vein. Intra-arterial or paravenous administration could lead to tissue damage. ■ Anaphylaxis, including fatal events, has been reported. Administer in a facility equipped to monitor the patient and respond to any medical emergency. ■ Disturbances of bone and mineral metabolism (e.g., hypocalcemia, hypovitaminosis D) must be treated before administration of ibandronate. ■ Bisphosphonates have been associated with a deterioration in renal function (e.g., increased SCr, acute renal failure [rare]). Use caution in patients who have concomitant diseases or are taking concomitant medications that may have adverse effects on the kidney. ■ Osteonecrosis of the jaw (ONJ) has been reported in patients receiving bisphosphonates. The majority of cases have been in cancer patients undergoing dental procedures. Risk factors include cancer, concomitant therapy (e.g., chemotherapy, radiotherapy, corticosteroids), and co-morbid conditions (e.g., anemia, coagulopathies, infection, pre-existing oral disease). Consider dental exam and appropriate preventive dentistry before beginning therapy with bisphosphonates. Avoid invasive dental procedures during bisphosphonate therapy. Dental surgery may exacerbate ONJ in patients who develop ONJ while on bisphosphonate therapy. ■ Severe and occasionally incapacitating bone, joint, and muscle pain has been reported rarely. Symptoms may occur from one day to several months after initiation of treatment. In most cases, pain resolves when ibandronate is discontinued; in some patients, however, symptoms resolved slowly or persisted. ■ Atypical, low-energy, or low-trauma fractures of the femoral shaft have been reported in bisphosphonate-treated patients. May be bilateral. Many patients report prodromal pain in the affected area, which usually presents as dull, aching thigh pain weeks to months before a complete fracture occurs. Patients presenting with thigh or groin pain should be

evaluated to rule out an incomplete femur fracture. Patients presenting with an atypical fracture should also be assessed for S/S of fracture in the contralateral limb.

Monitor: Obtain baseline measurements of serum calcium, magnesium, phosphate, and serum creatinine; see **Precautions**. Perform a routine oral examination before administration. ■ May cause a transient decrease in serum calcium values. ■ Daily supplements of calcium and vitamin D may be required during therapy with ibandronate if dietary intake is inadequate. ■ Monitor SCr before each dose. Nephropathy has been reported; see **Precautions**. Withhold treatment for renal deterioration. ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Influenza-like side effects (e.g., bone, muscle, or joint pains; chills; fever; fatigue) consistent with an acute-phase reaction have been reported. Incidence is higher with IV administration. Usually occurs within 3 to 7 days of injection. Symptoms generally subside within 24 to 48 hours, and treatment other than acetaminophen has not been required.

Patient Education: Read manufacturer's patient information sheet before each infusion. ■ Daily supplements of calcium and vitamin D may be required during therapy with ibandronate. ■ Avoid pregnancy; report a suspected pregnancy immediately. ■ Discuss your health history (e.g., kidney problems, diabetes, high blood pressure, heart disease, planned tooth extraction), and prescription and non-prescription medications with health care providers, including your dentist. ■ Promptly report jaw problems. ■ Promptly report chills and/or fever and other S/S of a hypersensitivity reaction (e.g., chest pain, dizziness, feeling faint, flushing, hives, itching, nausea, pruritus, rash, shortness of breath). ■ Report development of bone, joint, or muscle pain promptly. Onset of pain is variable. ■ Promptly report thigh or groin pain. ■ Do not administer more frequently than every 3 months; if a dose is missed, administer it as soon as it can be rescheduled, and schedule the next injection for 3 months from that date. ■ Laboratory monitoring of renal function required before each dose.

Maternal/Child: Category C: use during pregnancy only if benefits justify risks to the mother and fetus. Bisphosphonates do cause fetal harm in animals. ■ Found in milk of lactating animals; safety for use during breast-feeding not established. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response similar to that seen in younger patients; however, greater sensitivity cannot be ruled out. ■ Monitor renal function. Consider impaired renal function and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

Does not inhibit cytochrome P₄₅₀ isoenzymes. ■ Secretory pathway does not appear to include known acidic or basic transport systems involved in the excretion of other drugs. ■ Limited studies show no interaction between ibandronate and melphalan (Alkeran), oral prednisolone, or tamoxifen (Nolvadex). ■ Bisphosphonates are known to interfere with the use of **bone-imaging agents**; ibandronate has not been studied.

SIDE EFFECTS

Abdominal pain, arthralgia, and back pain are the most common side effects. Other commonly reported side effects include headache, increased SCr, influenza-like illness (bone, muscle, or joint pains; chills; fever; fatigue), and injection site reactions (redness or swelling). Less frequent side effects include bronchitis, constipation, cystitis, depression, diarrhea, dizziness, dyspepsia, extremity pain, gastritis, gastroenteritis, hypertension, hypocalcemia, insomnia, localized osteoarthritis, myalgia, nasopharyngitis, nausea, rash, upper respiratory infection, urinary tract infection.

Overdose: Hypocalcemia, hypomagnesemia, and hypophosphatemia.

Post-Marketing: Acute renal failure; atypical, low-energy, or low-trauma fractures of the femoral shaft; hypersensitivity reactions, including anaphylaxis; severe or incapacitating musculoskeletal pain.

ANTIDOTE

Keep physician informed of side effects. Most will respond to symptomatic treatment. Withhold treatment for renal deterioration. Treat clinically relevant reductions in serum levels of calcium, magnesium, and phosphorus with IV administration of calcium gluconate, magnesium sulfate, and/or potassium or sodium phosphate as indicated. Discontinue ibandronate if severe bone, joint, or muscle pain develops. To be beneficial, dialysis must be administered within 2 hours of overdose. Treat anaphylaxis and/or resuscitate as indicated.

IBRITUMOMAB TIUXETAN **BBW**(ib-rih-**TOO**-moh-mab ty-**UKS**-e-tan)Radiopharmaceutical
Monoclonal antibody
Antineoplastic**Zevalin**

pH 7.1 (Buffer Vial)

USUAL DOSE

A combination therapeutic regimen consisting of rituximab and yttrium-90 (Y-90) ibritumomab tiuxetan (a radiolabeled agent). Initiate regimen following recovery of platelet counts to 150,000/mm³ or greater at least 6 weeks, but no more than 12 weeks, following the last dose of first-line chemotherapy. Specific timing of the course of treatment based on the availability of the radioactive component is necessary; see **Dilution**. The radio-labeled agent should not be used without the rituximab pre-dose. ***It is imperative that the rituximab monograph be consulted; all information in that monograph must be considered.*** (Deaths from infusion reactions have occurred within 24 hours of rituximab infusion.) The rituximab dose in this combination regimen is reduced to 250 mg/M² versus 375 mg/M² when it is used as a single agent.

DAY 1

Premedication: Acetaminophen (Tylenol) 650 mg PO and diphenhydramine (Benadryl) 50 mg PO before rituximab to prevent or attenuate severe hypersensitivity reactions.

Rituximab: 250 mg/M² as an IV infusion at an initial rate of 50 mg/hr.

DAY 7, 8, OR 9 (SELECT ONE DATE)

Premedication: Acetaminophen (Tylenol) 650 mg PO and diphenhydramine (Benadryl) 50 mg PO before rituximab to prevent or attenuate severe hypersensitivity reactions.

Rituximab: 250 mg/M² as an IV infusion at an initial rate of 100 mg/hr.

Y-90 ibritumomab tiuxetan (Zevalin): Within 4 hours following completion of rituximab infusion, give Y-90 ibritumomab tiuxetan as an IV injection through a free-flowing IV line over 10 minutes based on platelet count:

0.4 mCi/kg (14.8 MBq/kg) for patients with a normal platelet count *or*

0.3 mCi/kg (11.1 MBq/kg) in relapsed or refractory patients with a platelet count of 100,000-149,000 cells/mm³

Do not treat patients with a platelet count less than 100,000/mm³.

Do not exceed the maximum allowable dose of Y-90 ibritumomab tiuxetan (32 mCi [1184 MBq]), regardless of the patient's weight.

DOSE ADJUSTMENTS

See Usual Dose.

DILUTION

Specific timing of the course of treatment based on the availability of the radioactive component is necessary. The Y-90 chloride sterile solution (the radioactive component of

Y-90 ibritumomab tiuxetan) is available from only one source and can be delivered on only 2 or 3 days of the week. Specific timing of the course of treatment moves backwards from the day of availability of the Y-90 ibritumomab tiuxetan radioactive component.

Rituximab: See rituximab monograph.

Y-90 ibritumomab tiuxetan: A specific kit provides the vials required to produce a single dose. The Y-90 chloride sterile solution (the radioactive component) will be shipped with the kit when ordered. Other supplies (listed in package insert) are required for the preparation of ibritumomab tiuxetan with Y-90 and radiolabeling.

All preparation, calibration, confirmation of radiochemical purity, and administration of this kit will be by personnel authorized to handle radiopharmaceuticals.

Filters: Administration through a 0.22-micron, low-protein binding filter is required.

Storage: Y-90 ibritumomab tiuxetan: Store kit at 2° to 8° C (36° to 46° F) until use and administer within 8 hours of radiolabeling. Do not freeze.

COMPATIBILITY

A radiopharmaceutical; use only the supplies provided in the kit. All components, including the rituximab, should not be mixed or diluted with other drugs.

RATE OF ADMINISTRATION

Rituximab: See rituximab monograph and **Usual Dose**.

The radiopharmaceutical requires the use of a 0.22-micron, low-protein binding filter and a vial and syringe shield. After injection of the radiopharmaceutical, the line should be flushed with at least 10 mL of NS.

Y-90 ibritumomab tiuxetan: A single dose as an IV injection through a free-flowing IV line over 10 minutes; see **Monitor**.

ACTIONS

A combination therapeutic regimen consisting of rituximab and yttrium-90 (Y-90) ibritumomab tiuxetan. Ibritumomab tiuxetan is the immunoconjugate resulting from a stable thiourea covalent bond between the monoclonal antibody ibritumomab and the linker-chelator tiuxetan. This linker-chelator provides a high affinity, specific chelation site for Y-90. The antibody (ibritumomab) is a murine IgG, kappa monoclonal antibody directed against the CD20 antigen found on the surface of normal and malignant B lymphocytes. The CD20 antigen is expressed on pre-B and mature B lymphocytes and on more than 90% of B-cell non-Hodgkin's lymphomas (NHL). Like rituximab, ibritumomab induces apoptosis (fragmentation of the cell). The beta emission from Y-90 induces cellular damage by the formation of free radicals in the target and neighboring cells. A small amount of all components is excreted in urine. Administration of the prescribed regimen results in sustained depletion of circulating B-cells (median was zero at 4 weeks [range 0 to 1,084 cells/mm³]). B-cell recovery begins approximately 12 weeks post-treatment and usually progresses to normal range (32 to 341 cells/mm³) by 9 months post-treatment.

INDICATIONS AND USES

Treatment of relapsed or refractory low-grade or follicular B-cell non-Hodgkin's lymphoma (NHL). ■ Treatment of previously untreated follicular NHL in patients who achieve a partial or complete response to first-line chemotherapy. Used in combination with rituximab.

CONTRAINDICATIONS

Manufacturer states, "None." Known hypersensitivity or anaphylactic reactions to murine proteins or any component of this regimen. ■ Do not administer Y-90 ibritumomab tiuxetan to patients with 25% or greater lymphoma marrow involvement and/or impaired bone marrow reserve. ■ Do not treat patients with a platelet count less than 100,000/mm³.

PRECAUTIONS

Radiopharmaceuticals are administered by or under the direction of the physician specialist whose experience and training in the safe use and handling of radionuclides have been approved by the appropriate government agency. ■ Contents of the kits are not radioactive; however, during and after radiolabeling, care should be taken to minimize

radiation exposure to patients and to medical personnel consistent with institutional good radiation safety practices and patient management procedures. Contact the radiation safety officer. ■ If a splash occurs, flush eyes for at least 15 minutes. For skin contact, wash affected areas thoroughly with soap and water and blot dry; do not abrade skin. In both situations, notify the radiation safety officer and continue the process until no more radiation can be detected. ■ Notify the radiation safety officer immediately if any ingestion occurs. ■ Administer in a facility with adequate personnel, equipment, and supplies to monitor the patient and respond to any medical emergency. ■ Y-90 ibritumomab tiuxetan results in severe and prolonged cytopenias; see [Contraindications](#), [Monitor](#), and [Antidote](#). ■ May cause severe, and potentially fatal, infusion reactions; see [Monitor](#), [Side Effects](#), and rituximab monograph. Deaths have occurred within 24 hours of rituximab infusion and were associated with hypoxia, pulmonary infiltrates, ARDS, MI, VF, or cardiogenic shock. Most fatalities occurred with the first rituximab infusion. ■ Use caution; hypersensitivity reactions and/or anaphylaxis can occur. ■ Severe cutaneous and mucocutaneous reactions, some fatal, have been reported. Onset of these reactions is variable and may be acute (occurring within days) or delayed (occurring after 3 to 4 months); see [Monitor](#) and [Side Effects](#). ■ Safety of ibritumomab tiuxetan for more than a single course of treatment or for use with other therapeutic regimens has not been established. ■ Contains albumin and carries a theoretical risk for transmission of viral diseases or Creutzfeldt-Jakob disease. Effective donor screening and product manufacturing processes make this risk extremely remote. ■ Secondary malignancies (e.g., myelodysplastic syndrome and/or acute myelogenous leukemia [AML]) have been reported. ■ Ability to generate a primary or anamnestic humoral response to any vaccine has not been studied; see [Drug Interactions](#).

Monitor: Obtain a baseline CBC, including differential and platelet count. Monitor weekly or more frequently if indicated (e.g., cytopenias, concurrent drugs). Continue until levels recover. Cytopenias (e.g., thrombocytopenia and neutropenia) can be severe; see [Precautions](#), [Contraindications](#), and [Antidote](#). Median time to nadir was 7 to 9 weeks, and the median duration of cytopenias was 22 to 35 days. Some cytopenias extended beyond 12 weeks, and some patients died without recovering. ■ Monitor for infusion reactions. Typically occur within 30 to 120 minutes of the first rituximab infusion and may cause interruption of rituximab or Y-90 ibritumomab tiuxetan. S/S may include angioedema, bronchospasm, hypotension, and hypoxia; see [Side Effects](#) for additional symptoms. ■ Monitor for serious cutaneous or mucocutaneous reactions (e.g., bullous dermatitis, erythema multiforme, exfoliative dermatitis, Stevens-Johnson syndrome, toxic epidermal necrolysis). ■ To reduce unnecessary radiation exposure to vital organs (e.g., thyroid, kidneys, bladder), patients should be well hydrated before, during, and for at least 1 day after administration. Encourage fluid intake and frequent voiding. ■ Establish a free-flowing IV line before administration of Y-90 ibritumomab tiuxetan; avoid extravasation. Monitor closely; if any signs of extravasation occur, discontinue immediately and restart in another vein. ■ Hemorrhage, including fatal cerebral hemorrhage, has occurred. Monitor for thrombocytopenia (platelet count less than 50,000/mm³) for up to 3 months. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Observe closely for signs of infection for up to 3 months. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ See rituximab monograph; additional monitoring may be required. ■ See [Precautions](#), [Drug/Lab Interactions](#), and [Antidote](#).

Patient Education: Avoid pregnancy; effective birth control recommended for males and females during treatment and for up to 12 months following therapy. Women should report a suspected pregnancy immediately. ■ Explain importance of increased fluid intake and frequent voiding. ■ Promptly report S/S of infection (e.g., fever, sore throat) or S/S of bleeding (e.g., bruising, nose bleed, dark stools).

Maternal/Child: Category D: avoid pregnancy; can cause fetal harm. Women of childbearing potential should avoid becoming pregnant. ■ Could cause toxic effects on testes and

ovaries. Effective contraceptive methods recommended for men and women during treatment and for a minimum of 12 months following therapy. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response similar to that found in younger patients; however, the elderly may have a greater sensitivity to its effects.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. ■ Risk of bleeding may be increased by **any medicine that affects blood clotting**, including **anticoagulants** (e.g., heparin, warfarin [Coumadin]); **glycoprotein GPIIb/IIIa receptor antagonists** (e.g., abciximab [Reo-Pro], eptifibatid [Integrilin], tirofiban [Aggrastat]); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel [Plavix], dipyridamole [Persantine], plicamycin [Mithracin], sulfinpyrazone [Anturane], ticlopidine [Ticlid], valproate [Depacon, Depakene]). ■ Do not administer **live virus vaccines** to patients who have recently received ibritumomab tiuxetan. Safety of immunization with live virus vaccines has not been studied. ■ Potential for additive effects with previously administered **bone marrow-suppressing agents and/or radiation therapy** has not been studied.

SIDE EFFECTS

The most common side effects are asthenia, cough, cytopenias (e.g., anemia, neutropenia, and thrombocytopenia), fatigue, fever, GI symptoms (e.g., abdominal pain, diarrhea, nausea, and vomiting), and sore throat. The most serious side effects are prolonged and severe cytopenias and secondary malignancies. Other side effects include anorexia, anxiety, arthralgias, dizziness, dyspnea, ecchymosis. Abdominal enlargement, asthenia, back pain, chills, constipation, flushing, headache, hypotension, insomnia, myalgia, peripheral edema, rhinitis, throat irritation, and many other side effects have been reported. Nonhematologic toxicities were considered mild in severity.

Major: Other major side effects include hemorrhage while thrombocytopenic (resulting in death), hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, hypotension, pruritus, rash), severe or fatal infusion reactions (e.g., ARDS, bacterial shock, hypoxia, MI, pulmonary infiltrates, VF), infections (predominantly bacterial in origin), and severe cutaneous or mucocutaneous reactions (e.g., bullous dermatitis, erythema multiforme, exfoliative dermatitis, Stevens-Johnson syndrome, toxic epidermal necrolysis).

Post-Marketing: Cutaneous and mucocutaneous reactions (e.g., erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis, bullous dermatitis, and exfoliative dermatitis). Infusion site erythema and ulceration following extravasation, radiation injury, and complications that occur within a month of administration in or near areas of lymphomatous involvement.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Hypersensitivity or infusion-related side effects to any component of the regimen may resolve with slowing or interruption of the infusion and with supportive care (IV saline, diphenhydramine, bronchodilators such as albuterol [Ventolin] or aminophylline, and acetaminophen). Discontinue entire regimen (rituximab and Y-90 ibritumomab tiuxetan) in patients who develop severe infusion reactions (usually to rituximab). Treat anaphylaxis with oxygen, antihistamines (diphenhydramine), epinephrine, and corticosteroids. Maintain a patent airway. Autologous stem cell support, administration of whole blood products (e.g., packed RBCs, platelets, leukocytes), and/or blood modifiers (e.g., filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity or to treat moderate to severe bleeding. However, in clinical studies, patients were prohibited from receiving growth factor

therapy for 2 weeks before the ibritumomab therapeutic regimen, as well as 2 weeks following completion of the regimen. Control minor bleeding by local pressure. For severe bleeding, discontinue therapy and obtain PT, aPTT, platelet count, and fibrinogen. Draw blood for type and cross-match. Antibiotic therapy is indicated for infections and may be indicated prophylactically. Patients who experience severe cutaneous or mucocutaneous reactions should not receive any further component of the therapeutic regimen and should seek prompt medical attention. Death may occur from the progression of some side effects. Resuscitate as indicated.

IBUPROFEN **BBW**

(EYE-bue-PROE-fen)

Caldolor

Analgesic
Antipyretic

pH 7.4

USUAL DOSE

Use the lowest effective dose for the shortest duration of time based on individual needs and response. Reevaluate after the initial dose. Adjust dose and frequency as indicated. Total daily dose should not exceed 3,200 mg. Adequate hydration required before administration to reduce the risk of adverse renal reactions.

Analgesia: 400 to 800 mg every 6 hours as necessary.

Antipyretic: 400 mg every 4 to 6 hours or 100 to 200 mg every 4 hours as necessary.

DOSE ADJUSTMENTS

Lower-end initial and reduced doses may be indicated in the elderly and/or debilitated. Consider potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Must be diluted to a final concentration of 4 mg/mL or less. Infusion without dilution can cause hemolysis. Further dilute in NS, D5W, or LR. An 800-mg dose requires dilution with no less than 200 mL of infusion fluid; a 400-mg dose, 100 mL; a 200-mg dose, 50 mL; and a 100-mg dose, no less than 25 mL of infusion fluid.

Filters: Specific information not available; consult pharmacist.

Storage: Store vials at CRT. Diluted solutions stable for up to 24 hours at 20° to 25° C (68° to 77° F) and with ambient room lighting.

COMPATIBILITY

Specific information not available; consult pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion over no less than 30 minutes.

ACTIONS

A nonsteroidal anti-inflammatory drug (NSAID) that has anti-inflammatory, analgesic, and antipyretic activity. Mechanism of action may be related to prostaglandin synthetase inhibition. Ibuprofen is a mixture of two isomers: [-]R- and [+]S-. The [+]S- isomer is responsible for the activity of ibuprofen. The [-]R- isomer slowly converts to the active [+]S- isomer to maintain levels of the active drug in the circulation. Highly protein bound; the mean half-life of a 400-mg dose is 2.2 hours, and the mean half-life of an 800-mg dose is 2.44 hours.

INDICATIONS AND USES

Management of mild to moderate pain. ■ Management of moderate to severe pain as an adjunct to opioid analgesics. ■ Reduction of fever in adults.

CONTRAINDICATIONS

Known hypersensitivity (anaphylactoid reactions, serious skin reactions) to ibuprofen or other NSAIDs. ■ Known history of asthma, urticaria, or allergic-type reactions after

taking aspirin or other NSAIDs. ■ Treatment of perioperative pain in patients undergoing coronary artery bypass graft (CABG) surgery. ■ See [Maternal/Child](#).

PRECAUTIONS

For IV infusion only. ■ NSAIDs (especially with longer-term use) have been shown to increase the risk of numerous and serious events, which may occur with short-term use in patients with or without a history of the event. ■ May increase risk for serious cardiovascular (CV) thrombotic events (e.g., MI, stroke), which can be fatal. Patients with risk factors for CV disease or known CV disease may be at greater risk. ■ May increase the risk of serious GI ulceration, bleeding, and/or perforation with or without warning signs (can be fatal). Use extreme caution in patients with a prior history of ulcer disease or GI bleeding. Risk is also increased in elderly or debilitated patients and with concomitant use of aspirin, oral corticosteroids, anticoagulants, alcohol, or smoking. ■ May cause elevations of liver function tests (e.g., ALT, AST). Rare cases of serious hepatic reactions (jaundice, liver necrosis, hepatic failure) have occurred, and some have been fatal. ■ May cause fluid retention and edema; use caution in patients with CHF or edema. ■ May precipitate hypertension or worsen pre-existing hypertension; see [Drug/Lab Interactions](#). ■ In addition to the usual caution in patients with reduced hepatic or renal function, NSAIDs may cause a dose-dependent reduction in renal prostaglandin formation and, secondarily, in renal blood flow, which can precipitate renal failure. Patients with impaired renal function, heart failure, or liver dysfunction; elderly patients; and patients receiving ACE inhibitors (e.g., enalapril [Vasotec], lisinopril [Zestril]) or diuretics are at greatest risk. ■ Use caution in dehydrated patients. ■ Anaphylactic reactions have occurred in patients without previous known exposure to ibuprofen; see [Contraindications](#). Use caution in patients with pre-existing asthma. ■ May cause serious skin reactions (e.g., exfoliative dermatitis, Stevens-Johnson syndrome, toxic epidermal necrolysis) without warning; some have been fatal. ■ Anti-inflammatory and antipyretic effects may reduce the utility of these diagnostic signs in detecting other illnesses. ■ May cause anemia. ■ NSAIDs inhibit platelet aggregation and may cause a prolonged bleeding time. ■ Aseptic meningitis and ophthalmologic effects (e.g., blurred or diminished vision, changes in color vision) have been reported with oral ibuprofen. ■ See [Maternal/Child](#).

Monitor: Correct hypovolemia before administration and maintain adequate hydration. ■ Obtain baseline vital signs and monitor frequently during therapy. CBC, liver function tests, and SCr or CrCl may be indicated for a baseline or as needed as symptoms develop. ■ Monitor patients with or without a previous history of CV disease for S/S of CV events (e.g., chest pain, dyspnea, edema, hypertension, limb or facial paralysis). ■ Observe for S/S of GI ulceration or bleeding and/or liver dysfunction. ■ Monitor renal function, especially in patients with impaired renal function. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, pruritus, rash, urticaria, or wheezing). ■ Monitor patients who may be adversely affected by alterations in platelet function (e.g., patients with coagulation disorders or patients receiving anticoagulants).

Patient Education: Side effects have resulted in extended hospitalization and could be fatal. ■ Promptly report any unusual S/S (e.g., abdominal pain, bloody emesis, changes in vision, chest pain, dark stools, dizziness, numbness of face or limbs, rash, shortness of breath, unexplained weight gain or edema).

Maternal/Child: Category C before 30 weeks' gestation; Category D starting at 30 weeks' gestation. Avoid use starting at 30 weeks' gestation; premature closure of the ductus arteriosus in the fetus may occur. Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ Effects during labor and delivery unknown. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response compared with younger patients unknown. ■ Increased risk for serious GI adverse events. ■ Dosing should be cautious; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Concurrent use with **aspirin** not recommended; may increase risk of serious GI events. Aspirin also reduces the protein binding of ibuprofen; clinical significance not

known. ■ Synergistic with **anticoagulants** (e.g., heparin, warfarin [Coumadin]); risk of GI bleeding increased. ■ NSAIDs may decrease the effectiveness of **ACE inhibitors** (e.g., enalapril [Vasotec], lisinopril [Zestril]). ■ Ibuprofen can reduce the natriuretic effects of **furosemide** (Lasix) and **thiazide diuretics** (e.g., hydrochlorothiazide [HydroDIURIL]); observe for signs of renal failure and ensure diuretic effectiveness. ■ Concurrent use of **lithium** with NSAIDs may decrease lithium clearance, increasing plasma levels of lithium; observe for signs of lithium toxicity. ■ Concurrent use of NSAIDs with **methotrexate** may enhance methotrexate toxicity. ■ Coadministration of cimetidine (Tagamet) or ranitidine (Zantac) did not affect ibuprofen serum concentrations.

SIDE EFFECTS

The most common side effects are dizziness, flatulence, headache, hemorrhage, and nausea and vomiting. Other side effects include abdominal discomfort, anemia, bacteremia, bacterial pneumonia, cough, diarrhea, dyspepsia, eosinophilia, hypernatremia, hypertension, hypoalbuminemia, hypokalemia, hypoproteinemia, hypotension, increased blood urea, increased lactic dehydrogenase (LDH), neutropenia, peripheral edema, thrombocytosis, urinary retention, wound hemorrhage. See **Precautions** for potential major side effects.

ANTIDOTE

Keep the physician informed of significant side effects. With increasing severity or onset of symptoms of any major side effect (e.g., CHF; edema; hypersensitivity reactions; GI bleeding, ulceration, or perforation; hepatic or renal effects; hypertension; skin reactions; thrombotic events), discontinue the drug and notify the physician. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly if indicated. Treat anaphylaxis with epinephrine (Adrenalin), diphenhydramine (Benadryl), and corticosteroids as indicated. No known antidote.

IBUPROFEN LYSINE(eye-byou-**PROH**-fen **LIE**-seen)

NSAID

(patent ductus arteriosus adjunct)

NeoProfen

pH 7

NEONATAL DOSE

All doses are based on birth weight. A course of therapy is three doses given at 24-hour intervals.

Initial dose: 10 mg/kg. Follow with a dose of 5 mg/kg in 24 hours and repeat at 48 hours; see [Dose Adjustments](#).

After completion of the first course, no further doses are indicated if the ductus arteriosus closes or is significantly reduced in size. If the ductus arteriosus fails to close or reopens, a second course, alternative pharmacologic therapy, or surgery may be necessary.

DOSE ADJUSTMENTS

If urine output is less than 0.6 mL/kg/hr at any time a dose is to be given, withhold dose until lab studies confirm a return to normal renal function.

DILUTION

Each single dose must be diluted to an appropriate volume for administration as an infusion over 15 minutes with dextrose or saline. Prepare for infusion and begin administration within 30 minutes of preparation. A fresh solution should be prepared just before each administration. Contains no preservatives; discard any unused portion.

Filters: Specific information not available.

Storage: Store vials in cartons at CRT and protect from light until use. Use reconstituted solution within 30 minutes of preparation.

COMPATIBILITY

Manufacturer states, "Should not be simultaneously administered in the same IV line with Total Parenteral Nutrition" (TPN). If required, interrupt TPN for 15 minutes before and after ibuprofen administration. Maintain IV line patency with dextrose or saline infusion.

RATE OF ADMINISTRATION

Administer via the IV port nearest the insertion site.

A single dose, properly diluted, and infused continuously over 15 minutes.

ACTIONS

A nonsteroidal anti-inflammatory drug (NSAID). Mechanism of action by which it causes closure of a patent ductus arteriosus (PDA) is unknown; however, in adults it is an inhibitor of prostaglandin synthesis. By closing the patent ductus arteriosus, the need for surgical intervention is eliminated. Half-life varies inversely with postnatal age, but in general the half-life in infants is more than 10 times longer than in adults. In lower birth weight premature infants, half-life may range from 20 to 51 hours. Metabolism and excretion have not been studied. In adults, it is metabolized in the liver and excreted in the urine and feces.

INDICATIONS AND USES

Closure of a clinically significant patent ductus arteriosus in premature infants weighing between 500 and 1,500 Gm who are no more than 32 weeks' gestational age when usual medical management (e.g., fluid restriction, diuretics, respiratory support) is not effective. Consequences beyond 8 weeks after treatment have not been evaluated.

CONTRAINDICATIONS

Bleeding (especially active intracranial hemorrhage or GI bleeding), coagulation defects, suspected necrotizing enterocolitis, infants with congenital heart disease (e.g., pulmonary atresia, severe coarctation of the aorta, severe tetralogy of Fallot) who require pa-

tency of the ductus arteriosus for satisfactory pulmonary or systemic blood flow, proven or suspected untreated infection, significant renal impairment, thrombocytopenia.

PRECAUTIONS

For IV use only; see **Monitor**. ■ Reserve for infants with clear evidence of a clinically significant PDA (three of the following five criteria: bounding pulse, hyperdynamic precordium, pulmonary edema, increased cardiac silhouette, systolic murmur) or as diagnosed by a neonatologist. ■ For use only in a highly supervised setting such as an intensive care nursery. ■ No long-term evaluations available. Effects of ibuprofen on neurodevelopmental outcome and growth and on disease processes associated with prematurity (e.g., retinopathy of prematurity, chronic lung disease) have not been assessed. ■ May alter the usual signs of infection. Use with extreme caution in the presence of an existing controlled infection and in infants at risk for infection. ■ Can inhibit platelet aggregation; observe for signs of bleeding. ■ Can prolong bleeding time in adults; use caution in infants with underlying hemostatic defects; see **Contraindications**. ■ Can displace bilirubin from albumin-binding sites; use with caution in infants with elevated total bilirubin. ■ Surgery indicated if condition is not responsive to two courses of therapy.

Monitor: Confirm absolute patency of vein. Avoid extravasation; will irritate tissue. Administration via an umbilical arterial line has not been studied. ■ Obtain baseline and monitor vital signs, oxygenation, acid-base status, fluid and electrolyte balance, and kidney function (SCr, BUN, urine output). ■ Can cause a reduction in urine output, increased BUN and SCr, and a decreased CrCl; may progress to oliguria or renal failure. Monitor all infants closely, especially those with some degree of renal impairment. ■ May inhibit platelet aggregation; monitor for signs of bleeding.

DRUG/LAB INTERACTIONS

Drug interactions have not been studied.

SIDE EFFECTS

Most commonly reported side effects include adrenal insufficiency, anemia, apnea, atelectasis, decreased urine output, edema, GI disorders (including non-necrotizing enterocolitis), hematuria, hypernatremia, hypocalcemia, hypoglycemia, increased BUN and SCr, intraventricular hemorrhage and other bleeding, renal failure, renal insufficiency, respiratory failure, respiratory infection, sepsis, skin lesion or irritation, and urinary tract infection. Other side effects of unknown association include abdominal distention, cardiac failure, cholestasis, convulsions, feeding problems, gastritis, gastroesophageal reflux, hypotension, ileus, infections, inguinal hernia, injection site reactions, jaundice, lab abnormalities (e.g., hyperglycemia, neutropenia, thrombocytopenia), and tachycardia.

Post-Marketing: GI perforation, necrotizing enterocolitis.

Overdose: Breathing difficulties, coma, drowsiness, hypotension, irregular heartbeat, kidney failure, seizures, and vomiting have occurred in individuals (not necessarily in premature infants) following overdose of oral ibuprofen.

ANTIDOTE

Discontinue the drug and notify the physician of all side effects. Based on severity, side effects may be treated symptomatically or drug will be completely discontinued in favor of surgical intervention. In case of overdose, there is no specific antidote. Treat symptomatically and follow for several days after apparent recovery; GI ulceration and hemorrhage may occur. Resuscitate as necessary.

IBUTILIDE FUMARATE **BBW**

Antiarrhythmic

(ih-BYOU-tih-lyd FU-mar-ayt)

Corvert

pH 4.6

USUAL DOSE

Guidelines for Ibutilide Dosing		
Patient Weight	Initial Infusion (over 10 minutes)	Second Infusion
60 kg (132 lb) or more	1 mg ibutilide fumarate (one vial [10 mL])	If the arrhythmia does not terminate within 10 minutes after the end of the initial infusion, a second 10-minute infusion of equal strength may be administered 10 minutes after completion of the first infusion.
Less than 60 kg (132 lb)	0.01 mg/kg ibutilide fumarate (0.1 mL/kg)	

Discontinue infusion promptly when the presenting arrhythmia is terminated (desired effect). Must also be discontinued immediately if sustained or nonsustained ventricular tachycardia or marked prolongation of QT or QTc occur (adverse effects). Postconversion treatment with appropriate antiarrhythmics (e.g., digoxin, verapamil, or propranolol) is usually required.

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy. ■ No adjustments required in patients with impaired hepatic or renal function; see **Monitor**. Lower doses may be indicated in post-cardiac surgery patients. In recent studies one or two infusions of 0.5 mg in patients weighing 60 kg or more or 0.005 mg/kg/dose for patients under 60 kg was effective in terminating atrial fibrillation and/or flutter.

DILUTION

May be given undiluted or may be diluted in 50 mL of NS or D5W and given as an infusion. 1 mg (10 mL of a 0.1-mg/mL solution) of ibutilide in 50 mL diluent yields 0.017 mg/mL.

Storage: Store at CRT in carton until use. Stable after dilution for 24 hours at room temperature, 48 hours if refrigerated.

COMPATIBILITY

Manufacturer lists as **compatible** with NS and D5W packaged in glass, polyvinyl chloride, or polyolefin infusion containers. Additional information not available; consult pharmacist.

RATE OF ADMINISTRATION

A single dose by injection or infusion over 10 minutes.

ACTIONS

A class III antiarrhythmic agent that produces mild slowing of the sinus rate and atrio-ventricular conduction. Delays repolarization by activation of a slow inward current (sodium) rather than blocking outward potassium currents. Prolonged atrial and ventricular action potential duration and refractoriness result. Produces dose-related prolongation of the QT interval (may result from dose of ibutilide or rate of injection). Conversion of atrial flutter/fibrillation usually occurs within 30 minutes but may take up to 90 minutes after the start of the infusion. Most patients remain in normal sinus rhythm (NSR) for 24 hours. At recommended doses, ibutilide has no clinically significant effects on cardiac output, mean pulmonary arterial pressure, or pulmonary capillary wedge pressure. Rapidly distributed and metabolized. Elimination half-life is 6 hours (range 2 to 12

hours). Primarily excreted in urine (7% as unchanged drug). Excreted in small amounts in feces.

INDICATIONS AND USES

Rapid conversion of recent onset atrial fibrillation or atrial flutter to sinus rhythm. Patients with more recent onset of arrhythmia have a higher rate of conversion. Effectiveness was less in those with a longer-duration arrhythmia.

CONTRAINDICATIONS

Known hypersensitivity to ibutilide or any of its components. ■ Not recommended in patients who have had a previous polymorphic ventricular tachycardia (e.g., torsades de pointes). ■ See [Drug/Lab Interactions](#).

PRECAUTIONS

For IV infusion only. ■ Usually administered by or under the direction of the physician specialist. ■ Skilled personnel and proper equipment (e.g., cardiac monitors, intracardiac pacing facilities, cardioverter/defibrillator, emergency drugs) must be immediately available. ■ May cause life-threatening arrhythmias (e.g., torsades de pointes) with or without documented QT prolongation. ■ Correct hypokalemia and hypomagnesemia before use; may exaggerate a prolonged QT and cause arrhythmias. ■ Adequate anticoagulation (usually at least 2 weeks) is required for any patient with atrial fibrillation of more than 2 to 3 days' duration. ■ Select patients carefully; benefits (potential for maintaining sinus rhythm) must outweigh risks. Patients with chronic atrial fibrillation are more likely to revert back to atrial fibrillation after conversion to sinus rhythm. Patients with a QTc interval greater than 440 msec or a serum potassium less than 4.0 mEq/L are at very high risk to develop life-threatening arrhythmias. ■ Patients with a history of CHF may be more susceptible to sustained polymorphic VT. ■ Slightly more effective in atrial flutter than atrial fibrillation. ■ See [Drug/Lab Interactions](#).

Monitor: Obtain weight, baseline vital signs, and ECG before administration. Continuous ECG monitoring during and after infusion indicated to observe for arrhythmias. Watch for QT or QTc prolongation; may cause arrhythmia (torsades de pointes) with or without QT prolongation. ■ Monitor BP and HR. Bradycardia, a varying HR, and/or hypokalemia may increase risk of arrhythmia. ■ Arrhythmia occurs most frequently within 40 minutes of completion of infusion but may occur for up to 3 hours after infusion. Monitor ECG for a minimum of 4 hours or until QTc has returned to baseline. Monitor longer if there are any episodes of arrhythmias or if the patient has impaired liver function.

Patient Education: Report promptly any feeling of faintness, difficulty breathing, or pain or stinging along injection site.

Maternal/Child: Category C: benefits must outweigh risks. Caused birth defects and was embryocidal in rats. ■ Temporarily discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly: No age-related differences observed. Median age in clinical trials was 65 years. ■ Lower-end initial doses may be indicated; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Should not be given concurrently with **Class Ia antiarrhythmics** (e.g., disopyramide [Norpace], procainamide [Pronestyl], quinidine) or **other Class III antiarrhythmics** (e.g., amiodarone [Nexterone], sotalol [Betapace]). Withhold any of these agents for at least 5 half-lives before ibutilide infusion and for 4 hours after. ■ Incidence of arrhythmia may be increased with **other drugs that prolong the QT interval** (e.g., phenothiazines [e.g., promethazine (Phenergan)], tricyclic antidepressants [e.g., amitriptyline (Elavil)], tetracyclic antidepressants [e.g., maprotiline (Ludiomil)]). ■ Monitor **serum digoxin levels** to avoid digoxin toxicity. ■ Use with **digoxin, beta-blockers, or calcium channel blockers** does not alter safety or effectiveness of ibutilide. However, **sotalol** is a beta-blocker, and its use with ibutilide is restricted because it has Class III antiarrhythmic activity; see first sentence above.

SIDE EFFECTS

Sustained polymorphic VT (1.7%) and nonsustained polymorphic VT (2.7%) can deteriorate into ventricular fibrillation and be fatal. May cause many other arrhythmias (e.g., first-, second-, or third-degree AV block [1.5%], bradycardia [1.2%], bundle branch

block [1.9%], nonsustained monomorphic VT [4.9%], prolonged QT segment [1.2%], PVCs [5.1%], tachycardia [2.7%], CHF (0.5%), headache (3.6%), hypertension (1.2%), hypotension (2%), nausea (1.9%), palpitation (1%).

Overdose: Side effects exaggerated with overdose in humans. Acute overdose in animals resulted in CNS depression, rapid gasping breathing, convulsions.

ANTIDOTE

If proarrhythmias occur, discontinue ibutilide; correct electrolyte abnormalities (e.g., potassium and magnesium). Overdrive cardiac pacing, electrical cardioversion, or defibrillation may be required. Infusions of magnesium sulfate may be helpful. Avoid treatment with antiarrhythmic agents. VT that deteriorates to VF will require immediate defibrillation.

IDARUBICIN HYDROCHLORIDE **BBW**

(eye-dah-**ROOB**-ih-sin hy-droh-**KLOR**-eyed)

Antineoplastic
(anthracycline antibiotic)

Idamycin PFS, Idarubicin PFS, IDR

pH 5 to 7

USUAL DOSE

Adult acute myeloid leukemia (AML) induction therapy:

Induction: Idarubicin 12 mg/M²/day for 3 days. Used in combination with cytarabine (Ara-C). Cytarabine 100 mg/M²/day may be given as a continuous infusion on Days 1 to 7 (daily for 7 days), or alternately the cytarabine may be given as an IV injection of 25 mg/M² followed immediately by a continuous infusion of cytarabine 200 mg/M²/day on Days 1 to 5 (daily for 5 days). See [Precautions/Monitor](#). If unequivocal evidence of leukemia remains after the first course, a second course may be given; see [Dose Adjustments](#). The benefit of an aggressive consolidation and maintenance program in prolonging the duration of remissions and survival has not been proven. See prescribing information for regimens used in clinical trials.

DOSE ADJUSTMENTS

Delay second course until full recovery if severe mucositis has occurred and reduce dose by 25%. ■ Consider dose reductions in impaired liver and kidney function based on bilirubin and/or creatinine levels above the normal range. Do not administer if bilirubin is above 5 mg/dL. In one Phase III clinical trial, patients with bilirubin levels between 2.6 and 5 mg/dL received a 50% reduction in dose.

DILUTION

Specific techniques required (see [Precautions](#)). Idamycin PFS is a liquid formulation; each 5 mg of powdered idamycin must be reconstituted with 5 mL of nonbacteriostatic NS for injection (1 mg/mL). Use extreme caution inserting the needle; vial contents are under negative pressure. Avoid any possibility of inhalation from aerosol or any skin contamination.

Filters: No data available from manufacturer.

Storage: PFS product must be refrigerated. Reconstituted idamycin is stable for 7 days under refrigeration (2° to 8° C [36° to 46° F]) or 3 days (72 hours) at room temperature (15° to 30° C [59° to 86° F]). Discard unused solution appropriately.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be mixed with other drugs unless specific **compatibility** data are available," and lists as **incompatible** with heparin. Prolonged contact with solutions of an alkaline pH (e.g., sodium lactate, sodium bicarbonate) will result in degradation of idarubicin.

One source suggests the following **compatibilities**:

Y-site: Amifostine (Ethyol), amikacin (Amikin), aztreonam (Azactam), cladribine (Leustatin), cyclophosphamide (Cytoxan), cytarabine (ARA-C), diphenhydramine (Benadryl), droperidol (Inapsine), erythromycin (Erythrocin), etoposide phosphate (Etopophos), filgrastim (Neupogen), gemcitabine (Gemzar), granisetron (Kytril), imipenem-cilastatin (Primaxin), magnesium sulfate, mannitol, melphalan (Alkeran), metoclopramide (Reglan), potassium chloride (KCl), ranitidine (Zantac), sargramostim (Leukine), thiotepea, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

A single dose of properly diluted medication over 10 to 15 minutes through Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS.

ACTIONS

A highly toxic, synthetic, antibiotic, antineoplastic agent. An analog of daunorubicin. Rapidly distributed; has an increased rate of cellular uptake compared to other anthracyclines. It inhibits synthesis of DNA and interacts with the enzyme topoisomerase II. Results in a greater number of remissions and longer survival than previous protocols (daunorubicin and cytarabine). It is severely immunosuppressive. Extensive extrahepatic metabolism. Half-life averages 20 to 22 hours. Slowly excreted in bile and urine.

INDICATIONS AND USES

Treatment of acute myeloid leukemia (AML) in adults in combination with other approved antileukemic drugs.

Unlabeled uses: Treatment of acute lymphoblastic leukemia in pediatric patients; see [Maternal/Child](#).

CONTRAINDICATIONS

Not absolute; pre-existing bone marrow suppression, impaired cardiac function, pre-existing infection; see [Precautions/Monitor](#). ■ Do not administer if bilirubin above 5 mg/dL.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist, with facilities for monitoring the patient and responding to any medical emergency. ■ For IV use only. Do not give IM or SC. ■ Use extreme caution in pre-existing drug-induced bone marrow suppression, existing heart disease, previous treatment with other anthracyclines (e.g., daunorubicin), other cardiotoxic agents (e.g., bleomycin), or radiation therapy encompassing the heart. ■ Myocardial toxicity may cause potentially fatal acute congestive heart failure, acute life-threatening arrhythmias, or other cardiomyopathies. Cardiac toxicity is more common in patients who have received prior anthracyclines (e.g., doxorubicin) or who have pre-existing cardiac disease. ■ May cause severe myelosuppression. ■ Use with caution in patients with hepatic or renal dysfunction. Metabolism and excretion of idarubicin may be impaired; see [Dose Adjustments](#).

Monitor: Determine absolute patency of vein. A stinging or burning sensation indicates extravasation, but extravasation may occur without stinging or burning; severe cellulitis and tissue necrosis can occur with extravasation. Discontinue injection; use another vein. ■ Monitoring of WBCs, RBCs, platelet count, liver function, kidney function, ECG, chest x-ray, echocardiography, and systolic ejection fraction indicated before and during therapy. ■ Severe myelosuppression occurs with effective therapeutic doses. Observe closely for all signs of infection or bleeding. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Monitor uric acid levels; maintain hydration; allopurinol and urine alkalization may be indicated. ■ See [Precautions](#).

Patient Education: Nonhormonal birth control recommended. ■ Report IV site burning or stinging promptly. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. May produce teratogenic effects on the fetus. Contraceptive measures indicated during childbearing years. ■ Discontinue breastfeeding before taking idarubicin. ■ Safety and efficacy for use in pediatric patients not established but has been used; consult literature.

Elderly: Cardiotoxicity or myelotoxicity may be more severe. Patients over 60 years of age who were undergoing induction experienced CHF, serious arrhythmias, chest pain, myocardial infarction, and asymptomatic declines in left ventricular ejection fraction more frequently than younger patients. ■ Monitor renal, hepatic, and hematologic functions closely.

DRUG/LAB INTERACTIONS

Bone marrow toxicity is additive with **other chemotherapeutic agents**. ■ Risk of cardiotoxicity increased in patients previously treated with maximum cumulative doses of **other anthracyclines** (e.g., doxorubicin [Adriamycin], mitoxantrone [Novantrone]) **and/or radiation encompassing the heart**. ■ Leukopenic and/or thrombocytopenic effects may be increased with **drugs that cause blood dyscrasias** (e.g., anticonvulsants [e.g., carbamazepine (Tegretol), phenytoin (Dilantin)], NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]). Adjust dose based on differential and platelet count. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ See [Precautions/Monitor](#).

SIDE EFFECTS

Acute congestive heart failure, alopecia (reversible), arrhythmias, bone marrow suppression (marked with average doses), cramping, decrease in systolic ejection fraction, depressed QRS voltage, diarrhea, erythema and tissue necrosis (if extravasation occurs), fever, headache, hemorrhage (severe), hepatic function changes, infection, mucositis, myocarditis, nausea, pericarditis, renal function changes, seizures, skin rash, urticaria (local), vomiting.

ANTIDOTE

Most side effects will be tolerated or treated symptomatically. Keep physician informed. Close monitoring of bone marrow, ECG, chest x-ray, echocardiography, and systolic ejection fraction may prevent most serious and potentially fatal side effects. There is no specific antidote, but adequate supportive care including platelet transfusions, antibiotics, and symptomatic treatment of mucositis is required. For extravasation, elevate the extremity and apply intermittent ice packs over the area immediately and 4 times a day for ½ hour. Continue for 3 days. Consider aspiration of as much infiltrated drug as possible, flooding of the site with NS, and injection of hydrocortisone sodium succinate (Solu-Cortef) throughout extravasated tissue. Use a 27- or 25-gauge needle. Site should be observed promptly by a reconstructive surgeon. If ulceration begins or there is severe persistent pain at the site, early wide excision of the involved area will be considered. Hemodialysis or peritoneal dialysis probably not effective in overdose.

IFOSFAMIDE **BBW**

(eye-FOS-fah-myd)

Antineoplastic
(alkylating agent/
nitrogen mustard)**Ifex, Ifosfamide/Mesna Kit**

pH 6

USUAL DOSESpecific testing recommended before each dose; see **Monitor**.

1.2 Gm/M²/day for 5 consecutive days. Repeat every 3 weeks as hematologic recovery permits. To initiate this protocol, platelets must be above 100,000/mm³ and WBCs must be above 4,000/mm³. To prevent hemorrhagic cystitis, ifosfamide should be given with extensive hydration (e.g., at least 2 liters of oral or IV fluid/day), and mesna should be administered with every dose. Ifosfamide dose has been mixed with the initial mesna dose each day in the same solution. Appears to be **compatible**.

DOSE ADJUSTMENTS

Reduced dose may be required for adrenalectomized patients and in renal or hepatic impairment. Adequate data not available. ■ Severe myelosuppression is frequent, especially when ifosfamide is given with other chemotherapeutic agents. Dose adjustments of all agents may be required. Adjustment of dose interval may be required. Unless clinically essential, the dose should be held for WBCs less than 2,000/mm³ and/or platelets less than 50,000/mm³.

DILUTION

Specific techniques required; see Precautions. Each 1 Gm must be diluted with 20 mL SWFI or bacteriostatic water for injection (parabens or benzyl alcohol preserved only). Shake solution to dissolve. May be further diluted with D5W, NS, LR, or SWFI. Further dilution with D2½W, ½NS, and D5NS is also acceptable for larger volumes. 1 Gm in 20 mL or 3 Gm in 60 mL equals 50 mg/mL; 1 Gm in 50 mL equals 20 mg/mL; 1 Gm in 200 mL equals 5 mg/mL. Generic product available in a kit containing ifosfamide and mesna.

Filters: Studies measured potency of ifosfamide in combination with mesna through a 5-micron filter. No significant drug loss for ifosfamide; mesna was not measured.

Storage: Store at CRT 20° to 25° C (68° to 77° F). Protect from temperatures above 30° C (86° F). Reconstituted and further diluted solution should be refrigerated and used within 24 hours. Solutions containing benzyl alcohol can reduce stability.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Carboplatin (Paraplatin), cisplatin (Platinol), epirubicin (Ellence), etoposide (VePesid), fluorouracil (5-FU), mesna (Mesnex).

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), aztreonam (Azactam), caspofungin (Cancidas), doripenem (Doribax), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), linezolid (Zyvox), melphalan (Alkeran), ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), palonosetron (Aloxi), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), propofol (Diprivan), sargramostim (Leukine), sodium bicarbonate, teniposide (Vumon), thiotepa, topotecan (Hycamtin), vinorelbine (Navelbine).

RATE OF ADMINISTRATION

A single dose over a minimum of 30 minutes as an infusion. Extend administration time based on amount of diluent and patient condition.

ACTIONS

An alkylating agent. A prodrug that requires activation by hepatic cytochrome P₄₅₀ isoenzymes to exert its cytotoxic activity. Exact mechanism of action not determined, but its cytotoxic action is primarily through DNA cross-links caused by alkylation by isophosphoramidate mustard at guanine N7 positions. The formation of inter- and intra-strand cross-links in the DNA results in cell death. Distribution takes place with minimal tissue binding and little plasma protein binding. Extensively bound by red blood cells. Extensively metabolized in the liver by cytochrome P₄₅₀ isoenzymes (considerable individual variation). Elimination half-life for a usual dose is about 7 hours. Larger doses extend half-life. Ifosfamide and its metabolites are excreted in urine. Secreted in breast milk.

INDICATIONS AND USES

Used in combination with other specific antineoplastic agents for third-line chemotherapy of germ cell testicular cancer. Should be used in combination with mesna for prophylaxis of hemorrhagic cystitis.

Unlabeled uses: Bladder, cervical, and ovarian cancers; Ewing's sarcoma; Hodgkin's and non-Hodgkin's lymphoma; non-small-cell lung cancer; osteosarcoma; soft tissue sarcomas.

CONTRAINDICATIONS

Hypersensitivity to ifosfamide; urinary outflow obstruction.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Usually administered by or under the direction of the physician specialist. ■ Exclude or correct any urinary tract obstructions; see **Contraindications**. ■ Administer cautiously, if at all, to patients with an infection, severe immunosuppression, or compromised bone marrow reserve as indicated by leukopenia, granulocytopenia, extensive bone marrow metastases, prior radiation therapy, or prior treatment with other cytotoxic agents. ■ **Myelosuppression can be severe and lead to fatal infections.** Deaths have been reported. Risk of myelosuppression is dose-dependent and is increased with a single high dose compared to fractionated doses. Severe myelosuppression is often observed when ifosfamide is used in combination with other chemotherapeutic/hematotoxic agents and/or radiation therapy. ■ **CNS toxicities can be severe and result in encephalopathy and death.** ■ **Nephrotoxic and urotoxic.** Acute tubular necrosis, acute renal failure, and chronic renal failure have been reported, and deaths have occurred. Benefits must outweigh risks if ifosfamide is used in patients with pre-existing renal impairment or reduced nephron reserve. Glomerular and tubular disorders of renal function are common and may become apparent during therapy or months and years after stopping treatment. They may resolve, remain stable, or progress even after completion of treatment. Hemorrhagic cystitis can be severe and may require blood transfusions. **Urotoxic effects can be reduced by the prophylactic use of mesna.** Past or concomitant radiation of the bladder or busulfan therapy may increase risk. ■ Use caution in patients with risk factors for cardiotoxicity or pre-existing cardiac disease. Cardiotoxicity (e.g., supraventricular or ventricular arrhythmias, decreased QRS voltage and ST-segment or T-wave changes, toxic cardiomyopathy leading to heart failure with congestion and hypotension, pericardial effusion, fibrinous pericarditis, epicardial fibrosis), sometimes with fatal outcomes, has been reported. Risk is dose dependent and is increased with prior or concomitant treatment with other cardiotoxic agents or radiation of the cardiac region and, possibly, renal impairment. ■ Pulmonary toxicity (e.g., interstitial pneumonitis, pulmonary fibrosis, and other forms of pulmonary toxicity) has been reported, sometimes with fatal outcomes. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. Cross-sensitivity between oxazaphosphorine cytotoxic agents (e.g., cyclophosphamide [Cytosan]) has been reported. ■ May interfere with normal wound healing. ■ Risk of secondary malignancies has been reported. ■ Risk of veno-occlusive liver disease has been reported. ■ Studies in patients with hepatic or renal impairment have not been conducted. Use with caution.

Monitor: Evaluate glomerular and tubular kidney function before, during, and after treatment. ■ Monitor urinary sediment regularly for erythrocytes and other signs of urotoxicity/nephrotoxicity. ■ Urinalysis before each dose recommended. Withhold drug if RBCs in urine exceed 10 per high-powered field. Reinstitute after complete resolution with vigorous oral or parenteral hydration. Mesna given concurrently should prevent hemorrhagic cystitis. ■ Monitor serum and urine chemistries, including phosphorus and potassium, regularly; administer replacement as indicated. ■ Monitor for S/S of renal dysfunction (e.g., decreased glomerular filtration rate, increased SCr, aminoaciduria, cylindruria, enzymuria, glycosuria, phosphaturia, proteinuria, and tubular acidosis). ■ Adequate hydration required; encourage fluid intake (minimum of 2 L/day) and frequent voiding to prevent cystitis. ■ Monitor blood counts prior to and at intervals after each treatment cycle. CBC with differential and platelet count and hemoglobin are recommended before each daily dose and as clinically indicated. Unless clinically essential, WBC count should be above 2,000/mm³ and platelet count above 50,000/mm³. ■ Nadir of the leukocyte count tends to be reached during the second week after administration. ■ Monitor for S/S of hypersensitivity (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Monitor for S/S of pulmonary toxicity and treat as indicated. ■ Pneumonias, as well as other bacterial, fungal, viral, and parasitic infections, have been reported, and latent infections can be reactivated. Observe constantly for signs of infection (e.g., fever, sore throat, tiredness) or unusual bleeding or bruising. Antimicrobial prophylaxis may be indicated in certain cases of neutropenia. Antibiotics and/or antimycotics must be given if neutropenic fever occurs. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for CNS toxicity. Blurred vision, coma, confusion, extrapyramidal symptoms, hallucinations, peripheral neuropathy, psychotic behavior, seizures, somnolence, and urinary incontinence have been reported. Neurotoxicity may appear within a few hours to a few days after the first administration and usually resolves within 48 to 72 hours of discontinuing ifosfamide, although symptoms may persist. Recurrence after several uneventful treatment courses has occurred. Discontinue treatment if encephalopathy occurs. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Prophylactic administration of antiemetics recommended. ■ See [Drug/Lab Interactions](#).

Patient Education: Nonhormonal birth control recommended. Females should avoid pregnancy, and males should not father a child; see [Maternal/Child](#). ■ CNS toxicity may impair the ability to operate an automobile or other heavy machinery. ■ Side effects are numerous and may be fatal; review all potential side effects with your health care professional before treatment. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: can cause fetal harm. Females should avoid pregnancy, and males should not father a child during therapy and for up to 6 months after the end of therapy. May cause amenorrhea in females and oligospermia or azoospermia in males. Sterility has been reported. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Fanconi syndrome, renal rickets, and growth retardation have been reported in pediatric patients. Prepubescent females may become sterile or are at risk for developing premature menopause. Prepubescent males may not develop secondary sexual characteristics normally and may have oligospermia or azoospermia.

Elderly: Monitor renal, hepatic, and hematologic functions closely.

DRUG/LAB INTERACTIONS

See [Dose Adjustments](#). ■ A substrate for both CYP3A4 and CYP2B6. **CYP3A4 inducers** (e.g., carbamazepine [Tegretol], phenytoin [Dilantin], phenobarbital [Luminal], rifampin [Rifadin], and St. John's wort) may increase the metabolism of ifosfamide to its active alkylating metabolites and increase the formation of the neurotoxic/nephrotoxic metabolite chloroacetaldehyde. Monitor closely for signs of toxicity; consider dose adjustment.

CYP3A4 inhibitors (e.g., aprepitant [Emend], fosaprepitant [Emend for injection], fluconazole [Diflucan], grapefruit and grapefruit juice, itraconazole [Sporanox], ketoconazole [Nizoral], sorafenib [Nexavar]) may decrease the metabolism of ifosfamide to its active alkylating metabolites and may decrease the effectiveness of treatment. May also decrease the formation of chloroacetaldehyde. ■ May have additive effects with **other drugs that act on the CNS** (e.g., antihistamines, antiemetics, narcotics, or sedatives). Use with caution or discontinue if encephalopathy occurs. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs.

SIDE EFFECTS

Hematuria, hemorrhagic cystitis, and bone marrow suppression are dose-limiting side effects. Common side effects included alopecia, anorexia, CNS toxicity, confusion, constipation, diarrhea, depressive psychosis with hallucinations, infection, nausea, somnolence, and vomiting. Cardiotoxicity, coagulopathy, coma, cranial nerve dysfunction, dermatitis, dizziness, disorientation, fatigue, fever of unknown origin, hypersensitivity reactions, hypertension, hypotension, infection, liver dysfunction, leukopenia, malaise, neutropenia, osteomalacia, phlebitis, polyneuropathy, pulmonary symptoms, thrombocytopenia, or seizures may occur.

Overdose: Manifestations of dose-dependent toxicities such as CNS toxicity, mucositis, myelosuppression, nephrotoxicity.

Post-Marketing: Angioedema; anaphylaxis; benign and malignant neoplasms; hematotoxicity (e.g., agranulocytosis, bone marrow failure, DIC, febrile bone marrow aplasia, hemolytic anemia, hemolytic uremic syndrome, methemoglobinemia, neonatal anemia); infections, including reactivation of latent infections (e.g., herpes zoster, *Pneumocystis jiroveci*, progressive multifocal leukoencephalopathy [PML], *Strongyloides*, viral hepatitis, and other viral and fungal infections); pneumonia; sepsis and septic shock (including fatal outcomes); psychiatric disorders; tumor lysis syndrome; syndrome of inappropriate antidiuretic hormone secretion (SIADH); and numerous other serious side effects have been reported.

ANTIDOTE

Minor side effects will be treated symptomatically if necessary. Discontinue ifosfamide and notify physician immediately if hematuria, hemorrhagic cystitis, confusion, coma, WBC below 2,000/mm³, or platelets below 50,000/mm³ occur. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow suppression. Maintain supportive therapy for CNS symptoms until complete resolution; occasionally, recovery has been incomplete. Discontinue treatment if encephalopathy occurs. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Cystitis prophylaxis with mesna may prevent or limit urotoxic effects. Ifosfamide and its metabolites are dialyzable.

IMIGLUCERASE ▪ VELAGLUCERASE ALFA

Enzyme replenisher
(glucocerebrosidase)

(em-ee-**GLUE**-sir-ace) ▪ (vel-a-**GLOO**-ser-ase **AL**-fa)

Cerezyme ▪ VPRIV

Imiglucerase pH 6.1

USUAL DOSE

Imiglucerase: Adults and pediatric patients over 2 years of age: Individualized to each patient based on the severity of illness and patient response. Initial doses range from 2.5 units/kg 3 times a week to 60 units/kg every 2 weeks. Imiglucerase should be given at least every 4 weeks. Patients with very severe Gaucher disease may require higher-range initial doses and/or increased frequency because they have accumulated more lipid throughout their bodies, requiring more enzyme to remove the excess stored lipid and bring their disease under control. See [Maternal/Child](#).

Velaglucerase alfa: Adult and pediatric patients over 4 years of age: 60 units/kg every other week. Patients currently being treated with a stable dose of imiglucerase may be switched to velaglucerase alfa at that same dose.

DOSE ADJUSTMENTS

Both preparations: Dose may increase or decrease based on achievement of each patient's therapeutic goals. Optimal goal is to establish the lowest dose that is effective in maintaining control of the disease and preventing recurrence of symptoms for each patient. ▪ Consider potential co-morbid conditions and dose the elderly cautiously.

Imiglucerase: To utilize each bottle fully and reduce waste, a single dose may be increased or decreased slightly as long as the total monthly dose remains unaltered.

Velaglucerase alfa: Clinical studies have evaluated doses ranging from 15 units/kg to 60 units/kg every other week.

DILUTION

Both preparations: Available in 200-unit and 400-unit vials.

$$\text{Weight in kg} \times \text{dose/kg desired} \div 200 \text{ or } 400 \text{ (units/vial)} = \# \text{ of vials required}$$

A 60-kg man requiring 60 units/kg would require 3,600 units. Number of vials required would be 18 vials at 200 units/vial or 9 vials at 400 units/vial. After patient is weighed and appropriate dose is calculated, remove sufficient vials from refrigerator.

Imiglucerase: Adjust number of vials up or down within monthly dose requirement to fully utilize each vial. Each 200-unit vial must be reconstituted with 5.1 mL of SWFI. Each 400-unit vial must be reconstituted with 10.2 mL of SWFI. Both equal 40 units/mL. Gently swirl to mix the solution. **Do not shake.** Let stand for several minutes to allow product to dissolve and bubbles to dissipate. Withdraw exactly 5 mL from the 200-unit vial or 10 mL from the 400-unit vial. A total dose must be further diluted with NS to a volume of 100 to 200 mL. Do not use if discolored or opaque or if particulate matter is present. After dilution, slight flocculation (thin translucent fibers) may occur.

Velaglucerase alfa: Reconstitute each 200-unit vial with 2.2 mL SWFI and each 400-unit vial with 4.3 mL SWFI. Both equal 100 unit/mL. Mix gently. **Do not shake.** Should be clear to slightly opalescent. Do not use if discolored or opaque or if particulate matter is present. Withdraw the calculated volume of drug from vials. A total dose must be further diluted in 100 mL of NS. Mix gently. **Do not shake.**

Filters: Both preparations: Administration through a low-protein binding, 0.2-micron in-line filter is recommended.

Storage: Imiglucerase: Refrigerate before use. Do not use after expiration date on bottle. Return of unsuitable vials (reconstituted, before reconstitution, or expired) may be authorized; contact manufacturer. Contains no preservative; do not store opened vials for future use. Should be promptly diluted after reconstitution but has been shown to be stable

after reconstitution for up to 12 hours at RT or under refrigeration. Diluted solutions stable for up to 24 hours under refrigeration.

Velaglycerase alfa: Refrigerate at 2° to 8° C (36° to 46° F) in carton before use. Do not use after expiration date on vial. Protect from light; do not freeze. Immediate use is preferred, but reconstituted and fully diluted solutions are stable for up to 24 hours if refrigerated and protected from light. Do not freeze. Complete infusion within 24 hours of reconstitution. For single use only; discard unused solution.

COMPATIBILITY

Imiglycerase: Specific information not available. Consider specific use; consult pharmacist.

Velaglycerase alfa: Manufacturer states, "Should not be infused with other products in the same infusion tubing." **Compatibility** studies have not been done.

RATE OF ADMINISTRATION

Both preparations: Use of an in-line, low-protein binding, 0.2-micron filter is recommended. Use of an infusion pump is helpful. Flush the IV line with NS at the end of the infusion to ensure the total dose is received.

Imiglycerase: A single dose equally distributed over 1 to 2 hours.

Velaglycerase alfa: A single dose equally distributed over 60 minutes.

ACTIONS

Imiglycerase is an analog of the human enzyme beta-glucocerebrosidase produced by recombinant DNA technology. **Velaglycerase alfa** is produced by gene activation technology in a human fibroblast cell line. Both have the same amino acid sequence as the naturally occurring human enzyme glucocerebrosidase. Gaucher disease is characterized by a functional deficiency in beta-glucocerebrosidase enzymatic activity and the resultant accumulation of lipid glucocerebroside in tissue macrophages (Gaucher cells). These cells are found in the liver, spleen, bone marrow, and occasionally in the lung, kidney, and intestine. These agents act like glucocerebrosidase, catalyzing the hydrolysis of glucocerebroside to glucose and ceramide. Effective in controlling and actually reversing disease symptoms. Increase in appetite and energy level and improvement in hemoglobin are often the first observable effects and may occur in 2 to 4 months. Cachexia and wasting in pediatric patients are reduced. Within 6 months splenomegaly and hepatomegaly are significantly reduced, and hemoglobin, hematocrit, erythrocyte, and platelet counts improved. Replenishment of bone marrow and improving mineralization of bone may take several years.

INDICATIONS AND USES

Imiglycerase: Long-term enzyme replacement therapy for pediatric and adult patients with confirmed diagnosis of Type I Gaucher disease, which results in one or more of the following conditions: anemia, thrombocytopenia, bone disease, hepatomegaly, or splenomegaly.

Velaglycerase alfa: Long-term enzyme replacement therapy for pediatric and adult patients with Type I Gaucher disease.

CONTRAINDICATIONS

Imiglycerase: None known. Reevaluate if there is significant clinical evidence of hypersensitivity to imiglycerase.

Velaglycerase alfa: Manufacturer states, "None."

PRECAUTIONS

Both preparations: Hypersensitivity and infusion reactions have been reported. Administer further enzyme replacement therapy treatment with caution in patients who have exhibited symptoms of hypersensitivity to other enzyme replacement therapy; see **Antidote**. ■ Effective only via IV route. ■ Should be used under the direction of a physician knowledgeable in the management of Gaucher disease. Administer in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency.

Imiglycerase: A recombinant product; risk of transmission of any bacterial, mycoplasmal, fungal, or viral agent is remote. ■ Approximately 15% of patients have developed IgG

antibodies. Most patients who develop antibodies to imiglucerase do so within 12 months of treatment. Patients with antibodies to imiglucerase are at increased risk for developing hypersensitivity reactions. Monitor periodically for IgG antibody formation during the first year of therapy. Patients who develop hypersensitivity reactions to imiglucerase may be premedicated (see [Antidote](#)) or consideration may be given to treatment with velaglucerase alfa (VPRIV). Most patients who previously received alglucerase (Ceredase) have been transferred to imiglucerase and will remain on imiglucerase or velaglucerase alfa unless a severe hypersensitivity reaction develops. Alglucerase availability is restricted to patients with severe hypersensitivity reactions who are not responsive to premedication. ■ Pulmonary hypertension and pneumonia have been reported. They are known complications of Gaucher disease and have been observed in these patients whether or not they are receiving imiglucerase. Evaluate patients with respiratory symptoms in the absence of fever for the presence of pulmonary hypertension.

Velaglucerase alfa: Infusion reactions have occurred usually during the first 6 months of treatment and occurred less frequently with time. Generally mild (e.g., asthenia, dizziness, fatigue, fever, headache, hypertension, hypotension, nausea). Development of IgG antibodies has been rare but is possible.

Monitor: Evaluate hemoglobin, hematocrit, platelets, WBC, acid phosphatase (AP), plasma glucocerebroside, liver and/or spleen size, and bone changes before and during therapy. Frequency determined by patient response; more frequent when determining response to initial dose and when dose is being adjusted. Blood tests will be done more frequently because anemia is the first symptom to improve. ■ Monitor weight before each dose (used to calculate dose) and monitor vital signs. ■ Observe for S/S of a hypersensitivity reaction; see [Antidote](#). ■ MRI may be used to evaluate liver and spleen. ■ Standard x-rays provide adequate evaluation of bone changes. ■ Observe patient closely for signs of improvement (e.g., increased energy, reduced bleeding tendency, reduction in size of liver and/or spleen, reduced joint swelling, reduced bone pain). ■ Continue to monitor for antibodies in patients who have developed an immune response to either alglucerase or imiglucerase and are transferred to velaglucerase alfa. ■ See [Precautions](#).

Patient Education: Treatment required for life. ■ Promptly report S/S of a hypersensitivity or infusion reaction (e.g., chills, dizziness, fatigue, fever, headache, itching, nausea, rash, shortness of breath, wheezing).

Maternal/Child: Imiglucerase: Category C: use in pregnancy only if potential benefit justifies the risk. ■ Has been used in pediatric patients under 2 years of age, but safety and effectiveness have not been established.

Velaglucerase alfa: Category B: use in pregnancy only if clearly needed.

Both preparations: Safety for use during breast-feeding not established. Not known if imiglucerase or velaglucerase are secreted in breast milk.

Elderly: Imiglucerase: Specific information not available in product information.

Velaglucerase alfa: Numbers in clinical studies insufficient to determine if the elderly respond differently from younger subjects; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

None indicated. Specific information not available.

SIDE EFFECTS

Imiglucerase: Headache, pruritus, and rash were most commonly reported. In addition, abdominal discomfort; backache; burning, discomfort, and pruritus at injection site; chills; diarrhea; dizziness; fatigue; fever; hypotension (mild); nausea; peripheral edema (transient); swelling or sterile abscess at venipuncture site; and tachycardia were reported.

Pediatric patients 2 to 12 years: Coughing, dyspnea, fever, flushing, nausea, and vomiting were most commonly reported in this age-group.

Velaglucerase alfa: Adults: Infusion-related reactions were the most common, and hypersensitivity reactions were the most serious. Other reported side effects include abdominal

pain, asthenia, back pain, dizziness, fatigue, fever, headache, joint pain, nausea, prolonged aPTT, and upper respiratory infections.

Pediatric patients: Adverse reactions similar to adults; however, fever, prolonged aPTT, rash, and upper respiratory infections were seen more commonly in pediatric patients.

Both preparations: A protein immune reaction may develop. Side effects may improve with continued therapy because antibody levels decrease. Hypersensitivity reactions (e.g., anaphylaxis, angioedema, chest discomfort, cyanosis, flushing, hypotension, pruritus, rash, respiratory symptoms, urticaria) have occurred.

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. Based on the severity of the reaction, temporarily interrupt or discontinue infusion for clinical evidence of hypersensitivity or an infusion reaction. Patients have successfully continued therapy after mild hypersensitivity or infusion reactions with pretreatment with antipyretics, antihistamines (e.g., diphenhydramine [Benadryl]), and/or corticosteroids (e.g., dexamethasone [Decadron]) and/or a reduction in rate of administration. Treat anaphylaxis as necessary.

IMIPENEM-CILASTATIN

(em-ee-PEN-em sigh-lah-STAT-in)

**Antibacterial
(carbapenem)**

Primaxin

pH 6.5 to 8.5

USUAL DOSE

Range is from 250 mg to 1 Gm every 6 to 8 hours. Dose based on severity of disease, susceptibility of pathogens, condition of the patient, age, weight, and CrCl. Adult doses in the following chart are limited to patients with a CrCl equal to or greater than 71 mL/min/1.73 M² and a body weight equal to or greater than 70 kg; see [Dose Adjustments](#). Because of high antimicrobial activity, do not exceed the lower of 50 mg/kg/24 hr or 4 Gm/24 hr in adult or pediatric patients. Continue for at least 2 days after all symptoms of infection subside.

Imipenem-Cilastatin Dosing Guidelines				
Type or Severity of Infection	Fully Susceptible Organisms	Total Daily Dose	Moderately Susceptible Organisms	Total Daily Dose
Mild	250 mg q 6 hr	1 Gm	500 mg q 6 hr	2 Gm
Moderate	500 mg q 8 hr or 500 mg q 6 hr	1.5 Gm 2 Gm	500 mg q 6 hr or 1 Gm q 8 hr	2 Gm 3 Gm
	500 mg q 6 hr	2 Gm	1 Gm q 8 hr or 1 Gm q 6 hr	3 Gm 4 Gm
Severe/life-threatening	500 mg q 6 hr	2 Gm	1 Gm q 8 hr or 1 Gm q 6 hr	3 Gm 4 Gm
Uncomplicated UTI	250 mg q 6 hr	1 Gm	250 mg q 6 hr	1 Gm
Complicated UTI	500 mg q 6 hr	2 Gm	500 mg q 6 hr	2 Gm

Adult and pediatric patients over 12 years of age with cystic fibrosis and normal renal function: Higher doses up to 90 mg/kg/day have been used. Do not exceed 4 Gm/24 hr.

PEDIATRIC DOSE

Not recommended for use in pediatric patients with CNS infections because of the risk of seizures, or in pediatric patients weighing less than 30 kg with impaired renal function

(no data available). Because of high antimicrobial activity, do not exceed the lower of 50 mg/kg/24 hr or 4 Gm/24 hr in adult or pediatric patients.

Infants 3 months of age or less, weighing 1,500 Gm or more: For non-CNS infections:

Less than 1 week of age: 25 mg/kg every 12 hours.

1 to 4 weeks of age: 25 mg/kg every 8 hours.

4 weeks to 3 months of age: 25 mg/kg every 6 hours.

Premature infants weighing from 670 to 1,890 Gm in the first week of life were given 20 mg/kg every 12 hours in one study (see package insert).

Infants and other pediatric patients over 3 months of age: For non-CNS infections: 15 to 25 mg/kg/dose every 6 hours. See statements in Usual Dose. Maximum dose is 2 Gm/day for treatment of infections caused by fully susceptible organisms and 4 Gm/day for moderately susceptible organisms.

DOSE ADJUSTMENTS

Dose adjustments are extensive and required for all patients weighing less than 70 kg, as well as all patients with a CrCl less than 71 mL/min/1.73 M². Dose adjustments also vary based on total daily dose required (e.g., 1, 1.5, 2, 3, or 4 Gm). See charts in package insert. ■ Reduced doses may be required in the elderly based on weight and/or decreased renal function. ■ Cleared by hemodialysis; administer after hemodialysis and at 12-hour intervals thereafter. ■ See [Precautions/Monitor](#) and [Drug/Lab Interactions](#).

DILUTION

Reconstitute each single dose with 10 mL of **compatible** infusion solutions (e.g., D5W, D10W, NS [see chart on inside back cover or literature]); also **compatible** in D5W with 0.15% KCl and mannitol 5% and 10%. Shake well and transfer the resulting suspension to 100 mL of the same infusion solution. Rinse vial with an additional 10 mL of infusion solution to ensure complete transfer of vial contents to the infusion solution. Agitate until clear. Also available in ADD-Vantage vials for use with ADD-Vantage infusion containers.

Neonatal dilution: Use preservative-free solutions for reconstitution of neonatal doses.

Filters: Manufacturer's data limited; indicates that use of a filter system when withdrawing the suspension from the vial would probably result in filter clogging and decrease the available antibiotic. An in-house study documented **compatibility** of the final diluted solution with a 0.22-micron in-line filter.

Storage: Store dry powder below 25° C (77° F). Diluted solutions are stable at room temperature for 4 hours after preparation or 24 hours if refrigerated. Do not freeze.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be mixed with or physically added to other antibiotics." See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), amifostine (Ethyol), anidulafungin (Eraxis), aztreonam (Azactam), casposfungin (Cancidas), cefepime (Maxipime), cisatracurium (Nimbex), diltiazem (Cardizem), docetaxel (Taxotere), famotidine (Pepcid IV), filgrastim (Neupogen), fludarabine (Fludara), foscarnet (Foscavir), granisetron (Kytril), idarubicin (Idamycin), insulin (regular), linezolid (Zyvox), melphalan (Alkeran), methotrexate, ondansetron (Zofran), propofol (Diprivan), remifentanyl (Ultiva), tacrolimus (Prograf), teniposide (Vumon), thiotepa, tigecycline (Tygacil), vasopressin, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Intermittent IV: Each 500 mg or fraction thereof over 20 to 30 minutes. Doses greater than 500 mg should be infused over 40 to 60 minutes. Slow infusion rate if patient develops nausea and vomiting, dizziness, hypotension, or sweating. May be given through Y-tube or three-way stopcock of infusion set.

ACTIONS

A potent broad-spectrum antibacterial agent. Imipenem is a carbapenem antibiotic; cilastatin inhibits the kidney enzyme responsible for the metabolism of imipenem. Both components are present in equal amounts. Bactericidal to many gram-negative, gram-positive, and anaerobic organisms. Bactericidal activity results from the inhibition of bacterial wall synthesis. Effective against many otherwise resistant organisms. Has a high degree of stability in the presence of beta-lactamases produced by gram-negative and gram-positive bacteria. Rapidly and widely distributed into many body fluids and tissues. Metabolized in the kidneys. Half-life is approximately 1 hour. Excreted in the urine. May cross the placental barrier.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, urinary tract, skin and skin structure, bone and joint, gynecologic, intra-abdominal, and polymicrobial infections; bacterial septicemia, and endocarditis. Most effective against specific organisms (see literature).

Unlabeled uses: Treatment of febrile neutropenia and melioidosis (a rare infection in humans and animals).

CONTRAINDICATIONS

Known sensitivity to any component of this product. ■ See [Maternal/Child and Precautions](#).

PRECAUTIONS

Specific sensitivity studies are indicated to determine susceptibility of the causative organism to imipenem-cilastatin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, imipenem-cilastatin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Serious and occasionally fatal hypersensitivity reactions have been reported in patients receiving therapy with beta-lactams (e.g., carbapenems, cephalosporins, penicillins). More likely in patients with a history of sensitivity to multiple allergens; obtain a careful history. Cross-sensitivity is possible. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ CNS adverse effects, including confusional states, myoclonic activity, and seizures, have been reported. Incidence increases with higher doses, compromised renal function, or pre-existing CNS disorders. ■ Not recommended in patients with a CrCl less than 5 mL/min/1.73 M² unless hemodialysis is instituted within 48 hours. ■ For patients on hemodialysis, benefits of use must outweigh risk of seizures. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with imipenem-cilastatin. ■ Safety and effectiveness for use in meningitis not established. ■ Clinical improvement has been observed in patients with cystic fibrosis, COPD, and lower respiratory tract infections caused by *Pseudomonas aeruginosa*; however, effective bacterial eradication may not occur. ■ See [Maternal/Child](#) and [Drug/Lab Interactions](#).

Monitor: May cause thrombophlebitis. Use small needles and large veins, and rotate infusion sites. ■ Electrolyte imbalance and cardiac irregularities resulting from sodium content are possible. Contains 3.2 mEq of sodium/Gm. ■ Monitor renal, hepatic, and hemopoietic systems in prolonged therapy. ■ Some strains of *Pseudomonas aeruginosa* may develop resistance fairly rapidly during treatment. Periodic susceptibility testing should be done when clinically indicated. ■ See [Drug/Lab Interactions](#).

Patient Education: Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Patients with a history of seizures should review medication profile with physician before taking imipenem; see [Drug/Lab Interactions](#).

Maternal/Child: Category C: use only if potential benefit outweighs potential risk during pregnancy and breast-feeding.

Elderly: Consider weight and age-related renal impairment. See [Dose Adjustments](#). ■ Response similar to that seen in younger patients; however, greater sensitivity in the elderly cannot be ruled out.

DRUG/LAB INTERACTIONS

Carbapenems may reduce serum **valproic acid** concentrations to subtherapeutic levels, resulting in loss of seizure control. Monitor valproic acid levels. Consider alternative antibacterial therapy. If administration of imipenem is necessary, supplemental anticonvulsant therapy should be considered. ■ May be used concomitantly with **aminoglycosides and other antibiotics**, but these drugs must never be mixed in the same infusion or given concurrently. ■ Use with **ganciclovir** (Cytovene) may cause generalized seizures. Use only if benefit outweighs risk. ■ Half-life and plasma levels slightly increased by **probenecid**. Avoid concurrent use. ■ Concurrent use with **cyclosporine** (Sandimmune) may decrease cyclosporine metabolism. Elevated cyclosporine levels and neurotoxicity (e.g., agitation, confusion, tremor) have been reported.

SIDE EFFECTS

Full scope of hypersensitivity reactions including anaphylaxis, pruritus, rash, and urticaria. Abdominal pain; abnormal clotting time; altered CBC and electrolytes; anuria; burning, discomfort, and pain at injection site; CDAD; confusion; diarrhea; dizziness; dyspnea; elevated alkaline phosphatase, AST, ALT, bilirubin, creatinine, BUN, LDH; fever; gastroenteritis; glossitis; headache; heartburn; hemorrhagic colitis; hepatic failure; hepatitis (including fulminant hepatitis); hyperventilation; hypotension; increased salivation; myoclonus; nausea and vomiting; paresthesia; pharyngeal pain; polyarthralgia; polyuria; positive direct Coombs' test; presence of WBCs or RBCs, protein casts, bilirubin, or urobilinogen in urine; seizures; somnolence; thrombophlebitis; tinnitus; tongue papillar hypertrophy; transient hearing loss in the hearing impaired; vertigo; and many others.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Resuscitate as necessary. Begin anticonvulsants if focal tremors, myoclonus, or seizures occur. If symptoms continue, decrease dose or discontinue the drug. Infusion rate reactions (e.g., dizziness, hypotension, N/V, and sweating) may respond to a decrease in rate of infusion. Mild cases of CDAD may respond to discontinuation of the drug. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis may be useful in overdose.

IMMUNE GLOBULIN INTRAVENOUS **BBW**

(im-MUNE GLAW-byoo-lin IV)

Bivigam, Carimune NF, Flebogamma, Gamimune S/D, Gammagard Liquid, Gammagard S/D, Gammar P-IV, Gamunex-C, IGIV, Iveegam EN, Priviligen

Immunizing agent (passive)
Platelet count stimulator
Antibacterial
Antiviral
Antipolyneuropathy agent

pH 4 to 7.2

USUAL DOSE

PRIMARY IMMUNODEFICIENCY (PID) DISEASES

Bivigam: 300 to 800 mg/kg as a single-dose IV infusion every 3 to 4 weeks. Monitor clinical response and trough levels to adjust dose as appropriate. Desired trough level of total IgG concentrations is a minimum of 500 mg/dL (target is 600 mg/dL).

Carimune NF: 200 mg/kg as a single-dose IV infusion. May be repeated monthly if indicated. If adequate IgG levels in the circulation or clinical response not achieved, may be increased to 300 mg/kg, or the 200 mg/kg dose may be given more frequently.

Gammagard S/D: 300 to 600 mg/kg as a single-dose IV infusion every 3 to 4 weeks.

Gammar P-IV: 200 to 400 mg/kg as a single-dose IV infusion every 3 to 4 weeks. Up to 600 mg/kg may be required. High-end doses may be given initially and for several doses at more frequent intervals based on individual patient response and adequate IgG levels. Reduce dose 100 to 200 mg/kg and/or increase interval when therapeutic IgG levels are achieved.

Flebogamma, Gamunex-C: 300 to 600 mg/kg as a single-dose IV infusion every 3 to 4 weeks. Individualize dose and interval based on clinical response. A target serum IgG trough level before the next infusion of at least 5 Gm/L is suggested. Gamunex-C may be given SC for PID at an initial dose 1.37 times the current IV dose in mg/kg. Do not administer SC for ITP patients. Must be given by IV infusion in ITP patients. See prescribing information for individualizing the SC dose, converting from monthly to weekly injections, and increasing the SC dose based on target serum IgG trough level.

Gammagard Liquid: 300 to 600 mg/kg as a single-dose IV infusion every 3 to 4 weeks. Individualize dose and interval based on clinical response.

Iveegam EN: 200 mg/kg/month as a single-dose IV infusion. If adequate IgG levels in the circulation or clinical response are not achieved, may be increased up to 800 mg/kg or intervals shortened. Do not exceed 800 mg/kg/month.

Priviligen: 200 to 800 mg/kg as a single-dose IV infusion every 3 to 4 weeks. Adjust dose to achieve desired serum trough levels and clinical response.

IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP)

Carimune NF: 400 mg/kg for 2 to 5 consecutive days based on platelet count and clinical response. May be discontinued in acute ITP of childhood if an initial platelet count response to the first two doses is adequate (30,000 to 50,000/mm³). If clinically significant bleeding occurs or the platelet count falls below 30,000/mm³, a maintenance dose of 400 mg/kg may be given as a single infusion. If response inadequate, increase to 800 to 1,000 mg/kg. May be given intermittently to maintain platelet count.

Gammagard S/D: 1 Gm/kg. Up to 3 doses can be given on alternate days based on clinical response and platelet count.

Gamunex-C: Do not administer SC for ITP patients due to a potential risk of hematoma formation. 1 Gm/kg/day (10 mL/kg/day) for 2 consecutive days or 0.4 Gm/kg/day (4 mL/kg/day) for 5 consecutive days. With either regimen the total dose is 2 Gm/kg. Dose is based on platelet count and clinical response. The second 1 Gm/kg dose may be withheld if an adequate increase in platelet count is observed at 24 hours. The high-dose

regimen (1 Gm/kg/day for 1 to 2 days) is not recommended for individuals with expanded fluid volumes or where fluid volume may be a concern.

Privigen: Chronic ITP: 1 Gm/kg IV daily for 2 consecutive days for a total dose of 2 Gm/kg.

B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

Gammagard S/D: 400 mg/kg every 3 to 4 weeks.

CHRONIC INFLAMMATORY DEMYELINATING POLYNEUROPATHY (CIDP)

Gamunex-C: The initial total loading dose of 2 Gm/kg should be given in divided doses (1 Gm/kg/day [10 mL/kg/day] for 2 consecutive days or 500 mg/kg/day [5 mL/kg/day] for 4 consecutive days). Follow with maintenance infusions of 1 Gm/kg every 3 weeks. The maintenance dose may be given as a total dose of 1 Gm/kg (10 mL/kg) on Day 1 or divided into 2 doses of 500 mg/kg given over 2 consecutive days.

PREVENTION OF INFECTION IN BONE MARROW TRANSPLANT PATIENTS

Gamimune N, which is no longer available, was the only IGIV preparation approved for this indication. Other IGIV preparations may be considered as an unlabeled use; consult literature for recommendations. Gamimune N was indicated only in transplant patients over 20 years of age and was given in a 500 mg/kg dose on Day 7 and Day 2 pre-transplant (or at time that conditioning therapy for transplant began). The same dose was given each week through day 90 post-transplant.

PREVENTION OF BACTERIAL INFECTIONS IN HIV-INFECTED CHILDREN AND ADULTS

Gamimune N, which is no longer available, was the only IGIV preparation approved for this indication. Other IGIV preparations may be considered as an unlabeled use; consult literature for recommendations. Gamimune N was given in a 400 mg/kg dose every 28 days.

KAWASAKI SYNDROME

Iveegam EN: 2 Gm/kg as a single dose over 10 to 12 hours. If symptoms persist an additional 2 Gm/kg dose may be given over 10 to 12 hours. Alternately, **Iveegam EN** may be given at 400 mg/kg/day for 4 days. Initiate within 10 days of onset of disease. Concomitantly give aspirin 80 to 100 mg/kg/day equally divided into 4 doses through 14th day after onset of symptoms or until fever subsides, then 3 to 10 mg/kg/day for 5 weeks or 3 to 5 mg/kg/day for 6 to 8 weeks or longer. Repeat regimen if symptoms persist or recur due to active Kawasaki disease.

PEDIATRIC DOSE

See mg/kg or Gm/kg dose recommendations under **Usual Dose**. Begin with the lowest recommended dose. With most brands, clinical studies suggested that no difference in dosing is necessary and no special precautions are indicated. According to the manufacturers, infants and neonates were not included in clinical studies for primary immunodeficiency diseases or Kawasaki disease. All age-groups were represented in clinical studies for idiopathic thrombocytopenic purpura. See **Maternal/Child**.

Another source recommends the following doses, some of which may be unlabeled in the pediatric population:

Primary immunodeficiency disease: 300 to 400 mg/kg monthly. Optimum dose and frequency are determined by monitoring clinical response and IgG trough levels (increases of 300 to 400 mg/dL over initial pretreatment level are considered ideal).

Idiopathic thrombocytopenic purpura (ITP): Initial therapy for acute ITP: 0.8 to 1 Gm/kg given in 1 or 2 doses. **Maintenance therapy:** Individualized.

Kawasaki disease: 2 Gm/kg as a single dose over 10 to 12 hours or 400 mg/kg daily on four consecutive days. Start within 10 days of illness. Treatment should include aspirin (see **Usual Dose**).

Pediatric HIV infection: 400 mg/kg every 28 days.

Bone marrow transplantation: 500 mg/kg on Day 7 and Day 2 pre-transplant. Repeat 500 mg/kg once each week through Day 90 post-transplant. May reduce incidence of infection and death; does not decrease graft-versus-host disease.

Continued

Low-birth-weight infants (less than 1,500 Gm): Variable. 500 mg/kg has been used each week or three times in the first week of life and then weekly (target IgG around 700 mg/dL). Not recommended for routine use in preterm infants to prevent late-onset infection.

Parvovirus B19 infection: 400 mg/kg/day for 5 consecutive days or 1 Gm/kg/day for 2 consecutive days.

DILUTION

All formulations: Do not mix with IGIV products from other manufacturers.

Bivigam, Flebogamma, Gamunex-C, Gammagard Liquid, and Privigen are liquid preparations and are ready to use; see complete information in the following sections.

For all other formulations, absolute sterile technique is required at all steps of the reconstitution process. Gently rotate to dissolve completely. Complete dilution may take 20 minutes or more. Check label for sucrose content; see **Precautions**. For most preparations, filtration is required as drawn into a syringe for administration or as administered through IV tubing. Check each brand for specific equipment. If prepared in a sterile laminar air flow hood, may be pooled into plastic IV infusion bags and refrigerated for up to 24 hours. Mark with date and time of reconstitution and pooling.

Bivigam: Formulated with SWFI, sodium chloride, glycine, and polysorbate 80; does not contain sucrose. A ready-to-use 10% sterile solution; do not dilute. Available as 5 Gm in 50 mL or 10 Gm in 100 mL. Warm to room temperature before use and maintain at room temperature during administration. **Do not shake.** pH 4 to 4.6.

Carimune NF: Contains sucrose; see **Precautions**. Reconstitute with diluent provided. Makes a 3% solution. Invert quickly so that the vacuum allows diluent to flow into the IV bottle. May also be reconstituted with desired amounts of NS, D5W, or SWFI. Available as 1 (3, 6, or 12) Gm with 33 (100 or 200) mL diluent. For a 6% solution, use one half the diluent provided. Remove diluent bottle and swirl vigorously; **do not shake**; should dissolve within a few minutes. Package insert has a chart with dilution requirements for 9% and 12% concentrations. Immediate use is recommended unless reconstituted under a sterile laminar flow hood; then it may be refrigerated and administration must begin within 24 hours. Must be warmed to room temperature before dilution if it has been refrigerated. pH 6.4 to 6.8.

Flebogamma: Contains sorbitol; does not contain sucrose. A ready-to-use 5% sterile solution; available as 0.5 Gm in 10 mL, 2.5 Gm in 50 mL, 5 Gm in 100 mL, and 10 Gm in 200 mL. Further dilution with other solutions not recommended. See **Filters**. pH 5 to 6.

Gammagard Liquid: Contains no added sugars. A ready-to-use 10% solution available as 1 Gm in 10 mL, 2.5 Gm in 25 mL, 5 Gm in 50 mL, 10 Gm in 100 mL, and 20 Gm in 200 mL. Warm to room temperature before use. May be further diluted only with D5W. See **Filters**. pH 4.6 to 5.1.

Gammagard S/D: Must be warmed to room temperature before dilution. Diluent (SWFI), transfer device, administration set with integral airway, and filter provided with each single-use vial. Available in 2.5-, 5-, and 10-Gm single-dose vials with diluent. Use full amount of diluent (50, 96, 192 mL) to prepare a 5% solution (50 mg/mL) or one half the amount of diluent (25, 48, 96 mL) to prepare a 10% solution (100 mg/mL). Must be used within 2 hours of dilution. pH 6.4 to 7.2.

Gammar P-IV: Contains sucrose; see **Precautions**. Must be warmed to room temperature before dilution. Diluent (SWFI) is provided. May provide a transfer device (plastic piercing pin to diluent vial; metal needle to product vial), administration set with integral airway. Available in 1-, 2.5-, 5-, and 10-Gm single-dose vials with diluent (50 mg/mL) and a bulk pack without diluent. **Do not shake** to dissolve; rotate or agitate vial. Must be used within 3 hours of dilution. pH 6.4 to 7.2. (Supplies limited.)

Gamunex-C: Does not contain sucrose. A ready-to-use 10% sterile solution. Available in 1-, 2.5-, 5-, 10-, and 20-Gm single-dose vials. Bring to room temperature before administration. Use an 18-gauge needle to penetrate the stopper of the 1-Gm size. Use a 16-gauge needle to penetrate the stopper of the 2.5- to 20-Gm sizes. Penetration of the stopper in the center of the raised ring and perpendicular to it is recommended. May be further diluted with D5W if required. Do not use any other diluent. Filtration during

administration is not required. Content of vials may be pooled under aseptic conditions into sterile infusion bags but must be infused within 8 hours of pooling. pH 4 to 4.5.

Iveegam EN: Diluent (SWFI), transfer device, administration set with integral airway, and filter provided with each vial. Available in 0.5-, 1-, 2.5-, and 5-Gm vials with 10, 20, 50, or 100 mL diluent providing 50 mg/mL. **Do not shake** to dissolve; rotate or agitate vial. Use immediately after dilution. May be further diluted with a given amount of D5W or NS.

Privigen: Does not contain sucrose. A ready-to-use 10% sterile solution. Available in 5-, 10-, and 20-Gm single-dose vials. **Do not shake.** May be further diluted with D5W if required. Do not use any other diluent. Filtration during administration is not required. Content of vials may be pooled under aseptic conditions into sterile infusion bags but should be infused as soon as possible; contains no preservatives.

Filters: Filter or filter needle is provided by most manufacturers. **Carimune NF, Flebogamma,** and **Gammar P-IV** may be filtered with a larger pore filter size but is not required by manufacturers (filters greater than or equal to 15 microns will be less likely to slow infusion [0.2-micron antibacterial filters may be used with **Carimune NF and Flebogamma**]). **Carimune NF** is nano-filtered. Filtration of **Gamunex-C** during administration is not required; however, use of a non-protein binding, 0.22-micron filter is permissible. Use of an in-line filter is optional with **Gammagard Liquid**.

Storage: Storage requirements are brand specific and vary considerably; see manufacturer's package insert. Do not use after expiration date. Discard partially used vials. Do not use if solution is turbid or has been frozen.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturers recommend administration through a separate IV line without admixture with other drugs and state, "Do not combine one IGIV product with an IGIV product from another manufacturer." **Gammagard Liquid** and **Gamunex-C** are **incompatible** with NS. **Flebogamma** should not be further diluted with any solution.

Most preparations may be infused sequentially into a primary IV of D5W or NS, or the tubing may be flushed with D5W or NS before and after administration. No **compatibility** studies available for **Bivigam, Gamunex-C,** or **Gammagard Liquid**. **Gamunex-C** and **Gammagard Liquid** are **compatible** only with D5W.

One source suggests the following **compatibilities**:

Y-site: Fluconazole (Diflucan), sargramostim (Leukine).

RATE OF ADMINISTRATION

Too-rapid infusion may cause a precipitous hypotensive reaction. Decrease rate in patients at risk for thrombotic events and/or neuromuscular disorders. In patients at risk for developing renal dysfunction, administer at the minimum concentration available and the minimum rate of infusion that is practicable. **Another source suggests decreasing the rate of infusion by one half (5% solution) to one quarter (10% solution). For specific rates recommended by various manufacturers, see prescribing information.** See **Precautions** and the following specific recommendations for each product. Decrease rate of infusion at onset of patient discomfort or any adverse reactions; see **Antidote**. Administer via separate IV tubing with filter or filter needle (provided by most manufacturers if required). Do not mix with IGIV products from other manufacturers or with other drugs or IV solutions. An infusion pump will facilitate an accurate rate of administration.

Bivigam: 0.5 mg/kg/min for the first 10 minutes. If no discomfort or adverse effects, may be increased every 20 minutes by 0.8 mg/kg/min up to 6 mg/kg/min. In patients at risk for developing renal dysfunction, the infusion rate should be the minimum practicable.

Carimune NF: Contains sucrose; see **Precautions**. 0.5 to 1 mL/min for 15 to 30 minutes. May then be increased to 1.5 to 2.5 mL/min. After the first infusion, the rate may be initiated at 2 to 2.5 mL/min. The first dose must be a 3% solution. After the first dose, a 6% solution may be used to facilitate the administration of larger doses. Begin at 1 to 1.5 mL/min and increase in 15 to 30 minutes to 2 to 2.5 mL/min. To keep the amount of

sucrose infused at less than 3 mg/kg/min in patients at risk for developing renal dysfunction, the concentration and infusion rate should be the minimum practicable.

Flebogamma: 0.01 mL/kg/min (0.5 mg/kg/min) for the first 30 minutes. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 0.10 mL/kg/min (5 mg/kg/min). In patients at risk for developing renal dysfunction, the infusion rate should be the minimum practicable.

Gammagard Liquid: 0.5 mL/kg/hr for the first 30 minutes. If no discomfort or adverse effects, may be gradually increased every 30 minutes to a maximum rate of 5 mL/kg/hr. In patients at risk for developing renal dysfunction or thrombotic episodes, the maximum infusion rate should be less than 2 mL/kg/hr.

Gammagard S/D: 5% solution 0.5 mL/kg/hr. May be gradually increased to 4 mL/kg/hr if no discomfort or adverse effects. If 5% solution well tolerated at 4 mL/kg/hr, a 10% solution can be used. Begin with 0.5 mL/kg/hr. If no adverse effects, gradually increase up to a maximum of 8 mL/kg/hr. In patients at risk for developing renal dysfunction, the concentration and infusion rate should be the minimum practicable.

Gammag P-IV: Contains sucrose; see **Precautions**. 0.01 mL/kg/min. May be increased to 0.02 mL/kg/min after 15 to 30 minutes. May be gradually increased to 0.03 to 0.06 mL/kg/min if no discomfort or adverse effects. To keep the amount of sucrose infused at less than 3 mg/kg/min in patients at risk for developing renal dysfunction, the concentration and infusion rate should be the minimum practicable.

Gamunex-C: 0.01 mL/kg/min (1 mg/kg/min) for the first 30 minutes. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 0.08 mL/kg/min (8 mg/kg/min). In patients at risk for developing renal dysfunction, the infusion rate should be the minimum practicable. The initial infusion rate in CIDP may begin at 0.02 mL/kg/min (2 mg/kg/min).

Iveegam EN: 1 mL/min. May be increased to a maximum of 2 mL/min in the standard 5% solution. Rate may be adjusted proportionately with further dilution. Note rate for single-dose regimen in Kawasaki disease. In patients at risk for developing renal dysfunction, the concentration and infusion rate should be the minimum practicable.

Privigen: IV line may be flushed with D5W or NS.

Primary immunodeficiency: 0.005 mL/kg/min (0.5 mg/kg/min) initially. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 0.08 mL/kg/min (8 mg/kg/min). In patients at risk for developing renal dysfunction or thrombotic events, the infusion rate should be the minimum practicable.

Chronic immune thrombocytopenic purpura: 0.005 mL/kg/min (0.5 mg/kg/min) initially. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 0.04 mL/kg/min (4 mg/kg/min). In patients at risk for developing renal dysfunction or thrombotic events, the infusion rate should be the minimum practicable.

Pediatric rate of administration: Begin at 0.01 mL/kg/min. Double rate every 15 to 30 minutes up to a maximum of 0.08 mL/kg/min. If side effects occur, discontinue infusion until they subside. Restart at previously tolerated rate.

ACTIONS

An immune serum containing immune globulin. Obtained, purified, and standardized from human serum or plasma. Specific methods (e.g., cold ethanol fractionation, detergents, solvents) inactivate blood-borne viruses (e.g., hepatitis, HIV). Provides antibodies that bind and neutralize pathogenic autoantibodies with immediate antibody levels against bacterial, viral, parasitic, and mycoplasmic antigens. Half-life variable; approximately 3 to 6 weeks but may be decreased by fever or infection (increased catabolism or consumption). Distribution into extravascular fluid, tissue, and cells causes a rapid fall in serum IgG in the first week after infusion. Crosses placental barrier.

INDICATIONS AND USES

Selected products are approved for different uses; see **Usual Dose**. All provide rapid onset, short-term passive immunization. Labeled uses include: **Primary immunodeficiency diseases:** Maintenance and treatment of adults, adolescents, and other pediatric patients unable to produce adequate amounts of IgG antibodies, especially in the following situ-

ations: need for immediate increase in intravascular immunoglobulin levels, small muscle mass or bleeding tendencies that contraindicate IM injection, and selected disease states (e.g., congenital agammaglobulinemia, common variable immunodeficiency (CVID), combined immunodeficiency, X-linked agammaglobulinemia, Wiskott-Aldrich syndrome). ■ **Treatment of acute and chronic idiopathic thrombocytopenic purpura:** Temporary increase in platelet counts in patients with idiopathic thrombocytopenic purpura and with thrombocytopenia associated with bone marrow transplant. ■ **Treatment of chronic inflammatory demyelinating polyneuropathy (CIDP):** Improvement of neuromuscular disability and impairment and maintenance therapy to prevent relapse. ■ **Adjunct in chronic lymphocytic leukemia:** Prevention of bacterial infections in patients with hypogammaglobulinemia or recurrent bacterial infection associated with B-cell CLL. ■ **Kawasaki syndrome:** Prevention of coronary artery aneurysms associated with Kawasaki syndrome. ■ Gamunex-C is approved for SC humoral administration for primary immunodeficiency disease (PID).

Unlabeled uses: Infection prophylaxis or control: and to improve immunologic parameters in select patients with symptomatic AIDS or ARC and pediatric patients with HIV. ■ **Bone marrow transplant:** Reduce risk of serious infections and graft-versus-host disease in bone marrow transplant patients. ■ Infection prophylaxis and control in low-birth-weight neonates, patients with iatrogenically induced or disease-associated immunosuppression (major surgery [e.g., bone marrow or cardiac transplants], hematologic malignancies, extensive burns, or collagen-vascular diseases). ■ Treatment of post-transfusion purpura. ■ Treatment of chronic Parvovirus B19 infection in immunodeficient patients. ■ Prevention of recurrent bacterial infections in patients with IgG subclass deficiencies (e.g., allergies, HIV). ■ Treatment or adjunct in the treatment of dermatomyositis, intractable epilepsy, multiple sclerosis, myasthenia gravis, polymyositis, polyneuropathies, rheumatoid arthritis, and other autoimmune disease (e.g., autoimmune neutropenia, pediatric patients with type 1 diabetes, chronic fatigue syndrome, Guillain-Barré syndrome, hyperimmunoglobulinemia E syndrome, multifocal motor neuropathy, and many others).

CONTRAINDICATIONS

Individuals known to have anaphylactic or severe hypersensitivity responses to gamma globulin or its components (e.g., thimerosal); patients with isolated or selective IgA deficiency, IgA deficiency when the patient has IgE-mediated antibodies to IgA, or pre-existing anti-IgA antibodies and/or a history of hypersensitivity. Manufacturer of **Flebo-gamma** adds anaphylactic or severe reactions to blood or blood-derived products. Manufacturer of **Gamunex-C** suggests IgA-deficient patients with antibodies against IgA are at greater risk for developing severe hypersensitivity reactions. Manufacturer of **Gammagard S/D** states, “None known.” **Privigen** is contraindicated in patients with selective IgA deficiency; it contains L-proline as a stabilizer and is contraindicated in patients with hyperprolinemia.

PRECAUTIONS

Check label; must state, “For IV use.” ■ Do not use IM or SC. Do not skin test. Will cause a localized chemical skin reaction. ■ Hypersensitivity reactions have occurred; administer in a facility with adequate equipment and supplies to monitor the patient and respond to any medical emergency. ■ Use extreme caution in individuals with a history of prior systemic hypersensitivity reactions. Incidence of anaphylaxis may be increased, especially with repeated injections. ■ Some packaging of these products may contain latex; use caution in sensitive individuals. ■ IGIV products have been associated with renal dysfunction, acute renal failure, osmotic nephrosis, and death. Use extreme caution in patients with any degree of renal insufficiency; in patients age 65 years and older; in patients with diabetes mellitus, paraproteinemia, sepsis, volume depletion; and/or in patients receiving known nephrotoxic drugs. If used, should be administered at the minimum concentration available and at the minimum rate of infusion practicable. **Products containing sucrose as a stabilizer (Carimune NF and Gammar P-IV) have demonstrated an increased risk of renal dysfunction.** Consider benefit versus risk before use. ■ Increases in SCr and/or BUN may progress to oliguria and anuria requiring dialysis; however, some patients improve spontaneously with discontinuation of IGIV. ■

May cause aseptic meningitis syndrome (AMS), especially with 2-Gm/kg doses. May begin from 2 hours to 2 days after treatment. Symptoms are drowsiness, fever, headache (severe), nausea and vomiting, nuchal rigidity, painful eye movements, and photophobia. Cerebrospinal fluid (CSF) studies are often positive with pleocytosis, predominantly from the granulocyte series and elevated protein levels. ■ Hyperproteinemia, increased serum viscosity, and hyponatremia may occur. Distinguish true hyponatremia from pseudohyponatremia to determine correct treatment. Volume depletion with a further increase in serum viscosity may predispose to thromboembolic events. ■ IGIV products have been associated with thrombotic events; use caution in patients with advanced age, impaired cardiac output, a history of cardiovascular disease, thrombotic episodes, and thrombotic risk factors (e.g., cerebrovascular disease, coronary artery disease, diabetes, hypertension, prolonged periods of immobilization). Octagam has been voluntarily withdrawn from the market until the root cause of reported thromboembolic events with this formulation can be determined. ■ Baseline assessment of blood viscosity should be made in patients at risk for hyperviscosity, including chylomicronemia, markedly high triglycerides, or monoclonal gammopathies. ■ May rarely cause hemolysis, which can result in hemolytic anemia. Cases of severe hemolysis-related renal dysfunction/failure or DIC have occurred following infusion of **Privigen**; see **Monitor**. ■ Consider risk/benefit before use of high-dose regimens in chronic ITP patients at increased risk for acute kidney injury, hemolysis, thrombosis, or volume overload. ■ Noncardiogenic pulmonary edema (transfusion-related acute lung injury [TRALI]) has been reported; see **Monitor**. ■ Derived from human blood. Despite purification processes, may carry risk of transmitting infectious agents (e.g., viruses [e.g., HIV, hepatitis] or Creutzfeldt-Jakob disease [CJD] agent).

Monitor: Use of larger veins recommended to reduce infusion-site discomfort, especially with 10% solutions. ■ Correct volume depletion before administration in all patients, especially patients with pre-existing renal insufficiency. ■ Recording of lot number on vials is recommended. ■ Monitor vital signs and observe patient continuously during infusion. A precipitous drop in BP or anaphylaxis can occur at any time. Emergency equipment and supplies must be at bedside. ■ Monitor renal function (e.g., BUN, SCr) and urine output in patients at increased risk for renal failure. Obtain baseline studies, monitor at intervals, and discontinue IGIV if renal function deteriorates. See **Precautions**. ■ Monitor for hyperproteinemia with resultant changes in serum viscosity and electrolyte imbalances. ■ Monitor for S/S of hemolysis (e.g., lysis of red blood cells, liberation of hemoglobin) and hemolytic anemia. ■ Monitor for S/S of TRALI (e.g., fever, hypoxemia, normal left ventricular function, pulmonary edema, severe respiratory distress). Usually occurs within 1 to 6 hours after completion of the infusion. Manage with oxygen and adequate ventilatory support. If TRALI is suspected, both the product and the patient serum should be tested for the presence of antineutrophil antibodies. ■ Monitor for volume overload. ■ Minimum serum level of IgG after infusion should exceed 300 mg/dL.

Patient Education: Report a burning sensation in the head, chills, cyanosis, diaphoresis, dyspnea, faintness or light-headedness, fatigue, fever, hives, itching or rash, neck pain or difficulty moving neck, tachycardia, wheezing. ■ Report chest pain or tightness, difficulty passing urine, decreased urine output, fluid retention, edema, shortness of breath, or sudden weight gain. ■ Remote risk of viral or CJD infection; consider risk versus benefit of therapy. See **Drug/Lab Interactions**.

Maternal/Child: Category C: use with caution in pregnancy; no adverse effects documented, but adequate studies are not available. ■ Safety for use in breast-feeding not established. ■ Response in pediatric patients usually exceeds response in adults. ■ **Gamimune-N** contains maltose and may cause osmotic diuresis. ■ Use of **Privigen** to treat primary immunodeficiency in pediatric patients under 3 years of age or to treat chronic immune thrombocytopenic purpura in pediatric patients under 15 years of age not established. ■ Safety and effectiveness of **Bivigam** not established for use in pediatric patients under 6 years of age.

Elderly: Use with extreme caution. Incidence of renal insufficiency and other side effects increased due to age, potential for decreased organ function, and pre-existing medical conditions; see **Precautions**.

DRUG/LAB INTERACTIONS

Do not administer **live virus vaccines** from 2 weeks before to at least 3 months after immune globulin IV. Passive transfer of antibodies may transiently interfere with the response to live virus vaccines, such as measles, mumps, and rubella; see prescribing information if there is a risk of measles exposure or if accidental exposure has occurred. ■ Provides immediate antibody levels that last for about 3 weeks. In selected patients, may have an immune-modulating effect that may alter their response to **corticosteroids or antineoplastic agents**. ■ Concurrent use with **nephrotoxic drugs** (e.g., aminoglycosides [e.g., gentamicin], amphotericin B [Amphotec, conventional], cidofovir [Vistide], rifampin [Rifadin]) may increase risk of renal insufficiency. ■ Products that contain **maltose** may interfere with blood and urine glucose tests. ■ Various antibody titers may be raised temporarily, resulting in **false-positive serologic testing**.

SIDE EFFECTS

Arthralgia, asthenia, back pain, chills, diarrhea, dizziness, fatigue, fever, headache, hypertension, infusion site reactions, lethargy, nausea and vomiting, rash, and sinusitis were reported most commonly. Full range of hypersensitivity symptoms, including anaphylaxis, is possible. Angioedema, erythema, fever, and urticaria are most frequently observed. Anxiety, chest tightness, cough, decreased diastolic BP, difficulty breathing, elevated ALT and AST (temporary), flushing, hemolytic anemia (reversible), increased BUN and SCr (may occur as soon as 1 to 2 days following infusion), leg cramps, lightheadedness, malaise, migraine, myalgia, pharyngitis, pharyngolaryngeal pain, tachycardia, and urticaria have been reported. Severe reactions (e.g., circulatory collapse, fever, loss of consciousness, nausea and vomiting, sudden onset of dyspnea) have occurred and are more common in patients with antibody deficiencies. Noncardiogenic pulmonary edema (transfusion-related acute lung injury [TRALI]) has been reported. Acute renal failure, acute tubular necrosis, osmotic nephrosis, and proximal tubular nephropathy have been reported; may result in death. Is made from human plasma; process attempts to eliminate risk of hepatitis or HIV infection. A precipitous hypotensive reaction can occur and is most frequently associated with too-rapid rate of injection. Aseptic meningitis syndrome and hemolysis occur infrequently. See **Precautions**.

Post-Marketing: Abdominal pain, apnea, ARDS, back pain, bronchospasm, bullous dermatitis, cardiac arrest, coma, cyanosis, dyspnea, epidermolysis, erythema multiforme, hepatic dysfunction, hypotension, hypoxemia, leukopenia, loss of consciousness, pancytopenia, positive direct antiglobulin (Coombs') test, pulmonary edema, seizures, Stevens-Johnson syndrome, thromboembolism, and tremor have been reported with IGIV products.

ANTIDOTE

Reduce rate for patient discomfort, any sign of adverse reaction, and in patients at risk for renal insufficiency. If symptoms subside promptly, the infusion may be resumed at a lower rate. Decreasing the volume of subsequent infusions may also prevent or decrease the incidence of adverse reactions. Loop diuretics (e.g., furosemide [Lasix]) may be helpful in the management of fluid overload. Patients who continue to experience adverse reactions, after rate and/or volume have been reduced, may be premedicated with hydrocortisone 1 to 2 mg/kg 30 minutes prior to the immune globulin infusion. Pretreatment with acetaminophen (Tylenol) and diphenhydramine (Benadryl) or trying a different brand of immune globulin may also be useful. Discontinue the drug immediately for any signs of a hypersensitivity reaction or renal insufficiency. Notify the physician. May be treated symptomatically, and infusion resumed at slower rate if symptoms subside. Treat anaphylaxis immediately. Epinephrine (Adrenalin), diphenhydramine (Benadryl), oxygen, vasopressors (e.g., dopamine), corticosteroids, and ventilation equipment must always be available. Manage TRALI with oxygen and ventilatory support. Resuscitate as necessary.

INDOMETHACIN SODIUM

(in-doh-METH-ah-sin SO-dee-um)

Prostaglandin inhibitor
(patent ductus arteriosus adjunct)

Indocin IV

pH 6 to 7.5

USUAL DOSE

Neonates: Three IV doses, specific to age at first dose, given at 12- to 24-hour intervals constitute a course of therapy.

Less than 48 hours of age: First dose (0.2 mg/kg of body weight), second dose (0.1 mg/kg), third dose (0.1 mg/kg).

2 to 7 days of age: 0.2 mg/kg for each of 3 doses.

Over 7 days of age: First dose (0.2 mg/kg), then 0.25 mg/kg for the next 2 doses.

If ductus arteriosus reopens, a second course of 1 to 3 doses as described for each neonate age may be repeated one time given at 12- to 24-hour intervals. If neonate remains unresponsive to indomethacin therapy after 2 courses, surgery may be required for closure of the ductus arteriosus.

DOSE ADJUSTMENTS

If urine output is less than 0.6 mL/kg/hr at any time a dose is to be given, withhold dose until lab studies confirm normal renal function.

DILUTION

Each 1 mg must be diluted with at least 1 mL NS or SWFI without preservatives (0.1 mg/0.1 mL); may be diluted with 2 mL diluent (0.05 mg/0.1 mL). The preservative benzyl alcohol is toxic in neonates. A fresh solution should be prepared just before each administration. Discard any unused portion.

Filters: No data available from manufacturer.

Storage: Store unopened vials in carton at CRT. Protect from light. Use reconstituted solution immediately.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Prepare only with preservative-free NS or SWFI"; further dilution with IV solutions is not recommended and may precipitate with solutions with a pH below 6.

One source suggests the following **compatibilities:**

Y-site: Dextrose, furosemide (Lasix), insulin (regular), potassium chloride (KCl), sodium bicarbonate, nitroprusside sodium.

RATE OF ADMINISTRATION

A single dose, properly diluted, by IV injection over 20 to 30 minutes.

ACTIONS

A potent inhibitor of prostaglandin synthesis. Through an unconfirmed method of action (thought to be inhibition of prostaglandin synthesis), it causes closure of a patent ductus arteriosus 75% to 80% of the time, eliminating the need for surgical intervention. Plasma half-life varies inversely with postnatal age and weight and ranges from 12 to 20 hours. Metabolized in the liver and eventually excreted in urine and bile.

INDICATIONS AND USES

Closure of a hemodynamically significant patent ductus arteriosus in premature infants weighing between 500 and 1,750 Gm if usual medical management (e.g., fluid restriction, diuretics, digoxin, respiratory support) has not been effective after 48 hours.

CONTRAINDICATIONS

Bleeding, especially active intracranial hemorrhage or GI bleeding; coagulation defects; necrotizing enterocolitis; infants with congenital heart disease (e.g., pulmonary atresia, severe coarctation of the aorta, severe tetralogy of Fallot) who require patency of the

ductus arteriosus for satisfactory pulmonary or systemic blood flow; proven or suspected untreated infection; significant renal impairment; thrombocytopenia.

PRECAUTIONS

Clinical evidence of a hemodynamically significant patent ductus arteriosus (respiratory distress, a continuous murmur, a hyperactive precordium, cardiomegaly and pulmonary plethora on chest x-ray) should be present before use is considered. ■ For use only in a highly supervised setting such as an intensive care nursery. ■ May increase potential for GI or intraventricular bleeding. ■ Use caution in presence of existing controlled infection; may mask signs and symptoms of exacerbation. ■ May suppress water excretion to a greater extent than sodium excretion. Hyponatremia may result. ■ For IV use only. ■ Surgery indicated if condition is not responsive to two courses of therapy.

Monitor: Vital signs, oxygenation, acid-base status, fluid and electrolyte balance, and kidney function (SCr, BUN, urine output) must be monitored and maintained. ■ Can cause marked reduction in urine output (over 50%), increase BUN and SCr, and reduce glomerular filtration rate and CrCl. These symptoms usually disappear when therapy completed but may cause acute renal failure, especially in infants with impaired renal function from other causes. ■ May inhibit platelet aggregation; monitor for signs of bleeding. ■ Discontinue drug if signs of impaired liver function appear. ■ Confirm absolute patency of vein. Avoid extravasation; will irritate tissue. ■ See [Drug/Lab Interactions](#).

DRUG/LAB INTERACTIONS

May reduce elimination and increase serum concentrations of **drugs that are renally excreted** (e.g., aminoglycosides [e.g., gentamicin], digoxin [Lanoxin]). Monitor drug levels and adjust doses as needed to avoid toxicity. ■ Observe neonate closely for signs of **digoxin toxicity**; frequent monitoring of ECG and digoxin serum levels is indicated. ■ Use with **furosemide** (Lasix) may help to maintain renal function. ■ Concomitant use with **anticoagulants** may increase risk of bleeding; monitoring of PT suggested. ■ Coadministration with **ACE inhibitors** (e.g., enalapril [Vasotec]) may result in deterioration of renal function, including renal failure.

SIDE EFFECTS

Abdominal distention; acidosis; alkalosis; apnea; bleeding into the GI tract (gross or microscopic); bradycardia; DIC; elevated BUN or creatinine; exacerbation of pre-existing pulmonary infection; fluid retention; gastric perforation; hyperkalemia; hypoglycemia; hyponatremia; intracranial bleeding; necrotizing enterocolitis; oliguria; oozing from needle puncture sites; pulmonary hemorrhage; pulmonary hypertension; reduced urine sodium, chloride, potassium, urine osmolality, free water clearance, or glomerular filtration rate; renal failure, retrolental fibroplasia; thrombocytopenia; transient ileus; uremia; vomiting.

ANTIDOTE

Discontinue the drug and notify the physician of all side effects. Based on severity, side effects may be treated symptomatically or drug will be completely discontinued in favor of surgical intervention. Resuscitate as necessary.

INFLIXIMAB **BBW**

(in-FLIX-ih-mab)

Monoclonal antibody
 Inflammatory bowel disease agent
 Antirheumatic agent

Remicade

pH 7.2

USUAL DOSE

Preliminary patient evaluation required; see **Monitor**.

Premedication: Administer at the physician's discretion. May include antihistamines (e.g., diphenhydramine [Benadryl]), H₂ blockers (e.g., famotidine [Pepcid IV]), acetaminophen, and/or corticosteroids (e.g., hydrocortisone).

Crohn's disease and fistulizing Crohn's disease: Begin with an initial dose of 5 mg/kg as an infusion. Repeat at 2 and 6 weeks and every 8 weeks thereafter. For patients who respond and then lose their response, consideration may be given to treatment with 10 mg/kg. If there is no response by Week 14, response with continued dosing is unlikely; consider discontinuing infliximab. See **Precautions**.

Rheumatoid arthritis: 3 mg/kg as an infusion. Repeat dose at 2 and 6 weeks, then every 8 weeks thereafter. Given in combination with methotrexate at a minimum dose of 12.5 mg/week (median dose of 15 mg/week). See methotrexate monograph. If response to infliximab is incomplete, dose may be adjusted up to 10 mg/kg or interval decreased to every 4 weeks. Risk of infection may be increased at higher doses.

Ankylosing spondylitis: 5 mg/kg as an infusion. Repeat at 2 and 6 weeks, then every 6 weeks thereafter.

Psoriatic arthritis: 5 mg/kg as an infusion. Repeat dose at 2 and 6 weeks, then every 8 weeks thereafter. May be used with or without methotrexate.

Ulcerative colitis and plaque psoriasis: 5 mg/kg as an infusion. Repeat dose at 2 and 6 weeks, then every 8 weeks thereafter.

PEDIATRIC DOSE

Preliminary patient evaluation required; see **Monitor**. See **Maternal/Child**.

Crohn's disease and ulcerative colitis: 5 mg/kg as an infusion. Repeat dose at 2 and 6 weeks. Follow with a maintenance regimen of 5 mg/kg every 8 weeks.

DOSE ADJUSTMENTS

Dose adjustment not required based on gender, age, weight, or hepatic or renal function. ■ Do not exceed a dose of 5 mg/kg in patients with moderate to severe CHF (NYHA class III/IV); see **Contraindications**.

DILUTION

Each vial contains 100 mg of infliximab. When reconstituted as directed below, each milliliter of solution contains 10 mg of infliximab. Calculate the dose and the number of vials required and the total volume of reconstituted infliximab solution required. Reconstitute each 100-mg vial with 10 mL of SWFI, using a syringe equipped with a 21-gauge or smaller needle. Direct the stream of SWFI to side of vial. Swirl gently; do not shake. Allow reconstituted solution to stand for 5 minutes. Solution should be colorless to light yellow and opalescent and may develop a few translucent particles as infliximab is a protein. Do not use if opaque particles, discoloration, or other foreign particles are present. The total dose of reconstituted solution must be further diluted with NS to a final volume of 250 mL. (May withdraw a volume of NS equal to the calculated volume of reconstituted infliximab from a 250-mL bottle or bag of NS and slowly add reconstituted solution.) Mix gently. Infusion concentration should range between 0.4 mg/mL and 4 mg/mL. The infusion should begin within 3 hours of reconstitution and dilution.

Filters: Must be administered through an infusion set with an in-line, sterile, non-pyrogenic, low-protein binding filter (pore size equal to or less than 1.2 micron). Flush and prime tubing/filter system with NS before administration of infusion.

Storage: Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Do not freeze. Discard any unused portion.

COMPATIBILITY

Manufacturer recommends not infusing concomitantly in the same IV line with other agents until specific **compatibility** data are available.

RATE OF ADMINISTRATION

Begin the infusion within 3 hours of reconstitution and dilution. Flush and prime tubing/filter system with NS before administration. A single dose should be given over a period of not less than 2 hours. Upon completion of infusion, IV line should be flushed thoroughly with 15 to 20 mL of NS to ensure all active drug is delivered to the patient. A slower rate of infusion may reduce the occurrence or severity of infusion reactions; see Antidote.

ACTIONS

A chimeric IgG1 monoclonal antibody that binds specifically to human tumor necrosis factor alpha (TNF α). Is composed of human constant and murine variable regions. Neutralizes the biologic activity of TNF α by binding with high affinity to the soluble and transmembrane forms of TNF α and inhibiting binding of TNF α with its receptors. Infliximab does not neutralize TNF β . Biologic activities attributed to TNF α include induction of pro-inflammatory cytokines such as IL-1 and IL-6, enhancement of leukocyte migration by increasing endothelial layer permeability and expression of adhesion molecules by endothelial cells and leukocytes, activation of neutrophil and eosinophil functional activity, and induction of acute phase and other liver proteins. Elevated concentrations of TNF α have been found in involved tissues and fluids of patients with Crohn's disease, rheumatoid arthritis, ankylosing spondylitis, ulcerative colitis, psoriatic arthritis, and plaque psoriasis. These elevated concentrations correlate with elevated disease activity. Treatment with infliximab reduces infiltration of inflammatory cells and TNF α production in inflamed areas of the joint and of the intestine and reduces the proportion of mononuclear cells from the lamina propria able to express TNF α and interferon γ . After treatment, patients have decreased levels of serum IL-6 and C-reactive protein compared to baseline. Infliximab is distributed predominantly within the vascular space. Has a prolonged terminal half-life of 7.7 to 9.5 days. Studies suggest median onset of response to be 2 to 4 weeks and median duration of response to be 12 weeks. Produced by a recombinant cell line cultured by continuous perfusion and is purified by a series of steps that include measures to inactivate and remove viruses.

INDICATIONS AND USES

Adult and pediatric patients 6 years of age and older: Reduce the S/S and induce and maintain clinical remission in patients with moderately to severely active Crohn's disease who have had an inadequate response to conventional therapy. ■ Reduce the S/S, induce and maintain clinical remission and mucosal healing, and eliminate corticosteroid use in patients with moderately to severely active ulcerative colitis who have had inadequate response to conventional therapy.

Adult patients: Reduce the number of draining enterocutaneous and rectovaginal fistula(s) and maintain fistula closure in fistulizing Crohn's disease. ■ Given in combination with methotrexate to improve physical function, inhibit progression of structural damage, and reduce S/S in patients with rheumatoid arthritis who have had an inadequate response to methotrexate. ■ Reduce S/S in active ankylosing spondylitis. ■ Reduce the S/S of active arthritis, inhibit progression of structural damage, and improve physical function in psoriatic arthritis. ■ Used for treatment of patients with chronic severe (i.e., extensive and/or disabling) plaque psoriasis who are candidates for systemic treatment and when other systemic treatments are less appropriate.

CONTRAINDICATIONS

Known hypersensitivity to infliximab, murine proteins, or other components of the product. ■ Administration of doses exceeding 5 mg/kg in patients with moderate to severe (NYHA class III/IV) CHF.

PRECAUTIONS

TNF α mediates inflammation and modulates cellular immune response. Anti-TNF therapies, including infliximab, may affect normal immune responses. Patients treated with infliximab are at increased risk for developing serious infections that may lead to hospitalization or death. Many of the serious infections have occurred in patients undergoing concomitant immunosuppressive therapy that, in addition to their underlying disease, may predispose them to infections; see [Drug/Lab Interactions](#). Patients over 65 years of age and those with co-morbid conditions may also be at increased risk for infections. Not recommended for patients with a clinically important active infection. Use caution in patients with a chronic infection, a history of recurrent infection, or a history of an opportunistic infection. ■ Tuberculosis (often disseminated or extrapulmonary at clinical presentation), invasive fungal infections, or opportunistic infections (e.g., aspergillosis, blastomycosis, candidiasis, coccidioidomycosis, histoplasmosis, legionellosis, listeriosis, and pneumocystosis) have been observed in patients receiving infliximab. Some of these infections have been fatal. Antituberculosis treatment of patients with a reactive TB skin test reduces the risk of TB reactivation in patients receiving infliximab. However, active TB has developed in patients receiving infliximab who had a negative skin test before initiating infliximab therapy. Consider risk versus benefit in patients who have resided or traveled in areas of endemic tuberculosis or endemic mycoses, such as histoplasmosis, coccidioidomycosis, or blastomycosis. ■ A higher incidence of worsening CHF and increased mortality have been seen in patients with moderate to severe CHF. Occurs more frequently in patients receiving a 10 mg/kg dose. Do not use doses greater than 5 mg/kg in patients with CHF. Discontinue for new-onset CHF or for worsening CHF, and consider discontinuing in patients with CHF who have not had a significant response to infliximab. Use with caution in patients with mild CHF (NYHA Class I/II); monitor closely. ■ Hypersensitivity reactions characterized by urticaria, dyspnea, and/or hypotension have occurred in association with infliximab infusion. Most occur during or within 2 hours of the infusion. Discontinue infusion if severe reaction occurs. Medications for management of hypersensitivity reaction (e.g., acetaminophen [Tylenol], diphenhydramine [Benadryl], corticosteroids [e.g., hydrocortisone] and/or epinephrine) should be readily available. ■ Serum sickness–like reactions (dyspnea, fever, hand and facial edema, headache, myalgias, polyarthralgias, sore throat) have been reported and have occurred as early as after the second dose and when infliximab was interrupted and then reinitiated after an extended period. These reactions are associated with a marked increase in antibodies to infliximab, a loss of detectable serum concentrations of infliximab, and a possible loss of drug efficacy. ■ Re-administration of infliximab after a period of no treatment resulted in a higher incidence of infusion reactions relative to regular maintenance treatment in clinical trials. Evaluate risk versus benefit of re-administration after a period of no treatment, especially if considering a re-induction regimen given at 0, 2, and 6 weeks. For cases in which maintenance therapy for psoriasis has been interrupted, infliximab should be reinitiated with a single dose followed by maintenance therapy. ■ Anti-TNF therapy may result in formation of autoimmune antibodies and, rarely, in the development of a lupus-like syndrome. Discontinue therapy if this occurs. In clinical studies, symptoms resolved with discontinuation of therapy. ■ Lymphoma and other malignancies, some fatal, have been reported in children and adolescent patients treated with TNF blockers, including infliximab. Most of the affected patients were receiving concomitant immunosuppressants. ■ The potential role of TNF-blocking therapy in the development of lymphoma, leukemia, melanoma, Merkel cell carcinoma, and other malignancies is not known. Patients with Crohn's disease, ulcerative colitis, rheumatoid arthritis, or plaque psoriasis, particularly with highly active disease and/or exposure to immunosuppressant therapies, may be at higher risk (up to several-fold) than the general population for the development of lymphoma, leukemia, and other malignancies, even in the absence of TNF-blocking therapy. ■ Cases of hepatosplenic T-cell lymphoma have been reported. They have primarily occurred in adolescents and young adult males being treated with infliximab for Crohn's disease or ulcerative colitis. This type of lymphoma has a very aggressive disease course and is usually fatal. All affected patients received concomitant treatment with azathioprine (Imuran) or 6-mercaptopurine (Purinethol) at or before diagnosis. When

treating patients with inflammatory bowel disease, particularly adolescents and young adults, the decision whether to use infliximab alone or in combination with other immunosuppressants should consider the possibility that there is a higher risk of hepatosplenic T-cell lymphoma (HSTCL) with combination therapy versus an observed increased risk of immunogenicity and hypersensitivity reactions with infliximab monotherapy. ■ Use caution in patients with moderate to severe COPD; may have an increased risk of malignancy, especially of the lungs and head or neck. ■ In studies of extended treatment, systemic accumulation of infliximab did not occur, clinical benefit was maintained, and retreatment was well tolerated. ■ Rare cases with CNS manifestations of systemic vasculitis, seizures, and new-onset or exacerbation of clinical symptoms and/or radiographic evidence of CNS demyelinating disorders (e.g., multiple sclerosis, optic neuritis) and peripheral demyelinating disorders (e.g., Guillain-Barré syndrome) have been reported. Use with caution in patients with any of these existing neurologic disorders. Consider discontinuing therapy if any of these disorders develop. ■ Patients with invasive fungal infections (e.g., aspergillosis, blastomycosis, candidiasis, coccidioidomycosis, histoplasmosis, pneumocystosis) may present with disseminated, rather than localized, disease. Antigen and antibody testing may be negative. Empiric antifungal therapy should be considered in patients at risk for invasive fungal infections who develop severe systemic illness. ■ Bacterial, viral, and other infections due to opportunistic pathogens, including *Legionella* and *Listeria*, have also been reported. ■ Severe hepatic reactions, including liver failure, jaundice, hepatitis, cholestasis, and autoimmune hepatitis, have been reported. Reactions have occurred anywhere from 2 weeks to more than a year after initiation of treatment and have resulted in death or the need for a liver transplant. ■ Reactivation of hepatitis B has occurred in chronic carriers of the virus who are being treated with infliximab. ■ Leukopenia, neutropenia, thrombocytopenia, and pancytopenia have been reported. ■ Use caution when switching between biological disease-modifying antirheumatic drugs (DMARDs [e.g., methotrexate, leflunomide, sulfasalazine]); overlapping biological activity may further increase the risk of infection; see [Drug/Lab Interactions](#). ■ See [Maternal/Child](#).

Monitor: Evaluate patients for latent tuberculosis (TB) with a TB skin test. Initiate treatment of latent TB before therapy with infliximab. Monitor patients for S/S of active TB (chest x-ray, cough [progressively more productive], dyspnea), including patients who had a negative skin test. ■ Before initiating TNF-blocker therapy, including infliximab, patients should be tested for HBV infection. Consultation with a physician with expertise in the treatment of hepatitis B is recommended if a patient tests positive for hepatitis B surface antigen. Evaluation and monitoring of patients who are chronic carriers of hepatitis B is required before, during, and for several months after treatment with infliximab. ■ Monitor cardiac status closely for new-onset or worsening CHF; see [Precautions](#). ■ Patients receiving infliximab may develop human antichimeric antibody (HACA). Patients who are HACA-positive may be more likely to experience an infusion reaction. The incidence of positive HACA is lower among patients receiving immunosuppressant therapies (e.g., 6-mercaptopurine, azathioprine, corticosteroids). ■ Monitor for S/S of hepatotoxicity (e.g., jaundice and/or marked liver enzyme elevations [equal to or greater than 5 times the upper limit of normal]). ■ Monitor CBC with differential and platelet count periodically. ■ Monitor BP and pulse every 30 minutes during infusion. If patient experiences a significant change in vital signs (e.g., drop in diastolic BP of 15 to 20 mm Hg) or exhibits any symptoms that may indicate hypersensitivity, stop infusion. Evaluate symptoms and treat appropriately. Continue to monitor patient for at least 30 minutes after completion of the infusion. ■ Monitor for S/S of infection; discontinue if a serious infection occurs and initiate appropriate antimicrobial treatment; see [Precautions](#). ■ Monitor psoriasis patients, particularly those who have had prolonged phototherapy treatment; may be at increased risk for nonmelanoma skin cancers. ■ Monitor for S/S of malignancies such as HSTCL (e.g., abdominal pain, hepatomegaly, night sweats, persistent fever, weight loss). ■ Periodic skin examination is recommended for all patients, particularly those with risk factors for skin cancer.

Patient Education: Read manufacturer's medication guide before each treatment with infliximab. ■ Tell health care professionals of heart conditions, previous or current infec-

tions, and recent or past exposure to TB or histoplasmosis. ■ Review all medicines and disease history with pharmacist or physician before initiating treatment. ■ Promptly report abdominal pain, fever, S/S of heart failure (e.g., shortness of breath, swelling feet), infection, numbness, tingling, or visual disturbances. ■ Report S/S of hypersensitivity reactions (e.g., itching, rash, swelling in the throat). Usually occur during or immediately following the infusion but may occur from 3 to 12 days later. ■ Report changes of growths on your skin during or after infliximab treatment.

Maternal/Child: Category B: use during pregnancy only if clearly needed. ■ Has potential for harm to the nursing infant; discontinue breast-feeding. ■ Use caution in the administration of live vaccines to infants born to female patients treated with infliximab during pregnancy. Infliximab crosses the placental barrier and has been detected in these infants up to 6 months after the last dose of infliximab to the mother, and they may be at increased risk for infection. ■ Safety and effectiveness for use in pediatric patients with ulcerative colitis, plaque psoriasis, and/or Crohn's disease who are less than 6 years of age not established. ■ Safety and effectiveness for use in pediatric patients with juvenile rheumatoid arthritis was evaluated in a multi-center trial. The study failed to establish effectiveness; see prescribing information for details. ■ Before initiating infliximab therapy in pediatric patients with Crohn's disease or ulcerative colitis, all vaccinations should be brought up-to-date. ■ Long-term (greater than 1 year) safety and effectiveness in pediatric patients with Crohn's disease not established.

Elderly: Specific differences in safety and effectiveness not noted; the incidence of serious side effects may be increased. An increase in the incidence of serious infections has been noted in patients 65 years and older, and because there is a higher incidence of infections in the elderly population in general, caution should be used in treating the elderly. See **Precautions**.

DRUG/LAB INTERACTIONS

Specific interaction studies have not been **performed**. ■ Concurrent administration with **anakinra** (Kineret), an interleukin-1 antagonist, or **abatacept** (Orencia), an anti-rheumatic agent, may be associated with an increased risk of serious infections. The added benefit of combination therapy has not been documented. Anakinra is also associated with an increased risk of neutropenia. Concurrent administration of TNF α -blocking agents (e.g., infliximab) with anakinra or abatacept is not recommended. ■ May cause increased immunosuppression and increased risk of infection with **tocilizumab** (Actemra); concurrent use should be avoided. Concurrent use of infliximab with other biological products (adalimumab [Humira], etanercept [Enbrel], selected DMARDs) used to treat the same conditions as infliximab is not recommended; may increase risk of infection. ■ The majority of patients with Crohn's disease, rheumatoid arthritis, or psoriatic arthritis received one or more of the following concomitant medications without evidence of any type of negative drug interaction: aminosaliculates, antibiotics, antivirals, corticosteroids, 6-mercaptopurine (Purinethol), azathioprine (Imuran), folic acid, methotrexate, narcotics, NSAIDs (e.g., ibuprofen [Motrin, Advil], naproxen [Aleve, Naprosyn]), and sulfasalazine. ■ Patients receiving **immunosuppressants** (e.g., 6-mercaptopurine, azathioprine, corticosteroids) tended to experience fewer infusion reactions as compared to patients on no immunosuppressants. ■ Concomitant **methotrexate** use may decrease incidence of anti-infliximab antibody production and increase infliximab concentrations. ■ **Corticosteroid** use increases the volume of distribution of infliximab. May be due to corticosteroid-mediated changes in fluid and electrolyte balance. ■ Concurrent administration of **live virus vaccines** is not recommended. ■ Cytochrome P₄₅₀ enzymes may be suppressed by increased levels of cytokines during inflammation. Infliximab antagonizes cytokine activity, and the formation of the CYP450 enzymes may be normalized. When initiating or discontinuing infliximab in patients treated with **CYP450 substrates with a narrow therapeutic index**, monitoring of the effect (e.g., warfarin [Coumadin]) or drug concentrations (e.g., cyclosporine [Sandimmune] or theophylline) is recommended. Dose adjustment may be necessary.

SIDE EFFECTS

Most common reasons for discontinuation of therapy were infusion-related reactions (e.g., chest pain, chills, dyspnea, fever, hypertension, hypotension, pruritus, or urticaria) occurring during or within 2 hours of infusion or infections (bacterial, fungal, protozoal, and viral). See **Precautions**. Most commonly reported side effects include abdominal pain, coughing, fatigue, headache, nausea, pharyngitis, upper respiratory tract infections, and vomiting. Other less common side effects include abscess, anaphylactic-like reactions (including laryngeal/pharyngeal edema and severe bronchospasm), anemia, anxiety, arthralgia, autoantibodies/lupus-like syndrome, back pain, conjunctivitis, constipation, depression, diarrhea, dizziness, dyspepsia, dysuria, flushing, hot flashes, HACA development, hepatitis B virus reactivation, hepatotoxicity (autoimmune hepatitis, increased liver function tests, jaundice, liver failure), insomnia, intestinal obstruction, lymphoproliferative disorders, malignancies including lymphoma, moniliasis, myalgia, pain, paresthesia, peripheral edema, rash, sarcoidosis, seizures, serum sickness-like reactions, stomatitis, tachycardia, vertigo, and visual disturbances. See **Precautions**. Infections (bacterial, fungal, protozoal, and viral) including TB, invasive opportunistic infections (e.g., histoplasmosis, listeriosis, and pneumocystosis), new-onset or worsening CHF, CNS demyelinating disorders, and deaths have been reported.

Post-Marketing: Cholestasis, erythema multiforme, hepatitis, hepatosplenic T-cell lymphomas, idiopathic and/or thrombotic thrombocytopenic purpura, interstitial lung disease (including pulmonary fibrosis/interstitial pneumonitis and, very rarely, rapidly progressive disease), jaundice, liver failure, melanoma and Merkel cell carcinoma, myocardial ischemia/infarction, neuropathies, neutropenia, pericardial effusion, peripheral demyelinating disorders (e.g., Guillain-Barré syndrome, chronic inflammatory demyelinating polyneuropathy, and multifocal motor neuropathy), psoriasis (including new-onset and pustular, primarily palmar/plantar), Stevens-Johnson syndrome, systemic and cutaneous vasculitis, toxic epidermal necrolysis, and transverse myelitis have been reported; fatalities have occurred.

Pediatric patients with Crohn's disease: Anemia, bacterial infection, blood in stool, bone fracture, flushing, leukopenia, neutropenia, respiratory tract allergic reactions, and viral infections were reported more commonly in pediatric patients than in adult patients receiving similar treatment regimens. Serious side effects were infections (some fatal), including opportunistic infections and tuberculosis, infusion reactions, and hypersensitivity reactions. Malignancies (including hepatosplenic T-cell lymphomas), transient hepatic enzyme abnormalities, lupus-like syndromes, and the development of autoantibodies were less common, yet serious, reactions.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Discontinue infliximab if patient experiences a serious infection, significant changes in vital signs, new or worsening S/S of heart failure, a hypersensitivity reaction, or a lupus-like syndrome (fever, pleuritic pain, pleural effusion). Treat with acetaminophen (Tylenol), antihistamines (diphenhydramine [Benadryl]), corticosteroids, dopamine, and epinephrine as indicated. If infusion is stopped but reaction is not severe and does not require treatment with drugs such as epinephrine or corticosteroids, infusion may be restarted with caution. Restart at lower rate and/or premedicate patient; see **Usual Dose**. A physician should be present during initiation of any subsequent infusion for a patient who has had a previous reaction. Lupus-like syndrome usually subsides within 10 days of discontinuing infliximab. Discontinue infliximab in patients who develop HBV reactivation, and initiate antiviral therapy with appropriate supportive treatment. Safety of resuming therapy after HBV is controlled is not known; use caution if resumption of therapy is considered, and monitor closely.

▪ NovoLog ▪ Apidra ▪ Humalog

pH 7 to 7.8 ▪ pH 7.2 to 7.6 ▪

pH 7.3 ▪ pH 7 to 7.8

USUAL DOSE

Only regular insulin, insulin aspart, insulin glulisine, and insulin lispro may be given IV. Confirm by label or package insert that a particular insulin product is for IV use; see **Precautions**.

Dose varies greatly. Will be dependent on patient's condition and response. Insulin requirements may be altered during stress or major illness or with changes in exercise, meal pattern, or coadministered drugs. It is imperative that dosing is individualized and adjusted based on blood glucose determinations because of the marked loss of insulin from adsorption to glass and plastic infusion containers and tubing; see **Precautions**.

Low-dose treatment in ketoacidosis: The American Diabetes Association recommends 0.15 units/kg as a loading dose (10.5 units for a 70-kg patient), followed by a continuous infusion of 0.1 units/kg/hr (7 units/hr for a 70-kg patient). Plasma glucose should decrease at a rate of 50 to 75 mg/dL/hr. If plasma glucose concentrations do not fall by 50 mg/dL within the first hour of insulin therapy, the insulin infusion rate may be doubled every hour, provided the patient is adequately hydrated. Decrease the rate of infusion when plasma glucose reaches 300 to 250 mg/dL. Start a separate IV of D5½NS when plasma glucose reaches 300 mg/dL. Administer insulin to maintain serum glucose concentrations between 150 and 200 mg/dL in patients with diabetic ketoacidosis. Continue until metabolic acidosis is corrected. Administer an appropriate dose of insulin SC 30 minutes before discontinuing the insulin infusion (intermediate-acting insulin recommended).

Diabetes mellitus with hyperosmolar coma, nonketotic (unlabeled): An initial bolus dose of 0.1 unit/kg followed by a continuous infusion of 0.1 unit/kg/hr until the blood glucose falls to 250 mg/dL.

Hyperkalemia (unlabeled): Insulin may be used in patients with or without diabetes mellitus to treat hyperkalemia. Must be administered with a dextrose solution in nondiabetic patients. Begin with an initial dose of 5 to 10 units of regular insulin and 50 mL of dextrose 50% as an IV bolus. Follow with a continuous infusion of 10% dextrose with regular insulin 20 units/L. Administer at 50 mL/hr to prevent fasting hyperkalemia.

Diagnosis of growth hormone deficiency (regular insulin [unlabeled use]): 0.05 to 0.15 units/kg of body weight as a rapid, one-time injection.

PEDIATRIC DOSE

Ketoacidosis or hyperosmolar hyperglycemia: Fluids: Consider initial potential for dehydration and administer 10 to 20 mL/kg of NS or LR over 1 hour.

Regular insulin and insulin aspart: Administer 0.1 unit/kg/hr as a continuous infusion. Goal is to reduce glucose by 80 to 100 mg/dL/hr. When glucose reaches 250 to 300 mg/dL, or if glucose decreases more than 100 mg/dL/hr, add D5W to fluids. SC insulin may be started once pH and bicarbonate are within normal limits. Discontinue insulin infusion 1 hour after SC dose. Monitor glucose levels and serum electrolytes and continue fluid replacement as appropriate.

DOSE ADJUSTMENTS

A reduced dose of insulin may be indicated when infusions are discontinued and SC administration is indicated. As in Usual Dose, base on blood glucose determinations and patient's response to therapy. ▪ Dose requirements may be reduced in patients with renal

or hepatic impairment. ■ Dose adjustment may be indicated if it is necessary to change from one insulin product to another.

DILUTION

Regular insulin: Use only if clear. May be given undiluted either directly into the vein or through a Y-tube or three-way stopcock. Another regimen adds 100 units of insulin (1 mL) to 100 mL of NS. This solution yields 1 unit/mL and is usually given at a rate of 0.1 unit/kg of body weight/hr (70-kg adult would receive 7 units/hr).

Insulin aspart: May be diluted in NS to a final concentration of 0.05 to 1 unit/mL. Use a polypropylene infusion bag. See [Precautions](#).

Humulin R U-100: Must be diluted with NS to achieve a final concentration of 0.1 to 1 unit/mL (100 units of insulin [1 mL] to 100 mL of NS yields 1 unit/mL). Use polyvinyl chloride (PVC) infusion bags.

Insulin glulisine: May be diluted with NS to achieve a final concentration of 0.05 unit/mL to 1 unit/mL (e.g., dilute 100 units in 100 mL NS). Polyvinyl chloride (PVC) Viaflex infusion bags and PVC tubing must be used. Use of other bags and tubings has not been studied.

Insulin lispro: Must be diluted with NS to achieve a final concentration of 0.1 to 1 unit/mL (100 units of insulin [1 mL] to 100 mL of NS yields 1 unit/mL).

Storage: Vials: Store unopened vials in refrigerator. A vial that is in use may be stored at RT for 28 days (*insulin aspart, insulin glulisine, and insulin lispro*) or 31 days (*regular insulin*). Protect from sunlight and freezing.

Infusions: Some insulin will be initially adsorbed to the material of the infusion bag.

Regular insulin and insulin lispro: Infusion bags prepared as indicated in dilution are stable for 48 hours refrigerated and then may be used at RT for up to an additional 48 hours.

Insulin glulisine: Infusion bags prepared as indicated in dilution are stable at RT for 48 hours. **Insulin aspart:** Infusion bags prepared as indicated in dilution are stable at RT for 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists **insulin glulisine** as **incompatible** with dextrose solution and Ringer's solutions and therefore cannot be mixed with these solutions. The use of **insulin glulisine (Apidra)** with other solutions has not been studied and is not recommended.

One source suggests the following **compatibilities**:

These compatibilities refer to regular insulin only; information on specific compatibilities for insulin aspart, insulin glulisine, and insulin lispro are not available.

Additive: Meropenem (Merrem IV).

Y-site: Amiodarone (Nexterone), ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), caspofungin (Cancidas), cefazolin (Ancef), cefepime (Maxipime), cefotetan, ceftazoline (Teflaro), ceftazidime (Fortaz), digoxin (Lanoxin), dobutamine, doripenem (Doribax), doxapram (Dopram), esmolol (Brevibloc), famotidine (Pepcid IV), gentamicin, heparin, 6% hydroxyethyl starch (Voluven), imipenem-cilastatin (Primaxin), indomethacin (Indocin IV), levofloxacin (Levaquin), magnesium sulfate, meperidine (Demerol), meropenem (Merrem IV), midazolam (Versed), milrinone (Primacor), morphine, nitroglycerin IV, nitroprusside sodium, oxytocin (Pitocin), pantoprazole (Protonix IV), pentobarbital (Nembutal), propofol (Diprivan), sodium bicarbonate, tacrolimus (Prograf), ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vasopressin.

RATE OF ADMINISTRATION

Each 50 units or fraction thereof over 1 minute. When given in an IV infusion, the rate should be ordered by the physician and will depend on insulin and fluid needs; see [Dilution](#) for example. Decrease rate when plasma glucose reaches 300 mg/dL. Manufacturer recommends that the rate of **insulin lispro** be regularly adjusted to maintain blood glucose concentrations between 100 and 160 mg/dL.

ACTIONS

A hormone produced by the pancreas that controls the storage and metabolism of carbohydrates, proteins, and fat. Responsible for regulation of glucose metabolism. Binds to insulin receptors on muscle and fat cells and lowers blood glucose by facilitating cellular uptake of glucose and inhibiting output of glucose from the liver. Also inhibits lipolysis and proteolysis and enhances protein synthesis. Rapidly and widely distributed. The glucose-lowering activities of regular insulin, insulin aspart, insulin glulisine, and insulin lispro are equipotent when administered by the IV route. The average elimination half-life is dose dependent and ranges from 0.25 to 1 hour depending on dose and product.

INDICATIONS AND USES

Regular insulin: Treatment of diabetes mellitus (Type I, Type II, and gestational). ■ Treatment of complications associated with diabetes (e.g., diabetic coma, hyperosmolar hyperglycemia with or without coma [hyperglycemia and dehydration], ketoacidosis with or without coma [plasma glucose exceeding 250 mg/dL with arterial pH of 7 to 7.24 or less and serum bicarbonate of 10 to 15 mEq/L or less]). ■ In combination with glucose to treat hyperkalemia. ■ Add to total parenteral nutrition to control hyperglycemia.

Humulin R U-100, insulin aspart, insulin glulisine, and insulin lispro: Treatment of patients with diabetes mellitus for control of hyperglycemia. Usually used as part of a SC injection regimen or as a SC infusion administered via an external insulin pump. May be given IV. Proper medical supervision is required to prevent hypoglycemia and hypokalemia.

Unlabeled uses: Diagnosis of growth hormone deficiency. ■ Continuous intravenous infusions administered via a special pump have been used to treat severe brittle diabetics who have failed more conventional therapy.

CONTRAINDICATIONS

Contraindicated during episodes of hypoglycemia and in patients hypersensitive to regular human insulin, insulin aspart, insulin glulisine, insulin lispro, or one of the excipients of any of these products.

PRECAUTIONS

Only regular insulin, insulin aspart, insulin glulisine, and insulin lispro may be given IV. All insulin formulations for IV use are standardized at 100 units/mL.

Regular insulin, insulin aspart, insulin glulisine, and insulin lispro: Circulating levels of insulin may be increased in patients with renal or hepatic failure; see **Dose Adjustments**. ■ Hypoglycemia and hypokalemia are potential side effects of insulin therapy. Use caution in patients in whom these side effects may be clinically relevant (e.g., patients who are fasting, have autonomic neuropathy, are using potassium-lowering drugs [e.g., diuretics], or are taking drugs sensitive to serum potassium levels [e.g., digoxin]). ■ Insulin requirements may be altered during illness or stress. ■ Anti-insulin antibodies have been reported. Clinical significance of anti-insulin antibodies is unknown. ■ Systemic hypersensitivity reactions have been reported. May include hypotension, pruritus, rash, shortness of breath, sweating, tachycardia, and/or wheezing. Anaphylaxis has occurred.

Regular insulin: Insulin potency may be reduced by at least 20% and possibly up to 80% via the glass or plastic infusion container and plastic IV tubing before it actually reaches the venous system when given by infusion. The percentage adsorbed is inversely proportional to the concentration of insulin (the larger the dose, the less adsorption) and takes place within 30 to 60 minutes. Albumin is sometimes added to reduce this adsorption. Other additives (e.g., electrolytes, other drugs, vitamins) may also reduce adsorption. Other methods of compensation for insulin loss include the addition of added insulin to saturate binding sites or the use of a syringe pump (instead of infusion containers) to reduce surface area for adsorption.

All insulin products: See **Drug/Lab Interactions**. Use with thiazolidinediones (TZDs [e.g., pioglitazone (Actos)]) may cause heart failure.

Monitor: Response to insulin measured by blood glucose, blood pH, acetone, BUN, sodium, potassium, chloride, and CO₂ levels. Monitor patient carefully in all situations. Glucose and potassium levels must be monitored closely during IV administration of insulin to avoid potentially fatal hypoglycemia and hypokalemia. Glycosylated hemoglo-

bin (HgbA1c) may be measured to assess long-term glycemic control. ■ Hypovolemia is a common complication of diabetic acidosis. ■ See [Drug/Lab Interactions](#). ■ Insulin is inactivated at pH above 7.5.

Patient Education: Monitor blood glucose as directed. ■ Adhere to consistent diet and exercise programs. ■ Avoid alcohol. ■ Review medications or changes in medication regimen with a health care professional. ■ Review S/S of hypoglycemia and hyperglycemia with a health care professional. Be familiar with the treatment for each. ■ Insulin requirements may change with onset of illness. Monitor glucose carefully and adjust insulin therapy as required.

Maternal/Child: Regular insulin: Category B: human insulin is drug of choice for control of diabetes in pregnancy. Additional insulin may be required to control serum glucose and avoid ketoacidosis. Monitor carefully; insulin requirements may drop immediately postpartum. Normal prepregnancy dose should be achieved within 6 weeks. Patients with gestational diabetes usually do not require insulin therapy following childbirth. ■ Use caution in breast-feeding. ■ Breast-feeding may decrease insulin requirements. ■ Inadequately controlled maternal blood glucose late in pregnancy may cause increased insulin production in the fetus. Monitor and treat neonatal hypoglycemia postpartum.

Insulin aspart and insulin lispro: Category B: careful monitoring of glucose control is essential; see comments under regular insulin. ■ Use caution during breast-feeding.

Insulin glulisine: Category C: use caution and assess risk versus benefit. Careful monitoring of glucose control is essential; see comments under regular insulin. ■ Safety and effectiveness of IV administration for use in pediatric patients not established.

DRUG/LAB INTERACTIONS

Hypoglycemic effect is potentiated by **ACE inhibitors** (e.g., enalapril [Vasotec], lisinopril [Zestril]), **anabolic steroids** (e.g., nandrolone [Durabolin]), **disopyramide** (Norpace), **fluoxetine** (Prozac), **fibrates** (e.g., fenofibrate [Tricor]), **guanethidine**, **MAO inhibitors** (e.g., selegiline [Eldepryl]), **oral antidiabetic agents** (e.g., glyburide [DiaBeta]), **pentoxifylline** (Trental), **salicylates**, **sulfonamides**, and **many others**. ■ Inhibited by **atypical antipsychotic medications** (e.g., olanzapine [Zyprexa], clozapine [Clozaril]), **corticosteroids**, **danazol** (Cyclomen), **diazoxide**, **diuretics** (e.g., furosemide [Lasix]), **dobutamine**, **glucagon**, **isoniazid** (INH), **niacin**, **oral contraceptives**, **phenothiazine derivatives** (e.g., chlorpromazine [Thorazine]), **protease inhibitors** (e.g., indinavir [Crixivan]), **somatropin** (Humatrope), **sympathomimetic agents** (e.g., epinephrine [Adrenalin], albuterol [Ventolin]), **thyroid preparations**, and **others**. ■ **Alcohol**, **beta-adrenergic blockers including ophthalmics** (e.g., propranolol, metoprolol [Lopressor]), **clonidine** (Catapres), and **lithium** may either potentiate or inhibit the blood glucose-lowering effect of insulin. ■ Hypoglycemic effects may be decreased in **smokers**; dose adjustment may be required. ■ Will affect serum potassium levels; use caution in patients taking **digoxin**. ■ **Octreotide** (Sandostatin) may alter insulin, glucagon, and growth hormone secretion, resulting in hypoglycemia or hyperglycemia. Monitor serum glucose and adjust insulin dose as indicated. Octreotide also markedly increases adsorption of insulin to glass and plastic and reduces availability. ■ **Pentamidine** is toxic to the beta cells of the pancreas. Patients may develop hypoglycemia initially as insulin is released. This may be followed by hypoinsulinemia and hyperglycemia with continued pentamidine therapy. ■ S/S of hypoglycemia may be masked in the presence of **beta-blockers**, **clonidine** (Catapres), **guanethidine** (Ismelin), and **reserpine**. ■ **Thiazolidinediones** (TZDs [e.g., pioglitazone (Actos)]) can cause dose-related fluid retention, particularly when used in combination with insulin. Fluid retention may lead to or exacerbate heart failure. Patients receiving concomitant therapy should be monitored for S/S of heart failure. Dose reduction or discontinuation of the TZD may be indicated if heart failure develops.

SIDE EFFECTS

Hypoglycemia with overdose. **Mild to moderate:** Abnormal behavior; anxiety; blurred vision; depressed mood; dizziness; drowsiness; headache; hunger; inability to concentrate; irritability; light-headedness; palpitation; personality changes; restlessness; sleep distur-

bances; slurred speech; sweating; tingling in the hands, feet, lips, or tongue; tremors; unsteady movement.

Severe: Coma, disorientation, hypokalemia (with ECG changes), seizures, unconsciousness, and death. Hypersensitivity reactions, including anaphylaxis, may occur; death is rare. Abdominal pain, chest pain, diarrhea, headache, hyporeflexia, nausea, and sensory disturbances have also been reported.

ANTIDOTE

Discontinue the drug immediately and notify physician of adverse reactions or hypoglycemia. **Glucagon** 1 to 2 mg IM or SC is the specific antidote for insulin overdose. It may be supplemented by glucose 50% IV and/or oral carbohydrates such as glucose gel or orange juice. Oral carbohydrates may be sufficient to combat early symptoms of hypoglycemia. Correct hypokalemia as indicated. Hypersensitivity reactions usually respond to symptomatic treatment.

INTERFERON ALFA-2b, RECOMBINANT **BBW**

(in-ter-**FEER**-on **AL**-fah)

Biologic response modifier
Antineoplastic

Intron A

pH 6.9 to 7.5

USUAL DOSE

(International units [IU])

Pretreatment with acetaminophen may lessen flu-like side effects.

Malignant melanoma: Induction: 20,000,000 IU/M² as an infusion each day for 5 consecutive days per week for 4 weeks. Begin therapy within 56 days of surgical resection.

Maintenance: Follow with 10,000,000 IU/M² as a SC injection three times each week for 48 weeks.

Total treatment regimen lasts for 1 year and should be completed unless there is progression of disease or the drug is discontinued because of specific side effects.

DOSE ADJUSTMENTS

Temporarily discontinued for serious adverse reactions, if granulocytes decrease to less than 500/mm³, or ALT/AST increases to more than 5 times upper limit of normal. When adverse reactions subside or improvement of granulocytes or liver function tests occur, treatment can be restarted at 50% of the previous dose. Discontinue permanently if serious adverse reactions persist, if granulocytes decrease to less than 250/mm³, or if ALT/AST increases to more than 10 times the upper limit of normal. ■ See **Elderly**.

DILUTION

(International units [IU])

Prepare immediately before use. Only the sterile powder is suitable for dilution for IV use. Do not use different brands of interferon in any single treatment regimen; variations exist and may adversely affect dosage and response to treatment. Available in 10, 18, and 50 million IU vials; select one most appropriate for desired dose. Reconstitute with the diluent provided. Gently swirl to dissolve. Withdraw desired dose and inject into 100 mL of NS. Final concentration should be at least 10 million IU/100 mL.

Storage: Unopened vials of powder for injection should be refrigerated. After reconstitution, solution should be used immediately but can be refrigerated at 2° to 8° C (36° to 46° F) for 24 hours.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist. One source indicates **compatibility** with NS, LR, and R solutions and **incompatibility** with dextrose solutions.

RATE OF ADMINISTRATION

A single dose equally distributed over 20 minutes. Administration at bedtime and the use of acetaminophen may prevent or partially reduce common side effects (e.g., fever, headache, “flu-like” symptoms).

ACTIONS

A naturally occurring small protein and glycoprotein of the interferon family produced by recombinant DNA techniques. It binds to specific membrane receptors on the cell surface and initiates a complex sequence of intracellular events (e.g., induction of specific enzymes, suppression of cell proliferation, immunomodulating activities [e.g., enhancement of phagocytic activity of macrophages, augmentation of the specific cytotoxicity of lymphocytes for target cells, inhibition of virus replication in virus-infected cells]). Peak concentration achieved within 30 minutes. Half-life about 2 hours; undetectable 4 hours after infusion. Has produced a significant increase in relapse-free and overall survival in patients with malignant melanoma. The kidney may be the site of interferon catabolism.

INDICATIONS AND USES

Adjuvant to surgical treatment in patients with malignant melanoma who are free of disease but at high risk for systemic recurrence within 56 days of surgery. ■ Used IM or SC to treat hairy cell leukemia, follicular non-Hodgkin’s lymphoma, AIDS-related Kaposi’s sarcoma, chronic hepatitis B, chronic hepatitis C in patients unresponsive to previous therapy, in combination with recombinant ribavirin to treat chronic hepatitis C in patients with compensated liver disease who have relapsed following interferon alfa therapy, and intralesionally to treat condylomata acuminata.

CONTRAINDICATIONS

Hypersensitivity to interferon alfa or any of its components (benzyl alcohol, glycine, human albumin, and sodium phosphate dibasic and monobasic). ■ Not recommended for patients with a pre-existing psychiatric condition, especially depression or a history of severe psychiatric disorder. ■ Not recommended for patients with pre-existing thyroid abnormalities if thyroid function cannot be maintained within the normal range with medication. ■ Not recommended for patients with decompensated liver disease, autoimmune hepatitis, or a history of autoimmune disease or for patients who are immunosuppressed transplant recipients.

PRECAUTIONS

Use cautiously in patients with a history of pulmonary disease (e.g., COPD), diabetes mellitus prone to ketoacidosis, coagulation disorders (e.g., thrombophlebitis, pulmonary embolism), or severe myelosuppression. ■ Use cautiously in patients with a history of cardiovascular disease (e.g., unstable angina, uncontrolled CHF, recent MI, and previous or current arrhythmic disorder). ■ May cause or aggravate depression and suicidal behavior; see [Maternal/Child](#). ■ May cause or aggravate life-threatening or fatal neuropsychiatric (e.g., depression, aggressive and/or suicidal behavior), autoimmune, ischemic, or infectious disorders. Close monitoring with periodic clinical and laboratory evaluations required. Discontinue therapy if S/S of any of the previous conditions worsen. Symptoms may resolve. ■ Severe cytopenias, including rare cases of aplastic anemia, have been reported; see [Monitor](#). ■ Ophthalmologic disorders (e.g., decreased vision or loss of vision; retinopathy including macular edema, retinal artery or vein thrombosis, retinal hemorrhages, and cotton wool spots; optic neuritis; papilledema) may be induced or aggravated by treatment with interferons; see [Monitor](#). ■ Use caution in patients with psoriasis and sarcoidosis; may exacerbate disease. ■ Rare cases of autoimmune diseases (e.g., lupus erythematosus, Raynaud’s phenomenon, rhabdomyolysis, rheumatoid arthritis, thrombocytopenia, and vasculitis) have been reported; may require discontinuation of therapy. ■ Use caution as combination therapy with ribavirin (Rebetol). Hemolytic anemia (less than 10 Gm/dL) can occur within 1 to 2 weeks. Combination should not be used in patients with creatinine clearance less than 50 mL/min. ■ Serum neutralizing antibodies have been detected in some patients; clinical significance unknown. ■ Ischemic and hemorrhagic cerebrovascular events have

been reported. A causal relationship between interferon therapy and these side effects is difficult to establish.

Monitor: Obtain baseline CBC including differential and platelet count, blood chemistries (electrolytes, liver function tests, and TSH), chest x-ray. Obtain baseline eye exam for all patients and periodically for patients with pre-existing ophthalmologic disorders (e.g., diabetic or hypertensive retinopathy). Obtain baseline ECG if there is a history of cardiovascular disease and/or patient is in advanced stages of cancer. Monitor all tests periodically during therapy. ■ Monitor CBC with differential and platelet count and liver function tests weekly during the induction phase and monthly during maintenance. Dose adjustments will be determined by results. Discontinue therapy if neutrophil count drops below 500 cells/mm³. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Discontinue therapy if platelet count drops below 25,000/mm³. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Closely monitor any patient with a history of cardiovascular disease (see **Precautions**); arrhythmias including tachycardia, hypotension, and transient reversible cardiomyopathy have occurred. ■ Monitor for S/S of a hypersensitivity reaction (e.g., anaphylaxis, angioedema, bronchoconstriction, urticaria). ■ Hypotension may occur during administration or up to 2 days posttherapy; monitor frequently. May require fluid replacement. ■ Maintain adequate hydration, particularly during initial states of treatment. ■ Monitor for signs of depression and/or aggressive or suicidal behavior. If psychiatric problems develop, patients should be carefully monitored during treatment and in the 6-month follow-up period. ■ Use of narcotics, hypnotics, or sedatives may be required to manage adverse effects; use with caution and monitor carefully. ■ Monitor thyroid function, liver function tests, blood glucose, and triglyceride levels; abnormalities not normalized by medication may require discontinuing interferon. ■ Determine cause of persistent fever. ■ Repeat chest x-ray if cough, dyspnea, fever, or other respiratory symptoms occur. Monitor closely if pulmonary infiltrates or evidence of pulmonary function impairment is present; may require discontinuing interferon. ■ Obtain an eye exam for any patient who complains of changes in visual acuity, visual fields, or other ophthalmologic symptoms. ■ See **Precautions**.

Patient Education: Female patients and female partners of male patients should use 2 forms of birth control during treatment and for 6 months after treatment is discontinued. ■ Cooperation for close monitoring and prompt reporting of side effects is imperative. Side effects may include depression, cardiovascular toxicity (e.g., chest pain), ophthalmologic toxicity (e.g., loss of or change in vision), pancreatitis (abdominal pain), cytopenias. ■ Review manufacturer's medication guide before each dose. ■ Home use may require extensive patient education. ■ See Appendix D, p. 1255. ■ Do not change brands of interferon without medical consultation. ■ Do not drive or operate machinery; mental alertness may be impaired. ■ Administration at bedtime and/or use of acetaminophen may be helpful to prevent the most common "flu-like" side effects. Remain well hydrated. ■ Side effects may decrease in severity as treatment continues. Avoid excessive sunlight or artificial ultraviolet light. Potential for photosensitivity; wear protective clothing, sunscreens, and sunglasses. ■ Dental and periodontal disorders have been reported in patients receiving combination therapy with interferon and ribavirin (Rebetol). Proper dental hygiene and regular dental exams recommended.

Maternal/Child: Category C: has abortifacient effects. Should be used only if benefits justify risks. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients under 18 years of age for indications other than chronic hepatitis B or C has not been established. ■ Suicidal ideation or attempts have occurred more often among pediatric patients (primarily adolescents) compared to adult patients. ■ For use in pediatric patients for indications other than SC administration in chronic hepatitis B and chronic hepatitis C; see prescribing literature.

Elderly: Incidence of encephalopathy, obtundation, and coma has occurred, especially at higher doses. ■ Cardiovascular adverse events and confusion have been reported more

frequently in the elderly. ■ Consider age-related decreases in organ function and concomitant disease and drug therapy. Careful monitoring required. Make dose adjustments based on symptoms and/or lab abnormalities.

DRUG/LAB INTERACTIONS

Specific information not available. Use caution with any **other potentially myelosuppressive agent** (e.g., cisplatin [Platinol], zidovudine [AZT, Retrovir]). ■ May increase serum levels of **theophylline**; monitoring of theophylline levels recommended. ■ May have synergistic additive effects with **zidovudine** (AZT, Retrovir) and increase incidence of neutropenia; monitor WBC closely. ■ See **Precautions**.

SIDE EFFECTS

Occur in high percentages of patients; may be serious enough to require a decreased dose or discontinuation of drug. Usually rapidly reversible after therapy discontinued, but may require up to 3 weeks to resolve. Alopecia, anemia, anorexia, arrhythmias, autoimmune disorders, bleeding, coughing, depression, diarrhea, dizziness, dyspnea, elevated triglycerides, “flu-like” symptoms (e.g., chills, fatigue, fever, headache, myalgia), granulocytopenia, hyperglycemia, increased AST and/or ALT, leukopenia, nausea, ophthalmologic disorders, pain (variable), paresthesia, psychiatric disorders (e.g., depression, aggressive or suicidal behavior), pulmonary disorders, rash, taste alteration, thrombocytopenia, vomiting. Many other side effects may occur. Acute serious hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchoconstriction, urticaria) are rare but have occurred.

Post-Marketing: Stevens-Johnson syndrome, toxic epidermal necrolysis, erythema multiforme, injection site necrosis, myositis, hearing loss, and a wide variety of autoimmune and immune-mediated disorders (e.g., idiopathic thrombocytopenic purpura and thrombotic thrombocytopenic purpura) have been identified in post-marketing reports.

ANTIDOTE

Keep physician informed of all side effects. Some will be tolerated or treated symptomatically. Discontinue interferon immediately for any acute serious hypersensitivity reactions and treat as appropriate; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Discontinue drug for any patient who develops severe depression or other psychiatric disorder. Close patient monitoring and psychiatric intervention may be indicated. Discontinue for myelosuppression that persists after dose reduction, endocrine thyroid abnormalities not normalized by medication, serious liver function abnormalities, new or worsening ophthalmologic disorders, serious pulmonary function impairment, or pulmonary infiltrates. Treatment of overdose with hemodialysis or peritoneal dialysis is not considered effective. Resuscitate as necessary.

IPILIMUMAB **BBW**

(ip-i-LIM-ue-mab)

Monoclonal antibody
Antineoplastic**Yervoy****pH 7****USUAL DOSE**

3 mg/kg administered as an IV infusion over 90 minutes every 3 weeks for a total of 4 doses.

DOSE ADJUSTMENTS

Withhold scheduled dose for any moderate (Grade 2), immune-mediated, adverse reaction or for symptomatic endocrinopathy. Patients with complete or partial resolution of adverse reactions (Grade 0 to 1) who are receiving less than 7.5 mg of prednisone or the equivalent per day may resume ipilimumab at a dose of 3 mg/kg every 3 weeks until administration of all 4 doses or until 16 weeks after the first dose, whichever occurs earlier. ■ Permanently discontinue ipilimumab for persistent moderate adverse reactions, an inability to reduce the corticosteroid dose to 7.5 mg prednisone or equivalent per day, or a failure to complete a full-treatment course within 16 weeks from administration of the first dose. ■ Permanently discontinue ipilimumab for severe or life-threatening adverse reactions; see [Precautions](#) and [Antidote](#). ■ No dose adjustment indicated in renal impairment or mild hepatic impairment.

DILUTION

Available as a 5 mg/mL solution in 50-mg and 200-mg vials. Solution may have a clear to pale yellow color and may contain translucent-to-white amorphous particles. Discard vial if solution is cloudy. **Do not shake.** Allow vials to stand at RT for approximately 5 minutes. Withdraw required volume of ipilimumab and transfer into a infusion bag containing NS or D5W. Final concentration of diluted solution should range from 1 to 2 mg/mL. Mix diluted solution by gentle inversion. For example, a dose for a 70-kg patient would be $70 \text{ kg} \times 3 \text{ mg/kg dose} = 210 \text{ mg}$. Withdraw 210 mg (42 mL of a 5 mg/mL solution) and transfer to a 100-mL bag of NS or D5W. Final concentration = $210 \text{ mg} \div 142 \text{ mL} = 1.5 \text{ mg/mL}$.

Filters: Administer through a separate line equipped with a sterile, non-pyrogenic, low-protein binding in-line filter.

Storage: Refrigerate vials at 2° to 8° C (36° to 46° F). Do not freeze. Protect from light. Store diluted solution for no more than 24 hours under refrigeration (2° to 8° C [36° to 46° F]) or at RT. Discard partially used vials.

COMPATIBILITY

Manufacturer states, “Do not mix with, or administer as an infusion with, other medicinal products.” Flush IV line with NS or D5W after each dose.

RATE OF ADMINISTRATION

A single dose equally distributed as an infusion over 90 minutes. Administer through a separate line equipped with a low-protein binding terminal filter. Flush line with NS or D5W after each dose; see [Filters](#).

ACTIONS

An IgG1 kappa immunoglobulin. A recombinant, human monoclonal antibody that binds to the cytotoxic, T-lymphocyte-associated antigen 4 (CTLA-4). CTLA-4 is a negative regulator of T-cell activation. Ipilimumab binds to CTLA-4 and blocks the interaction of CTLA-4 with its ligands, CD80/CD86. Blockade has been shown to augment T-cell activation and proliferation. The mechanism of action of ipilimumab's effect in patients with melanoma is indirect, possibly through T-cell-mediated anti-tumor immune responses. Terminal half-life is 15.4 days. Renal impairment and mild hepatic impairment did not have a clinically important effect on the pharmacokinetics of ipilimumab.

INDICATIONS AND USES

Treatment of unresectable or metastatic melanoma.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

May result in severe and fatal immune-mediated adverse reactions due to T-cell activation and proliferation. Reactions may involve any organ system; however, the most common severe immune-mediated adverse reactions are enterocolitis, hepatitis, dermatitis (including toxic epidermal necrolysis), neuropathy, and endocrinopathy. Most reactions are manifested during treatment; however, a minority occurred weeks to months after discontinuation of ipilimumab. Consider the risk for severe and fatal immune-mediated adverse reactions versus benefit before initiating therapy with ipilimumab. ■ Severe, life-threatening, or fatal immune-mediated enterocolitis, hepatotoxicity, and dermatitis have been reported. ■ Severe, life-threatening, or fatal motor or sensory neuropathy, Guillain-Barré syndrome, or myasthenia gravis have been reported. ■ Severe to life-threatening immune-mediated endocrinopathies that require hospitalization or urgent medical intervention or that interfere with activities of daily living have been reported. Endocrinopathies have included hypopituitarism, adrenal insufficiency, hypogonadism, hypothyroidism, hyperthyroidism, and Cushing’s syndrome. ■ Severe immune-mediated reactions involving other organ systems (e.g., nephritis, pneumonitis, pancreatitis, non-infectious myocarditis, uveitis, iritis) have been reported rarely. ■ A small number of patients have tested positive for binding antibodies against ipilimumab. Infusion-related or peri-infusional reactions consistent with hypersensitivity or anaphylaxis were not reported in these patients, and neutralizing antibodies against ipilimumab were not detected. ■ Immune-mediated ocular disease unresponsive to topical immunosuppressive therapy has been reported. ■ Has not been studied in patients with moderate to severe hepatic impairment.

Monitor: Obtain baseline clinical chemistries, including liver function tests and thyroid function tests. Repeat before each dose and as indicated based on symptoms. ■ Assess patients for signs and symptoms of enterocolitis (diarrhea [greater than 6 to 7 stools/day above baseline], abdominal pain, mucus or blood in stool, with or without fever), GI hemorrhage or perforation (peritoneal signs and ileus), and/or the need for IV hydration for more than 24 hours. In symptomatic patients, rule out infectious etiologies or malignant causes and consider endoscopic evaluation for persistent or severe symptoms. ■ Monitor for severe immune-mediated hepatitis (AST or ALT elevations of more than 5 times the ULN or total bilirubin elevations more than 3 times the ULN). In patients with hepatotoxicity, rule out infectious or malignant causes and increase the frequency of liver function test monitoring until resolution of symptoms. ■ Monitor for severe immune-mediated dermatitis (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis, rash complicated by full-thickness dermal ulceration, or necrotic, bullous, or hemorrhagic manifestations). Median time to immune-mediated dermatitis was 3.1 weeks. Unless an alternate etiology has been identified, S/S of dermatitis should be considered immune mediated. ■ Monitor for symptoms of severe motor or sensory neuropathy (e.g., unilateral or bilateral weakness, sensory alterations, or paresthesia that interfere with daily activities). ■ Monitor for clinical signs and symptoms of endocrinopathies, including hypophysitis (inflammation of the pituitary gland), adrenal insufficiency (including adrenal crisis), and hyperthyroidism or hypothyroidism. Patients may present with fatigue, headache, mental status changes, abdominal pain, unusual bowel habits, and hypotension. Median time to onset of immune-mediated endocrinopathy was 11 weeks. Unless an alternate etiology has been identified, S/S of endocrinopathies should be considered immune mediated. ■ Monitor for clinical S/S of immune-mediated ocular disease. ■ See [Precautions](#).

Patient Education: Review Medication Guide before each dose. Severe immune-mediated reactions have been reported. ■ Promptly report any side effects. ■ May cause fetal harm. Birth control recommended.

Maternal/Child: Category C: based on animal data; may cause fetal harm. Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: No overall differences in safety or efficacy were reported between elderly patients and younger patients.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed.

SIDE EFFECTS

The most common side effects are colitis, diarrhea, fatigue, pruritus, and rash. Severe to fatal immune-mediated reactions included dermatitis, endocrinopathy (adrenal insufficiency and hypopituitarism), enterocolitis (including intestinal perforation), eosinophilia, hepatotoxicity, meningitis, nephritis, pericarditis, and pneumonitis. Other reported side effects include acute respiratory distress syndrome, encephalitis, esophagitis, hearing loss, infusion reaction, intestinal ulcer, myositis, ocular myositis, polymyositis, renal failure, sarcoidosis, and urticaria. Other immune-mediated adverse reactions were reported in fewer than 1% of patients; see manufacturer's prescribing information.

ANTIDOTE

Keep physician informed of all side effects. Permanently discontinue ipilimumab and initiate systemic high-dose corticosteroid therapy (e.g., 1 to 2 mg/kg/day of prednisone or equivalent) for severe immune-mediated reactions (e.g., Grades 3 to 5). With improvement to Grade 1 or less, initiate corticosteroid taper and continue to taper over at least 1 month. In one clinical study, infliximab (Remicade) was administered to patients with moderate or severe enterocolitis following an inadequate response to corticosteroids. Withhold ipilimumab dosing for moderate enterocolitis; administer antidiarrheal treatment (e.g., loperamide [Imodium]) and, if persistent for more than 1 week, initiate systemic corticosteroids at a dose of 0.5 mg/kg/day of prednisone or the equivalent. Mycophenolate (CellCept) may be considered in patients with persistent, severe hepatitis despite high-dose corticosteroids. Withhold ipilimumab dosing in patients with moderate hepatotoxicity, dermatitis, or neuropathy (neuropathy not interfering with daily activities). For mild to moderate dermatitis, such as localized rash and pruritus, treat symptomatically with topical or systemic steroids if no improvement of symptoms within 1 week. Initiate appropriate hormone replacement therapy in patients with symptomatic endocrinopathies. Administer corticosteroid eyedrops to patients who develop uveitis, iritis, or episcleritis. Resuscitate as necessary.

IRINOTECAN HYDROCHLORIDE **BBW**

(eye-rih-noh-TEE-kan hy-droh-KLOR-eyed)

Antineoplastic
(topoisomerase 1 inhibitor)**Camptosar, CPT-11****pH 3 to 3.8****USUAL DOSE**

Premedication with antiemetics recommended. Dexamethasone 10 mg and a 5-HT₃ blocker (e.g., ondansetron or granisetron) should be given on the day of treatment. Begin at least 30 minutes before giving irinotecan. See [Monitor](#).

First-line treatment of colorectal cancer: The Saltz regimen or Regimen 1 is a combination therapy. It is administered once each week for 4 weeks (Days 1, 8, 15, and 22) followed by a 2-week rest period. Premedication as described above is recommended. In addition prophylactic or therapeutic atropine may be indicated in patients experiencing cholinergic symptoms. Initiate regimen with the dose of irinotecan over 90 minutes. Follow immediately with the dose of leucovorin calcium (see leucovorin calcium monograph). Follow the leucovorin immediately with the dose of fluorouracil (see fluorouracil monograph). Doses and modified dosing recommendations are based on the chart Combination-Agent Dosage Regimens and Dose Modifications. Doses of irinotecan and fluorouracil may require modification based on toxicity. See [Dose Adjustments](#), combination therapy and/or package insert.

Regimen 2, called the Douillard or European regimen, is another regimen. Used primarily in Europe, doses are considerably higher, intervals are different, and side effects more pronounced. See the following chart, [Combination-Agent Dosage Regimens and Dose Modifications](#), and see [Dose Adjustments](#), combination therapy and/or package insert.

Combination-Agent Dosage Regimens and Dose Modifications* (Irinotecan/Fluorouracil [5-FU]/Leucovorin Calcium [LV])				
Regimen 1 6-wk course with bolus 5-FU/LV (next course begins on Day 43)	irinotecan	125 mg/M ² IV over 90 min, Day 1, 8, 15, 22		
	leucovorin	20 mg/M ² IV bolus, Day 1, 8, 15, 22		
	5-FU	500 mg/M ² IV bolus, Day 1, 8, 15, 22		
	Starting Dose and Modified Dose Levels (mg/M²)			
		Starting Dose	Dose Level -1	Dose Level -2
	irinotecan	125 mg/M ²	100 mg/M ²	75 mg/M ²
	leucovorin	20 mg/M ²	20 mg/M ²	20 mg/M ²
	5-FU	500 mg/M ²	400 mg/M ²	300 mg/M ²
Regimen 2 6-wk course with infusional 5-FU/LV (next course begins on Day 43)	irinotecan	180 mg/M ² IV over 90 min, Day 1, 15, 29		
	leucovorin	200 mg/M ² IV over 2 hr, Day 1, 2, 15, 16, 29, 30		
	5-FU Bolus	400 mg/M ² IV bolus, Day 1, 2, 15, 16, 29, 30		
	5-FU Infusion†	600 mg/M ² IV over 22 hr, Day 1, 2, 15, 16, 29, 30		
	Starting Dose and Modified Dose Levels (mg/M²)			
		Starting Dose	Dose Level -1	Dose Level -2
	irinotecan	180 mg/M ²	150 mg/M ²	120 mg/M ²
	leucovorin	200 mg/M ²	200 mg/M ²	200 mg/M ²
	5-FU Bolus	400 mg/M ²	320 mg/M ²	240 mg/M ²
	5-FU Infusion†	600 mg/M ²	480 mg/M ²	360 mg/M ²

*Dose reductions beyond dose level -2 by decrements of ~20% may be warranted for patients continuing to experience toxicity. Provided intolerable toxicity does not develop, treatment with additional courses may be continued indefinitely as long as patients continue to experience clinical benefit.

†Infusion follows bolus administration.

Continued

Treatment of colorectal cancer after failure of treatment with fluorouracil: Irinotecan: Administer as an infusion based on the following chart, Irinotecan Single-Agent Regimens and Dose Modifications. See **Premedication**. After adequate recovery, additional doses may be repeated in a similar cycle and continued indefinitely in patients who attain a response or in those whose disease remains stable.

Irinotecan Single-Agent Regimens and Dose Modifications			
Weekly Regimen*	125 mg/M ² IV over 90 min, Day 1, 8, 15, 22 then 2-wk rest		
	Starting Dose and Modified Dose Levels‡ (mg/M²)		
	Starting Dose	Dose Level – 1	Dose Level – 2
	125 mg/M ²	100 mg/M ²	75 mg/M ²
Once-Every-3-Week Regimen†	350 mg/M ² IV over 90 min, once every 3 wks‡		
	Starting Dose and Modified Dose Levels (mg/M²)		
	Starting Dose	Dose Level – 1	Dose Level – 2
	350 mg/M ²	300 mg/M ²	250 mg/M ²

*Subsequent doses may be adjusted as high as 150 mg/M² or to as low as 50 mg/M² in 25 to 50 mg/M² decrements depending upon individual patient tolerance.

†Subsequent doses may be adjusted as low as 200 mg/M² in 50 mg/M² decrements depending upon individual patient tolerance.

‡Provided intolerable toxicity does not develop, treatment with additional courses may be continued indefinitely as long as patients continue to experience clinical benefit.

DOSE ADJUSTMENTS

Consider decreasing the **starting dose** by at least one level of irinotecan when administered in combination with other agents or as a single agent to a patient known to be homozygous for the UGT1A1*28 allele (an allele is an alternative form of a gene). The precise dose reduction for this patient population is not known. Subsequent dose modification should be based on individual patient tolerance as outlined in the following tables. Heterozygous patients (patients who carry one variant allele) appear to tolerate normal starting doses. ■ See **Precautions**.

Combination therapy: Decrease dose based on toxicity as described in the following chart.

Guidelines for Dose Adjustments in Combination Schedules (Irinotecan Fluorouracil [5-FU]/Leucovorin Calcium [LV])		
Patients should return to pretreatment bowel function without requiring antidiarrhea medications for at least 24 hours before the next chemotherapy administration. A new course of therapy should also not begin until the granulocyte count has recovered to $\geq 1,500/\text{mm}^3$, and the platelet count has recovered to $\geq 100,000/\text{mm}^3$. Treatment should be delayed 1 to 2 weeks to allow for recovery from treatment-related toxicities. If the patient has not recovered after a 2-week delay, consideration should be given to discontinuing therapy.		
Toxicity CTCAE Grade* (Value)	During a Course of Therapy	At the Start of Subsequent Courses of Therapy†
No toxicity	Maintain dose level	Maintain dose level
Neutropenia 1 (1,500 to 1,999/ mm^3) 2 (1,000 to 1,499/ mm^3) 3 (500 to 999/ mm^3) 4 ($< 500/\text{mm}^3$)	Maintain dose level ↓1 dose level Omit dose until resolved to \leq Grade 2, then ↓1 dose level Omit dose until resolved to \leq Grade 2, then ↓2 dose levels	Maintain dose level Maintain dose level ↓1 dose level ↓2 dose levels
Neutropenic fever	Omit dose, then ↓2 dose levels when resolved	
Other hematologic toxicities	Dose modifications for leukopenia or thrombocytopenia during a course of therapy and at the start of subsequent courses of therapy are also based on Common Terminology Criteria for Adverse Events and are the same as previously recommended for neutropenia.	
Diarrhea 1 (2-3 stools/day $>$ pretx‡) 2 (4-6 stools/day $>$ pretx) 3 (7-9 stools/day $>$ pretx) 4 (≥ 10 stools/day $>$ pretx)	Delay dose until resolved to baseline, then give same dose Omit dose until resolved to baseline, then ↓1 dose level Omit dose until resolved to baseline, then ↓1 dose level Omit dose until resolved to baseline, then ↓2 dose levels	Maintain dose level Maintain dose level ↓1 dose level ↓2 dose levels
Other nonhematologic toxicities Grade 1 Grade 2 Grade 3 Grade 4	Maintain dose level Omit dose until resolved to \leq Grade 1, then ↓1 dose level Omit dose until resolved to \leq Grade 2, then ↓1 dose level Omit dose until resolved to \leq Grade 2, then ↓2 dose levels <i>For mucositis/stomatitis decrease only 5-FU, not irinotecan</i>	Maintain dose level Maintain dose level ↓1 dose level ↓2 dose levels <i>For mucositis/stomatitis decrease only 5-FU, not irinotecan</i>

*Common Terminology Criteria for Adverse Events.

†All dose modifications should be based on the worst preceding toxicity.

‡Pretreatment.

Continued

Single-agent therapy: Reduce dose based on toxicity levels in the following chart, Irinotecan Guidelines for Dose Adjustments in Single-Agent Schedules. Most common reasons for dose reduction are late diarrhea, neutropenia, and leukopenia. ■ A reduction in the starting dose by one dose level may be required in patients with a performance status of 2, in patients who have previously received pelvic/abdominal irradiation, or in patients with increased bilirubin levels; see [Elderly](#).

Guidelines for Irinotecan Dose Adjustments in Single-Agent Schedules*			
A new course of therapy should not begin until the granulocyte count has recovered to $\geq 1,500/\text{mm}^3$, and the platelet count has recovered to $\geq 100,000/\text{mm}^3$, and treatment-related diarrhea is fully resolved. Treatment should be delayed 1 to 2 weeks to allow for recovery from treatment-related toxicities. If the patient has not recovered after a 2-week delay, consideration should be given to discontinuing irinotecan.			
Worst Toxicity CTCAE Grade† (Value)	During a Course of Therapy	At the Start of the Next Courses of Therapy (After Adequate Recovery). Compared with the Starting Dose in the Previous Course*	
		Weekly	Once Every 3 Weeks
No toxicity	Maintain dose level	$\uparrow 25 \text{ mg}/\text{M}^2$ up to a maximum dose of $150 \text{ mg}/\text{M}^2$	Maintain dose level
Neutropenia 1 ($1,500$ to $1,999/\text{mm}^3$) 2 ($1,000$ to $1,499/\text{mm}^3$) 3 (500 to $999/\text{mm}^3$) 4 ($< 500/\text{mm}^3$)	Maintain dose level $\downarrow 25 \text{ mg}/\text{M}^2$ Omit dose until resolved to \leq Grade 2, then $\downarrow 25 \text{ mg}/\text{M}^2$ Omit dose until resolved to \leq Grade 2, then $\downarrow 50 \text{ mg}/\text{M}^2$	Maintain dose level Maintain dose level $\downarrow 25 \text{ mg}/\text{M}^2$ $\downarrow 50 \text{ mg}/\text{M}^2$ dose levels	Maintain dose level Maintain dose level $\downarrow 50 \text{ mg}/\text{M}^2$ $\downarrow 50 \text{ mg}/\text{M}^2$
Neutropenic fever	Omit dose until resolved, then $\downarrow 50 \text{ mg}/\text{M}^2$	$\downarrow 50 \text{ mg}/\text{M}^2$	$\downarrow 50 \text{ mg}/\text{M}^2$
Other hematologic toxicities	Dose modifications for leukopenia, thrombocytopenia, and anemia during a course of therapy and at the start of subsequent courses of therapy are also based on Common Terminology Criteria for Adverse Events and are the same as recommended for neutropenia above.		
Diarrhea 1 (2-3 stools/day $>$ pretx‡) 2 (4-6 stools/day $>$ pretx) 3 (7-9 stools/day $>$ pretx) 4 (≥ 10 stools/day $>$ pretx)	Maintain dose level $\downarrow 25 \text{ mg}/\text{M}^2$ Omit dose until resolved to \leq Grade 2, then $\downarrow 25 \text{ mg}/\text{M}^2$ Omit dose until resolved to \leq Grade 2, then $\downarrow 50 \text{ mg}/\text{M}^2$	Maintain dose level Maintain dose level $\downarrow 25 \text{ mg}/\text{M}^2$ $\downarrow 50 \text{ mg}/\text{M}^2$	Maintain dose level Maintain dose level $\downarrow 50 \text{ mg}/\text{M}^2$ $\downarrow 50 \text{ mg}/\text{M}^2$
Other nonhematologic toxicities Grade 1 Grade 2 Grade 3 Grade 4	Maintain dose level $\downarrow 25 \text{ mg}/\text{M}^2$ Omit dose until resolved to \leq Grade 2, then $\downarrow 25 \text{ mg}/\text{M}^2$ Omit dose until resolved to \leq Grade 2, then $\downarrow 50 \text{ mg}/\text{M}^2$	Maintain dose level $\downarrow 25 \text{ mg}/\text{M}^2$ $\downarrow 25 \text{ mg}/\text{M}^2$ $\downarrow 50 \text{ mg}/\text{M}^2$	Maintain dose level $\downarrow 50 \text{ mg}/\text{M}^2$ $\downarrow 50 \text{ mg}/\text{M}^2$ $\downarrow 50 \text{ mg}/\text{M}^2$

*All dose modifications should be based on the worst preceding toxicity.

†Common Terminology Criteria for Adverse Events.

‡Pretreatment.

DILUTION

Specific techniques required; see Precautions. Must be diluted for infusion with D5W (preferred) or NS to concentrations between 0.12 to 2.8 mg/mL. Usually diluted in 250 to 500 mL D5W.

Storage: Packaged in a blister pack to protect against accidental breakage and leakage. Store in carton protected from light at CRT. Do not freeze. If damaged, incinerate the unopened package. Recommended that diluted solution be used within 24 hours if refrigerated, within 6 hours if kept at CRT. However, when mixed with D5W, is stable for 48 hours if refrigerated and protected from light and 24 hours at CRT. Do not refrigerate if mixed with NS; a precipitate may form. Stable for 24 hours at CRT when mixed in NS. Avoid freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Other drugs should not be added to the infusion solution." Consider specific use and toxicity.

One source suggests the following **compatibilities:**

Y-site: Oxaliplatin (Eloxatin) and palonosetron (Aloxi).

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 90 minutes.

ACTIONS

A semi-synthetic derivative of camptothecin. An alkaloid extract from plants such as *Camptotheca acuminata*. A class of antineoplastic agent that inhibits the enzyme topoisomerase I required for DNA replication. Together with its active metabolite SN-38 it causes cell death by damaging DNA produced during the S-phase of cell synthesis. Maximum plasma SN-38 levels are reached within 1 hour of infusion end. Extensively distributed to body tissues. Terminal half-life of irinotecan is about 6 to 12 hours; SN-38 is 10 to 20 hours. Irinotecan is moderately bound to plasma proteins (35%), but SN-38 is highly bound (95%). Metabolic conversion of irinotecan to SN-38 primarily occurs in the liver. SN-38 is conjugated to a glucuronide metabolite by the enzyme UDP-glucuronosyltransferase 1A1 (UGT1A1). Approximately 25% to 50% excreted through bile and urine.

INDICATIONS AND USES

First-line therapy for the treatment of metastatic colorectal cancer in combination with fluorouracil and leucovorin calcium. ■ As a single agent in the treatment of metastatic carcinoma of the colon or rectum that has recurred or progressed following treatment with fluorouracil.

CONTRAINDICATIONS

Hypersensitivity to irinotecan or any of its components. ■ Concomitant administration of St. John's wort and ketoconazole (Nizoral) is contraindicated; see [Drug/Lab Interactions](#).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be available. ■ Can induce both early and late forms of diarrhea that appear to be mediated by different mechanisms. Both forms may be severe. ■ Hepatic dysfunction may impair the metabolism of both irinotecan and SN-38. Patients with a bilirubin of 1 to 2 mg/dL are at increased risk for developing Grade 3 or 4 neutropenia. The manufacturer does not recommend a dose for patients with a bilirubin greater than 2 mg/dL and states that insufficient information is available. However, some clinicians recommend administering 75% of the recommended dose to patients who have a bilirubin of 1.5 to 3 mg/dL. ■ May cause severe myelosuppression. Deaths due to sepsis following severe neutropenia have been reported. ■ Use with caution in patients with renal impairment. Has not been studied. Not recommended for use in patients on dialysis. ■ Patients who are homozygous for the UGT1A1*28 allele have decreased UGT1A1 enzyme activity. This leads to a higher

exposure to SN-38 and an increased risk for neutropenia; see [Dose Adjustments](#). A laboratory test is available to determine the UGT1A1 status of patients. ■ Use caution in the elderly (may have an increased incidence and severity of diarrhea) and in patients who have had previous cytotoxic therapy or previous pelvic/abdominal irradiation (likely to have an increased incidence and severity of myelosuppression). Monitor closely. ■ Use caution in patients with poor performance status. Patients with a baseline performance status of 2 had higher rates of hospitalization, neutropenic fever, thromboembolism, first-cycle treatment discontinuation, and early deaths than patients with a performance status of 0 or 1. ■ Use caution in patients with a history of allergies. Severe hypersensitivity reactions, including anaphylaxis, have been reported. ■ Use caution in patients with pleural effusions and/or with impaired pulmonary function. Interstitial pulmonary disease has been reported rarely. Can be fatal. Risk factors may include pre-existing lung disease, use of pneumotoxic agents (e.g., amiodarone [Nexterone]), radiation therapy, or colony-stimulating factors; see [Antidote](#). ■ Colitis complicated by ulceration, ileus, and what was described as toxic megacolon has been reported. Any bowel obstruction must be resolved before treatment with irinotecan is initiated. ■ Contains sorbitol. Do not use in patients with hereditary fructose intolerance. ■ The Mayo Clinic regimen of 5-FU/LV (administered for 4 to 5 days every 28 days) should not be used in combination with irinotecan outside of a carefully controlled, well-designed clinical study. Regimen has caused increased toxicity and death. ■ Thromboembolic events have been observed; a specific cause has not been determined. ■ See [Monitor](#).

Monitor: Obtain a WBC with differential, hemoglobin, and platelet count before each dose. Expected nadir for platelets is 14 days, and 21 days for hemoglobin, neutrophils, and leukocytes. ■ Prophylactic antiemetics are recommended; see [Usual Dose](#). To reduce nausea and vomiting and increase patient comfort after initial dosing, additional antiemetics should be available (e.g., ondansetron, granisetron). ■ Obtain baseline electrolytes and liver function tests. ■ Not a vesicant, but monitor injection site for inflammation and/or extravasation. ■ Monitor vital signs. ■ Obtain an accurate bowel history to evaluate changes in bowel habits after administration of irinotecan. ■ Monitor for “early” diarrhea. Occurs during or within 24 hours of irinotecan administration and is cholinergic in nature. Usually transient and only infrequently is severe. May be accompanied by other cholinergic symptoms (e.g., abdominal cramping, diaphoresis, flushing, increased salivation, lacrimation, miosis, rhinitis). Patients who have a cholinergic reaction to irinotecan will probably have similar reactions to subsequent doses. Atropine 0.25 to 1 mg IV or SC may be considered for treatment or for prophylactic use unless clinically contraindicated. ■ Monitor for “late” diarrhea (more than 24 hours after irinotecan administration), which probably results from cytotoxic effects on GI epithelium. May be prolonged; cause dehydration, electrolyte imbalances, or sepsis; and can be life threatening. At first onset give loperamide (Imodium) 4 mg; give 2 mg every 2 hours (4 mg every 4 hours during the night) until diarrhea-free for a minimum of 12 hours. An alternate regimen suggests loperamide 4 mg every 3 hours in combination with diphenhydramine (Benadryl) 25 mg every 6 hours. Monitor carefully; replace fluids and electrolytes as needed; see [Patient Education](#). ■ Premedication or prophylaxis with loperamide is not recommended. If Grade 3 or 4 late diarrhea develops, hold irinotecan therapy until patient recovers, then decrease subsequent doses; see [Dose Adjustments](#). ■ Use of laxatives is not recommended; however, they may be used in patients requiring them for constipation caused by narcotics. Close supervision is required. ■ Initiate antibiotic therapy in patients who develop ileus, fever, or severe neutropenia. After the first treatment, subsequent weekly chemotherapy treatments should be delayed until the return of pretreatment bowel function for at least 24 hours without the need for antidiarrheal medication. ■ Closely monitor patients with pulmonary risk factors for adverse respiratory symptoms; see [Precautions](#) and [Antidote](#). ■ Maintain adequate hydration. Orthostatic hypotension or dizziness may indicate dehydration. Rare cases of renal impairment or acute renal failure have been reported, usually in patients who became dehydrated from vomiting and/or diarrhea. ■ Be alert for signs of bone marrow suppression or infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile or nonfebrile neu-

tropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See [Dose Adjustments](#).

Patient Education: Manufacturer provides a patient education brochure, “Important Facts About Your Chemotherapy.” ■ Report any unusual or unexpected symptoms or side effects as soon as possible. ■ Report black or bloody stools, diarrhea not under control within 24 hours, dry mouth, fever or chills, inability to retain oral fluids due to nausea and vomiting, infections, symptoms of dehydration (e.g., light-headedness, dizziness, fainting), urine changes, or vomiting immediately; each must be treated promptly. Have loperamide (Imodium) available. Dose of loperamide prescribed for late diarrhea is higher than the usual dose recommendation. Limit use at this dose to 48 hours to avoid risk of paralytic ileus. ■ May cause dizziness or visual disturbances (usually within 24 hours of administration); use caution in tasks that require alertness. ■ Compliance with regimen imperative (e.g., taking temperature, obtaining lab work, adequate rest, nourishment, and fluids). ■ Avoid caffeine and alcohol. May worsen dehydration. ■ Avoid raw fruits and vegetables, bran, fatty foods, or any other food that may aggravate diarrhea. ■ Nonhormonal birth control recommended. ■ Inform health care professionals of any problems with previous treatments. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. May cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Results from a few open-label studies have been evaluated. Significant Grade 3 and 4 toxicities were noted. See package insert.

Elderly: Half-life slightly extended. ■ Reduce starting dose by one dose level to 300 mg/M² in patients 70 years and older in the single agent once every 3-week regimen. No change in the starting dose is recommended for elderly patients receiving the weekly dose schedule of irinotecan. See [Usual Dose](#) and [Dose Adjustments](#). ■ Risk of early and late diarrhea increased in the elderly. ■ Monitor carefully; may dehydrate more quickly from diarrhea. Begin loperamide therapy promptly. Avoid laxatives.

DRUG/LAB INTERACTIONS

Interaction of irinotecan with other drugs has not been adequately studied. ■ Additive bone marrow suppression may occur with **radiation therapy and/or other bone marrow-suppressing agents** (e.g., azathioprine [Imuran], chloramphenicol, melphalan [Alkeran]). Dose reduction may be required. ■ Concurrent administration with **irradiation** is not recommended. ■ **Dexamethasone** for antiemetic prophylaxis may increase lymphocytopenia and may contribute to hyperglycemia in patients with diabetes. ■ Administration of **prochlorperazine** (Compazine) and irinotecan on the same day may increase the risk of akathisia (inability to sit still, urge to move about constantly). ■ Use caution or withhold **diuretics** (e.g., furosemide [Lasix]) **and laxatives** during treatment; may increase risk of dehydration secondary to vomiting and/or diarrhea. ■ Concomitant use with **phenytoin** (Dilantin), **phenobarbital**, **carbamazepine** (Tegretol) **or oxcarbazepine** (Trileptal) may increase the metabolism of irinotecan, which decreases concentrations and effectiveness. Discontinue treatment with these agents at least 2 weeks before starting irinotecan. Consider alternate anticonvulsant therapy. ■ **Rifampin** (Rifadin) **and rifabutin** (Mycobutin) may also increase metabolism and decrease the serum concentrations and effectiveness of irinotecan. ■ **Azole antifungals** (e.g., ketoconazole [Nizoral]) **and strong CYP3A4 inhibitors** (e.g., atazanavir [Reyataz]) may decrease metabolism, which increases serum concentrations and the risk of toxicity. Discontinue ketoconazole at least 1 week before starting irinotecan. ■ **St. John's wort** may decrease serum levels and effectiveness. Discontinue St. John's wort at least 2 weeks before starting irinotecan. ■ May prolong neuromuscular blockade of **depolarizing neuromuscular blocking agents** (e.g., succinylcholine) and antagonize neuromuscular blockade of **nondepolarizing neuromuscular blocking agents** (e.g., cisatracurium [Nimbex], vecuronium). ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs.

SIDE EFFECTS

Myelosuppression (anemia, leukopenia, neutropenia) and diarrhea (“early” [e.g., abdominal cramping or pain, diaphoresis] or “late”) occur in patients and are the most common dose-limiting toxicities. Nausea and vomiting occur in most patients and can be severe, may occur early (within 24 hours of administration) or late (more than 24 hours after administration). Abdominal bloating, alopecia, anorexia, asthenia, back pain, chills, confusion, constipation, coughing, dehydration, dizziness, dyspepsia, dyspnea, edema, exfoliative dermatitis, fever, flatulence, flushing, headache, hypersensitivity reactions (including anaphylaxis), hyponatremia, hypotension, increased alkaline phosphatase and AST, increased bilirubin, infection, insomnia, interstitial pulmonary disease, mucositis, muscular contractions or cramps, myocardial infarction, neutropenic fever, neutropenic infection, paresthesia, pneumonia, pulmonary embolism, rash, rhinitis, somnolence, stomatitis, thrombocytopenia, thrombophlebitis, and weight loss may occur. Death was preceded by cyanosis, tremors, respiratory distress, and convulsions. In addition, ileus without preceding colitis has occurred. Renal impairment or failure has occurred usually in patients who became volume depleted from severe vomiting and/or diarrhea.

Post-Marketing: Asymptomatic elevated pancreatic enzymes (e.g., amylase, lipase), dysarthria (transient), ischemic or ulcerative colitis, megacolon, myocardial ischemic events, pancreatitis.

ANTIDOTE

Keep physician informed of all side effects and monitor carefully. Adjust or omit dose as indicated for toxicity; see [Dose Adjustments](#). Treat diarrhea immediately; see [Monitor](#). In the event of an acute onset of new or progressive, unexplained pulmonary symptoms (e.g., cough, dyspnea, fever), interrupt irinotecan and other co-prescribed chemotherapeutic agents pending diagnostic evaluation. If interstitial pulmonary disease is diagnosed, discontinue irinotecan and other chemotherapy and initiate appropriate treatment as needed. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Death may occur from the progression of many side effects. No known antidote for overdose. Maximum supportive care (e.g., to prevent dehydration due to diarrhea and to treat any infectious complications) will help sustain patient in toxicity. If extravasation occurs, flush site with SWFI, elevate the extremity, and apply ice.

IRON DEXTRAN INJECTION **BBW**

(EYE-ern DEKS-tran in-JEK-shun)

Hematinic
Antianemic
Iron supplementDexFerrum, DexIron[®], InFeD, Infufer[®], Proferdex

pH 4.5 to 7

USUAL DOSE

Iron-deficiency anemia: Test dose: 0.5 mL (25 mg) on the first day as a test dose. Wait 1 hour. If no adverse reactions, administer a total dose of 2 mL (100 mg)/24 hr and repeat daily until results achieved or maximum calculated dosage reached (see dosage tables in literature or formula below). A total calculated dose has been given as an infusion. Though not FDA approved, this method is preferred by some to multiple small-dose infusions or injections. To calculate the total amount of iron dextran (mL) required to restore hemoglobin and to replenish iron stores in adults and pediatric patients weighing over 15 kg (lean body weight [LBW]):

$$\text{Dose (mL)} = 0.0442 (\text{Desired Hb} - \text{Observed Hb}) \times \text{LBW in kg} + (0.26 \times \text{LBW in kg})$$

If actual weight is less than LBW or in pediatric patients between 5 and 15 kg, use actual weight in kg. Calculated dose is in mL.

Iron replacement for blood loss: Dose should represent the equivalent amount of iron represented in blood loss. Begin with a test dose of 0.5 mL (25 mg). Wait 1 hour. If no adverse reactions, calculate the desired dose with the following formula and administer the balance of the replacement dose over 2 to 3 daily doses:

$$\text{Amount of replacement iron (mg)} = \text{Blood loss (mL)} \times \text{Hematocrit}$$

Calculated dose is in mg; convert to mL before administration.

Formula is based on the approximation that 1 mL of normocytic, normochromic red cells contains 1 mg of elemental iron.

PEDIATRIC DOSE

Injectable iron not normally used in infants less than 4 months of age. See [Maternal/Child](#).

Iron-deficiency anemia: Test dose: 0.5 mL (25 mg) for pediatric patients or 0.25 mL (12.5 mg) for infants over at least 5 minutes on the first day. Wait 1 hour. If no adverse reactions, may give remainder of daily dose. Direct IV push is not recommended; diluting with NS for infusion may lower the incidence of phlebitis. If actual weight is less than LBW or for pediatric patients between 5 and 15 kg, use actual weight in kg. The following daily doses have been recommended for IM injection by one source: **less than 5 kg**, 25 mg; **5 to 10 kg**, 50 mg; **more than 10 kg**, 100 mg. Repeat daily until results achieved or maximum calculated dosage reached (see dosage tables in literature or the formula listed earlier).

Iron replacement for blood loss: Calculate dose by formula used for adult dose. Dose should represent the equivalent amount of iron represented in blood loss. Begin with a test dose of 0.5 mL (25 mg) for pediatric patients or 0.25 mL (12.5 mg) for infants over at least 5 minutes on the first day. Wait 1 hour. If no adverse reactions, administer the balance of the replacement dose over 2 to 3 daily doses.

DILUTION

Given undiluted, or up to the total desired dose may be further diluted in 50 to 1,000 mL NS for infusion. D5W may cause additional local pain and phlebitis.

Filters: No data available from manufacturer.

Storage: Store unopened vials at CRT, protect from freezing.

COMPATIBILITY

Manufacturer states, “Do not mix with other medications or add to parenteral nutrition solutions.”

RATE OF ADMINISTRATION

Test dose: 25 mg over 5 minutes (DexFerrum) or over 30 seconds (InFeD). Specific rates of test dose infusions not available for other manufacturers.

IV injection: If no adverse reactions to the test dose, administer 1 mL (50 mg) or a fraction thereof over 1 minute or more. Extend injection time in pediatric patients.

Infusion: If no adverse reactions to the test dose, infuse remaining dose over 1 to 8 hours (based on amount of dose, amount of diluent, and patient comfort).

ACTIONS

Iron dextran is removed from the plasma by cells of the reticuloendothelial system, which split the complex into its components of iron and dextran. Iron is immediately bound to protein moieties to form hemosiderin or ferritin, the physiologic forms of iron, or to a lesser extent to transferrin. This iron replenishes hemoglobin and depleted iron stores. Serum ferritin peaks approximately 7 to 9 days after iron dextran administration and slowly returns to baseline after about 3 weeks. Dextran is metabolized or excreted. Negligible amounts of iron are lost via the urinary or alimentary pathways after administration of iron dextran. Some placental transfer of iron dextran may occur. Trace amounts of unmetabolized iron dextran are excreted in breast milk.

INDICATIONS AND USES

Iron deficiency anemia in patients for whom oral administration is unsatisfactory or impossible; identify and treat the cause of the anemia.

Unlabeled uses: Iron supplementation for patients taking epoetin alfa (Epogen).

CONTRAINDICATIONS

Manifestation of hypersensitivity reactions; any anemia other than iron deficiency.

PRECAUTIONS

Anaphylactic-type reactions, including fatalities, have been reported. Fatal reactions have occurred both after the test dose and in situations in which the test dose was tolerated. Administer in facilities equipped to monitor the patient and respond to any medical emergency. Patients with a history of drug allergy or multiple drug allergies may be at increased risk for anaphylactic-type reactions. Concomitant use of angiotensin-converting enzyme inhibitors (e.g., enalapril [Vasotec], lisinopril [Zestril]) may also increase the risk of reactions. Facilities for monitoring the patient and responding to any medical emergency must be readily available. ■ Iron dextran products are not clinically interchangeable. They differ in chemical characteristics and may differ in clinical and adverse effects. ■ Large IV doses have been associated with an increased incidence of side effects, including arthralgia, backache, chills, dizziness, fever, headache, malaise, myalgia, nausea, and vomiting. The onset of these side effects is often delayed (1 to 2 days) and symptoms generally subside within 3 to 4 days. Maximum daily recommended dose is 100 mg (2 mL) of undiluted iron dextran. ■ Use with caution in patients with severe liver impairment, cardiovascular disease, or a history of significant allergies and/or asthma. ■ Do not administer during the acute phase of infectious kidney disease. ■ Patients with rheumatoid arthritis may experience increased joint pain and swelling after administration of iron dextran. ■ Administration of parenteral iron therapy should be limited to patients in whom clinical and laboratory investigations have established an iron-deficient state. Unwarranted therapy may cause excess storage of iron and possible exogenous hemosiderosis.

Monitor: Keep patient lying down after injection to prevent postural hypotension. ■ Observe continuously for a hypersensitivity reaction during an infusion. Monitor vital signs. ■ Monitor hemoglobin, hematocrit, reticulocyte count, total iron-binding capacity (TIBC), and percent of saturation of transferrin as indicated to monitor therapy and iron status. May take up to 3 weeks to see response. ■ Monitor serum ferritin assays in prolonged therapy. Consider possibility of false results for months after injection caused by delayed

utilization. ■ In patients undergoing chronic renal dialysis who are receiving iron dextran complex, the correlation of body iron stores and serum ferritin may not be valid.

Patient Education: Promptly report S/S of hypersensitivity (e.g., rash, itching, SOB). ■ Promptly report any other side effects, immediate or delayed.

Maternal/Child: Category C: use only if absolutely necessary in pregnancy, breast-feeding, or childbearing years. ■ Injectable iron not normally used in infants younger than 4 months of age.

DRUG/LAB INTERACTIONS

Inhibited by **chloramphenicol**. ■ Concurrent administration of medicinal iron with **dimer-caprol** (BAL in Oil) will result in the formation of a toxic complex. Either postpone iron therapy or treat severe iron deficiency with transfusions. ■ Effectiveness negated by **deferoxamine** (Desferal), an iron chelating agent. May be affected by **other chelating agents** (e.g., edetate disodium). Give iron dextran at least 2 hours after a chelating agent. ■ May cause **false serum iron values** within 1 to 2 weeks of large doses of iron dextran. ■ May cause a **false elevated bilirubin, false decreased calcium, or affect numerous other tests or scans**. ■ See **Monitor**.

SIDE EFFECTS

Backache, dizziness, headache, itching, local phlebitis at injection site, malaise, nausea, rash, shivering, transitory paresthesias.

Major: Anaphylaxis (fatalities have occurred); arthritic reactivation; dyspnea; febrile episodes; hypotension; leukocytosis; local phlebitis; lymphadenopathy; peripheral vascular flushing, especially with too-rapid injection; urticaria; tachycardia; shock (severe iron toxicity increases vasodilation and venous pooling and decreases circulating blood volume. Results in decreased cardiac output, hypotension, increased peripheral vascular resistance, and shock).

Overdose: Serum iron levels greater than 300 mcg/dL may indicate iron poisoning. Overdose with iron dextran is unlikely. May result in hemosiderosis, and excess iron may increase susceptibility to infection. If acute toxicity is seen, it may present as:

Early: Abdominal pain, diarrhea, vomiting.

Late: Bluish-colored lips, fingernails, and palms of hands; acidosis, drowsiness, shallow and rapid breathing, clammy skin, weak and fast heartbeat, hypotension, hypoglycemia, cardiovascular collapse.

ANTIDOTE

Discontinue the drug and notify the physician of early symptoms. For severe symptoms, discontinue drug, treat hypersensitivity reactions, or resuscitate as necessary, and notify physician. Epinephrine (Adrenalin) and diphenhydramine (Benadryl) should always be available. In overdose, monitor CBC, iron studies, vital signs, blood gases, and glucose and electrolytes. Maintain fluid and electrolyte balance. Correct acidosis with sodium bicarbonate. Deferoxamine is an iron chelating agent and may be useful in iron toxicity or overdose. Dialysis will not remove iron alone but will remove the iron deferoxamine complex and is indicated if oliguria or anuria is present.

IRON SUCROSE

(EYE-ern SOO-kros)

Hematinic
Iron supplement
Antianemic

Venofer

pH 10.5 to 11.1

USUAL DOSE

Dose is expressed in terms of mg of elemental iron. The usual total treatment course of iron sucrose is 1,000 mg. Treatment may be repeated if iron deficiency recurs.

Test dose (optional): 50 mg. Test dose is not required but was administered in some of the clinical trials. May be given at the physician's discretion.

Adult patients with hemodialysis-dependent chronic kidney disease (HDD-CKD): 100 mg as a slow IV injection or as a 15-minute infusion during consecutive hemodialysis sessions. Administered early during the dialysis session. Repeat as needed to maintain target levels of hemoglobin, hematocrit, and laboratory parameters of iron stores within acceptable limits. Frequency of dosing should be no more than three times weekly.

Adult patients with non-dialysis dependent chronic kidney disease (NDD-CKD): 200 mg as a slow IV injection over 2 to 5 minutes or as an infusion of 200 mg in a maximum of 100 mL of NS over 15 minutes. Administer on 5 different days within a 14-day period to a total cumulative dose of 1,000 mg. Alternately, there is limited experience with administering a 500-mg dose on Day 1 and Day 14 as a 3.5- to 4-hour infusion in a maximum of 250 mL of NS.

Adult patients with peritoneal dialysis-dependent chronic kidney disease (PDD-CKD): 300 mg as an infusion on Day 1 and Day 14. Follow with 400 mg as an infusion on Day 28. A total cumulative dose of 1,000 mg given in 3 doses over 28 days. Each infusion is diluted in a maximum of 250 mL NS and administered over 1.5 to 2.5 hours; see [Rate of Administration](#).

PEDIATRIC DOSE

Pediatric patients (2 years of age and older) with hemodialysis-dependent chronic kidney disease (HDD-CKD) for iron maintenance treatment: The dosing for iron replacement treatment in pediatric patients with HDD-CKD has not been established.

Iron maintenance treatment: 0.5 mg/kg. Do not exceed 100 mg/dose. Administer every 2 weeks for 12 weeks; given undiluted by slow IV injection over 5 minutes or diluted in 25 mL of NS and administered over 5 to 60 minutes. Regimen may be repeated if necessary.

Pediatric patients (2 years of age and older) with non-dialysis dependent chronic kidney disease (NDD-CKD) or peritoneal dialysis-dependent chronic kidney disease (PDD-CKD) who are undergoing erythropoietin therapy for iron maintenance treatment: The dosing for iron replacement treatment in pediatric patients with NDD-CKD or PDD-CKD has not been established.

Iron maintenance treatment: 0.5 mg/kg. Do not exceed 100 mg/dose. Administer every 4 weeks for 12 weeks; given undiluted by slow IV injection over 5 minutes or diluted in 25 mL of NS and administered over 5 to 60 minutes. Regimen may be repeated if necessary.

DOSE ADJUSTMENTS

Begin at the low end of the dosing range in elderly patients. Consider the potential for decreased organ function and concomitant disease or drug therapy. ■ Withhold in patients with evidence of tissue iron overload; see [Monitor](#).

DILUTION

Available in several sizes of single-dose vials. Check vial carefully and select the size that is closest to the desired dose. All contain 20 mg/mL of elemental iron. May be given undiluted or further diluted in NS. Do not dilute to concentrations below 1 mg/mL.

Test dose (optional): 50 mg should be diluted in 50 mL of NS.

Adult patients with hemodialysis-dependent chronic kidney disease (HDD-CKD): 100-mg dose may be given undiluted or may be further diluted in a maximum of 100 mL of NS and given as an infusion.

Adult patients with non-dialysis-dependent chronic kidney disease (NDD-CKD): 200-mg dose may be given undiluted or may be further diluted in a maximum of 100 mL of NS. The 500-mg dose may be further diluted in a maximum of 250 mL of NS and given as an infusion.

Adult patients with peritoneal dialysis-dependent chronic kidney disease (PDD-CKD): Each 300- or 400-mg dose must be diluted in a maximum of 250 mL NS and given as an infusion.

Pediatric patients receiving iron maintenance treatment: A single dose may be given undiluted or diluted in 25 mL of NS and given as an infusion; see [Usual Dose](#).

Filters: No data available from manufacturer.

Storage: Store unopened vials in original carton at CRT. Do not freeze. Diluted iron infusions should be used immediately after preparation. Discard any unused portion. When diluted with NS to a concentration of 1 to 2 mg/mL in PVC or non-PVC infusion bags, iron sucrose is stable for 7 days at CRT. When undiluted (20 mg/mL) or diluted with NS to a concentration of 2 to 10 mg/mL and stored in a plastic syringe, iron sucrose is stable for 7 days at CRT or refrigerated.

COMPATIBILITY

Manufacturer states, “Do not mix with other medications or add to parenteral nutrition solutions.”

RATE OF ADMINISTRATION

Too-rapid administration may cause hypotension or symptoms of overdose; see [Side Effects](#).

Test dose (optional): A single dose over 3 to 10 minutes.

Slow IV injection in adults: A single undiluted dose over 2 to 5 minutes. In dialysis patients, administer into the dialysis line during the dialysis session.

Infusion in adults: This method of administration may reduce the risk of hypotensive episodes.

Adult hemodialysis-dependent chronic kidney disease patients (HDD-CKD): A single 100-mg dose given as a slow IV injection over 2 to 5 minutes. Alternately may be given as an infusion equally distributed over at least 15 minutes.

Adult non-dialysis dependent chronic kidney disease patients (NDD-CKD): A single 200-mg dose as a slow IV injection over 2 to 5 minutes or as an infusion equally distributed over 15 minutes. Has also been administered as an infusion in a 500-mg dose equally distributed over 3.5 to 4 hours.

Adult peritoneal dialysis-dependent chronic kidney disease patients (PDD-CKD): A single 300-mg dose equally distributed over 1.5 hours or a single 400-mg dose equally distributed over 2.5 hours.

Pediatric patients receiving iron maintenance treatment: A single dose as a slow IV injection over 5 minutes or diluted with 25 mL NS and administered as an infusion over 5 to 60 minutes; see [Usual Dose](#).

ACTIONS

An aqueous, complex of polynuclear iron (III)-hydroxide in sucrose. Used to replenish the total body iron stores in patients with iron deficiency. Iron is critical for normal hemoglobin synthesis to maintain oxygen transport and necessary for metabolism and synthesis of DNA and various other processes. Following intravenous administration, iron sucrose is dissociated by the reticuloendothelial system into iron and sucrose. Iron distributes into liver, spleen, and bone marrow. Since iron disappearance from serum depends on the need for iron in the iron stores and iron-utilizing tissues of the body, serum clearance of iron is expected to be more rapid in iron deficient patients as compared to healthy individuals. Half-life of the iron component is 6 hours. The sucrose component is eliminated mainly by urinary excretion. Most iron is stored in the body in hemoglobin,

bone marrow, spleen, liver, and ferritin. Small amounts are eliminated in the urine. Significant increases in serum iron and ferritin and significant decreases in total iron-binding capacity occur within 4 weeks of beginning iron sucrose treatment.

INDICATIONS AND USES

Treatment of iron deficiency anemia in patients with chronic kidney disease (CKD).

CONTRAINDICATIONS

Known hypersensitivity to iron sucrose or any of its inactive components. Should not be used in patients with evidence of iron overload or in patients with anemia not caused by iron deficiency.

PRECAUTIONS

Use only when truly indicated to avoid excess storage of iron. Not recommended for use in patients with iron overload. ■ Potentially fatal hypersensitivity reactions characterized by anaphylactic shock, loss of consciousness, collapse, hypotension, dyspnea, or convulsions have been reported. Medications and equipment for resuscitation must be readily available. ■ Hypotension has been reported frequently and may be related to rate of administration and/or total dose administered. Follow guidelines for dosing and administration. See [Usual Dose](#) and [Rate of Administration](#).

Monitor: Confirm IV placement and avoid extravasation; injection site discoloration has been reported following extravasation. ■ Monitor vital signs during and immediately following administration. Recumbent position during and after administration may help to prevent postural hypotension. Hypotensive effects may be additive to transient hypotension during dialysis and/or from too-rapid rate of administration. ■ Monitor for S/S of hypersensitivity reactions during and after administration for at least 30 minutes and until clinically stable; see [Precautions](#). Reactions may occur after the first dose or subsequent doses of iron sucrose. ■ Periodic monitoring of hematologic and hematinic parameters (hemoglobin, hematocrit, serum ferritin and transferrin saturation) is indicated during parenteral iron replacement therapy. Takes about 4 weeks of treatment to see increased serum iron and ferritin and decreased TIBC (total iron-binding capacity). Transferrin saturation values increase rapidly after IV administration of iron sucrose; thus serum iron values may be reliably obtained 48 hours after the last IV dose.

Patient Education: Review any possible reactions to past parenteral iron therapy. ■ Report S/S of a hypersensitivity reaction promptly.

Maternal/Child: Category B: use in pregnancy only if clearly needed. ■ Safety for use during breast-feeding not established. ■ Safety and effectiveness for iron replacement treatment in pediatric patients has not been established. Safety and effectiveness for iron maintenance treatment has been established for pediatric patients 2 years of age and older. ■ Necrotizing enterocolitis in 5 premature infants (weight less than 1,250 Gm) with 2 deaths has been reported in one country in which iron sucrose is approved for use in pediatric patients. No causal relationship to drugs could be established; it may be a complication of prematurity in very-low-birth-weight infants.

Elderly: Differences in response between elderly and younger patients have not been identified. Lower-end initial doses may be appropriate in the elderly; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Drug interactions involving iron sucrose have not been studied. May reduce the absorption of concomitantly administered **oral iron preparations**, concurrent use not recommended.

SIDE EFFECTS

Adult patients: Arthralgia, back pain, chest pain, diarrhea, dizziness, headache, hypotension, injection site burning or pain, muscle cramps, nausea, pain in extremity, peripheral edema, pruritus, and vomiting are most common. Other side effects varied according to the type of chronic kidney disease patient who is receiving iron sucrose (e.g., hemodialysis dependent, peritoneal dialysis-dependent, non-dialysis dependent) and included abdominal pain, altered taste, asthenia, catheter site infection, conjunctivitis, cough, dyspnea, ear pain, fecal occult blood positive, feeling abnormal, fever, fluid overload,

gout, graft complications, hyperglycemia, hypersensitivity reactions, hypertension, hypoaesthesia, hypoglycemia, injection site extravasation, myalgia, nasal congestion, nasopharyngitis, peritoneal infection, pharyngitis, sinusitis, upper respiratory infection.

Pediatric patients: Arteriovenous fistula thrombosis, cough, dizziness, fever, headache, hypertension, hypotension, nausea, peritonitis, renal transplant, respiratory tract viral infection, and vomiting occurred.

Overdose: Serum iron levels greater than 300 mcg/dL may indicate iron poisoning. May result in hemosiderosis. Excess iron may increase susceptibility to infection. If acute toxicity is seen, it may present as abdominal and muscle pain, cardiovascular collapse, dizziness, dyspnea, edema, headache, hemosiderosis, hypotension, joint aches, nausea, pale eyes, paresthesia, sedation, vomiting.

Post-Marketing: Life-threatening hypersensitivity reactions (e.g., anaphylactic shock, angioedema, bronchospasm, collapse, convulsions, dyspnea, loss of consciousness, pruritus, rash, shock, wheezing), bradycardia, chromaturia, confusion, CHF, light-headedness, sweating, swelling of joints.

ANTIDOTE

Reduce rate of infusion for hypotension or other symptoms. Most symptoms are successfully treated with IV fluids, hydrocortisone sodium succinate (Solu-Cortef), and/or antihistamines (e.g., diphenhydramine [Benadryl]). Volume expanders (e.g., albumin, dextran, hetastarch [Hespan]) may be indicated. Keep physician informed of all side effects. Discontinue drug if severe hypersensitivity reactions occur. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Resuscitate as needed. Not removed by dialysis.

ISOPROTERENOL HYDROCHLORIDE

(eye-so-PROH-ter-ih-nohl hy-droh-KLOR-eyed)

Cardiac stimulant
(inotropic/chronotropic)
Bronchodilator
Antiarrhythmic

Isuprel

pH 3.5 to 4.5

USUAL DOSE

In all situations, adjust the rate of infusion based on HR, CVP, BP, respiratory rate, and urine output.

Recommended Isoproterenol Dose for Adults with Atropine-Resistant Hemodynamically Significant Bradycardia, Heart Block, Adams-Stokes Attacks, and Cardiac Arrest			
Route of Administration	Preparation of Dilution	Initial Dose	Subsequent Dose Range*
Bolus intravenous injection	Dilute 1 mL (0.2 mg) to 10 mL with NS or D5W	0.02 to 0.06 mg (1 to 3 mL of diluted solution)	0.01 to 0.2 mg (0.5 to 10 mL of diluted solution)
Intravenous infusion	Dilute 10 mL (2 mg) in 500 mL D5W	5 mcg/min (1.25 mL of diluted solution per minute)	
Intracardiac	Use solution 1 : 5,000 undiluted	0.02 mg (0.1 mL)	

*Subsequent dose depends on the ventricular rate and the rapidity with which the cardiac pacemaker can take over when the drug is gradually withdrawn.

AHA recommendation is 2 to 10 mcg/min if an external pacemaker is not available.

Recommended Isoproterenol Dose for Adults with Shock (Cardiogenic, CHF, Hypoperfusion [Low Cardiac Output], Hypovolemic, Septic)		
Route of Administration	Preparation of Dilution*	Infusion Rate†
Intravenous infusion	Dilute 5 mL (1 mg) in 500 mL of D5W	0.5 to 5 mcg per minute (0.25 to 2.5 mL of diluted solution)

*Concentrations up to 10 times greater have been used when limitation of volume is essential.

†Rates over 30 mcg/min have been used in advanced stages of shock. Adjust infusion rate based on HR, CVP, BP, and urine flow. If HR exceeds 110 beats/min, consider decreasing rate or temporarily discontinue the infusion.

Recommended Isoproterenol Dose for Adults with Bronchospasm Occurring During Anesthesia			
Route of Administration	Preparation of Dilution	Initial Dose	Subsequent Dose
Bolus intravenous injection	Dilute 1 mL (0.2 mg) to 10 mL with NS or D5W	0.01 to 0.02 mg (0.5 to 1 mL of diluted solution)	Repeat initial dose as necessary

Complete heart block following closure of ventricular septal defects: 0.04 to 0.06 mg (2 to 3 mL of a 1 : 50,000 dilution) as a bolus injection. May maintain a sinus rhythm with a HR above 90 to 100 beats/min or may relapse into complete heart block again.

Diagnosis of mitral regurgitation (unlabeled): 4 mcg/min as an infusion (1 mL/min of a 1 : 250,000 dilution).

Diagnosis of coronary artery disease or lesions (unlabeled): 1 to 3 mcg/min as an infusion (0.25 to 0.75 mL/min of a 1 : 250,000 dilution).

Refractory torsades de pointes, bradycardia in heart transplant patients, beta-adrenergic blocker poisoning: AHA recommends 2 to 10 mcg/min (0.5 to 2.5 mL/min of a 1 : 250,000 dilution).

tion [4 mcg/mL]). Titrate to adequate heart rate. In torsades de pointes titrate to increase heart rate until VT is suppressed.

PEDIATRIC DOSE

See *Dilution* and *Maternal/Child*.

0.05 to 2 mcg/kg/min. Begin with 0.1 mcg/kg/min as an infusion. Increase by 0.1 mcg/kg/min until desired effect. Titrate to patient response and monitor cardiac status carefully. Maximum dose is 2 mcg/kg/min. Another source suggests a maximum dose of 1 mcg/kg/min.

Complete heart block after closure of ventricular septal defects in infants: 0.01 to 0.03 mg (0.5 to 1.5 mL of a 1:50,000 dilution) as a bolus injection. See comments in *Usual Dose*.

DOSE ADJUSTMENTS

Lower-end initial doses may be appropriate in the elderly; consider the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

IV injection: Available in a 1:50,000 solution or dilute 0.2 mg (1 mL) of a 1:5,000 solution with 10 mL NS or D5W to provide a concentration of 0.02 mg/mL (1:50,000 solution).

Infusion: Dilute 10 mL (2 mg) in 500 mL D5W (4 mcg/mL). **Shock:** Dilute 5 mL (1 mg) in 500 mL D5W (2 mcg/mL). Use an infusion pump or microdrip (60 gtt equals 1 mL) to administer. Less diluent may be used to reduce fluid intake.

Filters: No data available from manufacturer. Another source sites no significant loss in drug potency in several studies using various types and sizes of filters from 0.22 to 5 microns in size.

Storage: Store between 8° and 15° C (46° to 59° F) unless otherwise specified by manufacturer. Do not use if pink or brown in color or contains a precipitate.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Additive: Atracurium (Tracrium), calcium chloride, dobutamine, heparin, magnesium sulfate, multivitamins (M.V.I.), potassium chloride (KCl), ranitidine (Zantac), succinylcholine, verapamil.

Y-site: Amiodarone (Nexterone), atracurium (Tracrium), bivalirudin (Angiomax), cisatracurium (Nimbex), dexmedetomidine (Precedex), famotidine (Pepcid IV), fenoldopam (Corlopan), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), levofloxacin (Levaquin), milrinone (Primacor), nitroprusside sodium, pancuronium, potassium chloride (KCl), propofol (Diprivan), remifentanyl (Ultiva), tacrolimus (Prograf), vecuronium.

RATE OF ADMINISTRATION

IV injection: Each 1 mL of a 1:50,000 (0.02 mg) solution or fraction thereof over 1 minute. Follow with a 20 mL flush of NS if indicated to ensure distribution to circulation.

Infusion: Titrate to desired dose, HR, and rhythm; see the following infusion rate chart. Decrease rate of infusion as necessary. Ventricular rate generally should not exceed 110 beats/min.

Isoproterenol (Isuprel) Infusion Rates						
Desired Dose	1 mg in 500 mL D5W (2 mcg/mL)			1 mg in 250 mL D5W 2 mg in 500 mL D5W (4 mcg/mL)		
	mcg/min	mcg/hr	mL/min	mL/hr	mcg/hr	mL/min
2	120	1	60	120	0.5	30
5	300	2.5	150	300	1.25	75
10	600	5	300	600	2.5	150
15	900	7.5	450	900	3.75	225
20	1,200	10	600	1,200	5	300
25	1,500	12.5	750	1,500	6.25	375
30	1,800	15	900	1,800	7.5	450

ACTIONS

A non-selective synthetic cardiac beta receptor stimulant (sympathomimetic amine) similar to epinephrine and norepinephrine. Has positive inotropic and chronotropic actions more potent than those of epinephrine. It increases cardiac output, cardiac work, coronary flow, and venous return. Improves atrioventricular conduction. Stimulates only the higher ventricular foci, allowing a more normal cardiac pacemaker to take over, thus suppressing ectopic pacemaker activity. Decreases peripheral vascular resistance by relaxing arterial smooth muscle and is a most effective bronchial smooth muscle relaxant. Onset of action is immediate and lasts 1 to 2 hours. Metabolized by the liver and inactivated by various enzyme systems. Excreted in the urine.

INDICATIONS AND USES

Treatment of mild or transient episodes of heart block that do not require cardioversion or pacemaker therapy. ■ Treatment of serious episodes of heart block and Adams-Stokes attacks (except when caused by VT or VF). ■ May be used in cardiac arrest until defibrillation or pacemaker (the treatments of choice) are available. ■ Treatment of refractory torsades de pointes until pacemaker implanted. ■ Temporary control of symptomatic bradycardia in denervated hearts of heart transplant patients until pacemaker implanted. ■ Bronchospasm during anesthesia. ■ Management of shock (cardiogenic, CHF, hypoperfusion [low cardiac output], hypovolemic, septic). Adequate fluid and electrolyte replacement required. ■ Pulmonary embolism, to increase pulmonary blood volume and decrease pulmonary arterial pressure and vascular resistance. ■ AHA recommends cautious use in symptomatic bradycardia if a pacemaker is not available, and use in the treatment of refractory torsades de pointes unresponsive to magnesium sulfate, and poisoning from beta-adrenergic blockers (e.g., metoprolol [Lopressor]).

Unlabeled uses: Aid in diagnosis of the etiology of mitral regurgitation. ■ Aid in diagnosis of coronary artery disease or lesions.

CONTRAINDICATIONS

Tachyarrhythmias, patients with tachycardia or heart block caused by digoxin intoxication, angina pectoris, ventricular arrhythmias that require inotropic therapy.

PRECAUTIONS

IV injection in cardiac standstill must be accompanied by cardiac massage to perfuse drug into the myocardium. Current JAMA recommendations do not include isoproterenol in the treatment of cardiac arrest or hypotension. ■ Fourth-line agent for bradycardia; considered possibly helpful but may be harmful. ■ Can cause a severe drop in BP and can be very harmful in bradycardia. ■ Use extreme caution when inhalant anesthetics (e.g., cyclopropane) are being administered and supplementary to digoxin administration. ■ Use caution in coronary insufficiency, diabetes, hyperthyroidism, known sensitivity to sympathomimetic amines, history of seizures, hypertension, and pre-existing

cardiac arrhythmias with tachycardia. ■ Increased cardiac output and work can increase ischemia and worsen arrhythmias. ■ Contains sulfites; use caution in allergic patients.

Monitor: Decrease rate of infusion as necessary. Ventricular rate generally should not exceed 110 beats/min. Maintain adequate blood volume and correct acidosis. ■ Continuous cardiac monitoring, central venous pressure readings, BP, respiratory rate, and urine flow measurements are advisable during therapy with isoproterenol. ■ Monitoring of serum glucose, magnesium, and potassium may be indicated. ■ See [Drug/Lab Interactions](#) and [Maternal/Child](#).

Maternal/Child: Category C: safety for use in pregnancy or breast-feeding not established. Benefits must outweigh risks. ■ Safety and effectiveness in pediatric patients not established. ■ In asthmatic pediatric patients, IV infusion of isoproterenol has caused clinical deterioration, myocardial necrosis, CHF, and death. Risks of cardiac toxicity may be increased by other factors such as acidosis, hypoxemia, coadministration of corticosteroids or methylxanthines (e.g., aminophylline). Continuous assessment of VS, frequent ECGs, and daily measurement of cardiac enzymes (e.g., CPK, MB) is suggested if isoproterenol infusion is required.

Elderly: Difference in response from younger adults not known. May be more sensitive to the effects of beta-adrenergic agents (e.g., hypertension, hypokalemia, tachycardia, tremor). Patients with cardiac disease may be at increased risk for cardiac effects. ■ Lower-end initial doses may be appropriate; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

May be used alternately with epinephrine (Adrenalin), but they may not be used together. Both are direct cardiac stimulants; serious arrhythmias and death may result. An adequate interval between doses must be maintained. ■ Do not use concomitantly with other **sympathomimetic agents** (e.g., ephedrine, dopamine). Additive effects may cause toxicity. May be used after effects of previous drug have subsided. ■ Simultaneous use with **oxytoxics** may cause hypertensive crisis. ■ May cause hypertension with **guanethidine** (Ismelin). ■ **Digoxin, quinidine, and halogenated hydrocarbon anesthetics** (e.g., halothane) may sensitize myocardium and cause serious arrhythmias. ■ Antagonized by **propranolol**. May be used to treat tachycardia caused by isoproterenol, but tachycardia and hypotension secondary to peripheral vasodilation may occur. ■ Potentiated by **tricyclic antidepressants** (e.g., imipramine [Tofranil]). ■ Concomitant use with **theophylline** increases the risk of cardiotoxicity. ■ See [Contraindications](#).

SIDE EFFECTS

Anginal pain, cardiac arrhythmias, flushing, headache, hyperglycemia, hypokalemia, nausea, nervousness, palpitations, sweating, tachycardia, vomiting. Cardiac dilation, marked hypotension, pulmonary edema, and death may occur with prolonged use or overdose. Adams-Stokes attacks have been reported.

ANTIDOTE

Notify the physician of any side effect. Treatment will probably be symptomatic. For ventricular rate over 110 beats/min, PVCs, or ECG changes, decrease rate of infusion or discontinue drug. Vasodilators (e.g., nitrates) may be useful for treatment of hypertension. For accidental overdose, discontinue drug immediately, resuscitate and sustain patient, and notify physician.

IXABEPILONE **BBW**

(ix-ab-EP-i-lone)

Antineoplastic
(microtubule inhibitor)**Ixempra Kit****USUAL DOSE**

Premedication: An H₁ antagonist (e.g., diphenhydramine [Benadryl]) and an H₂ antagonist (e.g., ranitidine [Zantac], famotidine [Pepcid]) should be administered orally 60 minutes prior to ixabepilone to minimize the chance of a hypersensitivity reaction. Patients who experience a hypersensitivity reaction require premedication with a corticosteroid (e.g., dexamethasone 20 mg IV 30 minutes before infusion or orally 60 minutes before infusion) in addition to pretreatment with the H₁ and H₂ antagonists.

Ixabepilone: 40 mg/M² as an infusion over 3 hours every 3 weeks. Doses for patients with a body surface area (BSA) greater than 2.2 M² should be calculated based on 2.2 M². Administered alone or in combination with capecitabine (Xeloda) 1,000 mg/M² twice daily for 2 weeks followed by 1 week of rest.

DOSE ADJUSTMENTS

If toxicities are present, therapy should be delayed to allow recovery. ■ Dosing adjustment guidelines for monotherapy and combination therapy are listed in the following table. *If toxicities recur, an additional 20% dose reduction should be made.*

Dose Adjustments Guidelines	
Ixabepilone (Monotherapy or Combination Therapy)	Ixabepilone Dose Modification
NONHEMATOLOGIC	
Grade 2 neuropathy (moderate) lasting ≥7 days	Decrease the dose by 20%
Grade 3 neuropathy (severe) lasting <7 days	Decrease the dose by 20%
Grade 3 neuropathy (severe) lasting ≥7 days or disabling neuropathy	Discontinue treatment
Any Grade 3 toxicity (severe) other than neuropathy	Decrease the dose by 20%
Transient Grade 3 arthralgia/myalgia or fatigue	No change in dose required
Grade 3 hand-foot syndrome (palmar-plantar erythrodysesthesia)	No change in dose required
Any Grade 4 toxicity (disabling)	Discontinue treatment
HEMATOLOGIC	
Neutrophils <500 cells/mm ³ for ≥7 days	Decrease the dose by 20%
Febrile neutropenia	Decrease the dose by 20%
Platelets <25,000/mm ³ or platelets <50,000/mm ³ with bleeding	Decrease the dose by 20%
Capecitabine (When Used in Combination with Ixabepilone)	Capecitabine Dose Modification
NONHEMATOLOGIC	Follow capecitabine prescribing information
HEMATOLOGIC	
Platelets <25,000/mm ³ or platelets <50,000/mm ³ with bleeding	Hold for concurrent diarrhea or stomatitis until platelet count >50,000/mm ³ , then continue at same dose
Neutrophils <500 cells/mm ³ for ≥7 days or febrile neutropenia	Hold for concurrent diarrhea or stomatitis until neutrophil count >1,000/mm ³ , then continue at same dose

Dose adjustments at the start of a cycle should be based on nonhematologic toxicity or blood counts from the preceding cycle following the previous guidelines. Patients should not begin a new cycle unless the neutrophil count is at least 1,500 cells/mm³, the platelet count is at least 100,000 cells/mm³, and nonhematologic toxicities have improved to Grade 1 (mild) or have resolved. ■ Combined use with capecitabine is contraindicated in patients who have AST or ALT >2.5 times the ULN or bilirubin >1 times the ULN; see [Contraindications](#) and [Precautions](#). ■ Patients with hepatic impairment who are receiving monotherapy should be dosed according to the guidelines listed in the following table.

Dose Adjustments for Ixabepilone as Monotherapy in Patients with Hepatic Impairment					
	Transaminase Levels		Bilirubin Levels*		Ixabepilone Dose† (mg/M ²)
Mild	AST and ALT ≤2.5 × ULN	and	≤1 × ULN		40
	AST or ALT ≤10 × ULN	and	≤1.5 × ULN		32
Moderate	AST and ALT ≤10 × ULN	and	>1.5 × ULN to ≤3 × ULN		20-30
Severe	AST or ALT >10 × ULN	or	>3 × ULN		Not recommended

*Excluding patients whose total bilirubin is elevated due to Gilbert's disease.

†Dosage recommendations are for the first course of therapy; further decreases in subsequent courses should be based on individual tolerance.

Patients with moderate hepatic impairment should start with 20 mg/M². The dose in subsequent cycles may be increased up to, but should not exceed, 30 mg/M² if tolerated. ■ Reduce dose to 20 mg/M² when coadministered with a strong CYP3A4 inhibitor; see [Drug Interactions](#). If the strong inhibitor is discontinued, wait for at least 1 week before adjusting the ixabepilone dose upward to the indicated dose. ■ If coadministration of a strong CYP3A4 inducer is required and alternatives are not feasible (e.g., the patient has been maintained on a strong CYP3A4 inducer), the dose may be gradually increased from 40 mg/M² to 60 mg/M² if tolerated; see [Drug Interactions](#). Increase infusion duration of 60 mg/M² dose to 4 hours and monitor patient closely for toxicity. If CYP3A4 inducer is discontinued, return to original dose. ■ No dose adjustment indicated based on age, race, and gender. ■ Minimally excreted by the kidney; no studies conducted in patients with renal impairment.

DILUTION

Specific techniques required; see [Precautions](#). Available as a 15-mg or 45-mg IXEMPRA Kit that contains two vials; one vial contains the indicated amount of ixabepilone, and the other contains a manufacturer-supplied diluent. Only the manufacturer-supplied diluent may be used for reconstitution. Calculate dose and remove required number of kits from refrigerator. Let stand at RT for approximately 30 minutes. A white precipitate may appear in the diluent vial. This will dissolve as the vial warms to RT. Withdraw diluent and slowly inject it into the ixabepilone vial. (The 15-mg vial is reconstituted with 8 mL of diluent, and the 45-mg vial is reconstituted with 23.5 mL.) Gently swirl and invert until completely dissolved. Concentration of reconstituted solution is 2 mg/mL. Must be further diluted to a final concentration of 0.2 to 0.6 mg/mL with LR, Plasma-Lyte A Injection pH 7.4, or NS 250 to 500 mL (the pH of the NS must be adjusted to between 6 and 9 by adding 2 mEq [i.e., 2 mL of an 8.4% w/v solution or 4 mL of a 4.2% w/v solution] of sodium bicarbonate injection before adding the ixabepilone). A 250-mL bag will be sufficient for most doses. Withdraw the calculated dose from the ixabepilone vials and transfer to a DEHP-free IV bag containing an appropriate volume of infusion solution to achieve the final desired concentration. Thoroughly mix by manual rotation. Should be administered through a DEHP-free, polyethylene-lined administration set.

Filter: Must be administered through an in-line filter with a microporous membrane of 0.2 to 1.2 microns.

Storage: Store unopened vials at 2° to 8° C (36° to 46° F) in original carton. Protect from light. Reconstituted solution may be stored in vial for 1 hour at RT and room light. Once diluted, solution is stable for a maximum of 6 hours at RT. Administration must be completed within this 6-hour period.

COMPATIBILITY

Manufacturer states, “DEHP-free infusion containers and administration sets must be used.” Must be reconstituted with manufacturer-supplied diluent only and further diluted with the infusion solutions noted in Dilution. Indicated solutions have a pH between 6 to 9, which is required for ixabepilone stability.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 3 hours. In patients who experience a hypersensitivity reaction, increase duration of infusion and premedicate with corticosteroids and H₁ and H₂ antagonists; see [Usual Dose](#). Increase duration of infusion to 4 hours in patients receiving 60 mg/M² dose; see [Dose Adjustments](#).

ACTIONS

A microtubule inhibitor belonging to a class of antineoplastic agents, the epothilones. A semi-synthetic analog of epothilone B. Binds directly to β-tubulin subunits on microtubules, leading to suppression of microtubule dynamics. Blocks cells in the mitotic phase of the cell division cycle, leading to cell death. Has anti-tumor activity against multiple human tumor xenografts and is active in xenografts that are resistant to multiple agents, including taxanes, anthracyclines, and vinca alkaloids. Has demonstrated synergistic anti-tumor activity in combination with capecitabine. In addition to direct anti-tumor activity, ixabepilone has antiangiogenic activity. 67% to 77% bound to plasma proteins. Extensively metabolized in the liver, primarily by CYP3A4. Eliminated primarily as metabolized drug in feces and urine. Half-life is approximately 52 hours.

INDICATIONS AND USES

In combination with capecitabine (Xeloda) for the treatment of patients with metastatic or locally advanced breast cancer resistant to treatment with an anthracycline and a taxane or for patients whose cancer is taxane resistant and for whom further anthracycline therapy is contraindicated. Anthracycline resistance is defined as progression while on therapy or within 6 months in the adjuvant setting or 3 months in the metastatic setting. Taxane resistance is defined as progression while on therapy or within 12 months in the adjuvant setting or 4 months in the metastatic setting. ■ As monotherapy for the treatment of metastatic or locally advanced breast cancer in patients whose tumors are resistant or refractory to anthracyclines, taxanes, and capecitabine.

CONTRAINDICATIONS

History of severe (CTCAE Grade 3 or 4) hypersensitivity reaction to agents containing Cremophor® EL or its derivatives. ■ Neutrophil count less than 1,500 cells/mm³ or platelet count less than 100,000 cells/mm³. ■ In combination with capecitabine in patients with AST or ALT greater than 2.5 times the ULN or bilirubin greater than 1 times the ULN.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Should be administered by or under the direction of the physician specialist in facilities equipped to monitor the patient and respond to any medical emergency. ■ Ixabepilone in combination with capecitabine is contraindicated in patients with significant hepatic insufficiency due to increased risk of toxicity and neutropenia-related death; see [Contraindications](#). ■ Use caution in patients with hepatic insufficiency receiving monotherapy. Risk of toxicity is increased and data are limited; see [Dose Adjustments](#). ■ Premedication is required to minimize the chance of a hypersensitivity reaction; see [Usual Dose](#). ■ Peripheral neuropathy is a common side effect and was the most common cause of treatment discontinuation in clinical studies. It is cumulative and generally reversible. May require dose reduction or delay in therapy; see [Dose Adjustments](#). Use caution in patients with diabetes mellitus or pre-existing peripheral neuropathy. Risk of severe neuropathy may be increased. ■ Myelosuppression is dose dependent and primarily manifested as neutropenia. Hold therapy in

patients with a neutrophil count less than 1,500 cells/mm³; see [Dose Adjustments](#) and [Contraindications](#). ■ Use caution in patients with a history of cardiac disease. Adverse cardiac events (e.g., myocardial ischemia, ventricular dysfunction, and supraventricular arrhythmias) have been reported. ■ Not studied in patients with renal impairment.

Monitor: Obtain baseline and periodic CBC with differential and platelet count. ■ Obtain baseline and periodic bilirubin, AST, and ALT. ■ Monitor for S/S of a hypersensitivity reaction (e.g., bronchospasm, dyspnea, flushing, rash). ■ Monitor for S/S of peripheral neuropathy (primarily sensory [e.g., burning sensation, discomfort, hyperesthesia, hypoesthesia, neuropathic pain or paresthesia]). Most cases of new onset or worsening neuropathy occurred during the first 3 cycles. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³); see [Dose Adjustments](#) and [Contraindications](#). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Promptly report any numbness or tingling of feet, S/S of infection (fever, chills cough), or S/S of a hypersensitivity reaction (chest tightness, dyspnea, flushing, pruritus, rash, urticaria). ■ Avoid pregnancy. Use of nonhormonal birth control is required. ■ Promptly report chest pain, difficulty breathing, palpitations, or unusual weight gain; these may be signs of adverse cardiac events.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. ■ Discontinue breast-feeding. ■ Effectiveness for use in pediatric patients not established. Evaluation in two clinical studies suggests that pediatric patients have a safety profile consistent with that seen in adults.

Elderly: The incidence of Grade 3 and 4 adverse reactions was higher when used in combination with capecitabine in clinical studies. As monotherapy, no overall difference in safety was seen in the elderly compared with younger adults.

DRUG/LAB INTERACTIONS

Use of concomitant strong **CYP3A4 inhibitors** (e.g., amprenavir [Agenerase], atazanavir [Reyataz], clarithromycin [Biaxin], delavirdine [Rescriptor], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase], telithromycin [Ketek], or voriconazole [VFEND]) may increase plasma concentrations of ixabepilone. Avoid concomitant use if possible. If required, decrease dose of ixabepilone to 20 mg/M² and monitor closely for acute toxicity. If strong inhibitor is discontinued, wait for at least 1 week before adjusting ixabepilone dose upward to indicated dose. ■ **Grapefruit juice** may increase plasma concentrations of ixabepilone and should be avoided. ■ **Rifampin** (Rifadin), a potent CYP3A4 inducer, decreases ixabepilone plasma concentrations. Other strong **CYP3A4 inducers** (e.g., carbamazepine [Tegretol], dexamethasone [Decadron], phenobarbital [Luminal], phenytoin [Dilantin], rifabutin [Mycobutin]) may also decrease ixabepilone plasma concentrations, decreasing effectiveness. Avoid use if possible; see [Dose Adjustments](#). ■ **St. John's wort** may decrease ixabepilone plasma concentrations, decreasing effectiveness. Avoid use. ■ Ixabepilone does not inhibit CYP enzymes and is not expected to alter plasma concentrations of other drugs.

SIDE EFFECTS

The most common side effects in patients receiving monotherapy included alopecia, anemia, arthralgia, asthenia, diarrhea, fatigue, leukopenia, mucositis, musculoskeletal pain, myalgia, nausea, neutropenia, peripheral sensory neuropathy, stomatitis, thrombocytopenia, and vomiting. In combination therapy, the following additional side effects were commonly reported: abdominal pain, anorexia, constipation, nail disorder, and hand-foot syndrome (palmar-plantar erythrodysesthesia). Other less commonly reported side effects included chest pain, cough, dehydration, dizziness, dyspnea, edema, febrile neutropenia, fever, gastroesophageal reflux disease, headache, hot flush, hypersensitivity reactions (including anaphylaxis), increased lacrimation, infection, insomnia, pain, pruritus, rash, skin exfoliation, skin hyperpigmentation, taste disorder.

Overdose: Fatigue, GI symptoms (e.g., abdominal pain, anorexia, diarrhea, nausea, stomatitis), musculoskeletal pain/myalgia, and peripheral neuropathy.

Post-Marketing: Radiation recall has been reported.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. Monitor patient closely. Discontinuation should be considered in patients who develop cardiac ischemia or impaired cardiac function. Discontinue ixabepilone at the first sign of a severe hypersensitivity reaction. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids, (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Patients who experience a hypersensitivity reaction may be able to continue therapy. Rate reduction and additional pretreatment with corticosteroids may be attempted in subsequent cycles; see Usual Dose.

KETOROLAC TROMETHAMINE **BBW**

(kee-toh-ROH-lack tro-METH-ah-meen)

Analgesic
(NSAID)

Toradol

pH 6.9 to 7.9

USUAL DOSE

Adults less than 65 years: 30 mg. May repeat every 6 hours. Maximum dose is 120 mg/24 hr. Do not increase the dose or frequency for breakthrough pain. Consider alternating with low doses of opioids (e.g., morphine or meperidine). Ketorolac oral may be used only as continuation therapy to parenteral dosing. Maximum oral dose is 40 mg/24 hr. Do not administer for longer than 5 days (IV/IM alone or combined use with oral).

Adults over 65 years, patients with impaired renal function, and/or patients under 50 kg (110 lb): 15 mg. May repeat every 6 hours. Maximum dose is 60 mg in 24 hours. Note all restrictions for adults less than 65 years outlined above.

PEDIATRIC DOSE

See *Maternal/Child*.

Pediatric patients 2 to 16 years of age: One dose of 0.5 mg/kg up to a maximum dose of 15 mg. 0.5 mg/kg IV every 6 hours has been administered in a limited number of patients (unlabeled).

Short-term postoperative pain management (unlabeled): 1 mg/kg alone or as an adjunct.

DOSE ADJUSTMENTS

Required for patients under 50 kg (110 lb), patients over 65 years of age, and patients with reduced renal function (moderately elevated SCr); see *Usual Dose*. Further dose reductions may be required with high-dose salicylates; see *Drug/Lab Interactions*.

DILUTION

Confirm IV use. Some 2 mL tubex syringes are for IM use only. May be given undiluted through Y-tube or three-way stopcock of infusion set. Administration through a free-flowing IV is preferred.

Storage: Store at CRT; protect from light.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

May form a precipitate if admixed with drugs with a low pH (e.g., meperidine [Demerol], morphine, promethazine [Phenergan]).

One source suggests the following **compatibilities**:

Solution: D5W, NS, D5NS, LR, R.

Y-site: Cisatracurium (Nimbex), dexmedetomidine (Precedex), fentanyl (Sublimaze), hetastarch in electrolytes (Hexend), hydromorphone (Dilaudid), methadone (Dolophine), morphine, remifentanyl (Ultiva), sufentanyl (Sufenta).

RATE OF ADMINISTRATION

A single dose over a minimum of 15 seconds; evenly distributed over 1 to 2 minutes is preferred.

ACTIONS

A nonsteroidal anti-inflammatory drug (NSAID) with peripheral analgesic, anti-inflammatory, and antipyretic actions. Inhibits prostaglandin synthesis. 30 to 60 mg produces analgesia similar to morphine 12 mg or Demerol 100 mg. Studies reflect less drowsiness, nausea, and vomiting. Not a narcotic agonist or antagonist. Cardiac and hemodynamic parameters are not altered. Onset of action is 30 to 60 minutes. Half-life varies from 3.8 to 8.6 hours based on age and clinical status. Relief in some patients may last 6 to 8 hours. Excreted primarily in urine. Secreted in breast milk.

INDICATIONS AND USES

Short-term management of moderately severe, acute pain (no longer than 5 days). ■ NOT indicated for minor or chronic painful conditions.

Unlabeled uses: Postoperative short-term pain management in pediatric patients.

CONTRAINDICATIONS

Hypersensitivity to ketorolac, its components, or ASA or other NSAIDs; labor and delivery; breast-feeding; preoperative or intraoperative medication when hemostasis is critical due to increased risk of bleeding; patients currently receiving ASA or NSAIDs (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]); active peptic ulcer disease; recent GI bleeding or perforation; patients with a history of peptic ulcer disease or GI bleeding; suspected or confirmed cerebrovascular bleeding; hemorrhagic diathesis; incomplete hemostasis; high risk of bleeding; advanced renal impairment; or patients at risk for renal failure because of volume depletion. Do not use for epidural or intrathecal administration; contains alcohol. See [Drug/Lab Interactions](#).

PRECAUTIONS

Use only recommended doses; increased doses will not be more effective and will increase the risk of serious adverse events. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. Administer in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Inhibits platelet aggregation and may prolong bleeding time. ■ May cause serious GI ulceration and bleeding without warning. ■ In addition to the usual caution in patients with reduced hepatic or renal function, ketorolac may also cause a dose-dependent reduction in renal prostaglandin formation. Can precipitate renal failure in patients with impaired renal function, heart failure, or liver dysfunction; in the elderly or in patients receiving diuretics. ■ Use caution in patients with cardiac decompensation, hypertension, or similar conditions; may cause fluid retention and edema. ■ Use caution in patients with pre-existing asthma, especially aspirin-sensitive asthma. Severe bronchospasm has been reported.

Monitor: Correct hypovolemia before giving ketorolac and maintain adequate hydration. ■ Observe patient frequently, especially for heartburn or signs and symptoms of GI upset or bleeding, and monitor vital signs. ■ Monitor BUN, SCr, liver enzymes, occult blood loss, urinalysis, urine output, and signs of pain relief (e.g., increased appetite and activity). ■ Observe closely during ambulation. ■ Low doses of narcotics may be required to treat breakthrough pain.

Patient Education: Side effects have resulted in extended hospitalization and could be fatal. ■ Discard any remaining oral ketorolac at end of 5-day total cumulative maximum time for use.

Maternal/Child: See [Contraindications](#). ■ Category C: safety for use not established. Use only if other alternatives are not available. ■ Discontinue breast-feeding. ■ Multiple dose treatment in pediatric patients has not been studied; limited data available.

Elderly: See [Dose Adjustments](#) and [Precautions](#). ■ More sensitive to side effects. ■ Incidence of GI bleeding and acute renal failure increases with age.

DRUG/LAB INTERACTIONS

Probenecid inhibits clearance and may triple plasma levels of ketorolac. Concomitant use is contraindicated. ■ Potentiated by **salicylates** (especially high-dose regimens). May double plasma levels of ketorolac. Reduce dose of ketorolac by half. ■ May decrease clearance and increase toxicity of **methotrexate**. ■ Additive if used with other **NSAIDs** (see [Contraindications](#)); side effects may increase markedly. ■ May potentiate **lithium** levels. ■ May increase risk of bleeding, especially from the GI tract, when given concomitantly with **anticoagulants** (e.g., warfarin [Coumadin], heparin) or **thrombolytic agents** (e.g., alteplase [tPA]). ■ May increase risk of bleeding when given with **agents that may cause thrombocytopenia or inhibit or interfere with platelet aggregation** (e.g., clopidogrel [Plavix], valproic acid [Depacon]) and **serotonin reuptake inhibitors** (e.g., paroxetine [Paxil]). ■ Can precipitate renal failure concomitantly with **diuretics** (e.g., furosemide [Lasix]); see [Precautions](#). ■ Can reduce response to **furosemide (Lasix) or other diuretics** in normovolemic healthy individuals. ■ May increase risk of renal impairment with **ACE inhibitors** (e.g., enalapril [Vasotec]). ■ Nephrotoxicity of both agents may be increased with **other nephrotoxic agents** (e.g., aminoglycosides [e.g., gentamicin], cyclosporine [Sandimmune]). ■ May potentiate **nondepolarizing muscle relaxants** (e.g., atracurium [Tracrium]). ■ Has caused seizures in a few patients taking **antiepileptics** (e.g., phenytoin [Dilantin], carbamazepine [Tegretol]). ■ May cause hallucinations with **antipsychotics** (e.g., thiothixene [Navane]), **antidepressants** (e.g., fluoxetine [Prozac]). ■ May cause **elevations of liver function tests** AST and ALT.

SIDE EFFECTS

Average dose: Diarrhea, dizziness, dyspepsia, drowsiness, edema, GI bleeding, GI pain, headache, injection site pain, nausea, and sweating are most common. Capable of all side effects of other NSAIDs, especially with extended use: abnormal taste, abnormal vision, asthenia, asthma, confusion, constipation, depression, dry mouth, dyspnea, euphoria, excessive thirst, flatulence, inability to concentrate, insomnia, liver function abnormalities, melena, myalgia, nervousness, oliguria, pallor, paresthesia, peptic ulcer, rectal bleeding, stimulation, stomatitis, pruritus, purpura, urinary frequency, urticaria, vasodilation, vertigo, vomiting.

Overdose: Abdominal pain, diarrhea, labored breathing, metabolic acidosis, pallor, peptic ulcer, rales, vomiting.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly if indicated. Treat anaphylaxis with epinephrine (Adrenalin), diphenhydramine (Benadryl), and corticosteroids as indicated. Not significantly cleared by dialysis.

LABETALOL HYDROCHLORIDE

(lah-BET-ah-lohl hy-droh-KLOR-eyed)

Alpha/beta-adrenergic
blocking agent
Antihypertensive

pH 3 to 4

USUAL DOSE

Dose must be individualized based on degree of hypertension and patient response.

20 mg as an initial dose by IV injection. May repeat with injections of 40 to 80 mg at 10-minute intervals until desired BP is achieved, or may be diluted and given as a continuous infusion. Usually effective with 50 to 200 mg. Do not exceed a total dose of 300 mg. Initiate oral labetalol after desired BP has been achieved and the supine diastolic pressure starts to rise. See literature for dose regimen. AHA recommends 10 mg IV over 1 to 2 minutes. May repeat or double dose every 10 minutes to a maximum dose of 150 mg. Or initial dose may be given by IV injection followed by an infusion of 2 to 8 mg/min. Titrate slowly to achieve desired results without exceeding maximum dose.

DOSE ADJUSTMENTS

See Precautions and Drug/Lab Interactions.

DILUTION

IV injection: May be given undiluted in a 5 mg/mL concentration.

Continuous infusion: May be diluted in most commonly used IV solutions (see chart on inside back cover). Addition of 200 mg (40 mL) to 160-mL solution yields 1 mg/mL, 300 mg (60 mL) to 240 mL yields 1 mg/mL, or 200 mg (40 mL) to 250 mL yields 2 mg/3 mL. Amount of solution may be decreased if required by fluid restrictions of the patient.

Storage: Store unopened vial between 2° and 30° C (36° and 86° F). Do not freeze. Protect from light. Stable after dilution for 24 hours at room temperature or refrigerated.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists 5% sodium bicarbonate as **incompatible** and indicates to use care when administering alkaline drugs, including furosemide (Lasix).

One source suggests the following **compatibilities:**

Y-site: Amikacin (Amikin), aminophylline, amiodarone (Nexterone), ampicillin, bivalirudin (Angiomax), butorphanol (Stadol), calcium gluconate, cefazolin (Ancef), ceftazidime (Fortaz), chloramphenicol (Chloromycetin), clindamycin (Cleocin), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, dopamine, doripenem (Doribax), enalaprilat (Vasotec IV), epinephrine (Adrenalin), erythromycin (Erythrocin), esmolol (Brevibloc), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), gentamicin, heparin, hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, meperidine (Demerol), metronidazole (Flagyl IV), midazolam (Versed), milrinone (Primacor), morphine, nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), oxacillin (Bactocill), penicillin G potassium, potassium chloride (KCl), potassium phosphates, propofol (Diprivan), ranitidine (Zantac), sodium acetate, sulfamethoxazole/trimethoprim, telavancin (Vibativ), tobramycin, vancomycin, vecuronium.

RATE OF ADMINISTRATION

IV injection: Each 20 mg or fraction thereof over at least 2 minutes.

Continuous infusion: Begin at 2 mg/min. Adjust according to orders of physician and BP response. Another source suggests 0.5 to 2 mg/min. Use of a microdrip (60 gtt/mL) or an infusion pump may be helpful.

ACTIONS

An adrenergic receptor blocking agent with both selective alpha-1-adrenergic and nonselective beta-adrenergic receptor blocking activity. Causes dose-related falls in BP without reflex tachycardia or significant reduction in HR. Maximum effect of each dose is reached in 5 minutes. Half-life is 5.5 hours, but some effects last up to 16 hours. Metabolized and excreted as metabolites in urine and through bile to feces. Crosses the placental barrier. Present in small amounts in breast milk.

INDICATIONS AND USES

Control of BP in severe hypertension.

Unlabeled uses: Treatment of clonidine withdrawal hypertension. ■ Decrease BP and relieve symptoms in patients with pheochromocytoma.

CONTRAINDICATIONS

Obstructive airway disease including asthma, cardiogenic shock, greater than first-degree heart block, overt cardiac failure, severe bradycardia, other conditions associated with severe and prolonged hypotension, and hypersensitivity to labetalol or its components.

PRECAUTIONS

Use caution in impaired liver function. ■ Hepatic injury has been reported. Has occurred after both short-term and long-term treatment. Usually reversible, but hepatic necrosis and death have been reported. ■ Use extreme caution in patients with any degree of cardiac failure; may further depress myocardial contractility. Does not alter effectiveness of digoxin on heart muscle. ■ Effective in lowering BP in pheochromocytoma but has caused a paradoxical hypertensive response in some patients. ■ Use with extreme caution in diabetics or patients with a history of hypoglycemia. May mask the symptoms of hypoglycemia and reduce the release of insulin in response to hyperglycemia. ■ Routine withdrawal of chronic beta-blocker therapy before surgery is not recommended. However, the effect of the alpha-adrenergic activity of labetalol has not been evaluated in the surgical setting. Deaths have occurred when labetalol has been used during surgery. ■ Intraoperative floppy iris syndrome has been observed during cataract surgery in some patients treated with alpha-1 blockers. Characterized by a combination of a flaccid iris, progressive miosis despite preoperative dilation with standard mydriatic drugs, and potential prolapse of the iris. Modification of the surgical technique may be required. ■ See [Drug/Lab Interactions](#).

Monitor: Keep patient supine. Postural hypotension can occur for up to 3 hours after administration. Ambulate with care and assistance. ■ Monitor BP before and 5 and 10 minutes after each direct IV injection. Monitor at least every 5 minutes during infusion. Avoid rapid or excessive falls in either systolic or diastolic BP. When severely elevated BP drops too rapidly, catastrophic reactions can occur (e.g., cerebral infarction, optic nerve infarction, angina, ischemic ECG changes). ■ Monitor for S/S of CHF. ■ Although rebound angina, myocardial infarction, or ventricular arrhythmias have not been a problem with labetalol, it is recommended that the dose of beta-adrenergic blockers be reduced gradually to avoid these conditions. ■ See [Drug/Lab Interactions](#).

Patient Education: Report cough, dizziness, irregular pulse, or shortness of breath promptly. ■ May cause dizziness or fainting; request assistance with ambulation.

Maternal/Child: Category C: use in pregnancy only when clearly indicated and benefit outweighs risk. Hypotension, bradycardia, hypoglycemia, and respiratory depression have been reported in infants of mothers who were treated with labetalol for hypertension during pregnancy. Has been used during labor and delivery. ■ Use caution during breastfeeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Use with caution in age-related peripheral vascular disease; risk of hypothermia increased. ■ May exacerbate mental impairment.

DRUG/LAB INTERACTIONS

Amiodarone (Nexterone) may enhance the bradycardic effect of beta-blockers. ■ Inhibits **beta-agonist bronchodilators** (e.g., albuterol [Ventolin]); increased doses may be required, especially in asthmatics. ■ Synergistic with **halothane anesthesia**. High concentrations of halothane (3% or above) should not be used. The degree of hypotension will be in-

creased, and the possibility of a large reduction in cardiac output and an increase in central venous pressure exists. Notify anesthesiologist that patient is receiving labetalol. ■ Potentiated by **cimetidine** (Tagamet). May blunt the reflex tachycardia produced by **nitroglycerin**. May cause further hypotension with **nitroglycerin**. ■ The use of labetalol with **calcium channel blockers** (e.g., diltiazem [Cardizem], verapamil) may potentiate both drugs and result in severe depression of myocardium, AV conduction, and severe hypotension. ■ May mask the hypoglycemic effects of **insulin and other antidiabetic agents**. May inhibit the mobilization of glucose from hepatic stores. Monitor glucose carefully in diabetic patients. ■ Patients receiving beta-blockers who have a history of severe anaphylactic reaction to a variety of allergens may be unresponsive to the usual doses of **epinephrine** used to treat an allergic reaction. ■ May interfere with lab tests in the **diagnosis of pheochromocytoma**. ■ May cause a **false-positive urine test** for amphetamine use.

SIDE EFFECTS

Diaphoresis, dizziness, flushing, moderate hypotension, numbness, severe postural hypotension, nausea, somnolence, tingling of scalp, and ventricular dysrhythmias (e.g., intensified atrioventricular block) occur most frequently.

ANTIDOTE

Notify the physician of all side effects. Decrease rate or discontinue drug if hypotension occurs. Notify physician immediately. Trendelenburg position may be appropriate. May require treatment with IV fluids or vasopressors (e.g., norepinephrine [levarterenol], dopamine). Use atropine or epinephrine for severe bradycardia; digoxin, diuretics, dopamine, or dobutamine for cardiac failure; norepinephrine (Levophed) for hypotension; epinephrine (Adrenalin) and/or albuterol (Ventolin) for bronchospasm; and diazepam (Valium) for seizures. Unresponsive hypotension and bradycardia may be reversed by glucagon 5 to 10 mg over 30 seconds followed by a continuous infusion of 5 mg/hr. Reduce rate as condition improves. Treat other side effects symptomatically and resuscitate as necessary. Hemodialysis is not effective.

LACOSAMIDE

(la-KOE-sa-mide)

Anticonvulsant

Vimpat

pH 3.5 to 5

USUAL DOSE

Serum levels similar by oral or IV route; no dose or frequency adjustment is necessary. Transfer to oral therapy as soon as practical.

Initiate treatment: Begin with a daily dose of 100 mg/day equally divided into 2 doses (50 mg twice daily). May be increased at weekly intervals by 100 mg/day given as 2 divided doses up to the recommended maintenance dose of 200 to 400 mg/day based on individual patient response and tolerability. Titrate dose with caution in patients with renal or hepatic impairment and in the elderly. Twice-daily IV infusions have been used for up to 5 days. There is no evidence that doses greater than 400 mg/day offer additional benefit, and they have been associated with a higher incidence of side effects.

Transfer from an IV dose to an oral dose: Transfer at the equivalent daily dose and frequency of the IV dose.

DOSE ADJUSTMENTS

No dose adjustment is indicated for patients with mild to moderate renal impairment.

- 300 mg is the maximum recommended dose for patients with severe renal impairment (a CrCl equal to or less than 30 mL/min) and for patients with end-stage renal disease. A supplemental dose of up to 50% should be considered after a 4-hour hemodialysis treatment.
- A maximum dose of 300 mg/day is recommended for patients with mild or moderate hepatic impairment.
- Not recommended for patients with severe hepatic impairment.
- Dose adjustment not required based on gender or race or in the elderly; see [Elderly](#).

DILUTION

Available as a 200 mg/20 mL (10 mg/mL) solution for injection.

May be given undiluted or may be further diluted with NS, D5W, or LR. See [Rate of Administration](#).

Filters: Specific information not available.

Storage: Store unopened vials at CRT. Do not freeze. Diluted solutions are stable at ambient RT for 24 hours in glass or PVC bags. Discard unused portions of vial.

COMPATIBILITY

Solutions: **Compatible** with NS, D5W, and LR. Additional information not available.

RATE OF ADMINISTRATION

A single dose as an infusion over 30 to 60 minutes.

ACTIONS

An antiepileptic (anticonvulsant) drug. The precise mechanism of action is unknown. *In vitro* studies have shown that it selectively enhances the slow inactivation of voltage-gated sodium channels, resulting in stabilization of hyperexcitable neuronal membranes and inhibition of repetitive neuronal firing. Some effects are reached at the end of infusion. Steady-state plasma concentrations are achieved after 3 days of administration. Doses above 400 mg/day do not appear to have additional benefit. Less than 15% bound to plasma proteins. Partially metabolized. Half-life is approximately 13 hours. Excreted as metabolites and as unchanged drug in urine.

INDICATIONS AND USES

Adjunctive therapy in the treatment of partial-onset seizures in adult patients (17 years of age and older) with epilepsy. IV injection is used as a temporary alternative to oral therapy. Usually given in combination with other antiepileptic drugs.

CONTRAINDICATIONS

Manufacturer indicates none; see [Precautions](#).

PRECAUTIONS

For IV use only. ■ Psychotic symptoms and other behavioral changes have been reported with AEDs (anti-epileptic drugs) and may include aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies. In an analysis of AED clinical trials, symptoms occurred as early as 1 week after starting AEDs and persisted for the duration of treatment. May require a dose reduction or discontinuation of lacosamide. Many illnesses for which AEDs are prescribed, including epilepsy, are associated with morbidity and mortality and an increased risk of suicidal thoughts and behavior. Consider that these symptoms may also be related to the illness being treated. ■ Associated with CNS side effects in addition to behavioral problems and psychotic tendencies (e.g., ataxia, dizziness, somnolence). Onset of symptoms commonly observed during titration. ■ Dose-dependent prolongations in PR intervals have been observed. Use caution in patients with known conduction problems (e.g., marked first-degree AV block, second-degree or higher AV block, and sick sinus syndrome without a pacemaker) or severe cardiac disease such as myocardial ischemia or heart failure. ■ May cause atrial arrhythmias (atrial fibrillation or atrial flutter), especially in patients with diabetic neuropathy or cardiovascular disease. ■ Dizziness and loss of consciousness was reported in patients with diabetic neuropathy. ■ A delayed multiorgan hypersensitivity reaction (also known as Drug Reaction with Eosinophilia and Systemic Symptoms, or DRESS) occurred in one patient and manifested as symptomatic hepatitis and nephritis, which resolved over time. DRESS has been reported with other AEDs and typically presents with a fever and rash associated with other organ involvement, such as eosinophilia, hepatitis, nephritis, lymphadenopathy, and/or myocarditis. ■ Not recommended for patients with severe hepatic impairment. ■ To minimize the potential for increased seizure frequency, withdraw AEDs (including lacosamide) gradually (over a minimum of 1 week). ■ Physical dependence has not been demonstrated; however, psychological dependence cannot be excluded because of the ability of lacosamide to produce a euphoria-type response.

Monitor: Baseline CBC, CrCl, bilirubin, and liver function tests indicated; monitor as needed. ■ Monitor vital signs. ■ Monitor for seizure activity. ■ Monitor for the emergence or worsening of depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior. ■ Observe patient closely for signs of CNS side effects, prolonged PR interval, and/or symptoms of DRESS; see [Precautions](#). ■ Obtain a baseline ECG in patients with known conduction problems and/or severe cardiac disease. Repeat after lacosamide is titrated to steady-state concentrations.

Patient Education: Read patient information guide provided by manufacturer. ■ May cause dizziness, fainting, and somnolence; use caution performing tasks that require alertness (e.g., operating machinery, driving). ■ Inform your health care professional if you are pregnant or breast-feeding. ■ May cause alterations in mood (e.g., aggression, agitation, anger, anxiety, apathy, decreased ability to cope, depression, hostility, irritability, thoughts of suicide); report these changes promptly. ■ Has caused atrial arrhythmias. Promptly report palpitations, rapid pulse, and/or shortness of breath. ■ May cause various degrees of heart block. Report slow or irregular pulse, light-headedness, or fainting. ■ Promptly report S/S of hypersensitivity (e.g., fever, rash) or liver toxicity (e.g., fatigue, jaundice, dark urine). ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry.

Maternal/Child: Category C: animal studies demonstrated developmental toxicity (increased embryofetal and perinatal mortality, growth deficit). Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. Manufacturer has established a pregnancy registry to evaluate safety and outcomes; see manufacturer's literature and [Patient Education](#). ■ Effects during labor and delivery unknown. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 17 years of age not established.

Elderly: Higher plasma concentrations seen in the elderly may be due to differences in total body water and age-associated impaired renal function; see [Usual Dose](#).

DRUG/LAB INTERACTIONS

Coadministration with **other drugs that can affect cardiac conduction** may lead to conduction abnormalities (e.g., drugs that increase QT interval prolongation such as **antiarrhythmics** [e.g., amiodarone (Nexterone), disopyramide (Norpace), ibutilide (Corvert), mexiletine, procainamide (Pronestyl), quinidine], **antihistamines**, **azole antifungals** [e.g., itraconazole (Sporanox)], **fluoroquinolones** [e.g., levofloxacin (Levaquin)], **phenothiazines** [e.g., thioridazine (Mellaril)], and **tricyclic antidepressants** [e.g., amitriptyline (Elavil), imipramine (Tofranil)]). ■ No evidence of any relevant drug/drug interaction with **other antiepileptic drugs** (AEDs) such as carbamazepine (Tegretol), clonazepam (Klonopin), gabapentin (Neurontin), lamotrigine (Lamictal), levetiracetam (Keppra), oxcarbazepine (Trileptal), phenobarbital (Luminal), phenytoin (Dilantin), topiramate (Topamax), valproic acid (e.g., Depacon, Depakote), and zonisamide (Zonegran). ■ Concurrent administration with **carbamazepine, phenobarbital, or phenytoin** has resulted in small reductions in lacosamide plasma concentrations. ■ Minimal protein binding; unlikely to have interactions with drugs requiring protein-binding sites. ■ Has been administered with oral contraceptives (containing ethinyl estradiol and levonorgestrel), digoxin (Lanoxin), metformin (Glucophage), and omeprazole (Prilosec) with no interference on the pharmacokinetics of either drug. ■ Does not induce or inhibit the enzyme activity of many drugs metabolized by selected cytochrome P₄₅₀ isoforms. *In vitro* studies suggest lacosamide has the potential to inhibit CYP2C19 at therapeutic concentrations; see prescribing information.

SIDE EFFECTS

The most common side effects are diplopia, dizziness, headache, and nausea. Ataxia, blurred vision, diplopia, dizziness, nausea, vertigo, and vomiting led to discontinuation of lacosamide. Incidence of side effects increased with doses above 400 mg/day. Most side effects at recommended doses were considered mild or moderate and included anemia; asthenia; balance disorder; cerebellar syndrome; confusion; constipation; depression; diarrhea; dry mouth; dyspepsia; elevated liver function tests (e.g., ALT, AST); falls; fatigue; feeling drunk; fever; gait disturbance; hypoesthesia; injection site pain, discomfort, irritation, or erythema; muscle spasms; nystagmus; oral hypoesthesia; palpitations; paresthesia; pruritus; skin laceration; somnolence; tinnitus; and tremor. Psychiatric disorders, including aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies, have been reported. May produce euphoria-type reactions. One patient experienced profound bradycardia; another developed symptoms of DRESS, including hepatitis and nephritis. Both improved with discontinuation of lacosamide.

Post-Marketing: Agranulocytosis, bradycardia, hallucinations, rash.

ANTIDOTE

Keep physician informed of all side effects. Some may not require intervention, and others may improve with a reduced dose or discontinuation of lacosamide; see [Precautions](#) and [Side Effects](#). Discontinue lacosamide for symptoms of DRESS; use of an alternate treatment is recommended. Support patient as required in treatment of overdose. No specific antidote in overdose; however, hemodialysis will remove approximately 50% of a dose in 4 hours.

LANSOPRAZOLE

(lan-SAHP-rah-zohl)

Proton pump inhibitor
(Gastric acid inhibitor)

Prevacid IV

pH 9.5 to 11

USUAL DOSE

30 mg as an infusion once daily for up to 7 days.

Given as an alternative to continued oral therapy. Resume oral therapy as soon as practical. Dose and serum levels similar by IV or oral route. See [Rate of Administration](#).

DOSE ADJUSTMENTS

No dose adjustment is required based on age, race, or gender; in the elderly; or in patients with renal insufficiency. ■ Consider dose adjustment in patients with impaired hepatic function; half-life is increased and mean AUC is increased up to 500%.

DILUTION

Reconstitution in vial: Each 30-mg dose must be reconstituted with 5 mL of SWFI (6 mg/mL). The use of other solutions for reconstitution may result in precipitation. Mix gently until powder is dissolved. Must be further diluted for infusion in 50 mL of NS, LR, or D5W.

Reconstitution with Baxter MINI-BAG Plus Container: May be reconstituted directly into 50 mL of NS or D5W in a Baxter MINI-BAG Plus Container. Refer to specific instructions included with the MINI-BAG Plus Container.

Filters: Must be administered through the provided 1.2-micron in-line filter to remove precipitate that may form when the reconstituted drug is further diluted with IV solutions.

Storage: Store vials in carton at CRT to protect from light.

Vials: Reconstituted solution is stable for 1 hour at 25° C (77° F) before further dilution (pH 11). Fully diluted solutions are stable at 25° C (77° F) and should be administered within 24 hours when diluted in NS (pH 10.2) or LR (pH 10) and within 12 hours when diluted in D5W (pH 9.5). **MINI-BAG:** Store admixture at 25° C (77° F). Administer within 24 hours in NS (pH 10.2) and within 8 hours in D5W (pH 9.5).

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Do not mix with other drugs or diluents.” A dedicated line is not required; however, the IV line should be flushed with a **compatible** IV solution (NS, LR, or D5W) before and after administration of lansoprazole.

RATE OF ADMINISTRATION

Flush the IV line with at least 5 mL of a **compatible** IV solution (NS, LR, or D5W) before and after administration of lansoprazole. Must be administered through the provided in-line filter. Refer to package insert for manufacturer’s specific instructions for priming this filter and specific precautions required with the use of this filter.

A single 30-mg dose properly diluted as an infusion evenly distributed over 30 minutes. Remove and discard the administration set and filter after lansoprazole infusion is complete. Flush the IV port with at least 5 mL of a **compatible** solution. If the port is not flushed and the set is not removed, a brown/black particulate produced from lansoprazole degradation may appear in the tubing or filter.

ACTIONS

A proton pump inhibitor. A compound that does not exhibit anticholinergic or histamine H₂-receptor antagonist properties. It suppresses gastric acid secretion by specific inhibition of the (H⁺, K⁺)-ATPase enzyme system at the secretory surface of the gastric parietal cell. Blocks the final step of acid production. Effects are dose related, and both basal and stimulated gastric acid secretions are inhibited for at least 24 hours. Does not accu-

multate, and pharmacokinetics are not altered with multiple daily dosing (with the exception of patients with impaired hepatic function). Distributed in extracellular fluid and highly bound to serum protein. Extensively metabolized in the liver by the cytochrome P₄₅₀ isoenzyme system (CYP3A and CYP2C19 isozymes). Half-life is 1.3 hours (range is 0.8 to 1.8 hours) and does not reflect the duration of suppression of gastric acid secretion. Primarily excreted in bile and feces, with some excretion in urine.

INDICATIONS AND USES

Short-term treatment (up to 7 days) of all grades of erosive esophagitis as an alternative to oral therapy in patients who are unable to continue taking lansoprazole oral formulations. Safety and effectiveness for use in the initial treatment of erosive esophagitis not demonstrated.

CONTRAINDICATIONS

Known hypersensitivity to lansoprazole or its components.

PRECAUTIONS

For IV use only; do not give IM or SC. ■ Gastric malignancy may be present even though patient's symptoms improve. ■ May be associated with an increased risk for osteoporosis-related fractures of the hip, wrist, or spine. Risk is increased in patients receiving high-dose (multiple daily doses) and long-term therapy (a year or longer). Use lowest dose and shortest duration of therapy appropriate for the condition being treated. ■ Hypomagnesemia (symptomatic and asymptomatic) has been reported in patients treated with proton pump inhibitors (PPIs) for at least 3 months and in most cases after a year of treatment. Serious adverse events, including arrhythmias, seizures, and tetany, have occurred. Discontinuation of the PPI and magnesium replacement have been required. ■ May be associated with an increased risk of *Clostridium difficile*-associated diarrhea (CDAD), especially in hospitalized patients. Consider in patients who develop diarrhea that does not improve. ■ Discontinue as soon as the patient is able to resume oral therapy.

Monitor: Observe for S/S of allergic reaction; anaphylaxis has been reported in post-marketing reports. ■ Monitor vital signs, pain levels, and injection site. ■ Monitoring of magnesium levels may be indicated with prolonged PPI therapy; see [Precautions and Drug/Lab Interactions](#).

Patient Education: Review prescription and non-prescription drugs with physician. ■ Oral route preferred.

Maternal/Child: Category B; use during pregnancy only if clearly needed. Animal studies did not show harm to the fetus. ■ If the drug is indicated for the mother, breast-feeding should be discontinued. May have serious reactions in the infant and has a potential for tumorigenicity. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Safety and effectiveness similar to that seen in younger adults. ■ Consider potential for impaired liver function; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Because of profound and long-lasting inhibition of gastric acid secretion, lansoprazole may **interfere with the absorption of drugs** in which gastric pH is an important determinant of their bioavailability (e.g., ampicillin esters [Omnipen], digoxin [Lanoxin], iron salts [ferrous sulfate], ketoconazole [Nizoral]). ■ Increases in INR and PT have been reported when administered concurrently with **warfarin**; monitoring of INR and PT indicated. ■ Studies suggest that the metabolism and serum concentrations of lansoprazole are not significantly altered when used concurrently with other drugs metabolized by the cytochrome P₄₅₀ system (e.g., clarithromycin [Biaxin], diazepam [Valium], indomethacin [Indocin], ibuprofen [Advil, Motrin], phenytoin [Dilantin], propranolol, prednisone). ■ May cause a minor increase in the clearance of **theophylline**; certain patients may require some dose titration when lansoprazole is started or discontinued. ■ Concomitant administration with **tacrolimus** (Prograf) may increase whole blood levels of tacrolimus, especially in patients who are intermediate or poor metabolizers of CYP2C19. ■ Concomitant use of proton pump inhibitors with high-dose **methotrexate** may elevate

and prolong serum levels of methotrexate and/or its metabolite. May lead to methotrexate toxicity; consider withdrawal of lansoprazole.

SIDE EFFECTS

Most common side effects are headache, injection site pain or reaction, and nausea. Other side effects include abdominal pain, constipation, diarrhea, dizziness, dyspepsia, paresthesia, rash, taste perversion, vasodilation, and vomiting. Numerous other side effects may occur in fewer than 1% of patients. Other side effects reported with oral lansoprazole include abnormal albumin-to-globulin (A/G) ratio, abnormal or increased liver function tests (e.g., AST and ALT, alkaline phosphatase, bilirubinemia, LDH), abnormal RBC count, eosinophilia, hyperlipidemia, increased/decreased cholesterol, increased creatinine, increased/decreased electrolytes, increased/decreased/abnormal platelets, increased/decreased/abnormal WBC count, increased gastrin levels, increased GGTP (gamma-glutamyl transpeptidase), increased globulins, increased glucocorticoids, and urine abnormalities (e.g., albuminuria, glycosuria, hematuria).

Overdose: Ataxia, decreased locomotor response, ptosis, and tonic convulsions were symptoms of acute toxicity in heavily overdosed mice and rats.

Post-Marketing: Agranulocytosis, anaphylaxis, aplastic anemia, bone fracture, CDAD, hemolytic anemia, hepatotoxicity, hypomagnesemia, leukopenia, pancreatitis, pancytopenia, serious dermatologic reactions (including erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis [some fatal]), speech disorder, thrombocytopenia, thrombotic thrombocytopenic purpura, urinary retention.

ANTIDOTE

Keep physician informed of significant side effects. May be treated symptomatically. Discontinue and initiate appropriate treatment if S/S associated with post-marketing reports or overdose occur; see [Side Effects](#). Not removed by hemodialysis.

LEUCOVORIN CALCIUM

(loo-koh-VOR-in KAL-see-um)

Antidote
Antineoplastic adjunct

Citrovorum Factor, Folinic Acid,
Leucovorin Calcium PF

pH 6 to 8.1

USUAL DOSE

May be given IV/IM or PO. If GI toxicity is present, should be administered parenterally. **Delayed excretion or overdose of methotrexate (MTX):** 10 mg/M² every 6 hours until the serum MTX level is less than 0.05 micromolar. Milligram for milligram or greater than the dose of MTX is common. Administer within the first hour (or as soon as possible) in overdose or within 24 hours of MTX dose if there is delayed excretion. At least every 24 hours, obtain a SCr and MTX level. If SCr is more than 50% above pretreatment level, increase the leucovorin dose to 100 mg/M² every 3 hours until the serum MTX level is less than 0.05 micromolar.

Leucovorin rescue after high-dose MTX therapy: With high-dose methotrexate (12 to 15 Gm/M² as an infusion over 4 hours); begin leucovorin 15 mg (approximately 10 mg/M²) 24 hours after MTX infusion started. Repeat every 6 hours for 10 doses. If MTX elimination is delayed, extend every-6-hour dosing until MTX level is less than 0.05 micromolar. If there is evidence of acute renal injury, increase leucovorin to 150 mg every 3 hours until MTX level is less than 1 micromolar, then 15 mg every 3 hours until MTX level is less than 0.05 micromolar. In both situations obtain SCr and MTX level at least every 24 hours. Other protocols are in use. Amount of leucovorin is dependent on MTX dose, MTX serum levels, and SCr.

Megaloblastic anemia: Up to 1 mg daily.

Advanced colorectal cancer: 200 mg/M² followed by fluorouracil (5-FU) 370 mg/M² or leucovorin 20 mg/M² followed by 5-FU 425 mg/M² daily for 5 days. Repeat at 4-week intervals twice, then repeat every 28 to 35 days based on complete recovery from toxic effects. Reduce 5-FU dose based on tolerance to previous course, 20% for moderate hematologic or GI toxicity, 30% for severe. Leucovorin doses remain the same. Increase 5-FU dose 10% if no toxicity. Other protocols are in use. Also approved for use with irinotecan and 5-FU.

Pemetrexed toxicity (unlabeled): A single dose of 100 mg/M². Follow with 50 mg/M² every 6 hours for 8 days.

DOSE ADJUSTMENTS

See adjustments in [Usual Dose](#); larger reductions may be required in the elderly based on the potential for decreased renal function, especially in combination with fluorouracil. ■ See [Precautions/Monitor](#).

DILUTION

Each 50-mg, 100-mg, or 350-mg vial should be diluted to a 10 mg/mL to 20 mg/mL solution. For total doses less than 10 mg/M², dilute with bacteriostatic water for injection (contains benzyl alcohol as a preservative). Use SWFI without a preservative for any dose 10 mg/M² or greater. May be further diluted in 100 to 500 mL of D5W, D10W, NS, R, or LR. 1-mL (3-mg) ampules may be given undiluted (contain benzyl alcohol).

Storage: If prepared without a preservative, use immediately; stable up to 7 days with a preservative.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Several sources, including the manufacturer, cite **incompatibility** with fluorouracil (5-FU) as an additive; may form a precipitate.

One source suggests the following **compatibilities**:

Additive: Cisplatin (Platinol).

Y-site: Amifostine (Ethyol), anidulafungin (Eraxis), aztreonam (Azactam), bleomycin (Blenoxane), cisplatin (Platinol), cladribine (Leustatin), cyclophosphamide (Cytosan), docetaxel (Taxotere), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), filgrastim (Neupogen), fluconazole (Diflucan), fluorouracil (5-FU), furosemide (Lasix), gemcitabine (Gemzar), granisetron (Kytril), heparin, linezolid (Zyvox), methotrexate, metoclopramide (Reglan), mitomycin (Mutamycin), oxaliplatin (Eloxatin), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), tacrolimus (Prograf), teniposide (Vumon), thiotepe, vinblastine, vincristine.

RATE OF ADMINISTRATION

Because of calcium content, do not exceed a rate of 160 mg/min (16 mL of a 10-mg/mL or 8 mL of a 20-mg/mL solution). May be given more slowly. Large doses may be infused equally distributed over 1 to 6 hours. Never exceed above limits.

ACTIONS

Potent agent for neutralizing immediate toxic effects of methotrexate (and other folic acid antagonists) on the hematopoietic system. Preferentially rescues normal cells without reversing the oncolytic effect of methotrexate. Also enhances the therapeutic and toxic effects of fluoropyrimidines (e.g., fluorouracil [5-FU]).

INDICATIONS AND USES

Treatment of accidental folic acid antagonist (e.g., methotrexate) overdose or delayed excretion of MTX. ■ Folinic acid rescue to prevent or decrease the toxicity of massive MTX doses used to treat resistant neoplasms. ■ Treatment of megaloblastic anemia due to folic acid deficiency when oral therapy not appropriate. ■ In combination with fluorouracil or fluorouracil and irinotecan (Camptosar) to treat colorectal cancer.

Unlabeled uses: Adjunct in the treatment of Ewing's sarcoma, head and neck cancer, non-Hodgkin's lymphomas, and trophoblastic tumors. ■ Treatment of pemetrexed toxicity.

CONTRAINDICATIONS

Pernicious anemia and other megaloblastic anemias secondary to lack of vitamin B₁₂. None when used as indicated for other specific uses.

PRECAUTIONS

Usually administered in the hospital by or under the direction of the physician specialist. ■ Permits use of massive doses of methotrexate. ■ Do not discontinue leucovorin calcium until methotrexate serum levels fall below toxic levels. ■ Much less effective in accidental overdose after a 1-hour delay. ■ Delayed MTX excretion may occur from third-space fluid accumulation (ascites, pleural effusion), renal insufficiency, or inadequate hydration. ■ All doses over 25 mg should be given IM or IV (no more than 25 mg can be absorbed orally). ■ IM or IV dosing required in presence of GI toxicity, nausea, or vomiting. ■ Benzyl alcohol associated with gasping syndrome in premature infants.

Monitor: Monitor serum blood levels of MTX and SCr levels at least daily until level is less than 0.05 micromolar. Death can occur in 5 to 10 days if MTX remains at toxic levels longer than 48 hours. ■ Minimum fluid intake of 3 L/24 hr and alkalinization of urine to a pH of 7 or more with oral sodium bicarbonate recommended. Begin 12 hours before MTX dose and continue for 48 hours after final dose in each sequence. Does not reduce nephrotoxicity of MTX from drug or metabolite precipitation in the kidney. ■ See methotrexate or fluorouracil monograph.

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding not established. Benefits must outweigh risks. ■ Contains benzyl alcohol; do not use in neonates or dilute with SWFI if indicated; see *Dilution*.

Elderly: Response similar to that seen in younger patients; however, use caution, may have greater sensitivity to its toxic effects (e.g., greater risk for GI toxicity and severe diarrhea in combination with fluorouracil). Monitoring of renal function suggested. ■ See *Dose Adjustments*.

DRUG/LAB INTERACTIONS

May inhibit **phenytoins** (e.g., Dilantin), **phenobarbital, and primidone**; may cause increased frequency of seizures. ■ Is used in combination with **fluorouracil**; use caution; leucovorin calcium may increase toxic as well as therapeutic effects of fluorouracil. ■ When given with **MTX**, avoid any drug that may interfere with MTX elimination or binding to serum albumin (e.g., **NSAIDs** [e.g., ibuprofen (Advil, Motrin), indomethacin, ketoprofen, naproxen (Aleve, Naprosyn)], **probenecid, procarbazine** [Matulane], **salicylates, sulfonamides**). Consider as a possible cause of toxicity. ■ High doses of leucovorin may reduce the effectiveness of intrathecally administered **methotrexate**. ■ Leucovorin may enhance the toxic effects of **capecitabine** (Xeloda); monitor closely. ■ Concurrent use with **sulfamethoxazole and trimethoprim** may cause treatment failure and increased morbidity in HIV patients being treated for *Pneumocystis jiroveci* pneumonia.

SIDE EFFECTS

Allergic reactions including anaphylaxis have occurred rarely. Methotrexate or fluorouracil may cause many serious and dose-limiting side effects; see individual monographs.

ANTIDOTE

Keep physician informed of patient's condition. Symptomatic treatment indicated.

LEVETIRACETAM INJECTION

Anticonvulsant

(lee-ve-tye-**RA**-se-tam in-**JEK**-shun)

Keppra

pH 5.5

USUAL DOSE

Serum levels similar by oral or IV route; no dose or frequency adjustment is necessary. Transfer to oral therapy as soon as practical.

Transfer to an IV dose from an oral dose: The IV dose should be equivalent to the total daily dose and frequency of the oral dose prescribed for the individual patient (e.g., 500, 1,000, or 1,500 mg every 12 hours to achieve a total daily dose of 1,000, 2,000, or 3,000 mg).

Initiate treatment: Begin with a daily dose of 1,000 mg/day equally divided into 2 doses (500 mg every 12 hours). Monitor for 2 weeks. If needed, dose may be increased by a 1,000 mg/day increment (total dose of 2,000 mg/day equally divided into 2 doses [1,000 mg every 12 hours]). Monitor for another 2 weeks. If needed, increase dose by another 1,000 mg/day increment (total dose of 3,000 mg/day equally divided into 2 doses [1,500 mg every 12 hours]).

Patients with partial-onset seizures: Therapeutic daily dose may range from 1,000 to 3,000 mg. There is no evidence that doses **greater** than 3,000 mg/day offer additional benefit.

Patients with primary generalized tonic-clonic seizures or those with myoclonic seizures in juvenile myoclonic epilepsy: The recommended daily dose is 3,000 mg. The effectiveness of doses **lower** than 3,000 mg/day has not been adequately studied.

DOSE ADJUSTMENTS

No dose adjustment is required for gender, race, or impaired hepatic function. ■ Dose adjustment may be required in the elderly based on impaired renal function. ■ Dose adjustment in impaired renal function is calculated based on CrCl and is adjusted according to the following chart.

Levetiracetam Dose Adjustment in Adults with Impaired Renal Function		
Creatinine Clearance	Dose in mg	Frequency
>80 mL/min	500 to 1,500 mg	Every 12 hours
50 to 80 mL/min	500 to 1,000 mg	Every 12 hours
30 to 49 mL/min	250 to 750 mg	Every 12 hours
<30 mL/min	250 to 500 mg	Every 12 hours
ESRD patients on dialysis	500 to 1,000 mg	Every 24 hours*

*Administration of a 250- to 500-mg supplemental dose following dialysis is recommended.

DILUTION

Each vial contains 500 mg/5 mL (100 mg/mL). A single dose (500, 1,000, or 1,500 mg [1, 2, or 3 vials]) must be diluted in 100 mL of NS, LR, or D5W for infusion. Doses of 500, 1,000, or 1,500 mg are available prediluted in 100 mL of NS.

Filters: Specific information not available.

Storage: Store at CRT. Diluted solution stable for at least 24 hours at CRT stored in polyvinyl chloride (PVC) bags. Discard any unused portion of vial.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists solutions NS, LR, and D5W and other antiepileptic drugs lorazepam (Ativan), diazepam (Valium), and valproate sodium (Depacon) as **compatible** for at least 24 hours stored in polyvinyl chloride (PVC) bags at CRT.

RATE OF ADMINISTRATION

A single dose (500, 1,000, or 1,500 mg) properly diluted as an infusion over 15 minutes.

ACTIONS

An antiepileptic (anticonvulsant) drug. The precise mechanism of action is unknown. In animal studies it inhibited burst firing without affecting normal neuronal excitability, which suggests that it may selectively prevent hypersynchronization of epileptiform burst firing and propagation of seizure activity in human complex partial seizures. Less than 10% bound to plasma proteins. Not extensively metabolized in humans and not liver (cytochrome P₄₅₀) dependent. Half-life is 6 to 8 hours. Undergoes enzymatic hydrolysis. Primarily excreted in urine as unchanged drug and metabolites. Crossed the placental barrier in animal studies. Secreted in breast milk.

INDICATIONS AND USES

IV injection is used as a temporary alternative to oral therapy in adult patients (16 years and older). ■ Adjunctive therapy in the treatment of the following seizure types: partial-onset seizures in adults with epilepsy, myoclonic seizures in adults with juvenile myoclonic epilepsy (JME), and primary generalized tonic-clonic seizures in adults with idiopathic generalized epilepsy.

CONTRAINDICATIONS

Known hypersensitivity to levetiracetam or its active ingredients (sodium chloride, glacial acetic acid, sodium acetate trihydrate).

PRECAUTIONS

For IV use only. ■ Associated with CNS side effects (somnolence and fatigue, coordination difficulties [abnormal gait, ataxia, incoordination], and behavioral abnormalities [depression, hallucinations, psychotic symptoms, including psychosis and suicidal tendencies]). Somnolence and fatigue and coordination difficulties occurred most frequently within the first 4 weeks of treatment and resolved or improved with dose reduction or discontinuation of levetiracetam. ■ Psychotic symptoms and other behavioral changes have been reported and may include aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies. Some resolved without intervention. Others required dose reduction or discontinuation of levetiracetam. ■ To minimize the potential of increased seizure frequency, withdraw antiepileptic drugs (including levetiracetam) gradually.

Monitor: Baseline CBC and CrCl indicated; monitor as needed. Decreases in WBC, RBC, hemoglobin, and hematocrit have been reported. ■ Monitor for seizure activity. ■ Observe patient closely for signs of CNS side effects; see [Precautions](#). ■ Monitor vital signs.

Patient Education: May cause dizziness and somnolence; use caution performing tasks that require alertness (e.g., operating machinery, driving). ■ Inform your health care professional if you are pregnant or breast-feeding. ■ May cause alterations in mood (e.g., aggression, agitation, anger, anxiety, apathy, decreased ability to cope, depression, hostility, irritability, thoughts of suicide); report these changes promptly. ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry.

Maternal/Child: Category C: animal studies demonstrated fetal skeletal abnormalities and delayed offspring growth. Use during pregnancy only if potential benefit justifies the potential risk to the fetus. Manufacturer has established a pregnancy registry to evaluate safety and outcomes; see manufacturer's literature and [Patient Education](#). ■ Physiologic changes during pregnancy may decrease levetiracetam concentration. ■ Effects during labor and delivery unknown. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients younger than 16 years of age not established.

Elderly: Safety similar to that seen in younger adults; however, total body clearance is decreased and half-life is increased. ■ Reduced doses may be indicated; see [Dose Adjustments](#). Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

Manufacturer states that levetiracetam “is unlikely to produce, or be subject to, pharmacokinetic interactions.” ■ Other antiepileptic drugs (AEDs) such as carbamazepine (Tegretol), gabapentin (Neurontin), lamotrigine (Lamictal), phenobarbital (Luminal), phenytoin (Dilantin), primidone (Mysoline), and valproate (Depacon) do not influence the pharmacokinetics of levetiracetam, and it does not influence their pharmacokinetics. ■ Not an inhibitor or a substrate of cytochrome P₄₅₀ isoforms; unlikely to have interactions with drugs metabolized by these isoenzymes in the liver. ■ Minimal protein binding; unlikely to have interactions with drugs requiring protein-binding sites. ■ Has been administered with oral contraceptives, digoxin (Lanoxin), and warfarin (Coumadin) with no interference on the pharmacokinetics of either drug. ■ **Probenecid** (Benemid) decreases renal clearance and increases serum concentrations of one of the metabolites of levetiracetam.

SIDE EFFECTS

Asthenia, dizziness, infection, and somnolence occurred most frequently during the first 4 weeks of treatment. Other side effects presented anywhere from 1 to 4 weeks and include amnesia; anger; anorexia; anxiety; apathy; ataxia; cough; decreased RBC, WBC, Hct, and Hgb; depersonalization; depression; diplopia; emotional lability; headache; hostility; hypersomnia; influenza; insomnia; irritability; neck pain; nervousness; pain; paresthesia; pharyngitis; rhinitis; seizures; sinusitis; and vertigo.

Post-Marketing: Abnormal liver function tests, alopecia, choreoathetosis, dyskinesia, erythema multiforme, hepatic failure, hepatitis, leukopenia, neutropenia, pancreatitis, pancytopenia (with bone marrow suppression), Stevens-Johnson syndrome, suicidal behavior, thrombocytopenia, toxic epidermal necrolysis, and weight loss.

Overdose: Aggression, agitation, coma, depressed level of consciousness, respiratory depression, and somnolence.

ANTIDOTE

Keep physician informed of all side effects. Some may not require intervention, and others may improve with a reduced dose or discontinuation of levetiracetam; see [Precautions](#) and [Side Effects](#). Support patient as required in treatment of overdose. No specific antidote in overdose; however, hemodialysis will remove approximately 50% of a dose in 4 hours.

LEVOFLOXACIN **BBW**

(lee-voh-FLOX-ah-sin)

Antibacterial
(fluoroquinolone)**Levaquin****pH 3.8 to 5.8****USUAL DOSE**

250 to 750 mg once every 24 hours. Dose and duration of treatment are based on degree of infection and specific diagnosis. CrCl equal to or greater than 50 mL/min is required. Dose and serum levels similar by oral or IV route. Transfer to oral dose as soon as practical.

Levofloxacin Dosing Guidelines		
Type of Infection ^a	Dose Every 24 Hours	Duration (Days)
Acute Bacterial Exacerbation of Chronic Bronchitis	500 mg	7 days
Nosocomial Pneumonia	750 mg	7-14 days
Community Acquired Pneumonia	500 mg or 750 mg	7-14 days 5 days
Acute Bacterial Sinusitis	500 mg or 750 mg	10-14 days 5 days
Chronic Bacterial Prostatitis	500 mg	28 days
Complicated SSSI ^b	750 mg	7-14 days
Uncomplicated SSSI ^b	500 mg	7-10 days
Complicated UTI ^c or Acute Pyelonephritis	750 mg	5 days
Complicated UTI ^c or Acute Pyelonephritis	250 mg	10 days
Uncomplicated UTI ^c	250 mg	3 days
Inhalation Anthrax (post-exposure) and plague in adults ^d	500 mg	60 days (anthrax) 10 to 14 days (plague)
Inhalation Anthrax (post-exposure) and plague in pediatric patients >50 kg ^d	500 mg	60 days (anthrax) 10 to 14 days (plague) ^e
Inhalation Anthrax (post-exposure) and plague in pediatric patients <50 kg and ≥6 months of age ^d	8 mg/kg q 12 hr (not to exceed 250 mg/dose)	60 days (anthrax) 10 to 14 days (plague) ^e

^aDUE TO THE DESIGNATED PATHOGENS (See [Indications and Usage](#).)

^bSkin and Skin Structure Infections.

^cUrinary Tract Infections.

^dBegin drug administration as soon as possible after suspected or confirmed exposure to aerosolized *Bacillus anthracis* or to *Yersinia pestis*. If clinically indicated, higher doses of levofloxacin (e.g., equivalent to 750 mg) can be used for the treatment of plague.

^eSee [Precautions](#) and [Maternal/Child](#).

DOSE ADJUSTMENTS

Clearance is reduced and half-life is prolonged in patients with a CrCl equal to or less than 80 mL/min. See the following chart for dosing guidelines. See Important IV Therapy Facts on p. xxiii for formula to convert SCr to CrCl. ■ Supplemental doses are not required after hemodialysis or peritoneal dialysis. ■ No dose adjustment is required specifically for age, gender, race, or in impaired hepatic function.

Levofloxacin Dosing Guidelines in Impaired Renal Function			
Dosage in Normal Renal Function Every 24 hours	Creatinine Clearance 20 to 49 mL/min	Creatinine Clearance 10 to 19 mL/min	Hemodialysis or Chronic Ambulatory Peritoneal Dialysis (CAPD)
750 mg	750 mg q 48 hr	750 mg initial dose, then 500 mg q 48 hr	750 mg initial dose, then 500 mg q 48 hr
500 mg	500 mg initial dose, then 250 mg q 24 hr	500 mg initial dose, then 250 mg q 48 hr	500 mg initial dose, then 250 mg q 48 hr
250 mg	No dose adjustment required	250 mg q 48 hr; no dose adjustment required if treating uncomplicated UTI	No information on dose adjustment available

DILUTION

Available in single-use vials and as prediluted, ready-to-use infusions.

Single-use vials: Withdraw desired dose from single-use vial (10 mL for 250 mg, 20 mL for 500 mg, 30 mL for 750 mg). Each 10 mL (250 mg) must be further diluted with a minimum of 40 mL NS, D5W, D5NS, D5LR, D5/plasma-Lyte 56, D5/½NS with 0.15% KCl, or ½ M sodium lactate. Desired concentration is 5 mg/mL. No preservatives; enter vial only once. When 500-mg (20-mL) vial is used to prepare two 250-mg doses, withdraw entire contents of vial at once into separate syringes, prepare and store second dose for subsequent use.

Premix flexible containers: No further dilution necessary. Available as 250 mg in 50 mL, 500 mg in 100 mL, or 750 mg in 150 mL D5W. Instructions for access to and use of premix flexible containers are on its storage carton. Do not use flexible containers in series connections.

Filters: Not required; however, contents of both vials and premixed solutions were filtered during manufacturing with polyvinyl mixed ester cellulose filters. Size not specified by manufacturer. No significant loss of potency expected.

Storage: Store vials at CRT; protect from light. Store premix at or below 25° C (77° F); protect from freezing, light, and excessive heat. Both are stable to expiration date. Solutions diluted from vials are stable at CRT for 3 days, up to 14 days if refrigerated. May be frozen for up to 6 months. Do not force thaw (e.g., microwave or water bath) and do not refreeze. Discard any unused portion of premixed solutions and/or opened vials.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Limited **compatibility** information available; other intravenous substances, additives, or other medications should not be added to levofloxacin or infused simultaneously through the same intravenous line.” Never administer in the same IV or through the same tubing with any solution containing multivalent cations (e.g., calcium, magnesium). Flush line with a **compatible** solution before and after administration of levofloxacin and/or any other drug through the same IV line.

One source suggests the following **compatibilities**:

Y-site: Amikacin (Amikin), aminophylline, ampicillin, anidulafungin (Eraxis), bivalirudin (Angiomax), caffeine citrate (Cafcit), casprofungin (Cancidas), cefotaxime (Claforan), ceftazolin (Teflaro), clindamycin (Cleocin), daptomycin (Cubicin), dexamethasone (Decadron), dexmedetomidine (Precedex), dobutamine, dopamine, doripenem (Doribax), epinephrine (Adrenalin), fenoldopam (Corlopam), fentanyl (Sublimaze), gentamicin, hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), insulin (regular), isoproterenol (Isuprel), lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, metoclopramide (Reglan), morphine, oxacillin (Bactocill), pancuronium, penicillin G sodium, phenobarbital (Luminal), phenylephrine (NeoSynephrine), potassium chloride, sodium bicarbonate, vancomycin.

RATE OF ADMINISTRATION

Each 250- or 500-mg dose must be equally distributed over 60 minutes as an infusion. A 750-mg dose must be equally distributed over 90 minutes as an infusion. Too-rapid administration may cause hypotension. May be given through a Y-tube or three-way stopcock of infusion set. Temporarily discontinue other solutions infusing at the same site and flush tubing with **compatible** solutions before and after levofloxacin.

ACTIONS

A synthetic, broad-spectrum, fluoroquinolone antibacterial agent. Bactericidal to aerobic gram-negative and gram-positive organisms, as well as some anaerobic organisms through interference with an enzyme (topoisomerase II) needed for synthesis of bacterial DNA. May be active against bacteria resistant to aminoglycosides, beta-lactam antibiotics, and macrolides. Onset of action is prompt, and serum levels are dose related. Mean terminal half-life is 6 to 8 hours. Steady state is achieved within 48 hours. Widely distributed into body tissues, including blister fluid and lung tissues. Moderately bound to serum protein (24% to 38%). Metabolism is minimal; primarily excreted as unchanged drug in urine. Very small amounts found in bile and feces. May cross placental barrier. May be secreted in breast milk.

INDICATIONS AND USES

Treatment of adults with mild, moderate, and severe infections caused by susceptible strains of microorganisms in conditions including acute bacterial sinusitis, acute bacterial exacerbation of chronic bronchitis, and nosocomial pneumonia. ■ Treatment of community-acquired pneumonia due to many organisms, including *Streptococcus pneumoniae* (including multidrug-resistant strains (MDRSP). MDRSP strains are resistant to two or more of the following antibiotics: penicillin, second-generation cephalosporins (e.g., cefuroxime [Zinacef]), macrolides, tetracyclines, and sulfamethoxazole/trimethoprim. ■ Treatment of complicated skin and skin structure infections, mild to moderate uncomplicated skin and skin structure infections, complicated and uncomplicated urinary tract infections, and acute pyelonephritis. ■ To reduce the incidence and progression of inhalational anthrax following exposure to *Bacillus anthracis*. Begin administration as soon as possible after suspected or confirmed exposure. Transfer to oral therapy when practical. ■ Treatment of plague, including pneumonic and septicemic plague, due to *Yersinia pestis*, as well as prophylaxis for plague in adults and pediatric patients 6 months of age and older. ■ Treatment of chronic bacterial prostatitis (usually oral therapy).

CONTRAINDICATIONS

History of hypersensitivity to levofloxacin, its components, or any other quinolone antimicrobial agents (e.g., ciprofloxacin [Cipro], norfloxacin [Noroxin]).

PRECAUTIONS

For IV use only. ■ Culture and sensitivity studies indicated to determine susceptibility of the causative organism to levofloxacin. ■ *Pseudomonas aeruginosa* may develop resistance during treatment. Ongoing culture and sensitivity studies indicated. ■ The emergence of bacterial resistance to fluoroquinolones and the occurrence of cross-resistance with other fluoroquinolones have been observed and are of concern. Proper use of fluoroquinolones and other classes of antibiotics is encouraged to avoid the emergence of resistant bacteria from overuse. ■ Prolonged use may cause superinfection because of overgrowth of nonsusceptible organisms. ■ Use with caution in patients with known CNS disorders that predispose to seizures or alter seizure threshold (e.g., epilepsy, severe cerebral arteriosclerosis, concomitant drug therapy). Convulsions, toxic psychosis, increased intracranial pressure (including pseudotumor cerebri), and CNS stimulation have been reported. May cause other CNS effects, including confusion, depression, dizziness, hallucinations, tremors and, rarely, suicidal thoughts or acts. ■ Use caution in patients with impaired renal function; see **Dose Adjustments**. ■ May be used by patients who are allergic to penicillin or intolerant of macrolides (e.g., erythromycin). ■ Cross-resistance may occur with other fluoroquinolones, but some microorganisms resistant to other fluoroquinolones may be susceptible to levofloxacin. ■ Severe, sometimes fatal hepatotoxic-

ity has been reported. Symptoms appeared within 6 to 14 days of initiating therapy, and most cases were not associated with hypersensitivity and occurred in patients 65 years of age or older; see [Patient Education](#) and [Antidote](#). ■ Tendinitis and tendon rupture that required surgical repair or resulted in prolonged disability have been reported in patients of all ages receiving quinolones. Most frequently involves the Achilles tendon but has also been reported with the shoulder, hand, biceps, thumb, and other tendon sites. ■ Tendon rupture or tendinitis may occur during or after fluoroquinolone therapy. Risk may be increased in patients over 60 years of age; in patients taking corticosteroids; in patients with heart, kidney, or lung transplants; with strenuous physical activity; and in patients with renal failure or previous tendon disorders such as rheumatoid arthritis. ■ Prolongation of the QT interval on ECG and infrequent cases of arrhythmia (including torsades de pointes) have been reported. The risk of arrhythmia may be reduced by avoiding use of levofloxacin in patients with known prolongation of the QT interval, in the presence of hypokalemia, significant bradycardia, cardiomyopathy, or concurrent treatment with class IA antiarrhythmic agents (e.g., quinidine [Quinidex], procainamide [Procanbid, Procan SR]) or Class III antiarrhythmic agents (e.g., amiodarone [Nexterone], sotalol [Betapace]) and any other drug that can prolong the QT interval; avoid coadministration; see [Drug/Lab Interactions](#). ■ Fluoroquinolones have neuromuscular blocking activity and may exacerbate muscle weakness in persons with myasthenia gravis. Serious adverse events, including a requirement for ventilatory support and deaths, have been reported in these patients. **Avoid use in patients with a known history of myasthenia gravis.** ■ Rare cases of peripheral neuropathy (e.g., paresthesias, hypoesthesias, dysesthesias [impairment of sensitivity or touch], or weakness) have been reported and may lead to an irreversible condition; see [Antidote](#). ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with levofloxacin. ■ Other serious events (sometimes fatal) due to hypersensitivity or uncertain etiology have been reported with fluoroquinolones, including levofloxacin; see [Side Effects, Post-Marketing](#). Discontinue levofloxacin at the first appearance of a skin rash, jaundice, or other signs of hepatotoxicity or hypersensitivity. ■ Moderate to severe photosensitivity/phototoxicity reactions have been reported in patients receiving quinolones; see [Patient Education](#). ■ Not tested in humans for post-exposure prevention of inhalation anthrax; however, plasma concentrations are considered to be in a range to produce effective results. ■ Safety for use in adults beyond 28 days or in pediatric patients beyond 14 days not studied; use only for prescribed indication; benefits must outweigh risks. An increased incidence of musculoskeletal adverse events has been observed in pediatric patients.

Monitor: Hypersensitivity reactions, including anaphylaxis with the first or succeeding doses, has been reported in patients receiving quinolones, even in those without known hypersensitivity. Emergency equipment must always be available; see [Precautions](#). ■ Obtain baseline CBC with differential, CrCl, and blood glucose. Periodic monitoring of organ systems, including hematopoietic, hepatic, and renal, is recommended. ■ Monitor for S/S of peripheral neuropathy. Discontinue levofloxacin at the first symptoms of neuropathy (e.g., pain, burning, tingling, numbness and/or weakness) or if patient is found to have deficits in light touch, pain, temperature, position sense, vibratory sensation, and/or motor strength. ■ Maintain adequate hydration to prevent concentrated urine throughout treatment. Other quinolones have formed crystals. ■ Monitor infusion site for inflammation and/or extravasation. ■ Symptomatic hyperglycemia or hypoglycemia may occur, usually in diabetic patients receiving oral hypoglycemic agents (e.g., glyburide) or insulin. Monitor blood glucose closely. ■ See [Precautions, Drug/Lab Interactions](#), and [Antidote](#).

Patient Education: A patient medication guide is available from the manufacturer. ■ Review all medicines and disease history with pharmacist or physician before initiating treatment. ■ Inform physician of any history of myasthenia gravis. ■ Patients with a history of myasthenia gravis should avoid the use of levofloxacin. ■ Drink fluids liberally. ■ Promptly report skin rash or any other hypersensitivity reaction. ■ Promptly

report pain, burning, tingling, numbness and/or weakness in extremities. ■ Photosensitivity has occurred in a minimal number of patients, but it is best to avoid excessive sunlight or artificial ultraviolet light. May cause severe sunburn; wear protective clothing, use sunscreen, and wear dark glasses outdoors. Report a sunburn-like reaction or skin eruption promptly. ■ Dizziness or light-headedness may interfere with ambulation and motor coordination. Use caution in tasks that require alertness. ■ Effects of caffeine, theophylline preparations, and/or warfarin (Coumadin) may be increased; notify your physician if you take any of these agents. If diabetic and on medication, monitor your blood glucose carefully. If a hypoglycemia reaction occurs, discontinue levofloxacin and consult physician. ■ Promptly report S/S of liver injury (e.g., dark-colored urine, fever, itching, jaundice [yellowing of skin or whites of eyes], light-colored bowel movements, loss of appetite, nausea, right upper quadrant tenderness, tiredness, vomiting, weakness). ■ Promptly report tendon pain or inflammation; rest and refrain from exercise. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ See **Precautions, Monitor, Drug/Lab Interactions, and Antidote.**

Maternal/Child: Category C: safety for use in pregnancy not established; benefits must outweigh risks. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients under 18 years of age not established. Indicated in pediatric patients 6 months of age or older only for prevention of inhalation anthrax (post-exposure) and prevention and treatment of plague. Safety for use in pediatric patients less than 6 months of age not established. An increased incidence of musculoskeletal disorders (arthralgia, arthritis, tendinopathy, and gait abnormality) compared with controls has been observed in pediatric patients receiving levofloxacin.

Elderly: Half-life may be slightly extended due to age-related renal impairment. Dose reduction required only in the elderly with a CrCl of 50 mL/min or less. ■ Safety and effectiveness similar to that in younger adults; however, they may experience an increased risk of side effects (e.g., CNS effects, hepatotoxicity, tendinitis, tendon rupture, risk of QT prolongation). Monitoring of renal function may be useful. ■ See **Dose Adjustments and Precautions.**

DRUG/LAB INTERACTIONS

May cause ventricular arrhythmias or torsades de pointes with **drugs that prolong the QT interval**, such as class IA antiarrhythmic agents (e.g., quinidine [Quinidex], procainamide [Procanbid, Procan SR]), class III antiarrhythmic agents (e.g., amiodarone [Nexterone], sotalol [Betapace]), anticonvulsants (e.g., fosphenytoin [Cerebyx]), antihistamines (e.g., diphenhydramine [Benedryl]), astemizole (has been removed from market), antineoplastics (e.g., doxorubicin [Adriamycin]), phenothiazines (e.g., chlorpromazine [Thorazine]), serotonin reuptake inhibitors (e.g., fluoxetine [Prozac], paroxetine [Paxil]), tricyclic antidepressants (e.g., imipramine [Tofranil], amitriptyline [Elavil]). Avoid coadministration. ■ Risk of CNS stimulation and convulsive seizures may be increased with **NSAIDs** (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]). ■ May cause hyperglycemia and hypoglycemia with concurrent administration of **antidiabetic agents** (e.g., metformin [Glucophage], insulin); monitoring of blood glucose recommended. ■ Concomitant administration with **cimetidine or probenecid** reduces levofloxacin renal clearance by 24% and 35% respectively, but dose adjustment is not required. ■ Interactions with **theophylline** that occur with other quinolones have not been noted, but monitoring of theophylline levels is recommended with concomitant use. ■ Some quinolones, including levofloxacin, may enhance effects of **warfarin** (Coumadin); monitoring of PT or INR is recommended with concomitant use. ■ No dose adjustment required for either drug when levofloxacin is administered concomitantly with **cyclosporine or digoxin**. ■ See **Precautions**. ■ May cause **false-positive when testing urine for opiates**; more specific testing methods may be indicated.

SIDE EFFECTS

The most common side effects are chest pain, constipation, diarrhea, dizziness, dyspepsia, dyspnea, headache, insomnia, and nausea. Abdominal pain, edema, injection site

reaction, moniliasis, photosensitivity/phototoxicity (sun sensitivity), pruritus, rash, vaginitis, and vomiting have occurred. Abnormal dreaming, abnormal hepatic function, abnormal gait, abnormal renal function, acute renal failure, agitation, anemia, anorexia, anxiety, arthralgia, cardiac arrest, CDAD, confusion, convulsions, depression, epistaxis, esophagitis, gastritis, gastroenteritis, genital moniliasis, glossitis, granulocytopenia, hallucinations, hyperglycemia, hyperkalemia, hyperkinesias, hypersensitivity reactions, hypertonia, hypoglycemia, increased alkaline phosphatase, increased hepatic enzymes, myalgia, nightmares, palpitation, pancreatitis, paresthesia, phlebitis, pseudomembranous colitis, skeletal pain, sleep disorders, somnolence, stomatitis, syncope, tendinitis, thrombocytopenia, tremor, urticaria, ventricular arrhythmia, ventricular tachycardia, and vertigo have also been reported in fewer than 1% of patients.

Post-Marketing: Abnormal EEG; hematologic abnormalities (anemia [hemolytic and aplastic], eosinophilia, leukopenia, pancytopenia); diplopia; exacerbation of myasthenia gravis; hepatic failure, including fatal cases; fever; hepatitis; hypersensitivity reactions (sometimes fatal, including angioneurotic edema, anaphylaxis); interstitial nephritis; jaundice; leukocytoclastic vasculitis; multi-organ failure; muscle injury and increased muscle enzymes; paranoia; peripheral neuropathy; photosensitivity/phototoxicity reactions; prolonged PT; prolonged INR; prolonged QT interval; pseudotumor cerebri; psychosis; rhabdomyolysis; serum sickness; severe dermatologic reactions (e.g., toxic epidermal necrolysis [Lyell's syndrome], Stevens-Johnson syndrome); tachycardia; tendon rupture; tinnitus; vasodilation; vision blurred; visual acuity reduced; and isolated reports of allergic pneumonitis, encephalopathy, suicide attempts and suicidal ideation, and *torsades de pointes*.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically; monitor closely. Discontinue levofloxacin at the first sign of any major side effect (CDAD, CNS symptoms, dermatologic reactions, hepatotoxicity, hypersensitivity, hypoglycemic reactions, phototoxicity, symptoms of neuropathy, or tendon rupture). Treat hypersensitivity reactions as indicated with epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., Solu-Cortef), and pressor amines (e.g., dopamine). Treat CNS symptoms as indicated; may require diazepam (Valium) for seizures. Mild cases of CDAD may respond to discontinuation of levofloxacin. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Complete rest is indicated for an affected tendon until treatment is available. Maintain hydration in overdose. No specific antidote; not removed by hemodialysis or peritoneal dialysis. Maintain patient until drug is excreted and symptoms subside.

LEVOLEUCOVORIN

(lee-voh-loo-koh-**VOR**-in)

Fusilev

Folate analog
Antidote
Antineoplastic adjunct

USUAL DOSE

Dosed at one-half the usual dose of the racemic form (leucovorin calcium).

Levoleucovorin rescue after high-dose methotrexate therapy: Dose is based on a methotrexate dose of 12 Gm/M² infused over 4 hours; see methotrexate monograph. Obtain serum creatinine and methotrexate levels at least once daily. Additional hydration and urinary alkalinization (pH 7 or greater) is indicated and should be continued until the methotrexate level is less than 0.05 micromolar. Administer and/or adjust the levoleucovorin dose or extend rescue based on the following guidelines. See [Dose Adjustments](#), [Precautions](#), and [Monitor](#).

Guidelines for Levoleucovorin Administration, Adjustment, or Extension of Rescue		
Clinical Situation	Laboratory Findings	Levoleucovorin Dose and Duration
Normal methotrexate elimination	Serum methotrexate level approximately 10 micromolar at 24 hours, 1 micromolar at 48 hours, and less than 0.2 micromolar at 72 hours after methotrexate administration.	7.5 mg IV every 6 hours for 60 hours (10 doses starting at 24 hours after start of methotrexate infusion).
Delayed late methotrexate elimination	Serum methotrexate level remains above 0.2 micromolar at 72 hours and more than 0.05 micromolar at 96 hours after methotrexate administration.	Continue 7.5 mg IV every 6 hours until methotrexate level is less than 0.05 micromolar.
Delayed early methotrexate elimination and/or evidence of acute renal injury	Serum methotrexate level of 50 micromolar or more at 24 hours or 5 micromolar or more at 48 hours after methotrexate administration. OR 100% or greater increase in serum creatinine level at 24 hours after methotrexate administration (e.g., an increase from 0.5 mg/dL to a level of 1 mg/dL or more).	75 mg IV every 3 hours until methotrexate level is less than 1 micromolar; then 7.5 mg IV every 3 hours until methotrexate level is less than 0.05 micromolar.

Inadvertent methotrexate overdose: 7.5 mg IV every 6 hours (approximately 5 mg/M²) until the serum methotrexate level is less than 5×10^{-8} M (0.05 micromolar). Begin levoleucovorin rescue as soon as possible after an inadvertent methotrexate overdose and within 24 hours of methotrexate administration when there is delayed excretion. The effectiveness of levoleucovorin in counteracting toxicity may decrease as the time interval between methotrexate administration and levoleucovorin rescue increases. See [Dose Adjustments](#) and [Monitor](#).

Colorectal cancer: Several regimens are in use. See fluorouracil (5-FU) monograph for 5-FU specific information. Administer 5-FU and levoleucovorin separately to avoid the formation of a precipitate.

Consider flushing the IV line with NS between drugs.

Levoleucovorin 100 mg/M² by IV injection over a minimum of 3 minutes (see [Rate of Administration](#)) followed by **5-FU** 370 mg/M² by IV injection **or** **levoleucovorin** 10 mg/M² by IV injection followed by **5-FU** at 425 mg/M² by IV injection. Repeat either regimen daily for 5 days. This 5-day course is repeated at 4-week intervals for 2 courses and then at 4- to 5-week intervals provided that complete recovery from the toxic effects of the previous course has occurred. See [Dose Adjustments](#).

PEDIATRIC DOSE

See Usual Dose.

DOSE ADJUSTMENTS

Levoleucovorin rescue after high-dose methotrexate therapy: Some patients may have significant but less severe abnormalities in methotrexate elimination or renal function following methotrexate administration than the abnormalities described in the preceding table. These abnormalities may or may not be associated with significant clinical toxicity. If significant clinical toxicity is observed, levoleucovorin rescue should be extended for an additional 24 hours (a total of 14 doses over 84 hours) in subsequent courses of therapy. If lab abnormalities or clinical toxicities are observed, consider the possibility that the patient is taking other medications that interact with methotrexate (e.g., medications that may interfere with methotrexate elimination or binding to serum albumin [see methotrexate monograph]). ■ Delayed methotrexate excretion may also be caused by accumulation in a third space fluid collection (i.e., ascites, pleural effusion), inadequate hydration, or renal insufficiency. Higher doses of levoleucovorin or prolonged administration may be indicated.

Inadvertent methotrexate overdose: If the 24-hour serum creatinine has increased 50% over baseline or if the 24-hour methotrexate level is greater than 5×10^{-6} M (5 micromolar) or the 48-hour level is greater than 9×10^{-7} M (0.9 micromolar), increase the dose of levoleucovorin to 50 mg/M² IV every 3 hours until the methotrexate level is less than 0.05 micromolar. Hydrate with a minimum of 3 liters/day and use sodium bicarbonate for urinary alkalinization (adjust to maintain a urine pH of 7 or greater).

Colorectal cancer: In subsequent courses, adjust the dose of 5-FU based on patient tolerance of the previous treatment course. Reduce 5-FU dose by 20% for patients who experienced moderate hematologic or GI toxicity in the previous course and 30% for patients who experienced severe toxicity. 5-FU dose may be increased by 10% if no toxicity was experienced in the previous course. Levoleucovorin doses are not adjusted for toxicity.

DILUTION

Levoleucovorin for injection: Reconstitute each 50-mg vial of lyophilized powder with 5.3 mL of preservative-free NS (concentration equals 10 mg/mL). Do not use other diluents. A single dose may be further diluted immediately in NS or D5W to a concentration of 0.5 mg/mL to 5 mg/mL. Do not use if solution is cloudy or a precipitate is observed.

Levoleucovorin injection: Available in ready-to-use single-use vials containing 175 mg (17.5 mL) or 250 mg (25 mL). Concentration equals 10 mg/mL. A single dose of these solutions may be further diluted to a concentration of 0.5 mg/mL in NS or D5W.

Filters: Specific information not available.

Storage: Levoleucovorin for injection (reconstituted lyophilized powder): Store unopened vials in carton at CRT. Protect from light. Solutions reconstituted or further diluted in NS are stable for not more than 12 hours at RT. Reconstituted solutions further diluted in D5W are stable for not more than 4 hours at RT. **Levoleucovorin injection (ready-to-use solution):** Refrigerate unopened vials in carton at 2° to 8° C (36° to 46° F). Protect from light. Solutions diluted to 0.5 mg/mL in NS or D5W are stable for not more than 4 hours at RT.

COMPATIBILITY

Manufacturer states, "Due to the risk of precipitation, do not coadminister levoleucovorin with other agents in the same admixture." Dilute only with preservative-free NS; do not use other diluents or NS with preservatives.

RATE OF ADMINISTRATION

Because of the calcium content of the solution, do not exceed a rate of injection of 16 mL/min of reconstituted solution (160 mg of levoleucovorin). When given in combination with 5-FU, consider flushing the IV line with NS between drugs.

ACTIONS

A folate analog. An active isomer of 5-formyl tetrahydrofolic acid, the pharmacologically active isomer of leucovorin calcium. A replacement for leucovorin calcium, which also contains the pharmacologically inactive dextro isomer. Does not require reduction

by the enzyme dihydrofolate reductase. Actively and passively transported across cell membranes. Converted *in vivo* to the primary circulating form of active reduced folate. Levoleucovorin can counteract the therapeutic and toxic effects of folic acid antagonists such as methotrexate, which act by inhibiting dihydrofolate reductase. Terminal half-life is from 5.1 to 6.8 hours.

INDICATIONS AND USES

Levoleucovorin rescue is indicated after high-dose methotrexate therapy in patients with osteosarcoma. ■ Also indicated to diminish the toxicity and counteract the effects of impaired methotrexate elimination and of inadvertent overdose of folic acid antagonists (e.g., methotrexate, pemetrexed [Alimta]). ■ Indicated for use in combination chemotherapy with 5-fluorouracil (5-FU) in the palliative treatment of advanced metastatic colorectal cancer. ■ Not indicated for the treatment of pernicious anemia and megaloblastic anemias secondary to vitamin B₁₂ deficiency; improper use may cause a hematologic remission while neurologic manifestations continue to progress.

CONTRAINDICATIONS

Contraindicated in patients who have had previous hypersensitivity reactions to folic acid or folinic acid.

PRECAUTIONS

For IV use only; do not administer by any other route. ■ Contains calcium; limit rate of administration to no more than 16 mL/min (160 mg of levoleucovorin per minute). ■ Toxicities during combination use with 5-fluorouracil (5-FU) are similar to those observed with 5-FU alone; however, GI toxicities (particularly stomatitis and diarrhea) are observed more commonly and may be more severe or of prolonged duration. ■ Concomitant use with sulfamethoxazole/trimethoprim for the acute treatment of *Pneumocystis jiroveci* pneumonia in patients with HIV infection may cause treatment failure and morbidity.

Monitor: All situations with methotrexate: Obtain baseline serum methotrexate, serum creatinine, electrolytes, and urine pH. Monitor at least daily. ■ Adequate hydration and maintenance of a urinary pH of 7 or greater with sodium bicarbonate is indicated.

Levoleucovorin rescue after high-dose methotrexate therapy: Patients who experience delayed early methotrexate elimination are likely to develop reversible renal failure. Continuing hydration and urinary alkalization and close monitoring of fluid and electrolyte status is required until the serum methotrexate level has fallen to below 0.05 micromolar and the renal failure has resolved.

Inadvertent methotrexate overdose: See [Dose Adjustments](#); hydration with a minimum of 3 liters/day and the use of sodium bicarbonate for urinary alkalization (adjust to maintain a urine pH of 7 or greater) may be indicated.

Combination with 5-FU: Monitor for S/S of GI toxicity. See the 5-fluorouracil monograph for hematologic monitoring requirements.

Maternal/Child: Category C: use during pregnancy only if clearly needed. ■ Not known if levoleucovorin is excreted in human milk; has potential for harmful effects; discontinue breast-feeding.

Elderly: Studies of levoleucovorin in the treatment of osteosarcoma did not include adults age 65 or older. ■ Dehydration, diarrhea, and severe enterocolitis have been reported in elderly patients receiving weekly levoleucovorin and 5-fluorouracil (5-FU).

DRUG/LAB INTERACTIONS

May ameliorate the hematologic toxicity associated with **high-dose methotrexate**, but levoleucovorin has no effect on other established toxicities of methotrexate, such as nephrotoxicity resulting from drug and/or metabolite precipitation in the kidney. ■ Folic acid in large amounts may counteract the antiepileptic effects of **phenobarbital** (Luminal), **phenytoin** (Dilantin), and **primidone** (Mysoline). Seizure activity may be increased in susceptible patients. Levoleucovorin may or may not have the same effect due to shared metabolic pathways; use caution when administering concurrently with anticonvulsant

drugs. ■ Small amounts of systemically administered levoleucovorin may enter the cerebrospinal fluid (CSF). **Do not give levoleucovorin intrathecally**; see **Precautions**. ■ Increases the toxicity of **5-fluorouracil (5-FU)**; dehydration, diarrhea, and severe enterocolitis have been reported in elderly patients receiving weekly levoleucovorin and 5-fluorouracil. ■ Concomitant use with **sulfamethoxazole/trimethoprim** for the acute treatment of *Pneumocystis jiroveci* pneumonia in patients with HIV infection may cause treatment failure and morbidity. ■ High doses of levoleucovorin may reduce the effectiveness of intrathecally administered **methotrexate**. ■ Levoleucovorin may enhance the toxic effects of **capecitabine (Xeloda)**; monitor closely.

SIDE EFFECTS

Nausea and vomiting and stomatitis were reported most commonly. Abnormal renal function, confusion, dermatitis, diarrhea, dyspepsia, dyspnea, hypersensitivity reactions, leukopenia, neuropathy, thrombocytopenia, typhlitis (inflammation of the cecum), and taste perversion have been reported.

Combination therapy with 5-fluorouracil (5-FU): Abdominal pain, alopecia, anorexia, dermatitis, diarrhea, fatigue, nausea, stomatitis, vomiting. Hypersensitivity reactions have been reported.

Post-Marketing: Dyspnea, pruritus, rash, rigors, temperature change.

ANTIDOTE

Keep physician informed of patient's condition. Symptomatic treatment indicated.

LEVOTHYROXINE SODIUM **BBW**(lee-voh-thigh-**ROX**-een **SO**-dee-um)**Hormone**
(thyroid)**T₄, L-Thyroxine****USUAL DOSE**

When oral ingestion is not practical, IV dose should be ½ of any previously established oral dose; see **Indications, Limitations of Use**. Adjust in small increments as indicated. Initiate oral treatment as soon as possible.

Hypothyroidism (when oral therapy is not possible): Usual IV starting dose would be 6.25 to 12.5 mcg/day. Increase in increments of 12.5 mcg every 2 to 4 weeks. Base dosing on clinical response and serum thyroid and TSH levels. Average maintenance dose is 50 to 100 mcg/day PO.

Myxedema coma: 300 to 500 mcg as an initial dose. Follow with once-daily intravenous maintenance doses between 50 and 100 mcg.

PEDIATRIC DOSE

Given orally (may be crushed in food or liquid). See **Precautions**. Any IV dose should be 50% to 75% of the established oral dose. See pediatric literature for dosing guidelines.

DOSE ADJUSTMENTS

Age, general condition, cardiac risk factors, and clinical severity of myxedema symptoms should be considered when determining the starting and maintenance dosages.

■ Reduce dose in elderly, functional or ECG evidence of cardiovascular disease (including angina), long-standing thyroid disease, other endocrinopathies, and severe hypothyroidism. ■ See **Drug/Lab Interactions**.

DILUTION

Available in different strengths; read label carefully. Each vial of lyophilized powder is diluted with 5 mL of NS for injection (without preservatives). Shake well to dissolve completely. Reconstituted concentrations will be 20 mcg/mL for the 100-mcg vial and 100 mcg/mL for the 500-mcg vial. Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set.

Storage: Store dry product at CRT and protect from light. Reconstituted solution is preservative-free and stable for 4 hours; any remaining solution is discarded.

COMPATIBILITY

Manufacturer states, “Do not add to other IV fluids.”

RATE OF ADMINISTRATION

100 mcg or fraction thereof over 1 minute.

ACTIONS

A synthetic thyroid hormone. Effective replacement for decreased or absent thyroid hormone. Thyroid hormone synthesis and secretion is regulated by the hypothalamic-pituitary-thyroid axis. Thyroid hormones regulate multiple metabolic processes and play an essential role in normal growth and development. Actions are produced predominantly by T₃ (triiodothyronine). Approximately 80% of T₃ is derived from T₄ (levothyroxine) by deiodination in peripheral tissues. The metabolic actions of thyroid hormones include augmentation of cellular respiration and thermogenesis, as well as metabolism of proteins, carbohydrates, and lipids. Circulating thyroid hormones are greater than 99% bound to plasma proteins (thyroxine-binding globulin [TBG], thyroxine-binding prealbumin [TBPA], and albumin [TBA]). The higher affinity of both TBG and TBPA for T₄ partially explains the higher serum levels, slower metabolic clearance, and longer half-life of T₄ (6 to 8 days) compared with T₃ (less than 2 days). The major pathway of thyroid hormone metabolism is through sequential deiodination. The liver is the major site of degradation for both T₄ and T₃. Primary route of elimination is through the kidneys. Small amounts are eliminated into the bile and feces.

INDICATIONS AND USES

Treatment of myxedema coma. ■ Specific replacement therapy for reduced or absent thyroid function due to any cause (usually given orally).

Limitations of use: The relative bioavailability between oral and intravenous levothyroxine sodium for injection has not been established but has been estimated to be between 48% and 74%. Caution should be used when switching patients from oral products to the parenteral product because adequate dosing conversions have not been studied.

CONTRAINDICATIONS

Manufacturer states, “None.” ■ Not indicated for use in treatment of obesity. Risk can outweigh benefit.

PRECAUTIONS

Excessive bolus doses (greater than 500 mcg) are associated with cardiac complications, particularly in the elderly and in patients with underlying cardiac disease; see [Dose Adjustments](#). ■ Patients with undiagnosed endocrine disorders (e.g., adrenal insufficiency, hypopituitarism, diabetes insipidus) may experience new or worsening symptoms of these endocrinopathies. Patients should be treated with replacement glucocorticoids prior to initiation of treatment with levothyroxine until adrenal function has been adequately assessed. Failure to do so may precipitate an acute adrenal crisis when thyroid hormone therapy is initiated as a result of increased metabolic clearance of glucocorticoids by thyroid hormone. Patients with myxedema coma should be monitored for previously undiagnosed diabetes insipidus. ■ Not indicated for treatment of obesity or for weight loss. Doses within the range of daily hormonal requirements are ineffective for weight reduction. Larger doses may produce serious or even life-threatening manifestations of toxicity, particularly when given in conjunction with sympathomimetic amines, such as those used for the anorectic effects.

Monitor: Observe patient closely and monitor vital signs. ■ Monitor thyroid function tests (e.g., free T_4 index, TSH). ■ TSH and thyroid hormone levels should be measured a few weeks after switching from IV to oral therapy. Adjust dose according to results and clinical status. ■ Monitor TSH every 6 to 8 weeks until normalized, every 8 to 12 weeks after dose changes, and every 6 to 12 months throughout therapy.

Maternal/Child: Category A: may be used during pregnancy. ■ Presumed safe in breastfeeding; use caution and observe infant. ■ Myxedema coma is a disease of the elderly. An approved oral dosage form should be used in pediatric patients for maintaining a euthyroid state in noncomplicated hypothyroidism; see [Pediatric Dose](#).

Elderly: See [Dose Adjustments](#); more sensitive to effects. Atrial fibrillation is a common side effect associated with levothyroxine treatment in the elderly.

DRUG/LAB INTERACTIONS

Addition of levothyroxine to **antidiabetic or insulin** therapy may result in increased antidiabetic or insulin requirements. Monitor glucose values closely, especially when thyroid therapy is initiated, changed, or discontinued. ■ Levothyroxine increases response to **oral anticoagulant** therapy (e.g., warfarin). Reduction in dose of oral anticoagulant may be required. Monitor PT/INR. ■ May decrease therapeutic effects of **digoxin**, necessitating an increase in the digoxin dose. Monitor serum digoxin levels. ■ Concurrent use of **tricyclic** (e.g., amitriptyline) or **tetracyclic** (e.g., maprotiline) **antidepressants** and levothyroxine may increase the therapeutic and toxic effects of both drugs, possibly due to increased receptor sensitivity to catecholamines. ■ Administration of **sertraline** in patients stabilized on levothyroxine may result in increased levothyroxine requirements. ■ Concurrent use with **ketamine** may produce marked hypertension and tachycardia. Use caution. ■ Concurrent use with **sympathomimetics** (e.g., epinephrine, norepinephrine) may increase the effects of sympathomimetics or thyroid hormone. May increase risk of coronary insufficiency. ■ **Carbamazepine, fosphenytoin, phenytoin, and rifampin** may decrease the serum concentration of thyroid hormones. Monitor levels closely. ■ Levothyroxine can increase the metabolism of **theophylline**, necessitating an increase in theophylline dose. Monitor theophylline levels. ■ Changes in TBG concentration must be considered when interpreting T_3 and T_4 values, which necessitates measurement and

evaluation of unbound (free) hormone and/or determination of the free levothyroxine index. Several medications and disease states can alter TBG concentrations. See manufacturer's prescribing information.

SIDE EFFECTS

Abdominal cramps, angina, arrhythmias, chest pain, diarrhea, heart palpitations, heat intolerance, increased pulse and BP, insomnia, menstrual irregularities, muscle cramps, nervousness, sweating, tachycardia, tremors, vomiting, and weight loss.

ANTIDOTE

Notify the physician of any side effect. A reduction in dose will usually decrease symptoms. Supportive treatment should be initiated as dictated by the patient's medical status.

LIDOCAINE HYDROCHLORIDE

Antiarrhythmic

(LYE-doh-kayn hy-droh-KLOR-eyed)

Lidocaine PF, Xylocaine PF, Xylocard 

pH 5 to 7

USUAL DOSE

Ventricular arrhythmia: 50 to 100 mg as a **loading dose** (0.7 to 1.4 mg/kg). Repeat after 5 minutes if desired clinical response is not produced. Follow with an infusion of 1 to 4 mg/min (0.014 to 0.057 mg/kg/min). Should not exceed 200 to 300 mg/hr.

Refractory ventricular fibrillation or pulseless ventricular tachycardia: 1 to 1.5 mg/kg of body weight (50 to 100 mg) as a **loading dose**. May repeat 0.5 to 1.5 mg/kg every 5 to 10 minutes to desired effect, up to a total of 3 mg/kg. Should not exceed 200 to 300 mg/hr. AHA recommends 0.5 to 0.75 mg/kg up to 1 to 1.5 mg/kg. A dose of 0.5 to 0.75 mg/kg may be repeated every 5 to 10 minutes to a maximum total dose of 3 mg/kg.

Maintenance dose: With return of perfusion, initiate an infusion of 20 to 50 mcg/kg/min (1 to 4 mg/min in an average 70-kg adult). **Do not exceed 4 mg/min rate.** If arrhythmias occur during an infusion, give a small bolus of 0.5 mg/kg to increase plasma concentration.

Seizures unresponsive to other therapy (unlabeled): 1 mg/kg as a loading dose. If seizure does not terminate in 2 minutes, give an additional 0.5 mg/kg to prevent recurrences; a maintenance infusion of 30 mcg/kg/min has been used. Another source suggests a loading dose of 100 mg. Give an additional 50 mg in 20 minutes. Follow with a maintenance infusion of 1 to 3 mg/min. Reduce infusion rate gradually based on patient response; complete withdrawal may take several days.

Cardiac arrest: AHA guidelines recommend a single dose of 1 to 1.5 mg/kg. An additional dose of 0.5 to 0.75 mg/kg may be given in 5 to 10 minutes to a maximum of 3 doses or a total dose of 3 mg/kg.

PEDIATRIC DOSE

See **Maternal/Child** (unlabeled).

Antiarrhythmic: AHA recommends 1 mg/kg as an IV injection followed immediately by an infusion of 20 to 50 mcg/kg/min (average of 30 mcg/kg/min). If 15 minutes have elapsed since the initial bolus dose before the infusion is started, administration of an additional bolus (1 mg/kg/min) is recommended when the infusion is initiated. Another source recommends 1 mg/kg IV. May repeat in 10 to 15 minutes \times 2 if indicated. Maximum total dose is 3 to 4.5 mg/kg/hr. Follow with an infusion of 20 to 50 mcg/kg/min. Intratracheal dose suggested should be 2 to 2.5 times the IV dose.

DOSE ADJUSTMENTS

Reduce loading dose in digoxin toxicity with AV block. ■ Consider loading dose reduction (not universally recommended) in congestive heart failure, reduced cardiac output

and liver disease. ■ Lower-end initial doses may be indicated in the elderly based on potential for decreased organ function and concomitant disease or drug therapy. ■ Reduce maintenance dose by one half in presence of decreased cardiac output (e.g., acute MI, congestive heart failure, or shock from any cause), impaired liver function, the elderly (over 65), and in patients receiving drugs that may decrease clearance of lidocaine or decrease liver blood flow (e.g., beta-blockers [propranolol, cimetidine (Tagamet)]). ■ Reduce maintenance dose after 24 hours or monitor blood levels; half-life of lidocaine increases with prolonged administration.

DILUTION

Label must state, “for IV use” and be preservative free. Bolus dose may be given undiluted.

Infusion: Add 1 Gm of lidocaine to 500 or 250 mL of D5W (preferred), D5½NS, D5NS, LR, or other **compatible** solutions; see chart on inside back cover. Solution gives 2 or 4 mg/mL of lidocaine. Available prediluted (2, 4, or 8 mg/mL). Titrate to desired response.

Pediatric infusion: Add 120 mg of lidocaine to 100 mL of diluent (1,200 mcg/mL). 1 to 2.5 mL/kg/hr will deliver 20 to 50 mcg/kg/min.

Storage: Store at CRT. Discard diluted solution after 24 hours. Store prediluted products at RT; avoid excessive heat and protect from freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Additives should not be introduced into premixed solutions of lidocaine.

One source suggests the following **compatibilities**:

Additive: *Physically compatible with numerous drugs. Combination may not be practical because of extensive individualized rate adjustments of lidocaine to achieve desired effects; consult pharmacist.* Alteplase (Activase, tPA), aminophylline, amiodarone (Nexterone), atracurium (Tracrium), calcium chloride, calcium gluconate, chloramphenicol (Chloromycetin), chlorothiazide (Diuril), ciprofloxacin (Cipro IV), dexamethasone (Decadron), digoxin (Lanoxin), diphenhydramine (Benadryl), dobutamine, dopamine, ephedrine sulfate, erythromycin (Erythrocin), fentanyl (Sublimaze), flumazenil (Rozacon), furosemide (Lasix), heparin, hydrocortisone sodium succinate (Solu-Cortef), nafcillin (Nallpen), nitroglycerin IV, penicillin G potassium, pentobarbital (Nembutal), phenylephrine (Neo-Synephrine), potassium chloride (KCl), procainamide (Pronestyl), prochlorperazine (Compazine), ranitidine (Zantac), sodium bicarbonate, sodium lactate, theophylline, verapamil.

Y-site: Alteplase (Activase, tPA), amiodarone (Nexterone), argatroban, bivalirudin (Angiomax), cefazolin (Ancef), ceftazolin (Teflaro), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), daptomycin (Cubicin), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, dopamine, enalaprilat (Vasotec IV), etomidate (Amidate), famotidine (Pepcid IV), fenoldopam (Corlopam), heparin, hetastarch in electrolytes (Hexextend), hydrocortisone sodium succinate (Solu-Cortef), labetalol, levofloxacin (Levaquin), linezolid (Zyvox), meperidine (Demerol), micafungin (Mycamine), morphine, nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, palonosetron (Aloxi), potassium chloride (KCl), propofol (Diprivan), remifentanyl (Ultiva), theophylline, tigecycline (Tygacil), tirofiban (Aggrastat), vasopressin, warfarin (Coumadin).

RATE OF ADMINISTRATION

Bolus dose: 25 to 50 mg or fraction thereof over 1 minute. Too-rapid injection may cause seizures.

Infusion: Using a microdrip (60 gtt/mL) or an infusion pump delivers lidocaine in recommended doses. Adjust as indicated by progress in patient's condition. See [Dose Adjustments](#) and the [Infusion Rate](#) chart.

Lidocaine Infusion Rates						
Desired Dose	1 Gm in 500 mL Diluent (2 mg/mL)			1 Gm in 250 mL Diluent (4 mg/mL)		
	mg/min	mg/hr	mL/min	mL/hr	mg/hr	mL/min
1	60 mg/hr	0.5 mL/min	30 mL/hr	60 mg/hr	0.25 mL/min	15 mL/hr
2	120 mg/hr	1 mL/min	60 mL/hr	120 mg/hr	0.5 mL/min	30 mL/hr
3	180 mg/hr	1.5 mL/min	90 mL/hr	180 mg/hr	0.75 mL/min	45 mL/hr
4	240 mg/hr	2 mL/min	120 mL/hr	240 mg/hr	1 mL/min	60 mL/hr
Pediatric infusion: 120 mg to 100 mL diluent = 1,200 mcg/mL 1 to 2.5 mL/kg/hr = 20 to 50 mcg/kg/min						

ACTIONS

A local anesthetic agent. Exerts an antiarrhythmic effect similar to procainamide but is more potent. Decreases ventricular excitability. In usual therapeutic doses, produces no change in myocardial contractility, systemic arterial pressure, or absolute refractory period by increasing the stimulation threshold of the ventricle during diastole. Decreases cell membrane permeability and prevents loss of sodium and potassium ions. Onset of action should occur within 2 minutes and last approximately 10 to 20 minutes. Crosses placental barrier. Metabolized in the liver and excreted in the urine.

INDICATIONS AND USES

Treatment of ventricular arrhythmias (e.g., PVCs, ventricular tachycardia [VT], ventricular fibrillation [VF]) occurring during acute myocardial infarction or during cardiac manipulations, such as cardiac surgery. ■ Wide-complex tachycardia of uncertain origin. ■ Wide-complex PSVT.

Unlabeled uses: Pediatric cardiac arrest, seizures unresponsive to other therapy.

CONTRAINDICATIONS

Known sensitivity to lidocaine or any other local anesthetic of the amide type. Patients with Wolff-Parkinson-White syndrome, Stokes-Adams syndrome, or severe degrees of sinoatrial, atrioventricular, or intraventricular block. ■ Solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Oral antiarrhythmic drugs are preferred for maintenance. ■ Use caution in patients with severe liver or renal disease; accumulation may occur and lead to toxicity, especially with repeated use. ■ Use caution in hypovolemia, shock, all forms of heart block, and untreated bradycardia. ■ Systemic toxicity may result in CNS depression (sedation) or irritability (twitching). May progress to frank convulsions with respiratory depression and/or arrest. ■ Vasopressors (e.g., dopamine) may be used if circulatory depression occurs. ■ Has been associated with malignant hyperthermia. ■ Hypersensitivity reactions, including anaphylaxis, have been reported.

Monitor: Monitor IV flow rate and the patient's ECG continuously. Therapeutic serum levels range from 1.5 to 5 mcg/mL; above 6 mcg/mL is usually toxic. ■ Monitor electrolytes, fluid balance, and acid-base balance. ■ Half-life increases over time. Reduce dose of continuous infusion after 24 hours and monitor blood levels. ■ Keep patient lying down to reduce hypotensive effects. ■ Discontinue lidocaine when patient's cardiac condition is stable or any signs of toxicity become apparent. ■ Keep a bolus dose, 100 mg (5 mL), available at all times for emergency use in myocardial infarction. ■ Monitor for S/S of hypersensitivity (e.g., large hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face).

Patient Education: May cause dizziness; remain at bed rest; request assistance if ambulation permitted.

Maternal/Child: Category B: use during pregnancy only if clearly needed. ■ Safety for use in breast-feeding and pediatric patients not established.

Elderly: Lower-end initial dosing and/or mg/kg dose may be appropriate. See **Dose Adjustments**. ■ Decreased lidocaine clearance and increased sensitivity to adverse effects. ■ Consider age-related renal and hepatic impairment.

DRUG/LAB INTERACTIONS

Cross-sensitivity and/or potentiation may occur with **other antiarrhythmics** (e.g., procainamide or quinidine); may cause conduction abnormalities. ■ **Amiodarone** (Nexterone), **beta-blocking agents** (e.g., propranolol), and **cimetidine** (Tagamet) may decrease lidocaine clearance and increase lidocaine toxicity. ■ Monitor cardiac function. ■ May produce excessive cardiac depression with **phenytoin** (Dilantin). ■ Potentiates neuromuscular blockade of **muscle relaxants** (e.g., succinylcholine) and **aminoglycoside antibiotics** (e.g., gentamicin). ■ Use caution in patients with **digitalis toxicity** and AV block. ■ Effects may be altered by **smoking**; monitor carefully.

SIDE EFFECTS

Transient because of short duration of action of lidocaine.

Apprehension; blurred vision; confusion; dizziness; “doom” anxiety; drowsiness; edema; euphoria; hallucinations; light-headedness; methemoglobinemia; mood changes; nervousness; sensations of heat, cold, and numbness; slurred speech; tinnitus; urticaria; vomiting.

Major: Anaphylaxis, bradycardia, cardiac arrest, cardiovascular collapse, convulsions, hypotension, malignant hyperthermia (tachycardia, tachypnea, metabolic acidosis, fever), PR interval prolonged, QRS complex widening, respiratory depression, tremors, twitching, unconsciousness.

ANTIDOTE

Notify the physician of any side effects. For major side effects, discontinue the drug immediately and institute appropriate measures. Ensure patency of airway and adequacy of ventilation. Treat anaphylaxis immediately with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol (Ventolin), IV fluids, and ventilation equipment as indicated. To correct CNS stimulation use diazepam (Valium), rapid ultra-short-acting barbiturates (e.g., thiopental [Pentothal]), or if under anesthesia, muscle relaxants (e.g., succinylcholine). Use vasopressors (e.g., dopamine) and IV fluids to correct hypotension. Maintain and support patient; resuscitate as necessary.

LINEZOLID

(lih-NAY-zoh-lid)

**Antibacterial
(oxazolidinone)****Zyvox****USUAL DOSE**

Dose and duration of therapy are based on diagnosis and designated pathogens. May be transferred to oral dosing when appropriate; no dose adjustment is necessary. See **Precautions**.

Recommended Linezolid Doses in Pediatric and Adult Patients

Infection*	Dosage and Route of Administration		Recommended Duration of Treatment (Consecutive Days)
	Pediatric Patients† (Birth Through 11 Years of Age)	Adults and Adolescents (12 Years of Age and Older)	
Complicated skin and skin structure infections	10 mg/kg IV or PO‡ q 8 hr	600 mg IV or PO‡ q 12 hr	10 to 14
Community-acquired pneumonia, including concurrent bacteremia			
Nosocomial pneumonia			
Vancomycin-resistant <i>Enterococcus faecium</i> infections, including concurrent bacteremia	10 mg/kg IV or PO‡ q 8 hr	600 mg IV or PO‡ q 12 hr	14 to 28
Uncomplicated skin and skin structure infections	Less than 5 years: 10 mg/kg PO‡ q 8 hr 5-11 years: 10 mg/kg PO‡ q 12 hr	Adults: 400 mg PO‡ q 12 hr Adolescents: 600 mg PO‡ q 12 hr	10 to 14

*Due to the designated pathogens (see **Indications and Uses** and package insert).

†Neonates less than 7 days of age: Most preterm neonates less than 7 days of age (gestational age less than 34 weeks) have lower systemic linezolid clearance values and larger AUC values than many full-term neonates and older infants. These neonates should be initiated with a dosing regimen of 10 mg/kg q 12 hr. Consideration may be given to the use of 10 mg/kg q 8 hr regimen in neonates with a suboptimal clinical response. All neonatal patients should receive 10 mg/kg q 8 hr by 7 days of life.

‡Oral dosing using either linezolid tablets or linezolid for oral suspension.

PEDIATRIC DOSE

See **Usual Dose** and **Maternal/Child**.

DOSE ADJUSTMENTS

Dose adjustment based on age, gender, renal insufficiency, or hepatic insufficiency is not required. ■ 30% of a dose is removed during a 3-hour dialysis session. Administer linezolid after hemodialysis.

DILUTION

Available in ready-to-use flexible plastic infusion bags in a foil laminate overwrap. Available as a 2 mg/mL solution in 200-, 400-, and 600-mg infusion bags. Prior to use, remove overwrap and check for leaks by squeezing the bag. Do not use flexible containers in series connections.

Storage: Store at CRT. Protect from light and freezing. Keep in overwrap until ready to use. Solution may exhibit a yellow color that can intensify with time. Will not adversely affect potency.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Additives should not be added to the infusion bag.” If administered through the same tubing as other medications, flush line before and after infusion of linezolid with a solution that is **compatible** with linezolid (e.g., D5W, NS, LR) and with any medications administered through the common line. Manufacturer lists as **incompatible** at the **Y-site** with amphotericin B (conventional), ceftriaxone (Rocephin), chlorpromazine (Thorazine), diazepam (Valium), erythromycin (Erythrocin), pentamidine, phenytoin (Dilantin), and sulfamethoxazole/trimethoprim.

One source suggests the following **compatibilities**:

Solutions: D5W, NS, LR.

Additive: *Not recommended by manufacturer.* Aztreonam (Azactam), cefazolin (Ancef), ceftazidime (Fortaz), ciprofloxacin (Cipro IV), gentamicin, levofloxacin (Levaquin), tobramycin.

Y-site: Acyclovir (Zovirax), alfentanil (Alfenta), amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), aztreonam (Azactam), buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), caspofungin (Cancidas), cefazolin (Ancef), cefotetan, ceftiofloxacin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cyclosporine (Sandimmune), cytarabine (ARA-C), dexamethasone (Decadron), dexmedetomidine (Precedex), digoxin (Lanoxin), diphenhydramine (Benadryl), dobutamine, dopamine, doripenem (Doribax), doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), fluorouracil (5-FU), furosemide (Lasix), ganciclovir (Cytovene), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), labetalol, leucovorin calcium, levofloxacin (Levaquin), lidocaine, lorazepam (Ativan), magnesium sulfate, mannitol, meperidine (Demerol), meropenem (Merrem IV), mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), midazolam (Versed), mitoxantrone (Novantrone), morphine, nalbuphine, naloxone (Narcan), nifedipine (Cardene IV), nitroglycerin IV, ondansetron (Zofran), paclitaxel (Taxol), pentobarbital (Nembutal), phenobarbital (Luminal), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), propranolol, ranitidine (Zantac), remifentanyl (Ultiva), sodium bicarbonate, sufentanil (Sufenta), theophylline, tigecycline (Tygacil), tobramycin, vancomycin, vasopressin, vecuronium, verapamil, vincristine, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Administer as an infusion over 30 to 120 minutes. Flush line before and after administration if indicated; see **Compatibility**.

ACTIONS

A synthetic antibacterial agent. The first agent of a new class of antibiotics, the oxazolidinones. Clinically useful in the treatment of infections caused by aerobic gram-positive bacteria. See **Indications and Uses** and manufacturer’s literature. Inhibits bacterial protein synthesis through a mechanism of action different from that of other antibacterial agents; therefore, cross-resistance between linezolid and other classes of antibiotics is unlikely. Bacteriostatic against enterococci and staphylococci. Bactericidal against most strains of streptococci. Readily distributes into well-perfused tissues. Metabolized to two inactive metabolites. Metabolic pathway is not fully understood. Half-life is 4.8 hours. Approximately 30% of a dose is excreted in the urine as linezolid and 50% is excreted as metabolites.

INDICATIONS AND USES

Treatment of adults, adolescents, and other pediatric patients with the following infections caused by susceptible strains of the designated microorganisms: vancomycin-resistant *Enterococcus faecium* infections, including cases with concurrent bacteremia; nosocomial pneumonia caused by *Staphylococcus aureus* (methicillin-susceptible and methicillin-resistant strains) or *Streptococcus pneumoniae* (including multidrug-resistant strains [MDRSP]); complicated skin and skin-structure infections (including diabetic foot infections without concomitant osteomyelitis) caused by *Staphylococcus aureus* (methicillin-susceptible and methicillin-resistant strains), *Streptococcus pyogenes*, or *Streptococcus agalactiae*; uncomplicated skin and skin-structure infections caused by *Staphylococcus aureus* (methicillin-susceptible strains only) or *Streptococcus pyogenes*; and community-acquired pneumonia caused by *Streptococcus pneumoniae* (including multidrug-resistant strains [MDRSP] and cases with concurrent bacteremia) or *Staphylococcus aureus* (methicillin-susceptible strains only). ■ Treatment of decubitus ulcers has not been studied. ■ Given orally to treat uncomplicated skin and skin-structure infections. ■ Not indicated for treatment of gram-negative infections. Critical that specific gram-negative therapy be initiated immediately if a concomitant gram-negative pathogen is documented or suspected. ■ Not approved for and should not be used for treatment of patients with catheter-related bloodstream infections or catheter-site infections.

CONTRAINDICATIONS

History of hypersensitivity to linezolid or any of its components. ■ Avoid use in patients taking any medicinal products that inhibit monoamine oxidase A or B (e.g., isocarboxazid [Marplan], phenelzine [Nardil]) or within 2 weeks of taking any such product. ■ Unless closely monitored for potential increases in BP, avoid use in patients with uncontrolled hypertension, pheochromocytoma, or thyrotoxicosis and/or in patients taking any of the following types of medications: directly and indirectly acting sympathomimetic agents (e.g., pseudoephedrine [Sudafed]), vasopressive agents (e.g., epinephrine [Adrenalin], norepinephrine [Levophed]), dopaminergic agents (e.g., dobutamine, dopamine); see [Precautions](#) and [Drug/Lab Interactions](#). ■ Unless closely monitored for S/S of serotonin syndrome or neuroleptic malignant syndrome–like (NMS-like) reactions, avoid use in patients with carcinoid syndrome and/or in patients taking any of the following medications: serotonin reuptake inhibitors (e.g., fluoxetine [Prozac], sertraline [Zoloft]), tricyclic antidepressants (e.g., amitriptyline [Elavil]), serotonin 5-HT₁ receptor agonists (e.g., triptans [e.g., sumatriptan (Imitrex)]), meperidine (Demerol), or buspirone (BuSpar); see [Precautions](#) and [Drug/Lab Interactions](#).

PRECAUTIONS

Culture and sensitivity studies are indicated to determine susceptibility of the causative organism to linezolid. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, linezolid should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Reports of vancomycin-resistant *Enterococcus faecium* (VRE) becoming resistant to linezolid during its clinical use have been published. ■ There has been a report of methicillin-resistant *Staphylococcus aureus* (MRSA) developing resistance to linezolid during its clinical use. ■ Combination therapy may be clinically indicated in treatment of nosocomial pneumonia or complicated skin and skin-structure infections if the documented or presumptive pathogens include gram-negative organisms. ■ Should not be used for treatment of patients with catheter-related bloodstream infections or catheter site infections. ■ Myelosuppression (including anemia, leukopenia, pancytopenia, and thrombocytopenia) has been reported; see [Monitor](#). ■ Hypoglycemia, including symptomatic episodes, has been reported in patients with diabetes who have been treated with insulin or oral hypoglycemic agents and linezolid; see [Monitor](#) and [Drug/Lab Interactions](#). ■ Use with caution in patients with renal failure. Although dose adjustments are not recommended in this patient population, the metabolites may accumulate. The clinical significance of this accumulation is unknown. Dose should be given after hemodialysis. ■ Use with caution in patients with uncontrolled hypertension, severe hepatic insufficiency, pheochromocytoma,

toma, carcinoid syndrome, or untreated hyperthyroidism; see **Contraindications**. Use has not been studied in these patient populations. ■ Safety and efficacy of linezolid given for longer than 28 days have not been evaluated. ■ Neuropathy (peripheral and optic) has been reported, primarily in patients treated for longer than the maximum recommended duration of 28 days. May occur in patients treated with linezolid for shorter periods, as well as in patients treated for more than 28 days. ■ Superinfection, caused by the overgrowth of nonsusceptible organisms, may occur with antibiotic use. Treat as indicated. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with linezolid. ■ Lactic acidosis has been reported. In most cases, patients experienced repeated episodes of N/V. ■ Serotonin syndrome (e.g., cognitive dysfunction, hyperpyrexia, hyperreflexia, incoordination) has been reported in patients receiving linezolid and concomitant serotonergic agents; see **Drug/Lab Interactions**. ■ Convulsions have been reported; however, a history of seizures was reported in some of the cases. ■ See **Monitor, Patient Education**, and **Drug/Lab Interactions**.

Monitor: CBC with differential and platelet count should be monitored weekly, especially in patients who receive linezolid for longer than 2 weeks; those with pre-existing myelosuppression; those receiving concomitant drugs that produce bone marrow suppression (e.g., antineoplastics [cisplatin (Platinol), gemcitabine (Gemzar)], chloramphenicol, immunosuppressants [e.g., azathioprine (Imuran)]) or affect platelet function (e.g., aspirin, epoprostenol [Flolan], NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], platelet aggregation inhibitors [e.g., abciximab (ReoPro), clopidogrel (Plavix), dipyridamole (Persantine), eptifibatid (Integrilin)], selected antibiotics [e.g., piperacillin], valproic acid [Depacon, Depakene]); or those with a chronic infection who have received previous or concomitant antibiotics. Consider discontinuing therapy in patients who develop or have worsening myelosuppression. Myelosuppression appears to be reversible following discontinuation of linezolid. ■ Monitor patients with diabetes who are receiving insulin or hypoglycemic agents for hypoglycemia; see **Drug/Lab Interactions**. ■ Prompt ophthalmic evaluation is recommended in patients taking linezolid for extended periods (3 months or more) or if symptoms of visual impairment appear (e.g., blurred vision, changes in visual acuity or color vision, or visual field defect). ■ Monitor for S/S of lactic acidosis (e.g., recurrent N/V, unexplained acidosis, or a low bicarbonate level); immediate medical evaluation is indicated. ■ Monitor for S/S of serotonin syndrome (cognitive dysfunction, hyperpyrexia, hyperreflexia, incoordination) when administered concurrently with serotonergic agents; see **Drug/Lab Interactions**. ■ Monitor dietary intake of tyramine; see **Patient Education**. Hypertension may result from excessive tyramine intake (less than 100 mg/day). ■ See **Precautions and Drug/Lab Interactions**.

Patient Education: Avoid foods or beverages high in tyramine (e.g., aged cheeses, fermented or air-dried meats, sauerkraut, soy sauce, tap beers, red wines). ■ Inform physician of any history of hypertension or seizures. See **Precautions**. ■ Inform physician if taking any medications containing pseudoephedrine or phenylpropanolamine (found in many cold or allergy preparations or diet aids), if taking serotonin re-uptake inhibitors (e.g., fluoxetine [Prozac], sertraline [Zoloft], paroxetine [Paxil]) or other antidepressants, or if taking an antidiabetic agent (e.g., insulin or an oral hypoglycemic agent). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Report any vision changes promptly. See **Drug Interactions**.

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding not established; benefits must outweigh risks. ■ Volume of distribution is similar regardless of age in pediatric patients; however, clearance varies as a function of age. Clearance is most rapid in the youngest age-groups (ranging from less than 1 week old to 11 years of age), resulting in lower single-dose systemic exposure (AUC) and shorter half-life. ■ AUC values in patients from birth to 11 years of age dosed every 8 hours are similar

to adolescents and adults dosed every 12 hours. ■ Therapeutic concentrations are not consistent in CSF; not indicated for empiric treatment of CNS infections in pediatric patients.

Elderly: No overall difference in safety or effectiveness has been observed between these patients and younger patients. Pharmacokinetics are not significantly altered in the elderly. See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Linezolid is a reversible, nonselective inhibitor of monoamine oxidase and therefore has the potential to interact with **adrenergic and serotonergic agents and with tyramine-containing foods**. ■ A reversible enhancement of the pressor response to **indirect-acting sympathomimetic agents or vasopressor or dopaminergic agents** (e.g., pseudoephedrine [Sudafed], phenylpropranolamine, epinephrine [Adrenalin], dopamine) may be seen with concomitant use. Initial doses of adrenergic agents, such as epinephrine or dopamine, should be reduced and titrated to achieve the desired response; see [Contraindications](#). ■ Serotonin syndrome has been reported in patients receiving concurrent therapy with linezolid and **selective serotonin reuptake inhibitors** (SSRIs) (e.g., citalopram [Celexa], escitalopram [Lexapro], fluoxetine [Prozac], fluvoxamine [Luvox], paroxetine [Paxil], sertraline [Zoloft], and vilazodone [Viibryd]) or **serotonin norepinephrine reuptake inhibitors** (SNRIs) (e.g., duloxetine [Cymbalta], desvenlafaxine [Pristiq], venlafaxine [Effexor]). Linezolid use in patients taking serotonergic drugs should be limited to life-threatening or urgent situations in which linezolid is considered to be the drug of choice (e.g., treatment of vancomycin-resistant enterococcus [VRE] infections, serious infections such as nosocomial pneumonia, or complicated skin and skin structure infections, including cases caused by MRSA). Patients receiving both therapies should be monitored for the development of serotonin syndrome (e.g., blushing, cognitive dysfunction, confusion, delirium, diaphoresis, hyperpyrexia, restlessness, and tremors). If S/S of serotonin syndrome develop, consider discontinuing either the linezolid or the serotonergic agent. If the serotonergic agent is discontinued, specific symptoms due to the discontinuation may be observed; see prescribing information for the specific agent; see [Contraindications](#). ■ May cause hypoglycemia with **insulin or hypoglycemic agents**. Dose reduction or discontinuation of the antidiabetic agent and/or discontinuation of linezolid may be indicated. ■ Does not appear to induce, inhibit, or be induced by the cytochrome P₄₅₀ system and should therefore not affect drugs metabolized by this system (e.g., warfarin [Coumadin], phenytoin [Dilantin]); however, coadministration with **rifampin** (Rifadin) led to an observed reduction in linezolid plasma concentrations. The mechanism is unclear. **Other strong inducers of hepatic enzymes** (e.g., carbamazepine [Tegretol], phenytoin [Dilantin], phenobarbital [Luminal]) may also cause a decrease in linezolid concentration. ■ Has been coadministered with aztreonam (Azactam) and gentamicin. When linezolid was coadministered with either one of these agents, no alteration of pharmacokinetics occurred in either drug. ■ Severe myelosuppression may occur with **bone marrow suppressants and other drugs that affect platelet function**; see [Monitor](#).

SIDE EFFECTS

Most common side effects are diarrhea, headache, and nausea. Other reported side effects include abdominal pain; CDAD; constipation; dizziness; dysgeusia (change in sense of taste); dyspepsia; fever; hypertension; increased AST, BUN, SCr, total bilirubin; insomnia; lactic acidosis; myelosuppression (anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia); neuropathy (peripheral and optic [optic neuropathy may progress to vision loss]); oral moniliasis; pruritus; rash; seizures; serotonin syndrome (cognitive dysfunction, hyperpyrexia, hyperreflexia, lack of coordination); tongue discoloration; vaginal moniliasis; and vomiting.

Post-Marketing: Anaphylaxis, angioedema, bullous skin disorders such as Stevens-Johnson syndrome, hypoglycemia (including symptomatic episodes), and superficial tooth and tongue discoloration.

ANTIDOTE

Keep physician informed of all side effects. Discontinue drug if indicated. If S/S of serotonin syndrome develop, consider discontinuing linezolid or the serotonergic agent. Consider discontinuing linezolid in patients who develop or have worsening myelosuppression. Mild cases of CDAD may respond to discontinuation of linezolid. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. In the event of an overdose, initiate supportive care and maintain glomerular filtration. Both linezolid and its metabolites are partially removed by hemodialysis.

LIOTHYRONINE SODIUM **BBW**(lye-oh-**THIGH**-roh-neen **SO**-dee-um)**Hormone**
(thyroid)**T₃, Triostat****pH 9.5 to 11.5****USUAL DOSE**

Preadministration testing and adjunctive therapy with corticosteroids required (see [Precautions/Monitor](#)).

Initial and subsequent doses must be determined on the basis of continuous monitoring of clinical condition and response to liothyronine therapy. An adequate dose is important in determining clinical outcome.

Myxedema coma: 25 to 50 mcg as an initial dose. At least 4 hours but no more than 12 hours should elapse between doses; allows sufficient time to evaluate response and avoids fluctuation in hormone levels. Myxedematous patients have an increased sensitivity to thyroid hormones. Begin with lower doses and increase gradually. Use caution in adjusting dose to avoid large changes that may precipitate adverse cardiovascular events. A total daily dose of 65 mcg/day in the initial days of treatment has decreased mortality. Experience with doses above 100 mcg/day is limited.

Transfer to oral therapy: Initiate oral therapy as soon as condition is stabilized and patient is able to take oral medications. With oral liothyronine, discontinue IV liothyronine and begin with low doses. Increase gradually based on response. If levothyroxine (L-thyroxine, T₄) is used, discontinue IV therapy gradually to compensate for several-day delay in effectiveness of oral levothyroxine.

DOSE ADJUSTMENTS

Reduce initial dose to 10 to 20 mcg in known or suspected cardiovascular disease. ■ Begin with lower doses in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy. ■ See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted. Available as 10 mcg/mL in 1-mL vials.

Storage: Must be refrigerated until administration. Discard unused portion.

COMPATIBILITY

Specific references not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Each 10 mcg or fraction thereof over 1 minute.

ACTIONS

A synthetic form of the natural thyroid hormone triiodothyronine (T₃). Enters peripheral tissues readily and binds to specific nuclear receptor(s) to initiate hormonal, metabolic effects. Affinity for these receptors is 10-fold higher than prohormone T₄ (levothyroxine) and no additional conversion (T₄ to T₃) is required. Increases metabolic rate and reverses the loss of consciousness, hypothermia, lactic acidosis, and other symptoms of myxedema coma. Thyroid hormones have many beneficial effects on general metabolism and

the cardiovascular system. Liothyronine produces a detectable metabolic response in 2 to 4 hours. Achieves maximum therapeutic response within 48 hours. Has a rapid cutoff of activity, permitting quick dose adjustments and/or control of overdose. Metabolized in the liver to an inactive metabolite. Does not readily cross the placental barrier. Minimal secretion in breast milk.

INDICATIONS AND USES

Treatment of myxedema coma and precoma (patient not completely unconscious). ■ May be used in patients allergic to desiccated thyroid or thyroid extract derived from pork or beef.

CONTRAINDICATIONS

Concomitant use with artificial patient rewarming; generally contraindicated in diagnosed but uncorrected adrenal cortical insufficiency or untreated thyrotoxicosis; hypersensitivity to any components (no documented evidence of true hypersensitivity idiosyncratic reactions). Not indicated for use in treatment of obesity or male or female infertility without hypothyroidism. Risk can outweigh benefit.

PRECAUTIONS

For IV use only. ■ Myxedema coma is a medical emergency usually precipitated in a hypothyroid patient by illness, sedatives, or anesthetics. Has a 50% to 70% mortality rate even with aggressive therapy. ■ Use with caution in presence of any compromised cardiac function or cardiac disease, particularly of the coronary arteries. ■ May precipitate a hyperthyroid state or may aggravate existing hyperthyroidism. ■ Due to the rarity of myxedema coma and precoma, no systematic studies have been performed with IV liothyronine.

Monitor: Confirm diagnosis with serum TSH (greater than 60 mcU/mL), serum total T₄ and free T₄ (low), and serum total T₃ and free T₃ (normal or low). Repeat as indicated to evaluate response to treatment. ■ ECG, chest x-ray, CBC, AST, CPK, LDH, lipids, serum electrolytes, serum cortisol, cerebrospinal fluid examination, and EEG are helpful before dose administration. Monitor progress by repeat evaluations at selected intervals. ■ Correct adrenocortical insufficiency before administration or acute adrenal crisis and death may result. Corticosteroids (e.g., dexamethasone [Decadron], methylprednisolone [Solu-Medrol]) should be administered routinely in the initial emergency treatment of all myxedema coma patients; required before starting liothyronine or simultaneously with administration in pituitary myxedema; recommended in primary myxedema. During therapy metabolism increases at a greater rate than adrenocortical activity; can precipitate adrenocortical insufficiency and shock; corticosteroids may be needed throughout therapy. ■ In any patient with compromised cardiac function, monitoring of cardiac function is required. ■ Assisted or artificial ventilation may be required. ■ Treatment should correct electrolyte disturbances, possible infection, or other illness. ■ IV fluids will be required, but use caution to prevent cardiac decompensation and be alert for water intoxication from inappropriate secretion of ADH. ■ Do not rewarm patient artificially; may further decrease circulation to vital internal organs and increase shock. Normal body temperature can be restored in 24 to 48 hours by preventing heat loss. Keep patient covered with blankets in a warm room. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category A: clinical experience does not indicate adverse effect on fetus. ■ Observe infant carefully for any adverse symptoms if breast-feeding; minimal amounts secreted in breast milk. ■ Experience with pediatric patients under 18 years of age is limited; safety and effectiveness not established.

Elderly: Response similar to other age-groups; however, may be more sensitive to effects. Evaluate carefully for any occult cardiac disease; see [Precautions/Monitor](#). ■ Reduced dose may be indicated; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Metabolic requirements are markedly reduced in hypothyroid patients. Concomitant use with **vasopressors** (e.g., epinephrine, dopamine) may increase risk of coronary insufficiency, arrhythmias, or circulatory collapse. Use lower doses and extreme caution. ■ Observe any patient previously stabilized on **anticoagulants** carefully; dose reduction may be

required. Monitor PT. ■ Increased doses of **insulin or oral hypoglycemics** may be required. ■ Higher doses of levothyroxine may be required with **estrogens or estrogen-containing oral contraceptives** in the patient with a nonfunctioning thyroid. ■ May cause transient cardiac arrhythmias with **tricyclic antidepressants** (e.g., imipramine [Tofranil]). ■ May potentiate toxic effects of **digoxin**, whereas increased metabolism may require a higher digoxin dose. ■ Hypertension and tachycardia are probable with **ketamine anesthesia**. Be prepared to treat promptly. ■ Pregnancy, as well as many drugs (e.g., androgens, corticosteroids, estrogens, estrogen oral contraceptives, iodine preparations, salicylates) in combination with thyroid preparations, **interfere with accurate interpretation of lab tests**. Consult with lab personnel.

SIDE EFFECTS

Average dose: Arrhythmia (6%), cardiopulmonary arrest (2%), hypotension (2%), myocardial infarction (2%), tachycardia (3%). Angina, congestive heart failure, fever, hypertension, phlebitis, and twitching occurred in 1% or less.

Overdose: Acute myocardial infarction, angina pectoris, arrhythmia, congestive heart failure, headache, increased bowel motility, irritability, menstrual irregularities, nervousness, shock, sweating, tachycardia, thyroid storm, tremor.

ANTIDOTE

Keep physician informed of all side effects. If side effects progress or overdose occurs, reduce or temporarily discontinue liothyronine. Restart at lower doses when feasible. Treatment is symptomatic and supportive. Oxygen and artificial ventilation may be required. Treat increased sympathetic activity with beta-adrenergic antagonists (e.g., esmolol [Brevibloc]). Monitor fever, hypoglycemia, and fluid loss and treat as needed. Digoxin (Lanoxin) may be required in congestive heart failure.

LORAZEPAM(lor-**AYZ**-eh-pam)

Benzodiazepine

Sedative-hypnotic

Antianxiety agent

Anticonvulsant

Amnestic

Skeletal muscle relaxant

Antiemetic

Ativan, Lorazepam PF**USUAL DOSE**

Dose must be individualized, especially when used in conjunction with other medications that may cause CNS depression. See [Dose Adjustments](#), [Precautions](#), and [Drug/Lab Interactions](#).

Antianxiety/amnestic: 2 mg or 0.044 mg/kg of body weight, whichever is smaller, 15 to 20 minutes before procedure. For greater lack of recall 0.05 mg/kg up to 4 mg may be given. 2 mg is usually the maximum dose for patients over 50 years of age.

Sedation: 2 mg as the initial dose (may not be necessary if patient is receiving intermittent benzodiazepines [e.g., diazepam, midazolam]). Follow with an infusion of 0.5 to 1 mg/hr (0.25 to 0.5 mg/hr if less agitated or has cardiorespiratory problems). Titrate to achieve adequate sedation. Increase in 1 mg/hr increments. Up to 5 to 10 mg/hr has been used. When sedation is adequate, reduce to lowest amount needed.

Status epilepticus: 4 mg as the initial dose. May repeat once in 10 to 15 minutes if seizures continue. Experience with further doses is very limited. Additional intervention (e.g., concomitant administration of phenytoin) may be required. Another source suggests 0.05 mg/kg of body weight to a total dose of 4 mg. May repeat once in 10 to 15 min. If still not effective, use another anticonvulsant agent (e.g., phenytoin). Do not exceed a total dose of 8 mg in 12 hours.

High-dose therapy for refractory status epilepticus (unlabeled): With continuous EEG monitoring, begin a continuous infusion of lorazepam at 1 mg/hr. Increase by 1 mg/hr at 15-minute intervals until patient is seizure free. Maintain seizure-free state with lorazepam for 24 hours. Use therapeutic doses of phenytoin and phenobarbital in addition to lorazepam. At the end of 24 hours, begin to reduce the lorazepam by 1 mg/hr at hourly intervals. Observe closely and monitor EEG for signs of recurrent seizures. Repeat process if seizures recur.

Management of emetic-inducing chemotherapy (unlabeled): 0.025 mg/kg to 0.05 mg/kg (maximum dose is 4 mg) 30 minutes before chemotherapy is begun. Supplement with oral lorazepam 1 to 2 mg/hr as needed. Another source suggests 1.5 mg/M² (up to a maximum of 3 mg/M²) over 5 minutes. Administer 30 to 45 minutes before administration of antineoplastic agent. May be given in combination with other antiemetics (e.g., ondansetron [Zofran], dexamethasone). Repeat every 4 hours as needed.

PEDIATRIC DOSE

Safety for use in pediatric patients under 12 years of age has not been fully studied, but it has been used for status epilepticus in neonates, infants, and children; see [Maternal/Child](#).

Sedation: 0.05 mg/kg up to a maximum of 2 mg/dose every 4 to 8 hours.

Status epilepticus (unlabeled): Neonates, infants, and children: 0.05 to 0.1 mg/kg up to a maximum of 4 mg/dose. May repeat 0.05 mg/kg once in 5 to 10 minutes if needed.

Antiemetic, adjunct therapy (unlabeled): 0.02 to 0.05 mg/kg/dose up to a maximum of 2 mg/dose. May repeat every 6 hours as needed.

DOSE ADJUSTMENTS

Start with a small dose in the elderly and increase gradually based on response. Consider the potential for decreased organ function and concomitant disease or drug therapy. ■ Dose adjustments are not required with impaired liver function. ■ Dose adjust-

ments are not required with impaired renal function unless frequent doses are given over a short period of time. ■ Reduced dose may be indicated in the presence of other CNS depressants. ■ Reduce dose by 50% when given concurrently with probenecid (Benemid) or valproate (Depacon). ■ See [Drug/Lab Interactions](#).

DILUTION

IV injection: Dilute immediately before use with an equal volume of SWFI, D5W, or NS. Do not shake vigorously, will result in air entrapment. Gently invert repeatedly until completely in solution. May be given by IV injection or through Y-tube or three-way stopcock of infusion tubing.

Infusion (unlabeled): Has been further diluted in D5W or NS and given as an infusion. Best solubility is in concentrations of 0.1 mg/mL or 0.2 mg/mL.

Lorazepam Guidelines for Dilution and Infusion				
Base Concentration	2 mg/mL		4 mg/mL	
Desired Concentration	0.1 mg/mL	0.2 mg/mL	0.1 mg/mL	0.2 mg/mL
Volume of diluent required for each 1 mL lorazepam	19 mL	9 mL	39 mL	19 mL

Very viscous; mix well and observe for crystallization. Crystallization does occur and is thought to be due to propylene glycol preservative. May occur more frequently in NS than in D5W and with 4-mg/mL vials of lorazepam base than with 2-mg/mL vials. Prepare only enough to last for 12 hours. If necessary for fluid restriction, a 2-mg/mL vial has been stable for 24 hours when diluted in a 1 mg (lorazepam base) to 1 mL diluent (D5W preferred). Monitor carefully.

Storage: Refrigerate before dilution; protect from light. Use only freshly prepared solutions; discard if discolored or precipitate forms. Infusions stable at room temperature for 12 hours in plastic, 24 hours in glass.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), albumin (Albuminar), allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), amiodarone (Nexterone), amphotericin B cholesteryl (Amphotec), atracurium (Tracrium), bivalirudin (Angiomax), bumetanide, caspofungin (Cancidas), cefotaxime (Claforan), ceftazolin (Teflaro), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cladribine (Leustatin), dexamethasone (Decadron), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), epinephrine (Adrenalin), erythromycin (Erythrocin), etomidate (Amidate), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), fosphenytoin (Cerebyx), furosemide (Lasix), gemcitabine (Gemzar), gentamicin, granisetron (Kytrel), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), labetalol, levofloxacin (Levaquin), linezolid (Zyvox), melphalan (Alkeran), methadone (Dolophine), metronidazole (Flagyl IV), micafungin (Mycamine), midazolam (Versed), milrinone (Primacor), morphine, nicardipine (Cardene IV), nitroglycerin IV, norepinephrine (Levophed), oxaliplatin (Eloxatin), paclitaxel (Taxol), palonosetron (Aloxi), pancuronium, pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sulfamethoxazole/trimethoprim, tacrolimus (Prograf), teniposide (Vumon), thiotepa, vancomycin, vecuronium, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

IV injection: Each 2 mg or fraction thereof over 1 to 5 minutes.

Infusion: Use a microdrip or infusion pump for accuracy to deliver desired dose and/or titrate to desired level of sedation.

Pediatric rate: 1 mg or fraction thereof over 2 to 5 minutes.

ACTIONS

A benzodiazepine with antianxiety, sedative, and anticonvulsant effects. Inhibits ability to recall events. Interacts with the GABA-benzodiazepine receptor complex in the brain. Effective in 15 to 30 minutes. Effects last an average of 6 to 8 hours, but may last as long as 12 to 24 hours. Half-life is 9.5 to 19.5 hours. Distributed in body fluids. Metabolized by the liver to inactive metabolites; some is slowly excreted in urine. Crosses the placental barrier. Excreted in breast milk.

INDICATIONS AND USES

Preanesthetic medication for adult patients. ■ Produce sedation, relieve anxiety, and provide anterograde amnesia. ■ Management of status epilepticus.

Unlabeled uses: High-dose therapy for status epilepticus clinically or EEG diagnosed as refractory to high doses of phenytoin and phenobarbital. ■ Management of emetic-inducing chemotherapy. ■ Antipanic agent. ■ Treatment of alcohol withdrawal. ■ Amnesic during endoscopic procedures. ■ Skeletal muscle relaxant adjunct. ■ Treatment of tension headaches.

CONTRAINDICATIONS

Hypersensitivity to benzodiazepines (diazepam [Valium]) or the components (e.g., polyethylene glycol, propylene glycol, or benzyl alcohol). Patients with acute narrow angle glaucoma, sleep apnea syndrome, or severe respiratory insufficiency (except patients requiring relief of anxiety and/or diminished recall of events while being mechanically ventilated). Intra-arterial injection.

PRECAUTIONS

Rapidly and completely absorbed IM. ■ When given as a sedative, patient is able to respond to simple instructions. ■ Increased risk of respiratory depression; airway support, emergency drugs, and equipment must be immediately available. ■ Dependence is possible with prolonged use or high dose. ■ Use with extreme caution in the elderly, the very ill, or patients with limited pulmonary reserve; risk of hypoventilation and/or hypoxic cardiac arrest is increased. ■ Use as a premedicant before local or regional anesthesia may cause excessive drowsiness and interfere with assessment of levels of anesthesia. More likely to occur with doses greater than 0.05 mg/kg or when narcotic agents are used concomitantly. ■ Use with caution in patients with mild to moderate renal or hepatic disease. ■ There have been reports of possible propylene and polyethylene glycol toxicity (e.g., lactic acidosis, hyperosmolality, hypotension, acute tubular necrosis) when lorazepam has been administered at higher than recommended doses. Patients with renal impairment may be at increased risk of developing toxicity. Paradoxical reactions may occur. ■ See *Antidote* (e.g., risk of seizure with flumazenil).

Monitor: To reduce incidence of thrombophlebitis, avoid smaller veins. Extravasation is hazardous; arterial administration may cause arteriospasm and gangrene and/or require amputation. ■ Bed rest required for a minimum of 3 hours after IV injection and assistance required for up to 8 hours. ■ Monitor and maintain patent airway. Respiratory assistance and flumazenil (Romazicon) must be available. ■ Establish an IV and monitor vital signs. **Status epilepticus:** In addition to the above, observe for and correct any other possible cause of seizure (e.g., hypoglycemia, hyponatremia, other metabolic disorders). ■ Sedative effects may add to the impairment of consciousness seen in the postictal state (e.g., after a seizure). ■ Neurologic consult is suggested for any patient who fails to regain consciousness.

Patient Education: May produce drowsiness or dizziness; request assistance with ambulation and use caution performing tasks that require alertness for 24 to 48 hours or until the effects of the drug have subsided. ■ Avoid use of alcohol or other CNS depressants (e.g., antihistamines, barbiturates) for 24 to 48 hours or until the effects of the drug have sub-

sided. ■ May be habit-forming with long-term use or high-dose therapy. ■ Has amnesic potential; may impair memory. ■ Consider birth control options.

Maternal/Child: Category D: avoid pregnancy. May cause fetal damage. Not recommended during pregnancy, labor and delivery, breast-feeding, or in pediatric patients under 12 years of age. ■ Has FDA approval for treatment of status epilepticus in adults over 18 years of age. Safety for use in pediatric patients has not been fully studied, but has been used for status epilepticus in neonates, infants, and children. ■ May cause paradoxical excitement in pediatric patients. ■ Seizure activity and myoclonus have been reported in low-birth-weight neonates. ■ Contains benzyl alcohol, which has been associated with a fatal “gaspig syndrome” in neonates. ■ Half-life prolonged in pediatric patients.

Elderly: Dosing should be cautious in the elderly; see [Dose Adjustments](#). ■ More sensitive to therapeutic and adverse effects (e.g., ataxia, dizziness, oversedation). ■ IV injection may be more likely to cause apnea, bradycardia, CNS depression, hypotension, respiratory depression, and cardiac arrest. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

DRUG/LAB INTERACTIONS

Concurrent use with **other CNS depressants** such as alcohol, antihistamines, barbiturates, MAO inhibitors (e.g., selegiline [Eldepryl]), narcotics (e.g., morphine, meperidine [Demerol], fentanyl), phenothiazines (e.g., prochlorperazine [Compazine]), and tricyclic antidepressants (e.g., imipramine [Tofanil-PM]) may result in additive effects for up to 48 hours. Reduced dose may be indicated. ■ Concurrent administration with **valproate** (Depacon) or **probenicid** (Benemid) will decrease clearance of lorazepam. Reduce dose of lorazepam by one half in patients receiving concurrent valproate or probenicid. ■ Apnea, arrhythmia, bradycardia, cardiac arrest, coma, and death have been reported when used concurrently with **haloperidol** (Haldol). ■ Significant hypotension, respiratory depression, and stupor have been reported (rare) with concomitant use of **loxapine** (Loxapac). ■ May increase serum concentrations of **digoxin and phenytoin** (Dilantin); monitor digoxin and phenytoin serum levels. ■ Use with **rifampin** (Rifadin) increases clearance and reduces effects of benzodiazepines. ■ **Theophyllines** (Aminophylline) antagonize the sedative effects of benzodiazepines. ■ Marked sedation, salivation, ataxia and, rarely, death have been reported with concomitant use of **clozapine** (Clozaril) and lorazepam. ■ Estrogen-containing **oral contraceptives** increase clearance and decrease effects. ■ Inhibits antiparkinson effectiveness of **levodopa**. ■ Incidence of hallucinations and irrational behavior and an increased incidence of sedation have been observed with concurrent use of scopolamine.

SIDE EFFECTS

Airway obstruction, apnea, blurred vision, confusion, crying, delirium, depression, excessive drowsiness, hallucinations, hypotension, injection site reaction, respiratory depression, restlessness, somnolence.

Overdose: Ataxia, coma, hypotension, hypotonia, hypnosis, and very rarely death.

ANTIDOTE

Notify physician of all symptoms. Reduction of dose may be required. Treat hypotension with dopamine or norepinephrine (Levophed). In overdose, flumazenil (Romazicon) will reverse all sedative effects of benzodiazepines. See flumazenil monograph (risk of seizures). A patent airway, artificial ventilation, oxygen therapy, and other symptomatic and supportive treatment must be instituted promptly. Monitor vital signs and fluid status carefully. Forced diuresis and osmotic diuretics (e.g., mannitol) may increase rate of lorazepam elimination. The value of dialysis has not been adequately determined.

LYMPHOCYTE IMMUNE GLOBULIN **BBW**

Immunosuppressant

(LIM-foh-sight ih-MUNE GLAW-byoo-lin)

Anti-Thymocyte Globulin [Equine], Atgam

pH 6.8

USUAL DOSE

Intradermal skin test required before administration. Use 0.1 mL of a 1:1,000 dilution in NS and a saline control. If a systemic reaction (rash, dyspnea) occurs, do not administer. If a limited reaction (10 mm wheal or erythema) occurs, proceed with extreme caution. Anaphylaxis can occur even if skin test is negative.

Range is 10 to 30 mg/kg of body weight/24 hr. Actual potency and activity may vary from lot to lot. Given concomitantly with other immunosuppressive therapy (antimetabolites such as azathioprine [Imuran] and corticosteroids).

Delay onset of renal allograft rejection: 15 mg/kg/24 hr for 14 days, then every other day for 7 more doses. Initial dose should be given 24 hours before or after the transplant.

Treat allograft rejection: 10 to 15 mg/kg/24 hr for 14 days, then every other day for 7 more doses (optional). Initial dose should be given when first rejection episode is diagnosed.

Aplastic anemia: 10 to 20 mg/kg/24 hr for 8 to 14 days. Additional alternate-day therapy up to a total of 21 doses may be given.

PEDIATRIC DOSE

Experience with pediatric patients is limited and unlabeled. Intradermal skin test required; see **Usual Dose**. Has been administered to treat aplastic anemia, to manage renal allograft rejection, and to delay onset of renal allograft rejection using mg/kg doses recommended for adults.

DILUTION

Total daily dose must be further diluted with NS, D5/1/4NS, or D5/1/2NS for infusion. Invert solution while injecting drug so contact is not made with air in infusion bottle. Gently rotate diluted solution. Do not shake. Concentration should not exceed 4 mg/mL. May be infused into a vascular shunt, AV fistula, or high-flow central vein.

Filters: Use of a 0.2- to 1-micron filter recommended.

Storage: Keep refrigerated before and after dilution. Discard diluted solution after 24 hours.

COMPATIBILITY

Manufacturer states lymphocyte immune globulin may precipitate in dextrose solutions and may be unstable with highly acidic solutions.

RATE OF ADMINISTRATION

A total daily dose equally distributed over a minimum of 4 hours.

ACTIONS

A lymphocyte-selective immunosuppressant. Reduces the number of thymus-dependent lymphocytes and contains low concentrations of antibodies against other formed elements in blood. Effective without causing severe lymphopenia. Supports an increase in the frequency of resolution of an acute rejection episode. Has a serum half-life of 5 to 8 days.

INDICATIONS AND USES

Management of allograft rejection in renal transplant patients. ■ Adjunctive to other immunosuppressive therapy to delay onset of initial rejection episode. ■ Treatment of moderate to severe aplastic anemia in patients who are not candidates for bone marrow transplant.

CONTRAINDICATIONS

Systemic hypersensitivity reaction to previous injection of lymphocyte immune globulin or any other equine gamma-globulin preparation.

PRECAUTIONS

Administered only under the direction of a physician experienced in immunosuppressive therapy and management of renal transplant patients in a facility with adequate laboratory and supportive medical resources. ■ Use caution in repeated courses of therapy; observe for signs of hypersensitivity reactions.

Monitor: Will cause chemical phlebitis in peripheral veins. ■ Monitor carefully for signs of infection, leukopenia, or thrombocytopenia. Thrombocytopenia is usually transient in renal transplant patients. Platelet transfusions may be necessary in patients with aplastic anemia. Notify physician immediately so prompt treatment can be instituted and/or drug discontinued. ■ Prophylactic antibiotics may be indicated pending results of C/S. ■ Masked reactions may occur as dose of corticosteroids and antimetabolites is decreased. Observe carefully. ■ Antihistamines (e.g., diphenhydramine [Benadryl]) may be required to control itching. ■ Anaphylaxis can occur at any time. Monitor closely for S/S of a hypersensitivity reaction. Emergency equipment and supplies must be at bedside.

Patient Education: See Appendix D, p. 1255.

Maternal/Child: Category C: no studies conducted in pregnant patients. Use caution. ■ Safety for use in breast-feeding not established. ■ Limited experience on use in pediatric patients; see [Pediatric Dose](#).

DRUG/LAB INTERACTIONS

See [Monitor](#).

SIDE EFFECTS

Full range of hypersensitivity reactions, including anaphylaxis, is possible. Arthralgia, back pain, chest pain, chills, clotted AV fistula, diarrhea, dyspnea, fever, headache, hypotension, infusion site pain, leukopenia, nausea, night sweats, pruritus, rash, stomatitis, thrombocytopenia, thrombophlebitis, urticaria, vomiting, wheal and flare. Other reactions occur in fewer than 1% of patients.

ANTIDOTE

Notify physician of all side effects. Discontinue if anaphylaxis, severe and unremitting thrombocytopenia, and/or severe and unremitting leukopenia occur; see [Monitor](#). May be discontinued if infection or hemolysis present even if appropriately treated. Clinically significant hemolysis may require erythrocyte transfusion, IV mannitol, furosemide, sodium bicarbonate, and fluids. Prophylactic or therapeutic antihistamines (e.g., diphenhydramine [Benadryl]) or corticosteroids should control chills caused by release of endogenous leukocyte pyrogens. Treat anaphylaxis immediately. Epinephrine (Adrenalin), diphenhydramine (Benadryl), oxygen, vasopressors (e.g., dopamine), corticosteroids, and ventilation equipment must always be available. Resuscitate as necessary.

MAGNESIUM SULFATE

(mag-NEE-see-um SUL-fayt)

Electrolyte replenisher
Anticonvulsant
Antiarrhythmic
Uterine relaxant

pH 5.5 to 7

USUAL DOSE

Individualize dose based on patient requirement and response. Discontinue as soon as desired response is obtained.

Eclampsia: 4 Gm (32 mEq [40 mL of a 10% solution]) over 3 to 4 minutes. Subsequent doses may be given IM every 4 hours as needed, or a continuous infusion of 1 to 2 Gm/hr may be initiated. Do not exceed 30 to 40 Gm/24 hr. Frequent monitoring required; see [Dose Adjustments](#), [Precautions](#), and [Monitor](#).

Seizures associated with epilepsy, glomerulonephritis, or hypothyroidism: 1 Gm.

Hypomagnesemia (mild): 1 Gm every 6 hours for 4 doses.

Hypomagnesemia (severe): 5 Gm (40 mEq) in 1,000 mL D5W or NS as an infusion evenly distributed over 3 hours.

Hyperalimantation in adults: 8 to 24 mEq/24 hr (1 to 3 Gm).

Paroxysmal atrial tachycardia (unlabeled): 3 to 4 Gm (30 to 40 mL of a 10% solution) over 30 seconds with extreme caution. Reserve for patients in whom simpler measures have failed and in whom there is no evidence of myocardial damage.

Reduction of cerebral edema (unlabeled): 2.5 Gm (25 mL of a 10% solution).

Cardiac arrest (hypomagnesemia or torsades de pointes): AHA recommends 1 to 2 Gm (2 to 4 mL of a 50% solution) diluted in 10 mL D5W.

Torsades de pointes (with pulses) or AMI with hypomagnesemia: AHA recommends a loading dose of 1 to 2 Gm in 50 to 100 mL D5W as an infusion over 5 to 60 minutes. Follow with an infusion of 0.5 to 1 Gm/hr and titrate to control the torsades.

Refractory ventricular tachycardia/ventricular fibrillation (unlabeled): A loading dose of 1 to 2 Gm (8 to 16 mEq) in 50 to 100 mL D5W as an infusion over 5 to 60 minutes. Follow with an infusion of 0.5 to 1 Gm/hr.

Myocardial infarction (unlabeled): To reduce cardiovascular morbidity and mortality, administer 2 Gm as an IV injection over 5 to 15 minutes. Follow with an infusion of 18 Gm equally distributed over 24 hours (approximately 12.5 mg/min). Begin administration as soon as possible after onset of symptoms, preferably no later than 6 hours after symptom onset.

Barium poisoning: 1 to 2 Gm.

Alleviate bronchospasm in acute asthma (unlabeled): 2 Gm given IV over 20 minutes. Usually given concurrently with inhaled albuterol (Proventil) and IV corticosteroids.

PEDIATRIC DOSE

Hypomagnesemia or hypocalcemia: 25 to 50 mg/kg of body weight. May repeat at 4- to 6-hour intervals for 3 or 4 doses. Maximum recommended single dose is 2 Gm. Maintain with 30 to 60 mg/kg/24 hr (approximately 0.25 to 0.5 mEq/kg/24 hr). Maximum dose is 1 Gm/24 hr.

Pulseless VT with torsades de pointes: AHA recommends 25 to 50 mg/kg IV push. A 50% solution equals 500 mg/mL. Maximum recommended dose is 2 Gm.

Torsades de pointes (with pulses) or hypomagnesemia: 25 to 50 mg/kg as an infusion over 10 to 20 minutes. A 50% solution equals 500 mg/mL. Maximum recommended dose is 2 Gm.

Status asthmaticus: 25 to 50 mg/kg as an infusion over 15 to 30 minutes. A 50% solution equals 500 mg/mL. Another source recommends 25 to 75 mg/kg as an infusion over 20 minutes. Maximum recommended dose is 2 Gm.

Acute nephritis in pediatric patients (unlabeled): 100 to 200 mg/kg as a 1% to 3% solution (1 Gm in 100 mL = 1% solution, 3 Gm in 100 mL = 3%). One-half dose should be given slowly over 15 to 20 minutes. Complete balance of dose within 1 hour. Monitor BP closely.

Alleviate bronchospasm in acute asthma (unlabeled): 25 to 50 mg/kg. Given IV over 20 minutes. Do not exceed 2 Gm. Usually given concurrently with inhaled albuterol (Proventil) and IV corticosteroids. Monitor BP and HR closely.

Hyperalimentation: Infants: 2 to 10 mEq (0.25 to 1.25 Gm daily).

Other pediatric patients: 0.25 to 0.5 mEq/24 hr or 30 to 60 mg/kg/24 hr.

DOSE ADJUSTMENTS

Reduce dose of other CNS depressants (e.g., narcotics, barbiturates) when given in conjunction with magnesium sulfate. ■ Reduce dose in impaired renal function and in the elderly. ■ Decrease maximum daily dose to 10 Gm/24 hr in patients with severe renal insufficiency. Frequent serum magnesium concentrations must be obtained.

DILUTION

Must be diluted to a concentration of 20% (200 mg/mL) or less for IV administration. D5W or NS are the most common diluents. Available in vials or syringes as 10% (100 mg/mL), 12.5% (125 mg/mL), 20% (200 mg/mL), and 50% (500 mg/mL); premixed in SWFI as a 4% solution (40 mg/mL) in 100, 500, or 1,000 mL containers; premixed as an 8% solution (80 mg/mL) in 50 mL; and premixed as a 1% solution (10 mg/mL) in 100 or 1,000 mL D5W or a 2% solution (20 mg/mL) in 500 or 1,000 mL D5W. See [Usual Dose](#) for specific dilutions. May be given through Y-tube or three-way stopcock of infusion set.

Storage: Store at CRT.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Will form various precipitates with alkali carbonates and bicarbonates, alkali hydroxides, arsenates, barium, calcium, clindamycin (Cleocin), hydrocortisone sodium succinate (Solu-Cortef), lead, phosphates, salicylates, strontium, and tartrates. Use caution; consult pharmacist.

One source suggests the following **compatibilities**:

Additive: Calcium chloride, calcium gluconate, chloramphenicol (Chloromycetin), cisplatin (Platinol), heparin, hydrocortisone sodium succinate (Solu-Cortef), isoproterenol (Isuprel), meropenem (Merrem IV), methyldopate, norepinephrine (Levophed), penicillin G potassium, potassium chloride (KCl), sodium bicarbonate, verapamil.

Y-site: Acyclovir (Zovirax), aldesleukin (Proleukin), amifostine (Ethyol), amikacin (Amikin), amiodarone (Nexterone), ampicillin, aztreonam (Azactam), bivalirudin (Angiomax), caspofungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), cefoxitin (Mefoxin), ceftaroline (Teflaro), chloramphenicol (Chloromycetin), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), clindamycin (Cleocin), dexmedetomidine (Precedex), dobutamine, docetaxel (Taxotere), doripenem (Doribax), doxorubicin liposomal (Doxil), doxycycline, enalaprilat (Vasotec IV), erythromycin (Erythrocin), esmolol (Brevibloc), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fludarabine (Fludara), gallium nitrate (Ganite), gentamicin, granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), idarubicin (Idamycin), insulin (regular), labetalol, levofloxacin (Levaquin), linezolid (Zyvox), meperidine (Demerol), metronidazole (Flagyl IV), micafungin (Mycamine), milrinone (Primacor), morphine, nafcillin (Nallpen), nicardipine (Cardene IV), nitroprusside sodium, ondansetron (Zofran), oxacillin (Bactocill), oxaliplatin (Eloxatin), paclitaxel (Taxol), penicillin G potassium, piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), sulfamethoxazole/trimethoprim, telavancin (Vibativ), thiotepa, tobramycin, vancomycin.

RATE OF ADMINISTRATION

IV injection: 150 mg/min (1.5 mL of a 10% solution or its equivalent) over at least 1 minute or as directed in Usual Dose. Too-rapid administration may cause hypotension and asystole.

IV infusion: As directed in Usual Dose.

ACTIONS

An important cofactor for enzymatic reactions and plays an important role in neurochemical transmission and muscular excitability. A CNS depressant and a depressant of smooth, skeletal, and cardiac muscle. It also possesses a mild diuretic effect and vasodilating effect. It prevents or controls seizures by blocking neuromuscular transmission and decreasing the amount of acetylcholine release. Can reverse refractory VF caused by hypomagnesemia and help replenishment of intracellular potassium. Onset of action is immediate and effective for about 30 minutes. Excreted in the urine. Secreted in breast milk. Crosses the placental barrier.

INDICATIONS AND USES

Replacement therapy in magnesium deficiency (e.g., acute hypomagnesemia accompanied by signs of tetany similar to those seen in hypocalcemia); also used in magnesium deficiency associated with acute pancreatitis, alcoholism, cirrhosis of the liver, malabsorption syndromes, and prolonged IV therapy with magnesium-free fluids. ■ Correct or prevent hypomagnesemia in patients receiving TPN. ■ Prevention and control of seizures in toxemia of pregnancy (eclampsia and/or preeclampsia).

Unlabeled uses: Prevention and control of convulsive states (epilepsy, glomerulonephritis, hypoparathyroidism). ■ Cerebral edema. ■ Inhibit uterine contractions in premature labor. ■ Acute nephritis in pediatric patients to control hypertension, encephalopathy, and convulsions. ■ Treatment of torsades de pointes, recurrent and refractory ventricular tachycardia, and ventricular fibrillation (VT/VF). ■ Reduce the incidence of post-infarction arrhythmias by counteracting post-infarction hypomagnesemia (given on admission to CCU of a patient with suspected myocardial infarction). ■ Counteract muscle-stimulating effects of barium poisoning. ■ Treatment of paroxysmal atrial tachycardia. ■ Treatment of acute asthma in patients who do not respond to conventional therapy.

CONTRAINDICATIONS

Presence of heart block or myocardial damage, within 2 hours of delivery; see [Maternal/Child](#).

PRECAUTIONS

IV use in eclampsia should be reserved for immediate control of life-threatening conditions. ■ Each 1 Gm contains 8.12 mEq of magnesium. A normal adult body contains 20 to 30 Gm of magnesium. ■ Use caution in impaired renal function and in patients receiving digoxin. Even in normal renal function, use caution to prevent exceeding renal excretory capacity. ■ Some solutions may contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive greater than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. ■ Hypomagnesemia can precipitate refractory VF and hinder potassium replacement.

Monitor: Discontinue IV administration when the desired therapeutic effect is obtained. ■ Monitor magnesium levels. Deep tendon reflexes decrease at plasma magnesium levels above 4 mEq/L and disappear as levels approach 10 mEq/L. Respiratory paralysis will occur at this level. Heart block may occur at or below this level. Levels above 12 mEq/L may be fatal. ■ Test knee jerks and observe respirations before each additional dose. If the knee jerk is absent or respirations are less than 16/min, do not give additional magnesium sulfate. ■ Equipment to maintain artificial ventilation must be available at all times. Patient must be continuously observed. Maintain minimum of 100 mL of urine output every 4 hours. ■ Closely monitor patients with suspected or probable MI for hypotension or asystole and measure magnesium levels.

Maternal/Child: See [Precautions](#). ■ Category A: appears to be safe for use during pregnancy. May cause magnesium toxicity in the newborn if given IV to the mother within 2 hours of delivery. Risk may be decreased with IV administration. ■ A continuous infusion given to control convulsions in toxemic mothers before delivery (especially in the 24 hours preceding) may cause signs of magnesium toxicity in the newborn (e.g., respiratory depression); see [Drug/Lab Interactions](#). ■ Some literature indicates possible harm to the fetus during pregnancy if mother is not toxic. ■ Use caution during breastfeeding. ■ Safety for use in pediatric patients not established.

Elderly: See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Additive CNS depressant effects when used concomitantly with **barbiturates, hypnotics, narcotics, or systemic anesthetics**. See [Dose Adjustments](#) and [Monitor](#). ■ Potentiates **neuromuscular blocking agents** (e.g., vecuronium, succinylcholine). ■ If **calcium** is used to treat magnesium toxicity, use in digitalized patients may cause serious changes in cardiac conduction, resulting in heart block. Use with extreme caution.

SIDE EFFECTS

Usually the result of magnesium intoxication. Absence of knee-jerk reflex; cardiac arrest; circulatory collapse; CNS depression; complete heart block; flaccid paralysis; flushing; hypocalcemia with signs of tetany; hypotension; hypothermia; increased PR interval; increased QRS complex; prolonged QT interval; respiratory depression, paralysis, and failure; stupor; sweating.

ANTIDOTE

Discontinue the drug and notify the physician of the occurrence of any side effect. Calcium gluconate and calcium gluceptate are specific antidotes; 5 to 10 mEq should reverse respiratory depression and heart block; see [Drug/Lab Interactions](#). Physostigmine 0.5 to 1 mg SC may be helpful. Treat hypotension with dopamine. Employ artificial ventilation as necessary and resuscitate as necessary. Peritoneal dialysis or hemodialysis are effective in overdose.

Newborn resuscitation: Will require endotracheal intubation, assisted ventilation, and calcium 1 mEq as an antidote.

MANNITOL

(MAN-nih-tol)

Diuretic
(osmotic)

Osmitrol

pH 4.5 to 7

USUAL DOSE

Total dose, concentration, and rate of administration should be based on the nature and severity of the condition being treated, fluid requirements, and urine output. The usual adult dose may range from 20 to 100 Gm/24 hr. In most instances, an adequate response is achieved with doses of 50 to 100 Gm/24 hr. The rate of administration is usually adjusted to maintain a urine output of at least 30 to 50 mL/hr. See **Precautions** and **Monitor**.

A test dose may be required (e.g., patients with marked oliguria or inadequate renal function).

Test dose: Give 200 mg/kg of body weight over 3 to 5 minutes. 30 to 50 mL of urine should be produced in 1 hour. If adequate urine not produced, repeat once. If still ineffective, reevaluate patient.

1 Gm equal to approximately 5.5 mOsm.

Prevention of oliguric phase of acute renal failure: 50 to 100 Gm as a 5% to 25% solution. A concentrated solution may be used initially followed by a 5% to 10% solution.

Treatment of oliguria: 50 to 100 Gm of a 15% to 25% solution.

Management of intracranial pressure in neurologic emergencies: Manufacturer recommends 0.25 Gm/kg every 6 to 8 hours. AHA recommends 0.5 to 1 Gm/kg over 5 to 10 minutes through an in-line filter. Repeat 0.25 to 2 Gm/kg every 4 to 6 hours as needed. A third source suggests 1.5 to 2 Gm/kg of body weight as a 15% to 25% solution. An osmotic gradient between the blood and cerebrospinal fluid of approximately 10 mOsm should yield a satisfactory reduction in intracranial pressure.

Reduction of intraocular pressure: 1.5 to 2 Gm/kg of body weight as a 15% or 20% solution. To obtain maximal effect, this dose may be administered over a period as short as 30 minutes. May be used 60 to 90 minutes before surgery.

Promotion of urinary excretion of toxic substances: 50 to 200 Gm. Manufacturer recommends a 5% or 25% solution as indicated if urine output remains adequate. Numerous regimens are in use. Urine output of 100 to 500 mL/hr and a positive fluid balance of 1 to 2 L should be maintained. One regimen suggests an initial loading dose of 25 Gm followed by an infusion at a rate to maintain urine output at 100 mL/hr. Discontinue if no benefit derived from 200 Gm.

Diuretic for adjunctive treatment of ascites or edema: 100 Gm of a 10% to 20% solution over 2 to 6 hours.

PEDIATRIC DOSE

See **Maternal/Child**. **Test dose may be required (e.g., oliguria or anuria).**

Test dose: Give 200 mg/kg of body weight or 6 Gm/M² over 3 to 5 minutes. 30 to 50 mL of urine should be produced in 1 hour. If adequate urine not produced, repeat once. If still ineffective, reevaluate patient. Maximum test dose is 12.5 Gm.

Cerebral or ocular edema: 2 Gm/kg of body weight or 60 Gm/M² of body surface as a 15% to 20% solution over 30 to 60 minutes.

Promotion of urinary excretion of toxic substances: 2 Gm/kg or 60 Gm/M² as a 5% or 10% solution as needed if urine output remains adequate. Concentration depends on fluid requirement and urine output.

Anuria/oliguria: 0.5 to 1 Gm/kg as an initial dose. Maintain with 0.25 to 0.5 Gm/kg every 4 to 6 hours. Another source suggests 2 Gm/kg or 60 Gm/M² over 90 minutes to several hours.

Edema and ascites: 2 Gm/kg or 60 Gm/M² as a 15% to 20% solution over 2 to 6 hours.

DOSE ADJUSTMENTS

Reduce dose by one half for small or debilitated patients. ■ Dose selection in the elderly should be cautious (usually starting at the low end of the dosing range), reflecting the

greater frequency of decreased organ function and of concomitant disease or drug therapy.

- Reduced dose may be required in oliguria or impaired renal function; see [Monitor](#).

DILUTION

Available in concentrations of 5%, 10%, 15%, 20%, or 25%. May be in flexible IV bags or in flip-top vials. No further dilution is necessary; however, if there are any crystals present in the solution, they must be completely dissolved before administration. One manufacturer recommends: To dissolve crystals in the flexible container, warm the unit to 70° C (158° F) with agitation. Heat solution using a dry-heat cabinet with overwrap intact. Use of a water bath is not recommended. To dissolve the crystals in the flip-top vial, warm the bottle in hot water at 80° C (176° F). Shake vigorously periodically. 25% mannitol injection may be autoclaved at 121° C (250° F) for 20 minutes at 15 psi. Consult prescribing information; process may differ with specific brands. Cool to at least body temperature before administration.

Glomerular filtration rate: See [Usual Dose](#).

Filters: Use an in-line filter for 15%, 20%, and 25% solutions.

Storage: One manufacturer recommends storing at CRT. Protect from freezing. Consult prescribing information; may be brand specific. Discard unused portions.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Sources list as **incompatible** with strongly acidic or alkaline solutions. 20% or 25% solutions of mannitol may precipitate with potassium chloride (KCl) or sodium chloride. Concomitant administration of electrolyte-free mannitol solutions with whole blood may cause pseudoagglutination. If blood must be given simultaneously, at least 20 mEq of NaCl should be added to each liter of mannitol solution; consult pharmacist. Do not use PVC infusion bags with 25% mannitol; may form a precipitate.

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), aztreonam (Azactam), cefoxitin (Mefoxin), ceftriaxone (Rocephin), cisplatin (Platinol), dopamine, fosphenytoin (Cerebyx), furosemide (Lasix), gentamicin, levofloxacin (Levaquin), metoclopramide (Reglan), ondansetron (Zofran), sodium bicarbonate, tobramycin, verapamil.

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), amphotericin B cholesteryl (Amphotec), aztreonam (Azactam), bivalirudin (Angiomax), ceftaroline (Teflaro), cisatracurium (Nimbex), cladribine (Leustatin), docetaxel (Taxotere), doripenem (Doribax), etoposide phosphate (Etopophos), fenoldopam (Corlopam), fludarabine (Fludara), fluorouracil (5-FU), gallium nitrate (Ganite), gemcitabine (Gemzar), hetastarch in electrolytes (Hex-tend), idarubicin (Idamycin), linezolid (Zyvox), melphalan (Alkeran), ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), palonosetron (Aloxi), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), telavancin (Vibativ), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Variable; may be adjusted to obtain a urine output of at least 30 to 50 mL/hr. A single dose should be given over 30 to 90 minutes. Up to 3 Gm/kg have been given over this time span. A test dose (see [Monitor](#)) or loading doses may be given over 3 to 5 minutes.

Oliguria: A single dose over 90 minutes to several hours.

Reduction of intracranial pressure and brain mass: A single dose over 30 to 60 minutes.

Treatment of edema or ascites: A single dose over 2 to 6 hours.

ACTIONS

A sugar alcohol and most effective osmotic diuretic. It is a stable, inert, nontoxic solution. Distribution in the body is limited to extracellular compartments. Increases osmolarity of glomerular filtrate and the extracellular space. An increase in extracellular osmolarity causes the movement of water to the extracellular and vascular spaces. This action is responsible for the ability of mannitol to decrease intracranial pressure and

edema and to reduce elevated intraocular pressure. Mannitol is not reabsorbed or secreted by the tubules of the kidneys. It is excreted almost completely in the urine along with water, sodium, and chloride. Onset of diuresis is 1 to 3 hours. Reduction in cerebrospinal and intraocular fluid occurs within 15 minutes and lasts 4 to 8 hours. Rebound may occur within 12 hours.

INDICATIONS AND USES

Promotion of diuresis in the prevention and/or treatment of the oliguric phase of acute renal failure before irreversible renal failure becomes established. ■ Reduction of intracranial pressure and treatment of cerebral edema by reducing brain mass. ■ Reduction of extremely high intraocular pressure. ■ Promotion of excretion of toxic substances. ■ Reduction of generalized edema and ascites.

CONTRAINDICATIONS

Anuria, hypersensitivity to mannitol, intracranial bleeding except during craniotomy, progressive heart failure or pulmonary congestion after initiation of mannitol therapy, severe dehydration, severe pulmonary congestion or frank pulmonary edema, severe renal impairment or progressive renal dysfunction after initiation of mannitol therapy, including increasing azotemia or oliguria.

PRECAUTIONS

For IV use only. ■ Evaluate cardiac status to avoid fulminating congestive heart failure. Use caution in renal failure; fluid overload may result. ■ Loss of water in excess of electrolytes can cause hyponatremia. ■ May cause osmotic nephrosis, which may progress to severe irreversible nephrosis. ■ Use with caution in neurosurgical patients. May increase cerebral blood flow and increase risk of postoperative bleeding. ■ Increased cerebral blood flow may worsen intracranial hypertension in pediatric patients who develop a generalized cerebral hyperemia within 48 hours of injury.

Monitor: Test dose should be used in patients with marked oliguria or impaired renal functions; see **Usual Dose**. ■ Observe urine output continuously; should exceed 30 to 50 mL/hr. Insert Foley catheter if necessary. ■ Monitor fluid status and osmolality (not to exceed 310 mOsm/kg). ■ May obscure signs of inadequate hydration or hypovolemia. Electrolyte depletion (especially sodium and potassium) may occur. Administration of water and electrolytes is required to maintain fluid balance due to losses of these substances from urine, sweat, and expired air. Check with laboratory studies and replace as necessary. Monitor renal, cardiac, and pulmonary function. ■ Before attempting to reduce intracranial pressure and brain mass, evaluate circulatory and renal reserve, fluid and electrolyte balance, body weight, and total input and output before and after mannitol infusion. Support with adequate ventilation and oxygenation. Reduced cerebrospinal fluid pressure must be observed within 15 minutes after starting infusion. ■ Observe infusion site to prevent infiltration.

Maternal/Child: Category C: safety for use in pregnancy, labor, or delivery not established. Benefits must outweigh risks. ■ Use caution in breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 12 years of age not established; however, doses are used clinically.

Elderly: Response similar to that seen in younger patients. Lower-end initial doses may be appropriate; see **Dose Adjustments**.

DRUG/LAB INTERACTIONS

May increase **lithium** excretion, thereby decreasing its effectiveness. ■ Mannitol-induced hypokalemia may increase the potential for **digoxin** toxicity.

SIDE EFFECTS

Rare when used as directed but may include acidosis, backache, blurred vision, chest pain, chills, convulsions, decreased chloride levels, decreased sodium levels, dehydration, diuresis, dizziness, dryness of mouth, edema, fever, fulminating congestive heart failure, head-

ache, hyperosmolality, hypertension, hypotension, nausea, polyuria then oliguria, pulmonary edema, rhinitis, tachycardia, thirst, thrombophlebitis, and urinary retention.

ANTIDOTE

If minor side effects persist, notify the physician. For all major side effects or if urine output is under 30 to 50 mL/hr, discontinue the drug and notify the physician. Treatment will be supportive to correct fluid and electrolyte imbalances. Hemodialysis may be used to clear mannitol and reduce serum osmolality.

MELPHALAN HYDROCHLORIDE **BBW**

(MEL-fah-lan hy-droh-KLOR-eyed)

Antineoplastic
(alkylating agent/nitrogen mustard)

Alkeran, L-PAM, Phenylalanine Mustard, L-Sarcolysin

pH 6.5 to 7

USUAL DOSE

No exact dosage conversion from oral to parenteral or parenteral to oral.

Multiple myeloma: 16 mg/M² every 2 weeks for 4 doses. After recovery from toxicity, repeat a dose every 4 weeks. Prednisone is administered concurrently.

Ovarian cancer: 0.2 mg/kg daily for 5 successive days. Repeat every 4 to 5 weeks.

Conditioning regimen for autologous hematopoietic stem cell transplantation (unlabeled): 200 mg/M² 2 days before transplantation or 140 mg/M² as a single dose in combination with busulfan 2 days before transplantation. Other regimens are in use.

PEDIATRIC DOSE

See *Maternal/Child*.

Pediatric rhabdomyosarcoma (unlabeled): 10 to 35 mg/M²/dose every 21 to 28 days.

High-dose melphalan with bone marrow transplantation for neuroblastoma (unlabeled): 70 to 100 mg/M²/day on Days 7 and 6 before BMT or

140 to 220 mg/M² as a single dose before BMT or

50 mg/M²/day for 4 days before BMT or

70 mg/M²/day for 3 days before BMT.

DOSE ADJUSTMENTS

Manufacturer recommends reducing dose by 50% if BUN greater than 30 mg/dL. Other recommendations have been suggested in the literature. ■ Dose reduction based on myelotoxicity should be considered. In one clinical study, the following reductions based on cell count were followed: reduce dose by 25% if WBC between 3,000 and 4,000/mm³ and platelets between 75,000 and 100,000/mm³; by 50% if WBC between 2,000 and 3,000/mm³ and platelets between 50,000 and 75,000/mm³. Withhold dose for WBC below 2,000/mm³ and platelets below 50,000/mm³. ■ Lower-end initial doses may be indicated in the elderly. Consider impaired organ function and concomitant disease or drug therapy. ■ Somewhat reduced dose may be appropriate for patients undergoing hemodialysis.

DILUTION

Specific techniques required; see *Precautions*. Reconstitution to completion of administration must take place within 60 minutes due to instability of melphalan (rapid hydrolysis). Rapidly inject 10 mL of supplied diluent into vial. Shake vigorously until a clear solution results (5 mg/mL). Use only clear solutions. Further dilute in NS to a concentration of 0.1 to 0.45 mg/mL. Keep the time from reconstitution to dilution to administration to a minimum. Drug is very unstable and may begin to deteriorate within 30 minutes.

Filters: No data available from manufacturer. Another source indicates minimal adsorption with several types of filters from 0.2 to 0.45 microns in size.

Storage: Protect from light and store at room temperature before reconstitution. Reconstituted solution is stable for up to 2 hours maximum. Stable at a concentration of 0.1 to 0.45 mg/mL for only 60 minutes or less. Will precipitate if refrigerated.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following compatibilities:

Y-site: Acyclovir (Zovirax), amikacin (Amikin), aminophylline, ampicillin, aztreonam (Azactam), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), caspo-fungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), cefotetan, ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), daunorubicin (Cerubidine), dexamethasone (Decadron), diphenhydramine (Benadryl), doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), etoposide (VePesid), famotidine (Pepcid IV), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gallium nitrate (Ganite), ganciclovir (Cytovene), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), lorazepam (Ativan), mannitol, mechlorethamine (nitrogen mustard), meperidine (Demerol), mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), mitomycin (Mutamycin), mitoxantrone (Novantrone), morphine, nalbuphine, ondansetron (Zofran), pentostatin (Nipent), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, streptozocin (Zanosar), sulfamethoxazole/trimethoprim, teniposide (Vumon), thiotepa, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vinblastine, vincristine, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Keep the time from reconstitution to dilution to administration to a minimum. Drug is very unstable and may begin to deteriorate within 30 minutes. Do not administer directly into a peripheral vein. Administration by injecting slowly into a fast-running IV solution via an injection port or via a central venous line is recommended.

Intravenous infusion: A single dose over 15 to 20 minutes. Complete administration within 60 minutes of reconstitution.

ACTIONS

A phenylalanine derivative of nitrogen mustard that is a bifunctional alkylating antineoplastic agent. Cytotoxicity is related to the extent of its interstrand cross-linking with DNA. Not dependent on cell cycle phase. Active against both resting and dividing tumor cells. Binding to plasma proteins ranges from 53% to 92%. Approximately 30% is irreversibly bound to proteins. Eliminated from plasma primarily by chemical hydrolysis rather than metabolism. Half-life is approximately 75 minutes. About 10% excreted as unchanged drug in urine.

INDICATIONS AND USES

Palliative treatment of patients with multiple myeloma and ovarian cancer when oral therapy is not appropriate.

Unlabeled uses: Treatment of multiple myeloma in combination with other cytotoxic agents. ■ Treatment of cancers of the breast when oral therapy is not appropriate. ■ Conditioning regimen before autologous hematopoietic stem cell transplantation (HSCT). ■ Component of combination therapy to treat relapsed, resistant Hodgkin's lymphomas. ■ Pediatric rhabdomyosarcoma. ■ High-dose melphalan with BMT for pediatric neuroblastoma. ■ Intra-arterial injection (hyperthermic isolated limb perfusion) is used for extremity melanoma and as a palliative treatment with locally advanced, unresectable malignant melanoma of the extremity.

CONTRAINDICATIONS

Prior resistance to or hypersensitivity to melphalan.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist, with facilities for monitoring the patient and responding to any medical emergency. ■ Use extreme caution in patients whose bone marrow is compromised by or recovering from previous radiation or chemotherapy. ■ Severe myelotoxicity (WBC below 1,000/mm³ and platelets below 25,000/mm³) with resulting infection or bleeding is more common with IV dosing. ■ Do not abandon treatment prematurely. Improvement may continue slowly over many months with repeated courses. ■ Patients with an elevated BUN had a greater incidence of severe bone marrow suppression. ■ Secondary malignancies, including acute nonlymphocytic leukemia, myeloproliferation syndrome, and carcinoma have been reported in patients treated with alkylating agents, including melphalan. ■ See [Drug/Lab Interactions](#).

Monitor: Determine absolute patency of vein. A stinging or burning sensation indicates extravasation; cellulitis and tissue necrosis may result. Discontinue injection; use another vein; see [Rate of Administration](#). ■ Monitor platelet count, hemoglobin, white blood cell count, and differential frequently. Indicated before each dose as well as between doses to determine optimal dose and avoid toxicity. Nadirs occur 2 to 3 weeks after treatment, recovery should occur in 4 to 5 weeks. ■ Severe myelosuppression can occur with effective doses. Withhold further doses until blood cell counts have recovered if thrombocytopenia and/or leukopenia occur. ■ Monitor kidney function before and during therapy. ■ Hypersensitivity reactions may occur with initial treatment but often are delayed and occur after multiple courses. Observe closely; anaphylaxis and death have occurred. ■ Observe closely for all signs of infection or bleeding. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Some facilities are using ice pops to help prevent stomatitis. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid pregnancy; nonhormonal birth control recommended. ■ Promptly report IV site burning or stinging. ■ Acute side effects are related to bone marrow suppression, hypersensitivity reactions, GI toxicity, and pulmonary toxicity. Promptly report S/S of a hypersensitivity reaction or any potential side effects (e.g., bleeding, cough, fever, rash). ■ Major long-term toxicities are related to infertility and secondary malignancy. Discuss risks with health care provider. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. Can cause chromosomal damage and severe birth defects in the fetus and impairment of fertility in men and women. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established; see [Unlabeled Uses](#).

Elderly: Response similar to that seen in younger adults. ■ See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Coadministration with **cyclosporine** (Sandimmune) may result in acute renal failure. May occur after the first dose of each drug. ■ Renal dysfunction and increased toxicity may occur with concurrent **cisplatin**. ■ Threshold for lung toxicity associated with **carmustine** (BiCNU) may be reduced with concurrent use. ■ **Interferon alfa** may decrease serum concentrations of melphalan. ■ Use with **nalidixic acid** (NegGram) may cause severe hemorrhagic necrotic enterocolitis in pediatric patients. ■ Do not administer **live virus vaccines** to immunocompromised patients receiving antineoplastic agents.

SIDE EFFECTS

Reversible bone marrow suppression (e.g., anemia, leukopenia, thrombocytopenia) is dose-limiting. Irreversible bone marrow failure has been reported. Alopecia, cardiac arrest, diarrhea, elevated BUN, hemolytic anemia, hepatic toxicity (including veno-occlusive disease), hypersensitivity reactions (2% [e.g., anaphylaxis, bronchospasm,

dyspnea, edema, hypotension, pruritus, urticaria, tachycardia], interstitial pneumonitis, nausea and vomiting, oral ulceration, pulmonary fibrosis, secondary malignancies (long-term use), skin ulceration at injection site, vasculitis.

Overdose: Severe bone marrow suppression, cholinomimetic effects (e.g., bradycardia, increased peristalsis and salivation, incontinence), convulsions, decreased consciousness, hyponatremia (inappropriate secretion of ADH), muscular paralysis, severe nausea and vomiting.

ANTIDOTE

Keep physician informed of all side effects. Close monitoring of bone marrow may prevent most serious and potentially fatal side effects. WBC and platelet count nadirs occur 2 to 3 weeks after treatment with recovery in 4 to 5 weeks. Withhold further doses until blood cell counts have recovered if leukopenia or thrombocytopenia occur. There is no specific antidote, but adequate supportive care including administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Appropriate antibiotics may be indicated. Monitor closely until recovery (6 weeks or more). Discontinue the infusion and treat hypersensitivity reactions with antihistamines, corticosteroids, pressor agents, or volume expanders; do not readminister melphalan (IV or oral). Hemodialysis probably not effective in overdose.

MEPERIDINE HYDROCHLORIDE

(meh-**PER**-ih-deen hy-droh-**KLOR**-eyed)

Opioid analgesic
(agonist)
Anesthesia adjunct

Demerol, Demerol HCl, Meperidine HCl PF

pH 3.5 to 6

USUAL DOSE

Determination of dose should be based on severity of pain and patient response.

IV injection: 5 to 10 mg every 5 minutes as needed. Do not exceed 600 mg/24 hr. IV dosing in acute pain should be limited to 48 hours or less; see [Precautions](#).

Supplement anesthesia: 1 to 10 mg/mL dilution is usually used. Titrate under the direct observation and control of the anesthesiologist. Dose dependent on premedication, type of anesthesia, type and duration of procedure and patient's condition.

Treatment or prevention of shaking chills (unlabeled): 0.5 mg/kg 20 minutes before shaking chills are expected to begin or 50 mg after onset of chills. Up to 150 mg has been required within 30 minutes if administered after onset.

PEDIATRIC DOSE

1 mg/kg/dose; see [Maternal/Child](#).

DOSE ADJUSTMENTS

Reduced dose may be required in the elderly or debilitated, in hepatic or renal disease, or in numerous other disease entities; see [Precautions](#). ■ Doses appropriate for the general population may cause serious respiratory depression in vulnerable patients. ■ Increase doses as required if analgesia is inadequate, tolerance develops, or pain severity increases. The first sign of tolerance is usually a reduced duration of effect. ■ Decrease dose by 25% to 50% when administered concomitantly with phenothiazines and other centrally acting medications (e.g., sedatives). ■ See [Drug/Lab Interactions](#).

DILUTION

IV injection: May be given undiluted; however, further dilution with 5 mL of SWFI, NS, or other IV solutions to facilitate titration is appropriate; see chart on inside back cover.

Filters: No data available from manufacturer.

Storage: Before use, store at CRT protected from light. Do not freeze.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Cefazolin (Ancef), dobutamine, metoclopramide (Reglan), ondansetron (Zofran), sodium bicarbonate, succinylcholine, verapamil.

Y-site: Acyclovir (Zovirax), amifostine (Ethyol), amikacin (Amikin), ampicillin, ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), bumetanide, caspofungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftaroline (Teflaro), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chloramphenicol (Chloromycetin), cistracurium (Nimbex), cladribine (Leustatin), clindamycin (Cleocin), dexamethasone (Decadron), dexmedetomidine (Precedex), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxycycline, droperidol (Inapsine), erythromycin (Erythrocin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopan), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), furosemide (Lasix), gallium nitrate (Ganite), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, heta-starch in electrolytes (Hexend), hydrocortisone sodium succinate (Solu-Cortef), 6% hydroxyethyl starch (Voluven), insulin (regular), labetalol, lidocaine, linezolid (Zyvox), magnesium sulfate, melphalan (Alkeran), methylodopate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metoprolol (Lopressor), metronidazole (Flagyl IV), ondansetron (Zofran), oxacillin (Bactocill), oxaliplatin (Eloxatin), oxytocin (Pitocin), paclitaxel (Taxol), palonosetron (Aloxi), pemetrexed (Alimta), penicillin G potassium, piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), propranolol, ranitidine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), sulfamethoxazole/trimethoprim, teniposide (Vumon), thiotepa, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, verapamil, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

IV injection: A single dose over 4 to 5 minutes. Frequently titrated according to symptom relief and respiratory rate. Rapid IV administration increases the possibility of hypotension and respiratory depression.

ACTIONS

A synthetic narcotic analgesic and descending CNS depressant, similar to morphine. Has multiple actions; the most prominent involve the CNS and organs composed of smooth muscle. Principal actions of therapeutic value are analgesia and sedation. May produce less smooth muscle spasm, constipation, and depression of the cough reflex than equianalgesic doses of morphine. A parenteral dose of meperidine 60 to 80 mg is approximately equivalent in analgesic effect to 10 mg of morphine. Onset of action occurs in about 5 minutes and lasts for about 2 to 4 hours. Readily absorbed and distributed throughout the body. Metabolized to an active, toxic metabolite (normeperidine) in the liver, its extended half-life (15 to 30 hours) may lead to cumulative effects. Excreted in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Short-term relief of moderate to severe pain. ■ Preoperative medication. ■ Support of anesthesia. ■ Obstetric analgesia.

Unlabeled uses: Treatment or prevention of shaking chills (rigors) caused by some medications (e.g., amphotericin B [all formulations], aldesleukin [Proleukin]). ■ Treatment of postoperative shivering.

CONTRAINDICATIONS

Hypersensitivity to meperidine, patients who have received MAO inhibitors (e.g., selegiline [Eldepryl]) in the previous 14 days.

PRECAUTIONS

Use of meperidine as a first-line analgesic for pain is discouraged due to its short duration of action and the risk of accumulation of its toxic metabolite, normeperidine. Accumulation of normeperidine may increase the risk of toxicity (e.g., seizures). If its use in acute pain (in patients without renal or CNS disease) cannot be avoided, the American Pain Society and ISMP recommend limiting treatment to 48 hours or less and not exceeding 600 mg/24 hr. ■ Use with caution in glaucoma, head injuries, increased intracranial pressure (elevates spinal fluid pressure), asthma, chronic obstructive pulmonary disease, decreased respiratory reserve or respiratory depression, supraventricular tachycardia, convulsions, acute abdominal conditions before diagnosis, the elderly and debilitated, and hepatic or renal insufficiency. ■ Use with caution and in reduced doses in patients receiving concurrent therapy with other narcotic analgesics, general anesthetics, phenothiazines (e.g., promethazine [Phenergan], prochlorperazine [Compazine]), sedative-hypnotics (including barbiturates [e.g., phenobarbital]), tricyclic antidepressants (e.g., imipramine [Tofranil]), and other CNS depressants, including alcohol. Use may result in respiratory depression, hypotension, and profound sedation or coma. See [Drug/Lab Interactions](#). ■ Use with caution in patients with renal dysfunction; normeperidine may accumulate resulting in increased CNS toxicity. ■ May cause severe hypotension in postoperative patients or in any patient whose ability to maintain blood pressure has been compromised by depleted blood volume or concomitant administration of drugs that can cause hypotension (e.g., anesthetics, phenothiazines). ■ Use with caution in patients with sickle cell anemia, hypothyroidism, Addison's disease, pheochromocytoma, and prostatic hypertrophy or urethral stricture. Reduced doses may be indicated; see [Dose Adjustments](#). ■ Cough reflex may be suppressed. ■ Morphine is usually preferred for pain during an acute MI. ■ IM route frequently used. Frequent IM injections may lead to severe fibrosis of muscle tissue. ■ Do not use in patients for any long-term pain relief (e.g., cancer). ■ Psychological and physical dependence and tolerance may develop with repeated administration.

Monitor: Oxygen, controlled respiratory equipment, and naloxone (Narcan) must always be available. ■ Observe patient frequently to continuously based on amount of dose and monitor vital signs. ■ Assess baseline pain, then assess pain with vital signs. Reassess after administration of meperidine and adjust dose or interval as required. ■ Keep patient supine; orthostatic hypotension and fainting may occur; less likely with continuous low doses, but observe closely during ambulation. ■ Uncontrolled pain causes sleep deprivation, decreases pain threshold, and increases pain. When pain is finally controlled, expect the patient to sleep more until recovery from sleep deprivation. ■ With use the active metabolite normeperidine accumulates to toxic levels; will lower seizure threshold. Monitor for twitching, jerking, shaky hands, tremors; may lead to grand mal seizure. ■ Laxatives with or without stool softeners may be required to avoid constipation and fecal impaction. Maintain adequate hydration.

Patient Education: Avoid alcohol or other CNS depressants (e.g., barbiturates, benzodiazepines [e.g., diazepam (Valium)]). ■ May cause blurred vision, dizziness, or drowsiness; use caution in tasks that require alertness. ■ Request assistance with ambulation. ■ May be habit forming.

Maternal/Child: Category C: safety for use before labor not established. ■ Use during delivery may cause depression of respiration and psychophysiologic functions in the newborn requiring resuscitation. ■ May cause serious adverse reactions in nursing infants; discontinue breast-feeding or discontinue meperidine. ■ Not recommended for IV use in pediatric patients but is used. Consider risk versus benefit before use in neonates or young infants. Rate of elimination is slower in neonates and young infants compared to older children or adults. May be more sensitive to effects (e.g., respiratory depression) and may cause paradoxical excitation.

Elderly: See [Dose Adjustments](#) and [Precautions](#). ■ Elimination rate is slower than in younger adults. ■ May be more sensitive to effects (e.g., respiratory depression, consti-

pation, urinary retention). ■ Lower doses may provide effective analgesia. ■ Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

Potentiated by **acyclovir** (Zovirax), **anticholinergics**, **cimetidine** (Tagamet), **tricyclic antidepressants** (e.g., imipramine [Tofranil]), **isoniazid** (INH), **neostigmine**, **neuromuscular blocking agents** (e.g., atracurium [Tracrium]), **phenothiazines**, **general anesthetics**, **other narcotic analgesics**, and **CNS depressants including alcohol**. Side effects (e.g., CNS depression, constipation, hypotension) may be additive. Reduced dosage of both drugs may be indicated. ■ Do not use with **MAO inhibitors** (e.g., selegiline [Eldepryl]); may cause cardiovascular collapse. ■ Avoid concurrent use with **sibutramine** (Meridia); may precipitate serotonin syndrome (e.g., altered consciousness, CNS irritability, motor weakness, myoclonus, shivering). ■ **Mixed agonists/antagonists** (e.g., pentazocine [Talwin], nalbuphine, butorphanol [Stadol]) may decrease analgesic effect of meperidine and/or precipitate withdrawal symptoms. ■ Concurrent use with **protease inhibitors** (e.g., saquinavir [Invirase], ritonavir [Norvir]) not recommended. May increase meperidine serum concentrations and increase the risk of side effects, including seizures and cardiac arrhythmias. ■ **Hydantoins** (e.g., phenytoin [Dilantin]) may increase metabolism and decrease the half-life of meperidine; however, increased normeperidine levels have been seen. ■ Metabolism increased and analgesic effects may be decreased or delayed in **smokers**.

SIDE EFFECTS

Dizziness, flushing, light-headedness, nausea, postural hypotension, rash, restlessness, sedation, sweating, syncope, vomiting. Side effects associated with histamine release, convulsions, and constipation may be more common with meperidine than with most other narcotic analgesics.

Major: Apnea, cardiac arrest, cardiovascular collapse, cold and clammy skin, convulsions, dilated pupils, hypersensitivity reactions (e.g., anaphylaxis, pruritus), normeperidine toxicity (jerking, tremor, twitching, shaky hands, grand mal seizure), respiratory depression, shock, tremor.

ANTIDOTE

With increasing severity of minor side effects or onset of any major side effect, discontinue the drug and notify the physician. A patent airway, artificial respiration, oxygen therapy, and other symptomatic treatment must be instituted promptly. Naloxone hydrochloride (Narcan) will reverse serious reactions. In patients who are physically dependent on narcotics, either avoid the use of a narcotic antagonist or use extreme caution and doses as small as one-fifth to one-tenth of the usual initial dose to avoid precipitating an acute withdrawal syndrome. In all patients, adjust and titrate the dose of a narcotic antagonist to reverse side effects without reversing pain control. Avoid total reversal of pain control. Resuscitate as necessary.

MEROPENEM

(mer-oh-PEN-em)

**Antibacterial
(carbapenem)****Merrem I.V.****pH 7.3 to 8.3****USUAL DOSE**

Dose ranges from 500 mg to 2 Gm and depends on type and severity of infection.

Skin and skin structure infections (complicated) in adults and pediatric patients weighing 50 kg or more: 500 mg every 8 hours. Increase to 1 Gm every 8 hours in diabetic foot infections.

Intra-abdominal infections in adults and pediatric patients weighing 50 kg or more: 1 Gm every 8 hours.

Febrile neutropenia in adults and pediatric patients weighing 50 kg or more (unlabeled): 1 Gm every 8 hours.

Meningitis (unlabeled): 40 mg/kg every 8 hours (up to 6 Gm daily). Other clinicians recommend the use of a total dose of 6 Gm daily (2 Gm every 8 hours). Has been given concurrently with ceftriaxone (Rocephin) or cefotaxime (Claforan).

Burkholderia infections (melioidosis [unlabeled]): 25 mg/kg every 8 hours (up to 6 Gm daily) with concomitant administration of sulfamethoxazole/trimethoprim (8 mg/kg of oral trimethoprim daily in four divided doses). Other clinicians recommend meropenem 0.5 to 1 Gm every 8 hours with or without sulfamethoxazole/trimethoprim. Continue treatment for at least 14 days or until clinical improvement.

Liver abscess (unlabeled): 1 Gm every 8 hours for 2 to 3 weeks. Transfer to oral therapy and continue for 2 to 3 additional weeks.

Mild to moderate infection, other severe infections (unlabeled): 500 mg to 1 Gm every 8 hours.

Complicated urinary tract infections (unlabeled): 500 mg to 1 Gm every 8 hours.

PEDIATRIC DOSE

See [Maternal/Child](#).

Skin and skin structure infections in pediatric patients over 3 months of age and less than 50 kg: 10 mg/kg every 8 hours. Maximum single dose every 8 hours is 500 mg.

Intra-abdominal infections in pediatric patients over 3 months of age and less than 50 kg: 20 mg/kg every 8 hours. Maximum single dose every 8 hours is 1 Gm.

Meningitis in pediatric patients over 3 months of age and less than 50 kg: 40 mg/kg every 8 hours. Maximum single dose every 8 hours is 2 Gm.

Meningitis in pediatric patients weighing 50 kg or more: 2 Gm every 8 hours.

Febrile neutropenia in pediatric patients 3 months of age and older and less than 50 kg (unlabeled): 20 mg/kg every 8 hours.

Burkholderia infections in pediatric patients over 3 months of age and less than 40 kg (unlabeled): 10 to 20 mg/kg every 8 hours for melioidosis or glanders. Concomitant administration of sulfamethoxazole/trimethoprim may be indicated in severely ill patients.

Burkholderia infections in pediatric patients weighing 40 kg or more (unlabeled): Same as adult dose.

DOSE ADJUSTMENTS

Reduce dose required if CrCl is less than 51 mL/min based on the following chart.

Meropenem Recommended IV Dosage Schedule for Adults with Impaired Renal Function		
Creatinine Clearance (mL/min)	Dose (dependent on type of infection)	Dosing Interval
26-50 mL/min	Recommended dose	Every 12 hours
10-25 mL/min	One half recommended dose	Every 12 hours
<10 mL/min	One half recommended dose	Every 24 hours

Consult package insert or front matter of this text for formula to convert SCr to CrCl. ■ No dose adjustment necessary in impaired hepatic function. ■ Reduced dose may be required in the elderly based on decreased renal function. ■ Information is inadequate for use in patients on hemodialysis, and there is no experience with peritoneal dialysis. ■ No experience in pediatric patients with renal impairment.

DILUTION

Injection: Reconstitute each 500 mg with 10 mL SWFI (1 Gm with 20 mL). Yields 50 mg/mL. Shake to dissolve and let stand until clear. May be given as an IV injection or further diluted with 50 to 250 mL of **compatible** infusion solutions (see **Infusion and Compatibility**).

Infusion: Available as infusion vials that may be directly reconstituted with a **compatible** solution and then infused. Concentration may range from 2.5 to 50 mg/mL. Alternately, withdraw 10 or 20 mL of a **compatible** solution (see **Compatibility**) from an infusion bag for the reconstitution. Inject the reconstituted solution into the same infusion bag for administration.

Storage: Store unopened vials (dry powder) at RT (20° to 25° C [68° to 77° F]). Use of freshly prepared solutions preferred. Vials for injection stable at room temperature for 2 hours after reconstitution and for 12 hours refrigerated. Infusion vials reconstituted with NS having a final concentration of 2.5 to 50 mg/mL are stable for up to 2 hours at CRT and up to 18 hours at 4° C (39° F). Stability of all other dilutions (syringe for injection or solutions for infusion) is dependent on diluent and room temperature or refrigeration. Range is from 1 hour to 4 hours at 15° to 25° C (59° to 77° F) and 4 to 24 hours at 4° C (39° F); see package insert or consult pharmacist. Do not freeze.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Meropenem should not be mixed or physically added to solutions containing other drugs; **compatibility** not established.”

One source suggests the following **compatibilities**:

Solution: Compatible under specific conditions (see **Storage**) with NS, D5W, D10W, D5NS, D5¹/₄NS, KCl 0.15% in D5W, Na Bicarbonate 0.02% in D5W, D5 in Normosol-M, D5LR, D2¹/₂ in ¹/₂NS, Mannitol 2.5%, R, LR, Na Lactate ¹/₆ M, Na Bicarbonate 5%.

Additive: Not recommended by manufacturer. Acyclovir (Zovirax), aminophylline, atropine, dexamethasone (Decadron), dobutamine, dopamine, doxycycline, enalaprilat (Vasotec IV), fluconazole (Diflucan), furosemide (Lasix), gentamicin, heparin, insulin (regular), magnesium sulfate, metoclopramide (Reglan), morphine, norepinephrine (Levophed), ondansetron (Zofran), phenobarbital (Luminal), ranitidine (Zantac), vancomycin, zidovudine (AZT, Retrovir).

Y-site: Acyclovir (Zovirax), aminophylline, anidulafungin (Eraxis), atropine, calcium gluconate, caspofungin (Cancidas), cyclosporine (Sandimmune), dexamethasone (Decadron), digoxin (Lanoxin), diphenhydramine (Benadryl), docetaxel (Taxotere), doxycycline, enalaprilat (Vasotec IV), fluconazole (Diflucan), furosemide (Lasix), gentamicin, heparin, insulin (regular), linezolid (Zyvox), metoclopramide (Reglan), milrinone (Primacor), morphine, norepinephrine (Levophed), ondansetron (Zofran), phenobarbital (Luminal), potassium chloride (KCl), telavancin (Vibativ), vancomycin, vasopressin, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Same rate is used for adults and pediatric patients over 3 months of age.

IV injection: A single dose (up to 1 Gm [20 mL] after dilution) over 3 to 5 minutes.

Intermittent infusion: A single dose over 15 to 30 minutes.

ACTIONS

A synthetic, broad-spectrum, carbapenem antibiotic. Bactericidal to selected gram-negative, gram-positive, and anaerobic organisms. Bactericidal activity results from the inhibition of cell wall synthesis. Readily penetrates the cell wall of susceptible organisms to reach penicillin-binding protein targets. Has significant stability to hydrolysis by

penicillinases and cephalosporinases produced by gram-positive and gram-negative bacteria. Peak plasma concentrations reached by the end of an infusion. Penetrates well into most body fluids and tissues, including cerebrospinal fluid. Peak fluid and tissue concentrations reached in 0.5 to 1.5 hours. Minimal protein binding. Elimination half-life averages 1 hour in adults, 1.5 hours in pediatric patients age 3 months to 2 years. 70% recovered as unchanged drug in urine within 12 hours. Not yet known if it crosses the placental barrier or is secreted in breast milk.

INDICATIONS AND USES

Treatment of intra-abdominal infections (e.g., complicated appendicitis, peritonitis) caused by specific susceptible organisms. ■ Treatment of complicated skin and skin structure infections, including diabetic foot infections, caused by specific susceptible organisms. ■ Treatment of bacterial meningitis in pediatric patients 3 months of age and older caused by specific susceptible organisms.

Unlabeled uses: Treatment of febrile neutropenia. ■ Treatment of meningitis in adults. ■ Treatment of Burkholderia infections. ■ Treatment of acute pulmonary exacerbations in cystic fibrosis patients with chronic lower respiratory tract infections with susceptible organisms (orphan drug status). ■ Treatment of liver abscess, complicated urinary tract infections, and other mild, moderate, or severe infections.

CONTRAINDICATIONS

History of hypersensitivity to meropenem, its components, any other carbapenem antibiotic (e.g., imipenem-cilastatin [Primaxin]), or patients with hypersensitivity to beta-lactams; see [Precautions](#).

PRECAUTIONS

Specific sensitivity studies are indicated to determine susceptibility of the causative organism to meropenem. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, meropenem should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Serious and occasionally fatal hypersensitivity reactions have been reported in patients receiving therapy with beta-lactams (e.g., penicillins, cephalosporins, carbapenems). More likely in patients with a history of sensitivity to multiple allergens; obtain a careful history. Cross-sensitivity is possible. ■ May cause seizures in patients with a history of CNS disorders (e.g., brain lesions, history of seizures) or with bacterial meningitis and/or compromised renal function. Use extreme caution; continue administration of anticonvulsants in patients with known seizure disorders. ■ Use with caution in patients with moderately severe impaired renal function (CrCl 10 to 26 mL/min); thrombocytopenia may occur and incidence of heart failure, kidney failure, and shock may be increased; see [Dose Adjustments](#). ■ Staphylococci resistant to methicillin/oxacillin must be considered resistant to meropenem. ■ May have cross-resistance with strains resistant to other carbapenems (e.g., imipenem-cilastatin [Primaxin]). ■ Localized clusters of infections resulting from carbapenem-resistant bacteria have been reported in some regions. ■ Has been found to eliminate concurrent bacteremia associated with bacterial meningitis. ■ Has the potential for neuromotor impairment (e.g., headaches, paresthesias, seizures) that can interfere with mental alertness and/or cause motor impairment; see [Patient Education](#). ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with meropenem. ■ See [Drug/Lab Interactions](#).

Monitor: Anaphylaxis has been reported. Emergency equipment must always be available. ■ Monitor infusion site for inflammation and/or extravasation. May cause thrombophlebitis. ■ Monitor for S/S of CNS reactions (e.g., focal tremors, myoclonus, seizures). ■ Monitor renal, hepatic, and hemopoietic systems in prolonged therapy. ■ Each 1 Gm contains 3.92 mEq of sodium; monitoring of electrolytes may be indicated. ■ See [Drug/Lab Interactions](#) and [Side Effects](#).

Patient Education: Report any itching, rash, shortness of breath, or twitching sensation immediately. ■ Report any burning, pain, or stinging at injection site. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Patients with a history of seizures should review medication profile with physician before taking meropenem; see [Drug/Lab Interactions](#). ■ May interfere with mental alertness and/or cause motor impairment. Do not operate machinery or drive until tolerance is established.

Maternal/Child: Category B: safety for use in pregnancy not established; use only if clearly needed. ■ Use caution during breast-feeding. Not known if meropenem is secreted in breast milk; safety not established. ■ Approved only for use in infants and other pediatric patients over 3 months of age. ■ Safety data are limited to support the administration of a 40 mg/kg (up to a maximum of 2 Gm) bolus dose.

Elderly: Consider age-related renal impairment; plasma clearance is decreased with decreased renal function; see [Dose Adjustments](#). Monitoring of renal function is suggested. Response is similar to that seen in younger patients; however, greater sensitivity in the elderly cannot be ruled out. See [Precautions](#).

DRUG/LAB INTERACTIONS

Carbapenems may reduce serum **valproic acid** concentrations to subtherapeutic levels, resulting in a loss of seizure control. Monitor valproic acid levels. Consider alternative antibacterial therapy. If administration of meropenem is necessary, supplemental anticonvulsant therapy should be considered. ■ **Probenecid** inhibits renal excretion and increases serum levels of meropenem, extending its half-life and increasing systemic exposure; coadministration is not recommended. ■ May be synergistic with **aminoglycosides** against some isolates of *Pseudomonas aeruginosa*.

SIDE EFFECTS

Toxicity rate is usually low. **Pediatric patients:** Diarrhea, diaper area moniliasis, glossitis, oral moniliasis, rash, vomiting. **Adults:** Anemia, constipation, diarrhea, headache, nausea and vomiting, neuromotor impairment, rash. Injection site reactions (e.g., edema, inflammation, pain, phlebitis, pruritus) are most common. Apnea, pruritus, sepsis, and shock also occurred in more than 1% of patients. Many other side effects including increases or decreases in hematologic, hepatic, and renal lab tests may occur in fewer than 1% of patients. **Adults and pediatric patients:** Full scope of hypersensitivity reactions, including anaphylaxis, have occurred in a few patients.

Post-Marketing: Agranulocytosis, angioedema, bleeding events (e.g., GI bleeding, epistaxis), CDAD, erythema multiforme, hemolytic anemia, leukopenia, neutropenia, positive direct or indirect Coombs' test, Stevens-Johnson syndrome, seizures, shock, sepsis, thrombocytopenia, and toxic epidermal necrolysis can occur.

ANTIDOTE

Notify physician of all side effects. Most treated symptomatically. Discontinue immediately if a hypersensitivity reaction occurs. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). If focal tremors, myoclonus, or seizures occur, evaluate neurologically, initiate anticonvulsant therapy, and decide whether to decrease or discontinue meropenem. Mild cases of CDAD may respond to discontinuation of meropenem. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Readily removed by hemodialysis.

MESNA

(MEZ-nah)

Antidote
 Antineoplastic adjunct
 Prophylactic for hemorrhagic cystitis

Ifosfamide/Mesna Kit, Mesnex, Uromitexan 

pH 6.5 to 8.5

USUAL DOSE

Specific testing recommended before each dose of ifosfamide; see **Monitor**.

Intravenous dose: Total daily dose is 60% of the ifosfamide dose equally divided into 3 doses. A single dose of mesna equal to 20% of the ifosfamide dose is given at the time of the ifosfamide injection and repeated 4 hours and 8 hours later (e.g., ifosfamide 1.2 Gm/M² would require mesna 240 mg/M² with the ifosfamide, 240 mg/M² in 4 hours, and again at 8 hours). The initial mesna dose each day may be mixed with the ifosfamide. Appears to be **compatible**. Available combined in solution with ifosfamide and as a single agent in tablet form.

Combination of intravenous and oral doses: At the time of the ifosfamide injection, give a single IV dose of mesna equal to 20% of the ifosfamide dose. At 2 hours and at 6 hours after each dose of ifosfamide, administer mesna tablets PO in a dose equal to 40% of the ifosfamide dose. The total daily dose of mesna (IV [20%] and PO [80%] combined) is 100% of the ifosfamide dose.

DOSE ADJUSTMENTS

Dose of mesna must be repeated each day ifosfamide is administered and adjusted with each increase or decrease of the ifosfamide dose.

DILUTION

Each 100 mg (1 mL) must be diluted in a minimum of 4 mL D5W, D5NS, D5¹/₄NS, D5¹/₃NS, D5¹/₂NS, NS, or LR. Desired concentration is 20 mg/mL.

Filters: Manufacturer's studies measured the potency of ifosfamide in combination with mesna through a 5-micron filter. No significant drug loss for ifosfamide; mesna was not measured.

Storage: Store at CRT before use. Opened multidose vials may be stored at CRT and used for up to 8 days. Diluted solutions are stable for 24 hours at 25° C (77° F). Mesna oxidizes to disulfide dimesna when exposed to oxygen.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Cyclophosphamide (Cytoxan), ifosfamide (Ifex).

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), aztreonam (Azactam), cladribine (Leustatin), docetaxel (Taxotere), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), linezolid (Zyvox), melphalan (Alkeran), methotrexate, micafungin (Mycamine), ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), sargramostim (Leukine), sodium bicarbonate, teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

A single dose over a minimum of 1 minute given as a single agent. Administer at rate for ifosfamide if given together. Another source recommends administering as an infusion over 15 to 30 minutes or as a continuous infusion maintained for 12 to 24 hours after completion of the ifosfamide infusion.

ACTIONS

A detoxifying agent. Reacts chemically in the kidney with urotoxic ifosfamide metabolites to detoxify them and inhibit hemorrhagic cystitis. Remains in the intravascular compartment and much of a single dose is excreted within 4 hours in urine. Does not appear to interfere with the anti-tumor efficacy of ifosfamide.

INDICATIONS AND USES

A prophylactic agent used to reduce the incidence of hemorrhagic cystitis caused by ifosfamide.

Unlabeled uses: May reduce the incidence of hemorrhagic cystitis caused by cyclophosphamide.

CONTRAINDICATIONS

Hypersensitivity to mesna or other thiol compounds.

PRECAUTIONS

Repeated doses are required to maintain adequate levels of mesna in the kidneys and bladder to detoxify urotoxic ifosfamide metabolites. ■ Hemorrhagic cystitis caused by ifosfamide is dose dependent. Mesna is most effective when ifosfamide dose is less than 1.2 Gm/M²/24 hr. Somewhat less effective when ifosfamide dose is 2 to 4 Gm/M²/24 hr. If hematuria develops with appropriate doses of mesna, ifosfamide dose may need to be reduced or discontinued. ■ Does not inhibit any other side effects or toxicities caused by ifosfamide therapy. ■ Not effective in preventing hematuria caused by other conditions (e.g., thrombocytopenia). ■ Hypersensitivity reactions ranging from mild to anaphylaxis have been reported. Patients with autoimmune disorders who are treated with cyclophosphamide and mesna may have a higher incidence of hypersensitivity reactions.

Monitor: Before administering each dose of ifosfamide, obtain a morning specimen of urine and test for hematuria. Depending on the severity of the hematuria, dose reduction or discontinuation of ifosfamide may be required. ■ If emesis occurs within 2 hours of taking PO mesna, either repeat the PO dose or administer an IV dose.

Patient Education: Drink at least one quart of liquid daily. ■ Report pink or red urine immediately. ■ Report emesis within 2 hours of taking PO mesna.

Maternal/Child: Category B: use during pregnancy only if benefits clearly outweigh risks. ■ Discontinue breast-feeding. ■ Multidose vial contains benzyl alcohol. Do not use in neonates or infants.

Elderly: Dosing should be cautious; however, the ratio of ifosfamide to mesna should remain the same.

DRUG/LAB INTERACTIONS

May cause a false-positive reaction for **urinary ketones**. If a red-violet color develops, glacial acetic acid returns the coloring to violet.

SIDE EFFECTS

Average dose: Anorexia, bad taste in the mouth, coughing, decreased platelets associated with hypersensitivity reactions, diarrhea, dizziness, fever, flushing, headache, hyperesthesia, hypersensitivity reactions, hypertension, hypotension, increased liver enzymes, influenza-like symptoms, injection site reactions, malaise, myalgia, nausea, pharyngitis, soft stool, somnolence, ST-segment elevation, tachycardia, tachypnea, vomiting.

Overdose: Convulsions, cyanosis, diarrhea, dyspnea, fatigue, headache, hematuria, hypersensitivity reactions, hypotension, limb pain, nausea, tremor.

ANTIDOTE

No specific antidote. Keep physician informed of all side effects. Notify promptly if signs of overdose occur. Resuscitate as necessary.

METHADONE HYDROCHLORIDE **BBW**

(METH-ah-dohn hy-droh-KLOR-eyed)

Opioid analgesic
(agonist)
Narcotic abstinence
syndrome suppressant**Dolophine**

pH 4.5 to 6.5

USUAL DOSE

Parenteral administration permitted only under specific conditions; see [Indications](#) and [Precautions](#).

Dosing is complex and requires extensive individualization. Extended half-life, potential for prolonged respiratory depressant effects, retention in the liver (prolonging the potential duration of action), and high interpatient variability in absorption, metabolism, and relative analgesic potency must be considered.

Treatment of pain: Consider the following factors for each patient before determining an initial dose:

- Total daily dose, potency, and specific characteristics of any previously administered opioid.
- Will it be used for acute or chronic methadone dosing?
- Patient's degree of opioid tolerance.
- Patient's age, general condition, and medical status.
- Concurrent medications; see [Drug/Lab Interactions](#).
- Type, severity, and expected duration of patient's pain.
- Acceptable balance between pain control and adverse effects.

Initial analgesic in patients who are not being treated with other opioids and are not tolerant to other opioids: 2.5 to 10 mg every 8 to 12 hours. Titrate slowly to effect. More frequent dosing may be required to maintain adequate analgesia; use extreme caution, consider extended half-life, and avoid overdose.

Conversion from oral to parenteral methadone: Begin with a 2:1 ratio (e.g., 10 mg oral methadone to 5 mg parenteral methadone); see [Precautions](#).

Switching from other chronic opioids to parenteral methadone: Dose conversion ratios and cross-tolerance are uncertain; deaths have occurred in opioid-tolerant patients during conversion to methadone. Individualize dose based on patient's prior opioid exposure, general medical condition, concomitant medication, and anticipated breakthrough medication use. Titrate to achieve adequate pain relief balanced against tolerability of side effects. Adjust dose and/or dosing interval as necessary. The following charts are examples of conversions.

Conversion from Oral Morphine to IV Methadone for Chronic Administration		
Total Daily Baseline Oral Morphine Dose	Estimated Total Daily Oral Methadone Dose as a Percentage of Total Daily Morphine Dose*	Estimated Daily IV Methadone Dose as a Percentage of Total Daily Oral Morphine Dose*
<100 mg	20% to 30%	10% to 15%
100 mg to 300 mg	10% to 20%	5% to 10%
300 mg to 600 mg	8% to 12%	4% to 6%
600 mg to 1,000 mg	5% to 10%	3% to 5%
>1,000 mg	Less than 5%	Less than 3%

*Divide total daily methadone dose as necessary to achieve desired dosing schedule (e.g., divide by 3 for administration every 8 hours).

Conversion from Parenteral Morphine to IV Methadone for Chronic Administration	
Total Daily Baseline Parenteral Morphine Dose	Estimated Daily IV Methadone Dose as a Percentage of Total Daily Morphine Dose*
10 mg to 30 mg	40% to 66%
30 mg to 50 mg	27% to 66%
50 mg to 100 mg	22% to 50%
100 mg to 200 mg	15% to 34%
200 mg to 500 mg	10% to 20%

*Divide total daily methadone dose as necessary to achieve desired dosing schedule (e.g., divide by 3 for administration every 8 hours).

DOSE ADJUSTMENTS

Lower-end initial doses are indicated in the elderly; consider impaired organ function and concomitant disease or drug therapy. ■ Reduced initial doses are indicated in debilitated patients and in those with severe impaired hepatic or renal function. ■ Clearance may be increased and half-life decreased during pregnancy. Increased doses or shorter intervals between doses may be indicated; see [Maternal/Child](#).

DILUTION

May be given undiluted; however, to facilitate titration, further dilution of each mL with 1 to 5 mL of NS is appropriate. May be given through Y-tube or three-way stopcock of infusion set.

Storage: A multidose vial; store in carton at CRT protected from light until contents have been used.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Atropine, dexamethasone (Decadron), diazepam (Valium), diphenhydramine (Benadryl), ketorolac (Toradol), lorazepam (Ativan), metoclopramide (Reglan), midazolam (Versed), phenobarbital (Luminal).

RATE OF ADMINISTRATION

A single dose as an injection over a minimum of several minutes. Titrate according to symptom relief and respiratory rate; side effects may be increased if rate of injection is too rapid.

ACTIONS

A synthetic opioid analgesic with actions similar to those of morphine. Duration of analgesic action is from 4 to 8 hours. Respiratory depressant effects occur later and persist longer than its peak analgesic effects. With repeated dosing, methadone may be retained in the liver and then slowly released, thereby prolonging the duration of action while plasma concentrations are low. Highly protein bound (85% to 90%). Metabolized in the liver by various enzymes (including cytochrome P₄₅₀ enzymes) to inactive metabolites. Half-life is prolonged (ranges from 8 to 59 hours). Eliminated by extensive biotransformation followed by renal and fecal elimination. Secreted in saliva, breast milk, amniotic fluid, and umbilical cord plasma.

INDICATIONS AND USES

Treatment of moderate to severe pain not responsive to non-narcotic analgesics. ■ Temporary treatment in opioid-dependent patients unable to take oral medication. ■ Used PO for detoxification or maintenance in opioid addiction. ■ Parenteral products are not approved for outpatient use.

CONTRAINDICATIONS

Known hypersensitivity to methadone or any of its components. ■ Any situation in which opioids are contraindicated (e.g., patients with respiratory depression [where resuscitative equipment is not readily available or in unmonitored settings], patients with acute bronchial asthma or hypercarbia). ■ Other sources add paralytic ileus and concurrent use of selegiline (Zelapar, Eldepryl).

PRECAUTIONS

If the parenteral route is indicated, the IV route is preferred; absorption by the IM or SC routes is unpredictable and may cause local tissue reaction. ■ Schedule II opioid agonists, including hydromorphone, morphine, oxycodone, fentanyl, and methadone, have the highest potential for abuse and risk of producing respiratory depression. Alcohol, CNS depressants, and other opioids potentiate the respiratory depressant effects of hydromorphone, increasing the risk of respiratory depression that might result in death; see [Drug/Lab Interactions](#). ■ Deaths, cardiac and respiratory, have been reported during initiation and conversion of pain patients to methadone treatment from treatment with other opioid agonists. Close monitoring is required during these times as well as during dose titration. ■ The peak respiratory depressant effects of methadone usually occur later and last longer than the peak analgesic effects. Iatrogenic overdose may occur with short-term use, particularly during treatment initiation and dose titration. ■ Patients tolerant to other opioids may still be sensitive to methadone. This incomplete cross-tolerance makes dose selection difficult when converting to methadone. Deaths have been reported. A high degree of “opioid tolerance” does not eliminate the possibility of methadone toxicity. ■ Prolongation of the QT interval and infrequent cases of arrhythmia (including torsades de pointes) have been reported. May occur with any dose but appears to be more common with higher dose treatment (greater than 200 mg/day). ■ Use with caution in patients at risk for development of prolonged QT interval (e.g., cardiac conduction abnormalities, cardiac hypertrophy, hypokalemia, hypomagnesemia) and in patients receiving concurrent treatment with other drugs that may induce electrolyte disturbances (e.g., diuretics, laxatives and, rarely, mineralocorticoid hormones) or other drugs that may prolong the QT interval; see [Drug/Lab Interactions](#). ■ Initiate treatment for analgesic therapy in patients with acute or chronic pain only if benefits outweigh the increased risk of QT prolongation with high doses. ■ Use extreme caution in patients with potential respiratory insufficiency (e.g., elderly or debilitated patients, conditions accompanied by hypoxia or hypercapnia or decreased respiratory reserve [e.g., asthma, COPD, pulmonary disease or cor pulmonale, severe obesity, sleep apnea syndrome, myxedema, kyphoscoliosis, CNS depression, or coma]). Usual doses may decrease respiratory drive and simultaneously increase airway resistance, resulting in apnea. Consider use of non-opioid analgesics. If methadone is required, administer at lowest effective dose under close medical supervision. ■ Use caution in elderly or debilitated patients, severe impaired hepatic or renal function, Addison’s disease, hypothyroidism, prostatic hypertrophy, or urethral stricture; see [Dose Adjustments](#). ■ Use with caution in patients with head injury, other intracranial lesions, or pre-existing increased intracranial pressure. Cerebrospinal fluid pressure may be markedly exaggerated, and the clinical course of head injuries may be obscured. ■ May mask symptoms and make diagnosis of acute abdominal conditions difficult. ■ May cause severe hypotension in patients whose ability to maintain normal blood pressure is compromised (e.g., severe volume depletion). ■ Patients with impaired hepatic function may be at increased risk of accumulating methadone after multiple dosing. ■ Because of their opioid tolerance, patients receiving maintenance doses may require increased or more frequent doses of opioids to treat physical trauma, postoperative pain, or other acute pain. ■ Do not increase methadone dose for symptoms of anxiety. ■ Abrupt discontinuation of methadone is not rec-

ommended; may result in withdrawal symptoms (e.g., chills, lacrimation, myalgia, mydriasis, perspiration, restlessness, rhinorrhea, yawning), and may lead to relapse of illicit drug use.

Monitor: Oxygen, controlled ventilation equipment, and naloxone (Narcan) must always be available. ■ Observe patient frequently to continuously based on amount of dose, and monitor VS. ■ Assess baseline pain, then assess pain with vital signs or more frequently if needed. Reassess after administration of methadone and adjust dose or interval as required. Keep patient supine; orthostatic hypotension and fainting may occur; monitor closely during ambulation. ■ Uncontrolled pain causes sleep deprivation, decreases pain threshold, and increases pain. When pain is finally controlled, expect the patient to sleep more until recovered from sleep deprivation. ■ Monitor ECG in patients who develop QT prolongation and assess for modifiable risk factors (e.g., drugs with cardiac effects, drugs that may cause electrolyte abnormalities, or drugs that may inhibit the metabolism of methadone); see [Drug/Lab Interactions](#). Consider alternate therapies for pain management. ■ Laxatives with or without stool softeners will be required to avoid constipation and fecal impaction, especially with increased doses and extended use. Maintain adequate hydration. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Promptly report dizziness, light-headedness, palpitations, or syncope; may indicate a need for ECG monitoring. ■ Avoid alcohol or other CNS depressants (e.g., barbiturates, benzodiazepines [e.g., diazepam (Valium)]). ■ May cause blurred vision, dizziness, or drowsiness; use caution in tasks that require alertness. ■ Request assistance with ambulation. ■ May be habit forming.

Maternal/Child: Category C: potential benefit should justify potential risk to fetus. Compare the benefit of methadone to the risk of untreated addiction to illicit drugs. ■ Total body clearance is increased during pregnancy and half-life is decreased (during 2nd and 3rd trimesters). May lead to withdrawal symptoms. Increases in dose or dosing at more frequent intervals may be indicated. ■ Data is insufficient; however, women treated with methadone during pregnancy had improved prenatal care and did not appear to have an increased risk of miscarriage or premature delivery. Methadone in amniotic fluid and cord plasma has similar concentrations to maternal plasma. Newborn urine concentrations are less than maternal. ■ Infants born to women treated with methadone during pregnancy may experience respiratory depression (consider methadone's long duration of action), and may be born physically dependent. Onset of withdrawal may occur in days or be delayed for 2 to 4 weeks. Withdrawal signs include fever, hyperactive reflexes, increased respiratory rate, increased stools, irritability and excessive crying, sneezing, tremors, vomiting, and yawning. May have reduced birth weight, length, and/or head circumference and some deficits in psychometric and behavioral tests. ■ Discontinue or do not start breast-feeding. Women who are breast-feeding should wean gradually to prevent withdrawal symptoms in their infants. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established. ■ See [Drug/Lab Interactions](#).

Elderly: Dosing should be cautious; see [Dose Adjustments](#). ■ Differences in response compared to younger adults not identified. ■ See [Precautions](#).

DRUG/LAB INTERACTIONS

May have additive effects with **other CNS depressants** (e.g., alcohol, general anesthetics, hypnotics or sedatives [e.g., benzodiazepines (e.g., diazepam [Valium], midazolam [Versed]), barbiturates [e.g., phenobarbital (Luminal)], other opioid analgesics, phenothiazines [e.g., prochlorperazine (Compazine)]). Concurrent use may result in hypotension, profound sedation, respiratory depression, coma, or death. ■ Not recommended for concurrent administration with **opioid antagonists** (e.g., naloxone [Narcan], naltrexone [ReVia]), **mixed agonist/antagonists, or partial agonists** (e.g., buprenorphine [Buprenex], butorphanol [Stadol], nalbuphine, pentazocine [Talwin]); may precipitate withdrawal

symptoms and/or reduce analgesic effect in patients maintained on methadone. ■ Metabolism increased and serum concentrations decreased by **cytochrome P₄₅₀ inducers** (e.g., carbamazepine [Tegretol], phenobarbital [Luminal], phenytoin [Dilantin], rifampin [Rifadin], St. John's wort), efavirenz (Sustiva), nevirapine (Viramune), ritonavir (Norvir), and ritonavir/lopinavir combination (Kaletra). With concurrent administration, the effects of methadone are decreased; monitor for S/S of withdrawal, and adjust methadone dose as indicated. ■ Metabolism decreased and serum concentrations increased by **cytochrome P₄₅₀ inhibitors** (e.g., azole antifungal agents [e.g., itraconazole (Sporanox), ketoconazole (Nizoral)], macrolide antibiotics [e.g., erythromycin], selective serotonin reuptake inhibitors (SSRIs) [e.g., fluvoxamine (Luvox), sertraline (Zoloft)]). With concurrent administration, monitor methadone serum concentrations to prevent methadone toxicity. ■ May increase serum levels of **desipramine** (Norpramin). ■ May increase AUC of **zidovudine** and result in zidovudine toxicity. ■ May decrease AUC and peak levels of **didanosine** (Videx) and **stavudine** (Zerit). ■ Use caution with **MAO inhibitors** (e.g., selegiline [Eldepryl]) administered within 14 days and test for sensitivity. MAO inhibitors have caused cardiovascular collapse with other opioids (e.g., meperidine [Demerol]), not reported with methadone; see **Contraindications**. ■ Use extreme caution with other **drugs that prolong the QT interval** (e.g., class IA antiarrhythmic agents [e.g., quinidine, procainamide (Pronestyl)], class III antiarrhythmic agents [e.g., amiodarone (Nexterone), sotalol (Betapace)], calcium channel blockers [e.g., diltiazem (Cardizem), verapamil], some neuroleptics [e.g., phenothiazines (e.g., chlorpromazine [Thorazine])], and tricyclic antidepressants [e.g., amitriptyline (Elavil), imipramine (Tofranil)]).

SIDE EFFECTS

Hypotension and respiratory depression are dose limiting. Respiratory arrest, shock, cardiac arrest, and death have occurred.

Dizziness, light-headedness, nausea and vomiting, sedation, and sweating occur most frequently. Other reported side effects include abdominal pain, agitation, anorexia, an-

tidiuretic effect, arrhythmias, asthenia, biliary tract spasm, cardiomyopathy, confusion, constipation, chronic hepatitis, dry mouth, edema, euphoria, flushing, glossitis, headache, heart failure, hypokalemia, hypomagnesemia, hypotension, palpitations, phlebitis, prolonged QT interval, pulmonary edema, pruritus, seizures, skin rashes, syncope, thrombocytopenia (reversible), torsades de pointes, urticaria, urinary retention or hesitancy, visual disturbances.

Overdose: Bradycardia, cold and clammy skin, constricted pupils, hypotension, respiratory depression (decrease in respiratory rate and/or tidal volume, Cheyne-Stokes respiration, cyanosis), skeletal muscle flaccidity, somnolence progressing to stupor or coma. Apnea, circulatory collapse, cardiac arrest, and death may occur.

ANTIDOTE

Keep physician informed of all side effects; may be treated symptomatically. During prolonged administration (patients on maintenance), side effects usually decrease with time. Lower doses of methadone may be indicated for dizziness, light-headedness, nausea and vomiting, sedation, and sweating. Management of major side effects or overdose requires establishing a patent airway, instituting assisted or controlled ventilation, IV fluids, vasopressors, and other supportive measures as indicated. Nontolerant patients may be treated with naloxone (Narcan). These opioid antagonists have a much shorter duration of action than methadone and may need repeating for up to 48 hours. Continuous monitoring is required. Do not administer opioid antagonists to physically dependent patients unless clinically significant respiratory or cardiovascular depression occurs. May precipitate an acute withdrawal syndrome. Forced diuresis, peritoneal dialysis, hemodialysis, or charcoal hemoperfusion may not be useful to increase methadone or metabolite elimination; however, urine acidification has been shown to increase renal elimination of methadone.

METHOTREXATE SODIUM **BBW**

(meth-oh-TREKS-ayt SO-dee-um)

Antineoplastic (antimetabolite)

Antipsoriatic

Antirheumatic

Methotrexate PF, MTX

pH 8.5

USUAL DOSE

Many dose limitations based on patient condition, renal and hepatic function, and concomitant drugs or therapies; see [Precautions/Monitor](#). Doses between 100 and 500 mg/M² **may require** leucovorin calcium rescue. Doses over 500 mg/M² **require** leucovorin calcium rescue; see leucovorin calcium or levoleucovorin (Fusilev) monograph. Part of numerous protocols that change as new advances in antileukemic therapy are developed for all diagnoses. Selections from those protocols are included in the following text.

Acute lymphoblastic leukemia: Induction: 3.3 mg/M² in combination with prednisone 60 mg/M². Give daily if tolerated, and continue for up to 8 weeks or until satisfactory response (usually 4 to 6 weeks). Usually given PO.

Maintenance: Dose individualized; 15 mg/M²/dose administered 2 times weekly IM or PO (a total dose of 30 mg/M²) or 2.5 mg/kg IV every 14 days has been used.

Gastric cancers (unlabeled): One regimen administers methotrexate 1.5 Gm/M² on Day 1 followed by 1.5 Gm/M² of fluorouracil on Day 1 (administer 1 hour after methotrexate infusion is complete), leucovorin calcium 15 mg/M² PO every 6 hours for 48 hours starting 24 hours after methotrexate, and doxorubicin 30 mg/M² IV on Day 15. Repeated every 4 weeks.

Mycosis fungoides: 5 to 50 mg once weekly in the early stages of disease. Adjust dose or discontinue as indicated by patient response and hematologic monitoring. 15 to 37.5 mg twice weekly may be used in patients who respond poorly to weekly therapy. Usually given PO or IM, but combination chemotherapy regimens, including higher doses of IV methotrexate with leucovorin calcium rescue, have been used in advanced stages of the disease.

Breast cancer (unlabeled): One regimen administers methotrexate 40 mg/M² on Days 1 and 8 of each cycle. Given in combination with PO cyclophosphamide 100 mg/M² on Days 1 through 14 of each cycle and fluorouracil 600 mg/M² on Days 1 and 8 of each cycle. In patients over 60 years of age, reduce the initial methotrexate dose to 30 mg/M² and the initial fluorouracil dose to 400 mg/M². Repeat monthly (allows a 2-week rest period between cycles) for 6 to 12 cycles. Another source suggests methotrexate 30 to 60 mg/M² on Days 1 and 8 every 3 to 4 weeks.

Psoriasis: 10 to 25 mg once a week until adequate response. Some references suggest an initial test dose of 5 to 10 mg/week before initiating therapy to detect sensitivity to adverse reactions. Sources suggest 30 mg/week as a maximum dose. Use smallest effective dose. Usually given PO or IM. May be used in combination with infliximab; see infliximab monograph.

Osteosarcoma: One regimen recommends 12 Gm/M² as a single dose given as an infusion over 4 hours. Begin the fourth week after surgery and repeat weekly at Weeks 5, 6, 7, 11, 12, 15, 16, 29, 30, 44, and 45. A peak serum concentration of 1,000 micromol/L at the end of the infusion is desired. Dose may be increased to 15 Gm/M² if required. Must be accompanied by leucovorin calcium rescue; see leucovorin calcium or levoleucovorin (Fusilev) monograph. Leucovorin calcium may be given IV or PO; levoleucovorin is IV only. **Osteosarcoma also requires combination chemotherapy.** Protocols vary but may include methotrexate in combination with doxorubicin, with cisplatin, and with the combination of bleomycin, cyclophosphamide, and dactinomycin (BCD regimen). These massive doses are highly individualized and require exacting calculations and constant patient monitoring; see [Precautions/Monitor](#).

PEDIATRIC DOSE

Safety for use in pediatric patients is limited to chemotherapy and in polyarticular-course juvenile rheumatoid arthritis. May contain benzyl alcohol; not recommended for use in neonates. See [Maternal/Child](#).

DOSE ADJUSTMENTS

Administer 75% of dose if bilirubin is between 3.1 and 5 or if transaminases are greater than 3 times the ULN; if bilirubin above 5, omit dose. ■ Reduced doses may be required in patients with impaired renal function. Suggested guidelines are to administer 75% of a dose with a CrCl of 61 to 80 mL/min, 70% of a dose with a CrCl of 51 to 60 mL/min, 30% to 50% of a dose with a CrCl of 10 to 50 mL/min, and avoid use with a CrCl of less than 10 mL/min. Supplemental doses are not necessary in hemodialysis or peritoneal dialysis patients; methotrexate is not dialyzable. ■ Reduced dose may be required in patients with ascites or pleural effusions, in the very young or very elderly, in the debilitated, and in other diseases; see [Precautions](#). ■ Often used with other antineoplastic drugs to achieve tumor remission. ■ See [Drug/Lab Interactions](#).

DILUTION

Specific techniques required; see [Precautions](#). 25 mg/mL is the maximum concentration that can be given IV. Reconstitution of each 5 mg with 2 mL of preservative-free D5W or NS is suggested. Each milliliter equals 2.5 mg of methotrexate. Available in preservative-free solution. Do not use formulations or diluents with preservatives (e.g., bacteriostatic) for high-dose therapy or intrathecal injection. 1-Gm vial available for high-dose use with appropriate dilution. Not usually added to IV solutions when given in smaller doses (less than 100 mg). Discard solution if a precipitate forms. May be given through Y-tube or three-way stopcock of a free-flowing IV.

A single dose may be further diluted with D5W or NS immediately before use as an infusion with higher (100 mg or more) methotrexate doses.

Filters: No data available from manufacturer. Another source indicates no significant drug loss filtered through a nylon 0.2-micron filter.

Storage: Store in unopened container at CRT; protect from light. If prepared without a preservative, use immediately. May be stable up to 24 hours with a preservative.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Cyclophosphamide (Cytoxan), cytarabine (ARA-C), fluorouracil (5-FU), ondansetron (Zofran), sodium bicarbonate, vincristine. Other sources add dacarbazine (DTIC), furosemide (Lasix), hydrocortisone sodium succinate (Solu-Cortef), leucovorin calcium.

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), amphotericin B cholesteryl (Amphotec), asparaginase (Elspar), aztreonam (Azactam), bleomycin (Blenoxane), ceftriaxone (Rocephin), cisplatin (Platinol), cyclophosphamide (Cytoxan), cytarabine (ARA-C), daunorubicin (Cerubidine), doripenem (Doribax), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), etoposide (VePesid), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gallium nitrate (Ganite), granisetron (Kytril), heparin, imipenem-cilastatin (Primaxin), leucovorin calcium, linezolid (Zyvox), melphalan (Alkeran), mesna (Mesnex), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), mitomycin (Mutamycin), ondansetron (Zofran), oxacillin (Bactocill), oxaliplatin (Eloxatin), paclitaxel (Taxol), piperacillin/tazobactam (Zosyn), sargramostim (Leukine), teniposide (Vumon), thiotepa, vancomycin, vinblastine, vincristine, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

IV injection: Each 10 mg or fraction thereof over 1 minute.

Infusion: A single dose equally distributed over 30 minutes to 4 hours or as prescribed by protocol.

ACTIONS

An antimetabolite and folic acid antagonist. Cell cycle–specific for the S phase. It interferes with DNA synthesis, repair, and cellular replication. Rapidly proliferating malignant cells are inhibited by a cytostatic effect. Widely distributed and is approximately 50% protein bound. Undergoes some hepatic and intracellular metabolism. Half-life is dose dependent and is 3 to 10 hours in patients receiving low-dose antineoplastic therapy and 8 to 15 hours in patients receiving high-dose methotrexate therapy. 80% to 90% of the administered dose is excreted unchanged in the urine within 24 hours. Clearance rates decrease with higher doses. Does not cross blood-brain barrier. Secreted in breast milk.

INDICATIONS AND USES

Used for life-threatening neoplastic disease alone or in combination with other anti-cancer agents in the treatment of acute lymphocytic leukemia, breast cancer, epidermal tumors of the head and neck, small-cell and squamous cell lung cancer, non-Hodgkin's lymphoma, advanced mycosis fungoides (cutaneous T-cell lymphoma). ■ Severe disabling psoriasis or rheumatoid arthritis unresponsive to other treatment. ■ High-dose regimen for treatment of osteosarcoma. ■ Given PO or IM for early-stage mycosis fungoides, trophoblastic disease, polyarticular-course juvenile rheumatoid arthritis, rheumatoid arthritis, and other diagnoses and intrathecally for meningeal leukemia.

Unlabeled uses: Treatment of bladder, gastric, and testicular cancer. Treatment of acute nonlymphocytic leukemia, soft tissue sarcomas, and CNS tumors. Management of Crohn's disease and ectopic pregnancy and prevention of acute graft-versus-host disease. High-dose regimens for neoplastic diseases other than osteosarcoma are investigational, and therapeutic effects are not established.

CONTRAINDICATIONS

Hypersensitivity to methotrexate; breast-feeding mothers. Contraindicated in pregnant females with psoriasis or rheumatoid arthritis and in psoriasis or rheumatoid arthritis patients with immunodeficiency syndromes, pre-existing blood dyscrasias, or chronic liver disease. Not absolute, but methotrexate is not recommended during pregnancy or with hepatic, renal, or bone marrow damage.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Deaths have been reported with methotrexate use in the treatment of malignancy, psoriasis, and rheumatoid arthritis. ■ Methotrexate elimination is reduced in patients with impaired renal function, ascites, or pleural effusions. Careful monitoring, dose reduction and, in some cases, discontinuation of therapy is required; consider evacuating excess fluid from ascites and pleural effusions before treatment if possible. ■ Serious and sometimes fatal bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant use of methotrexate (usually high doses) and some NSAIDs; see [Drug/Lab Interactions](#). ■ Leukoencephalopathy has been reported in patients who have received both IV methotrexate and craniospinal irradiation. ■ A transient stroke-like encephalopathy has been reported with high-dose methotrexate therapy. Symptoms may include confusion, hemiparesis, transient blindness, seizures, and coma. ■ Methotrexate-induced lung disease, including acute or chronic interstitial pneumonitis, may occur at any time, may occur even with low doses, and has been fatal. Patients may present with fever, dry cough, dyspnea, hypoxemia, and an infiltrate on chest x-ray. May require interruption of therapy. ■ Severe skin reactions can occur at any time and have been fatal. ■ Elevated liver enzymes may occur early during treatment, but hepatotoxicity (may be fatal) occurs more frequently with prolonged use. ■ Use with extreme caution in patients with ascites, bone marrow suppression, folate deficiency, GI obstruction, infection, impaired renal or liver function, peptic ulcer, pleural effusion, or ulcerative colitis; in debilitated patients; and in the very young or very elderly. ■ Diarrhea and ulcerative stomatitis will require interrupting therapy; otherwise hemorrhagic enteritis and death from intestinal perforation may occur.

■ Tumor lysis syndrome may occur, and S/S include hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure. Prevent or alleviate tumor lysis syndrome with appropriate supportive and pharmacologic measures; see **Monitor**. ■ Potentially fatal opportunistic infections, especially *Pneumocystis jiroveci* pneumonia, may occur. ■ Risk of soft tissue necrosis and osteonecrosis may be increased with concomitant use of methotrexate and radiotherapy. ■ May cause renal damage that may lead to acute renal failure. Nonreversible oliguric renal failure is likely to develop in patients who experience delayed early methotrexate elimination. ■ Malignant lymphomas have been reported. May occur in patients receiving low-dose methotrexate and may not require cytotoxic treatment; discontinue methotrexate first and initiate appropriate treatment if the lymphoma does not regress.

Monitor: Close patient observation is mandatory. Course of therapy is not repeated until all signs of toxicity from the previous course subside. ■ CBC with platelets, chest x-ray, and renal and liver function tests before, during, and after therapy are essential to comprehensive treatment. ■ Monitor closely for bone marrow, liver, lung, kidney, and skin toxicities. ■ Nadir of leukocyte and platelet count usually occurs after 7 to 10 days, with recovery 7 days later. Liver biopsy, pulmonary studies, and bone marrow studies may be indicated in high-dose or long-term therapy. ■ Monitor renal function closely; verify by CrCl levels; see **Precautions**. Maintain continuing adequate hydration and urine alkalinization. ■ Prevention and treatment of hyperuricemia due to tumor lysis syndrome may be accomplished with adequate hydration and, if necessary, allopurinol and alkalinization of urine. ■ Monitor serum methotrexate levels. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ **Administration of high-dose methotrexate** requires a WBC count greater than 1,500 mm³; neutrophil count greater than 200/mm³; platelet count greater than 75,000 mm³; serum bilirubin less than 1.2 mg/dL; alanine aminotransferase (ALT) level less than 450 units; any mucositis must be healing; ascites or pleural effusion must be drained dry; SCr must be normal; CrCl greater than 60 mL/min; 1 L/M² of IV fluid over 6 hours before dosing and 3 L/M²/day on day of infusion and for 2 days after; alkalinization of urine with sodium bicarbonate; and repeat serum methotrexate and SCr levels at least daily until methotrexate level is below 0.05 micromolar. ■ See **Drug/Lab Interactions**.

Patient Education: Avoid pregnancy. Nonhormonal birth control recommended for both females and males. Continue for at least 3 months after treatment is complete in male patients and for at least one ovulatory cycle after therapy is complete for female patients. ■ Avoid alcohol and take only prescribed medications. Reactions can be lethal. ■ Close follow-up with physician is imperative. ■ See Appendix D, p. 1255.

Maternal/Child: Category X: avoid pregnancy. Has caused fetal death and congenital anomalies. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients established for cancer chemotherapy and polyarticular-course juvenile rheumatoid arthritis. Not a labeled use but has been used in pediatric patients 2 to 16 years of age to treat rheumatoid arthritis.

Elderly: See **Dose Adjustments**. Dose selection should be cautious and based on the potential for decreased organ function, decreased folate stores, and concomitant disease or drug therapy. ■ Consider monitoring CrCl and methotrexate levels. ■ Monitor for early signs of hepatic, renal, or bone marrow toxicity. ■ In chronic administration, certain toxicities may be decreased by folate supplementation. ■ Post-marketing experience suggests that the occurrence of bone marrow suppression, thrombocytopenia, and pneumonitis may increase with age.

DRUG/LAB INTERACTIONS

The following drugs may enhance methotrexate toxicity when administered concomitantly: **alcohol**, **amiodarone** (Nexterone), **antibacterials** (e.g., tetracycline, chloramphenicol), **cyclosporine** (Sandimmune), **any hepatotoxic drug** (e.g., azathioprine [Imuran], reti-

noids [vitamin A]), **etretinate** (Tegison), **acetylated salicylates** (e.g., aspirin), **NSAIDs** (e.g., ibuprofen [Advil, Motrin], ketoprofen, naproxen [Aleve, Naprosyn]), **penicillins** (e.g., amoxicillin, mezlocillin), **probenecid**, **salicylates**, **sulfonamides**, **paraaminobenzoic acid** (PABA), **phenytoin** (Dilantin), **pyrimethamine**, **trimethoprim** (component of sulfamethoxazole/trimethoprim), and **vancomycin** (given up to 10 days prior to methotrexate); interactions may be life threatening. Monitoring serum levels and/or reduced doses of methotrexate may be indicated or a longer duration of leucovorin calcium rescue may be required. One source suggests delaying administration of aspirin, NSAIDs, and probenecid for 48 hours after larger doses of methotrexate; see **Precautions**. ■ **NSAIDs** are used in the treatment of rheumatoid arthritis in combination with low doses of methotrexate (e.g., 7.5 to 15 mg/week). Do not administer NSAIDs before or concomitantly with high doses of methotrexate (e.g., treatment of osteosarcoma); deaths have been reported. ■ Use caution if high-dose methotrexate is administered in combination with **nephrotoxic chemotherapy agents** (e.g., cisplatin [Platinol]). ■ Concurrent use of methotrexate (primarily at high dose) with **some proton pump inhibitors**, such as esomeprazole (Nexium), omeprazole (Prilosec), and pantoprazole (Protonix), may cause prolonged elevation of methotrexate levels, leading to toxicity. Discontinue several days before methotrexate administration. Consider an H₂ antagonist (e.g., ranitidine [Zantac]). ■ **Doxycycline** may increase toxicity of methotrexate in high-dose regimens. ■ **Vitamins with folic acid** may inhibit the antifolate effects of methotrexate. ■ May increase serum levels of **mercaptapurine** (Purinethol); dose adjustment may be required. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ May decrease **phenytoin** (Dilantin) serum levels. ■ **Procarbazine** (Matulane) may increase nephrotoxicity of methotrexate. Allow 72 hours between last dose of procarbazine and first dose of methotrexate. ■ Monitor for signs of increased bone marrow suppression with **sulfonamides** (e.g., sulfisoxazole [Gantrisin], SMZ-TMP [Bactrim]), **bone marrow-suppressing agents** (e.g., antineoplastics), and **radiation therapy**. May also cause SMZ-TMP (Bactrim)-induced megaloblastic anemia. ■ May decrease **theophylline** clearance and increase serum levels; monitor theophylline serum levels with concurrent use. ■ **Urinary alkalizers** increase renal excretion and may reduce effectiveness.

SIDE EFFECTS

Toxicity usually dose related. Death can occur from average doses, high doses, drug interactions (e.g., NSAIDs), bone marrow toxicity, GI toxicity, hepatic toxicity, pulmonary toxicity, and/or severe skin reactions. Abdominal distress, chills, decreased resistance to infection, dizziness, fatigue, fever, leukopenia, malaise, nausea, and ulcerative stomatitis occur most frequently. Other side effects reported include abortion (spontaneous), acne, acute hepatitis, agranulocytosis, alopecia, alveolitis, anaphylaxis, anemia, anorexia, aplastic anemia, azotemia, blurred vision, chronic fibrosis and cirrhosis, convulsions, COPD, cystitis, decreased serum albumin, defective oogenesis or spermatogenesis, diabetes, diarrhea, drowsiness, enteritis, eosinophilia, erythema multiforme, erythematous rashes, exfoliative dermatitis, fetal defects or death, furunculosis, gingivitis, GI ulceration and bleeding, gynecomastia, headache, hematemesis, hematuria, hemiparesis, hepatic failure, hepatotoxicity, hypotension, infertility, interstitial pneumonitis, liver enzyme elevations, lymphadenopathy and lymphoproliferative disorders, melena (passage of dark tarry stools), menstrual dysfunction, nephropathy (severe), neutropenia, oligospermia (transient), opportunistic infections (e.g., cytomegalovirus infection, herpes zoster, histoplasmosis, *Pneumocystis jiroveci* pneumonia), pancreatitis, pancytopenia, paresis, pericardial effusion, pericarditis, pharyngitis, photosensitivity, pigmentary changes, proteinuria, pruritus, pseudomembranous colitis, renal failure, respiratory failure, respiratory fibrosis, skin necrosis, skin ulceration, speech impairment (aphasia, dysarthria), Stevens-Johnson syndrome, stomatitis, suppressed hematopoiesis (blood cell formation), telangiectasia, thrombocytopenia, thromboembolic events (e.g., arterial thrombosis, cerebral thrombosis, deep vein thrombosis, pulmonary embolus, retinal vein thrombosis, thrombophlebitis), toxic epidermal necrolysis, transient blindness, tumor lysis syndrome, urticaria, vaginal discharge, vomiting.

ANTIDOTE

Discontinue methotrexate and notify the physician of any side effects. **Leucovorin calcium (citrovorum factor, folinic acid)** may be given PO, IM, or IV promptly to counteract inadvertent overdose. Leucovorin calcium is also indicated as a planned rescue mechanism for large doses of methotrexate required to treat some malignancies. Doses equal to dose of methotrexate are frequently required. Should be given within 1 hour in overdose, 24 hours in rescue. See specific process for overdose and for rescue for high-dose MTX; in leucovorin calcium monograph. Doses up to 150 mg or 100 mg/M² every 3 hours may be required if SCr is 50% or greater than baseline measurement before methotrexate administration. Serum methotrexate must come down to below 0.05 micromolar. Continuing hydration and urinary alkalinization are mandatory to prevent precipitation in renal tubules. Monitor fluid and electrolyte status until serum methotrexate has fallen to less than 0.05 micromolar and renal failure has resolved. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Death may occur from the progression of most of these side effects. Symptomatic and supportive therapy is indicated. Charcoal hemoperfusion may be helpful, and/or acute intermittent hemodialysis with a high-flux dialyzer may be used to counteract toxicity or inadvertent overdose.

METHYLERGONOVINE MALEATE

(meth-ill-er-GON-oh-veen MAL-ee-ayt)

**Uterine stimulant
(oxytocic)****Methergine****pH 2.7 to 3.5****USUAL DOSE**

1 mL (0.2 mg); repeat doses should be IM or PO.

DILUTION

Check expiration date on vial; methylergonovine deteriorates with age. May be given undiluted. Some clinicians recommend dilution with 5 mL of NS. Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set.

Filters: No data available from manufacturer; suggests following hospital protocol for filtering from ampules.

Storage: Store in refrigerator (2° to 8° C [36° to 46° F]); protect from light.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Y-site: Heparin, hydrocortisone sodium succinate (Solu-Cortef).

RATE OF ADMINISTRATION

0.2 mg or fraction thereof over 1 minute. Too-rapid injection may cause severe nausea and vomiting. See **Precautions**.

ACTIONS

A semi-synthetic ergot alkaloid used for prevention and control of postpartum hemorrhage. An oxytocic. It exerts a direct stimulation on the smooth muscle of the uterus. Increases tone, rate, and amplitude of rhythmic contractions. Shortens third-stage labor and reduces blood loss. In therapeutic doses the prolonged initial contraction of the uterus is followed by periods of relaxation and contraction. May also produce vasoconstriction, increase CVP and BP, and may rarely produce peripheral ischemia. Effective within minutes. Half-life approximately 3.4 hours. It is probably metabolized in the liver and excreted in feces. Secreted in breast milk.

INDICATIONS AND USES

Routine management of uterine atony, hemorrhage, and subinvolution of the uterus following delivery of the placenta. ■ Control of uterine hemorrhage in the second stage of labor following delivery of the anterior shoulder.

CONTRAINDICATIONS

Hypersensitivity, hypertension, pregnancy before third stage of labor (delivery of the placenta) except as stated in Indications, toxemia. ■ Contraindicated for concomitant use with potent CYP3A4 inhibitors (e.g., protease inhibitors [ritonavir (Norvir)], macrolide antibiotics [erythromycin], and azole antifungals [ketoconazole (Nizoral)]); see **Drug/Lab Interactions**.

PRECAUTIONS

IV administration is for emergency use only. IM or oral routes are preferred and should be used after the initial IV dose. ■ IV use may induce hypertension and/or CVA. Give slowly and monitor BP. ■ Use caution in presence of sepsis, obliterative vascular disease, and hepatic or renal disease. ■ Patients with coronary artery disease or risk factors for coronary artery disease (e.g., diabetes, high cholesterol, obesity, smoking) may be more susceptible to developing myocardial ischemia and infarction associated with methylergonovine-induced vasospasm. ■ Use with caution during the second stage of labor. The necessity for manual removal of a retained placenta should occur rarely with proper technique and adequate allowance of time for a spontaneous separation. ■ Avoid intra-arterial or peri-arterial injection. ■ See **Contraindications**.

Monitor: Monitor BP. ■ Observe for signs of excessive bleeding. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: see [Contraindications](#) and [Precautions](#). ■ Avoid breast-feeding during treatment with methylergonovine. Wait at least 12 hours after administration of the last dose before initiating or resuming breast-feeding. Milk secreted during this period should be discarded. May be given orally with caution during breast-feeding for up to 1 week after delivery. ■ Inadvertent administration of methylergonovine to newborn infants resulting in convulsions, cyanosis, oliguria, and respiratory depression has been reported. Methylergonovine should be stored separately from medications intended for neonatal administration (e.g., vitamin K, hepatitis B vaccine). ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Difference in safety and effectiveness compared to younger adults not observed. ■ If used in the elderly, dose selection should be cautious.

DRUG/LAB INTERACTIONS

Severe hypertension and cerebrovascular accidents can result with **ephedrine and other vasopressors**. Hydralazine IV will reduce this hypertension. ■ **Do not administer with potent CYP3A4 inhibitors**, such as **macrolide antibiotics** (e.g., erythromycin [Erythrocin], troleandomycin [TAO], clarithromycin [Biaxin]), **HIV protease inhibitors** (e.g., indinavir [Crixivan], nelfinavir [Viracept], ritonavir [Norvir]), **reverse transcriptase inhibitors** (e.g., delavirdine [Rescriptor]), or **azole antifungals** (e.g., ketoconazole [Nizoral], voriconazole [VFEND]). Serum levels increased. Elevated levels of ergot alkaloids can cause ergotism (i.e., risk for vasospasm potentially leading to cerebral ischemia and/or ischemia of the extremities). ■ May be used cautiously with **less potent CYP3A4 inhibitors** (e.g., saquinavir [Invirase], nefazodone, fluconazole [Diflucan], grapefruit juice, fluoxetine [Prozac], fluvoxamine [Luvox], zileuton [Zyflo], and clotrimazole [Gyne-Lotrimin, Mycelex]). ■ **Strong CYP3A4 inducers** (e.g., rifampin [Rifadin], nevirapine [Viramune]) may decrease effectiveness of methylergonovine. ■ **Anesthetics** (e.g., halothane, methoxyflurane) may reduce oxytocic effect of methylergonovine. ■ Produces vasoconstriction and can be expected to reduce the effect of **antianginal drugs** (e.g., nitroglycerin). ■ Concomitant use with **other ergot alkaloids or prostaglandins** will produce additive effects. Use caution.

SIDE EFFECTS

Rare in therapeutic doses but may include the following:

Abdominal pain (caused by uterine contractions), bradycardia, chest pain (temporary), coronary artery spasm, diaphoresis, diarrhea, dilated pupils, dizziness, dyspnea, hallucinations, headache, hematuria, hypertension (transient), hypersensitivity reactions, hypotension, leg cramps, MI, nasal congestion, nausea, palpitations, rash, seizures, tachycardia, thrombophlebitis, tinnitus, vasoconstriction, vasospasm, vomiting, water intoxication, weakness.

Overdose: Cerebrovascular accident, coma, convulsions, hypertension (followed by hypotension in severe cases), hypothermia, numbness, oliguria, palpitations, respiratory depression, severe nausea and vomiting, tachycardia, tingling of the extremities.

Post-Marketing: Angina, atrioventricular block, cerebrovascular accident, paresthesia, ventricular fibrillation, ventricular tachycardia.

ANTIDOTE

Discontinue the drug immediately at the onset of any side effect and notify the physician. Most side effects are transient unless there is severe toxicity and will be treated symptomatically. Use antiemetics (e.g., prochlorperazine [Compazine], ondansetron [Zofran]) for nausea and vomiting. Treat seizures with anticonvulsants (e.g., diazepam [Valium], phenytoin [Dilantin]). Maintain adequate pulmonary ventilation, especially if convulsions or coma develop. Correct hypotension with pressor drugs (e.g., dopamine). Apply warmth to extremities to control peripheral vasospasm.

METHYLPREDNISOLONE SODIUM SUCCINATE

(meth-ill-pred-NISS-oh-lohn SO-dee-um SUK-sih-nayt)

Hormone
(corticosteroid)
Anti-inflammatory

A-Methapred, Solu-Medrol

pH 7 to 8

USUAL DOSE

Use the lowest possible dose to control the condition being treated. When reduction in dose is possible, the reduction should be gradual.

Average dose range is 10 to 40 mg initially. May be repeated every 4 to 6 hours as necessary. IV methylprednisolone is usually given in an emergency situation or when oral dosing is not feasible. Larger doses may be justified by patient condition. Repeat until adequate response, then decrease dose as indicated. Total dose usually does not exceed 1.5 Gm/24 hr, but higher doses have been used in life-threatening shock. High-dose treatment is used until patient condition stabilizes, usually no longer than 48 to 72 hours.

Anti-inflammatory: 10 to 40 mg. May be repeated every 4 to 6 hours as necessary.

Acute spinal cord injury high-dose therapy (unlabeled): Spinal cord injury must be less than 8 hours old and above L-2. The earlier methylprednisolone therapy begins, the better the results. **Loading dose:** 30 mg/kg of a specifically diluted solution (see [Dilution](#)) evenly distributed over 15 minutes. Maintain IV line with standard IV fluids for 45 minutes, then begin a **maintenance dose** of 5.4 mg/kg/hr for 23 hours. Discontinue 24 hours after loading dose initiated.

Status asthmaticus: Newer asthma guidelines recommend 40 to 80 mg/day in 1 to 2 divided doses until peak expiratory flow is 70% of predicted or personal best. Another source recommends a **loading dose** of 2 mg/kg followed by 0.5 to 1 mg/kg/dose every 6 hours for up to 5 days.

Acute exacerbation of multiple sclerosis: 160 mg as a single dose each day for 7 days. Follow with 64 mg every other day for 1 month.

Pneumocystis jiroveci pneumonia (unlabeled): Initiate within 24 to 72 hours of initial antibiotic PCP therapy. 30 mg twice daily for 5 days. Follow with 30 mg once daily for 5 days (Days 6 to 10). Then reduce to 15 mg once daily for 11 days (Days 11 to 21) or until antibiotic regimen is complete.

Severe lupus nephritis (unlabeled): 1 Gm as an infusion over 1 hour for 3 days. Follow with long-term prednisolone oral therapy.

PEDIATRIC DOSE

See [Maternal/Child](#). Dose may be reduced for infants and pediatric patients but should be governed more by the severity of the condition and the response of the patient than by age or size. Dose should not be less than 0.5 mg/kg every 24 hours.

Anti-inflammatory/immunosuppressive: The range of initial doses is 0.11 to 1.6 mg/kg/day (3.2 to 48 mg/M²/day) in 3 to 4 divided doses (0.0275 to 0.4 mg/kg every 6 hours or 0.036 to 0.53 mg/kg every 8 hours, or 0.8 to 12 mg/M² every 6 hours or 1.06 to 16 mg/M² every 8 hours). Another source recommends 0.5 to 1.7 mg/kg/day or 5 to 25 mg/M²/day in divided doses every 6 to 12 hours (0.125 to 0.425 mg/kg or 1.25 to 6.25 mg/M² every 6 hours, or 0.25 to 0.85 mg/kg or 2.5 to 12.5 mg/M² every 12 hours).

Status asthmaticus: Newer asthma guidelines recommend 0.5 to 1 mg/kg every 12 hours (maximum 60 mg/day) until peak expiratory flow is 80% of predicted or personal best. Another source recommends 2 mg/kg as a **loading dose**. **Maintain** with 0.5 to 1 mg/kg every 6 hours for up to 5 days.

Severe lupus nephritis (unlabeled): 30 mg/kg every other day for 6 doses. Follow with long-term prednisolone oral therapy.

DOSE ADJUSTMENTS

Reduced dose may be required; see [Precautions](#) and [Drug/Lab Interactions](#). ■ Clearance of corticosteroids is decreased in patients with hypothyroidism and increased in patients with hyperthyroidism. Dose adjustment may be required.

DILUTION

Available in Act-O-Vials containing 40 mg, 125 mg, 500 mg, and 1,000 mg. Each vial has an appropriate amount of diluent. Reconstitute by pressing down on the plastic activator, allowing the diluent into the lower chamber. Agitate gently. Remove the plastic tab covering the center of the stopper and sterilize the stopper with a suitable germicide. Using sterile technique, insert a needle through the center of the rubber stopper to withdraw diluted solution. To be diluted only with diluent supplied in Act-O-Vial. Also available in vials, including a 2,000-mg dose. Should be diluted with accompanying diluent or BWFI with benzyl alcohol. May be given direct IV, as an infusion, or further diluted in desired amounts of D5W, D5NS, or NS.

Acute spinal cord injury loading and maintenance doses: Each 1-Gm vial must be diluted to 16 mL with bacteriostatic water to maintain potency and avoid precipitation (62.5 mg/mL). Further dilute in D5W, D5NS, or NS with an amount to facilitate dose of 5.4 mg/kg/hr. (Example for a patient weighing 50 kg: $[50 \text{ kg} \times 5.4 \text{ mg/hr} = 270 \text{ mg/hr}]$. $270 \text{ mg/hr} \times 23 \text{ hours} = 6,210 \text{ mg total dose}$]. With a total dose of 6,210 mg at 62.5 mg/mL, you will have 99.36 [100] mL of reconstituted methylprednisolone. Add an additional 100 mL diluent to achieve 31.25 mg/mL. 270 mg/hr is the desired dose for this patient. 270 mg/hr divided by 31.25 mg/mL [strength of solution] equals 8.6. Administer at 8.6 mL/hr to achieve desired dose over 23 hours.)

Storage: Protect from light. Store both unreconstituted product and solution at RT (20° to 25° C [68° to 77° F]). Use solution within 48 hours of mixing. Heat sensitive; do not autoclave.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Because of possible physical **incompatibilities**, should not be diluted or mixed with other solutions."

One source suggests the following **compatibilities**:

Additive: Aminophylline, chloramphenicol (Chloromycetin), clindamycin (Cleocin), cytarabine (ARA-C), dopamine, granisetron (Kytril), heparin, norepinephrine (Levophed), penicillin G potassium, ranitidine (Zantac), theophylline, verapamil.

Y-site: Acyclovir (Zovirax), alprostadil, amifostine (Ethyol), amiodarone (Nexterone), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), cefepime (Maxipime), ceftaroline (Teflaro), ceftazidime (Fortaz), cisatracurium (Nimbex), cladribine (Leustatin), cytarabine (ARA-C), dexmedetomidine (Precedex), diltiazem (Cardizem), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), famotidine (Pepcid IV), fludarabine (Fludara), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), 6% hydroxyethyl starch (Voluven), linezolid (Zyvox), melphalan (Alkeran), meperidine (Demerol), methotrexate, metronidazole (Flagyl IV), midazolam (Versed), milrinone (Primacor), morphine, nocardipine (Cardene IV), oxaliplatin (Eloxatin), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), remifentanyl (Ultiva), sodium bicarbonate, tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepa, topotecan (Hycamtin).

RATE OF ADMINISTRATION

IV injection: A single dose of 10 to 40 mg over several minutes. When higher doses are needed, administer up to 30 mg/kg over 30 minutes or more. Too-rapid administration of high doses (greater than 500 mg administered over a period of less than 10 minutes) may precipitate hypotension, cardiac arrhythmia, and sudden death. Direct IV administration of lower doses (10 to 40 mg) is usually the route of choice and eliminates the possibility of overloading the patient with IV fluids. May be given as an **infusion** in its own diluent.

At the discretion of the physician, a continuous infusion may be given, properly diluted, over a specified time. Another source suggests the following:

A single dose of up to 1.8 mg/kg or 125 mg may be given **IV push** over 3 to 15 minutes.

A single dose of 2 mg/kg or 250 mg or more may be given as an **infusion** over 15 to 30 minutes.

A single dose of 15 mg/kg or greater than 500 mg may be given as an **infusion** over 30 minutes or more.

Acute spinal cord injury: See [Usual Dose](#) and [Dilution](#).

ACTIONS

A glucocorticoid steroid with potent metabolic, anti-inflammatory actions and innumerable other effects. Has a greater anti-inflammatory potency than prednisolone and less tendency to cause excessive potassium and calcium excretion and sodium and water retention. Has five times the potency of hydrocortisone sodium succinate. Has minimal mineralocorticoid activity. Primarily used for anti-inflammatory and immunosuppressive effects. Demonstrable effects seen within 1 hour of administration. Primarily metabolized in the liver and excreted in the urine and feces. Dose almost completely excreted after 12 hours, which allows the use of very large doses with reasonable safety. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Includes treatment of allergic states, dermatologic diseases, endocrine disorders, gastrointestinal diseases, hematologic disorders, neoplastic diseases, nervous system disorders, ophthalmic diseases, renal diseases, respiratory diseases, and rheumatic disorders. See prescribing information for a complete list. Used primarily as an anti-inflammatory or immunosuppressant agent. May be used in conjunction with other forms of therapy, such as epinephrine for acute hypersensitivity reactions. Oral therapy should be used when appropriate.

Unlabeled uses: High-dose therapy as an adjunct to traditional spinal cord injury management; to improve neurologic recovery in an acute (less than 8 hours old) spinal cord injury above L-2. ■ Treatment of *Pneumocystis jiroveci* pneumonia as an adjunct to antibiotics.

CONTRAINDICATIONS

Absolute contraindications in long-term therapy, except in life-threatening situations: Hypersensitivity to any product component, including sulfites; systemic fungal infections.

■ Formulations containing benzyl alcohol are contraindicated in neonates and for intrathecal administration.

Relative contraindications: Active or healed tuberculosis, amebiasis (latent or active), cerebral malaria, chickenpox, ocular herpes simplex, pregnancy.

PRECAUTIONS

Not the drug of choice to treat acute adrenocortical insufficiency. ■ May produce hypothalamic-pituitary-adrenal (HPA) axis suppression with resulting glucocorticosteroid insufficiency in patients undergoing chronic or prolonged therapy. To avoid relative adrenocortical insufficiency, do not stop therapy abruptly; taper off. Patient is observed carefully, especially under stress, for up to 2 years; exception is very short-term therapy.

■ Increased doses of rapidly acting corticosteroids are indicated when patients on corticosteroid therapy are subjected to any unusual stress (e.g., surgery, hospitalization). These increased doses should be used before, during, and after the stressful situation.

■ Formulation may contain benzyl alcohol; see [Contraindications](#) and [Maternal/Child](#). ■ Rare instances of anaphylactoid reactions have been reported in patients receiving corticosteroid therapy.

■ In one study, an increase in mortality was seen in patients with cranial trauma who had no other clear indication for corticosteroid treatment. Should not be used for treatment of traumatic brain injury. ■ Use with caution in patients who have had a recent MI. Ventricular free wall rupture has been reported. ■ Patients taking corticosteroids may be more susceptible to infections. Latent disease may be activated. Intercurrent infections may be exacerbated; see [Contraindications](#). ■ Use with caution in patients with CHF, hypertension, or renal insufficiency. May affect fluid

and electrolyte balance. ■ Use with caution in patients with thyroid dysfunction; see [Dose Adjustments](#). ■ Use with caution in patients with active or latent peptic ulcers, diverticulitis, fresh intestinal anastomoses, and nonspecific ulcerative colitis. May be at increased risk for perforation. ■ Metabolism of corticosteroids is decreased in patients with cirrhosis; effects may be enhanced. ■ Use with caution in patients at risk for osteoporosis. Corticosteroids decrease bone formation, increase bone resorption, and decrease protein matrix of the bone. May lead to inhibition of bone growth in pediatric patients and the development of osteoporosis at any age. ■ An acute myopathy has been reported with the use of high doses of corticosteroids. Most often seen in patients with disorders of neuromuscular transmission (e.g., myasthenia gravis) or in patients receiving concomitant therapy with neuromuscular blocking drugs. Myopathy is generalized, may involve ocular and respiratory muscles, and may result in quadriplegia. Clinical improvement following discontinuation of corticosteroids may take weeks to years. ■ May induce psychological changes (e.g., depression, euphoria, insomnia, mood swings, personality changes, psychosis). May aggravate existing emotional instability or psychotic tendencies. ■ Kaposi's sarcoma has been reported in patients receiving corticosteroid therapy, most often for chronic conditions. Clinical improvement has been seen with discontinuation of the corticosteroid. ■ Prophylactic antacids may prevent peptic ulcer complications.

Monitor: Monitor electrolytes. May cause sodium retention and potassium and calcium excretion. ■ May cause hypertension secondary to fluid and electrolyte disturbances. Monitor BP. ■ May mask signs of infection. ■ May increase insulin needs in patients with diabetes. Monitor serum glucose. ■ Administer single dose before 9 AM to reduce suppression of adrenocortical activity. ■ During prolonged therapy, routine laboratory studies such as urinalysis, 2-hour postprandial blood sugar, BP, body weight assessment, and chest x-ray should be obtained at regular intervals. Upper GI x-rays are suggested for patients with a history of ulcers or significant dyspepsia. ■ May increase intraocular pressure. Periodic ophthalmic exams may be necessary with prolonged treatment. ■ See [Drug/Lab Interactions](#).

Patient Education: Report edema, tarry stools, or weight gain promptly. Report anorexia, diarrhea, dizziness, fatigue, low blood sugar, nausea, weakness, weight loss, or vomiting; may indicate adrenal insufficiency after dose reduction or discontinuing therapy. ■ May mask signs of infection and/or decrease resistance. ■ Diabetics may have increased requirement for insulin or oral hypoglycemics. ■ Avoid immunizations with live virus vaccines. ■ Avoid exposure to measles or chickenpox. Seek immediate medical advice if exposure occurs. ■ Carry ID stating steroid dependent if receiving prolonged therapy.

Maternal/Child: Category C: corticosteroids have been shown to be teratogenic in many species. ■ Discontinue breast-feeding. ■ Infants born to mothers who received corticosteroids during pregnancy should be carefully monitored for signs of hypoadrenalism. ■ May contain benzyl alcohol, which has been associated with a fatal "gaspings syndrome" in neonates. ■ Monitor growth and development of pediatric patients receiving prolonged treatment.

Elderly: Differences in response between the elderly and younger patients have not been identified. Dose selection should be cautious based on the possibility of age-related organ impairment (e.g., bone marrow reserve, renal, hepatic). May be more sensitive to effects.

DRUG/LAB INTERACTIONS

Aminoglutethimide (Cytadren) may lead to a loss of corticosteroid-induced adrenal suppression. ■ Metabolism increased and effects reduced by **hepatic enzyme-inducing agents** (e.g., alcohol, barbiturates [e.g., phenobarbital], hydantoins [e.g., phenytoin (Dilantin)], rifampin [Rifadin]); dose adjustments may be required when adding or deleting from drug profile. ■ Risk of hypokalemia increased with **amphotericin B** or **potassium-depleting diuretics** (e.g., thiazides, furosemide, ethacrynic acid). Monitor potassium levels and cardiac function. Increased risk of **digoxin** toxicity secondary to hypokalemia. ■ May decrease effectiveness of **potassium supplements**; monitor serum potassium. ■ **Diuretics** decrease sodium and fluid retention effects of corticosteroids; corticosteroids decrease

sodium excretion and diuretic effects of diuretics. ■ Use with **cyclosporine** in organ transplants is therapeutic but may increase cyclosporine toxicity; seizures have been reported; use caution. ■ Clearance decreased and effects increased with **estrogens, oral contraceptives, triazole antifungals** (e.g., itraconazole [Sporanox]), and **macrolide antibiotics** (e.g., azithromycin [Zithromax], erythromycin, troleandomycin [TAO]). ■ Coadministration of **aprepitant** (fosaprepitant [Emend]) may increase methylprednisolone levels. Dose reduction of methylprednisolone may be indicated. ■ May interact with **anticoagulants, nondepolarizing muscle relaxants** (e.g., atracurium [Tracrium]), or **theophyllines**; may inhibit or potentiate action; monitor carefully. ■ Monitor patients receiving **antidiabetic agents** (e.g., insulin, glyburide) or **thyroid hormones** carefully; dose adjustments of either or both agents may be required. ■ May antagonize effects of **isoniazid and salicylates**; dose adjustments may be required. ■ Administration of **live virus or live-attenuated vaccines** is contraindicated in patients receiving immunosuppressive doses of corticosteroids. Inactivated vaccines may be administered, but the response to such vaccines cannot be predicted. ■ Concomitant use with **NSAIDs** (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]), may increase the risk of adverse GI effects. ■ Concomitant use with **anticholinesterase agents** (e.g., neostigmine) may produce severe weakness in patients with myasthenia gravis. If possible, anticholinesterase agents should be withdrawn at least 24 hours before initiating corticosteroid therapy. ■ Altered **protein-binding capacity** will impact effectiveness of this drug. ■ Corticosteroids may **suppress reactions to skin tests**. ■ See [Dose Adjustments](#).

SIDE EFFECTS

Do occur but are usually reversible: Cushing's syndrome; electrolyte and calcium imbalance; euphoria; glycosuria; hyperglycemia; hypersensitivity reactions, including anaphylaxis; hypertension; increased appetite; increased intracranial pressure; menstrual irregularities; peptic ulcer perforation and hemorrhage; protein catabolism; spontaneous fractures; transitory burning or tingling; sweating, headache, or weakness; thromboembolism and many others.

ANTIDOTE

Notify the physician of any side effect. Will probably treat the side effect if necessary. Resuscitate as necessary for anaphylaxis and notify physician. Keep epinephrine immediately available.

METOCLOPRAMIDE HYDROCHLORIDE **BBW**

(meh-toe-kloh-PRAH-myd hy-droh-KLOR-eyed)

GI stimulant
Antiemetic

Reglan

pH 4.5 to 6.5

USUAL DOSE

Small bowel intubation and/or radiologic examination of the small bowel: 10 mg (2 mL) as a single dose.

Antiemetic: High-dose regimen for highly emetogenic chemotherapy is rarely used; 5HT₃ receptor antagonists (e.g., granisetron [Kytril], ondansetron [Zofran]) preferred. 2 mg/kg of body weight 30 minutes before giving emetogenic cancer chemotherapy (e.g., cisplatin, dacarbazine). Repeat every 2 hours for 2 doses, then every 3 hours for 3 doses; see [Dose Adjustments](#). For less emetogenic regimens, 1 mg/kg/dose may be adequate.

Diabetic gastroparesis: 10 mg immediately before each meal and at bedtime. Use IV for up to 10 days if symptoms are severe. Continue treatment PO for 2 to 8 weeks.

Prevention of postoperative nausea and vomiting: 10 mg, usually given IM toward the end of surgery. Up to 20 mg may be used.

PEDIATRIC DOSE

Small bowel intubation and/or radiologic examination of the small bowel: 6 to 14 years: 2.5 to 5 mg. **Under 6 years:** 0.1 mg/kg of body weight.

Gastroesophageal reflux or GI dysmotility (unlabeled): 0.1 to 0.2 mg/kg/dose. May be given every 6 hours if required. Maximum dose 0.8 mg/kg/24 hr (0.2 mg/kg/dose every 6 hours).

Antiemetic (unlabeled): Rarely used. 5HT₃-receptor antagonists preferred. A high-dose regimen for highly emetogenic chemotherapy of 1 to 2 mg/kg/dose every 2 to 6 hours has been administered but is rarely used. Premedicate with diphenhydramine (Benadryl) to reduce extrapyramidal symptoms.

DOSE ADJUSTMENTS

Antiemetic dose may be reduced to 1 mg/kg if initial doses suppress vomiting. Initial doses may be reduced to 1 mg/kg for less emetogenic regimens. ■ Reduce initial dose by half in any patient with a CrCl less than 40 mL/min. Adjust subsequent doses as indicated. ■ Caution and lower-end dosing suggested in elderly patients. Consider potential for decreased organ function and concomitant disease or drug therapy. ■ See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted if dose does not exceed 10 mg. For doses exceeding 10 mg dilute in at least 50 mL of D5W, NS, D5½NS, R, or LR, and give as an infusion.

Storage: Light sensitive; store in carton before use. Diluted solutions stable for 24 hours in normal light, 48 hours if protected from light. Do not freeze unless diluted in NS. Discard if color or particulate matter is observed.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with chloramphenicol (Chloromycetin) and sodium bicarbonate.

Sources suggest the following **compatibilities**:

Additive: Manufacturer lists ampicillin, ascorbic acid, benztropine (Cogentin), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytosan), cytarabine (ARA-C), dexamethasone (Decadron), diphenhydramine (Benadryl), doxorubicin (Adriamycin), erythromycin (Erythrocin), heparin, insulin (regular), lidocaine, mannitol, methotrexate, multivitamins (M.V.I.), penicillin G potassium, potassium acetate, and potassium phosphates. Other sources add meperidine (Demerol), meropenem (Merrem IV), morphine, potassium chloride (KCl), verapamil.

Y-site: All drugs listed by the manufacturer as **compatible** under **Additive**. Other sources add acyclovir (Zovirax), aldesleukin (Proleukin), amifostine (Ethyol), aztreonam (Azac-tam), bivalirudin (Angiomax), bleomycin (Blenoxane), ceftaroline (Teflaro), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cisplatin (Platinol), cladribine (Leustatin), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doripenem (Doribax), doxapram (Dopram), doxorubicin (Adriamycin), droperidol (Inapsine), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), foscarnet (Foscavir), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, heptastarch in electrolytes (Hextend), levromorphone (Dilaudid), idarubicin (Idamycin), leucovorin calcium, levofloxacin (Levaquin), linezolid (Zyvox), melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), methadone (Dolophine), methotrexate, mitomycin (Mutamycin), morphine, ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), palonosetron (Aloxi), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), quinupristin/dalfopristin (Synercid), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), thiotepa, tigecycline (Tygacil), topotecan (Hycamtin), vinblastine, vincristine, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Too-rapid IV injection will cause intense anxiety, restlessness, and then drowsiness.

IV injection: 10 mg or fraction thereof over 2 minutes. Reduce rate of injection in pediatric patients.

Infusion: Administer over a minimum of 15 minutes.

ACTIONS

A dopamine antagonist. Antiemetic properties appear to be the result of antagonism of central and peripheral dopamine receptors. Blocks the stimulation of medullary chemoreceptor trigger zones by dopamine. Inhibits nausea and vomiting. Increases tone and amplitude of gastric contractions, relaxes the lower pyloric sphincter and duodenal bulb, and increases peristalsis of the duodenum and jejunum, resulting in accelerated gastric emptying. Does not stimulate gastric, biliary, or pancreatic secretions. Acts even if vagal innervation not present. Action negated by anticholinergic drugs. Distributes extensively into tissues. Onset of action occurs in 1 to 3 minutes and lasts 1 to 2 hours. Average half-life is 5 to 6 hours. Excreted in urine. Secreted in breast milk.

INDICATIONS AND USES

Facilitate small bowel intubation. ■ Stimulate gastric and intestinal emptying of barium to permit radiologic examination of the stomach and small intestine. ■ Prevention of nausea and vomiting associated with emetogenic cancer chemotherapy. ■ Prophylaxis of postoperative nausea and vomiting when nasogastric suction is not indicated. ■ Diabetic gastroparesis.

CONTRAINDICATIONS

Situations in which gastric motility is contraindicated (i.e., gastric hemorrhage, obstruction, or perforation); known hypersensitivity to metoclopramide; patients with epilepsy or patients taking drugs that may also cause extrapyramidal reactions; pheochromocytoma.

PRECAUTIONS

May produce sedation, extrapyramidal symptoms, or Parkinson-like symptoms, similar to those seen with phenothiazines. Use caution in patients with pre-existing disease. ■ Acute dystonic reactions (a type of extrapyramidal symptom [EPS]) are usually seen during the first 24 to 48 hours of treatment and are more common in pediatric patients, in adults under 30 years of age, and at higher doses used for prophylaxis of N/V due to chemotherapy. ■ Tardive dyskinesia may develop and is usually related to duration of treatment and total cumulative dose. Avoid use for longer than 12 weeks unless benefit outweighs risk of tardive dyskinesia. ■ Neuroleptic malignant syndrome (NMS) has been reported rarely. Potentially fatal. Discontinue metoclopramide immediately; see [Monitor](#). ■ Produces a transient increase in plasma aldosterone, patients with cirrhosis or CHF may develop fluid retention and volume overload. If S/S occur, discontinue metoclopramide. ■ Use with caution in patients with hypertension. May cause release of catecholamines, exacerbating the condition. ■ A prolactin-elevating compound; may be carcinogenic. Risk with a single dose almost nonexistent. ■ May cause serious depression and suicidal tendencies; use extreme caution in any patient with a history of depression. ■ Patients with NADH-cytochrome b₅ reductase deficiency are at increased risk for developing methemoglobinemia and/or sulfhemoglobinemia. In patients with G6PD deficiency who develop methemoglobinemia, methylene blue treatment is not recommended. Can cause hemolytic anemia. ■ See [Maternal/Child](#).

Monitor: Monitor vital signs. ■ Pretreatment with diphenhydramine may reduce incidence of extrapyramidal symptoms with larger doses (e.g., antiemetic). ■ Monitor for S/S of NMS (e.g., hyperthermia, muscle rigidity, altered consciousness, and evidence of autonomic instability [irregular pulse or BP, tachycardia, diaphoresis, and arrhythmias]). ■ Discontinue therapy in patients who develop S/S of tardive dyskinesia (syndrome of potentially irreversible involuntary movements of the tongue, face, mouth, jaw, trunk, or extremities). ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Use caution performing any task that requires alertness, coordination, or physical dexterity; may produce dizziness and drowsiness. ■ If any involuntary

movement of eyes, face, or limbs occurs, notify physician promptly. ■ Avoid alcohol or other CNS depressants (e.g., barbiturates, benzodiazepines [e.g., diazepam (Valium)]).

Maternal/Child: Category B: use caution in pregnancy and breast-feeding. ■ May increase milk production (elevates prolactin). ■ Pharmacokinetics highly variable in children and neonates. ■ Safety and effectiveness for use in pediatric patients not established except when administered to facilitate small bowel intubation. ■ Dystonic reactions are more common in pediatric patients. ■ Prolonged clearance in neonates may produce excessive serum concentrations. ■ May cause methemoglobinemia in premature and full-term neonates at doses exceeding 0.5 mg/kg/24 hr. ■ See **Precautions** and **Side Effects**.

Elderly: May be more sensitive to therapeutic or adverse effects. ■ Long-term use increases risk of extrapyramidal effects (e.g., parkinsonism, tardive dyskinesia). ■ See **Dose Adjustments** and **Precautions**.

DRUG/LAB INTERACTIONS

Antagonized by **anticholinergic drugs** (e.g., atropine) and **narcotic analgesics** (e.g., morphine). ■ May potentiate **alcohol** and **cyclosporine**. ■ Drugs ingested orally may be absorbed more slowly or more rapidly depending on the absorption site (e.g., inhibits **ci-metidine**, **digoxin**). ■ Potentiates **MAO inhibitors** (e.g., selegiline [Eldepryl]); use extreme caution or do not use. ■ **Insulin** reactions may result from gastric stasis, making diabetic control difficult. Dose or timing of insulin may need adjustment. ■ Extrapyramidal effects may be potentiated with concomitant use of **phenothiazines**, **butyrophenones**, and **thioxanthines** (antipsychotic drugs). ■ Used concurrently, metoclopramide and **levodopa** have opposite effects on dopamine receptors; metoclopramide is inhibited and levodopa is potentiated.

SIDE EFFECTS

Usually mild, transient, and reversible after metoclopramide discontinued. Hypersensitivity reactions can occur. Acute CHF, anxiety, arrhythmias, bowel disturbances, confusion, convulsions, depression (severe, may have suicidal tendencies), dizziness, drowsiness, extrapyramidal reactions, fatigue, fluid retention, hallucinations, headache, hypertension, hypotension, insomnia, methemoglobinemia in neonates, nausea, NMS (hyperthermia, muscle rigidity, altered consciousness, and evidence of autonomic instability [irregular pulse or BP, tachycardia, diaphoresis, and arrhythmias]), restlessness, sulfhemoglobinemia in adults, tardive dyskinesia. Numerous other side effects may occur.

Overdose: Disorientation, drowsiness, and extrapyramidal reactions.

ANTIDOTE

Notify physician of all side effects. Most will respond to a reduced dose or discontinuation of metoclopramide. Treat overdose or extrapyramidal reactions with diphenhydramine (Benadryl) or benztropine (Cogentin). Symptoms should disappear within 24 hours. To manage NMS, immediately discontinue metoclopramide. Intensive symptomatic treatment and monitoring is required. Bromocriptine (Parlodel) and dantrolene (Dantrium) have been used to treat NMS, but effectiveness not established. **Discontinue therapy in patients who develop S/S of tardive dyskinesia; symptoms may resolve.** Treat methemoglobinemia with IV methylene blue. Hemodialysis is not likely to be useful in an overdose. Resuscitate as necessary.

METOPROLOL TARTRATE **BBW**(me-toe-**PROH**-lohl **TAHR**-trayt)Beta-adrenergic blocking agent
Antiarrhythmic (post MI)

Lopressor

pH 7.5

USUAL DOSE

Treatment of myocardial infarction: 5 mg as an IV bolus dose. Initiate as soon as the patient's hemodynamic condition has stabilized. Repeat at 2-minute intervals for 2 more doses; a total dose of 15 mg (AHA recommends 5 mg at 5-minute intervals to a total dose of 15 mg). If IV doses are well tolerated, give 50 mg PO every 6 hours for 48 hours beginning 15 minutes after the last bolus. Follow with an oral maintenance dose of 100 mg twice daily. In patients who do not tolerate the full IV dose start 25 to 50 mg PO within 15 minutes of the last IV dose. Dosage based on degree of intolerance. May have to discontinue metoprolol.

Treatment of atrial fibrillation (unlabeled): 2.5 to 5 mg as an IV injection over 2 to 5 minutes as necessary to control rate up to a total dose of 15 mg in a 10- to 15-minute period if indicated.

Treatment of ventricular rate control/hypertension (unlabeled): 1.25 to 5 mg every 6 to 12 hours. Begin with a lower initial dose and titrate to response. Up to 15 mg every 3 to 6 hours has been used.

DOSE ADJUSTMENTS

See **Drug/Lab Interactions**. ■ Not required in impaired renal function. ■ In patients with impaired hepatic function, start at a low dose and titrate upwards slowly.

DILUTION

May be given undiluted.

Storage: Store at CRT. Protect from light.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Abciximab (ReoPro), alteplase (tPA), amiodarone (Nexterone), argatroban, bivalirudin (Angiomax), ceftaroline (Teflaro), diltiazem (Cardizem), eptifibatide (Integrilin), furosemide (Lasix), heparin, meperidine (Demerol), milrinone (Primacor), morphine, nesiritide (Natrecor), nitroprusside sodium (Nitropress), procainamide (Pronestyl).

RATE OF ADMINISTRATION

A single dose over 1 minute. Monitor ECG, HR, and BP and discontinue metoprolol if adverse symptoms occur (bradycardia less than 45 beats/min, heart block greater than first degree, systolic BP less than 100 mm Hg, or moderate to severe cardiac failure).

ACTIONS

Metoprolol is a cardioselective (B₁) adrenergic receptor blocker. Its mechanism of action in patients with suspected or definite myocardial infarction is not known, but its use has been shown to reduce the 3-month mortality rate in this patient population. It reduces the incidence of recurrent myocardial infarctions and reduces the size of the infarct and the incidence of fatal arrhythmias. Reduces HR, systolic BP, and cardiac output. Well distributed throughout the body, it acts within 1 to 2 minutes and lasts about 3 to 4 hours. Maximum beta blockade is achieved in approximately 20 minutes. Metabolized in the liver by the cytochrome P₄₅₀ enzyme system, primarily CYP2D6. Excreted as metabolites in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

To reduce cardiac mortality in hemodynamically stable individuals with suspected or definite myocardial infarction (used in conjunction with oral metoprolol maintenance therapy). ■ Treatment of hypertension, angina pectoris, and CHF in oral dosage form.

Unlabeled uses: Treatment of atrial fibrillation and unstable angina. ■ Has been used in the perioperative period to reduce cardiac morbidity and mortality in patients at risk. ■ Treatment of ventricular rate control and hypertension in patients who cannot take PO medications.

CONTRAINDICATIONS

HR below 45 beats/min, second- or third-degree heart block, significant first-degree heart block (PR interval equal to or greater than 0.24 second), systolic BP below 100 mm Hg, or moderate to severe cardiac failure. ■ Hypersensitivity to metoprolol or to any of the excipients. Use caution in patients with hypersensitivity to other beta-blockers (e.g., atenolol [Tenormin], esmolol [Brevibloc], propranolol). Cross-sensitivity between beta-blockers can occur. ■ Severe peripheral arterial circulatory disorders or sick sinus syndrome in patients with angina or hypertension.

PRECAUTIONS

Use caution in CHF. Beta blockade may depress myocardial contractility and precipitate or exacerbate heart failure and cardiogenic shock. ■ Use caution in presence of heart failure controlled by digoxin. Both drugs slow AV conduction. Bradycardia, sinus pause, heart block, and cardiac arrest have occurred. Patients with first-degree AV block, sinus node dysfunction, or conduction disorders may be at increased risk; see [Antidote](#). ■ May produce significant first- (PR interval equal to or greater than 0.26 second), second-, or third-degree heart block. Acute MI can also cause heart block. ■ Metoprolol decreases sinus heart rate. MI may also produce significant lowering of HR; see [Antidote](#). ■ Routine withdrawal of chronically administered beta-blockers before major surgery is not necessary; however, the risks of general anesthesia and surgical procedures may be increased by the impaired ability of the heart to respond to reflex adrenergic stimuli. ■ Use caution in patients with a history of severe anaphylactic reactions to a variety of allergens; they may be more reactive to repeated challenge (either accidental, diagnostic, or therapeutic) and may be unresponsive to the usual doses of epinephrine used to treat hypersensitivity reactions; see [Drug/Lab Interactions](#). ■ May mask tachycardia occurring with hypoglycemia in diabetes and tachycardia of hyperthyroidism. ■ In general, patients with bronchospastic disease should not receive beta-blockers, including metoprolol. Because of its relative beta selectivity, metoprolol may be used with extreme caution in these patients. Monitor pulmonary function closely; see [Antidote](#). ■ Use with caution in patients with impaired hepatic function; see [Dose Adjustments](#). ■ **May cause arrhythmia, angina, MI, or death if stopped abruptly (more of an issue with chronic oral therapy); see prescribing information.** ■ May cause severe bradycardia in patients with Wolff-Parkinson-White syndrome. ■ Contraindicated in patients known to have or suspected of having a pheochromocytoma. If metoprolol is required, it should be given in combination with an alpha-blocker (e.g., phenoxybenzamine [Dibenzylin]) and only after the alpha-blocker has been initiated. ■ See [Drug/Lab Interactions](#).

Monitor: Continuous ECG, HR, and BP monitoring is mandatory with use of IV metoprolol. ■ Hemodynamic status must be closely monitored. If heart failure or hypotension occurs or persists despite appropriate treatment, metoprolol should be discontinued. Assess extent of myocardial damage. Invasive monitoring of central venous, pulmonary capillary wedge, and arterial pressure may be required. ■ See [Drug/Lab Interactions](#) and [Antidote](#).

Patient Education: Report any breathing difficulty promptly.

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding and in pediatric patients not established. ■ If a pregnancy occurs, women should inform their physician.

Elderly: Age-related differences in safety and effectiveness not identified; however, greater sensitivity of some elderly cannot be ruled out. Dose with caution. ■ May exacerbate mental impairment.

DRUG/LAB INTERACTIONS

Concurrent use with **calcium channel blockers** (e.g., diltiazem, verapamil) may potentiate both drugs and result in severe depression of myocardium and AV conduction and severe

hypotension. ■ Concurrent use with **antihypertensive agents**, including **alpha-adrenergic blockers** (e.g., clonidine [Catapres], guanfacine [Tenex], methyldopa, reserpine), may result in excessive hypotension. Dose adjustment may be required. ■ Concurrent administration with **hydralazine** may decrease metabolism and increase concentrations of metoprolol. ■ **Potent inhibitors of the CYP2D6 enzyme** may increase plasma concentrations of metoprolol and decrease its cardioselectivity. These inhibitors include **antidepressants** (e.g., clomipramine [Anafranil], desipramine [Norpramin], fluoxetine [Prozac], fluvoxamine [Luvox], paroxetine [Paxil], sertraline [Zoloft], bupropion [Wellbutrin]), **antipsychotics** (e.g., chlorpromazine, fluphenazine, haloperidol [Haldol], thioridazine [Mellaril]), **antiarrhythmics** (e.g., quinidine, propafenone [Rythmol]), **antiretrovirals** (e.g., ritonavir [Norvir]), **antihistamines** (e.g., diphenhydramine [Benadryl]), **antimalarials** (e.g., hydroxychloroquine [Plaquenil], quinidine), **allylamine antifungals** (e.g., terbinafine [Lamisil]) and **medications for stomach ulcers** (e.g., cimetidine [Tagamet]). ■ Concurrent use within 14 days of **MAO inhibitors** (selegiline [Eldepryl]) may cause severe hypertension. ■ Use with **sympathomimetic agents** (e.g., epinephrine, norepinephrine, phenylephrine) or **xanthines** (e.g., aminophylline) may negate therapeutic effects of both drugs. ■ Effects of beta-adrenergic blocking agents may be decreased by **anti-inflammatory drugs** (e.g., NSAIDs), **barbiturates, rifampin, salicylates, and others**. ■ **Inhalation anesthetics, phenytoin (Dilantin), and quinolone antibiotics** (e.g., ciprofloxacin) may increase myocardial depressant effects and hypotension. ■ Beta-adrenergic blocking agents may be continued during the perioperative period in most patients; however, use caution with **selected anesthetic agents** that may depress the myocardium. ■ Potentiates effects of **oral antidiabetics, catecholamine-depleting drugs** (e.g., reserpine), insulin, lidocaine, and skeletal muscle relaxants; monitor carefully. Dose adjustment may be required. ■ Concurrent use with **clonidine** may precipitate acute hypertension if one or both agents are stopped abruptly. Withdraw metoprolol first. ■ Effects decreased when hypothyroid patient is **converted to a euthyroid state**; adjust dose as indicated. ■ Used concurrently with **digoxin or alphaadrenergic blockers** (e.g., phentolamine [Regitine]) as indicated. ■ Use caution; both **digoxin** and beta-blockers (e.g., atenolol, esmolol, metoprolol, propranolol) slow AV conduction. May increase risk of bradycardia. ■ Patients taking beta-blockers who are exposed to a potential allergen may be unresponsive to the usual dose of **epinephrine** used to treat a hypersensitivity reaction. ■ May enhance the vasoconstrictive action of **ergot alkaloids**. ■ In general, withhold administration of a beta-blocker before **dipyridamole** testing; monitor HR carefully following dipyridamole injection.

SIDE EFFECTS

Abdominal pain, bradyarrhythmias, bronchospasm, cardiac failure, claudication, confusion, dizziness, dyspnea, elevated liver function tests, first-degree heart block, hallucinations, headache, hepatitis, hypotension, jaundice, nausea, nightmares, pruritus, rash, reduced libido, respiratory distress, second- or third-degree heart block, sleep disturbances, syncopal attacks, tiredness, unstable diabetes, vertigo, visual disturbances.

ANTIDOTE

For any side effect, discontinue drug and notify physician immediately. Patients with myocardial infarction may be more hemodynamically unstable; treat with caution. Use atropine (0.25 to 0.5 mg) for bradycardia or heart block; use isoproterenol with caution if atropine is not effective. Glucagon 5 to 10 mg IV may be effective if atropine and isoproterenol are not (investigational use). Transvenous cardiac pacing may be needed. Treat hypotension with IV fluids if indicated or vasopressors (dopamine or norepinephrine [Levarterenol]); treat cause of hypotension (e.g., bradycardia). Use all vasopressors with extreme caution; severe hypotension can result. Use digoxin and diuretics at first sign of cardiac failure; dobutamine, isoproterenol, or glucagon may be required. Use aminophylline or isoproterenol (with extreme care) for bronchospasm, and glucagon or IV glucose for hypoglycemia. Treat other side effects symptomatically; resuscitate as necessary.

METRONIDAZOLE HYDROCHLORIDE **BBW**

Antibacterial
Antiprotozoal

(meh-troh-NYE-dah-zohl hy-droh-KLOR-eyed)

Flagyl IV, Flagyl IV RTU, Metronidazole RTU

pH 4.5 to 7

USUAL DOSE

May transfer to oral therapy when condition warrants (usual PO dose is 7.5 mg/kg every 6 hours).

Anaerobic infections: Begin with an initial loading dose of 15 mg/kg of body weight. Follow with 7.5 mg/kg (up to 1 Gm/dose) in 6 hours and every 6 hours thereafter for 7 to 10 days or longer if indicated. Do not exceed 4 Gm in 24 hours.

Complicated intra-abdominal infections: 500 mg every 6 hours given in combination with ciprofloxacin 400 mg every 12 hours or cefepime 2 Gm every 12 hours.

Prevent postoperative infection in contaminated or potentially contaminated colorectal surgery: 15 mg/kg infused over 30 to 60 minutes and completed 1 hour before surgery. Follow with 7.5 mg/kg over 30 to 60 minutes in 6 hours and in 12 hours. If *Bacteroides fragilis* is the suspected or confirmed organism, an alternate regimen is to give a 1,500-mg dose at the beginning of surgery to ensure adequate metronidazole levels.

PEDIATRIC DOSE

Safety for use in infants and other pediatric patients not established, but is used for anaerobic infections; see [Maternal/Child](#).

Anaerobic infections: Pediatric patients more than 7 days of age: An initial loading dose of 15 mg/kg. Follow with 7.5 mg/kg every 6 hours. Another source recommends 7.5 mg/kg every 6 hours with a maximum dose of 4 Gm/24 hr.

Preterm infants: An initial loading dose of 15 mg/kg. 48 hours after loading dose, begin 7.5 mg/kg every 12 hours.

Term infants: Same as preterm except begin maintenance dose (7.5 mg/kg) 24 hours after loading dose.

Another source recommends age- and weight-specific doses as follows:

Less than 7 days of age weighing less than 1.2 kg: 7.5 mg/kg every 48 hours.

Less than 7 days of age weighing 1.2 to 2 kg: 7.5 mg/kg every 24 hours.

Less than 7 days of age weighing 2 or more kg: 7.5 mg/kg every 12 hours.

7 days of age or older weighing less than 1.2 kg: 7.5 mg/kg every 24 hours.

7 days of age or older weighing 1.2 to 2 kg: 7.5 mg/kg every 12 hours.

7 days of age or older weighing 2 or more kg: 15 mg/kg every 12 hours.

DOSE ADJUSTMENTS

Reduce dose in severe hepatic disease and in the elderly. Increase intervals in neonates; see [Pediatric Dose](#). ■ No dose adjustment is indicated in mild to moderate impaired renal function. Recommendations vary for patients with a CrCl of less than 10 mL/min who are not on dialysis; consider reducing dose by 50% or increasing the interval to every 12 hours. ■ Dose adjustment not indicated in anuric patients; accumulated metabolites readily removed by dialysis. ■ Continuous NG suction may remove sufficient metronidazole in gastric aspirate to reduce serum levels. No dose adjustment is recommended.

DILUTION

All solutions are prediluted and ready to use (5 mg/mL) except Flagyl IV. Do not use plastic containers in series connections. Risk of air embolism is present. Avoid all contact with aluminum in needles and syringes in all situations. Color change will occur. The powder form (Flagyl IV) is not readily available, but it requires a specific dilution process; initially add 4.4 mL SWFI or NS for injection (100 mg/mL). Solution must be clear. Will be yellow to yellow-green in color with a pH of 0.5 to 2. Must be further diluted to

at least 8 mg/mL with NS, D5W, or LR and be neutralized before infusion with 5 mEq of sodium bicarbonate per 500 mg metronidazole. Mix thoroughly. CO₂ gas will be generated and may require venting.

Storage: Store at room temperature before and after dilution. Discard diluted and neutralized solutions in 24 hours. Do not refrigerate; a precipitate will result. Protect from light when storing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends, "Administer separately, discontinue the primary IV during administration, and do not introduce additives into the solution." Do not use equipment containing aluminum.

One source suggests the following **compatibilities:**

Additive: Not recommended by manufacturer. Ampicillin, cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), ciprofloxacin (Cipro IV), fluconazole (Diflucan), gentamicin, hydrocortisone sodium succinate (Solu-Cortef), midazolam (Versed), penicillin G potassium, tobramycin.

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), anidulafungin (Eraxis), bivalirudin (Angiomax), caspofungin (Cancidas), ceftaroline (Teflaro), cisatracurium (Nimbex), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), dimenhydrinate, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxapram (Dopram), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), fenoldopam (Corlopam), fluconazole (Diflucan), foscarnet (Foscavir), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), labetalol, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), methylprednisolone (Solu-Medrol), midazolam (Versed), milrinone (Primacor), morphine, nicardipine (Cardene IV), palonosetron (Aloxi), piperacillin/tazobactam (Zosyn), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), teniposide (Vumon), theophylline, thiotepa, vasopressin, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Must be given as a slow intermittent or continuous IV infusion, each single dose evenly distributed over 1 hour. Discontinue primary IV during administration. Rate should be ordered by physician.

Surgical prophylaxis: Administer each single dose over 30 to 60 minutes.

ACTIONS

A bactericidal agent with cytotoxic effects, active against specific anaerobic bacteria and protozoa. Widely distributed in therapeutic levels to all body fluids (including abscesses). Levels are directly proportional to dose given. Onset of action is prompt. Metabolized in the liver. Half-life is 8 hours. Crosses placental and blood-brain barriers. Excreted in urine, some in feces. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious intra-abdominal, skin and skin structure, gynecologic, bone and joint, CNS, and lower respiratory tract infections; bacterial septicemia; and endocarditis caused by susceptible anaerobic bacteria. ■ Perioperative prophylaxis to reduce infection rates in contaminated or potentially contaminated colorectal surgery. ■ Given orally for antibiotic-related CDAD, amebiasis, and other indications.

CONTRAINDICATIONS

Hypersensitivity to metronidazole or nitroimidazole derivatives; first trimester of pregnancy.

PRECAUTIONS

A mixed (anaerobic/aerobic) infection will require use of additional appropriate antibiotics. ■ Sensitivity studies indicated to determine susceptibility of the causative organism

to metronidazole. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, metronidazole should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Avoid prolonged use of the drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Symptoms of candidiasis may be exacerbated and require treatment. ■ Encephalopathy has been reported in association with cerebellar toxicity characterized by ataxia, dizziness, and dysarthria. CNS lesions have been seen on MRI. Generally reversible within days to weeks after metronidazole is discontinued. ■ Optic neuropathy and peripheral neuropathy (mainly sensory with S/S of numbness or paresthesia of extremities) have been reported. ■ May cause seizures. ■ Aseptic meningitis has been reported. Symptoms may occur within hours of dose administration and generally resolve after metronidazole is discontinued. ■ Use caution in patients predisposed to edema and/or taking corticosteroids, in patients with impaired cardiac function (contains 27 to 28 mEq sodium/Gm), CNS disease, hepatic disease or impairment, or a history of blood dyscrasias. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with metronidazole. ■ Carcinogenic in rodents; use only when necessary.

Monitor: Rotate IV site frequently to avoid thrombophlebitis. Avoid extravasation. ■ Mild leukopenia has been reported. Obtain total and differential leukocyte counts before and after therapy. ■ Monitor serum levels (suggested) and observe for toxicity in patients with hepatic disease receiving reduced doses and in the elderly. ■ Monitor for neurologic S/S (e.g., ataxia, dizziness, dysarthrias, numbness, paresthesia, and seizures). Prompt evaluation of risk versus benefit of continuing metronidazole required. ■ Transfer to oral dosing as soon as practical. ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid alcohol, alcohol-containing preparations, and disulfiram; toxic reactions will occur. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: use during pregnancy only if clearly needed. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients and neonates not established. Half-life markedly extended in newborns; adjust intervals; see [Pediatric Dose](#). ■ See [Contraindications](#).

Elderly: Pharmacokinetics altered in the elderly; monitor serum levels if possible and adjust dose accordingly.

DRUG/LAB INTERACTIONS

Avoid **alcohol and alcohol-containing preparations** for at least 3 days after taking any dose of metronidazole; avoid for 2 weeks after disulfiram. Toxic reactions will occur. ■ Concurrent use with **drugs that induce microsomal enzyme activity** (e.g., phenobarbital, phenytoin [Dilantin]) may increase metabolism of metronidazole and decrease plasma levels. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, and tetracyclines); bactericidal action may be negated. ■ Administration with **drugs that inhibit microsomal liver enzyme activity** (e.g., cimetidine [Tagamet]) may prolong the half-life of metronidazole and increase metronidazole plasma levels. ■ Potentiates **hydantoin**s (e.g., phenytoin [Dilantin]). ■ May decrease metabolism and increase anticoagulant effects of **warfarin** (Coumadin). Monitor PT/INR periodically. ■ May increase **lithium** levels and cause toxicity. ■ May interfere with **selected chemical studies** (e.g., AST, ALT, LDH, triglycerides, hexokinase glucose).

SIDE EFFECTS

The most serious side effects include aseptic meningitis, encephalopathy, and optic and peripheral neuropathy. Abdominal cramping; anorexia; ataxia; CDAD; constipation; cystitis; darkened deep red urine; decreased libido; diarrhea; dizziness; dryness of the mouth, vagina, or vulva; dysuria; epigastric distress; fever; fleeting joint pain; flushing; furry tongue; glossitis; headache; incontinence; metallic taste (expected); nasal congestion; nausea; neutropenia (reversible); numbness; painful coitus; paresthesia; pelvic pressure; polyuria; proctitis; pruritus; rash; seizures; Stevens-Johnson syndrome; stomatitis;

syncope; thrombocytopenia (reversible); thrombophlebitis; T-wave flattening; urticaria; and vomiting have occurred.

ANTIDOTE

Notify physician of all side effects. Treatment will be symptomatic and supportive. Discontinue metronidazole with onset of seizures or signs of peripheral neuropathy (e.g., numbness or paresthesia of an extremity); benefit/risk of therapy must be reconsidered with onset of convulsions or peripheral neuropathy. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Rapidly removed by hemodialysis. Treat anaphylaxis and resuscitate as necessary.

MICAFUNGIN SODIUM

(my-kah-FUN-gin SO-dee-um)

Antifungal

Mycamine

pH 5 to 7

USUAL DOSE

Treatment of candidemia, acute disseminated candidiasis, *Candida* peritonitis and abscesses: 100 mg/day as an infusion. Mean duration of treatment during clinical studies was 15 days (range 10 to 47 days).

Treatment of esophageal candidiasis: 150 mg/day as an infusion. Mean duration of treatment during clinical studies was 15 days (range 10 to 30 days).

Prophylaxis of *Candida* infections in hematopoietic stem cell transplant (HSCT) recipients: 50 mg/day as an infusion. Mean duration of treatment in patients who responded successfully during clinical studies was 19 days (range 6 to 51 days).

DOSE ADJUSTMENTS

No dose adjustment indicated based on gender or race, in the elderly, or in patients with severe renal dysfunction or mild to moderate or severe hepatic insufficiency. ■ Not dialyzable; a supplementary dose following hemodialysis should not be required. ■ See [Drug/Lab Interactions](#).

DILUTION

Each 50- or 100-mg vial must be reconstituted with 5 mL of NS without a bacteriostatic agent (preferred). Alternately, 5 mL of D5W may be used. The use of strict aseptic technique is required. Swirl vial(s) gently to dissolve. **Do not shake.** Do not use if precipitation or foreign matter is observed. Each single dose (50, 100, or 150 mg) must be further diluted in 100 mL NS (preferred) or D5W for infusion.

Filters: No study data available; if filtering is necessary, contact manufacturer.

Storage: Store unopened vials at CRT. Reconstituted solution in original vial or diluted solution is stable up to 24 hours at 25° C (77° F). Protect diluted solution from light. Discard partially used vials.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Do not mix or co-infuse micafungin with other medications. Has been shown to precipitate when mixed directly with a number of other commonly used medications.” Flush IV line with NS before and after infusion.

One source suggests the following **compatibilities**:

Y-site: Aminophylline, bumetanide, calcium chloride, calcium gluconate, carboplatin (Paraplatin), cyclosporine (Sandimmune), dopamine, doripenem (Doribax), eptifibatide

(Integrilin), esmolol (Brevibloc), etoposide (VePesid), fenoldopam (Corlopam), furosemide (Lasix), heparin, hydromorphone (Dilaudid), lidocaine, lorazepam (Ativan), magnesium sulfate, mesna (Mesnex), milrinone (Primacor), nitroglycerin IV, nitroprusside (Nitropress), norepinephrine (Levophed), phenylephrine (Neo-Synephrine), potassium chloride, potassium phosphates, sodium phosphates, tacrolimus (Prograf), theophylline, vasopressin.

RATE OF ADMINISTRATION

Flush IV line with NS before and after infusion.

A single dose as an infusion equally distributed over 1 hour. Rapid infusion may result in more frequent histamine-mediated reactions (e.g., facial swelling, pruritus, rash, vasodilation).

ACTIONS

A semi-synthetic lipopeptide and the first of a new class of antifungal agents, the echinocandins. Acts by inhibiting the synthesis of 1,3-beta-D-glucan, an integral component of the fungal cell wall not present in mammalian cells. The AUC increases as doses are increased (e.g., from 50 to 150 mg or from 3 to 8 mg/kg). Highly protein bound primarily to albumin but does not competitively displace bilirubin binding to albumin. 85% of steady-state concentration achieved after three daily doses. Metabolized in the liver. A substrate and weak inhibitor of CYP3A, but CYP3A is not a major pathway for metabolism. Half-life ranges from 11 to 21.3 hours. Primarily excreted in feces, with some excretion in urine.

INDICATIONS AND USES

Treatment of patients with candidemia, acute disseminated candidiasis, and *Candida* peritonitis and abscesses. ■ Treatment of esophageal candidiasis. ■ Prophylaxis of *Candida* infections in patients undergoing hematopoietic stem cell transplantation. ■ Efficacy against infections caused by fungi other than *Candida* not established.

CONTRAINDICATIONS

Hypersensitivity to micafungin, any of its components, or other echinocandins (e.g., anidulafungin [Eraxis]), caspofungin (Cancidas).

PRECAUTIONS

Do not give as an IV bolus; for IV infusion only. ■ Isolated anaphylactoid reactions (including shock) and anaphylaxis have been reported. ■ Abnormal liver function tests have been reported. Isolated cases of significant hepatic dysfunction, hepatitis, or worsening hepatic failure have occurred. Incidence may be increased in patients with serious underlying conditions who are receiving additional concomitant medications. Evaluate risk versus benefit of continued micafungin therapy. ■ Elevations in BUN and creatinine have been reported. Isolated cases of significant renal dysfunction or acute renal failure have occurred. ■ Intravascular hemolysis and hemoglobinuria have been reported. Isolated cases of significant hemolysis and hemolytic anemia have occurred. Evaluate risk versus benefit of continued micafungin therapy. ■ Reports of clinical failures resulting from development of drug resistance have been reported. ■ See [Monitor](#) and [Antidote](#).

Monitor: Specimens for fungal culture, serologic testing, and histopathologic testing should be obtained before therapy to isolate and identify causative organisms. Therapy may begin as soon as all specimens are obtained and before results are known. Reassess after test results are known. ■ Baseline CBC with differential and platelet count, BUN, SCr, and liver function tests (e.g., ALT, AST) may be indicated. ■ Monitor for S/S of a hypersensitivity reaction (e.g., bronchospasm, dyspnea, hives, hypotension, rash, pruritus, swelling of eyelids, lips, or face); discontinue infusion if a hypersensitivity reaction occurs. ■ Monitor for evidence of worsening hepatic function (e.g., increased ALT, AST, serum alkaline phosphatase). ■ Monitor for evidence of worsening renal function (e.g., increased BUN, SCr). ■ Monitor for S/S of hemolytic anemia, hemolysis, and hemoglo-

binuria as indicated (lysis of RBCs, liberation of hemoglobin, blood in the urine). ■ Hematologic, hepatic, and renal effects may require discontinuation of micafungin.

Patient Education: Promptly report shortness of breath, dizziness or fainting, itching, rash, or swelling of extremities. ■ Report S/S of liver dysfunction (anorexia, fatigue, jaundice, nausea and vomiting, dark urine, or pale stools). ■ Report any S/S of hemoglobinuria (blood in the urine). ■ Report S/S of renal dysfunction (decrease in urine output). ■ Review list of current medications with physician. Drug interactions are possible; see [Drug/Lab Interactions](#).

Maternal/Child: Pregnancy category C: use during pregnancy only if benefits justify risk to fetus. Some abnormalities, including abortion, occurred in animal studies. ■ Use caution if required during breast-feeding. Secreted in milk of drug-treated rats; not known if micafungin is secreted in human milk. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Differences in response compared to younger adults not identified; however, greater sensitivity in the elderly cannot be ruled out.

DRUG/LAB INTERACTIONS

No alteration of micafungin pharmacokinetics observed with concurrent administration of amphotericin B, cyclosporine (Sandimmune), fluconazole (Diflucan), itraconazole (Sporanox), mycophenolate (CellCept), nifedipine (ProCardia XL), prednisolone, rifampin (Rifadin), ritonavir (Norvir), sirolimus (Rapamune), tacrolimus (Prograf), or voriconazole (VFEND). ■ Concurrent doses of micafungin did not appear to alter the pharmacokinetics of cyclosporine, mycophenolate, fluconazole, prednisolone, tacrolimus, or voriconazole. ■ The effects of **itraconazole, nifedipine, and sirolimus** are increased with concurrent administration of micafungin. Monitor for itraconazole, nifedipine, or sirolimus toxicity and reduce their dose as indicated. ■ Effects of micafungin on the pharmacokinetics of **rifampin and ritonavir** not available. ■ Not expected to alter effects of drugs metabolized by the CYP3A system.

SIDE EFFECTS

Most common side effects include diarrhea, fever, headache, hypokalemia, nausea, thrombocytopenia, and vomiting. The most serious side effects that may occur regardless of indication include acute intravascular hemolysis, decreased WBC, hemoglobinuria, hemolytic anemia, histamine-mediated reactions (e.g., facial swelling, pruritus, rash, vasodilation), hypersensitivity reactions (e.g., anaphylaxis and anaphylactoid reactions [including shock]), significant hepatic dysfunction (e.g., hepatitis, hepatocellular damage, hyperbilirubinemia, or worsening hepatic failure), significant renal dysfunction, and/or acute renal failure. Abdominal pain, anemia, chills, delirium, dizziness, increased liver function tests (e.g., alkaline phosphatase, ALT, AST, BUN, transaminases), injection site reactions (including inflammation, phlebitis, and thrombophlebitis), leukopenia, lymphopenia, neutropenia, and somnolence occurred in patients treated for esophageal candidiasis. In addition, constipation, decreased appetite, dysgeusia (altered sense of taste), dyspepsia, fatigue, febrile neutropenia, flushing, hiccups, hyperbilirubinemia, hypertension, hypocalcemia, hypokalemia, hypomagnesemia, hypophosphatemia, hypotension, increased drug levels, increased SCr, and mucosal inflammation occurred in patients undergoing prophylactic use during HSCT.

Patients with esophageal candidiasis: Also reported rash and phlebitis.

Patients with candidemia and other *Candida* infections and prophylaxis of *Candida* infection in HSCT: Both reported bacteremia, hypertension, hypokalemia, hypomagnesemia, hypotension, peripheral edema, tachycardia, and thrombocytopenia.

Patients with candidemia and other *Candida* infections: Also reported aggravated anemia, atrial fibrillation, bradycardia, decubitus ulcer, hyperkalemia, hypernatremia, hypoglycemia, increased blood alkaline phosphatase, pneumonia, sepsis, septic shock, vascular disorders.

Prophylaxis of *Candida* infection in HSCT: Also reported anorexia, anxiety, constipation, cough, dizziness, dyspepsia, dyspnea, epistaxis, erythema, fatigue, febrile neutropenia,

fluid overload, fluid retention, flushing, hypocalcemia, mucosal inflammation, neutropenia, pruritus, rash, and rigors.

Post-Marketing: Disseminated intravascular coagulation (DIC), Stevens-Johnson syndrome, and toxic epidermal necrolysis.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. If a hypersensitivity reaction occurs, discontinue micafungin and treat as indicated. Appropriate treatment may include oxygen, epinephrine, antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, IV fluids, and ventilation equipment. S/S indicative of hepatic, renal, or hematologic side effects may require evaluation of benefits versus risk of continuing micafungin therapy. Not removed by hemodialysis. Resuscitate as indicated.

MIDAZOLAM HYDROCHLORIDE **BBW**

(my-**DAYZ**-oh-lam hy-droh-**KLOR**-eyed)

Benzodiazepine
Sedative-hypnotic
Anesthetic adjunct
Amnestic

Midazolam HCl PF, Versed

pH 3

USUAL DOSE

Dose requirements for each patient may vary and will depend on the type and amount of premedication used. Doses given below are general guidelines. Individualize dose and titrate slowly to effect. Allow 3 to 5 minutes between each small injection to evaluate the full effect before administering additional doses.

SEDATION, ANXIOLYSIS (ANTI-ANXIETY), AND/OR AMNESIA FOR SHORT DIAGNOSTIC, ENDOSCOPIC, AND THERAPEUTIC PROCEDURES

The desired endpoint for conscious sedation can usually be achieved in 3 to 6 minutes. Time will depend on total dose and type or dose of narcotic premedication used concomitantly.

Healthy adults less than 60 years of age: 1 to 2.5 mg immediately before the procedure.

Begin with 1 mg and titrate slowly up to slurred speech or 2.5 mg. Some patients respond adequately to 1 mg. If additional medication is needed, wait a full 2 minutes, then titrate additional dosage slowly in small increments (usually no more than 1 mg). Wait a full 2 minutes between each increment. A total dose exceeding 5 mg is rarely necessary. Reduce dose by 30% in the presence of narcotic premedication or other CNS depressants. 25% of the sedating dose can be used for maintenance only when clearly indicated by clinical evaluation.

Patients over 60 years of age or debilitated or chronically ill patients: 1 to 1.5 mg. Begin with 1 mg and titrate slowly up to slurred speech or 1.5 mg. May respond adequately to 1 mg. If additional medication is needed, wait a full 2 minutes, then titrate additional dosage in small increments (no more than 1 mg). Wait a full 2 minutes between each increment. A total dose exceeding 3.5 mg is rarely necessary. Reduce dose by 50% in the presence of narcotic premedication or other CNS depressants. 25% of the sedating dose can be used for maintenance only when clearly indicated by clinical evaluation.

INDUCTION OF ANESTHESIA BEFORE ADMINISTRATION OF OTHER ANESTHETIC AGENTS AND/OR MAINTENANCE OF ANESTHESIA AS A COMPONENT OF BALANCED ANESTHESIA DURING SURGICAL PROCEDURES

In all patients (unpremedicated and premedicated), allow 2 minutes from initial dose to reach peak effect. If necessary, complete induction with 25% of initial dose or use inhalational anesthesia (e.g., halothane). Doses of any agents used after induction of anesthesia with

Continued

midazolam may need to be reduced to as little as 25% of the usual initial dose. 25% of the induction dose can be repeated when indicated by lightening of anesthesia.

Unpremedicated patients under 55 years of age: 0.3 to 0.35 mg/kg as an initial dose. A total dose of up to 0.6 mg/kg has been required; recovery may be prolonged.

Unpremedicated patients over 55 years of age (ASA I or II): 0.15 to 0.3 mg/kg as an initial dose.

Unpremedicated debilitated patients or those with severe systemic disease (ASA III or IV): 0.15 to 0.25 mg/kg as an initial dose. As little as 0.15 mg/kg may be adequate.

Patients premedicated with sedatives or narcotics under 55 years of age: 0.25 mg/kg as an initial dose may be adequate. Range is 0.15 to 0.35 mg/kg of body weight.

Patients premedicated with sedatives or narcotics over 55 years of age (Good risk [ASA I & II]): 0.2 mg/kg as an initial dose may be adequate.

Patients premedicated with sedatives or narcotics who are debilitated or those with severe systemic disease (ASA III or IV): 0.15 mg/kg as an initial dose may be adequate.

Premedication usually includes narcotics (e.g., fentanyl 1.5 to 2 mcg/kg IV 5 minutes before induction, or morphine [up to 0.15 mg/kg IM] or meperidine [up to 1 mg/kg IM]) 1 hour before induction with midazolam. Sedative premedication usually includes hydroxyzine (Vistaril) 100 mg PO or a barbiturate PO 1 hour before induction.

SEDATION FOR ANESTHESIA OR TREATMENT IN A CRITICAL CARE SETTING FOR INTUBATED AND MECHANICALLY VENTILATED PATIENTS

Continuous infusion (concentration 0.5 mg/mL): Begin with a *loading dose* of 0.01 to 0.05 mg/kg (0.5 to 4 mg for a typical adult) to rapidly initiate sedation. Infuse over several minutes. May be repeated at 10- to 15-minute intervals until adequate sedation achieved.

For maintenance of sedation: An initial infusion rate of 0.02 to 0.1 mg/kg/hr (1 to 7 mg/hr) may be used. Upper-end doses may be required, but use the lowest recommended doses in patients with residual effects from anesthetic drugs or in those concurrently receiving other sedatives or opioids. Initial infusion rate may be titrated up or down by 25% to 50% to maintain desired level of sedation. Decrease by 10% to 25% every few hours to find the minimum effective infusion rate. The lowest rate that produces the desired level of sedation is recommended. Agitation, hypertension, or tachycardia in response to stimulation in adequately sedated patients may indicate need for an opioid analgesic. Reduced rate of midazolam infusion may be indicated with the addition of an opioid analgesic. Taper dose gradually if midazolam has been used for more than a few days. Abrupt discontinuation may result in withdrawal symptoms.

REFRACTORY STATUS EPILEPTICUS (UNLABELED)

0.15 to 0.3 mg/kg (usual dose 5 to 15 mg); may repeat every 10 to 15 minutes or has been given as a continuous infusion at a rate of 0.05 to 0.6 mg/kg/hr.

PEDIATRIC DOSE

In all situations dose is based on lean body weight in obese pediatric patients. See [Precautions](#) and [Maternal/Child](#).

SEDATION, ANXIOLYSIS (ANTI-ANXIETY), AND/OR AMNESIA BEFORE AND DURING PROCEDURES OR BEFORE ANESTHESIA

All increments of midazolam are on a mg/kg basis. Initial dose is age, procedure, and route dependent. Total dose will depend on patient response, type and duration of the procedure, and type and dose of concomitant medications. Titrate dose of midazolam and other concomitant medications slowly to the desired clinical effect. With concomitant medications, dose of midazolam should be reduced (usually by 25% to 30%). Before beginning a procedure or repeating a dose, wait a full 2 to 3 minutes to fully evaluate the sedative effect. If further sedation is necessary, continue to titrate with small increments at 2- to 3-minute intervals until desired level of sedation achieved. Prolonged sedation and risk of hypoventilation may be associated with higher-end doses.

Nonintubated infants less than 6 months of age: Uncertain when patient transfers from neonatal physiology to pediatric physiology; manufacturer has no specific dosing recom-

mendations. Titrate with very small increments to clinical effect and monitor very carefully for airway obstruction and hypoventilation.

Pediatric patients 6 months to 5 years of age: Begin with an initial dose of 0.05 to 0.1 mg/kg. Up to 0.6 mg/kg may be required, but a total dose of 6 mg is usually not exceeded.

Pediatric patients 6 to 12 years of age: Begin with an initial dose of 0.025 to 0.05 mg/kg. Up to 0.4 mg/kg may be required, but a total dose of 10 mg is usually not exceeded.

Pediatric patients 12 to 16 years of age: See **Usual Dose**. May require higher-than-recommended adult doses, but total dose usually does not exceed 10 mg.

SEDATION, ANXIOLYSIS, AMNESIA

Intubated pediatric patients in critical care settings: Begin with a loading dose of 0.05 to 0.2 mg/kg. May be allowed to breathe on own through intubation tube but assisted ventilation recommended in pediatric patients receiving other CNS depressants. In hemodynamically compromised pediatric patients, titrate the loading dose in small increments and monitor for hypotension, respiratory rate, and oxygen saturation. May be followed by a continuous IV infusion at 0.06 to 0.12 mg/kg/hr (1 to 2 mcg/kg/min). Increase or decrease infusion in 25% increments or use supplemental IV injection to maintain desired effect.

SEDATION OF INTUBATED NEONATES IN CRITICAL CARE SETTINGS

Neonates less than 32 weeks: A continuous infusion at a rate of 0.03 mg/kg/hr (0.5 mcg/kg/min).

Neonates 32 weeks or older: A continuous infusion at a rate of 0.06 mg/kg/hr (1 mcg/kg/min).

Do not use loading doses in neonates. Infusion may be run more rapidly for the first several hours to establish therapeutic plasma levels. Reassess rate carefully and frequently to use the lowest possible effective dose and reduce the potential for drug accumulation. Midazolam contains benzyl alcohol and must be used with extreme caution in neonates.

REFRACTORY STATUS EPILEPTICUS (UNLABELED)

Pediatric patients 2 months of age or older: **Loading dose:** 0.15 mg/kg followed by a continuous infusion of 1 mcg/kg/min. Titrate dose upward every 5 minutes to effect. Mean dose is 2.3 mcg/kg/min (range is 1 to 18 mcg/kg/min).

DOSE ADJUSTMENTS

Reduce dose by 30% to 50%, depending on age, in the presence of narcotic premedication or other CNS depressants; see **Usual Dose**. ■ Reduce dose in congestive heart failure, chronic obstructive pulmonary disease, impaired hepatic or renal function, debilitated patients, and patients over 55 years of age. Half-life is extended and depressant effects will be potentiated; see **Usual Dose**. ■ Dose based on lean body weight in obese pediatric patients. ■ See **Drug/Lab Interactions**.

DILUTION

Read Label Carefully and Confirm mg Dose. Available in Two Strengths, 1 mg/mL and 5 mg/mL.

IV injection: May be diluted with D5W or NS. Dilute in a sufficient amount to permit slow titration (i.e., 1 mg in 4 mL or 5 mg in 20 mL [0.25 mg/mL]). Maximum concentration after dilution should not exceed 0.5 mg/mL.

Infusion: Dilute in either of the previously listed solutions to a maximum concentration of 0.5 mg/mL. 5 mL of a 1 mg/mL (5 mg) in 5 mL of diluent yields 0.5 mg/mL. 5 mL of a 5 mg/mL (25 mg) in 45 mL diluent is usually a 24-hour supply and also yields 0.5 mg/mL. Use a controlled infusion device or at the very least a metriset (60 gtt/mL) to facilitate titration and control flow to prevent overdose.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Aminophylline, cefuroxime (Zinacef), ciprofloxacin (Cipro IV), furosemide (Lasix), gentamicin, hydromorphone (Dilaudid), metronidazole (Flagyl IV), ranitidine (Zantac).

Y-site: Abciximab (ReoPro), amikacin (Amikin), amiodarone (Nexterone), anidulafungin (Eraxis), argatroban, atracurium (Tracrium), bivalirudin (Angiomax), calcium gluconate, caspofungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), ceftaroline (Teflaro), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), clindamycin (Cleocin), dexmedetomidine (Precedex), digoxin (Lanoxin), diltiazem (Cardizem), dobutamine, dopamine, doripenem (Doribax), epinephrine (Adrenalin), erythromycin (Erythrocin), esmolol (Brevibloc), etomidate (Amidate), famotidine (Pepcid IV), fenoldopam (Corlopan), fentanyl (Sublimaze), fluconazole (Diflucan), gentamicin, heparin, hetastarch in electrolytes (Hexend), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), insulin (regular), labetalol, linezolid (Zyvox), lorazepam (Ativan), methadone (Dolophine), methylprednisolone (Solu-Medrol), metronidazole (Flagyl IV), milrinone (Primacor), morphine, nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), palonosetron (Aloxi), pancuronium, potassium chloride (KCl), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), theophylline, tirofiban (Aggrastat), tobramycin, vancomycin, vecuronium.

RATE OF ADMINISTRATION

IV injection: **Sedation:** Any single increment of a total dose titrated slowly over at least 2 minutes. Stop at any point that the speech becomes slurred.

Induction of anesthesia: Any single increment of a total dose over 20 to 30 seconds. Rapid injection in any situation may cause respiratory depression or apnea.

Infusion: See **Usual Dose**. The American Academy of Critical Care recommends limiting the use of midazolam in the critical care setting to 24 hours because its metabolites accumulate in peripheral tissue, especially with long-term infusion.

Pediatric rate: Any single increment of a total dose over a minimum of 2 to 3 minutes. Rapid injection or infusion may cause severe hypotension or seizures in infants and neonates; incidence increased with concomitant fentanyl. See comments under **Infusion**.

ACTIONS

A short-acting benzodiazepine CNS depressant 3 to 4 times as potent as diazepam. Has anxiolytic, hypnotic, anticonvulsant, muscle relaxant, and anterograde amnesic effects. Depressant effects are dependent on dose, route of administration, and the presence or absence of other premedications. Can depress the ventilatory response to CO₂ stimulation. Mechanics of respiration are not adversely affected with usual doses. Mean arterial pressure, cardiac output, stroke volume, and systemic vascular resistance may be slightly decreased. May cause HRs of less than 65/min to rise and more than 85/min to fall. Produces sleepiness and relief of apprehension, and diminishes patient recall very effectively. Widely distributed. Onset of action occurs within 1.5 to 5 minutes. Half-life is approximately 2.5 hours (range is 1 to 5 hours), shorter than that of diazepam (Valium). Time to recovery is usually within 2 hours but may take as long as 6 hours. Metabolized in the liver by cytochrome P₄₅₀ mediation and excreted as metabolites in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

To produce sedation, relieve anxiety, and impair memory of perioperative events. ■ May be used with or without narcotic sedation for conscious sedation before short diagnostic, endoscopic, or therapeutic procedures (e.g., bronchoscopy, gastroscopy, cystoscopy, coronary angiography, cardiac catheterization). ■ Induction of anesthesia before administration of other anesthetic agents. ■ As a component in the induction and maintenance of balanced anesthesia in short surgical procedures. ■ Continuous infusions may be used in intubated and mechanically ventilated patients for sedation as a component of anesthesia or during treatment in a critical care setting.

Unlabeled use: Treatment of refractory status epilepticus.

CONTRAINDICATIONS

Acute narrow-angle glaucoma, known hypersensitivity to midazolam, open-angle glaucoma unless receiving appropriate treatment. Not recommended in pregnancy, childbirth, breast-feeding, shock, coma, acute alcohol intoxication with depression of vital signs. Contraindicated with ritonavir (Norvir).

PRECAUTIONS

Respiratory depression and/or respiratory arrest may occur. Should be used only in a hospital or ambulatory care setting with continuous monitoring of respiratory and cardiac function (e.g., pulse oximetry). Resuscitative drugs (including flumazenil [Romazicon]) and age- and size-appropriate equipment for bag/valve/mask ventilation and intubation must be immediately available. Personnel must be skilled in airway management. ■ A dedicated individual with no other responsibilities should monitor deeply sedated patients throughout any procedure. ■ A topical anesthetic agent should be used with midazolam during perioral endoscopy, and premedication with a narcotic is recommended in bronchoscopy since increased cough reflex and laryngospasm frequently occur. Premedication with a narcotic is also recommended with balanced anesthesia. ■ For IV/IM use only. Contains benzyl alcohol. Do not use for intrathecal or epidural administration. ■ Use caution in neonates. At recommended doses benzyl alcohol is not expected to be toxic, but excessive benzyl alcohol may result in hypotension, metabolic acidosis, and increased incidence of kernicterus, especially in small preterm infants. ■ Use extreme caution in the elderly, in patients with chronic disease states, decreased pulmonary reserve, hepatic or renal impairment, neuromuscular disorders, and in those with uncompensated acute illness (e.g., severe fluid or electrolyte disturbances); may have increased risks of hypoventilation, airway obstruction, or apnea. Peak effect may take longer. ■ Use with caution in obese patients and patients with CHF. Half-life is prolonged. ■ See [Pediatric Dose](#) and [Maternal/Child](#) for additional precautions with infants and other pediatric patients. ■ Does not protect against increased intracranial pressure or circulatory changes noted with succinylcholine or pancuronium or associated with intubation under light general anesthesia. ■ Some clinicians prefer midazolam over diazepam because of effectiveness, minimum pain if any on injection, and miscibility with many drugs and solutions.

Monitor: Obtain a careful premedication history (e.g., medical conditions, concomitant meds), and complete a physical exam. Check for airway abnormalities. ■ Monitor respiratory and cardiac function (e.g., BP, HR, pulse oximetry) continuously. **Has caused apnea and cardiac arrest.** Monitoring of ECG desirable. Maintain a patent airway and support adequate ventilation. Record assessments using standard assessment charts for scoring, especially in pediatric patients. Monitor for both adequate and excessive sedation. ■ Extravasation or arterial administration hazardous. ■ Bed rest required for a minimum of 3 hours after IV injection. ■ See [Drug/Lab Interactions](#).

Patient Education: Do not drive or operate hazardous machinery until the day after surgery or longer. All effects must have subsided. Avoid use of alcohol or other CNS depressants (e.g., antihistamines, barbiturates) for 24 hours after last dose. ■ May impair memory; request written postop instructions. ■ Consider birth control options.

Maternal/Child: Category D: avoid pregnancy. ■ Not recommended during pregnancy, labor and delivery, or breast-feeding. ■ Elimination rate is faster in infants and children. ■ Neonate has reduced or immature organ function. Clearance is decreased and half-life is increased in critically ill neonates. May be susceptible to profound and/or prolonged respiratory effects. ■ See [Precautions](#) and [Monitor](#).

Elderly: See [Usual Dose](#) and [Dose Adjustments](#). Start with a small dose and increase gradually based on response. ■ Clearance is reduced compared to younger adults, and time to recovery may be prolonged. ■ All elderly are more sensitive to therapeutic and adverse effects (e.g., oversedation, ataxia, dizziness). Patients over 70 years of age may be particularly sensitive. IV injection may be more likely to cause apnea, bradycardia, hypotension, and cardiac arrest. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

DRUG/LAB INTERACTIONS

Concurrent use with **other CNS depressants** (e.g., alcohol, antihistamines, barbiturates, inhalation anesthetics [e.g., halothane], MAO inhibitors [e.g., selegiline (Eldepryl)], narcotics [e.g., morphine, meperidine (Demerol), fentanyl], phenothiazines [e.g., prochlorperazine (Compazine)], thiopental, and tricyclic antidepressants [e.g., imipramine (Tofranil)]) may result in additive effects for up to 48 hours. May produce apnea or prolonged effect, depress ventilatory response to CO₂, or cause hypotension. Reduce doses

of midazolam. ■ **Agents that inhibit cytochrome P₄₅₀ activity** (e.g., triazole antifungals [e.g., itraconazole (Sporanox), ketoconazole (Nizoral), miconazole (Monistat)], cimetidine [Tagamet], diltiazem [Cardizem], verapamil, macrolide antibiotics [e.g., erythromycin], omeprazole [Prilosec], and ranitidine [Zantac]) decrease clearance and increase effects of midazolam resulting in prolonged sedation. ■ Reduce doses of **inhalation anesthetics** (e.g., halothane) **and/or thiopental** when used with midazolam. ■ **Protease inhibitors** (e.g., indinavir [Crixivan], nelfinavir [Viracept], and saquinavir [Invirase]) may increase risk of prolonged sedation and respiratory depression. Concurrent use not recommended. Half-life may double with saquinavir. **Contraindicated with ritonavir (Norvir)**; may cause life-threatening increased sedation and respiratory depression. Benzodiazepines metabolized by alternate routes may be safer (e.g., lorazepam [Ativan], oxazepam [Serax], temazepam [Restoril]). ■ May increase serum concentrations of **digoxin**; monitor digoxin serum levels. ■ Hypotensive effects of benzodiazepines may be increased by any **agent that induces hypotension** (e.g., antihypertensives, CNS depressants, diuretics, lidocaine, paclitaxel). Monitor BP during and after use. ■ Use with **rifampin** (Rifadin) increases clearance and reduces effects of benzodiazepines. ■ **Theophyllines** (Aminophylline) antagonize sedative effects of benzodiazepines. ■ **Smoking** increases metabolism and clearance of midazolam, decreasing plasma levels and sedative effects.

SIDE EFFECTS

The incidence of cardiorespiratory events is higher in patients undergoing procedures involving the upper airway (e.g., upper endoscopy or dental procedures). Serious cardiorespiratory events may include airway obstruction, apnea, hypotension (especially with narcotic premedication), oxygen desaturation, respiratory arrest, and/or cardiac arrhythmias or arrest. Inadequate or excessive dosing may cause agitation, combativeness, involuntary movements (e.g., clonic, tonic, muscle tremor), and hyperactivity; may be caused by cerebral hypoxia or be true paradoxical reactions. Other common reactions are coughing, drowsiness, fluctuation in vital signs, headache, hiccups, nausea and vomiting, nystagmus (especially in pediatric patients), induration, redness, or phlebitis at injection site. Capable of numerous other side effects. Has caused death and hypoxic encephalopathy. Withdrawal may be seen in patients receiving an infusion for extended periods of time.

Overdose: Sedation, somnolence, confusion, impaired coordination, diminished reflexes, coma, and untoward effect on vital signs.

ANTIDOTE

Notify the physician of all side effects. Reduction of dosage may be required or will be treated symptomatically. Discontinue the drug for major side effects or paradoxical reactions. Flumazenil (Romazicon) will reverse all sedative effects of benzodiazepines. A patent airway, artificial ventilation, oxygen therapy and other symptomatic treatment must be instituted promptly. Treat hypotension with IV fluids, Trendelenburg position, or vasopressors (e.g., dopamine) as indicated. May cause emesis; observe closely. Treat hypersensitivity reactions and resuscitate as necessary.

MILRINONE LACTATE

(MILL-rih-nohn LAK-tayt)

Antiarrhythmic
Inotropic agent

Primacor

pH 3.2 to 4

USUAL DOSE

50 mcg/kg (0.05 mg/kg) of body weight as the initial loading dose.
Follow with a maintenance infusion according to the following chart.

Milrinone Maintenance Dose Guidelines			
	Infusion Rate (mcg/kg/min)	Total Daily Dose (24 Hours)	
Minimum	0.375 mcg/kg/min	0.59 mg/kg	Administer as a continuous IV infusion.
Standard	0.50 mcg/kg/min	0.77 mg/kg	
Maximum	0.75 mcg/kg/min	1.13 mg/kg	

Titrate the infusion dose between 0.375 mcg/kg/min to 0.75 mcg/kg/min (26 mcg/min to 52 mcg/min for a 70-kg person) based on hemodynamic and clinical response. Do not exceed a total dose of 1.13 mg/kg/24 hr. Duration of infusion usually does not exceed 48 hours.

DOSE ADJUSTMENTS

Reduced dose required in impaired renal function based on CrCl according to the following chart.

Milrinone Dose Guidelines in Impaired Renal Function	
Creatinine Clearance (mL/min/1.73 M ²)	Infusion Rate (mcg/kg/min)
5 mL/min/1.73 M ²	0.2 mcg/kg/min
10 mL/min/1.73 M ²	0.23 mcg/kg/min
20 mL/min/1.73 M ²	0.28 mcg/kg/min
30 mL/min/1.73 M ²	0.33 mcg/kg/min
40 mL/min/1.73 M ²	0.38 mcg/kg/min
50 mL/min/1.73 M ²	0.43 mcg/kg/min

DILUTION

Loading dose: May be given undiluted, or each 1 mg (1 mL) may be diluted in 1 mL NS or ½NS for injection. Alternately, the loading dose may be diluted with NS, ½NS, or D5W to a total volume of 10 or 20 mL for injection.

Infusion: Dilute with NS, ½NS, or D5W. Available prediluted as 200 mcg/mL in D5W. Amount of diluent may be increased or decreased based on patient fluid requirements. Another source suggests dilution with LR.

Guidelines for Dilution of Milrinone for Infusion			
Desired Infusion Concentration (mcg/mL)	Milrinone 1 mg/mL (mL)	Diluent (mL)	Total Volume (mL)
200 mcg/mL	10 mL	40 mL	50 mL
200 mcg/mL	20 mL	80 mL	100 mL

May be given through Y-tube or three-way stopcock of IV infusion set but should never come in contact with furosemide (Lasix). Use only freshly prepared solutions.

Filters: No data available from manufacturer.

Storage: Store at room temperature before dilution; avoid freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not add supplementary medications." Forms an immediate precipitate with furosemide (Lasix).

One source suggests the following **compatibilities:**

Additive: Not recommended by manufacturer. Quinidine gluconate.

Y-site: Acyclovir (Zovirax), amikacin (Amikin), amiodarone (Nexterone), ampicillin, argatroban, atracurium (Tracrium), bivalirudin (Angiomax), bumetanide, calcium chloride, calcium gluconate, caspofungin (Cancidas), cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), ceftazoline (Teflaro), ceftazidime (Fortaz), cefuroxime (Zinacef), ciprofloxacin (Cipro IV), clindamycin (Cleocin), dexamethasone (Decadron), dexmedetomidine (Precedex), digoxin (Lanoxin), diltiazem (Cardizem), dobutamine, dopamine, doripenem (Doribax), epinephrine (Adrenalin), fenoldopam (Corlopan), fentanyl (Sublimaze), gentamicin, heparin, hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), insulin (regular), isoproterenol (Isuprel), labetalol, lorazepam (Ativan), magnesium sulfate, meropenem (Merrem IV), methylprednisolone (Solu-Medrol), metoprolol (Lopressor), metronidazole (Flagyl IV), miconazole (Mycamine), midazolam (Versed), morphine, nesiritide (Natrecor), nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), oxacillin (Bactocill), pancuronium, piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), propranolol, quinidine gluconate, ranitidine (Zantac), rocuronium (Zemuron), sodium bicarbonate, telavancin (Vibativ), theophylline, ticarcillin/clavulanate (Timentin), tobramycin, torsemide (Demadex), vancomycin, vasopressin, vecuronium, verapamil.

RATE OF ADMINISTRATION

Loading dose: A single dose evenly distributed over 10 minutes.

Infusion: Use an infusion pump to deliver milrinone in recommended doses. The following manufacturer's dose chart defines selected dose in mcg/kg/min in infusion rate of mL/hr. Adjust as indicated by physician's orders and progress in patient's condition. Reduce rate or stop infusion for excessive drop in BP.

Milrinone Infusion Rate (mL/hr) Using 200 mcg/mL Concentration										
Maintenance Dose (mcg/kg/min)	Patient Body Weight (kg)									
	30	40	50	60	70	80	90	100	110	120
0.375	3.4	4.5	5.6	6.8	7.9	9	10.1	11.3	12.4	13.5
0.4	3.6	4.8	6	7.2	8.4	9.6	10.8	12	13.2	14.4
0.5	4.5	6	7.5	9	10.5	12	13.5	15	16.5	18
0.6	5.4	7.2	9	10.8	12.6	14.4	16.2	18	19.8	21.6
0.7	6.3	8.4	10.5	12.6	14.7	16.8	18.9	21	23.1	25.2
0.75	6.8	9	11.3	13.5	15.8	18	20.3	22.5	24.8	27

ACTIONS

A class of cardiac inotropic agent different in chemical structure and mode of action from digitalis glycosides and catecholamines. Similar to inamrinone (Amrinone), with fewer side effects. With a loading dose, peak effect occurs within 10 minutes. Continuous administration is required to maintain serum levels. It has positive inotropic action with vasodilator activity. Reduces afterload and preload by direct relaxant effect on vascular smooth muscle. Produces slight enhancement of AV node conduction. Cardiac output is improved without significant increases in HR or myocardial oxygen consumption or changes in arteriovenous oxygen difference. Pulmonary capillary wedge pressure, total peripheral resistance, diastolic BP, and mean arterial pressure are decreased. HR generally remains the same. Mean half-life is 2.4 hours. Primary route of excretion is in urine.

INDICATIONS AND USES

Short-term management of patients with acute decompensated heart failure.

CONTRAINDICATIONS

Hypersensitivity to milrinone or inamrinone (Amrinone).

PRECAUTIONS

Not shown to be safe or effective for use longer than 48 hours. No improvement in symptoms and an increased risk of death have been reported. ■ Use caution in impaired renal function; serum levels may increase considerably. ■ May be given to digitalized patients without causing signs of digoxin toxicity; correct hypokalemia with potassium supplements. ■ May increase ventricular response in atrial flutter/fibrillation. Consider pretreatment with digoxin. ■ Additional fluids and electrolytes may be required to facilitate appropriate response in patients who have been vigorously diuresed and may have insufficient cardiac filling pressure. Use caution. ■ Safety for use in the acute phase of myocardial infarction not established. ■ Should not be used in patients with severe obstructive aortic or pulmonary valvular disease in lieu of surgical relief of the obstruction. May aggravate outflow tract obstruction in hypertrophic subaortic stenosis.

Monitor: Observe closely. Continuous ECG monitoring required to allow for prompt detection and management of cardiac events, including life-threatening ventricular arrhythmias. Emergency equipment must be readily available. ■ Monitoring of BP, urine output, renal function, fluid and electrolyte changes (especially potassium), liver function tests, and body weight are recommended. ■ Monitoring of cardiac index, pulmonary capillary wedge pressure, central venous pressure, and plasma concentration is very useful. ■ Observe for orthopnea, dyspnea, and fatigue. ■ Reduce rate or stop infusion for excessive drop in BP. ■ As cardiac output and diuresis improves, a reduction in diuretic dose may be indicated. ■ Possible risk of arrhythmias. Risk further increased with excessive diuresis and/or hypokalemia. Replace potassium as indicated. ■ Infusion site reactions may occur. Monitor site carefully.

Maternal/Child: Category C: safety for use during pregnancy, breast-feeding, and in pediatric patients not established. Use during pregnancy only if potential benefit justifies potential risk.

Elderly: Consider impaired renal function; may require a reduced dose.

DRUG/LAB INTERACTIONS

Theoretical potential for interaction with **calcium channel blockers** (e.g., verapamil); no clinical evidence to date. ■ May cause additive hypotensive effects with **any drug that produces hypotension** (e.g., alcohol, benzodiazepines [e.g., diazepam, midazolam], lidocaine, paclitaxel). ■ No untoward drug interactions observed when used in a limited number of patients concurrently with captopril (Capoten), chlorthalidone (Hygroton), diazepam (Valium), digoxin (Lanoxin), furosemide (Lasix), heparin, hydralazine, hydrochlorothiazide, insulin, isosorbide dinitrate (Sorbitrate), lidocaine, nitroglycerin, prazosin (Minipress), quinidine, spironolactone (Aldactone), warfarin (Coumadin), and potassium supplements. ■ See [Monitor](#).

SIDE EFFECTS

Supraventricular and ventricular arrhythmias including nonsustained ventricular tachycardia do occur; rare cases of torsades de pointes have been reported. Abnormal liver function tests, anaphylactic shock (rare), angina, bronchospasm, chest pain, headaches, hypokalemia, hypotension, infusion site reactions, rash, and tremor have been reported.

ANTIDOTE

Notify the physician of any side effect. Based on degree of severity and condition of the patient, may be treated symptomatically, and dose may remain the same, be decreased, or the milrinone may be discontinued. Reduce rate or discontinue the drug at the first sign of marked hypotension and notify the physician. May be resolved by these measures alone or vasopressors (e.g., dopamine) may be required. Treat dysrhythmias with the appropriate drug. Resuscitate as necessary.

MITOMYCIN **BBW**(my-toe-**MY**-sin)**Antineoplastic
(antibiotic)****MTC, Mutamycin****pH 6 to 8****USUAL DOSE**

10 to 20 mg/M² as a single dose. May be repeated in 6 to 8 weeks after adequate bone marrow recovery; see [Dose Adjustments](#). Discontinue drug if no response after two courses of treatment.

DOSE ADJUSTMENTS

Subsequent doses based on post-treatment leukocyte and platelet counts. Withhold dose for leukocytes below 4,000/mm³ or platelet count below 100,000/mm³. Adjust subsequent doses based on nadir after the prior dose according to the following chart. ■ Lower usual dose range is indicated when used with other antineoplastic drugs and radiation.

Guide to Mitomycin Dose Adjustment		
Nadir After Prior Dose		
Leukocytes/mm ³	Platelets/mm ³	Percentage of Prior Dose to Be Given
≥4,000	≥100,000	100%
3,000 to 3,999	75,000 to 99,999	100%
2,000 to 2,999	25,000 to 74,999	70%
<2,000	<25,000	50%

DILUTION

Specific techniques required; see [Precautions](#). Each 5 mg must be diluted with 10 mL SWFI. Allow to stand at room temperature until completely in solution. May be given through Y-tube or three-way stopcock of a free-flowing infusion of NS or D5W or further diluted in either of the same solutions or sodium lactate 1/8 M and given as an infusion.

Storage: Store unopened vial at CRT. Stable after initial reconstitution at room temperature for 7 days, up to 14 days if refrigerated. When further diluted to a concentration of 20 to 40 mcg/mL, it is stable at room temperature for 3 hours in D5W, 12 hours in NS, and 24 hours in sodium lactate 1/8 M.

COMPATIBILITY**(Underline Indicates Conflicting Compatibility Information)**

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Sources suggest the following **compatibilities:**

Additive: Manufacturer states that mitomycin (5 to 15 mg) and heparin (1,000 to 10,000 units) in 30 mL NS is stable at CRT for 48 hours. Other sources list dexamethasone (Decadron), heparin, hydrocortisone sodium succinate (Solu-Cortef).

Y-site: Amifostine (Ethylol), bleomycin (Blenoxane), caspofungin (Cancidas), cisplatin (Platinol), cyclophosphamide (Cytosan), doxorubicin (Adriamycin), droperidol (Inapsine), fluorouracil (5-FU), furosemide (Lasix), granisetron (Kytril), heparin, leucovorin calcium, melphalan (Alkeran), methotrexate, metoclopramide (Reglan), ondansetron (Zofran), teniposide (Vumon), thiotepa, vinblastine, vincristine.

RATE OF ADMINISTRATION

IV injection: A single dose over 5 to 10 minutes.

Infusion: Rate determined by amount and type of solution, typically 15 to 30 minutes.

ACTIONS

A highly toxic antibiotic, antineoplastic agent. Cell cycle phase–nonspecific, it is most useful in G and S phases. Interferes with cell division by binding with DNA to slow production of RNA. Rapidly distributed to body tissues and ascitic fluid. Does not cross blood-brain barrier. Metabolized primarily in the liver, but some metabolism occurs in other tissues as well. Some excreted in urine.

INDICATIONS AND USES

Treatment of disseminated adenocarcinoma of the stomach or pancreas. Used in combination with other drugs. Used intravesically in bladder cancer.

Unlabeled uses: Combination chemotherapy in anal, cervical, head and neck, metastatic breast, non–small cell lung cancers, and malignant mesothelioma.

CONTRAINDICATIONS

Not recommended as single-agent primary therapy. Known hypersensitivity to mitomycin, thrombocytopenia, coagulation disorders, increased bleeding from other causes, potentially serious infections, SCr greater than 1.7 mg/100 mL.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities for monitoring the patient and responding to any medical emergency. ■ Use extreme caution in impaired renal function; see [Contraindications](#). ■ Acute shortness of breath and bronchospasm have occurred within minutes to hours following administration of vinca alkaloids (e.g., vincristine) in patients who have received mitomycin previously or are receiving mitomycin simultaneously. Bronchodilators, steroids and/or oxygen may be used to treat respiratory distress. ■ Bone marrow suppression (leukopenia and thrombocytopenia) may be severe and contribute to overwhelming infections in an already compromised patient. ■ Hemolytic uremic syndrome (hemolytic anemia, thrombocytopenia, and irreversible renal failure) has occurred in patients receiving mitomycin as a single agent or in combination with other agents. It can occur at any time during treatment, but most cases have occurred with a cumulative dose greater than 60 mg. Administration of blood products may exacerbate the symptoms.

Monitor: Monitor WBC, RBC, platelet count, PT, bleeding time, differential, and hemoglobin before, during, and 7 to 10 weeks after therapy. ■ Monitor all patients, especially those nearing a cumulative dose of 60 mg, for unexplained anemia with fragmented cells on peripheral blood smear, thrombocytopenia, and decreased renal function; see [Precautions](#). ■ Determine absolute patency of vein; use of an IV catheter is preferred because severe cellulitis and tissue necrosis will result from extravasation. If extravasation occurs, discontinue injection and use another vein. Elevate extremity and apply cold compresses to extravasated area. Delayed erythema with or without ulceration has occurred at or distant to the injection site. May occur weeks to months after mitomycin administration, even when no obvious evidence of extravasation was observed during administration. ■ May precipitate acute respiratory distress syndrome. Oxygen can be toxic to the lungs; monitor intake carefully and use only enough to provide adequate arterial saturation. ■ Monitor fluid balance; avoid overhydration. ■ Be alert for signs of bone marrow suppression or infection. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ See [Precautions and Drug/Lab Interactions](#).

Patient Education: Nonhormonal birth control recommended. ■ Report shortness of breath and IV site burning and stinging promptly. ■ See Appendix D, p. 1255.

Maternal/Child: Avoid pregnancy; may produce teratogenic effects on the fetus. ■ Information on safety in breast-feeding or in pediatric patients not available; discontinue breast-feeding.

Elderly: Consider diminished hepatic function; monitor for early signs of toxicity.

DRUG/LAB INTERACTIONS

Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ May cause shortness of breath, severe bronchospasm, and acute pneumonitis with **vinca alkaloids** (e.g., vinblastine).

SIDE EFFECTS

Alopecia, anaphylaxis, anorexia, bleeding, blurring of vision, cellulitis at injection site, confusion, CHF (patient has usually received doxorubicin [Adriamycin, Doxil]), coughing, diarrhea, drowsiness, dyspnea with nonproductive cough, edema, elevated BUN or SCr, fatigue, fever, headache, hematemesis, hemolytic uremic syndrome (microangiopathic hemolytic anemia [hematocrit less than 25%], irreversible renal failure [SCr greater than 1.6 mg/dL], and thrombocytopenia [less than 100,000/mm³]), hemoptysis, hypertension, leukopenia, mouth ulcers, nausea, paresthesias, pneumonia, pruritus, pulmonary edema, purple discoloration of vein, radiographic evidence of pulmonary infiltrates, rash, renal failure, respiratory distress syndrome (acute), skin toxicity, stomatitis, syncope, thrombocytopenia, thrombophlebitis, vomiting.

ANTIDOTE

Most side effects will be treated symptomatically. Keep the physician informed. All are potentially serious and many can be life threatening. Hematopoietic depression requires cessation of therapy until recovery occurs. Discontinue drug if dyspnea, nonproductive cough, or radiographic evidence of pulmonary infiltrates is present. Discontinue drug for any symptoms of hemolytic uremic syndrome. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity; see **Precautions**. If extravasation has occurred, L.A. dexamethasone injected into the indurated area with a fine hypodermic needle may be helpful; elevate extremity.

MITOXANTRONE HYDROCHLORIDE **BBW**

(my-toe-ZAN-trohn hy-droh-KLOR-eyed)

**Antineoplastic
(antibiotic)****Novantrone****pH 3 to 4.5****USUAL DOSE****Preliminary evaluations and testing required; see Monitor.****Combination initial therapy for acute nonlymphocytic leukemia (ANLL) in adults:****Induction:** 12 mg/M²/day of mitoxantrone on Days 1 through 3 and cytarabine 100 mg/M²/day as a continuous 24-hour infusion on Days 1 through 7. Should a complete remission not be achieved, repeat mitoxantrone, 12 mg/M²/day for only 2 days, and cytarabine 100 mg/M²/day for 5 days after all signs or symptoms of severe or life-threatening nonhematologic toxicity have cleared.**Consolidation:** After full hematologic recovery (usually 6 weeks after induction therapy), administer mitoxantrone 12 mg/M²/day by IV infusion on Days 1 and 2 and cytarabine 100 mg/M²/day as a continuous 24-hour infusion on Days 1 to 5. May repeat in 4 weeks. Severe myelosuppression occurred in these subsequent courses. See **Monitor**.**Prostate cancer:** 12 to 14 mg/M² as a short IV infusion once every 21 days. Used concurrently with steroids.**Multiple sclerosis (MS):** 12 mg/M² as an infusion over 5 to 15 minutes. Repeat every 3 months. May be given for up to 2 years or until a cumulative dose of 140 mg/M² has been administered.**DOSE ADJUSTMENTS**Adjust dose based on clinical response and development and severity of toxicity. ■ Clearance is reduced by impaired hepatic function. Treat patients with impaired hepatic function with caution, dose adjustment may be indicated. Specific recommendations not available; see **Precautions**.**DILUTION****Specific techniques required; see Precautions.** A single dose must be diluted with at least 50 mL of NS or D5W. May be further diluted in NS, D5W, or D5NS. Must be given through Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS, or may be diluted in larger amounts of the same solutions and given as a continuous infusion.**Filters:** No data available from manufacturer.**Storage:** Store unopened vial at RT (15° to 25° C [59° to 77° F]). Do not freeze. Diluted solution should be used immediately. After penetration of the stopper on a multidose vial, the undiluted mitoxantrone may be stored at RT for 7 days or refrigerated for up to 14 days. Do not freeze.**COMPATIBILITY****Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.**Manufacturer recommends not mixing in the same infusion with other drugs until **compatibility** data available, and states that it may form a precipitate if mixed in the same infusion with heparin.One source suggests the following **compatibilities**:**Additive: Not recommended by manufacturer.** Cyclophosphamide (Cytoxan), cytarabine (ARA-C), etoposide (VePesid), fluorouracil (5-FU), hydrocortisone sodium succinate (Solu-Cortef), potassium chloride (KCl).**Y-site:** Allopurinol (Aloprim), amifostine (Ethyol), cladribine (Leustatin), etoposide (VePesid), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), gemcitabine (Gemzar), granisetron (Kytril), linezolid (Zyvox), melphalan (Alkeran), ondansetron (Zofran), oxaliplatin (Eloxatin), sargramostim (Leukine), teniposide (Vumon), thiotepea, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

IV injection: A single dose of properly diluted medication over at least 3 to 5 minutes. Must be given through Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS.

Intermittent infusion: A single dose over 15 to 30 minutes.

Infusion: Sometimes a single dose is given as a continuous infusion over 24 hours. Is combined with cytarabine.

ACTIONS

An anthracenedione, a synthetic antibiotic antineoplastic agent. Has achieved complete remissions with a single course of combination therapy. Has a cytotoxic effect on proliferating and nonproliferating cells. Probably not cell-cycle specific. Inhibits DNA and RNA synthesis. Thought to reduce the number of relapses and slow down progression of MS through its ability to suppress the activity of T-cells, B-cells, and macrophages. These cells attack the myelin sheath around nerve cells, causing the symptoms of MS. Improves the presentation of brain lesions on MRI studies. Extensive distribution to tissue occurs rapidly. Partially metabolized. Exact pathways unknown. Half-life varies from 23 to 213 hours (median 75 hours). Slowly excreted in bile, urine, and feces as either unchanged drug or as inactive metabolites.

INDICATIONS AND USES

Treatment of acute nonlymphocytic leukemia in adults; includes erythroid, monocytic, myelogenous, and promyelocytic acute leukemias. Given in combination with other approved drugs. ■ Treatment of bone pain in patients with advanced prostate cancer resistant to hormones. Used concurrently with steroids. ■ To reduce neurologic disability and/or the frequency of clinical relapses in patients with secondary (chronic) progressive, progressive relapsing, or worsening relapsing-remitting multiple sclerosis (i.e., patients whose neurologic status is significantly abnormal between relapses). Not indicated in the treatment of patients with primary progressive MS.

Unlabeled uses: Treatment of acute lymphocytic leukemia (ALL), breast cancer, Hodgkin's lymphoma, non-Hodgkin's lymphomas, myelodysplastic syndrome, pediatric acute leukemias, pediatric sarcoma, and part of a conditioning regimen for autologous hematopoietic stem cell transplantation (HSCT).

CONTRAINDICATIONS

Hypersensitivity to mitoxantrone or other anthracyclines. ■ Not for intrathecal use; severe injury with permanent sequelae can result.

PRECAUTIONS

For IV use only. Do not administer SC, IM, intra-arterially, or intrathecally. ■ Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Use of goggles, gloves, and protective gown recommended. Flush skin copiously with warm water should any contact occur. Irrigate eyes immediately in case of contact. Clean spills with 5.5 parts calcium hypochlorite to 13 parts by weight of water for each 1 part of mitoxantrone. ■ Usually administered by or under the direction of the physician specialist with facilities for monitoring the patient and responding to any medical emergency. ■ Will cause severe myelosuppression; use extreme caution in pre-existing drug-induced bone marrow suppression. ■ Should not be given to patients with baseline neutrophil counts of less than 1,500 cells/mm³ (except for the treatment of acute nonlymphocytic leukemia). ■ MS patients with a baseline left ventricular ejection fraction (LVEF) below the lower limit of normal or patients who have received a cumulative dose equal to or greater than 140 mg/M² should not be treated with mitoxantrone. ■ May cause severe cardiac toxicity (e.g., acute congestive heart failure) in all patients, even if cardiac risk factors are not present. May occur early during therapy or months to years after completion. Risk increased with cumulative doses (equal to or greater than 140 mg/M²), in patients with pre-existing heart disease, and in patients previously treated with anthracyclines (see [Drug/Lab Interactions](#)), other cardiotoxic drugs, or radiation therapy encompassing the heart. ■ Use caution in impaired liver function. Clearance is decreased; see [Dose Adjustments](#). Patients with MS who have hepatic impairment should ordinarily not be treated with mitoxantrone. ■ Use caution if renal function is

impaired; has not been studied. ■ Urine and sclera may turn bluish in color. ■ Therapy with mitoxantrone increases the risk of developing secondary leukemia in patients with multiple sclerosis and in patients with cancer. Most commonly reported types are acute promyelocytic leukemia and acute myelocytic leukemia. The occurrence is more common when mitoxantrone is given in combination with other cytotoxic agents and/or radiotherapy or when doses of anthracyclines (e.g., doxorubicin [Adriamycin], idarubicin [Idamycin]) have been escalated. ■ Rapid lysis of cancer cells may cause tumor lysis syndrome. ■ See **Monitor**.

Monitor: Obtain baseline CBC with differential and platelet count; repeat before each dose and if S/S of infection occur. ■ Complete a physical exam and ECG and obtain a complete history to assess for S/S of pre-existing cardiac disease. ■ In all patients, obtain an evaluation of left ventricular ejection fraction (LVEF) by echocardiogram or MUGA (multiple-gated acquisition) before therapy begins. ■ Evaluation of LVEF and assessment of cardiotoxicity by history, physical exam, and ECG should be repeated before each dose in MS patients. ■ Obtain repeat LVEF as indicated in all patients. ■ Mitoxantrone should not ordinarily be administered to MS patients who have received a cumulative dose equal to or greater than 140 mg/M² or to patients who experience a drop in LVEF to below the lower limit of normal or a clinically significant reduction in LVEF. MS patients should have an annual quantitative evaluation of LVEF after discontinuing mitoxantrone therapy to monitor for late-occurring cardiotoxicity. ■ Monitoring of liver function is indicated before and during therapy. ■ Because of rapid lysis of cancer cells, initiate hypouricemic therapy with allopurinol or similar agents before beginning treatment. Monitor uric acid levels, maintain hydration, and alkalinize urine if necessary. ■ Observe closely and frequently for all signs of bleeding or infection. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Determine absolute patency of vein. Severe local tissue damage may occur with extravasation. Phlebitis at the infusion site has also been reported. Should extravasation or phlebitis occur, discontinue injection and use another vein. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for S/S of acute leukemia (secondary leukemia); may include excessive bruising, bleeding, and recurrent infections. ■ See **Precautions** and **Drug/Lab Interactions**.

Patient Education: Nonhormonal birth control recommended; see **Maternal/Child**. ■ Blood and cardiac tests are imperative; keep all appointments. ■ Report IV site burning or stinging promptly. ■ Urine may turn blue-green for 24 hours following administration. Bluish discoloration of sclera may also occur. ■ Medication guide available; read before beginning treatment with mitoxantrone. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. May produce teratogenic effects on the fetus. Women with MS who are biologically capable of becoming pregnant should have a pregnancy test before each dose of mitoxantrone regardless of other methods of birth control used, including birth control pills. ■ Secreted in breast milk. Discontinue breastfeeding. ■ Safety for use in pediatric patients not established.

Elderly: Specific age-related differences have not been identified; consider age-related organ impairment (e.g., bone marrow reserve, renal, hepatic) and possibility of increased sensitivity.

DRUG/LAB INTERACTIONS

Additive bone marrow suppression may occur with **radiation therapy and/or other bone marrow-suppressing agents** (e.g., azathioprine [Imuran], chloramphenicol, melphalan [Alkeran]). Dose reduction may be required. ■ Risk of cardiotoxicity increased in patients previously treated with maximum cumulative doses of **other anthracyclines** (e.g., doxorubicin [Adriamycin], epirubicin [Ellence], idarubicin [Idamycin]) **and/or radiation encompassing the heart**. ■ Do not administer **live virus vaccines** to patients receiving anti-neoplastic drugs.

SIDE EFFECTS

Alopecia (reversible), bladder infections, menstrual disorders, mucositis, and nausea occur frequently. Other side effects include abdominal pain, acute congestive heart failure,

altered electrolytes, altered liver function tests (e.g., increased ALT, AST, BUN), arrhythmias, arthralgias, bleeding, bone marrow suppression (severe with standard doses), cardiotoxicity, conjunctivitis, cough, decrease in LVEF, diarrhea, dyspnea, erythema, fever, GI bleeding, headache, hematuria, hypersensitivity reactions (e.g., dyspnea, hypotension, rash, urticaria), infections, injection site burning, jaundice, leukemia (including secondary AML), mucositis, myalgias, nail bed changes, phlebitis, renal failure, seizures, skin discoloration, stomatitis, swelling, vomiting. Interstitial pneumonitis has been reported. Anaphylaxis has been reported rarely.

Post-Marketing: Secondary acute myelogenous leukemia (AML).

ANTIDOTE

There is no specific antidote. Notify physician of all side effects. Most will be treated symptomatically. Blood and blood products, antibiotics and other adjunctive therapies must be available. Blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epo-gen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Nadir of leukocyte count occurs within 10 days. Recovery is within 21 days. For extravasation, elevate extremity and apply ice. Monitor closely and obtain surgical consult if necessary. Overdose has resulted in death. Peritoneal dialysis or hemodialysis not effective. Supportive therapy as indicated will help sustain the patient in toxicity.

MORPHINE SULFATE **BBW**

(MOR-feen SUL-fayt)

Opioid analgesic
(agonist)
Adjunct, pulmonary edema
Anesthesia adjunct

Astramorph PF, Duramorph PF

pH 2.5 to 7

USUAL DOSE

IV injection: Manufacturer recommends an initial dose of 2 to 10 mg/70 kg of body weight. Repeat every 3 to 4 hours as necessary. Doses may range from 2 to 20 mg based on patient requirements and response. Titrate to achieve pain relief with lowest dose. Frequent, repeated doses (e.g., up to every 5 minutes if needed) in small-dose increments (e.g., 1 to 4 mg) may be associated with fewer side effects than the administration of larger, less frequent doses.

Cancer patients suffering with severe chronic pain often require higher doses because of increased tolerance (up to 150 mg/hr has been given). Very high doses (275 to 440 mg/hr) are occasionally used for short periods of time (hours to days) for extreme exacerbations of pain in these drug-tolerant individuals. 1 to 3 mg/kg over 15 to 20 minutes will induce unconsciousness.

Acute MI: 2 to 4 mg initially. May give additional doses of 2 to 8 mg at 5- to 15-minute intervals as needed (AHA guidelines).

Infusion: 1 mg/mL (range is 0.1 to 1 mg/mL) in NS or D5W per controlled infusion device (may be patient activated). **Based on a 1 mg/mL dilution**, an initial loading dose may be as high as 15 mg (15 mL). The continuous background infusion to provide a level of pain relief and maintain patency of the vein may range from 1 to 2.5 mg/hr (1 to 2.5 mL). Additional doses averaging 0.5 to 1.5 mg (0.5 to 1.5 mL) may be activated by the patient at selected intervals every 3 to 60 minutes (averaging 10 to 15 min). Additional boluses averaging 1 to 2 mg (1 to 2 mL) may be given by health care professionals (e.g., every 30 min prn). In selected cancer patients all of these doses may be considerably higher.

Open heart surgery: 0.5 to 3 mg/kg as the sole anesthetic or with an anesthetic agent. Cardiovascular function not depressed if oxygen is used and adequate ventilation maintained.

Dyspnea during end-of-life care (unlabeled): 2 to 5 mg IV every 5 to 10 minutes until relief. Patient-controlled anesthesia (PCA) is recommended in the inpatient setting. Higher doses may be needed for patients taking chronic opioids.

PEDIATRIC DOSE

Analgesic: Usual range is 0.05 to 0.1 mg/kg. Administer very slowly.

Postoperative analgesia: 0.01 to 0.04 mg/kg/hr (10 to 40 mcg/kg/hr).

Selected pediatric patients with severe chronic cancer pain: 0.025 to 2.6 mg/kg/hr (average 0.04 to 0.07 mg/kg/hr).

Selected pediatric patients with severe pain during sickle cell crisis: 0.025 to 2.6 mg/kg/hr (average 0.04 to 0.07 mg/kg/hr).

NEONATAL DOSE

Elimination is reduced in neonates, and they have an increased susceptibility to CNS side effects.

Analgesia/tetralogy (cyanotic) spells (unlabeled): 0.05 to 0.2 mg/kg/dose every 4 hours. Titrate to individual response. Another source suggests an **IV injection** of 0.05 to 0.1 mg/kg/dose every 4 to 8 hours or an **IV infusion** of 0.01 to 0.02 mg/kg/hr. Titrate to individual response.

Mechanical ventilation of neonates (unlabeled): 50 mcg/kg as an initial loading dose. Administer over 30 to 60 minutes. Follow with a continuous infusion of 10 to 30 mcg/kg/hr. Titrate to individual response.

Postoperative analgesia (unlabeled): 50 mcg/kg as an initial loading dose. Administer over 30 to 60 minutes. Follow with a continuous infusion of 15 mcg/kg/hr. Titrate to individual response.

DOSE ADJUSTMENTS

Reduced dose and/or extended intervals may be required in impaired renal or hepatic function and in the elderly. ■ Doses appropriate for the general population may cause serious respiratory depression in vulnerable patients. ■ Increase doses as required if analgesia is inadequate, tolerance develops, or pain severity increases. The first sign of tolerance is usually a reduced duration of effect. ■ See [Drug/Lab Interactions](#).

DILUTION

IV injection: May be given undiluted; however, further dilution with 5 mL of SWFI or NS for injection or other IV solutions to facilitate titration is appropriate. May be given through Y-tube or three-way stopcock of infusion set.

Infusion: Each 0.1 to 1 mg is usually diluted in 1 mL NS or D5W and administered via a controlled infusion device that may be patient activated (e.g., a narcotic syringe infuser system). Available in 60-mL ampules containing 1 to 2 mg/mL for direct transfer to syringe infuser systems. (*Astramorph PF and Duramorph* are preservative free and expensive; can be used IV, but are the only choice for epidural or intrathecal injection; see drug literature. *Duramorph* is **NOT** for use in continuous microinfusion devices. *Infumorph* is **NOT** for IV use.) Fluid restriction or high doses may require more concentrated solutions. Concentrations above 5 mg/mL are rarely exceeded. Available in vials containing 25 mg/mL, which must be further diluted before infusion. Also available in ADD-Vantage vials for use with ADD-Vantage infusion containers. Is sometimes added to larger amounts (500 mL to 1 L) of IV solution in selected situations and infused via a large volume controlled infusion pump (requires close titration).

Storage: Store at CRT. Protect from light and freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Alteplase (tPA, Activase), atracurium (Tracrium), dobutamine, fluconazole (Diflucan), furosemide (Lasix), ketamine (Ketalar), meropenem (Merrem IV), metoclopramide (Reglan), ondansetron (Zofran), succinylcholine, verapamil.

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), aminophylline, amiodarone (Nexterone), ampicillin, ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), argatroban, atracurium (Tracrium), atropine, aztreonam (Azactam), bivalirudin (Angiomax), bumetanide, calcium chloride, caspofungin (Cancidas), cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftaroline (Teflaro), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chloramphenicol (Chloromycetin), cisatracurium (Nimbex), cladribine (Leustatin), clindamycin (Cleocin), dexamethasone (Decadron), dexmedetomidine (Precedex), diazepam (Valium), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxycycline, enalaprilat (Vasotec IV), epinephrine (Adrenalin), erythromycin (Erythrocin), esmolol (Brevibloc), etomidate (Amidate), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), furosemide (Lasix), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, heta-starch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydro-morphone (Dilaudid), 6% hydroxyethyl starch (Voluven), insulin (regular), ketorolac (Toradol), labetalol, levofloxacin (Levaquin), lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meropenem (Merrem IV), methyl-dopate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metoprolol (Lopressor), metronidazole (Flagyl IV), midazolam (Versed), milrinone (Primacor), nafcillin (Nallpen), nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepineph-

rine (Levophed), ondansetron (Zofran), oxacillin (Bactocill), oxaliplatin (Eloxatin), oxytocin (Pitocin), paclitaxel (Taxol), palonosetron (Aloxi), pancuronium, pantoprazole (Protonix IV), pemetrexed (Alimta), penicillin G potassium, phenobarbital (Luminal), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), propranolol, ranitidine (Zantac), remifentanyl (Ultiva), sodium bicarbonate, sulfamethoxazole/trimethoprim, tacrolimus (Prograf), teniposide (Vumon), thiotepa, ticarcillin/clavulanate (Timentin), tirofiban (Aggrastat), tobramycin, vancomycin, vecuronium, vinorelbine (Navelbine), warfarin (Coumadin), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Frequently titrated according to symptom relief and respiratory rate. Side effects markedly increased if rate of injection too rapid. Rapid IV administration may result in chest wall rigidity.

IV injection: 15 mg or fraction thereof over 4 to 5 minutes.

Infusion: Initial loading dose, basal rate (continuous rate of infusion), patient self-administered dose and interval, additional boluses permitted, and total dose for 1 hour should be ordered by physician. Administer initial dose and boluses at rate for IV injection. For continuous infusion and self-administered dose and interval, note range of mL/hr under Usual Dose.

ACTIONS

An opium-derivative, opioid analgesic, which is a descending CNS depressant. Produces a wide spectrum of pharmacologic effects, including analgesia, diminished GI mobility, dysphoria, euphoria, physical dependence, respiratory depression, and somnolence. Pain relief is effected almost immediately and lasts up to 4 to 5 hours (mean is 2 hours). Morphine induces sleep and inhibits perception of pain by binding to opiate receptors, decreasing sodium permeability, and inhibiting transmission of pain impulses. Depresses many other senses or reflexes. Relieves pulmonary congestion, lowers myocardial oxygen requirements, and reduces anxiety. Metabolized in the liver and primarily excreted in the urine and feces. Crosses the blood-brain barrier, but plasma concentration of morphine is higher than CSF concentration. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Relief of moderate to severe acute and chronic pain (e.g., postop or cancer pain). ■ Analgesic of choice in pain associated with myocardial infarction. ■ Treatment of acute pulmonary edema associated with left ventricular failure. ■ Used before surgery to sedate, decrease anxiety, and facilitate induction of anesthesia. ■ Management of neonatal opiate withdrawal.

Unlabeled uses: Treatment of dyspnea in end-of-life care. ■ Control of pain during mechanical ventilation in neonates. ■ Control of postoperative pain in neonates.

CONTRAINDICATIONS

Hypersensitivity to morphine sulfate or any component of the formulation, bronchial asthma (acute or severe), and upper airway obstruction. Other sources include paralytic ileus, premature infants, or labor and delivery of premature infants. Specific formulations may have additional contraindications; see prescribing information. ■ **Duramorph** is **NOT** for use in continuous microinfusion devices.

PRECAUTIONS

Schedule II opioid agonists, including hydromorphone, morphine, oxycodone, fentanyl, and methadone, have the highest potential for abuse and risk of producing respiratory depression. Alcohol, CNS depressants, and other opioids potentiate the respiratory depressant effects of hydromorphone, increasing the risk of respiratory depression that might result in death; see [Drug/Lab Interactions](#). ■ Use caution in the elderly, in patients with impaired hepatic or renal function, and in pulmonary disease. ■ May cause severe hypotension in an individual whose ability to maintain BP has been compromised by a depleted blood volume or a concurrent administration of drugs such as phenothi-

azines or general anesthetics; see [Drug/Lab Interactions](#). ■ Use extreme caution in craniotomy, head injury, and increased intracranial pressure; respiratory depression and intracranial pressure may be further increased. ■ May cause sedation and pupillary changes (miosis) that may obscure the existence, extent, and course of intracranial pathology. ■ May cause apnea in asthmatic patients. ■ Symptoms of acute abdominal conditions may be masked. ■ May increase ventricular response rate in presence of supraventricular tachycardias. ■ Cough reflex is suppressed. ■ Tolerance as well as psychological and physical dependence can develop. Tolerance for the drug gradually increases, but abstinence for 1 to 2 weeks will restore effectiveness. Risk of using a narcotic antagonist in patients chronically receiving narcotic therapy should be considered. ■ A marked increase in dose may precipitate seizures. Use with caution in patients with known seizure disorders.

Monitor: Oxygen, controlled respiratory equipment, and naloxone (Narcan) must always be available.

■ Observe patient frequently to continuously based on amount of dose and monitor vital signs. ■ Assess baseline pain, then assess pain with vital signs and/or more frequently if needed. Reassess after administration of morphine and adjust dose or interval as required. ■ Keep patient supine; orthostatic hypotension and fainting may occur; less likely with continuous low doses, but observe closely during ambulation. ■ Uncontrolled pain causes sleep deprivation, decreases pain threshold, and increases pain. When pain is finally controlled, expect the patient to sleep more until recovery from sleep deprivation. ■ Adhere to prescribed bowel care regimen to avoid constipation and/or impaction. Maintain adequate hydration. ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid alcohol or other CNS depressants (e.g., barbiturates, benzodiazepines [e.g., diazepam (Valium)]). ■ May cause blurred vision, dizziness, or drowsiness; use caution in tasks that require alertness. ■ Request assistance with ambulation. ■ May be habit forming.

Maternal/Child: Category C: safety for use in pregnancy or breast-feeding not established. Benefits must outweigh risks. ■ May reduce strength, duration, and frequency of uterine contractions during labor and delivery. ■ See [Contraindications](#). ■ Pediatric patients may be more sensitive to effects, especially respiratory depressant effects. ■ May cause paradoxical excitation. ■ May cause respiratory depression in the neonate when given during labor and delivery. Have naloxone and resuscitative equipment available. ■ Infants born to mothers who have been taking morphine chronically may exhibit withdrawal symptoms.

Elderly: See [Dose Adjustments](#) and [Precautions](#). ■ May be more sensitive to effects (e.g., respiratory depression, constipation, urinary retention). ■ Lower doses may provide effective analgesia. ■ Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

Alcohol, other CNS depressants (e.g., narcotic analgesics, general anesthetics, antidepressants [e.g., amitriptyline (Elavil), imipramine (Tofranil), nortriptyline (Aventyl)], barbiturates, hypnotics, sedatives), H_2 antagonists (e.g., cimetidine [Tagamet]), and some phenothiazines (e.g., chlorpromazine [Thorazine]) may increase CNS depression, respiratory depression, and hypotension; reduced dose of one or both agents indicated. ■ **Anticholinergics** (e.g., atropine) and **antidiarrheals** may increase risk of constipation or paralytic ileus. ■ Hypotensive effects will be increased with **diuretics** (e.g., furosemide [Lasix]), **antihypertensive agents** (especially ganglionic blockers [e.g., guanethidine (Ismelin)]), or **hypotension-producing agents** (e.g., antidepressants, benzodiazepines [e.g., diazepam], adrenergic blocking agents [e.g., propranolol], calcium channel blocking agents [e.g., diltiazem], calcium, nitroprusside sodium, nitroglycerin). ■ Concurrent use with **rifampin** (Rifadin) may decrease analgesic effects of morphine; an alternate analgesic may be required. ■ Markedly reduced doses of **MAO inhibitors** (e.g., selegiline [Eldepryl]) required with opiates. ■ Administration of **agonist/antagonist analgesics** (e.g., butorphanol [Stadol] or buprenorphine [Buprenex]) to an opiate-dependent patient re-

ceiving a pure opiate may precipitate withdrawal symptoms. ■ May potentiate anticoagulant effect of oral **warfarin**.

SIDE EFFECTS

Average dose: Anxiety, bradycardia, confusion, constipation, depression of cough reflex, decreased libido in men and women, delayed absorption of oral medications, dizziness, drowsiness/sedation, euphoria, histamine-related reactions (e.g., local tissue irritation, pruritus, urticaria, wheals), hypersensitivity reactions, hypothermia, increased intracranial pressure, interference with thermal regulation, menstrual irregularities (including amenorrhea), nausea, neonatal apnea, oliguria, orthostatic hypotension, physical or psychological dependence, reduced male potency, respiratory depression (slight), skeletal muscle rigidity, tremors, urinary retention, vomiting. Side effects associated with histamine and constipation may be more common with morphine than with most other narcotic analgesics.

Higher doses: CNS excitation (convulsions), respiratory depression (severe).

Overdose: Anaphylaxis, cardiac arrest, Cheyne-Stokes respiration, circulatory collapse, coma, excitation, hypotension (severe), inverted T-wave on ECG, myocardial depression (severe), pinpoint pupils, respiratory depression or arrest, tachycardia, death.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. Naloxone (Narcan) will reverse serious reactions. Question the diagnosis of narcotic-induced toxicity if no response is observed after administration of 10 mg of naloxone. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Resuscitate as necessary.

MOXIFLOXACIN HYDROCHLORIDE **BBW**

(mox-ee-FLOX-ah-sin hy-droh-KLOR-eyed)

Antibacterial
(fluoroquinolone)

Avelox

pH 4.1 to 4.6

USUAL DOSE

400 mg once every 24 hours. Duration of therapy is based on diagnosis as listed in the following chart. Serum levels similar by oral or IV route. Transfer to oral therapy as soon as practical; no dose adjustment necessary. The magnitude of QT prolongation may increase with increasing serum concentrations. Do not exceed recommended dose.

Moxifloxacin Dosing Guidelines		
Infection*	Daily Dose (mg)	Duration (days)
Acute bacterial sinusitis	400 mg	10 days
Acute bacterial exacerbation of chronic bronchitis	400 mg	5 days
Community-acquired pneumonia	400 mg	7-14 days
Uncomplicated skin and skin structure infections	400 mg	7 days
Complicated skin and skin structure infections	400 mg	7-21 days
Complicated intra-abdominal infections†	400 mg	5-14 days

*Due to the designated pathogens.

†Therapy should usually be started with the IV formulation.

DOSE ADJUSTMENTS

Dose adjustment is not indicated based on age, gender, or race; in impaired renal function (including patients on hemodialysis or CAPD); or in mild, moderate, or severe impaired hepatic function (Child Pugh Classes A, B, and C). See **Precautions**.

DILUTION

Available in ready-to-use latex-free plexibags containing 400 mg moxifloxacin in 0.8% saline. No further dilution is necessary. Refer to directions provided with administration set.

Filters: No data available from manufacturer.

Storage: Store at CRT. Do not refrigerate; a precipitate will form. Discard unused portions.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Limited **compatibility** data available. Manufacturer states, "Other IV substances, additives, or other medications should not be added to moxifloxacin or infused simultaneously through the same IV line." Flush line with a solution **compatible** to both drugs before and after administration of moxifloxacin and/or any other drug through the same IV line. May be administered through a Y-tube or three-way stopcock. Temporarily discontinue other solutions infusing at the same site.

Y-site: Manufacturer lists as **compatible** with NS, D5W, D10W, SWFI, LR at ratios from 1:10 to 10:1.

One source suggests the following **compatibilities**:

Y-site: Ceftaroline (Teflaro), doripenem (Doribax), 6% hydroxyethyl starch (Voluven), vasopressin.

RATE OF ADMINISTRATION

Single dose equally distributed over 60 minutes as an infusion. Avoid rapid or bolus IV infusion. Incidence and magnitude of QT prolongation may increase with increasing concentrations or increasing rates of infusion. Flush tubing before and after moxifloxacin with a **compatible** solution.

ACTIONS

A synthetic broad-spectrum methoxy fluoroquinolone antibacterial agent. Effective against a wide range of gram-negative and gram-positive organisms, including common respiratory pathogens such as *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis*, and atypicals such as *Chlamydomphila pneumoniae* and *Mycoplasma pneumoniae*. Bactericidal action results from inhibition of topoisomerase II and IV, which are required for bacterial DNA replication, transcription, repair, and recombination. Mode of action helps minimize selection of resistant mutants of gram-positive bacteria, which cause many respiratory tract infections. Mechanism of fluoroquinolones differs from that of aminoglycosides, cephalosporins, macrolides, penicillins, and tetracyclines, and fluoroquinolones may be active against pathogens resistant to these antibiotics. There is no cross-resistance between fluoroquinolones and these other antibiotics. Widely distributed throughout the body. Concentrations in most target tissues are higher than those found in serum. Mean half-life is approximately 10.7 to 13.3 hours. Partially metabolized in the liver by glucuronide and sulfate conjugation. Excreted as unchanged drug and metabolites in feces and urine. May be secreted in breast milk.

INDICATIONS AND USES

Treatment of adults with infections caused by susceptible strains of microorganisms in conditions, including acute bacterial sinusitis, acute bacterial exacerbation of chronic bronchitis, complicated and uncomplicated skin and skin structure infections, and complicated intra-abdominal infections. ■ Treatment of community-acquired pneumonia caused by many organisms, including *Streptococcus pneumoniae* (including multidrug-resistant strains [MDRSP]). MDRSP strains are resistant to two or more of the following antibiotics: penicillin, second-generation cephalosporins (e.g., cefuroxime [Zinacef]), macrolides, tetracyclines, and sulfamethoxazole/trimethoprim.

CONTRAINDICATIONS

History of hypersensitivity to moxifloxacin or other quinolone antibiotics (e.g., ciprofloxacin [Cipro], levofloxacin [Levaquin], norfloxacin [Noroxin]).

PRECAUTIONS

For IV use only. ■ C/S studies indicated to determine susceptibility of the causative organism to moxifloxacin. ■ Prolonged use may cause superinfection because of overgrowth of nonsusceptible organisms. ■ Cross-resistance has been observed between moxifloxacin and other fluoroquinolones against gram-negative bacteria. However, gram-positive bacteria resistant to other fluoroquinolones may still be susceptible to moxifloxacin. Observed emergence of bacterial resistance to fluoroquinolones and the occurrence of cross-resistance with other fluoroquinolones are of concern. Proper use of fluoroquinolones and other classes of antibiotics is encouraged to avoid the emergence of resistant bacteria from overuse. ■ Prolongation of the QTc interval on ECG has been reported with moxifloxacin. Infrequent cases of arrhythmia (including torsades de pointes) have been reported with the use of other fluoroquinolones. The risk of arrhythmia may be reduced by avoiding quinolone use in patients with known prolongation of the QTc interval and in the presence of hypokalemia, significant bradycardia, acute myocardial ischemia, or concurrent treatment with class IA antiarrhythmic agents (e.g., quinidine [Quinidex], procainamide [Procanbid, Procan SR]) or class III antiarrhythmic agents (e.g., amiodarone [Nexterone], sotalol [Betapace]); see [Rate of Administration](#). ■ Use with caution in patients receiving drugs that prolong the QTc interval (e.g., antipsychotics, cisapride [Propulsid], erythromycin, and tricyclic antidepressants). ■ Use caution in patients with mild, moderate, or severe hepatic insufficiency; associated metabolic disturbances may lead to QT prolongation. ■ Use with caution in patients with known or suspected CNS disorders, such as severe cerebral atherosclerosis, epilepsy, or other factors that may predispose to seizures. Convulsions, increased intracranial pressure (including pseudotumor cerebri), psychosis, and CNS stimulation have been reported; see [Side Effects](#). CNS events, including agitation, anxiety, confusion, depression, dizziness, hallucinations, insomnia, nervousness, nightmares, paranoia, suicidal thoughts or acts, and tremors may be caused by fluoroquinolones, including moxifloxacin. ■ Tendinitis and tendon rupture that required surgical repair or resulted in prolonged disability have been reported in patients of all ages receiving quinolones. Most frequently involves the Achilles tendon but has also been reported with the shoulder, hand, biceps, thumb, and other tendon sites. ■ Tendinitis or tendon rupture may occur during or after fluoroquinolone therapy. Risk may be increased in patients over 60 years of age; in patients taking corticosteroids; in patients with heart, kidney, or lung transplants; with strenuous physical activity; and in patients with renal failure or previous tendon disorders such as rheumatoid arthritis. ■ Fluoroquinolones have neuromuscular blocking activity and may exacerbate muscle weakness in persons with myasthenia gravis. Serious adverse events, including requirement for ventilatory support and deaths, have been reported in these patients. Avoid use in patients with a known history of myasthenia gravis. ■ Rare cases of peripheral neuropathy (e.g., paresthesias, hypoesthesias, dysesthesias [impairment of sensitivity or touch], or weakness) have been reported and may lead to an irreversible condition; see [Antidote](#). ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with moxifloxacin. ■ Other serious events (sometimes fatal) due to hypersensitivity or uncertain etiology have been reported with fluoroquinolones, including moxifloxacin; see [Side Effects](#), [Post-Marketing](#). Discontinue moxifloxacin at the first appearance of a skin rash, other signs of hypersensitivity, or jaundice. ■ Moderate to severe photosensitivity/phototoxicity reactions have been reported in patients receiving quinolones; see [Patient Education](#). ■ See [Monitor](#).

Monitor: Serious and occasionally fatal hypersensitivity reactions have been reported in patients receiving quinolone therapy. May be seen with first or subsequent doses. Emergency equipment must be readily available; see [Side Effects](#). Watch for early symptoms of a hypersensitivity reaction. ■ Monitor for S/S of peripheral neuropathy. Discontinue

moxifloxacin at first symptoms of neuropathy (e.g., pain, burning, tingling, numbness and/or weakness) or if patient has deficits in light touch, pain, temperature, position sense, vibratory sensation, and/or motor strength. ■ Obtain baseline and periodic CBC with differential. ■ ECG monitoring for QT prolongation may be indicated in select patients. ■ Maintain adequate hydration to prevent concentrated urine throughout treatment. Other quinolones have formed crystals. ■ See [Precautions](#), [Drug/Lab Interactions](#), and [Antidote](#). **Patient Education:** A patient medication guide is available from the manufacturer. ■ Drink fluids liberally. ■ Inform physician of any history of myasthenia gravis. ■ Patients with a history of myasthenia gravis should avoid use of moxifloxacin. ■ Report skin rash or any other hypersensitivity reaction promptly. ■ Dizziness or light-headedness may interfere with ambulation or motor coordination. Use caution in tasks that require alertness. ■ Discontinue moxifloxacin and promptly report CNS side effects such as confusion, depression, dizziness, hallucinations, seizures, suicidal thoughts, tremors, or vision loss. ■ Report tendon pain or inflammation promptly; rest and refrain from exercise. ■ Promptly report burning, numbness, pain, tingling, or weakness in extremities. ■ May produce changes in ECG. Report fainting spells or palpitations promptly. ■ Review medicines and disease states with physician or pharmacist before initiating therapy. ■ Photosensitivity has occurred in patients receiving other quinolones and, infrequently, moxifloxacin. It is best to avoid excessive sunlight or artificial ultraviolet light. May cause severe sunburn; wear protective clothing, use sunscreen, and wear dark glasses outdoors. Report a sunburn-like reaction or skin eruption promptly. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ See [Precautions](#), [Monitor](#), [Drug/Lab Interactions](#), and [Antidote](#).

Maternal/Child: Category C: safety for use in pregnancy not established. Benefit must outweigh risk to fetus. ■ Has potential for harmful effects on breast-feeding infants; either discontinue breast-feeding or choose an alternate drug. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established. ■ Quinolones have caused erosion of cartilage in weight-bearing joints and other signs of arthropathy in juvenile animals; however, they have been used in infants and children to treat serious infections unresponsive to other antibiotic regimens.

Elderly: Safety and effectiveness similar to that of younger adults; however, they may experience an increased risk of side effects (e.g., CNS effects, tendinitis, tendon rupture, risk of QT prolongation). ■ See [Precautions](#).

DRUG/LAB INTERACTIONS

May cause ventricular arrhythmias or torsades de pointes with **drugs that prolong the QT interval**; avoid concurrent administration with Class IA and Class III antiarrhythmics; see [Precautions](#). ■ Risk of CNS stimulation and seizures may be increased with concurrent use of **NSAIDs** (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]). ■ Not metabolized by the cytochrome P₄₅₀ isoenzyme system. Drug-drug interactions with atenolol (Tenormin), digoxin, glyburide (DiaBeta), itraconazole (Sporanox), oral contraceptives, theophylline, and warfarin have not been observed. ■ Does not inhibit the P₄₅₀ isoenzyme system. Drugs metabolized by this system (e.g., cyclosporine [Sandimmune], midazolam [Versed], theophylline, or warfarin [Coumadin]) are not affected by coadministration of moxifloxacin. ■ Digoxin, itraconazole, morphine, probenecid, ranitidine (Zantac), theophylline, and warfarin (Coumadin) have been shown not to alter the pharmacokinetics of moxifloxacin; dose adjustments are not indicated. ■ Some quinolones, including moxifloxacin, may enhance the effects of **warfarin** (Coumadin); monitoring of PT or INR is recommended with concomitant use. ■ See literature for additional drug/drug interactions on transfer to oral moxifloxacin. ■ May cause a false-positive when **testing urine for opiates**; more specific testing methods may be indicated.

SIDE EFFECTS

Diarrhea, dizziness, headache, and nausea were most common and described as mild to moderate in severity. Capable of numerous other reactions in fewer than 1% of patients.

Major: Cardiovascular effects (e.g., cardiac arrest, palpitations, QT interval prolongation, tachycardia, torsades de pointes, vasodilation, ventricular tachyarrhythmias); CDAD; CNS stimulation (e.g., anxiety, confusion, depression, hallucinations, insomnia, nightmares, paranoia, restlessness, seizures, suicidal thoughts, tremor); hepatic failure; hepatitis and jaundice (predominantly cholestatic); hyperglycemia; hypersensitivity reactions (e.g., anaphylaxis, cardiovascular collapse, death, dyspnea, edema [facial, laryngeal, or pharyngeal], hypotension, itching, rash, shock, urticaria); hypotension; increased bilirubin; increased intracranial pressure; pain, inflammation, and ruptures of the shoulder, hand, and Achilles tendon; peripheral neuropathy (e.g., pain, burning, tingling, numbness and/or weakness [see **Precautions, Monitor**]); photosensitivity/phototoxicity; prolonged PT and INR; Stevens-Johnson syndrome; syncope; and toxic psychoses; see **Precautions**.
Post-Marketing: Allergic pneumonitis; arthralgia; exacerbation of myasthenia gravis; hearing impairment, including deafness (reversible in most); hematologic abnormalities (agranulocytosis, anemia [hemolytic and aplastic], leukopenia, pancytopenia, thrombocytopenia, thrombotic thrombocytopenic purpura); interstitial nephritis; jaundice; liver abnormalities (e.g., acute hepatic necrosis or failure, hepatitis, jaundice); muscle weakness; myalgia; peripheral neuropathy; polyneuropathy; rash; serum sickness; severe dermatologic reactions (e.g., toxic epidermal necrolysis [Lyell's syndrome], Stevens-Johnson syndrome); suicidal ideation/thoughts; vasculitis; vision loss (transient in most cases).

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically or will resolve with continued dosing (e.g., dizziness, light-headedness); monitor closely. Discontinue at first sign of hypersensitivity (e.g., skin rash), CDAD, CNS symptoms, dermatologic reactions, hypoglycemic reactions, phototoxicity, symptoms of neuropathy, or tendon rupture. Treat allergic reactions as indicated with epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., Solu-Cortef), and pressor amines (e.g., dopamine). Treat CNS symptoms as indicated; may require anticonvulsants (e.g., phenytoin [Dilantin], diazepam [Valium]) for seizures and discontinuation of moxifloxacin. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Complete rest is indicated for an affected tendon until treatment is available. Discontinue if photosensitivity occurs. Monitoring of the ECG and adequate hydration are indicated in overdose. No specific antidote. Less than 10% of moxifloxacin and its glucuronide metabolite are removed by CAPD or hemodialysis.

MULTIVITAMIN INFUSION

(mul-ti-**VI**-tah-min in-**FU**-zhun)

Nutritional supplement
(vitamin)

Infuvite Adult, Infuvite Pediatric, M.V.I.-12, M.V.I. Adult, M.V.I. Pediatric

USUAL DOSE

Multiples of the daily dose may be given for 2 or more days in patients (adult and pediatric patients) with multiple vitamin deficiencies or markedly increased requirements. Individual components may be indicated in specific or long-standing deficiencies. Monitor blood vitamin concentrations to ensure maintenance of adequate levels. Formulations differ in the amount of each vitamin supplied and in their content (some contain vitamin K [e.g., *M.V.I. Adult and Pediatric, Infuvite (Adult and Pediatric)*], and others do not [e.g., *M.V.I.-12*]); see [Drug/Lab Interactions](#).

All adult formulations: One 5- to 10-mL dose every 24 hours.

PEDIATRIC DOSE

See [Maternal/Child](#).

INFUVITE PEDIATRIC

Supplemental vitamin A may be required for low-birth-weight infants.

Less than 1 kg: 30% of the contents of vial 1 and vial 2 (1.2 mL of vial 1 and 0.3 mL of vial 2).

1 to 3 kg: 65% of the contents of vial 1 and vial 2 (2.6 mL of vial 1 and 0.65 mL of vial 2).

Over 3 kg to 11 years of age: Entire contents of vial 1 (4 mL) and entire contents of vial 2 (1 mL).

M.V.I. PEDIATRIC

Less than 1 kg: 1.5 mL/24 hr.

1 to 3 kg: 3.25 mL/24 hr.

Over 3 kg to 11 years of age: 5 mL/24 hr.

DILUTION

Various preparations. Most may be reconstituted with 5 mL of SWFI or supplied diluent. All preparations must be further diluted in at least 500 mL but preferably 1,000 mL of IV fluids. Soluble in commonly used infusion fluids, including dextrose, saline, electrolyte replacement fluids, plasma, and selected protein amino acid products. Do not use if any crystals have formed. When reconstituted as directed, *Infuvite Adult* contains no more than 70 mcg/L of aluminum. *M.V.I.-12* also contains aluminum.

Pediatric dilution: *Infuvite Pediatric* and *M.V.I. Pediatric*: Each dose should be added to at least 100 mL of dextrose, saline, or other **compatible** infusion solution. When reconstituted as directed, *M.V.I. Pediatric* contains no more than 42 mcg/L of aluminum, and *Infuvite Pediatric* contains no more than 30 mcg/L of aluminum; see [Precautions](#). See [Maternal/Child](#).

Storage: Before use, refrigerate at 2° to 8° C (36° to 46° F) protected from light. Manufacturers recommend immediate use of fully diluted Infuvite Pediatric and M.V.I. Adult and Pediatric. Fully diluted M.V.I.-12 and Infuvite Adult should be refrigerated and used within 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Compatibility may vary with preparation; consult prescribing information for specifics of a preparation. Direct addition to IV fat emulsions is not recommended. Some manufacturers suggest that admixture or **Y-site** administration with vitamin solutions should be avoided. Alkaline or moderately alkaline solutions (e.g., acetazolamide [Diamox], aminophylline, chlorothiazide [Diuril], sodium bicarbonate), as well as ampicillin and tetra-

cycline, are listed as **incompatible** by one manufacturer. Folic acid may be unstable with calcium salts. **All formulations must be diluted in infusion solutions.**

One source suggests the following **compatibilities**:

Additive: Cefoxitin (Mefoxin), isoproterenol (Isuprel), methyl dopate, metoclopramide (Reglan), norepinephrine (Levophed), sodium bicarbonate, verapamil.

Y-site: **All formulations must be diluted in infusion solutions before administration at the Y-site.** Acyclovir (Zovirax), ampicillin, cefazolin (Ancef), ceftazoline (Teflaro), clindamycin (Cleocin), diltiazem (Cardizem), erythromycin (Erythrocin), fludarabine (Fludara), gentamicin, 6% hydroxyethyl starch (Voluven), tacrolimus (Prograf).

RATE OF ADMINISTRATION

A single dose given as an infusion at prescribed rate of infusion fluids.

ACTIONS

A multiple vitamin solution containing fat-soluble and water-soluble vitamins in an aqueous solution. Provides B complex and vitamins A, D, and E. Some multivitamin preparations presently available do not contain vitamin K. **Infuvite Adult, M.V.I. Adult, Infuvite Pediatric, and M.V.I. Pediatric** do contain vitamin K. Provides daily requirements or corrects an existing deficiency.

INDICATIONS AND USES

A daily multivitamin maintenance supplement for patients receiving parenteral nutrition. Provides the necessary vitamins required to maintain the body's normal resistance and repair processes. Used in situations such as surgery, trauma, burns, severe infectious disease, and comatose states which may provoke a stress response and alteration in the body's metabolic demands. Used when oral administration is contraindicated, not possible, or insufficient. Solutions without vitamin K are indicated for patients on warfarin anticoagulant therapy who are receiving parenteral nutrition.

CONTRAINDICATIONS

Known hypersensitivity to thiamine hydrochloride or other product components; pre-existing hypervitaminosis. ■ Contraindicated prior to blood sampling for detection of megaloblastic anemia. Folic acid and cyanocobalamin in formulation may mask serum deficits.

PRECAUTIONS

Do not wait for the development of clinical signs of vitamin deficiency before initiating vitamin therapy. ■ Hypersensitivity reactions have occurred following IV administration of multivitamin solutions containing vitamin B₁ (thiamine) and vitamin K. ■ Hypervitaminosis A manifested by blurred vision, dizziness, headache, and nausea and vomiting has been reported in patients with renal failure or liver disease who are receiving vitamin A supplementation. Use caution. ■ Vitamin A may adhere to plastic, resulting in inadequate vitamin A administration in the doses recommended; see **Maternal/Child**. ■ Elevated blood levels of vitamin E may result if doses larger than recommended or oral or parenteral vitamin E are administered. ■ Solutions containing multivitamins may contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. ■ Blood draws for the detection of folic acid and cyanocobalamin deficiencies are indicated before administration to patients with megaloblastic anemia. ■ See **Drug/Lab Interactions**.

Monitor: Monitor VS. ■ Monitor for any symptoms of a hypersensitivity reaction. ■ Moderate increase in ALT may occur in patients with active inflammatory enterocolitis. Usually reversible following discontinuation of vitamin infusion. Monitoring of ALT levels suggested. ■ Monitor vitamin A levels in patients with liver disease and/or high alcohol consumption. ■ Monitor renal function, calcium, phosphorous, and vitamin A levels in patients with impaired renal function. ■ Measure blood vitamin concentrations periodically in patients receiving parenteral nutrition to determine if vitamin deficiencies or

excesses are developing. Blood levels of A, C, D, and folic acid may decline in patients receiving parenteral multivitamins as their sole source of vitamins for 4 to 6 months. ■ See [Precautions](#), [Maternal/Child](#), and [Drug/Lab Interactions](#).

Maternal/Child: Recommendations for use during pregnancy vary by product. Range is from vitamin needs may exceed those of nonpregnant women to Category C: safety for use in pregnancy not established; use only if clearly needed. ■ Recommendations for use during breast-feeding vary by product. Range is from vitamin needs may exceed those of nonpregnant women to not known if secreted in breast milk; use caution if required during breast-feeding. ■ Vitamin A may adhere to plastic resulting in inadequate vitamin A administration in the doses recommended. Additional vitamin A supplementation may be necessary, especially in low-birth-weight infants. ■ Polysorbates (a component of some multivitamins) have been associated with E-Ferol syndrome (ascites, cholestasis, hepatomegaly, hypotension, metabolic acidosis, renal dysfunction, and thrombocytopenia) in low-birth-weight infants; however, this has not been reported with the use of pediatric multivitamins. ■ See [Precautions](#).

Elderly: Consider age-related decreased organ function and/or medical problems.

DRUG/LAB INTERACTIONS

Folic acid may lower serum concentration of **phenytoin**, resulting in increased seizure frequency; monitor serum levels of both drugs. ■ **Phenytoin** may decrease serum folic acid concentrations; avoid during pregnancy. ■ Folic acid may obscure pernicious anemia and may decrease the patient's response to **methotrexate** therapy. ■ Pyridoxine may reduce effectiveness of **levodopa**. ■ Concomitant administration of **hydralazine** or **isoniazid** (INH) may increase pyridoxine requirements. ■ Vitamin K may antagonize the anti-coagulant effects of **warfarin** (Coumadin) and reduce its effectiveness; monitor INR/PT. ■ The hematologic response to vitamin B₁₂ therapy in patients with pernicious anemia may be inhibited by concomitant administration of **chloramphenicol**. ■ Thiamine, riboflavin, pyridoxine, niacinamide, and ascorbic acid may decrease the antibiotic activity of **erythromycin**, **kanamycin**, **streptomycin**, **doxycycline**, and **lincomycin**. ■ **Bleomycin** is inactivated in vitro by ascorbic acid and riboflavin. ■ Ascorbic acid in the urine may cause **false-negative urine glucose** determinations.

SIDE EFFECTS

Rare when administered as recommended: Agitation; allergic reactions including anaphylaxis, angioedema, periorbital and digital edema, shortness of breath, urticaria, and wheezing; anxiety; diplopia; dizziness; erythema; fainting; headache; pruritus; rash. Vitamin A and vitamin D hypervitaminosis (symptomatology related to hypercalcemia) may occur with prolonged use of significant doses.

ANTIDOTE

With onset of any side effect, discontinue administration immediately and notify physician. Treat anaphylaxis or resuscitate as necessary.

MUROMONAB-CD3 **BBW**

(myour-oh-MON-ab)

Monoclonal antibody
Immunosuppressant

Orthoclone, OKT3

pH 6.5 to 7.5

USUAL DOSE

Do not give initial or subsequent doses unless patient temperature is less than 37.8° C (100° F). Administration of IV methylprednisolone sodium succinate 8 mg/kg of body weight 1 to 4 hours before muromonab-CD3 is recommended to reduce the side effects of cytokine release syndrome (CRS) associated with the first two to three doses. Acetaminophen and antihistamines may also be used concomitantly. See [Monitor](#).

Renal allograft rejection: 5 mg/24 hr for 10 to 14 days. Initiate on diagnosis of acute renal rejection.

Cardiac/hepatic allograft rejections: 5 mg/24 hr for 10 to 14 days if rejection has not been reversed by corticosteroid therapy.

PEDIATRIC DOSE

Initiate on diagnosis of acute renal rejection. Initiate in cardiac/hepatic allograft rejections if rejection has not been reversed by corticosteroid therapy. See comments under [Usual Dose](#) for patient temperature and premedication requirements. See [Dose Adjustments](#) and [Maternal/Child](#).

Pediatric patients 1 month to 16 years of age:

Weight 30 kg or less: 2.5 mg/day for 10 to 14 days.

Weight more than 30 kg: 5 mg/day for 10 to 14 days.

Another source recommends:

Less than 12 years of age: 0.1 mg/kg/day.

12 years of age or older: See [adult dose](#).

DOSE ADJUSTMENTS

Adults and pediatric patients: Doses of concomitant immunosuppressive therapy must be reduced to the lowest level compatible with a therapeutic response during muromonab-CD3 therapy. Resume maintenance doses 3 days before completion of muromonab-CD3 therapy.

Pediatric patients: Pediatric patients have higher CD3 lymphocyte counts than adults. Daily increases in 2.5-mg increments may be required to achieve depletion of CD3-positive cells (less than 25 cells/mm³) and to ensure therapeutic serum concentrations (greater than 800 ng/mL).

DILUTION

May be given undiluted. Must be withdrawn from vial through a low-protein binding 0.2- or 0.22-micron filter. Discard filter and attach needle for direct IV administration. Do not shake.

Filters: Use of a low-protein binding, 0.2- or 0.22-micron filter is recommended to withdraw from vial; see [Dilution](#).

Storage: Keep unopened ampules under refrigeration. May have some fine translucent particles. Will not affect potency, and use of filter will clear. Do not freeze or shake.

COMPATIBILITY

Until specific data are available, the manufacturer states, "Other IV medications/substances should not be added or infused simultaneously through the same IV line," and recommends flushing line with NS before and after administration of muromonab-CD3 and/or any other drug through the same IV line. Also states, "Do not give by IV infusion or in conjunction with other drug solutions."

RATE OF ADMINISTRATION

A single dose as an IV bolus in less than 1 minute.

ACTIONS

A murine monoclonal antibody to the T3 (CD3) antigen of human T-cells. An immunosuppressive agent that reverses graft rejection by blocking all known T-cell functions. Binds to and blocks the function of CD3 in the membrane of the T-cells. Results in early activation of T-cells, which leads to cytokine release and, later, to blocking of T-cell functions. The released cytokines/lymphokines are believed to be responsible for many of the acute clinical manifestations seen following muromonab-CD3 administration. Reacts with most peripheral blood T-cells and T-cells in some body tissues but has not been found to react with other hematopoietic elements or other tissues of the body. Onset of action is within minutes. CD3-positive cells reappear within several days and reach pre-treatment levels in 1 week after daily injections are stopped.

INDICATIONS AND USES

Treatment of acute allograft rejection in renal transplant patients. ■ Treatment of acute rejection in heart and liver transplant patients resistant to standard steroid therapy.

Unlabeled uses: Prophylaxis of cardiac and renal transplant rejection. ■ Treatment of rejection of lung or pancreas transplant.

CONTRAINDICATIONS

Hypersensitivity to muromonab-CD3 or any product of murine origin; anti-mouse antibody titer equal to or greater than 1:1,000; patients in uncompensated heart failure or fluid overload as evidenced by chest x-ray or greater than 3% weight gain within the week before treatment; history of seizures or patients who may be predisposed to seizures; uncontrolled hypertension; pregnancy and breast-feeding.

PRECAUTIONS

Usually administered in the hospital by or under the direction of a physician experienced in immunosuppressive therapy and management of organ transplant patients. Adequate laboratory and supportive medical resources, including airway management, emergency drugs, and equipment, must be available.

■ Serious and occasionally fatal immediate (usually within 10 minutes) hypersensitivity (anaphylactic) reactions have been reported. S/S may include airway obstruction, angioedema (including facial, laryngeal, or pharyngeal edema), bronchospasm, cardiorespiratory arrest, cardiovascular collapse, dyspnea, hypotension/shock, loss of consciousness, tachycardia, tingling, urticaria, and pruritus. ■ Serious, occasionally life-threatening or lethal, systemic, cardiovascular, and CNS reactions have been reported, including blindness, cardiac or respiratory arrest, cardiac collapse, coma, cerebral edema, cerebral herniation, coma, paralysis, pulmonary edema (especially in patients with volume overload), seizures, and shock. ■ A protein substance that induces antibodies; use extreme caution if a second course of therapy is needed. Serious hypersensitivity events, including anaphylactic reactions, have been reported in patients re-exposed to muromonab-CD3 after their initial course of therapy. In this setting, pretreatment with steroids and/or antihistamines may not be effective in preventing anaphylaxis. Weigh benefits versus risk. ■ Most patients develop an acute clinical syndrome called cytokine release syndrome (CRS), which is temporarily associated with the first few doses of muromonab-CD3. CRS typically begins 30 to 60 minutes after administration and may persist for several hours. May range from a mild, flu-like illness to a severe, life-threatening, shock-like reaction that may include serious cardiovascular and CNS manifestations. Common clinical manifestations may include abdominal pain, arthralgia/myalgia, chills/rigors, fever (high), headache, and tremor. Cardiorespiratory findings may include angina, apnea, ARDS, arrhythmias, bronchospasm, cardiac arrest, cardiovascular collapse, heart failure, hemodynamic instability, hypertension, hypotension, hypoxemia, MI, pulmonary edema, respiratory distress/arrest/failure, SOB, tachycardia, and tachypnea. ■ Patients with pre-existing cardiovascular disease, cerebrovascular disease, a history of seizures, pulmonary disease, or intravascular volume overload or depletion of any etiology are at risk for more serious complications of CRS. Correct or stabilize background conditions before initiating therapy. ■ Acute and transient declines in GFR and diminished urine output have occurred. ■ Immunosuppression may increase the risk of lymphomas, skin cancers, or lymphoproliferative disorders. ■ Also increases the risk of serious infections, including bacterial, viral (CMV, HSV, EBV), and other opportunistic infections. ■ Neuropsychiat-

ric events, including seizures, encephalopathy, cerebral edema, aseptic meningitis, and headache have been reported. Patients at increased risk for CNS adverse events include those with known or suspected CNS disorders (e.g., seizures), cardiovascular disease (small or large vessel), conditions with associated neurologic problems (e.g., head trauma), or underlying vascular disease, or patients who are receiving a medication that may affect the CNS. ■ Arterial, venous, and capillary thromboses of allografts and other vascular beds (e.g., heart, lungs, brain, bowel) have been reported. Patients with a history of thrombosis or vascular disease may be at increased risk; consider benefits versus risk.

Monitor: To reduce the incidence of serious side effects, evaluate patients for fluid overload. Monitor fluid status carefully during administration. Must have a clear chest x-ray within 24 hours and have gained no more than 3% above minimal weight present 7 days before injection. ■ Monitor WBC count and differential, circulating T-cells as CD3 antigen, and 24-hour trough values of muromonab-CD3 (rise rapidly for the first 3 days of treatment and then average 0.9 mcg/mL thereafter during treatment). ■ Monitor renal and hepatic function. ■ Testing for human-mouse antibody titers is strongly recommended; see **Contraindications**. ■ Monitor for S/S of anaphylaxis/hypersensitivity and CRS; see **Precautions**. ■ Anaphylaxis may occur immediately. ■ May be difficult to distinguish between CRS and anaphylaxis. If hypersensitivity is suspected, do not reexpose patient to muromonab-CD3. ■ Monitor for S/S of CNS side effects such as aseptic meningitis, manifestations of encephalopathy, or seizures. ■ Increased susceptibility to infection; observe closely. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Treat any fever over 37.8° C (100° F) with antipyretics to lower before giving any single dose. ■ See **Dose Adjustments**.

Patient Education: Side effects from first few doses are expected. Incidence lessens with subsequent doses. ■ Avoid pregnancy; consider birth control options. ■ See Appendix D, p. 1255. ■ Review potentially serious symptoms of CRS. ■ Report difficulty in breathing, swallowing, rapid heartbeat, rash, or itching immediately. ■ Use caution performing tasks that require mental alertness.

Maternal/Child: Category C: safety for use in pregnancy and men and women capable of conception not established. Use only when absolutely necessary. ■ Discontinue breastfeeding. ■ Response in pediatric patients with renal or hepatic transplants is similar to adults. Data insufficient to compare results in cardiac transplants. ■ Pediatric patients may be at increased risk for cerebral edema with or without herniation and thrombosis.

DRUG/LAB INTERACTIONS

Do not administer **live virus vaccines** to patients receiving immunosuppressive drugs. ■ **Immunosuppressive agents** (e.g., azathioprine, cyclophosphamide, corticosteroids, cyclosporine) increase the risk of infection and development of lymphoproliferative disorders. Use reduced doses with caution.

SIDE EFFECTS

Cytokine release syndrome (chills, dyspnea, fever, and malaise) is very common with early doses and can progress to shock; incidence lessens with subsequent doses. Abnormal chest sounds, anaphylaxis, arthralgia, asthenia, chest pain, diarrhea, dyspnea, edema, fever (high), headache, hypertension, hypotension, infections (e.g., cytomegalovirus, Epstein Barr, herpes simplex, *Staphylococcus epidermidis*, *Pneumocystis jiroveci*, *Legionella*, *Cryptococcus*, *Serratia*), lymphoproliferative disorders (including lymphomas), nausea, rash, rigors, serum sickness, severe pulmonary edema, tachycardia, tremors, vomiting, wheezing, and many others have occurred; see **Precautions**.

ANTIDOTE

Notify the physician of all side effects. Most can be treated symptomatically. Pretreat as indicated in Usual Dose to reduce side effects with early doses. Use antipyretics and antihistamines as indicated. Proper patient screening should reduce the incidence of pulmonary edema, anaphylaxis, or shock. Shock from CRS may require epinephrine, O₂, IV fluids, corticosteroids, pressor amines (e.g., dopamime [Intropin]), antihistamines (e.g., diphenhydramine [Benadryl]), and intubation. Drug may be decreased or discontinued or other immunosuppressive agents utilized. Resuscitate as necessary.

MYCOPHENOLATE MOFETIL HYDROCHLORIDE **BBW**

Immunosuppressant

(my-koh-FEN-oh-layt MAH-fuh-teel hy-droh-KLOR-eyed)

CellCept Intravenous

pH 2.4 to 4.1

USUAL DOSE

Used in combination with cyclosporine (Sandimmune) and corticosteroids. Oral form should be used as soon as tolerated by the patient. Initial dose should be given within 24 hours of transplantation. The IV preparation may be used for up to 14 days.

Kidney or liver transplant: 1 Gm as an infusion twice daily (total daily dose of 2 Gm).

Heart transplant: 1.5 Gm as an infusion twice daily (total daily dose of 3 Gm).

PEDIATRIC DOSE

Limited data available; see [Indications](#) and product insert. Safety and efficacy of IV formulation not established. Usually given orally.

DOSE ADJUSTMENTS

No dose adjustments are indicated in renal transplant patients who experience delayed graft function postoperatively. ■ Avoid doses greater than 1 Gm twice a day in renal transplant patients with severe chronic renal impairments (GFR less than 25 mL/min/1.73 M²) outside the immediate posttransplant period. ■ Data not available for cardiac or hepatic transplant patients with severe chronic renal impairment; potential benefits must outweigh risks. ■ Reduce dose or interrupt the dosing cycle if neutropenia (ANC less than 1.3×10^3 [1,300 cells/mm³]) occurs. ■ Dose adjustment not indicated in impaired liver function. ■ See [Precautions/Monitor](#).

DILUTION

Specific techniques required; see [Precautions](#). Use caution in handling and preparation. Avoid skin contact with the solution. If skin contact occurs, wash thoroughly with soap and water; rinse eyes with plain water.

Reconstitute each 500-mg vial with 14 mL of D5W (500 mg/15 mL). Shake gently to dissolve. Discard if particulate matter or discoloration is observed or if a lack of vacuum in vial is noted when diluent is added. To achieve a final concentration of 6 mg/mL, each 500 mg must be further diluted with 70 mL of D5W (1 Gm with 140 mL; 1.5 Gm with 210 mL).

Filters: Not required by manufacturer; however, no significant loss of potency is expected with the use of a filter.

Storage: Store powder and reconstituted or diluted solutions at 15° to 30° C (59° to 86° F). Most desired storage temperature is 25° C (77° F). Reconstituted or diluted solutions are best used immediately after preparation. Keep reconstituted or diluted solutions at CRT; the infusion must begin within 4 hours of reconstitution/dilution.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Mycophenolate is **incompatible** with other IV solutions and should not be mixed or administered concurrently via the same infusion catheter with other intravenous drugs or infusion admixtures."

One source lists the following **compatibilities**:

Y-site: Anidulafungin (Eraxis), casprofungin (Cancidas), cefepime (Maxipime), dopamine, norepinephrine (Levophed), tacrolimus (Prograf), vancomycin.

RATE OF ADMINISTRATION

A single dose must be given as an infusion over a minimum of 2 hours. **Do Not** administer by rapid or bolus IV injection.

ACTIONS

A hydrochloride salt of mycophenolate mofetil. A potent immunosuppressive agent, inhibiting proliferation of both B- and T-lymphocytes. Has been shown to prolong the survival of allogeneic transplants (kidney, heart, liver, intestine, limb, small bowel, pancreatic islets, and bone marrow) and to reverse ongoing acute rejection episodes in animal models. Rapidly and completely metabolized to MPA, its active metabolite. MPA is then metabolized predominantly to its inactive metabolite, MPAG. Secondary peak in plasma MPA concentration is usually noted 6 to 12 hours postdose. Enterohepatic recirculation is thought to contribute to MPA concentrations. Both MPA and MPAG are highly bound to albumin. In patients with renal impairment or delayed graft function, levels of MPAG may be elevated. Binding of MPA may then be reduced as a result of competition between MPAG and MPA. Plasma concentrations of metabolites are increased in patients with renal impairment. Half-life is 11.4 to 24.4 hours. Excreted primarily as MPAG in urine. Small amount excreted in feces. May cross the placental barrier. May be secreted in breast milk.

INDICATIONS AND USES

Used as part of an immunosuppressive regimen that includes cyclosporine and corticosteroids. ■ Prophylaxis of acute organ rejection in patients receiving allogeneic kidney, heart or liver transplants. ■ Capsules, tablets, and oral solution approved for prevention of rejection in pediatric renal transplant patients.

CONTRAINDICATIONS

Hypersensitivity to mycophenolate mofetil, mycophenolic acid, any component of the drug product, or polysorbate 80 (TWEEN).

PRECAUTIONS

For IV use only. ■ Use caution in handling and preparation. Avoid skin contact of the solution. If contact occurs, wash thoroughly with soap and water; rinse eyes with plain water. Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Usually administered by or under the direction of a physician experienced in immunosuppressive therapy and the management of organ transplant patients. Adequate laboratory and supportive medical resources must be available. ■ Use caution; hypersensitivity reactions have been observed; emergency equipment and drugs for treatment of severe hypersensitivity reactions must be immediately available. ■ Risk of developing lymphoproliferative diseases, lymphomas, and other malignancies, particularly of the skin, is increased. Appears to be related to the intensity and duration of immunosuppression rather than to any specific agent. ■ Oversuppression of the immune system can also increase susceptibility to infection, including opportunistic infections, sepsis, fatal infections, and activation of latent viral infections (e.g., progressive multifocal leukoencephalopathy [PML] and BK virus-associated nephropathy [BKVAN]). ■ **PML has been reported. PML is a serious progressive neurologic disorder caused by infection of the CNS by JC virus, a member of the papovavirus family. It typically occurs in immunocompromised patients. PML is rare but may result in irreversible neurologic deterioration and death, and there is no known effective treatment. Hemiparesis, apathy, confusion, cognitive deficiencies, and ataxia are the most commonly observed clinical signs.** ■ BKVAN has been reported. May lead to deterioration in renal function and renal graft loss. Reduction in immunosuppression may be indicated. ■ Pure red cell aplasia (PRCA) has been reported in patients receiving mycophenolate in combination with other immunosuppressive agents. May be reversible with dose reduction or discontinuation of mycophenolate. In transplant patients, reduced immunosuppression may place the graft at risk. ■ Has been associated with an increased incidence of GI adverse effects (e.g., GI tract ulceration, hemorrhage, and/or perforation). Use caution in patients with active serious digestive system disease. ■ Use with caution in patients with hepatic insufficiency. Metabolism of MPA may be affected by certain types of hepatic disease. ■ Use caution in patients with severe chronic renal impairment; see [Dose Adjustments](#). ■ Avoid use in patients with selected rare hereditary deficiency diseases (e.g., Lesch-Nyhan, Kelley-Seegmiller syndrome). ■ See [Monitor](#), [Patient Education](#), and [Maternal/Child](#).

Monitor: Obtain baseline CBC with differential before treatment. Repeat weekly during the first month, twice monthly for the second and third months, then monthly thereafter for the first year. ■ Monitor for neutropenia. Has been observed most frequently in the period from 31 to 180 days posttransplant. May be due to mycophenolate, concomitant medications, viral infections, or some combination of these causes. If neutropenia develops (ANC less than 1,300 cells/mm³), mycophenolate should be interrupted or the dose reduced. Appropriate diagnostic tests and treatment should be instituted. ■ Assess neurologic status frequently. ■ Monitor patients with severe chronic renal impairment and patients with delayed graft function closely. See [Dose Adjustments](#) and [Actions](#).

Patient Education: Read the manufacturer's medication guide before beginning treatment with mycophenolate. ■ In women of childbearing age, a negative pregnancy test is indicated within 1 week of starting mycophenolate; effective contraception must be used during therapy and for 6 weeks following cessation of therapy. Females with reproductive potential must be counseled regarding pregnancy prevention and planning. Females with reproductive potential include girls who have entered puberty and all women who have a uterus and have not passed through menopause (menopause must be confirmed). See manufacturer's prescribing information for acceptable contraceptive methods. Birth control pills alone may be ineffective. If a pregnancy occurs, do not stop mycophenolate; call your health care provider. See [Maternal/Child](#). ■ Promptly report any S/S of infection or bone marrow suppression (e.g., unexpected bruising, bleeding). May cause serious infections. ■ May increase risk of lymphoproliferative disease and some other malignancies. ■ Although most vaccinations may be less effective, the manufacturer suggests that flu vaccinations may be of value. ■ Risk of skin cancer may be increased. Reduce exposure to sunlight and UV light. Wear protective clothing and use a sunscreen with a high protection factor. ■ Cooperation with repeated laboratory tests imperative. ■ Review medications with the physician responsible for mycophenolate therapy. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. Increased risk of first-trimester pregnancy loss and increased risk of congenital malformations, especially external ear and other facial abnormalities (including cleft lip and palate) and anomalies of the distal limbs, heart, esophagus, and kidney. See manufacturer's literature for details. A negative serum or urine pregnancy test with a sensitivity of at least 25 mIU/mL within 1 week of beginning therapy is indicated in all women of childbearing age. Repeat pregnancy test 8 to 10 days later and during routine follow-up visits. Contraception required before, during, and after use. See [Patient Education](#). Use during pregnancy only if benefit justifies risk; should pregnancy occur during treatment, discuss the desirability of continuing the pregnancy. Women using mycophenolate at any time during pregnancy are encouraged to enroll in the National Transplantation Pregnancy Registry. Patients considering pregnancy should discuss with their physician appropriate alternative immunosuppressants with less potential for embryo-fetal toxicity. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established; see [Indications](#).

Elderly: No specific recommendations. Consider age-related decreased organ function and/or additional medical problems and medications. May be at increased risk of adverse reactions. Observe carefully.

DRUG/LAB INTERACTIONS

Cyclosporine (Sandimmune) may decrease serum levels of MPA (mycophenolate). Monitor levels closely when cyclosporine is added or removed from a drug regimen containing mycophenolate. ■ Has been administered in combination with **antithymocyte globulin (ATGAM)**, **cyclosporine**, **corticosteroids**, and **muromonab-CD3** (Orthoclone). Safety for use with other agents has not been determined. ■ Manufacturer recommends not administering concomitantly with **azathioprine**. Both agents may cause bone marrow suppression and concomitant administration has not been studied. ■ Use caution with **drugs that interfere with enterohepatic recirculation or alter the intestinal flora** (e.g., cholestyramine [Questran]). ■ In impaired renal function, **acyclovir** (Zovirax) and/or **ganciclovir** (Cyto-

vene) and mycophenolate may compete for tubular secretion, further increasing the serum levels of each drug; monitor patients closely. ■ Coadministration with **probenicid** (Benemid) results in an increase in the AUC of MPAG and MPA. **Other agents that undergo renal tubular secretion** (e.g., acyclovir, ganciclovir) may also result in increased serum levels of mycophenolate. ■ MPA may slightly decrease protein binding of **phenytoin** (Dilantin) and **theophylline**, increasing the free fraction of these drugs; clinical significance unknown. ■ **Oral contraceptives and other hormonal contraceptives** (e.g., transdermal patch, vaginal ring, injection, and implant) may be less effective; use additional barrier contraceptive measures. ■ Not recommended for concurrent administration with a combination of **metronidazole** (Flagyl) and **norfloxacin** (Noroxin); may decrease mycophenolate levels. Interaction not observed when mycophenolate is administered with either antibiotic separately. ■ Not recommended for concurrent use with **rifampin** (Rifadin); may decrease mycophenolate levels. ■ Coadministration with **ciprofloxacin** (Cipro) or **amoxicillin/clavulanic acid** (Augmentin) may cause a reduction in median MPA trough concentrations. Clinical significance unknown. ■ Use caution when coadministered with **proton pump inhibitors** (e.g., lansoprazole [Prevacid], pantoprazole [Protonix]); effectiveness of mycophenolate may be reduced. ■ Do not use **live virus vaccines** in patients receiving mycophenolate; vaccinations may be less effective. See [Patient Education](#).

SIDE EFFECTS

Principal side effects include diarrhea, infection, leukopenia, phlebitis, thrombosis, and vomiting occur most frequently. Abdominal pain, acne, asthenia, back pain, bone marrow suppression (e.g., anemia, hypochromic anemia, leukocytosis, leukopenia, neutropenia, thrombocytopenia), chest pain, colitis, constipation, cough, dizziness, dyspepsia, dyspnea, edema, fever, GI hemorrhage (3%), headache, hematuria, hypercholesterolemia, hyperglycemia, hyperkalemia, hypertension, hypokalemia, hypomagnesemia, hypophosphatemia, infection (a higher frequency of opportunistic infections including TB and atypical mycobacterial infections [fatal infections occurred in less than 2% of patients]), insomnia, kidney tubular necrosis, nausea, oral moniliasis, pain, pancreatitis, peripheral edema, pharyngitis, progressive multifocal leukoencephalopathy, rash, severe neutropenia (2% to 3% of patients), tremor, and UTI may occur. In renal transplant patients, those receiving 2 Gm/day demonstrated an overall better safety profile than those receiving 3 Gm/day. In addition, arrhythmias, abnormal kidney function, accidental injury, bradycardia, ecchymosis, heart failure, hypotension, increased kidney and liver function tests, oliguria, pericardial effusion, tachycardia, and other side effects occurred in cardiac transplant patients.

Post-Marketing: BK virus–associated nephropathy and pure red cell aplasia. Embryo-fetal toxicity and increased incidence of first-trimester pregnancy loss.

ANTIDOTE

Notify the physician of all side effects. Most can be treated symptomatically. Drug may be decreased or discontinued or other immunosuppressive agents utilized. Some side effects (e.g., neutropenia) may require temporary reduction of dosage or withholding of treatment. Consider reducing the amount of immunosuppression in patients who develop PML, taking into account the risk this may represent to the graft. At clinically encountered concentrations, MPA and MPAG are not usually removed by hemodialysis. However, at high concentrations (greater than 100 mcg/mL) small amounts of MPAG are removed. MPA may be removed by bile and acid sequestrants such as cholestyramine (Questran).

NAFILLIN SODIUM

(naf-SILL-in SO-dee-um)

Antibacterial
(penicillinase-resistant penicillin)**Nallpen****pH 6 to 8.5****USUAL DOSE**

500 mg to 1 Gm every 4 hours. Up to 12 Gm in 24 hours has been used in severe infections. Continue therapy for at least 48 hours after patient is afebrile and asymptomatic and cultures are negative. Usual duration of therapy is at least 14 days for severe staphylococcal infections and longer (4 to 6 weeks) for endocarditis and osteomyelitis.

Endocarditis, meningitis, osteomyelitis, or pericarditis: 1.5 to 2 Gm every 4 to 6 hours.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established. All pediatric doses are unlabeled; see **Maternal/Child**. Limited clinical experience with IV route in neonates and infants. Maximum dose is 12 Gm/24 hr.

Pediatric patients less than 40 kg and over 1 month of age: Moderate infections: 50 to 100 mg/kg/24 hr in equally divided doses every 6 hours (12.5 to 25 mg/kg every 6 hours).

Serious infections (e.g., osteomyelitis, pericarditis, endocarditis): 100 to 200 mg/kg/24 hr in equally divided doses every 4 to 6 hours (16.6 to 33.3 mg/kg every 4 hours or 25 to 50 mg/kg every 6 hours).

NEONATAL DOSE

Safety and effectiveness for use in neonates not established. All pediatric doses are unlabeled; see **Maternal/Child**. Limited clinical experience with IV route in neonates and infants.

10 to 20 mg/kg every 8 to 12 hours, or 25 mg/kg with the interval adjusted based on age and weight as follows:

0 to 7 days of age and under 2,000 Gm: Every 12 hours.

Over 7 days of age and under 1,200 Gm: Every 12 hours.

Over 7 days of age and 1,200 to 2,000 Gm: Every 8 hours.

0 to 7 days of age and over 2,000 Gm: Every 8 hours.

Over 7 days of age and over 2,000 Gm: Every 6 hours.

Increase dose to 50 mg/kg every 6, 8, or 12 hours in meningitis.

DOSE ADJUSTMENTS

Dose adjustment not required for patients with renal dysfunction, including those receiving hemodialysis. ■ Measure nafcillin serum levels and adjust dose accordingly in patients with hepatic insufficiency and renal failure.

DILUTION

Each 500-mg vial is diluted with 1.7 mL of SWFI (1-Gm vial with 3.4 mL, 2-Gm vial with 6.8 mL). Each 1 mL equals 250 mg. Further dilute each dose with a minimum of 15 to 30 mL of SWFI, NS, or ½NS, or other **compatible** IV solutions (see chart on inside back cover or literature). Concentration should be 2 to 40 mg/mL. Available prediluted and in ADD-Vantage vials for use with ADD-Vantage infusion containers. May be given through Y-tube, three-way stopcock, or with additive tubing, or may be added to larger volume of **compatible** solutions.

Filters: Not required by manufacturer. Premixed and frozen solutions are filtered during manufacturing.

Storage: Store unopened vials at CRT. Refrigerate unused medication after initial dilution and discard after 7 days. Stable in specific solutions at concentrations of 2 to 40 mg/mL for 24 hours at room temperature and 96 hours if refrigerated. Frozen, premixed solutions should be stored at -20°C (-4°F). Thaw at room temperature or under refrigeration. Thawed solutions are stable for 72 hours at RT or 21 days refrigerated. Do not refreeze.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Inactivated in solution with aminoglycosides (e.g., amikacin [Amikin], gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

Additive: Aminophylline, chloramphenicol (Chloromycetin), chlorothiazide (Diuril), dexamethasone (Decadron), dextran 40, diphenhydramine (Benadryl), ephedrine sulfate, heparin, lidocaine, potassium chloride (KCl), prochlorperazine (Compazine), sodium bicarbonate, sodium lactate, verapamil.

Y-site: Acyclovir (Zovirax), atropine, cyclophosphamide (Cytosan), diazepam (Valium), diltiazem (Cardizem), enalaprilat (Vasotec IV), esmolol (Brevibloc), famotidine (Pepcid IV), fentanyl (Sublimaze), fluconazole (Diflucan), foscarnet (Foscavir), heparin, hydro-morphone (Dilaudid), magnesium sulfate, morphine, nicardipine (Cardene IV), propofol (Diprivan), theophylline, vancomycin, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

IV injection: Each 500 mg or fraction thereof properly diluted over 5 to 10 minutes.

Intermittent IV: Administration over 30 to 60 minutes may decrease incidence of thrombophlebitis.

Infusion: When diluted in large volumes of infusion fluids, give at rate prescribed.

ACTIONS

A semi-synthetic penicillinase-resistant penicillin, used for its bactericidal activity against gram-positive organisms, primarily penicillinase-producing staphylococci. Mode of action involves inhibition of bacterial cell wall biosynthesis. Highly resistant to inactivation by staphylococcal penicillinase. Readily distributes into most body fluids and tissues except spinal fluid. Binds to serum proteins, primarily albumin. Mainly eliminated by hepatic inactivation and excretion in bile; a small amount is excreted in urine. Half-life is 30 to 60 minutes. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of infections caused by penicillinase-producing staphylococci.

CONTRAINDICATIONS

Known hypersensitivity to any penicillin or cephalosporin (not absolute); see [Precautions](#). Prediluted solutions containing dextrose may be contraindicated with known allergies to corn products.

PRECAUTIONS

Sensitivity studies necessary to determine susceptibility of the causative organism to nafcillin. Nafcillin should not be used in infections caused by an organism susceptible to penicillin G or due to an organism other than a resistant staphylococcus. Modify antimicrobial treatment as indicated by C/S. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, nafcillin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Use with caution in patients with both impaired hepatic and renal function; elevated serum concentrations may cause neurotoxic reactions. See [Dose Adjustments](#). ■ Hypersensitivity reactions, including fatalities, have been reported in patients undergoing penicillin therapy; most likely to occur in patients with a history of penicillin hypersensitivity or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Avoid prolonged use of the drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with

nafcillin. ■ Manufacturer's premixed solutions contain dextrose; may be contraindicated in patients with an allergy to corn or corn products.

Monitor: Obtain baseline CBC with differential and monitor during treatment. Monitor urinalysis, SCr, BUN, ALT, and AST periodically, especially with prolonged treatment. ■ Watch for early symptoms of a hypersensitivity reaction, especially in individuals with a history of allergic problems. ■ May cause thrombophlebitis, especially in the elderly or with too-rapid injection. Limit IV treatment to 24 to 48 hours when possible. Change to oral therapy as soon as practical. ■ Electrolyte imbalance and cardiac irregularities from sodium content are possible. Contains up to 3.3 mEq sodium/Gm. May aggravate CHF. Observe for hypokalemia. ■ See **Drug/Lab Interactions**.

Patient Education: May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: use only if clearly needed. ■ Safety and effectiveness for use in pediatric patients not established, but it is used; see **Pediatric Dose**. ■ May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Elimination rate markedly reduced in neonates and infants due to immature hepatic and renal function.

Elderly: Response similar to that seen in younger adults. Consider age-related organ impairment and concomitant disease or drug therapy. ■ May be at increased risk for thrombophlebitis. ■ See **Precautions/Monitor** and **Dose Adjustments**.

DRUG/LAB INTERACTIONS

May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines), may interfere with bactericidal action. ■ Potentiated by **probenecid** (Benemid); toxicity may result. ■ Synergistic when used in combination with **aminoglycosides** (e.g., amikacin [Amikin], gentamicin). Synergism may be inconsistent; see **Compatibility**. ■ Concomitant use with **beta-adrenergic blockers** (e.g., propranolol) may interfere with the treatment of a hypersensitivity reaction to nafcillin. ■ Risk of bleeding with **anticoagulants** (e.g., heparin) is increased. ■ May decrease serum levels and effectiveness of **cyclosporine** (Sandimmune). ■ Inhibits effectiveness of **oral contraceptives**; breakthrough bleeding or pregnancy could result. ■ High doses (9 to 12 Gm daily) may decrease serum half-life of **warfarin** (Coumadin); monitor PT up to 30 days after nafcillin completed. ■ May reduce effectiveness of **nifedipine** (Procardia XL) by reducing its serum plasma levels. ■ May cause **false values in common lab tests**; see literature.

SIDE EFFECTS

Bleeding abnormalities, bone marrow suppression (e.g., agranulocytosis, neutropenia), diarrhea, hypersensitivity reactions (e.g., anaphylaxis, bronchospasm, pruritus, rash, serum sickness-like symptoms, urticaria [may be immediate or delayed]), local reactions (e.g., pain, phlebitis, thrombophlebitis, and occasionally skin sloughing with extravasation), nausea and vomiting, renal tubular damage, and interstitial nephritis have been reported. CDAD and hypersensitivity myocarditis (fever, eosinophilia, rash, sinus tachycardia, ST-T changes, and cardiomegaly) can occur. Higher-than-normal doses may cause neurologic adverse reactions, including convulsions, especially with concomitant impaired hepatic insufficiency and renal dysfunction.

ANTIDOTE

Notify physician immediately of any adverse symptoms. For severe symptoms discontinue the drug, treat hypersensitivity reaction (antihistamines, epinephrine, corticosteroids), and resuscitate as necessary. Hemodialysis or peritoneal dialysis is minimally effective in overdose. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Mild cases may respond to drug discontinuation alone.

NALBUPHINE HYDROCHLORIDE

(NAL-byoo-feen hy-droh-KLOR-eyed)

Narcotic analgesic
(agonist-antagonist)
Anesthesia adjunct

pH 3.5 to 3.7

USUAL DOSE

Pain control: 10 mg/70 kg. May repeat every 3 to 6 hours. In nontolerant patients, the recommended single maximum dose is 20 mg. Maximum total daily dose is 160 mg. Adjust dose and interval according to severity of pain, physical status of patient, and other medications administered concomitantly; see [Dose Adjustments](#).

Adjunct to balanced anesthesia: A loading dose of 300 mcg (0.3 mg) to 3 mg/kg over 10 to 15 minutes. Maintain desired level of balanced anesthesia with 250 to 500 mcg/kg (0.25 to 0.5 mg/kg) as required. Administered only under the direction of the anesthesiologist.

DOSE ADJUSTMENTS

In patients dependent on opioids, initiate a dose of nalbuphine at one-fourth the usual dose if their previous medication was a narcotic. Observe for symptoms of withdrawal. Increase to effective dose gradually. ■ Reduced dose may be required in the elderly or debilitated; in impaired liver or renal function; in patients with limited pulmonary reserve; and in the presence of other CNS depressants. ■ See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted.

Filters: No data available from manufacturer.

Storage: Store at CRT. Avoid freezing and/or prolonged exposure to light.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with nafcillin (Nallpen) and ketorolac (Toradol).

One source suggests the following **compatibilities**:

Solution: D5NS, D10W, LR, NS.

Y-site: Acyclovir (Zovirax), amifostine (Ethyol), aztreonam (Azactam), bivalirudin (Angiomax), cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), etoposide phosphate (Etopophos), fenoldopam (Corlopam), filgrastim (Neupogen), fludarabine (Fludara), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hextend), linezolid (Zyvox), melphalan (Alkeran), oxaliplatin (Eloxatin), paclitaxel (Taxol), propofol (Diprivan), remifentanyl (Ultiva), teniposide (Vumon), thiopeta, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Pain control: Each 10 mg or fraction thereof over 3 to 5 minutes. Frequently titrated according to symptom relief and respiratory rate.

Anesthesia adjunct: See [Usual Dose](#).

ACTIONS

A synthetic narcotic agonist-antagonist analgesic. Binds to kappa, mu, and delta receptors. Acts as an agonist at kappa receptors and as a partial antagonist at mu receptors. It equals morphine in analgesic effect. Does produce respiratory depression, but this does not increase markedly with increased doses. Onset of pain relief occurs within 2 to 3 minutes and lasts about 3 to 6 hours. Metabolized in the liver. Some excretion in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Relief of moderate to severe pain. ■ Preoperative and postoperative analgesia. ■ Surgical anesthesia supplement. ■ Obstetric analgesia during labor and delivery.

Unlabeled uses: 10 mg SC to reduce pruritus from epidural morphine.

CONTRAINDICATIONS

Hypersensitivity to nalbuphine or its components.

PRECAUTIONS

May precipitate withdrawal symptoms if stopped too quickly after prolonged use or if patient has been on opiates. ■ Use caution in patients with impaired respiration (e.g., from other medications, uremia, asthma, severe infection, cyanosis, or respiratory obstruction); see [Dose Adjustments](#). ■ Use caution in patients with myocardial infarction who have nausea and vomiting or compromised cardiac function; effect on heart not fully evaluated. ■ Use caution in ambulatory patients; see [Patient Education](#). ■ Use caution in patients with head injuries, intracranial lesions, or pre-existing increases in intracranial pressure. Nalbuphine may elevate CSF pressure and may produce effects that can obscure the clinical course of patients with head injuries (e.g., pupillary changes, sedation). ■ Use caution in patients with a history of drug abuse or emotional instability; close monitoring is required. ■ Use caution in the elderly and debilitated and in patients with renal or hepatic impairment; see [Dose Adjustments](#). ■ Use caution in patients about to undergo surgery of the biliary tract. Can cause spasm of the sphincter of Oddi. ■ Administration during labor has caused severe fetal bradycardia; naloxone (Narcan) may reverse effects; see [Maternal/Child](#). ■ Should be administered as a supplement to general anesthesia only by persons specifically trained in the use of IV anesthetics and in the management of the respiratory effects of potent opioids. ■ When used with anesthesia, a high incidence of bradycardia has been reported in patients who did not receive atropine preoperatively.

Monitor: Naloxone (Narcan), oxygen, and controlled respiratory equipment must be available. ■ Observe frequently; monitor vital signs. ■ Keep patient supine to minimize side effects; orthostatic hypotension and fainting may occur. Observe closely during ambulation. ■ Pain control usually more effective with routinely administered doses. Determine appropriate interval through clinical assessment ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid use of alcohol or other CNS depressants (e.g., antihistamines, diazepam [Valium]). ■ Request assistance for ambulation. ■ Use caution performing any task that requires alertness; may cause dizziness, euphoria, and sedation. ■ May be habit forming. Can cause withdrawal if stopped too quickly after prolonged use or if other opioids are used.

Maternal/Child: Category B: use during pregnancy (other than labor and delivery) only if benefits justify risks. Take appropriate measures (e.g., fetal monitoring) to detect and manage potential adverse effects to the fetus. ■ Safety for use during breast-feeding not established. ■ Fetal and neonatal bradycardia, respiratory depression at birth, apnea, cyanosis, and hypotonia have been reported. Maternal or neonatal administration of naloxone (Narcan) may reverse these effects. Fetal death has been reported when mothers received nalbuphine during labor and delivery. Use during labor and delivery only if clearly indicated and if benefit outweighs risk. Newborns should be monitored for respiratory depression, apnea, bradycardia, and arrhythmias if nalbuphine has been used. ■ Not recommended for pediatric patients under 18 years of age.

Elderly: May be more sensitive to effects (e.g., respiratory depression, constipation, dizziness, urinary retention). ■ Analgesia should be effective with lower doses. ■ Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

Potentiated by [cimetidine](#) (Tagamet), [phenothiazines](#) (e.g., chlorpromazine [Thorazine]), by **other CNS depressants** such as narcotic analgesics, general anesthetics, alcohol, anticholinergics, antihistamines, barbiturates, hypnotics, neuromuscular blocking agents (e.g., atracurium [Tracrium]), psychotropic agents, and sedatives. Reduced doses of both drugs may be indicated. ■ May decrease analgesic effects of **other narcotics**; avoid concurrent use. ■ Plasma **amylase and lipase** determinations may be unreliable for 24 hours following narcotic administration. ■ Depending on the test used, nalbuphine may interfere with enzymatic methods for the detection of **opiates**. Consult test manufacturer's literature.

SIDE EFFECTS

Abdominal pain, agitation, anaphylaxis, anxiety, blurred vision, bradycardia, clammy skin, dizziness, dry mouth, fever, headache, hypertension, hypotension, injection site reaction, nausea, psychotomimetic effect (symptoms resembling a psychosis), pulmonary edema, respiratory depression, sedation, seizures, symptoms associated with histamine release, tachycardia, tremor, urinary urgency, vertigo, vomiting.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. Naloxone hydrochloride (Narcan) will reverse severe reactions. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment (e.g., fluids, vasopressors) must be instituted promptly.

NALOXONE HYDROCHLORIDE

(nal-**OX**-ohn hy-droh-**KLOR**-eyed)

Antidote
Narcotic antagonist

pH 3 to 4

USUAL DOSE

Narcotic overdose: 0.4 to 2 mg. Repeat in 2 to 3 minutes if indicated. The diagnosis of narcotic overdose should be questioned if no response is observed after 10 mg of naloxone. If effective, dosage may be repeated as necessary for recurrence of symptoms.

Postoperative narcotic depression: 0.1 to 0.2 mg at 2- to 3-minute intervals to desired response. Titrate to avoid excessive reduction of narcotic analgesic action.

Challenge test for suspected opioid dependence: 0.2 mg. Observe for 30 seconds for S/S of withdrawal (e.g., abdominal cramps, diaphoresis, dysphoria, nausea and vomiting, rhinorrhea). If no evidence of withdrawal, inject 0.6 mg of naloxone and observe for an additional 20 minutes. Monitor VS and observe patient again for S/S of opiate withdrawal.

PEDIATRIC DOSE

Ampules containing 0.02 mg/mL are available, but larger doses are frequently required. Adult strength is often used to reduce amount of injection and to effect desired response, which may require increased or repeat doses. One source states, "Up to 10 times a dose has been required."

Narcotic overdose: Less than 20 kg: 0.01 to 0.1 mg/kg of body weight initially. Based on estimated degree of overdose and respiratory depression. May repeat every 2 to 3 minutes. May dilute with SWFI. American Academy of Pediatrics recommends 0.1 mg/kg. Manufacturer recommends 0.01 mg/kg.

Over 20 kg or over 5 years of age: 2 mg. Repeat every 2 to 3 minutes as needed. A continuous infusion may be used after initial effective dose. Add 75% to 100% of effective dose to a specific amount of IV fluid and infuse evenly distributed over 1 hour. For some overdoses (e.g., methadone), weaning in 50% increments may take up to 48 hours. For others, 6 to 12 hours is adequate. If symptoms recur, rebolus and go back to 100%.

Postoperative narcotic depression: 0.005 to 0.01 mg IV at 2- to 3-minute intervals to desired response.

NEONATAL DOSE

Neonatal opiate depression: Administration into umbilical vein is preferred. 0.01 to 0.1 mg/kg of body weight initially. Based on estimated degree of overdose and respiratory depression. May repeat every 2 to 3 minutes to achieve a satisfactory response. May dilute with SWFI. American Academy of Pediatrics recommends 0.1 mg/kg repeated every 2 to 3 minutes. Manufacturer recommends 0.01 mg/kg repeated every 2 to 3 min-

utes. Another source suggests an initial dose of 0.01 mg/kg. If response is not satisfactory, increase subsequent doses to 0.1 mg/kg.

DILUTION

May be given undiluted, diluted with SWFI, or further diluted in NS or D5W and given as an infusion (2 mg in 500 mL equals a concentration of 0.004 mg/mL). Discard infusions after 24 hours.

Storage: Store below 40° C. Protect from light.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with bisulfites, sulfites, long-chain or high-molecular-weight anions, solutions with an alkaline pH.

One source suggests the following **compatibilities**:

Additive: Verapamil.

Y-site: Fenoldopam (Corlopam), linezolid (Zyvox), propofol (Diprivan).

RATE OF ADMINISTRATION

Each 0.4 mg or fraction thereof over 15 seconds. Titrate infusion to patient response.

ACTIONS

A potent narcotic antagonist. Overcomes effects of narcotic overdose including respiratory depression, sedation, and hypotension. Unlike other narcotic antagonists, it does not have any narcotic effect itself. Onset of action is within 2 minutes. Duration of action is dependent on dose and route of naloxone administration. Requirement for repeat doses is dependent on amount, type, and route of narcotic administration. Metabolized in the liver and excreted in urine.

INDICATIONS AND USES

Reversal of narcotic depression. ■ Antidote for natural (e.g., morphine) and synthetic narcotics (e.g., butorphanol, methadone, nalbuphine, and pentazocine). ■ Diagnosis of suspected opioid tolerance or acute opiate overdose.

Unlabeled uses: Reversal of alcoholic coma and improvement of circulation in refractory shock.

CONTRAINDICATIONS

Known hypersensitivity to naloxone. ■ The naloxone challenge test should not be performed in patients showing S/S of withdrawal or whose urine contains opioids.

PRECAUTIONS

Does not produce respiratory depression with non-narcotic drug overdose, a beneficial action. ■ It is ineffective against respiratory depression caused by barbiturates, anesthetics, other non-narcotic agents, or pathologic conditions. ■ Will precipitate acute withdrawal symptoms in narcotic addicts; use caution, especially in newborns of narcotic-dependent mothers. ■ Use caution in cardiac disease patients or those receiving cardiotoxic drugs.

Monitor: Symptomatic treatment with oxygen and artificial ventilation as necessary should be continued until naloxone is effective. Observe patient continuously. Duration of narcotic action may exceed that of naloxone.

Maternal/Child: Category B: use in pregnancy and breast-feeding only when clearly needed. Safety for use not established. ■ See [Precautions](#).

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Hypertension, irritability and increased crying in the newborn, nausea and vomiting, sweating, tachycardia, tremulousness. Overdose postoperatively may result in excitement, hypertension, hypotension, reversal of analgesia, pulmonary edema, ventricular tachycardia and fibrillation.

ANTIDOTE

Notify the physician of any side effect. Treatment will probably be symptomatic. Resuscitate as necessary.

NATALIZUMAB **BBW**(nah-tah-**LIZZ**-u-mab)Monoclonal antibody
Immunomodulator**Tysabri**

pH 6.1

USUAL DOSE**Multiple sclerosis (MS):** 300 mg as an infusion every 4 weeks.**Crohn's disease (CD):** 300 mg as an infusion every 4 weeks. Discontinue if no benefit is seen after 12 weeks of therapy. For patients with CD who initiate natalizumab therapy while on chronic corticosteroids, begin steroid tapering as soon as therapeutic benefit of natalizumab has occurred. Discontinue natalizumab if the patient cannot be tapered off of steroids within 6 months. Consider discontinuing therapy in patients who require more than 3 months of steroid use (excluding the original 6-month taper) in a calendar year to control their CD. Aminosalicylates may be continued during therapy with natalizumab.**DOSE ADJUSTMENTS**

None indicated. Pharmacokinetics have not been studied in patients with renal or hepatic insufficiency.

DILUTION

Available in 300 mg/15 mL single-use vials. Withdraw 15 mL of concentrate (300 mg) from the vial and inject into 100 mL of NS. Gently invert to mix completely. Do not shake. No other IV diluents may be used to prepare the solution. Solution is a colorless, clear to slightly opalescent concentrate. Do not use if particulates are present or if solution is discolored.

Filters: Use of filtration devices during administration not evaluated.**Storage:** Refrigerate vials at 2° to 8° C (36° to 46° F). Do not use beyond the expiration date on the vial. Do not shake or freeze. Protect from light. Following dilution, solution should be infused immediately. However, it may be refrigerated and used within 8 hours of preparation. If refrigerated, allow to warm to room temperature before infusion.**COMPATIBILITY**

Manufacturer states, "Other medications should not be injected into infusion set side ports or mixed with natalizumab." Flush line with NS before and after infusion.

RATE OF ADMINISTRATION

Do not administer as an IV push or bolus injection. Infuse over approximately 1 hour. Flush line with NS before and after infusion.

ACTIONS

A recombinant humanized IgG4κ monoclonal antibody produced in murine myeloma cells. An integrin receptor antagonist. Natalizumab is thought to bind to a subunit on the surface of all leukocytes except neutrophils and inhibit the adhesion of leukocytes to their counterreceptors. The receptors for the α4 family of integrins include vascular cell adhesion molecule-1 (VCAM-1), which is expressed on activated vascular endothelium, and mucosal addressin cell adhesion molecule-1 (MAdCAM-1), which is present on vascular endothelial cells of the GI tract. Disruption of these molecular interactions prevents transmigration of leukocytes across the endothelium into inflamed parenchymal tissue. Specific mechanisms of how natalizumab exerts its effects in MS and CD have not been fully defined. In multiple sclerosis (MS), lesions are believed to occur when activated inflammatory cells, including T-lymphocytes, cross the blood-brain barrier (BBB). Leukocyte migration across the BBB involves the interaction between adhesion molecules on inflammatory cells and their counterreceptors on the endothelial cells of the vessel wall, thereby preventing immune cells from migrating from the bloodstream into the brain, where they can cause inflammation and potentially damage nerve fibers and their insulation. This action may be secondary to blockade of the molecular interaction of α4β1 integrins expressed by inflammatory cells with VCAM-1 on vascular endothelial cells and with CS-1 and/or osteopontin expressed by parenchymal cells in the brain. In

clinical trials, natalizumab reduced the rate of clinical relapse and the appearance of new or newly enlarging T2 hyperintense lesions on MRI studies. The number of gadolinium-enhancing lesions on the 1-year MRI scan follow-up was also reduced. In Crohn's disease (CD), the $\alpha 4\beta 7$ integrin with the endothelial receptor MAdCAM-1 expression has been found to be increased at active sites of inflammation in the mucosa and to contribute to the inflammatory response characteristic of CD. It is mainly expressed on gut endothelial cells. The action of natalizumab may be secondary to blockade of MAdCAM-1 and reduce this inflammatory response in the GI tract. Distribution is limited primarily to vascular space (plasma volume). Half-life is 3 to 17 days.

INDICATIONS AND USES

Monotherapy for the treatment of patients with relapsing forms of multiple sclerosis (MS) to delay the accumulation of physical disability and to reduce the frequency of clinical exacerbations. Should be reserved for patients who have had an inadequate response to or are unable to tolerate alternate MS therapies. ■ Safety and efficacy in patients with chronic progressive MS not established. ■ Induction and maintenance of clinical response and remission in adults with moderately to severely active Crohn's disease with evidence of inflammation who have had an inadequate response to or are unable to tolerate conventional therapy and inhibitors of TNF α (e.g., infliximab [Remicade]). Should not be used in combination with immunosuppressants (e.g., 6-mercaptopurine, azathioprine [Imuran], cyclosporine [Sandimmune], or methotrexate) or inhibitors of TNF α ; see [Precautions](#).

CONTRAINDICATIONS

Hypersensitivity to natalizumab or any of its components, patients who have or have had progressive multifocal leukoencephalopathy (PML).

PRECAUTIONS

Has been associated with hypersensitivity reactions, including anaphylaxis. Reactions usually occur within 2 hours of the start of the infusion. Generally associated with antibodies to natalizumab. ■ Anti-natalizumab antibodies have been detected in some patients. Persistently positive antibodies were associated with a substantial decrease in effectiveness and an increase in infusion-related reactions. 90% of patients who became persistently antibody-positive developed detectable antibodies by 12 weeks. Patients who receive therapeutic monoclonal antibodies, including natalizumab, after an extended period without treatment may be at increased risk of hypersensitivity reactions with re-exposure. Consider testing for the presence of antibodies in patients who want to resume therapy after a dose interruption. ■ Effects on immune system may increase the risk of infection, including opportunistic infection. ■ **Progressive multifocal leukoencephalopathy (PML) has been reported. PML is a serious progressive neurologic disorder caused by infection of the CNS by JC virus (JCV), a member of the papovavirus family. It typically occurs in immunocompromised patients. PML is rare but may result in irreversible neurologic deterioration and death, and there is no known effective treatment. Most cases of PML have occurred in patients with recent or concomitant exposure to immunomodulators (e.g., interferon beta-1a [Avonex]) or immunosuppressants (e.g., azathioprine [Imuran]). However, there have been reports of PML in patients receiving natalizumab monotherapy. Because of the risk of PML, natalizumab is available only through a special restricted distribution program called the TOUCH™ Prescribing Program. See prescribing information or contact manufacturer for specific details and requirements.** ■ Use of a gadolinium-enhanced MRI scan of the brain is recommended for diagnosis and, when indicated, CSF analysis for JC viral DNA. ■ Three known risk factors for PML include longer duration of natalizumab treatment (especially beyond 2 years), prior treatment with an immunosuppressant medication (e.g., azathioprine [Imuran], cyclophosphamide [Cytoxan], methotrexate, mitoxantrone [Novantrone], or mycophenolate [CellCept]), or the presence of anti-JCV antibodies. ■ A patient's anti-JCV antibody status may be determined using the Stratify JCV Antibody ELISA test. Testing positive for anti-JCV antibodies means that a person has been exposed to JCV in the past. Consider testing patients before treatment or during treatment if antibody status is unknown. Patients who test negative for anti-JCV antibodies are still at risk for the development of PML because of the potential for a new JCV infection or a false-negative test result. Periodic re-testing of antibody status should be considered in patients

previously determined to be anti-JCV antibody negative. ■ Patients who develop PML and have discontinued natalizumab have developed immune reconstitution inflammatory syndrome (IRIS). In most cases IRIS occurred after plasma exchange was used to eliminate circulating natalizumab. This syndrome has not been seen in patients discontinuing treatment for reasons unrelated to PML. ■ Liver injury has been reported; it has occurred as early as 6 days after the first dose and after multiple doses. The combination of ALT, AST, and bilirubin elevations without evidence of obstruction is generally recognized as an important predictor of severe liver injury that may lead to death or the need for liver transplantation. ■ No data available on secondary transmission of infections by live virus vaccines.

Monitor: Obtain baseline CBC and differential. Monitor periodically during treatment.

■ Obtain a baseline MRI before initiating treatment and periodically throughout treatment. In MS patients it may be helpful in differentiating subsequent MS symptoms from PML and assessing disease progression. In CD patients it may be helpful in distinguishing pre-existing lesions from newly developed lesions. ■ Consider determining anti-JCV antibody status before initiating natalizumab. Reassess status periodically; see **Precautions**. ■ Observe patients during the infusion and for 1 hour after the infusion is complete. Discontinue infusion at the first sign of any hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Antibodies detected within the first 6 months of therapy may be transient and disappear. Repeat testing in 3 months. If antibodies are persistent, consider risk versus benefit of continued therapy; see **Precautions**. ■ Monitor for S/S of infection. ■ Monitor for signs of clinical relapse. ■ Assess neurologic status frequently. S/S associated with PML are diverse and occur over days to weeks. May include progressive weakness on one side of the body, clumsiness of limbs, disturbances of vision, or changes in thinking, memory, and orientation leading to confusion and personality changes. Progression of deficits usually leads to severe disability or death over weeks to months. **Withhold natalizumab if PML is suspected.** If clinical suspicion of PML remains after initial evaluations are negative, continue to withhold natalizumab and repeat evaluations. ■ Monitor for S/S of IRIS; may occur within days to weeks after plasma exchange. IRIS presents as a clinical decline in condition (may occur after clinical improvement); decline may be rapid and cause serious neurologic complications or death. Associated with characteristic changes in the MRI. ■ Monitor for S/S of liver injury (e.g., elevated bilirubin or liver function tests, jaundice).

Patient Education: Read medication guide carefully. ■ Review medical conditions and medications with health care provider. ■ Promptly report any new medical problems (e.g., new or sudden change in thinking, eyesight, balance, or strength). ■ Report infections. ■ Report jaundice and any symptoms of infusion or hypersensitivity reactions immediately (e.g., difficulty breathing, dizziness, feeling faint, itching, nausea). ■ Discuss potential risks and benefits of treatment (e.g., risk of PML). ■ Your physician may order a blood test to see if you have ever been exposed to JCV. Risk of PML is greatest if you have all three known risk factors; see **Precautions**. ■ Scheduled follow-up visits are required as part of the TOUCH™ Program.

Maternal/Child: Category C: if a woman becomes pregnant while taking natalizumab, consider discontinuing natalizumab. If continued, encourage enrollment in TYSARBI Pregnancy Exposure Registry. ■ Has been detected in breast milk. Discontinue nursing or natalizumab, taking into account the importance of therapy to the mother. ■ Safety and effectiveness in pediatric patients with MS or CD under 18 years of age has not been studied.

Elderly: Studies did not include sufficient numbers of patients 65 years of age and older to determine whether they respond differently than younger patients.

DRUG/LAB INTERACTIONS

Formal studies not completed. Concurrent use with **antineoplastic, immunosuppressant, or immunomodulating agents** may further increase the risk of infection, including PML and other opportunistic infections, over the risk observed with the use of natalizumab alone.

Safety and efficacy of natalizumab in combination with any of these agents not established. ■ Concurrent use of short courses of **corticosteroids** was associated with an increase in infections in clinical trials. However, the increase in infections in both the natalizumab-treated and placebo-treated patients who received steroids was similar. Corticosteroids should be tapered in patients with CD who are initiating natalizumab therapy; see **Usual Dose**. ■ No data are available on the effects of **vaccination** in patients receiving natalizumab. ■ Increases circulating **lymphocytes, monocytes, eosinophils, basophils, and nucleated red blood cells**. A return to baseline usually occurs within 16 weeks after the last dose. Elevations of **neutrophils** are not observed. ■ May induce mild decreases in **hemoglobin**, frequently transient.

SIDE EFFECTS

Most commonly reported serious adverse reactions were infections (including influenza, pneumonia, and UTIs), hypersensitivity reactions (including anaphylaxis), depression (including suicidal ideation), and cholelithiasis. The most commonly reported adverse reactions resulting in clinical intervention (i.e., discontinuation of natalizumab) were urticaria and other hypersensitivity reactions. Infusion-related reactions (defined as any adverse event occurring within 2 hours of the start of an infusion) included headache, dizziness, fatigue, hypersensitivity reactions, nausea, pruritus, rigors, urticaria, and vomiting. Other reported adverse reactions included abdominal discomfort, abnormal liver function tests, amenorrhea, antibody formation, arthralgia, chest discomfort, dermatitis, diarrhea, fatigue, gastroenteritis, irregular menstruation/dysmenorrhea, local bleeding, muscle cramps, night sweats, pain in extremities, pruritus, rash, somnolence, syncope, tonsillitis, tremor, urinary urgency and frequency, vaginitis, and vertigo. Adverse reactions reported in persistently antibody-positive patients included anxiety, dyspnea, hypertension, myalgia, and tachycardia.

Post-Marketing: Herpes simplex virus encephalitis and meningitis, herpes zoster virus meningitis, PML in patients treated with natalizumab monotherapy.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically. Discontinue natalizumab at the first sign of liver injury, S/S suggestive of PML, or with any change in neurologic status. Discontinue infusion if any S/S of a hypersensitivity or infusion reaction occur. Treat with epinephrine, corticosteroids, diphenhydramine, bronchodilators, and oxygen as indicated. Patients who experience a hypersensitivity reaction should not be retreated with natalizumab.

NELARABINE **BBW**(nell-ah-**RA**-ben)

Antineoplastic

Arranon

pH 5 to 7

USUAL DOSE

1,500 mg/M² administered as an infusion over 2 hours on Days 1, 3, and 5. Repeat every 21 days. The recommended duration of treatment has not been clearly established. In clinical trials, treatment was generally continued until there was evidence of disease progression or until the patient experienced unacceptable toxicity, became a candidate for bone marrow transplant, or no longer continued to benefit from treatment.

PEDIATRIC DOSE

650 mg/M² administered as an infusion over 1 hour daily for 5 consecutive days. Repeat every 21 days; see **Usual Dose**.

DOSE ADJUSTMENTS

Discontinue therapy for neurologic events of Common Terminology Criteria for Adverse Events (CTCAE) Grade 2 or greater. Dosage may be delayed for other toxicity, including hematologic toxicity. ■ Has not been studied in patients with hepatic or renal impairment. Because nelarabine and ara-G are partially eliminated by the kidneys, clearance may be reduced in patients with renal insufficiency. No dose adjustment is recommended for patients with a CrCl equal to or greater than 50 mL/min. Dose recommendations are not available for patients with a CrCl less than 50 mL/min; see **Precautions**. ■ Use caution in dose selection for the elderly.

DILUTION

Specific techniques required; see Precautions. Nelarabine is not diluted prior to administration. Available in a 250 mg/50 mL (5 mg/mL) vial. Transfer the appropriate dose into a polyvinylchloride (PVC) infusion bag or glass container and administer as an infusion. Example: An adult patient with a body surface area of 2 M² would require a dose of 3,000 mg (1,500 mg/M² × 2 M² = 3,000 mg). 3,000 mg ÷ 250 mg/vial = 12 vials.

Filters: Specific information not available.

Storage: Store unopened vials at CRT. Stable in PVC infusion bags or glass containers for up to 8 hours at up to 30° C (86° F).

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Adult dose: A single dose evenly distributed over 2 hours.

Pediatric dose: A single dose evenly distributed over 1 hour.

ACTIONS

A prodrug of ara-G, a T-cell selective nucleoside metabolic inhibitor. Nelarabine is demethylated to ara-G and then converted through various metabolic processes to the active 5'-triphosphate, ara-GTP. Ara-GTP is incorporated into DNA, leading to inhibition of DNA synthesis and cell death. Nelarabine and ara-G are extensively distributed throughout the body and are rapidly eliminated from the plasma, with a mean half-life of 18 minutes and 3.2 hours, respectively. They are partially eliminated by the kidneys.

INDICATIONS AND USES

Treatment of patients with T-cell acute lymphoblastic leukemia and T-cell lymphoblastic lymphoma whose disease has not responded to treatment or has relapsed following treatment with at least two chemotherapy regimens. This use is based on the induction of complete responses. Randomized trials demonstrating increased survival or other clinical benefit have not been conducted.

CONTRAINDICATIONS

Hypersensitivity to nelarabine or any of its components.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ For IV use only. ■ Administered by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Neurotoxicity is the dose-limiting toxicity. Severe neurologic events have been reported and may include altered mental states (e.g., coma, confusion, severe somnolence), central nervous system effects (e.g., ataxia, convulsions), and peripheral neuropathy ranging from numbness and paresthesias to motor weakness and paralysis. Events associated with demyelination and ascending peripheral neuropathies similar in appearance to Guillain-Barré syndrome have also been reported. Full recovery from these events has not always occurred with cessation of therapy. ■ Patients treated previously or concurrently with intrathecal chemotherapy or previously with craniospinal irradiation may be at increased risk for neurologic adverse events. ■ Hematologic toxicity (e.g., anemia, leukopenia, neutropenia [including febrile neutropenia], thrombocytopenia) is common. ■ Use caution in patients with renal or hepatic impairment. Use has not been studied. Patients with a CrCl less than 50 mL/min or a bilirubin greater than 3 times the ULN may be at increased risk for toxicity. Monitor closely. ■ May develop tumor lysis syndrome. ■ See [Drug/Lab Interactions](#).

Monitor: Close monitoring for neurologic events is strongly recommended; see [Precautions](#) and [Antidote](#). ■ Obtain a baseline CBC with platelets and monitor regularly. ■ Monitor renal and hepatic function (BUN, SCr, bilirubin). ■ Monitor for S/S of tumor lysis syndrome (e.g., hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure). ■ Adequate hydration, alkalization of urine, and allopurinol are indicated to prevent and/or treat hyperuricemia due to tumor lysis syndrome. ■ Monitor for S/S of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Avoid administration of live virus vaccines to immunocompromised patients.

Patient Education: Avoid pregnancy; nonhormonal birth control is recommended. ■ Use caution in tasks that require alertness. ■ Notify physician at first sign of infection or of new or worsening neurotoxicity (e.g., numbness, tingling, difficulty with fine motor coordination, unsteadiness, weakness, seizures).

Maternal/Child: Category D; avoid pregnancy; may cause fetal harm. ■ Discontinue breast-feeding. ■ The mean clearance of nelarabine is about 30% higher in pediatric patients than in adult patients. Half-lives of nelarabine and ara-G are shorter than those seen in adults—13 minutes and 2 hours, respectively.

Elderly: May be at increased risk of neurologic adverse events. Clearance may be reduced in the elderly due to age-related renal impairment; see [Dose Adjustments and Precautions](#).

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been completed. ■ Concurrent administration with **adenosine deaminase inhibitors** (e.g., pentostatin [Nipent]) is not recommended; may decrease conversion of nelarabine to its active form and decrease its effectiveness. ■ Nelarabine and ara-G do not appear to inhibit the activities of human hepatic cytochrome P₄₅₀ isoenzymes. ■ Fludarabine does not appear to affect the pharmacokinetics of nelarabine, ara-G, or ara-GTP. ■ Do not administer **live virus vaccines** to immunocompromised patients receiving antineoplastic agents.

SIDE EFFECTS

Adults: Side effects most frequently reported were anemia, constipation, cough, diarrhea, dizziness, dyspnea, fatigue, fever, headache, hyperuricemia, hypoesthesia, nausea, neutropenia, paresthesia, peripheral neurologic disorders, somnolence, thrombocytopenia, and vomiting. Other reported side effects included abdominal distention, abdominal pain, abnormal gait, anorexia, arthralgia, asthenia, back pain, blurred vision, chest pain, chills,

confusion, dehydration, depression, edema, epistaxis, exertional dyspnea, extremity pain, febrile neutropenia, hyperglycemia, hypotension, increased AST, infection, insomnia, pain, muscular weakness, myalgia, peripheral edema, petechiae, pleural effusion, pneumonia, sinusitis, sinus tachycardia, stomatitis, and wheezing. **Neurologic** side effects in adults were mostly Grade 1 or 2 and included amnesia, ataxia, balance disorder, depressed level of consciousness, headache, hypoesthesia, neuropathy (peripheral, peripheral motor, and peripheral sensory), paresthesia, sensory loss, taste alteration, and tremor. Grade 3 events included aphasia, convulsion, hemiparesis, and loss of consciousness. Cerebral hemorrhage, coma, intracranial hemorrhage, leukoencephalopathy, and metabolic encephalopathy also were reported. One patient had a cerebral hemorrhage (fatal), coma, and leukoencephalopathy.

Pediatric patients: Side effects most frequently reported were anemia, decreased blood albumin and potassium levels, headache, increased transaminase levels, leukopenia, neutropenia, peripheral neurologic disorders, thrombocytopenia, and vomiting. Other reported side effects included asthenia; decreased calcium, glucose, and magnesium levels; increased bilirubin and SCr; and infection. **Neurologic** side effects that were greater than Grade 2 included ataxia, headache, hypertonia, hypoesthesia, motor dysfunction, neuropathy (peripheral, peripheral motor, and peripheral sensory), paralysis of the third and sixth nerves, paresthesia, seizures (convulsions, grand mal convulsions, status epilepticus), somnolence, tremor.

Overdose: Myelosuppression, severe neurotoxicity (coma, paralysis), and potentially death.

Post-Marketing: Demyelination and ascending peripheral neuropathies similar in appearance to Guillain-Barré syndrome, increased blood creatine phosphokinase, opportunistic infections (fatal), rhabdomyolysis, tumor lysis syndrome.

ANTIDOTE

Notify physician of any side effects. Most will be treated symptomatically. Discontinue therapy for neurologic events of Common Terminology Criteria for Adverse Events (CTCAE) Grade 2 or greater. Dosage may be delayed for other toxicity, including hematologic toxicity. Blood and blood products, antibiotics, and other adjunctive therapies must be available. Blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. No known antidote; provide supportive care in overdose. Resuscitate as necessary.

NEOSTIGMINE METHYLSULFATE

(nee-oh-**STIG**-meen **METH**-ill-**SUL**-fayt)

Cholinergic
Cholinesterase inhibitor
Antidote
Antimyasthenic

pH 5.9

USUAL DOSE

Muscle relaxant antagonist: Atropine: Administer atropine sulfate 0.6 to 1.2 mg for each 0.5 to 2 mg of neostigmine. Administer in a separate syringe a few minutes before neostigmine.

Neostigmine: 0.5 to 2 mg. Administer neostigmine when patient is being hyperventilated and carbon dioxide level of blood is low. Repeat as required to restore voluntary respiration. 5 mg is the normal maximum total dose. Use caution and monitor pulse rate. Pulse rate must be at least 80 beats/min. Alternately, glycopyrrolate 0.2 mg for each 1 mg of neostigmine can be used and can be mixed in the same syringe as neostigmine.

Treatment of myasthenia gravis: 0.5 mg; titrate carefully; usually given IM.

PEDIATRIC DOSE

Muscle relaxant antagonist: 40 mcg/kg (0.04 mg/kg) of body weight with 20 mcg/kg (0.02 mg/kg) of atropine. An alternate dose regimen is:

Infants: 0.025 to 0.1 mg/kg with atropine 0.0125 to 0.05 mg/kg.

Other pediatric patients: 0.025 to 0.08 mg/kg with atropine 0.0125 to 0.04 mg/kg. Maximum dose is 2.5 mg. Glycopyrrolate 0.2 mg for each 1 mg of neostigmine can be used instead of atropine. See all comments under [Usual Dose](#).

Treatment of myasthenia gravis: 0.01 to 0.04 mg/kg. May repeat every 2 to 3 hours. Usually given IM. See [Maternal/Child](#).

DOSE ADJUSTMENTS

Use extreme caution and minimum effective dose in small children, cardiac disease, asthma, epilepsy, hypothyroidism, vagotonia, peptic ulcer, and severely ill patients. Titrate exact dose; evaluate response with a peripheral nerve stimulator device.

DILUTION

Confirm ampule or vial is for IV use. May be given undiluted through Y-tube or three-way stopcock of infusion set. Do not add to IV solutions.

Storage: Store below 40° C. Protect from light.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Consider specific use and potential toxicity.

One source suggests the following **compatibilities**:

Y-site: Heparin, hydrocortisone sodium succinate (Solu-Cortef), palonosetron (Aloxi), potassium chloride (KCl).

RATE OF ADMINISTRATION

0.5 mg or fraction thereof over 1 minute.

ACTIONS

An anticholinesterase and antagonist of nondepolarizing neuromuscular blocking agents. Inhibits the enzyme cholinesterase, allowing acetylcholine to accumulate at the myoneural junction. Restores normal transmission of nerve impulses and makes muscle contraction stronger and more prolonged. Onset of action is 4 to 8 minutes. Duration of action is 2 to 4 hours. Hydrolyzed by cholinesterases and metabolized by microsomal enzymes in the liver. Excreted primarily in urine.

INDICATIONS AND USES

Antidote for nondepolarizing muscle relaxants (e.g., atracurium [Tracrium]), atropine, hyoscine. ■ Treatment of myasthenia gravis.

CONTRAINDICATIONS

High concentrations of inhalant anesthesia (e.g., halothane, cyclopropane); known sensitivity to bromides and neostigmine, mechanical intestinal or urinary obstruction, peritonitis.

PRECAUTIONS

A physician should be present when this drug is used IV. ■ Has many additional uses given IM or orally. ■ Edrophonium (Tensilon) can differentiate between myasthenic and cholinergic crisis. ■ See [Dose Adjustments](#).

Monitor: A peripheral nerve stimulator device should be used to monitor effectiveness. ■ **Caution:** Atropine may mask symptoms of neostigmine overdose. ■ Epinephrine should always be available. ■ Maintain airway and ensure adequate ventilation until complete recovery of normal respiration; see [Antidote](#). ■ Hyperventilate the patient before administration; carbon dioxide level of blood should be low. ■ See [Dose Adjustments](#) and [Drug/Lab Interactions](#).

Maternal/Child: Category C: may induce premature labor in pregnancy near term. ■ Transient muscular weakness in swallowing, sucking, and breathing has been observed in neonates of myasthenic mothers. Confirm distinction between cholinergic or myasthenic crisis in neonate with edrophonium test. Treat neonate with IM pyridostigmine 0.05 to 0.15 mg/kg of body weight if indicated. ■ Discontinue breast-feeding.

Elderly: Duration of antagonism of neuromuscular blockade prolonged.

DRUG/LAB INTERACTIONS

Potentiates **narcotic analgesics** (e.g., morphine, codeine, meperidine) and **succinylcholine**. ■ Antagonized by **ganglionic blocking agents** (e.g., trimethaphan [Arfonad], guanethidine [Ismelin], mecamlamine [Inversine]) and **aminoglycoside antibiotics** (e.g., gentamicin). ■ May be inhibited by **corticosteroids and magnesium**.

SIDE EFFECTS

Usually caused by overdose: abdominal cramps, anorexia, anxiety, bradycardia, cardiac arrhythmias and arrest, cholinergic crises, cold moist skin, convulsion, diaphoresis, diarrhea, hypotension, increased bronchial secretions, increased lacrimation, increased salivation, miosis, muscle cramps, muscle weakness, nausea, pulmonary edema, vomiting.

ANTIDOTE

Atropine sulfate. If side effects occur, discontinue drug and notify the physician. Atropine sulfate in doses of 0.6 mg IV will counteract most side effects and may be repeated every 3 to 10 minutes. Endotracheal intubation or tracheostomy is considered prophylactic in anesthesia or crises. Artificial ventilation, oxygen therapy, cardiac monitoring, adequate suctioning, and treatment of shock or convulsions must be instituted and maintained as necessary. Treat hypersensitivity reactions with epinephrine. Pralidoxime chloride (PAM) 2 Gm IV followed by 250 mg every 5 minutes may be required to reactivate cholinesterase and reverse paralysis.

NESIRITIDE

(nih-SIR-ih-tide)

Cardiotonic
Vasodilator

Natrecor

USUAL DOSE

Prime the IV tubing with the diluted nesiritide solution before connecting to the patient and before giving the bolus dose and infusion. **Bolus must be drawn from the prepared infusion bag.**

An initial dose of 2 mcg/kg of diluted solution is given as an IV bolus over 60 seconds. Follow immediately with the diluted solution as an infusion of 0.01 mcg/kg/min (0.1 mL/kg/hr); see [Dilution](#) and [Rate of Administration](#). **Do not initiate nesiritide at a dose that is above the recommended dose.** Do not increase rate of titration more frequently than every 3 hours. Use central hemodynamic monitoring, and do not exceed 0.03 mcg/kg/min. Experience is limited in the use of the infusion for more than 96 hours. See [Dose Adjustments](#) and [Precautions](#).

DOSE ADJUSTMENTS

Use of the loading dose may not be appropriate for patients with low systolic blood pressure (less than 110 mm Hg) or for patients recently treated with afterload reducers (e.g., nitroprusside [Nitropress], nitroglycerin). ■ Reduced doses are not required in impaired renal function or based on age, gender, race, baseline endogenous human B-type natriuretic peptide (hBNP) concentration, severity of CHF, or concomitant administration of an ACE inhibitor (e.g., enalapril [Vasotec]). ■ If hypotension occurs, reduce the dose or discontinue nesiritide. Use IV fluids or changes in body position to support BP. Discontinue nesiritide if symptomatic hypotension occurs. Hypotension may be prolonged. Observe closely; reduce dose by 30% and restart nesiritide infusion (no bolus) when patient is stabilized. ■ See [Antidote](#).

DILUTION

Each 1.5-mg vial must be reconstituted with 5 mL of diluent withdrawn from a pre-filled, preservative-free, 250 mL plastic IV bag of D5W, NS, D5½NS, or D5¼NS. Do not shake. Ensure complete dilution by rotating the vial gently so all surfaces, including the stopper, are in contact with the diluent. Withdraw the entire contents of the vial and add to the 250-mL plastic IV bag used for the initial reconstitution. Invert several times to ensure complete mixing. Yields a concentration of 6 mcg/mL. **Prime the tubing and withdraw the bolus dose from this final dilution.** The IV tubing should be primed with 5 mL of the infusion solution before connecting to the IV access port and before withdrawing the bolus. Use the remaining solution for the infusion.

Filters: Manufacturer did two studies. Data indicate no loss of drug potency through a 5-micron needle filter in a 500 mcg/mL concentration. With the use of an in-line, 0.22-micron filter and concentrations of 2 and 50 mcg/mL at a rate of 9 mL/hr, drug potency was initially lower but recovered to 90% in 1 hour and 100% at 2 hours.

Storage: Vials should be stored in the carton below 25° C (77° F); protect from light; do not freeze. Reconstituted solutions may be stored at 2° to 25° C (36° to 77° F) for up to 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with bumetanide, enalaprilat (Vasotec IV), ethacrynic acid (Edecrin), furosemide (Lasix), heparin, hydralazine, insulin (regular), and any injectable drug that contains the preservative sodium metabisulfite. Manufacturer states, "Do not coadminister as infusions with nesiritide through the same IV catheter." If an **incompatible** drug has been administered, the IV catheter must be flushed with a **compat-**

ible solution (see **Dilution**) before and after the administration of nesiritide. Do not administer through a heparin-coated catheter (central or peripheral). Binds to heparin and could bind to the lining of a heparin-coated catheter and decrease the amount of nesiritide delivered to the patient.

One source suggests the following **compatibilities**:

Y-site: Amiodarone (Nexterone), argatroban, digoxin (Lanoxin), diltiazem (Cardizem), fentanyl (Sublimaze), metoprolol (Lopressor), milrinone (Primacor), nicardipine (Cardene IV), nitroglycerin IV, nitroprusside (Nitropress), propranolol, quinidine gluconate, torsemide (Demadex), verapamil.

RATE OF ADMINISTRATION

If the IV line has been used to administer other drugs, flush it with a solution **compatible** to nesiritide before administration and then prime it with nesiritide solution. The IV tubing should be primed with 5 mL of the infusion solution before connecting to the IV access port and before withdrawing the bolus.

IV bolus: A single dose over 60 seconds through an IV port in the tubing.

IV infusion: Use a volume-controlled infusion pump and administer at a flow rate of 0.1 mL/kg/hr to deliver the desired dose of 0.01 mcg/kg/min.

Adjust bolus volumes and rates of infusion by weight according to the following chart.

Nesiritide Weight-Adjusted Bolus Volume and Infusion Flow Rate (2 mcg/kg Bolus Followed by a 0.01 mcg/kg/min Infusion)		
Patient Weight (kg)	Volume of Bolus (mL)	Rate of Infusion (mL/hr)
60 kg	20 mL	6 mL/hr
70 kg	23.3 mL	7 mL/hr
80 kg	26.7 mL	8 mL/hr
90 kg	30 mL	9 mL/hr
100 kg	33.3 mL	10 mL/hr
110 kg	36.7 mL	11 mL/hr

Alternately, the following formulas can be used to calculate the correct bolus volume and infusion rate:

$$\text{Bolus volume (mL)} = \text{Patient weight (kg)} \div 3$$

$$\text{Infusion flow rate (mL/hr)} = 0.1 \times \text{Patient weight (kg)}$$

ACTIONS

A recombinant form of human B-type natriuretic peptide (hBNP). Has the same 32–amino acid sequence as the endogenous peptide produced by the ventricular myocardium. Binds to specific receptors of vascular smooth muscle and endothelial cells, resulting in increased intracellular concentrations of cGMP and smooth muscle cell relaxation. Dilates veins and arteries. Produces dose-dependent reductions in PCWP and systemic arterial pressure in patients with heart failure. Has no effect on cardiac contractility or measures of cardiac electrophysiology (e.g., atrial and ventricular refractory times or atrioventricular node conduction) in animals. 60% of the 3-hour effect on PCWP reduction and 70% of the 3-hour effect on SBP reduction is achieved within 15 minutes. Half-life is approximately 18 minutes. Duration of action may be longer than predicted based on half-life and may be dose dependent. Mechanism of elimination has not been studied.

INDICATIONS AND USES

Treatment of acutely decompensated CHF in patients who have dyspnea at rest or with minimal activity. Has been shown to reduce PCWP and improve short-term symptoms of dyspnea (3 hours).

CONTRAINDICATIONS

Hypersensitivity to nesiritide or its components (a recombinant protein manufactured using *Escherichia coli*). ■ Cardiogenic shock. ■ Patients with a persistent systolic BP less than 100 mm Hg. ■ Not recommended in patients for whom vasodilating agents are not appropriate (e.g., restrictive or obstructive cardiomyopathy, constrictive pericarditis, pericardial tamponade, significant valvular stenosis), for other conditions in which cardiac output is dependent on venous return, or for patients who may have or are known to have low cardiac filling pressures.

PRECAUTIONS

Safety and effectiveness for use longer than 96 hours not established. ■ Administered by or under the supervision of a physician experienced in its use and in a facility equipped to monitor the patient and respond to any medical emergency. ■ An *E. coli*-derived protein product; hypersensitivity reactions have been reported and may be more likely to occur in individuals with a history of sensitivity to recombinant peptides; obtain patient history. ■ May decrease renal function; see **Monitor**. ■ May cause azotemia in patients with severe CHF whose renal function may depend on the activity of the renin-angiotensin-aldosterone system. Some patients have required first-time dialysis.

Monitor: Incidence of hypotension is similar to nitroglycerin, but duration of hypotension is longer. Monitor BP closely. Reduce rate or stop infusion for excessive drop in BP; see **Dose Adjustments** and **Antidote**. ■ Observe patient continuously; monitor urine output, renal function, fluid and electrolyte changes, and body weight. Monitor SCr during treatment and after treatment is completed until values have stabilized. Monitoring of cardiac index and PCWP useful. ■ Observe for orthopnea, dyspnea, and fatigue. ■ Monitor for S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face). ■ As cardiac output and diuresis improves, a reduction in diuretic dose may be indicated. ■ See **Precautions** and **Drug/Lab Interactions**. **Patient Education:** Report dizziness or faintness; request assistance for ambulation.

Maternal/Child: Pregnancy Category C: use only if potential benefit justifies possible risk to the fetus. ■ Not known if nesiritide is secreted in breast milk; use caution in women who are breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response similar to that found in younger patients; however, use with caution in the elderly; may have a greater sensitivity to its effects.

DRUG/LAB INTERACTIONS

Trials specifically examining potential drug interaction studies have not been conducted.

■ May cause additive hypotension with **ACE inhibitors** (e.g., enalapril [Vasotec]) **and other drugs that may cause hypotension** (e.g., antidepressants [e.g., amitriptyline (Elavil)], antihypertensives, benzodiazepines [e.g., diazepam (Valium), lorazepam (Ativan)], magnesium sulfate). ■ Has been administered with angiotensin II receptor antagonists, anticoagulants, beta-blockers (e.g., atenolol [Tenormin]), calcium channel blockers (e.g., diltiazem [Cardizem], verapamil), class III antiarrhythmic agents (e.g., amiodarone [Nexterone], sotalol [Betapace]), digoxin, diuretics, dobutamine, dopamine, oral ACE inhibitors, oral nitrates, and statins (e.g., simvastatin [Zocor]). No specific effect on the action of nesiritide was noted, but hypotensive effects are additive. ■ Effects of concurrent use with **other IV vasodilators** (e.g., milrinone, nitroglycerin, or nitroprusside sodium), **drugs affecting the renin-angiotensin system** (e.g., angiotensin receptor blockers [e.g., losartan (Cozaar), candesartan (Atacand)] and/or angiotensin-converting enzyme inhibitors [e.g., enalapril (Vasotec), captopril (Capoten)]), **and afterload reducers** (e.g., nitroprusside [Nitropress], enalapril [Vasotec], captopril [Capoten]) have not been studied, but hypotensive effects would be additive.

SIDE EFFECTS

Hypotension is the primary side effect; may be symptomatic and can be dose limiting; see **Antidote**. Back pain, dizziness, headache, increased serum creatinine (SCr), and nausea are most common. Other reported side effects include abdominal pain, amblyopia

(vision impairment), anemia, angina, anxiety, apnea, arrhythmias (e.g., atrial fibrillation, AV node conduction abnormalities, bradycardia, PVCs, tachycardia, VT), catheter pain, confusion, fever, hemoptysis, increased cough, increased serum creatinine, injection site reaction, insomnia, leg cramps, paresthesia, somnolence, sweating, tremor, and vomiting. Hypersensitivity reactions and anaphylaxis may occur. A meta-analysis of seven clinical trials demonstrated that nesiritide did not increase mortality rate in patients with acute decompensated heart failure at Day 30 or Day 180.

Post-Marketing: Hypersensitivity reactions, infusion site extravasation, pruritus, rash.

ANTIDOTE

Notify the physician of any side effects. Based on degree of severity and condition of the patient; may be treated symptomatically; dose may remain the same, be decreased, or be discontinued. Reduce rate or discontinue nesiritide at the first sign of marked hypotension and notify the physician. Hypotension may respond to a Trendelenburg position and IV fluids (avoid fluid overload). Hypotension may last for hours; observation for a prolonged period may be indicated before restarting nesiritide. After hypotension is stabilized, nesiritide may be restarted; do not administer a bolus dose and reduce the rate of infusion by 30%. Treat hypersensitivity reactions as indicated.

NICARDIPINE HYDROCHLORIDE

(nye-KAR-dih-peen hy-droh-KLOR-eyed)

Calcium channel blocker
Antihypertensive

Cardene IV

pH 3.7 to 4.7

USUAL DOSE

Must be individualized based on the severity of hypertension and the response of each patient. Blood pressure decrease is dependent on the rate of infusion and frequency of dose adjustments. Gradual reduction based on clinical situation is best. Avoid too-rapid or excessive drop in BP. See **Precautions**. Transfer to oral medication as soon as clinical condition permits.

To substitute for oral nicardipine therapy: 0.5 mg/hr will achieve similar plasma concentration to an oral dose of 20 mg every 8 hours; 1.2 mg/hr to an oral dose of 30 mg every 8 hours; 2.2 mg/hr to an oral dose of 40 mg every 8 hours.

Gradual reduction of BP in a drug-free patient: Initiate therapy at 5 mg/hr. May be increased by 2.5 mg/hr every 15 minutes until desired BP reduction is achieved. Do not exceed 15 mg/hr.

Rapid reduction of BP in a drug-free patient: Initiate a 5-mg/hr dose as above, but increases of 2.5 mg/hr may be given every 5 minutes until desired BP reduction is achieved (AHA guidelines recommend 5 to 15 minutes). Do not exceed 15 mg/hr.

Maintenance: When desired BP is achieved, reduce rate to 3 mg/hr. This is the average maintenance rate. Adjust as needed to maintain desired response.

Transfer to an oral antihypertensive agent: The first dose of oral nicardipine should be given 1 hour before discontinuing infusion. Initiate any other oral antihypertensive agent on discontinuation of infusion.

DOSE ADJUSTMENTS

Lower doses and slower titration suggested in heart failure and impaired hepatic or renal function; see **Precautions**. ■ Lower-end initial doses may be indicated in the elderly. Consider potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Available as a premixed solution containing 0.1 mg/mL in D5W or NS or in a vial that requires further dilution. Each vial (25 mg in 10 mL) must be diluted with 240 mL of **compatible** infusion solution to equal a concentration of 0.1 mg/mL; in this 0.1 mg/mL concentration, 2.5 mg/hr equals 25 mL/hr, 3 mg/hr equals 30 mL/hr, 5 mg/hr equals 50 mL/hr, and 15 mg/hr equals 150 mL/hr. **Compatible** in ½NS, NS, D5W, D5/½NS, D5NS. Also **compatible** in D5W with 40 mEq of potassium added.

Fluid-restricted or pediatric patients: One source recommends mixing up to 50 mg in 100 mL (0.5 mg/mL). To avoid superficial phlebitis, administration via a central line is recommended for this concentration.

Filters: No data available from manufacturer.

Storage: Store vials in carton, protected from light at CRT. Has a light yellow color. Diluted solution is stable at room temperature for 24 hours. Store prediluted solutions at CRT; protect from light and excessive heat and avoid freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Do not combine with any product in the same IV line or premixed container. Do not add supplementary medication to the bag.” Manufacturer lists as **incompatible** with sodium bicarbonate 5% and LR.

One source suggests the following **compatibilities**:

Additive: *Not recommended by manufacturer.* Potassium chloride (KCl).

Y-site: *Not recommended by manufacturer.* Amikacin (Amikin), aminophylline, aztreonam (Azactam), butorphanol (Stadol), calcium gluconate, cefazolin (Ancef), ceftazidime

(Fortaz), chloramphenicol (Chloromycetin), clindamycin (Cleocin), dextran 40 in 5% dextrose, diltiazem (Cardizem), dobutamine, dopamine, enalaprilat (Vasotec IV), epinephrine (Adrenalin), erythromycin (Erythrocin), esmolol (Brevibloc), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), gentamicin, heparin, hetastarch in NS (Hespan), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), labetalol, lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, methylprednisolone (Solu-Medrol), metronidazole (Flagyl IV), midazolam (Versed), milrinone (Primacor), morphine, nafcillin (Nallpen), nesiritide (Natrecor), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), penicillin G potassium, potassium chloride (KCl), potassium phosphates, ranitidine (Zantac), sodium acetate, sulfamethoxazole/trimethoprim, tobramycin, vancomycin, vecuronium.

RATE OF ADMINISTRATION

Must be administered as a slow continuous infusion. Adjust as indicated in [Usual Dose and Dose Adjustments](#).

ACTIONS

The first dihydropyridine calcium channel blocker for IV use. Inhibits influx of calcium ions into cardiac muscle and smooth muscle without altering serum calcium. Contractile processes are dependent on calcium movement through specific channels. Effects seen are more selective to vascular smooth muscle than cardiac muscle. Causes coronary and peripheral blood vessels to dilate and relax, reducing systemic vascular resistance. Increases cardiac output, coronary blood flow, and myocardial oxygen supply without increasing cardiac oxygen demand. Reduces BP without significantly affecting cardiac conduction and usually does not depress cardiac function. Produces dose-dependent decreases in BP. Begins to reduce BP in minutes; achieves 50% of ultimate decrease in 45 minutes. When discontinued, can lose 50% of effect within 30 minutes, but gradually decreasing effects persist for up to 50 hours. Effects more prominent in hypertensive than in normotensive volunteers. Highly protein bound. Extensively metabolized in the liver. Half-life is 14.4 hours. Excreted in urine and feces. Crosses placental barrier. Minimally secreted in breast milk.

INDICATIONS AND USES

Short-term treatment of hypertension when oral therapy is not feasible or not desirable.

CONTRAINDICATIONS

Advanced aortic stenosis (reduced diastolic pressure may worsen rather than improve myocardial oxygen balance). ■ Known hypersensitivity to nicardipine.

PRECAUTIONS

Use caution in patients with coronary artery disease. May cause increase in frequency, duration, or severity of angina. ■ Has improved left ventricle function after beta-blockade. ■ Use caution and titrate slowly in patients with heart failure or significant left ventricular dysfunction, particularly when used in combination with a beta-blocker; possible negative inotropic effects may occur. ■ Use caution with impaired hepatic or renal function; lower doses, slower titration, and close monitoring indicated. ■ May produce symptomatic hypotension or tachycardia. Avoid systemic hypotension (systolic BP less than 90 mm Hg), and use with caution in patients with acute cerebral infarction or hemorrhage.

Monitor: To reduce the possibility of venous thrombosis, phlebitis, local irritation, swelling, extravasation, and/or vascular impairment, administer through a central vein or large peripheral vein rather than a small peripheral vein. Avoid intra-arterial administration. If administered via a peripheral vein, change the infusion site every 12 hours. ■ Avoid tachycardia or too-rapid or excessive reduction in either systolic or diastolic BP. Monitor BP and HR continually during infusion and frequently after infusion. Additional monitoring of BP and HR is indicated when used in combination with a beta-blocker in patients with HF or significant left ventricular dysfunction ■ Transfer to oral therapy as soon as clinical condition permits. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Request assistance to change position or ambulate.

Maternal/Child: Category C: use during pregnancy only if benefit justifies potential risk to the fetus. ■ Dizziness, flushing, headache, hypotension, nausea, postpartum hemorrhage, reflex tachycardia, and tocolysis have occurred in pregnant women treated for hypertension during pregnancy. Produced hypotension in some neonates. ■ During use in preterm labor, dyspnea, headache, hypotension, hypoxia, phlebitis at the injection site, and pulmonary edema have been reported. Neonatal side effects included acidosis (pH less than 7.25). ■ Use caution during breast-feeding; infant exposure may occur. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly: Response similar to that seen in younger adults; however, greater sensitivity in the elderly cannot be ruled out. ■ Half-life may be prolonged. ■ See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

May cause possible negative inotropic effects with concurrent administration of a **beta-blocker** (e.g., atenolol [Tenormin], metoprolol [Lopressor]); see [Precautions](#). ■ **Cimetidine** (Tagamet) increases oral nicardipine plasma concentrations; monitor patients receiving IV nicardipine carefully. ■ Oral nicardipine does not appear to alter **digoxin** levels. However, as a precaution, evaluate digoxin levels with concomitant use. ■ Will increase plasma levels of **cyclosporine** (Sandimmune); monitor and decrease cyclosporine dose if indicated. ■ May potentiate the effects of **other antihypertensives**. Monitor BP closely and adjust doses as indicated. ■ Metabolism may be increased and serum concentrations decreased by **rifampin** (Rifadin). Adjust dose as needed. ■ Plasma protein binding of nicardipine not altered with therapeutic concentrations of furosemide (Lasix), propranolol, dipyridamole (Persantine), warfarin (Coumadin), quinidine, or naproxen (Naprosyn).

SIDE EFFECTS

Average dose: Most common side effects include headache, hypotension, nausea and vomiting, and tachycardia. Many other side effects, including ECG abnormality (e.g., angina pectoris, atrioventricular block, ST-segment depression, inverted T wave), confusion, conjunctivitis, deep vein thrombophlebitis, dyspepsia, ear disorder, fever, hypertension, hypophosphatemia, neck pain, peripheral edema, respiratory difficulties, thrombocytopenia, tinnitus, and urinary frequency, occurred in fewer than 3% of patients. Hypersensitivity reactions (e.g., angioedema, rash, wheezing) have been reported.

Overdose: Bradycardia (following initial tachycardia), confusion, drowsiness, flushing, hypotension (marked), palpitations, slurred speech. Progressive AV block may occur with lethal overdose.

ANTIDOTE

Keep physician informed of all side effects. Headache, hypotension, and tachycardia have required a reduction in dose or discontinuation of nicardipine. When symptoms subside, nicardipine may be restarted at low doses (e.g., 3 to 5 mg/hr [30 to 50 mL/hr of a 0.1 mg/mL solution or 15 to 25 mL/hr of a 0.2 mg/mL solution]) and adjusted to maintain desired BP. In overdose, monitor BP, cardiac and respiratory functions; put patients in Trendelenburg position; use vasopressors (e.g., dopamine) for excessive hypotension. IV calcium gluconate may reverse effects of calcium entry blockade. Not removed by hemodialysis.

NITROGLYCERIN IV

(NYE-troe-GLIS-er-in)

Antianginal
Antihypertensive
Vasodilator

pH 3 to 6.5

USUAL DOSE

See **Compatibility**; these doses are recommended for use with non-PVC administration sets. Increased doses are required if using PVC administration sets. Effectiveness is short term; see **Actions**. Initiate concurrent therapy before tolerance develops (e.g., doses exceeding 200 mcg/min or administration over 12 to 24 hours).

Unstable angina, persistent ischemia, and/or congestive heart failure associated with MI: An IV bolus of 12.5 to 25 mcg followed by a continuous infusion of 10 to 20 mcg/min; increase by 5 to 10 mcg/min every 5 to 10 minutes until desired hemodynamic response. AHA recommends an IV bolus of 12.5 to 25 mcg followed by an infusion at 10 mcg/min. Increase rate by 10 mcg/min every 3 to 5 minutes until desired effect. 200 mcg/min is the usual maximum dose.

Treatment of angina in patients unresponsive to therapeutic doses of nitrates or beta-blockers: 5 mcg/min initially. Increase by 5 mcg/min increments every 3 to 5 minutes until some BP response is noted. Reduce increments and/or increase time to fine-tune to desired hemodynamic response. If no response at 20 mcg/min, 10 mcg/min increases may be used. Incremental increases of up to 20 mcg/min may be needed to achieve desired effect. No fixed optimum dose. Tolerance may develop if administered over 12 to 24 hours.

Severe hypertension or hypertensive emergency: Doses up to 100 mcg/min may be required (range is 5 to 100 mcg/min). Doses that will reduce mean arterial BP by no more than 25% over several minutes to 1 hour are suggested to prevent overaggressive therapy. If stable, follow with further reductions toward 160/100 to 110 mm Hg within the next 2 to 6 hours. When an initial response is achieved, increases in dosage increments should be reduced and/or the intervals between dose increases lengthened.

PEDIATRIC DOSE

0.25 to 0.5 mcg/kg/min initially. May increase by 0.5 to 1 mcg/kg/min increments every 3 to 5 minutes until desired response. See **Maternal/Child**. AHA guidelines recommend titrating by 1 mcg/kg/min every 15 to 20 minutes and states the typical dose range is 1 to 5 mcg/kg/min.

DOSE ADJUSTMENTS

Reduced dose may be required with persistent headache unrelieved by analgesics. Reduce dose gradually when weaning to prevent rebound symptoms. ■ Lower-end initial doses may be appropriate in the elderly based on potential for decreased organ function, concomitant disease, or other drug therapy.

DILUTION

Available premixed in D5W with various concentrations of nitroglycerin. All other preparations must be diluted and administered as an infusion. Use only non-PVC plastic or glass infusion bottles and specific (nonpolyvinyl chloride) infusion tubing (provided by manufacturer). Do not use filters. Dilute in a given amount of D5W or NS for infusion. Concentration dependent on initial preparation (0.5 mg/mL or 5 mg/mL) and patient fluid tolerances. 10 mL of 0.5 mg/mL in 250 mL diluent equals 20 mcg/mL (in 1,000 mL, 5 mcg/mL). 10 mL of 5 mg/mL in 250 mL diluent equals 200 mcg/mL (in 1,000 mL, 50 mcg/mL). See the following dilution chart.

Guidelines for Dilution of Nitroglycerin IV for Infusion		
Diluent Volume (mL)	Quantity of Nitroglycerin (5 mg/mL)	Approximate Final Concentration (mcg/mL)
100 mL	10 mg (2 mL)	100 mcg/mL
100 mL	20 mg (4 mL)	200 mcg/mL
100 mL	40 mg (8 mL)	400 mcg/mL
250 mL	25 mg (5 mL)	100 mcg/mL
250 mL	50 mg (10 mL)	200 mcg/mL
250 mL	100 mg (20 mL)	400 mcg/mL
500 mL	50 mg (10 mL)	100 mcg/mL
500 mL	100 mg (20 mL)	200 mcg/mL
500 mL	200 mg (40 mL)	400 mcg/mL

May be used in dilutions from 25 to 400 mcg/mL.

Pediatric dilution: 6 mg/kg nitroglycerin IV in 100 mL D5W at an infusion rate of 1 mL/hr equals 1 mcg/kg/min.

Filters: Do not use filters; see [Dilution](#).

Storage: Protect vials from light. Solution stable for up to 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Do not admix with any other drug.” See [Dilution](#). Non-PVC plastic or glass infusion bottles and nonpolyvinyl chloride infusion tubing is required to deliver accurate dosing with minimal adsorption. Calculated dose will not be correct if other infusion containers or tubing are used because of excess adsorption.

One source suggests the following **compatibilities**:

Additive: **Not recommended by manufacturer.** Alteplase (tPA, Activase), aminophylline, dobutamine, dopamine, enalaprilat (Vasotec IV), furosemide (Lasix), lidocaine, verapamil.

Y-site: Amiodarone (Nexterone), amphotericin B cholesteryl (Amphotec), argatroban, atracurium (Tracrium), bivalirudin (Angiomax), cisatracurium (Nimbex), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, dopamine, epinephrine (Adrenalin), esmolol (Brevibloc), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), furosemide (Lasix), heparin, hetastarch in electrolytes (Hextend), hydralazine, hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), insulin (regular), labetalol, lidocaine, linezolid (Zyvox), lorazepam (Ativan), micafungin (Mycamine), midazolam (Versed), milrinone (Primacor), morphine, nesiritide (Natrecor), nicardipine (Cardene IV), nitroprusside sodium, norepinephrine (Levophed), pancuronium, pantoprazole (Protonix IV), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), tacrolimus (Prograf), theophylline, tirofiban (Aggrastat), vasopressin, vecuronium, warfarin (Coumadin).

RATE OF ADMINISTRATION

Dependent on patient response and effective dose. Specific adjustments required; see [Usual Dose](#). Use extreme caution in patients responsive to initial 5 mcg/min dose. Decrease adjustments and increase time between doses as patient begins to respond. Use of an infusion pump or microdrip (60 gtt/mL) required. Exact and constant delivery mandatory. See the following chart.

Nitroglycerin IV Guidelines for Infusion				
Concentration (mcg/mL)	50	100	200	400
Desired Dose (mcg/min)	60 Microdrops = 1 mL Flow Rate (microdrops/min = mL/hr)			
	5 mcg/min	6	3	—
10 mcg/min	12	6	3	—
15 mcg/min	18	9	—	—
20 mcg/min	24	12	6	3
30 mcg/min	36	18	9	—
40 mcg/min	48	24	12	6
60 mcg/min	72	36	18	9
80 mcg/min	96	48	24	12
120 mcg/min	—	72	36	18
160 mcg/min	—	96	48	24
240 mcg/min	—	—	72	36
320 mcg/min	—	—	96	48
480 mcg/min	—	—	—	72
640 mcg/min	—	—	—	96

ACTIONS

A vascular smooth-muscle relaxant and vasodilator. Affects arterial and venous beds. Reduces myocardial oxygen consumption, preload, and afterload by reducing systolic, diastolic, and mean arterial blood pressure; central venous and pulmonary capillary wedge pressures; and pulmonary and systemic vascular resistance. Effective coronary perfusion is usually maintained. Low doses (30 to 40 mcg/min) produce venodilation; high doses (150 to 500 mcg/min) produce arteriolar dilation. Widely distributed throughout the body. Onset of action occurs in 1 to 2 minutes and lasts 3 to 5 minutes. Metabolized in the liver and excreted in urine.

INDICATIONS AND USES

Control of BP in perioperative hypertension (especially cardiovascular procedures). ■ Drug of choice in unstable angina or congestive heart failure associated with acute myocardial infarction. May be used in combination with dobutamine 2 to 20 mcg/kg/min to produce hemodynamic improvement while reducing risk of ischemic damage. ■ Treatment of angina pectoris if patient unresponsive to therapeutic doses of organic nitrates and/or a beta-blocker. ■ Controlled hypotension during surgical procedures.

CONTRAINDICATIONS

Anemia (severe), hypersensitivity to nitrates, hypotension or uncorrected hypovolemia, cerebral hemorrhage, closed-angle glaucoma, head trauma, increased intracranial pressure, patients taking sildenafil (Viagra), pericardial tamponade, constrictive pericarditis.

PRECAUTIONS

Special tubing causes problems with infusion pump control. Patient may still be receiving nitroglycerin IV even though pump is off or tubing clamped. Low flow rates may actually be higher and not deliver accurate dosage. ■ Plastic (polyvinyl chloride) tubing or containers will absorb up to 80% of diluted nitroglycerin IV. Use extreme caution and adjust dose if changing infusion equipment (e.g., IV tubing, extension tubing). Absorption greatest with slowest rate. ■ If changing preparations from 0.8 mg/mL to 5 mg/mL, use new tubing or clear tubing with a minimum of 15 mL, adjust dose carefully, and observe effects. ■ Use caution in patients with low left ventricular filling pressure or low

pulmonary capillary wedge pressure. May have exaggerated response to low dosage. ■ Use caution in hepatic or renal disease, pericarditis, or postural hypotension.

Monitor: Maintain adequate systemic BP and coronary perfusion pressure. HR and BP measurements mandatory; pulmonary wedge pressure recommended. ■ Observe for tachycardia, which can decrease diastolic filling time. ■ Observe for fall in pulmonary wedge pressure. Precedes arterial hypotension and impending shock. Reduce or discontinue drug temporarily. ■ Headache may improve with analgesics or slightly lower dose; usually improves with time. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: safety for use in pregnancy, breast-feeding, and in pediatric patients not established.

Elderly: Hypotensive effects may be increased. ■ Differences in response compared to younger patients not identified. ■ Lower-end initial doses may be indicated; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

May cause irreversible hypotension if given within 24 to 48 hours of **impotence agents** (e.g., sildenafil citrate [Viagra, Revatio], tadalafil [Cialis], vardenafil [Levitra]). ■ Potentiated by **alcohol** (may cause hypotension and cardiovascular collapse), **antihypertensives**, **aspirin**, **beta-adrenergic blockers** (e.g., propranolol), **other vasodilators**, **phenothiazines** (e.g., prochlorperazine [Compazine]), and **tricyclic antidepressants**. ■ Inhibited by **dihydroergotamine and sympathomimetics** (e.g., vasopressors [phenylephrine], bronchodilators, decongestants, glaucoma agents, mydriatics). ■ Inhibits **acetylcholine**, **histamine**, **norepinephrine**. ■ Potentiates **nondepolarizing muscle relaxants** (e.g., atracurium [Tracrium]); may cause apnea. ■ May cause marked orthostatic hypotension with **calcium channel blockers** (e.g., verapamil). ■ May antagonize anticoagulant effects of **heparin**; monitor. ■ Concurrent use with **alteplase** (tPA); reduces the thrombolytic effects of alteplase.

SIDE EFFECTS

Abdominal pain, angina, apprehension, dizziness, headache, hypersensitivity reactions (e.g., itching, tracheobronchitis, wheezing), hypotension, methemoglobinemia, muscle twitching, nausea, palpitations, postural hypotension, restlessness, retrosternal discomfort, tachycardia, vomiting.

Overdose: Bloody diarrhea, colic, confusion, diaphoresis, dyspnea, flushing, heart block, paralysis, tachycardia, visual disturbances. Severe hypotension may result in shock, reflex paradoxical bradycardia, inadequate cerebral circulation, constrictive pericarditis, pericardial tamponade, decreased organ perfusion, and death.

ANTIDOTE

Notify physician of all side effects. Discontinue if blurred vision or dry mouth occur. For accidental overdose with severe hypotension and reflex tachycardia and/or fall in pulmonary wedge pressure, reduce rate or temporarily discontinue until condition stabilizes. Lower head of bed (Trendelenburg position). Administer IV fluids. Use O₂ and assisted ventilation if indicated. An alpha-adrenergic agonist (e.g., phenylephrine [Neo-Synephrine]) is rarely required. Epinephrine and related compounds (dopamine) are contraindicated. Monitor levels and treat methemoglobinemia if indicated with methylene blue 0.2 mL/kg of body weight (1 to 2 mg/kg) IV and high-flow oxygen. Treat anaphylaxis and resuscitate as necessary.

NITROPRUSSIDE SODIUM **BBW**

(nye-troh-PRUS-eyed SO-dee-um)

Antihypertensive
Vasodilator

Nitropress

pH 3.5 to 6

USUAL DOSE

Begin with 0.25 to 0.3 mcg/kg of body weight/min. Under continuous BP monitoring, titrate upward very gradually (small increments every 2 to 3 minutes). 3 mcg/kg/min is the average effective dose; range is 0.1 to 10 mcg/kg/min. AHA guidelines recommend beginning with 0.1 mcg/kg/min. Titrate upward every 3 to 5 minutes to desired effect (up to 5 mcg/kg/min). Small adjustments can lead to major fluctuations in BP. Never exceed 10 mcg/kg/min. If 10 mcg/kg/min does not promote adequate BP reduction in 10 minutes, discontinue administration and use another antihypertensive agent. Cyanide toxicity can occur with as little as 2 mcg/kg/min and could begin to occur after 10 minutes at the maximum dose.

Acute CHF: Titrate as described previously until one of the following occurs: cardiac output is no longer increasing, perfusion of vital organs would be compromised by further reduction of BP, or maximum infusion rate (10 mcg/kg/min) is reached.

PEDIATRIC DOSE

Begin with 0.3 mcg/kg/min. Adjust slowly to individual response as in Usual Dose. AHA guidelines recommend 0.3 to 1 mcg/kg/min initially; titrate up to 8 mcg/kg/min as needed.

DOSE ADJUSTMENTS

Average effective dose may be as little as 0.5 mcg/kg/min in patients who are receiving other antihypertensive agents by any route. ■ Reduced dose may be required in the elderly.

DILUTION

Available in a liquid formulation (25 mg/mL), or each 50 mg must be reconstituted with 2 to 3 mL of D5W or SWFI without a preservative. Must be further diluted in a minimum of 250 mL of D5W (manufacturer's recommendation). JAMA suggests NS may be used. Must be administered as an infusion. Larger amounts of solution may be used. 50 mg in 250 mL equals 200 mcg/mL. 50 mg in 500 mL equals 100 mcg/mL. Immediately after mixing, wrap infusion bottle in opaque material (e.g., aluminum foil) to protect from light. Use only freshly prepared solutions; usually discard infusion within 4 hours of mixing. (Literature now states, "Stable for 24 hours if properly protected.") ■ Solution has a faint brownish tint; discard immediately if highly colored, blue, green, or dark red.

Pediatric dilution: Add 0.6 mg/kg to 100 mL diluent. 1 mL/hr equals 0.1 mcg/kg/min.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Additive: Enalaprilat (Vasotec IV), ranitidine (Zantac), verapamil.

Y-site: Alprostadil, amiodarone (Nexterone), argatroban, atracurium (Tracrium), bivalirudin (Angiomax), calcium chloride, cisatracurium (Nimbex), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, dopamine, enalaprilat (Vasotec IV), epinephrine (Adrenalin), esmolol (Brevibloc), famotidine (Pepcid IV), furosemide (Lasix), heparin, hetastarch in electrolytes (Hextend), indomethacin (Indocin IV), insulin (regular), isoproterenol (Isuprel), labetalol, lidocaine, magnesium sulfate, metoprolol (Lopresor), micafungin (Mycamine), midazolam (Versed), milrinone (Primacor), morphine, nesiritide (Natrekor), nicardipine (Cardene IV), nitroglycerin IV, norepinephrine (Levophed), pancuronium, potassium chloride (KCl), potassium phosphates, procainamide (Pronestyl), propofol (Diprivan), tacrolimus (Prograf), theophylline, vecuronium.

RATE OF ADMINISTRATION

Use of an infusion pump (volumetric preferred) required to regulate dose accurately. Increase mcg/kg/min rate as outlined in Usual Dose to reduce BP gradually to preset or desired levels. Do not exceed maximum dose. Response should be noted almost immediately. Manufacturer provides the following infusion rate chart in mL/hr to achieve initial (0.3 mcg/kg/min) and maximal (10 mcg/kg/min) for 50-, 100-, and 200-mcg/mL dilutions.

Nitroprusside Sodium Guidelines for Infusion							
Volume		250 mL		500 mL		1,000 mL	
Nitroprusside Sodium		50 mg		50 mg		50 mg	
Injection Concentration		200 mcg/mL		100 mcg/mL		50 mcg/mL	
Patient Weight		Infusion Rate (mL/hr)					
kg	lbs	Initial	Maximum	Initial	Maximum	Initial	Maximum
		10	22	1	30	2	60
20	44	2	60	4	120	7	240
30	66	3	90	5	180	11	360
40	88	4	120	7	240	14	480
50	110	5	150	9	300	18	600
60	132	5	180	11	360	22	720
70	154	6	210	13	420	25	840
80	176	7	240	14	480	29	960
90	198	8	270	16	540	32	1,080
100	220	9	300	18	600	36	1,200

ACTIONS

A potent, rapid-acting antihypertensive agent. Produces peripheral vasodilation through direct action on smooth muscle of the blood vessels. Effective almost immediately. Will lower diastolic BP 30% to 40% or more below pretreatment levels. May increase HR and/or cardiac output slightly. Effectiveness ends when IV infusion is stopped. BP will return to pretreatment levels in 1 to 10 minutes. Rapidly converted to thiocyanate and eventually excreted in the urine.

INDICATIONS AND USES

Drug of choice for hypertensive emergencies. ■ Cardiogenic shock. ■ Controlled hypotension during surgery. ■ Acute congestive heart failure.

Unlabeled uses: In combination with dopamine to reduce afterload in hypertensive patient with myocardial infarction. ■ Treatment of left ventricular failure in combination with oxygen, morphine, and a loop diuretic.

CONTRAINDICATIONS

Compensatory hypertension (e.g., arteriovenous shunt or coarctation of the aorta); known inadequate cerebral circulation; emergency surgery on moribund patients.

PRECAUTIONS

Use only when adequate personnel and appropriate equipment are available for continuous monitoring. ■ Precipitous decreases in BP can occur quickly. Can lead to irreversible ischemic injuries or death. ■ Cyanide toxicity can occur with doses less than the average effective dose and will begin to occur as the maximum dose of 10 mcg/kg/min is approached. May be rapid, serious, and lethal. ■ Methemoglobinemia may begin to occur within 16 hours if larger doses are required. ■ Use caution in hypothyroidism, increased intracranial pressure, liver or renal impairment, and the elderly. ■ May increase ischemia in myocardial infarction.

Monitor: Determine patency of vein; avoid extravasation. ■ Continuous automatic BP monitoring is mandatory (intra-arterial pressure sensor preferred). Never allow systolic BP to fall below 60 mm Hg. ■ Monitor pulmonary wedge pressure in patients with myocardial infarction or severe congestive heart failure. ■ Monitor acid/base balance and venous oxygen concentration; may indicate cyanide toxicity. ■ Oral antihypertensive agents may be given concomitantly to maintain ongoing BP regulation. Reduced nitroprusside sodium dose may be indicated; see [Dose Adjustments](#). ■ Measure blood thiocyanate levels daily if dose is 3 mcg/kg/min (1 mcg/kg/min in the anuric patient). Desired level of steady-state thiocyanate is less than 1 mmol/L. Coadministration of sodium thiosulfate in doses 5 to 10 times that of nitroprusside sodium has been used to avoid toxicity with larger doses or necessary long-term therapy. May potentiate hypotensive action; use with extreme caution. ■ In controlled hypotension, monitor blood loss and correct hypovolemia before and during surgery. ■ Persistent hypotension (lasting more than 1 to 10 minutes) after nitroprusside sodium is discontinued is due to another source. Monitor for sodium retention.

Patient Education: Report IV site burning or stinging promptly. ■ Request assistance to ambulate.

Maternal/Child: Category C: safety for use in pregnancy and in pediatric patients not yet established. Has caused cyanide toxicity in fetuses of ewes, but not in humans. ■ Discontinue breast-feeding.

Elderly: See [Dose Adjustments](#) and [Precautions](#). ■ Hypotensive effects may be increased. ■ Consider age-related renal impairment.

DRUG/LAB INTERACTIONS

Potentiated by **ganglionic blocking agents** (e.g., trimethaphan [Arfonad]), **volatile liquid anesthesia** (e.g., halothane), and **circulatory depressants**. ■ Will cause profound hypotension with **diazoxide**.

SIDE EFFECTS

Usually occur with too-rapid rate of infusion and are reversible: abdominal pain, apprehension, bradycardia, coma, decreased platelet aggregation, diaphoresis, dizziness, ECG changes, flushing, headache, hypotension (profound), ileus, increased intracranial pressure, muscle twitching, nausea, palpitations, rash, restlessness, retching, retrosternal discomfort, venous streaking. With prolonged therapy or overdose, cyanide intoxication (air hunger, bright red venous blood, confusion, elevated cyanide levels, marked clinical deterioration, metabolic acidosis, and death), hypothyroidism, or methemoglobinemia (chocolate brown blood, impaired oxygen delivery even though cardiac output and arterial PO_2 are adequate) can occur.

ANTIDOTE

At first sign of side effects, decrease rate of administration. Never allow systolic BP to fall below 60 mm Hg. If BP begins to rise or side effects persist, notify the physician. Hemodialysis or peritoneal dialysis may be indicated for thiocyanate levels over 10 mg/dL. For massive overdose with signs of cyanide toxicity or tachyphylaxis, discontinue nitroprusside sodium. Cyanide antidote kits contain all needed medications (see sodium nitrite/sodium thiosulfate monograph for complete information). Administer amyl nitrite inhalations for 15 to 30 seconds each minute until 3% sodium nitrite solution can be initiated as an IV infusion or immediately start the infusion (4 to 6 mg/kg) over 2 to 4 minutes. Monitor BP carefully; may cause hypotension that will also require treatment. Next, inject sodium thiosulfate 150 to 200 mg/kg (usually about 12.5 Gm or 50 mL of the 25% solution) in 50 mL of 5% dextrose in water IV over 10 minutes. Observe patient. If signs of overdose reappear, may repeat the previously described process after 2 hours; but use one half the original dosage. Sodium nitrite provides a buffer for cyanide by converting HgB into methemoglobin; sodium thiosulfate converts cyanide into thiocyanate, which is then excreted in urine. For hypotension, slow or discontinue the IV and put the patient in Trendelenburg position. Should improve in 1 to 10 minutes. Correct hypotension with vasopressors (e.g., dopamine). Treat methemoglobinemia with methylene blue 1 to 2 mg/kg. Use with caution if considerable amounts of cyanide are bound to methemoglobin.

NOREPINEPHRINE BITARTRATE **BBW**

Vasopressor

(nor-ep-ih-NEF-rin by-TAR-trayt)

Levarterenol Bitartrate, Levophed

pH 3 to 4.5

USUAL DOSE

8 to 12 mcg/min initially. Other clinicians suggest an initial dose of 0.5 to 1 mcg/min titrated to maintain the desired BP range. Usual maintenance dose is 2 to 4 mcg/min (AHA recommendation is 0.1 to 0.5 mcg/kg/min; titrate to response). Larger doses may be given safely as long as the patient remains hypotensive and blood volume depletion is corrected. Up to 30 mcg/min may be required in patients with refractory shock. 2 mg bitartrate equals 1 mg of norepinephrine. All doses are expressed in terms of norepinephrine.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established.

Begin with an initial dose of 0.05 to 0.1 mcg/kg/min. Titrate up to a maximum dose of 2 mcg/kg/min to maintain desired BP. AHA recommends 0.1 to 2 mcg/kg/min in advanced life support. Another source suggests 0.05 to 0.3 mcg/min. Initiate the infusion at 0.1 mcg/kg/min and titrate to desired BP. A third source suggests 2 mcg/M²/min. Titrate to maintain desired BP, but do not exceed 6 mcg/min.

DOSE ADJUSTMENTS

Lower-end initial doses may be indicated in the elderly based on potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Must be diluted in 250 to 1,000 mL of D5W or D5NS and given as an infusion. 4 mg (4 mL) in 1 L of diluent equals 4 mcg/mL. Final concentration based on fluid volume requirements of the patient. Administration in a dextrose solution reduces loss of potency resulting from oxidation. NS without dextrose is not recommended. Phentolamine (Reg-*itine*) 5 to 10 mg and/or heparin sodium to provide 100 to 200 units/hr may be added to the diluent to prevent any sloughing, necrosis, and/or thrombosis from slight leakage along the vein pathway.

Storage: Before dilution, store at CRT; protect from light.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Consult pharmacist; may be inactivated by solutions with a pH above 6. **Incompatible** with whole blood; administer through **Y-site** or a separate IV line. Avoid contact with iron salts, alkalis, or oxidizing agents.

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), calcium chloride, calcium gluconate, ciprofloxacin (Cipro IV), dimenhydrinate, dobutamine, heparin, hydrocortisone sodium succinate (Solu-Cortef), magnesium sulfate, meropenem (Merrem IV), methylprednisolone (Solu-Medrol), multivitamins (M.V.I.), potassium chloride (KCl), ranitidine (Zantac), succinylcholine, verapamil.

Y-site: Amiodarone (Nexterone), anidulafungin (Eraxis), argatroban, bivalirudin (Angio-max), caspofungin (Cancidas), ceftaroline (Teflaro), cisatracurium (Nimbex), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, dopamine, doripenem (Doribax), epinephrine (Adrenalin), esmolol (Brevibloc), famotidine (Pepcid IV), fenoldopam (Corlopan), fentanyl (Sublimaze), furosemide (Lasix), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), labetalol, lorazepam (Ativan), meropenem (Merrem IV), micalfungin (Mycamine), midazolam (Versed), milrinone (Primacor), morphine, mycophenolate mofetil (CellCept IV), nicardipine (Cardene IV), ni-

troglycerin IV, nitroprusside sodium, pantoprazole (Protonix IV), potassium chloride (KCl), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), telavancin (Vibativ), vasopressin, vecuronium.

RATE OF ADMINISTRATION

See Usual Dose. Use the slowest possible flow rate to correct hypotension gradually and maintain adequate or preset BP. Some response should be noted within 1 to 2 minutes of IV administration. Use of an infusion pump or microdrip (60 gtt/mL) is an aid to correct evaluation of dose. Reduce infusion rate gradually. Avoid sudden discontinuation.

Norepinephrine (Levophed) Infusion Rate						
Desired Dose	4 mg in 1,000 mL D5W or D5NS 2 mg in 500 mL D5W or D5NS 4 mcg/mL			8 mg in 1,000 mL D5W or D5NS 4 mg in 500 mL D5W or D5NS 8 mcg/mL		
	mcg/min	mcg/hr	mL/min	mL/hr	mcg/hr	mL/min
2 mcg/min	120	0.5	30	120	0.25	15
3 mcg/min	180	0.75	45	180	0.375	22.5
4 mcg/min	240	1	60	240	0.5	30
6 mcg/min	360	1.5	90	360	0.75	45
8 mcg/min	480	2	120	480	1	60
9 mcg/min	540	2.25	135	540	1.125	67.5
10 mcg/min	600	2.5	150	600	1.25	75
11 mcg/min	660	2.75	165	660	1.375	82.5
12 mcg/min	720	3	180	720	1.5	90

ACTIONS

Levarterenol is the levo-isomer of norepinephrine. It is a sympathomimetic drug that functions as a peripheral vasoconstrictor (alpha-adrenergic action) and inotropic stimulator of the heart and dilator of coronary arteries (beta-adrenergic action). Dilates the coronary arteries more than twice as much as epinephrine can. It is rapidly inactivated in the body by various enzymes and excreted in changed form in the urine.

INDICATIONS AND USES

All hypotensive states, including those associated with spinal anesthesia, blood reactions, drug reactions, hemorrhage, myocardial infarction, pheochromocytectomy, septicemia, surgery, sympathectomy, and trauma. ■ Adjunct in treatment of cardiac arrest and profound hypotension.

CONTRAINDICATIONS

Do not use in hypotension from blood loss unless an emergency, in mesenteric or peripheral vascular thrombosis, or with cyclopropane or halothane (inhalant) anesthesia.

PRECAUTIONS

Whole blood or plasma should be given in a separate IV site. May be given through Y-tube connection. ■ Use caution in the elderly and in those with peripheral vascular disease or ischemic heart disease. ■ Use caution in previously hypertensive patients. Raise BP no more than 40 mm Hg below pre-existing systolic pressure. ■ Use caution in patients with allergies; some formulations contain sulfites. ■ Therapy may be continued until the patient can maintain own BP. Decrease dosage gradually.

Monitor: Check BP every 2 minutes until stabilized at the desired level. Check every 5 minutes thereafter during therapy. Avoid hypertension. One source suggests limiting rise in BP in previously hypertensive patients to no more than 40 mm Hg below previously systolic normal. ■ Observe for hypovolemia and replace fluids immediately. In an emergency, norepinephrine can be effective in a hypovolemic state before fluid replace-

ment has been accomplished. ■ Check flow rate and injection site constantly. ■ Infusion should be through a large vein, preferably the antecubital vein, to prevent complications of prolonged peripheral vasoconstriction. Avoid veins in the hands, ankles, and legs. Use of the femoral vein may be considered. ■ Causes severe tissue necrosis, sloughing, and gangrene. Insert a plastic IV catheter or similar intravascular device at least 6 inches long well into the large vein chosen to prevent extravasation into any surrounding tissue; see **Dilution**. ■ Blanching along the vein pathway is a preliminary sign of extravasation. Change the injection site. ■ See **Drug/Lab Interactions**.

Patient Education: Report IV site burning or stinging promptly. ■ Request assistance to ambulate.

Maternal/Child: Category C: use only if clearly needed; benefits must outweigh risks. ■ Use caution in breast-feeding.

Elderly: See **Precautions**. ■ Lower-end initial doses may be indicated; see **Dose Adjustments**. ■ Differences in response versus younger patients not documented.

DRUG/LAB INTERACTIONS

Pressor effects may be potentiated by **amphetamines, anesthetics, antihistamines, tricyclic antidepressants** (e.g., desipramine [Norpramin]), **rauwolfia alkaloids** (e.g., reserpine), **thyroid preparations, and methylphenidate** (Ritalin). ■ May cause severe hypertension with **ergot alkaloids and guanethidine** (Ismelin), and severe prolonged hypertension with **MAO inhibitors** (e.g., selegiline [Eldepryl]). ■ May cause hypotension and bradycardia with **hydantoins** (e.g., phenytoin [Dilantin]). ■ **Halogenated hydrocarbon anesthetics** (e.g., halothane) may cause serious arrhythmias. ■ Interacts in numerous and sometimes contradictory ways with many drugs.

SIDE EFFECTS

Rare when used as directed; anxiety, arrhythmias (e.g., bradycardia and VT), chest pain, decreased cardiac output, dyspnea, headache, ischemia, necrosis caused by extravasation, pallor, photophobia, seizures, vomiting. Persistent headache may indicate overdose and severe hypertension. Gangrene has been reported.

ANTIDOTE

To prevent sloughing and necrosis in areas where extravasation has occurred, use a fine hypodermic needle to inject 5 to 10 mg of phentolamine (Regitine) diluted in 10 to 15 mL of NS liberally throughout the tissue in the extravasated area. Phentolamine causes immediate and conspicuous local hyperemic changes if the area is infiltrated within 12 hours. Treatment should be started as soon as extravasation is recognized. Atropine may be used to counteract the bradycardia. Notify physician of any side effect. Should a sudden or uncontrolled hypertensive state occur, discontinue levarterenol, notify the physician, and if necessary, treat with an adrenergic blocking agent (e.g., phentolamine [Regitine] or phenoxybenzamine [Dibenzylin]).

OCTREOTIDE ACETATE

(ok-TREE-oh-tide AS-ah-tayt)

Antidiarrheal**Growth hormone suppressant****Octreotide Acetate PF, Sandostatin****pH 3.9 to 4.5****USUAL DOSE**

Usually given SC. Check label, confirm for IV use; Sandostatin LAR Depot is for IM use only; see **Precautions**. In most situations begin with a lower dose to allow gradual tolerance to GI side effects. Increase gradually based on patient response and tolerance. Begin SC or IM (LAR Depot) dosing as soon as practical.

Antidiarrheal (GI tumor): 50 mcg once or twice daily. Increase gradually if indicated.

Antidiarrheal (unlabeled for AIDS): 100 mcg as an IV bolus over 10 minutes. Follow with a continuous infusion, intermittent infusion, or bolus dose of 10 mcg/hr. Increase gradually to 100 mcg/hr. When adequate control is achieved, decrease to 75 mcg/hr. SC dose range is from 100 mcg up to 3,000 mcg/24 hr.

Carcinoid tumors: 100 to 600 mcg/24 hr in equally divided doses 2 to 4 times daily during first 2 weeks of therapy (50 to 300 mcg every 12 hours or 25 to 150 mcg every 6 hours). Average total daily dose ranges from 300 to 450 mcg, but therapeutic response is obtained with ranges from 50 to 750 mcg. Up to 1,500 mcg/day has been used in selected patients.

Carcinoid crisis (unlabeled): 100 mcg as an IV bolus. May be given to treat carcinoid crisis during anesthesia or given before induction of anesthesia as a prophylactic measure.

Vasoactive intestinal peptide tumors: Average dose range is 200 to 300 mcg/24 hr in equally divided doses 2 to 4 times daily during first 2 weeks of therapy (100 to 150 mcg every 12 hours or 50 to 75 mcg every 6 hours). Average total daily dose ranges from 150 to 750 mcg but therapeutic response usually achieved with doses under 450 mcg/24 hr.

Treatment of GI bleeding (unlabeled): Begin with a loading dose of 50 to 100 mcg. Follow with a continuous infusion of 25 to 50 mcg/hr for 1 to 5 days. Intermittent infusion or bolus doses may be substituted for the continuous infusion.

Growth hormone suppression (acromegaly): 50 mcg every 8 hours is the initial dose. Increase dose gradually as indicated by IGF-1 levels; see **Monitor**. Acromegaly has been suppressed at doses of 300 to 500 mcg/24 hr. May be maintained at home with infusions through an implantable IV or SC pump or SC dosing of 50 to 100 mcg every 8 hours.

Antihypoglycemic: Life-threatening hypoglycemia secondary to insulinoma (unlabeled): 100 mcg as an IV bolus.

Reduce output from GI or pancreatic fistulas (unlabeled): 50 to 200 mcg every 8 hours. In one study, 250 mcg/hr was given as a continuous infusion for 48 hours, followed with SC dosing. Fistula became dry within 72 hours and eventually closed.

PEDIATRIC DOSE

Experience is limited, and doses are **unlabeled**. See **Maternal/Child**.

Intractable diarrhea: 1 to 10 mcg/kg of body weight/24 hr. May be given as a single daily dose or divided and given every 12 hours. Dose may be increased within the recommended range by 0.3 mcg/kg/dose every 3 days as needed. Maximum dose is 1,500 mcg/24 hr.

Diarrhea associated with graft versus host: 1 mcg/kg/dose bolus followed by 1 mcg/kg/hr as a continuous infusion has been used.

DOSE ADJUSTMENTS

In all situations dose adjustment may be required on a daily basis to maintain symptomatic control. After initial 2 weeks of therapy, gradually decrease dose to achieve therapeutically effective maintenance dose. ■ Reduce dose in the elderly; half-life extended and clearance decreased. Start at the lower end of the dosing range. Consider the greater

frequency of decreased organ function and of concomitant disease or drug therapy. ■ Half-life markedly extended in severe renal failure requiring dialysis. Reduction of maintenance dose indicated. ■ See [Drug/Lab Interactions](#).

DILUTION

Available in several different concentrations and formulations; read label carefully. May be given undiluted or may be diluted with 50 to 200 mL of NS or D5W and given as an intermittent infusion or further diluted and given as a continuous infusion.

Storage: Before use store in refrigerator (2° to 8° C [36° to 46° F]) or at CRT for 14 days; protect from light. May store at room temperature on day of use. Diluted solution stable for 24 hours. Multi-dose vial must be dated on opening and discarded after 14 days.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists TPN as **incompatible** (forms a conjugate that decreases effectiveness). If used as an additive with insulin, octreotide markedly increases adsorption of insulin and reduces insulin availability.

One source suggests the following **compatibilities**:

Additive: Heparin.

Y-site: 6% Hydroxyethyl starch (Voluven), pantoprazole (Protonix IV).

RATE OF ADMINISTRATION

IV injection: A single dose over 3 minutes.

Intermittent infusion: A single dose over 15 to 30 minutes.

Continuous infusion: Give at a rate consistent with the required hourly dose in an amount of fluid appropriate for the specific patient.

ACTIONS

A long-acting octapeptide. Mimics the actions of the natural hormone somatostatin, suppressing secretion of serotonin, gastroenteropancreatic peptides (e.g., gastrin, vasoactive intestinal peptide, insulin, glucagon, secretin, motilin, pancreatic polypeptide), and growth hormone. Decreases splanchnic blood flow. Stimulates fluid and electrolyte absorption from GI tract and prolongs GI transit time. These pharmacologic actions provide a means of treating the symptoms associated with metastatic carcinoid tumors (flushing and diarrhea) and vasoactive intestinal peptide (VIP)-secreting tumors (watery diarrhea). Other actions include inhibition of gallbladder contractility and bile secretion and suppression of thyroid-stimulating hormone (TSH) secretion. Distribution from plasma is rapid. About 65% bound to plasma protein. Half-life longer than the natural hormone (1.7 to 1.9 hours compared to 1 to 3 minutes). Action may extend to 12 hours. Some excreted unchanged in urine.

INDICATIONS AND USES

To suppress or inhibit the severe diarrhea and flushing episodes associated with carcinoid tumor. ■ Treatment of profuse watery diarrhea associated with vasoactive intestinal peptide tumors (VIPomas). ■ Treatment of acromegaly to suppress growth hormone and achieve normalization of growth hormone and IGF-1 levels.

Unlabeled uses: Treatment of severe diarrhea in patients with AIDS; treatment of chemotherapy-induced diarrhea. Carcinoid crisis during anesthesia, adjunct to treatment of life-threatening hypoglycemia, treatment of GI bleeding. Adjunct to pancreatectomy and treatment of GI or pancreatic fistulas.

CONTRAINDICATIONS

Sensitivity to octreotide acetate or any of its components.

PRECAUTIONS

IV use is limited to emergency situations. SC injection with rotation of injection sites is preferred route of administration. ■ Sandostatin LAR Depot must be administered intragluteally but has the advantage of extending the interval between injections to every 4 weeks. ■ May decrease size of tumors and slow rate of growth and metastases. Data not definitive. ■ May inhibit gallbladder contractility and decrease bile secretion. ■ Use

caution in patients with diabetes. In patients with type I diabetes, octreotide is likely to affect glucose regulation, and insulin requirements may be decreased. Severe, symptomatic hypoglycemia has been reported. In nondiabetics and type II diabetics with partially intact insulin reserves, octreotide may result in decreased insulin levels and hyperglycemia. Glucose tolerance and antidiabetic treatment should be closely monitored. ■ Cardiac abnormalities (e.g., arrhythmias, bradycardia, conduction abnormalities, QT prolongation) have been reported. More common in patients with acromegaly; see [Side Effects](#). ■ Suppresses thyroid-stimulating hormone. May cause hypothyroidism.

Monitor: Observe for transient hyperglycemia or hypoglycemia during induction and dose changes because of changes in balance of hormones (e.g., insulin, glucagon, and growth hormone). ■ Monitor fluids and electrolytes carefully. ■ 5-HIAA, plasma serotonin, and plasma substance P may be useful lab studies to evaluate patient response with carcinoid tumor. Measurement of plasma vasoactive intestinal peptide will be helpful in VIPoma. ■ In acromegaly, initial response may be monitored with growth hormone levels at 1- to 4-hour intervals for 8 to 12 hours after a dose. IGF-1 levels every 2 weeks and/or multiple growth hormone levels taken 0 to 8 hours after administration may be used to make dose adjustments. Goal is to achieve growth hormone levels less than 5 ng/mL or IGF-1 (somatomedin C) levels less than 1.9 units/mL in males and less than 2.2 units/mL in females. After stabilization, IGF-1 or growth hormone levels should be re-evaluated at 6-month intervals. ■ In patients with acromegaly who have received irradiation, octreotide should be withdrawn yearly for 4 weeks to assess disease activity. If growth hormone or IGF-1 levels increase and S/S recur, octreotide therapy should be resumed. ■ Can alter fat absorption and decrease gallbladder motility; observe for gallbladder disease. Baseline and periodic ultrasound of gallbladder and bile ducts indicated in long-term SC therapy. Periodic fecal fat and carotene studies also indicated. ■ Pancreatitis has been reported. Monitor pancreatic enzymes as indicated. ■ Depressed B₁₂ levels have been observed. Monitor in prolonged therapy. ■ Monitor baseline and periodic thyroid function tests (TSH, total, and/or free T₄), especially in long-term SC therapy. ■ See [Dose Adjustments](#) and [Drug/Lab Interactions](#).

Patient Education: Instruct patient and/or family in appropriate skills if self-administration indicated. To avoid or lessen incidence of GI side effects, schedule injections between meals and at bedtime. ■ In women with acromegaly being treated with octreotide, normalization of GH and IGF-1 may restore fertility. Adequate contraception is recommended.

Maternal/Child: Category B: although studies do not indicate harm to the fetus or infants, use in pregnancy and breast-feeding only if clearly needed. ■ Safety and effectiveness for use in pediatric patients not established; see Literature. In post-marketing reports, hypoxia, necrotizing enterocolitis, and death have been reported, most notably in pediatric patients under 2 years of age, many of which had serious underlying co-morbid conditions. Relationship to octreotide not established.

Elderly: See [Dose Adjustments](#). ■ Response similar to that seen in younger patients; however, may be more sensitive to side effects; observe carefully.

DRUG/LAB INTERACTIONS

Use caution in patients receiving concomitant **beta-blockers** (e.g., atenolol [Tenormin], propranolol), **calcium channel blockers** (e.g., diltiazem [Cardizem], verapamil), or **any agents used for fluid and electrolyte balance**. Will require adjustment in these therapies as symptoms are controlled by octreotide. ■ May affect absorption of **orally administered medications**. ■ May inhibit effectiveness of **cyclosporine** and may result in transplant rejection. ■ Markedly increases adsorption of **insulin** and reduces availability. ■ Concurrent use with **oral antidiabetic agents, glucagon, growth hormone, or insulin** may cause hypoglycemia or hyperglycemia. Monitor patient carefully and give adjunct dose of these agents as indicated. ■ May increase availability of **bromocriptine** (Parlodel). ■ Suppression of growth hormones may cause a decreased clearance of drugs metabolized by selected cytochrome P₄₅₀ enzymes. Use caution with concurrent use of **drugs metabolized by**

CYP3A4 (e.g., cisapride [Propulsid], erythromycin, HMG-CoA reductase inhibitors [lovastatin (Mevacor) and simvastatin (Zocor)], itraconazole [Sporanox], oral midazolam [Versed], quinidine, terfenadine).

SIDE EFFECTS

Most side effects are of mild to moderate severity and of short duration. Abdominal pain/discomfort, abnormal stools, anorexia, anxiety, biliary sludge, cholelithiasis, constipation, convulsions, depression, diarrhea, dizziness, drowsiness, fatigue, fat malabsorption, flatulence, fluttering sensation, GI bleeding, headache, heartburn, hepatitis, hyperesthesia, hyperglycemia, hypoglycemia, increase in liver enzymes, insomnia, irritability, jaundice, nausea, pancreatitis, pounding in the head, rectal spasm, swollen stomach, vomiting. In rare cases, GI side effects may resemble intestinal obstruction with progressive abdominal distention, severe epigastric pain, abdominal tenderness, and guarding. Many other side effects occur in fewer than 1% of patients. Side effects that occur more often in patients with acromegaly include cardiac abnormalities (e.g., sinus bradycardia, ECG changes [including QT prolongation], conduction abnormalities, and arrhythmias) and hypothyroidism.

Post-Marketing: Thrombocytopenia.

ANTIDOTE

Keep physician informed of all side effects. A dose adjustment of either octreotide or other concomitant therapies may be required. Symptomatic and supportive treatment may be indicated. Overdose will cause hyperglycemia or hypoglycemia depending on tumor involved and endocrine status of patient. Discontinue octreotide temporarily, notify the physician, and monitor the patient carefully. Symptomatic treatment should be sufficient.

OFATUMUMAB

(oh-FAT-oo-moo-mab)

Monoclonal antibody
Antineoplastic

Arzerra

pH 5.5

USUAL DOSE

Premedication: 30 minutes to 2 hours before ofatumumab administration, premedicate with oral acetaminophen 1,000 mg (or equivalent), an oral antihistamine (cetirizine [Zyrtec] 10 mg [or equivalent]), or an IV antihistamine (diphenhydramine [Benadryl] 50 mg), and an IV corticosteroid (prednisolone 100 mg or equivalent [e.g., methylprednisolone (Solu-Medrol) 80 mg]).

Ofatumumab: 300 mg as the initial dose (Dose 1). Follow 1 week later with 2,000 mg weekly for 7 doses (Doses 2 through 8), followed 4 weeks later with 2,000 mg every 4 weeks for 4 doses (Doses 9 through 12).

DOSE ADJUSTMENTS

Ofatumumab: Interrupt infusion for an infusion reaction of any severity. ■ Do not resume the infusion for a Grade 4 infusion reaction. ■ If a Grade 1, 2, or 3 infusion reaction resolves with interruption or remains less than or equal to Grade 2, resume infusion with the following modifications based on the initial grade of the infusion reaction: *Grade 1 or 2:* infuse at one-half of the previous infusion rate. *Grade 3:* infuse at 12 mL/hr. After resuming the infusion, the rate may be increased according to the chart in Rate of Administration. ■ No dose adjustment is indicated for age, body weight, gender, or renal impairment.

Premedication: Do not reduce the corticosteroid dose for Doses 1, 2, and 9. ■ Doses 3 through 8: If a Grade 3 or greater infusion reaction did not occur with the preceding dose, gradually reduce the corticosteroid dose with successive infusions. ■ Doses 10 through 12: If a Grade 3 or greater infusion reaction did not occur with Dose 9, administer prednisolone 50 to 100 mg or equivalent (e.g., methylprednisolone [Solu-Medrol] 40 to 80 mg).

DILUTION

Do not shake ofatumumab in vial or solution. Should be a clear to opalescent colorless solution and may have some visible translucent-to-white particles. Prepare all doses in 1,000 mL of NS.

300-mg dose: Withdraw and discard 15 mL from a 1,000 mL bag of NS. Withdraw 5 mL from each of 3 (100-mg) vials of ofatumumab and add to the bag of NS.

2,000-mg dose: Withdraw and discard 100 mL from a 1,000 mL bag of NS. Withdraw 50 mL from each of 2 (1,000-mg) vials of ofatumumab and add to the bag of NS.

Mix diluted solution by gentle inversion. Administer using an infusion pump, the provided in-line filter(s), and PVC administration sets.

Filters: Must be administered with the in-line filter provided by the manufacturer. An in-line filter set is supplied with each 1,000-mg vial.

Storage: Refrigerate vials and prepared solutions between 2° to 8° C (36° to 46° F). Protect vials from light and do not freeze. Start infusion within 12 hours of preparation and discard the prepared solution after 24 hours.

COMPATIBILITY

Manufacturer states, “Do not mix ofatumumab with, or administer as an infusion with, other medicinal products.” Flush the IV line with NS before and after each dose. “No **incompatibilities** observed with polyvinylchloride or polyolefin bags and administration sets.”

RATE OF ADMINISTRATION

Use of an in-line filter (provided by manufacturer), an infusion pump, and PVC administration set is required. Flush the IV line with NS before and after each dose.

Dose 1: Initiate infusion at a rate of 3.6 mg/hr (12 mL/hr).

Dose 2: Initiate infusion at a rate of 24 mg/hr (12 mL/hr).

Doses 3 through 12: Initiate infusion at a rate of 50 mg/hr (25 mL/hr).

If there is no infusion reaction, the rate may be increased every 30 minutes as described in the following table. Do not exceed these infusion rates.

Ofatumumab Infusion Rates			
Interval After Start of Infusion	Dose 1*	Dose 2†	Doses 3 to 12†
0 to 30 minutes	12 mL/hr	12 mL/hr	25 mL/hr
31 to 60 minutes	25 mL/hr	25 mL/hr	50 mL/hr
61 to 90 minutes	50 mL/hr	50 mL/hr	100 mL/hr
91 to 120 minutes	100 mL/hr	100 mL/hr	200 mL/hr
>120 minutes	200 mL/hr	200 mL/hr	400 mL/hr

*Dose 1 = 300 mg (0.3 mg/mL).

†Doses 2 and 3 through 12 = 2,000 mg (2 mg/mL).

ACTIONS

A CD20-directed cytolytic monoclonal antibody (also known as an IgG1k human monoclonal antibody). The CD20 molecule is expressed on normal B lymphocytes and on B-cell CLL. Ofatumumab binds specifically to both the small and large extracellular loops of the CD20 molecule, resulting in B-cell lysis. Possible mechanisms of cell lysis include complement-dependent cytotoxicity and antibody-dependent, cell-mediated cytotoxicity. Decreases circulating CD19-positive B-cells. With depletion of B-cells, the clearance of ofatumumab decreases substantially after subsequent infusions compared with the first infusion.

INDICATIONS AND USES

Treatment of patients with chronic lymphocytic leukemia (CLL) refractory to fludarabine (Fludara) and alemtuzumab (Campath).

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Do not administer as an IV push or bolus. For IV infusion only. ■ Administered under the supervision of a physician experienced in the use of antineoplastic therapy in a facility equipped to monitor the patient and respond to any medical emergency. ■ Serious infusion reactions have occurred and seem to occur more frequently with the first 2 infusions; see **Monitor**. ■ Prolonged (1 week or longer) severe neutropenia and thrombocytopenia can occur. ■ Progressive multifocal leukoencephalopathy (PML) can occur. ■ Screen patients at high risk for hepatitis B virus (HBV) before initiating therapy. Fulminant and fatal hepatitis B virus (HBV) infection and reactivation can occur in patients following treatment with ofatumumab. Insufficient data exist regarding the safety of ofatumumab administration in patients with active hepatitis. ■ Obstruction of the small intestine can occur. ■ A protein substance, it has the potential for producing immunogenicity. ■ No studies of ofatumumab use in impaired hepatic or renal function have been conducted; use with caution. ■ Not approved for use in patients with moderate to severe COPD. Grade 3 bronchospasm has been reported in patients with moderate to severe COPD who have received ofatumumab. ■ See **Monitor**.

Monitor: Obtain baseline CBC and platelet counts and monitor at regular intervals during therapy. Increase the frequency of monitoring in patients who develop Grade 3 or 4 cytopenias. ■ Monitor for S/S of infusion reactions. S/S have included abdominal pain, angioedema, back pain, bronchospasm, cardiac ischemia/infarction, dyspnea, fever, flushing, hypertension, hypotension, laryngeal edema, pulmonary edema, rash, syncope, and urticaria. ■ Monitor for new onset of or changes in pre-existing neurologic signs or symptoms. Evaluation for PML includes consultation with a neurologist, brain MRI, and lumbar puncture. ■ Monitor carriers of hepatitis B closely for clinical and laboratory

signs of active HBV infection during treatment and for 6 to 12 months after the last infusion. ■ Monitor for S/S of bowel obstruction. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Use of prophylactic antiemetics may be indicated to reduce nausea and/or vomiting and to increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated.

Patient Education: Blood counts will be required at regular intervals. ■ Avoid vaccination with live virus vaccines. ■ Promptly report symptoms of the following potential side effects: bleeding, easy bruising or petechiae, fatigue, infection (e.g., cough, fever), infusion reactions (e.g., breathing problems, chills, fever, rash that occurs within 24 hours of infusion), pallor or worsening weakness, new or worsening abdominal pain or nausea, new or worsening neurologic S/S, worsening fatigue or yellow discoloration of skin or eyes. ■ See Appendix D, p. 1255.

Maternal/Child: Category C: use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ Use caution if breast-feeding. The effects of local gastrointestinal and limited systemic exposure to ofatumumab are unknown. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Numbers of patients over 65 years of age in studies were not sufficient to determine a response that might differ from younger patients.

DRUG/LAB INTERACTIONS

Formal drug-drug interaction studies have not been conducted. ■ Do not administer **live virus vaccines** to patients who have recently received ofatumumab.

SIDE EFFECTS

Most common side effects are anemia, bronchitis, cough, diarrhea, dyspnea, fatigue, fever, nausea, neutropenia, pneumonia, rash and upper respiratory infections. Fever, infections (some fatal) including pneumonia and sepsis, infusion reactions, and neutropenia were the most common serious side effects. Other side effects reported include back pain, chills, headache, hepatitis B reactivation, herpes zoster, hypertension, hypotension, insomnia, intestinal obstruction, muscle spasms, nasopharyngitis, peripheral edema, PML, sinusitis, tachycardia, thrombocytopenia, and urticaria.

ANTIDOTE

Notify physician of significant side effects. Temporarily discontinue the infusion for an infusion reaction, angina, or S/S of myocardial ischemia. Delay therapy for serious infection or serious hematologic toxicity until the infection or adverse event resolves. Treatment of most reactions will be supportive. Discontinue medication permanently for severe reactions, including Grade 4 infusion reactions or S/S of PML or in patients who develop viral hepatitis or reactivation of viral hepatitis. Infusion reactions may be treated with acetaminophen, antiemetics (e.g., ondansetron [Zofran]), antihistamines (e.g., diphenhydramine [Benadryl]), or corticosteroids (e.g., hydrocortisone) as indicated. Discontinue ofatumumab and provide supportive therapy in overdose. Treat hypersensitivity reactions with epinephrine, antihistamines, and corticosteroids as needed. Resuscitate as indicated.

ONDANSETRON HYDROCHLORIDE

(on-DAN-sih-tron hy-droh-KLOR-eyed)

Antiemetic
5HT₃ receptor antagonist

Ondansetron HCl PF, Zofran, Zofran PF

pH 3 to 4

USUAL DOSE

Nausea associated with emetogenic cancer chemotherapy in adult and pediatric patients 6 months to 18 years of age: Three 0.15 mg/kg doses of body weight up to a maximum of 16 mg/dose. Administer the first dose 30 minutes before giving emetogenic cancer chemotherapy (e.g., cisplatin, methotrexate). Given as an intermittent infusion over 15 minutes. Repeat 0.15 mg/kg dose up to a maximum of 16 mg/dose at 4 and 8 hours after the first dose. Concurrent use with dexamethasone may improve the effectiveness of ondansetron in controlling cisplatin-induced nausea and vomiting.

Postoperative nausea in adults and pediatric patients weighing 40 kg or more: 4 mg *undiluted* before anesthesia induction or postoperatively if the patient did not receive prophylactic antiemetics and experiences nausea or vomiting within 2 hours after surgery. Although repeat doses are not recommended by the manufacturer, they have been given. Benefit of repeat dosing has not been demonstrated in studies.

PEDIATRIC DOSESee [Maternal/Child](#).

Nausea associated with emetogenic cancer chemotherapy agents in pediatric patients 6 months to 18 years of age: See [adult dose](#).

Postoperative nausea in pediatric patients 1 month to 12 years of age: Given immediately before or following anesthesia induction or postoperatively if the patient did not receive prophylactic antiemetics and experiences nausea or vomiting shortly after surgery. See comments under [Usual Dose](#).

Weight 40 kg or less: 0.1 mg/kg.**Weight more than 40 kg:** See [Adult dose](#).**DOSE ADJUSTMENTS**

No dose adjustment required for the elderly or in renal disease. ■ Before emetogenic chemotherapy, a single maximum daily dose of 8 mg is suggested for patients with severe hepatic disease (Child-Pugh score of 10 or greater).

DILUTION**IV injection:** 4 mg dose may be given undiluted.**Intermittent infusion:** A single dose should be diluted in 50 mL of NS or D5W. See [Compatibility](#).

Storage: Store unopened vials between 2° and 30° C (36° and 86° F). Protect from light. Stable at RT under normal lighting conditions for 48 hours after dilution. However, manufacturer recommends that the dilution not be used beyond 24 hours. Shake vigorously to resolubilize if a precipitate forms at the stopper/vial interface.

COMPATIBILITY[\(Underline Indicates Conflicting Compatibility Information\)](#)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be mixed with alkaline solutions as a precipitate may form" and lists as **compatible** and stable for up to 48 hours with D5¹/₂NS, D5NS, or 3% NaCl injection; see [Dilution](#).

One source suggests the following **compatibilities**:

Additive: Not recommended by manufacturer. Cisplatin (Platinol), cyclophosphamide (Cytosan), cytarabine (ARA-C), dacarbazine (DTIC), dexamethasone (Decadron), doxorubicin (Adriamycin), etoposide (VePesid), hydromorphone (Dilaudid), mannitol (Osmirol), meperidine (Demerol), meropenem (Merrem IV), methotrexate, morphine.

Y-site: Aldesleukin (Proleukin), amifostine (Ethylol), amikacin (Amikin), azithromycin (Zithromax), aztreonam (Azactam), bleomycin (Blenoxane), carboplatin (Paraplatin),

carmustine (BiCNU), caspofungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), cefoxitin (Mefoxin), ceftaroline (Teflaro), ceftazidime (Fortaz), cefuroxime (Zinacef), chlorpromazine (Thorazine), cisatracurium (Nimbex), cisplatin (Platinol), cladribine (Leustatin), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), daunorubicin (Cerubidine), dexamethasone (Decadron), dexmedetomidine (Precedex), diphenhydramine (Benadryl), docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), doxycycline, droperidol (Inapsine), etoposide (VePesid), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), gallium nitrate (Ganite), gemcitabine (Gemzar), gentamicin, heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), linezolid (Zyvox), magnesium sulfate, mannitol, mechlorethamine (nitrogen mustard), melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), mesna (Mesnex), methotrexate, metoclopramide (Reglan), mitomycin (Mutamycin), mitoxantrone (Novantrone), morphine, oxaliplatin (Eloxatin), paclitaxel (Taxol), pentostatin (Nipent), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), remifentanyl (Ultiva), sodium acetate, streptozocin (Zanosar), telavancin (Vibativ), teniposide (Vumon), thiotepa, ticarcillin/clavulanate (Timentin), toptecan (Hycamtin), vancomycin, vinblastine, vincristine, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

IV injection (postop N/V in adults and pediatric patients): A single 4-mg dose over at least 30 seconds; 2 to 5 minutes preferred.

Intermittent infusion adults and pediatric patients: A single dose equally distributed over 15 minutes.

ACTIONS

A selective antagonist of serotonin (5HT₃) receptors. 5-HT₃ receptors are found both peripherally on vagal nerve terminals and centrally in the chemoreceptor trigger zone. It is unclear whether antiemetic action in chemotherapy-induced nausea and vomiting is mediated centrally, peripherally, or at both sites. Chemotherapeutic agents such as cisplatin increase the release of serotonin from specific cells in the GI tract, causing emesis. By antagonizing these receptors, chemotherapy-induced nausea and vomiting are prevented. Lacks the activity at dopamine receptors of metoclopramide (Reglan), so it does not cause the same level of sedation. No correlation between plasma levels and antiemetic activity. Metabolized by specific hepatic enzymes of the cytochrome P₄₅₀ isoenzyme system; onset of action is prompt. Half-life is 3.5 to 5.5 hours. Excreted in feces and urine.

INDICATIONS AND USES

Prevention of nausea and vomiting associated with initial and repeat courses of emetogenic cancer chemotherapy, including high-dose cisplatin. ■ Prevention or treatment of postoperative nausea. ■ Used orally (available as liquid, tablets, and orally disintegrating tablets) for prevention of nausea and vomiting, including postoperative N/V, and N/V associated with chemotherapy and radiotherapy (including total body irradiation). Approved for IM injection as an alternative to IV in the prevention of postoperative nausea and vomiting.

CONTRAINDICATIONS

Hypersensitivity to ondansetron or any of its components. ■ Concomitant use of apomorphine.

PRECAUTIONS

Sterile technique imperative in withdrawing a single dose from the multidose vial. Available as a single-dose vial and in 4- and 8-mg tablets. ■ Cross-sensitivity has been reported between ondansetron and other 5HT₃ receptor agonists (e.g., dolasetron [Anzemet] or granisetron [Kytril]). ■ Use with caution in patients with hepatic impairment.

Clearance is decreased; see [Dose Adjustments](#). ■ Not indicated instead of gastric suction. Use in abdominal surgery or in patients with chemotherapy-induced nausea and vomiting may mask a progressive ileus or gastric distention. ■ May cause ECG changes, including QT-interval prolongation (prolongs the QT interval in a dose-dependent manner). Post-marketing cases of torsades de pointes have been reported. Avoid use in patients with congenital long QT syndrome. Use with caution in patients with electrolyte abnormalities (e.g., hypokalemia, hypomagnesemia), CHF, or bradyarrhythmias or in patients taking other medicines that may lead to QT prolongation; see [Monitor](#) and [Drug/Lab Interactions](#).

Monitor: Observe closely. Ambulate slowly to avoid orthostatic hypotension. ■ ECG monitoring is recommended in patients with electrolyte abnormalities (e.g., hypokalemia, hypomagnesemia), CHF, or bradyarrhythmias or in patients taking other medicines that may lead to QT prolongation. ■ Stool softeners or laxatives may be required to prevent constipation.

Patient Education: May cause dizziness or fainting; request assistance to ambulate. ■ Promptly report difficulty breathing, tightness in the chest, or wheezing. ■ May cause cardiac arrhythmias; discuss personal and family history and all prescription and non-prescription medications with a health care professional.

Maternal/Child: Category B: no evidence of impaired fertility or harm to fetus. Use in pregnancy only if potential benefit justifies potential risk. ■ Use caution if required during breast-feeding. ■ Information limited in pediatric cancer patients under 6 months of age and in pediatric surgical patients under 1 month of age. ■ In general, surgical and cancer pediatric patients younger than 18 years tend to have a higher clearance compared with adults, leading to a shorter half-life (2.9 hours). Infants 1 to 4 months of age have a lower clearance, resulting in a longer half-life (6.7 hours).

Elderly: See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Does not appear to induce or inhibit the **cytochrome P₄₅₀ isoenzyme system**. However, it is metabolized by this system, and medications that induce or inhibit this system may affect its clearance and half-life. Dose adjustment is not recommended. ■ **Phenytoin** (Dilantin), **carbamazepine** (Tegretol), and **rifampin** (Rifadin) increase clearance and decrease levels of ondansetron. Dose adjustment not recommended. ■ Concomitant use of **apomorphine** may result in profound hypotension and loss of consciousness; see [Contraindications](#). ■ Concomitant use with **tramadol** (Ultram) may result in reduced analgesic activity of tramadol. ■ Coadministration does not affect pharmacokinetics or pharmacodynamics of temazepam (Restoril). ■ Does not alter respiratory depressant effects produced by alfentanil (Alfenta) or the degree of neuromuscular blockade produced by atracurium (Tracrium). ■ Carmustine (BiCNU), etoposide (VePesid), etoposide phosphate (Etoposfos), and cisplatin (Platinol) do not affect the pharmacokinetics of ondansetron. ■ Ondansetron does not increase the concentrations of high-dose methotrexate. ■ Has been used with cyclophosphamide (Cytosan), doxorubicin (Adriamycin), etoposide (VePesid), fluorouracil (5-FU), ifosfamide (Ifex), methotrexate, mitoxantrone (Novantrone), and vincristine.

SIDE EFFECTS

The most common side effects reported were diarrhea, fever, and headache.

Adults: Agitation, arrhythmias (including ventricular and supraventricular tachycardia, PVCs, atrial fibrillation, and bradycardia), chest pain, cold sensation, constipation, cramps, diarrhea, dizziness, drowsiness, ECG alterations (including second-degree heart block, QT-interval prolongation, and ST segment depression), faintness, fatigue, fever, flushing, headache, hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, cardiopulmonary arrest, hypotension, laryngospasm, shock, shortness of breath, stridor, urticaria), hiccups, hypokalemia, injection site reactions, oculogyric crisis, pain (abdominal, joint, musculoskeletal, rib cage, shoulder), palpitations, paresthesia, pruritus, shivering, transient blurred vision or blindness, transient elevation of AST or ALT,

urinary retention. Other side effects have occurred (e.g., extrapyramidal reaction, rash) in fewer than 1% of patients. Overdose caused sudden blindness in one patient.

Infants 1 to 24 months: Bronchospasm, diarrhea, fever, post-procedural pain.

Pediatric patients 2 to 12 years of age: Anxiety/agitation, drowsiness/sedation, fever, headache, wound problems.

Post-Marketing: Arthralgia; dyspnea; ECG changes, including QT/QTc interval prolongation; erythema; hepatitis, hepatic necrosis, hepatic failure, and death (in patients receiving potentially hepatotoxic cytotoxic chemotherapy and antibiotics; etiology unclear); hyperhidrosis; increased alkaline phosphatase (ALP), gamma-glutamyl transferase (GGT), and bilirubin; jaundice; laryngeal edema; lethargy; torsades de pointes; ventricular fibrillation.

ANTIDOTE

Most side effects will be treated symptomatically. Keep physician informed as indicated. Overdose of 10 times the usual dose has not caused significant problems. Treat anaphylaxis and resuscitate as necessary.

OXACILLIN SODIUM

(ox-ah-SILL-in SO-dee-um)

Antibacterial
(penicillinase-resistant penicillin)

Bactocill

pH 6 to 8.5

USUAL DOSE

Mild to moderate infections: 250 to 500 mg every 4 to 6 hours.

Severe infections: Increase to 1 Gm every 4 to 6 hours. Up to 1.5 to 2 Gm every 4 to 6 hours has been used to treat *acute or chronic osteomyelitis*. Continue therapy for at least 48 hours after patient becomes afebrile and asymptomatic and cultures are negative. Usual duration of therapy is at least 14 days for severe staphylococcal infections and longer (4 to 6 weeks) for endocarditis and osteomyelitis.

PEDIATRIC DOSE

Infants and pediatric patients under 40 kg: Mild to moderate infections: 50 mg/kg of body weight/24 hr in equally divided doses every 6 hours (12.5 mg/kg of body weight every 6 hours).

Severe infections: Increase to 100 mg/kg/24 hr in equally divided doses every 4 to 6 hours (16.7 mg/kg to 33.3 mg/kg every 4 hours or 25 mg/kg to 50 mg/kg every 6 hours). Maximum dose is 12 Gm/24 hr.

NEONATAL DOSE

25 mg/kg/day in equally distributed doses every 6 hours (6.25 mg/kg every 6 hours) for premature infants and neonates.

Another source suggests:

Under 1,200 Gm; less than 7 days of age: 25 mg/kg every 12 hours.

Under 2,000 Gm; less than 7 days of age: 25 to 50 mg/kg every 12 hours.

Under 2,000 Gm; 1 to 4 weeks of age: 25 to 50 mg/kg every 8 hours.

Under 1,200 Gm; 1 to 4 weeks of age: 25 mg/kg every 12 hours.

2,000 Gm or more; less than 7 days of age: 25 to 50 mg/kg every 8 hours.

2,000 Gm or more; 1 to 4 weeks of age: 25 to 50 mg/kg every 6 hours.

DOSE ADJUSTMENTS

Decreased dose may be required in severe renal impairment.

DILUTION

Each 500 mg or fraction thereof should be diluted in 5 mL of SWFI or NS for injection. May be further diluted for intermittent or continuous infusion in 50 to 1,000 mL of D5W,

D5NS, NS, LR, or other **compatible** IV solutions to a final concentration of 0.5 to 40 mg/mL (see literature or chart on inside back cover). Available prediluted and in ADD-Vantage vials for use with ADD-Vantage infusion containers.

Storage: Diluted solution stable for at least 6 hours. See literature. Store Galaxy premixed frozen solutions at -20°C (-4°F).

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not physically mix with other agents." May degrade in infusion solutions containing acidic agents. Inactivated in solution with aminoglycosides (e.g., amikacin [Amikin], gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

Additive: **Not recommended by manufacturer.** Amikacin (Amikin), chloramphenicol (Chloromycetin), dextran 40, dopamine, hetastarch in NS (Hespan), potassium chloride (KCl), verapamil.

Y-site: Acyclovir (Zovirax), cyclophosphamide (Cytoxan), diltiazem (Cardizem), doxapram (Dopram), famotidine (Pepcid IV), fluconazole (Diflucan), foscarnet (Foscavir), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), labetalol, levofloxacin (Levaquin), magnesium sulfate, meperidine (Demerol), methotrexate, milrinone (Primacor), morphine, potassium chloride (KCl), tacrolimus (Prograf), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Too-rapid rate may cause seizures.

IV injection: 1 Gm (10 mL) or fraction thereof slowly over 10 minutes.

Intermittent IV: A single dose over 10 to 30 minutes.

Infusion: May be administered in specific IV solutions (check literature) over up to a 6-hour period.

ACTIONS

A semi-synthetic penicillinase-resistant penicillin used for its bactericidal activity against gram-positive organisms, primarily penicillinase-producing *Staphylococcus aureus*. Mode of action involves inhibition of bacterial cell wall biosynthesis. Highly resistant to inactivation by staphylococcal penicillinase. Readily distributes into most body fluids and tissues except spinal fluid. Binds to serum proteins, primarily albumin. Excreted primarily as unchanged drug in urine. Nonrenal elimination includes hepatic inactivation and excretion in bile. Half-life is 30 minutes. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Infection caused by susceptible strains of penicillinase-producing staphylococci.

CONTRAINDICATIONS

Known sensitivity to any penicillin or cephalosporin (not absolute; see [Precautions](#)). Prediluted solutions containing dextrose may be contraindicated in patients with known allergies to corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients undergoing penicillin therapy; most likely to occur in patients with a history of penicillin hypersensitivity or sensitivity to multiple allergens. ■ There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies necessary to determine susceptibility of the causative organism to oxacillin. It should not be used in infections caused by an organism susceptible to penicillin G or an organism other than a resistant staphylococcus. Modify antimicrobial therapy as indicated by C/S. ■ To reduce the development of drug-resistant bacteria and maintain its effective-

ness, oxacillin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Superinfection caused by overgrowth of nonsusceptible organisms is a possibility. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with oxacillin. ■ Change to appropriate oral therapy as soon as practical.

Monitor: Periodic liver, kidney, and hematopoietic studies are advised (CBC with differential, urinalysis, BUN, SCr, AST [SGOT], ALT [SGPT]). ■ Electrolyte imbalance and cardiac irregularities from sodium content are possible. Contains up to 4.02 mEq sodium/Gm. May aggravate CHF. Observe for hypokalemia. ■ May cause thrombophlebitis; observe carefully and rotate infusion sites. ■ See [Drug/Lab Interactions](#).

Patient Education: May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: use only if clearly needed. ■ May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Safety and effectiveness for use in pediatric patients not established. Limited experience in use on premature infants and neonates. Use with caution. Elimination rate markedly reduced in neonates.

Elderly: Response similar to that seen in younger patients. Consider age-related organ impairment and concomitant disease or drug therapy. ■ See [Precautions/Monitor and Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **aminoglycosides** (e.g., amikacin [Amikin], gentamicin). Synergism may be inconsistent; see [Compatibility](#). ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Potentiated by **probenecid** (Benemid); toxicity may result. ■ May potentiate **heparin**. ■ Concomitant use with **beta-adrenergic blockers** (e.g., propranolol) may interfere with treatment of a hypersensitivity reaction to oxacillin. ■ May decrease clearance and increase toxicity of **methotrexate**. ■ May inhibit effectiveness of **oral contraceptives**; breakthrough bleeding or pregnancy could result. ■ May cause false values in **common lab tests**; see literature.

SIDE EFFECTS

Relatively infrequent: diarrhea, elevated AST, hepatic dysfunction, hypersensitivity with anaphylaxis, nausea, pruritus, skin rash, thrombophlebitis, transient hematuria in newborns, urticaria, vomiting. Hypersensitivity myocarditis (fever, eosinophilia, rash, sinus tachycardia, ST-T changes, and cardiomegaly) and CDAD can occur. Higher-than-normal doses may cause neurologic adverse reactions including convulsions, especially with impaired renal function.

ANTIDOTE

Notify the physician of any adverse symptoms. For severe symptoms, discontinue the drug, treat hypersensitivity reactions (antihistamines, epinephrine, corticosteroids), and resuscitate as necessary. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis or peritoneal dialysis are minimally effective in overdose.

OXALIPLATIN **BBW**

(OX-al-ee-plah-tin)

Antineoplastic

Eloxatin

USUAL DOSE

Both indications: Given in combination with 5-FU and leucovorin calcium in a dose schedule that repeats every 2 weeks. When used as adjuvant therapy in patients with stage III colon cancer, a treatment period repeated every 2 weeks for 6 months is recommended (a total of 12 cycles). For advanced disease, treatment is recommended until disease progression or unacceptable toxicity. For information on 5-FU and leucovorin calcium, see respective monographs. Prehydration is not required. Premedication with antiemetics recommended; see **Monitor**. Some clinicians are administering magnesium and calcium before and after oxaliplatin to decrease neurotoxicity.

Day 1: Oxaliplatin 85 mg/M² and leucovorin calcium 200 mg/M², both given as an IV infusion over 120 minutes at the same time in separate bags using a Y-line. Follow with 5-FU 400 mg/M² IV bolus given over 2 to 4 minutes, followed by 5-FU 600 mg/M² in 500 mL D5W (recommended) as a 22-hour continuous infusion.

Day 2: Leucovorin calcium 200 mg/M² IV infusion over 120 minutes. Follow with 5-FU 400 mg/M² IV bolus given over 2 to 4 minutes, followed by 5-FU 600 mg/M² in 500 mL D5W (recommended) as a 22-hour continuous infusion.

DOSE ADJUSTMENTS

Decrease starting dose to 65 mg/M² in patients with severe renal impairment (CrCl less than 30 mL/min).

Advanced colorectal cancer: Dose adjustments are based on clinical toxicities. Reduce dose of oxaliplatin to 65 mg/M² in patients who experience persistent Grade 2 neurosensory events that do not resolve. (See **Monitor** for study-specific neurotoxicity scale.) The infusional 5-FU/leucovorin calcium regimen need not be altered. ■ Reduce dose of oxaliplatin to 65 mg/M² and 5-FU by 20% (300 mg/M² bolus and 500 mg/M² as a 22-hour infusion) in patients who develop Grade 3 or 4 gastrointestinal toxicity (despite prophylactic treatment), Grade 4 neutropenia, or Grade 3 or 4 thrombocytopenia. Delay next dose until neutrophils are greater than or equal to $1.5 \times 10^9/L$ [1,500 cells/mm³] and platelets are greater than or equal to $75 \times 10^9/L$ [75,000 cells/mm³].

Adjuvant therapy in stage III colon cancer (postoperative): Reduce dose of oxaliplatin to 75 mg/M² in patients who experience persistent Grade 2 neurosensory events that do not resolve (NCICTC scale version 1 used). The infusional 5-FU/leucovorin calcium regimen need not be altered. ■ Reduce dose of oxaliplatin to 75 mg/M² and 5-FU by 20% (300 mg/M² bolus and 500 mg/M² as a 22-hour infusion) in patients who develop Grade 3 or 4 gastrointestinal toxicity (despite prophylactic treatment), Grade 4 neutropenia, or Grade 3 or 4 thrombocytopenia. Delay next dose until neutrophils are greater than or equal to $1.5 \times 10^9/L$ (1,500 cells/mm³) and platelets are greater than or equal to $75 \times 10^9/L$ (75,000 cells/mm³).

Both indications: Consider discontinuing therapy in patients with persistent Grade 3 neurosensory events.

DILUTION

Specific techniques required; see Precautions.

Do not reconstitute or dilute with a sodium chloride solution (e.g., NS, ½NS, ¼NS) or other chloride-containing solutions. Available as a powder for solution and as a concentrate for solution. To reconstitute powder for solution, add 10 mL (for the 50-mg vial) or 20 mL (for the 100-mg vial) of SWFI or D5W. Both the reconstituted powder for solution and the concentrate for solution must be further diluted with 250 to 500 mL of D5W. **Do not use NS or any chloride-containing solutions; see Compatibility.** Do not use needles or administration sets with aluminum parts; a precipitate may form, and potency may decrease.

Storage: Store unopened vials containing powder for solution under normal lighting conditions at CRT. Store vials with concentrate in the original carton at CRT. Protect vials with concentrate from light and do not freeze. The reconstituted solution may be stored up to 24 hours under refrigeration. After final dilution with 250 to 500 mL of D5W, the solution may be stored for up to 6 hours at RT (20° to 25° C [68° to 77° F]) or up to 24 hours under refrigeration.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states oxaliplatin “is **incompatible** in solution with alkaline medications or media (such as basic solutions of 5-FU) and must not be mixed with these or administered simultaneously through the same infusion line. *The infusion line should be flushed with D5W prior to administration of any concomitant medication.*” Reconstitution or final dilution must not be performed with a sodium chloride solution or other chloride-containing solutions. Do not use needles or administration sets with aluminum parts; a precipitate may form, and potency may decrease.

Sources suggest the following **compatibilities:**

Y-site: Manufacturer lists leucovorin calcium. Another source lists bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), chlorpromazine (Thorazine), cyclophosphamide (Cytosan), dexamethasone (Decadron), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dolasetron (Anzemet), dopamine, doxorubicin (Adriamycin), droperidol (Inapsine), enalaprilat (Vasotec IV), epirubicin (Ellence), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fentanyl (Sublimaze), furosemide (Lasix), gemcitabine (Gemzar), granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), irinotecan (Camptosar), leucovorin calcium, lorazepam (Ativan), magnesium sulfate, mannitol (Osmitol), meperidine (Demerol), mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), mitoxantrone (Novantrone), morphine, nalbuphine, ondansetron (Zofran), paclitaxel (Taxol), palonosetron (Aloxi), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), theophylline, topotecan (Hycamtin), verapamil, vincristine, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

The infusion line should be flushed with D5W prior to administration of any concomitant medication.

Day 1: Oxaliplatin and leucovorin calcium are given as infusions and equally distributed over 120 minutes. Given at the same time in separate bags using a Y-line. When complete, flush the IV line with D5W. Follow with a **5-FU bolus** administered over 2 to 4 minutes, followed by a **5-FU continuous infusion** equally distributed over 22 hours. ■ Increasing the infusion time of oxaliplatin from 2 to 6 hours may mitigate acute toxicities. The infusion times for 5-FU and leucovorin calcium need not be altered.

Day 2: Leucovorin calcium is given as an infusion equally distributed over 120 minutes. Follow with a **5-FU bolus** administered over 2 to 4 minutes, followed by a **5-FU continuous infusion** equally distributed over 22 hours.

ACTIONS

A platinum-based antineoplastic agent. Undergoes nonenzymatic conversion to active derivatives that inhibit DNA replication and transcription. Cytotoxicity is cell-cycle non-specific. Rapidly distributed into tissues or eliminated in the urine. Highly protein bound. Undergoes rapid and extensive nonenzymatic biotransformation. No evidence of cytochrome P₄₅₀-mediated metabolism. Major route of elimination is renal excretion.

INDICATIONS AND USES

Used in combination with infusional 5-FU and leucovorin calcium for the treatment of patients with advanced colorectal cancer and for adjuvant therapy of stage III colon cancer patients who have undergone complete resection of the primary tumor.

CONTRAINDICATIONS

Hypersensitivity to oxaliplatin or other platinum-containing compounds (e.g., carboplatin [Paraplatin], cisplatin [Platinol]).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities and emergency resuscitation equipment and supplies must always be available. ■ Hypersensitivity and anaphylactic-like reactions, some fatal, have been reported and may occur within minutes of administration and during any cycle. Re-challenge is contraindicated. See [Side Effects](#) and [Antidote](#). ■ Use with caution in patients with renal impairment; see [Dose Adjustments](#). ■ Associated with two types of neuropathy. *The first type is an acute, reversible, primarily peripheral sensory neuropathy that is of early onset, occurs within hours or 1 to 2 days of dosing, resolves within 14 days, and frequently recurs with further dosing.* Symptoms may be precipitated or exacerbated by exposure to cold temperature or cold objects. Usually presents as transient paresthesia (abnormal sensation [e.g., burning, prickling]), dysesthesia (decreased sensitivity to stimulation), and hypoesthesia (impairment of any sense, especially touch) in the hands, feet, perioral area, or throat. *The second type is a persistent (lasting more than 14 days), primarily peripheral, sensory neuropathy that is usually characterized by paresthesias, dysesthesias, and hypoesthesias but may also include deficits in proprioception (stimulus of the sensory end organs [e.g., muscles, tendons]), which can interfere with daily activities (e.g., writing, buttoning, swallowing, and walking).* May occur without any prior acute neuropathy event. Symptoms may or may not improve with discontinuation of oxaliplatin. ■ Posterior reversible encephalopathy syndrome (PRES) has been reported; see [Monitor](#). ■ Has been associated with pulmonary fibrosis, which may be fatal; see [Monitor](#). ■ Hepatotoxicity has been reported; see [Monitor](#). ■ See [Drug/Lab Interactions](#).

Monitor: CBC with differential, platelet count, and blood chemistries (including ALT, AST, bilirubin, and creatinine) are recommended before each cycle. See [Dose Adjustments](#) and [Precautions](#). ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Monitor for S/S of PRES; may include abnormal vision from blurriness to blindness, altered mental functioning, headache, or seizures. Diagnosis of PRES is based on confirmation by brain imaging. ■ Monitor for unexplained respiratory symptoms such as nonproductive cough, dyspnea, crackles, or radiologic pulmonary infiltrates. Discontinue oxaliplatin until pulmonary investigation rules out interstitial lung disease or pulmonary fibrosis. ■ Monitor for S/S of neuropathy (e.g., transient paresthesia [abnormal sensation (e.g., burning, prickling)], dysesthesia [decreased sensitivity to stimulation], and hypoesthesia [impairment of any sense, especially touch] in the hands, feet, perioral area, or throat). Neurotoxicity scale used during advanced colorectal cancer studies differed from National Cancer Institute toxicity grading. Grading scale for paresthesias/dysesthesias was as follows: Grade 1, resolved and did not interfere with functioning; Grade 2, interfered with function but not daily activities; Grade 3, pain or functional impairment that interfered with daily activities; Grade 4, persistent impairment that is disabling or life threatening. ■ Nausea and vomiting may be severe. Prophylactic administration of antiemetics, including 5HT₃ blockers (e.g., ondansetron [Zofran]), with or without dexamethasone (Decadron), is recommended. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient.

Patient Education: Avoid pregnancy. Nonhormonal birth control recommended. ■ Report any neurologic symptoms (e.g., confusion or a change in the way you think; headache; numbness, pain, or tingling in extremities; seizures; vision problems; sensitivity to cold; troubled breathing or swallowing). Acute neurosensory toxicity may be precipitated or exacerbated by exposure to cold. Avoid cold drinks and use of ice. Cover exposed skin

prior to exposure to cold temperature. ■ Promptly report persistent vomiting, diarrhea, breathing difficulty, cough, or any sign of infection, allergic reaction, or dehydration. ■ Use caution while driving or using machines; neurologic symptoms (e.g., dizziness), nausea and vomiting, and vision abnormalities (e.g., transient vision loss) may interfere with abilities. ■ Manufacturer supplies a patient information leaflet; read before taking oxaliplatin. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Has been studied in a small number of solid tumors in pediatric patients. No significant response was observed. See manufacturer's literature.

Elderly: The overall rates of adverse events, including Grade 3 and 4 events, were similar for all age-groups. However, the incidence of dehydration, diarrhea, fatigue, Grade 3 to 4 granulocytopenia, hypokalemia, leukopenia, and syncope were higher in patients 65 years of age or older. Adjustment of starting dose is not required.

DRUG/LAB INTERACTIONS

Formal studies have not been performed. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents. ■ Platinum-containing species are eliminated primarily through the kidney; clearance of these products may be decreased by coadministration of potentially **nephrotoxic compounds** (e.g., aminoglycosides [e.g., gentamicin], amphotericin B [all formulations], NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], pamidronate [Aredia], tacrolimus [Prograf]). ■ Oxaliplatin is not metabolized by, nor does it inhibit, cytochrome P₄₅₀ isoenzymes. P₄₅₀-mediated interactions are not anticipated. ■ A prolonged PT and INR (occasionally associated with hemorrhage) has been reported when oxaliplatin is used concomitantly with **anticoagulants** (e.g., warfarin [Coumadin]); close monitoring of PT and INR recommended.

SIDE EFFECTS

Are frequent and numerous. Most common adverse reactions are anemia, diarrhea, fatigue, increased liver function tests (e.g., alkaline phosphatase, total bilirubin, and transaminases), nausea, neutropenia, peripheral sensory neuropathies, stomatitis, thrombocytopenia, and vomiting; see **Precautions**. Other reported reactions include abdominal pain, alopecia, angioedema, anorexia, arthralgia, back pain, chest pain, colitis (including *Clostridium difficile* diarrhea), conjunctivitis, constipation, coughing, deafness, dehydration, dizziness, dyspepsia, dyspnea, dysuria, edema, elevated serum creatinine, epistaxis, fever, flushing, gastroesophageal reflux, hand-foot syndrome, headache, hematuria, hemolytic uremic syndrome, hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, erythema, hypotension, pruritis, rash, urticaria), hypertension, hypokalemia, immunoallergic hemolytic anemia, infection, injection site reaction, insomnia, intestinal obstruction, lacrimation abnormalities, metabolic acidosis, mucositis, pain, pancreatitis, persistent vomiting, pharyngitis, pulmonary fibrosis, rhinitis, rigors, secondary malignancies, taste perversion, thromboembolism, veno-occlusive disease of the liver, visual disorders (e.g., decrease of visual acuity, visual field disturbance, optic neuritis), weight gain. Many other side effects have been reported and may occur.

Overdose: Chest pain, dehydration, diarrhea, dyspnea, enlarged abdomen and Grade 4 intestinal obstruction, hypersensitivity reactions, myelosuppression, nausea and vomiting, neurotoxicity, paresthesia, respiratory failure, severe bradycardia, stomatitis, wheezing, and death.

Post-Marketing: Acute interstitial nephritis, acute tubular necrosis, acute renal failure, colitis (including *Clostridium difficile* diarrhea), convulsions, cranial nerve palsies, dysarthria, fasciculations, hemolytic uremic syndrome, ileus, immunoallergic thrombocytopenia, Lhermitte's sign, metabolic acidosis, perisinusoidal fibrosis, PRES, pulmonary fibrosis and other interstitial lung diseases (sometimes fatal), severe diarrhea/vomiting resulting in hypokalemia, transient vision loss (reversible after oxaliplatin is discontinued).

ANTIDOTE

Notify physician of all side effects. Oxaliplatin may need to be discontinued permanently or until recovery. Slowing of infusion rate may help mitigate acute toxicities. Symptomatic and supportive treatment is indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Treat anaphylaxis with epinephrine, corticosteroids, oxygen, and antihistamines (diphenhydramine). There is no specific antidote. Resuscitate as indicated.

OXYMORPHONE HYDROCHLORIDE

(ox-ee-MOR-fohn hy-droh-KLOR-eyed)

**Opioid analgesic
(agonist)****Opana****pH 2.7 to 4.5****USUAL DOSE**

Individualize dose. Consider age, general condition, and medical status of the patient as well as type and severity of pain and prior analgesic treatment experience.

0.5 mg initially. May repeat every 2 to 4 hours. Up to 1.5 mg may be required.

When seeking the required dose to achieve pain relief for an individual patient, increases in increments of at least 25% of the previous dose are suggested. Lower slightly if pain controlled but patient is too drowsy, or lower dose and increase frequency.

DOSE ADJUSTMENTS

Reduced dose or extended intervals may be required in the elderly, in hepatic or renal disease, and in emphysema. ■ Doses appropriate for the general population may cause serious respiratory depression in vulnerable patients. ■ Reduce dose by one third to one half in patients who are concurrently receiving other CNS depressants; see [Drug/Lab Interactions](#). ■ Increase doses as required if analgesia is inadequate, tolerance develops, or pain severity increases. The first sign of tolerance is usually a reduced duration of effect.

DILUTION

May be given undiluted; however, further dilution with 5 mL of SWFI or NS to facilitate titration is appropriate. May give through Y-tube or three-way stopcock of infusion set.

Storage: Store at CRT. Protect from light.

COMPATIBILITY

Specific information not available.

RATE OF ADMINISTRATION

Rapid IV administration increases the possibility of hypotension and respiratory depression.

A single dose over 2 to 5 minutes. Usually titrated according to symptom relief and respiratory rate.

ACTIONS

A semi-synthetic opioid analgesic closely related to morphine. Ten times more potent than morphine milligram for milligram. Produces a wide range of pharmacologic effects, including analgesia, anxiolysis, cough suppression, diminished GI motility, dysphoria, euphoria, physical dependence, respiratory depression, and somnolence. Onset of action is 5 to 10 minutes. Duration of action is 3 to 6 hours. Metabolized in the liver and excreted in urine and feces. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Relief of moderate to severe pain. ■ Support of anesthesia. ■ Obstetric analgesia. ■ Relief of anxiety in patients with dyspnea associated with pulmonary edema secondary to acute left ventricular dysfunction.

CONTRAINDICATIONS

Acute bronchial asthma, pediatric patients under 12 years of age, diarrhea caused by poisoning until toxic material eliminated, hypercarbia, known hypersensitivity to oxymorphone or other morphine analogs (e.g., codeine), moderate to severe hepatic impairment, paralytic ileus, premature infants and labor and delivery of premature infants, pulmonary edema caused by chemical respiratory irritant, upper airway obstruction.

PRECAUTIONS

Schedule II opioid agonists, including hydromorphone, morphine, oxymorphone, oxycodone, fentanyl, and methadone, have the highest potential for abuse and risk of producing respiratory depression. Alcohol, CNS depressants, and other opioids potentiate the respiratory depressant effects of hydromorphone, increasing the risk of respiratory depression that might result in death; see [Drug/Lab Interactions](#). ■ Use extreme caution in patients with conditions accompanied by hypoxia, hypercapnia, or decreased respiratory reserve such as asthma, COPD, cor pulmonale, severe obesity, sleep apnea syndrome, myxedema, kyphoscoliosis, CNS depression, or coma. May decrease respiratory drive and increase airway resistance to the point of apnea. ■ Use with caution in the elderly or debilitated and in patients known to be sensitive to CNS depressants, such as those with cardiovascular, pulmonary, renal, or hepatic disease. ■ Use extreme caution in craniotomy, head injury, and increased intracranial pressure; respiratory depression and intracranial pressure may be further increased. ■ Can also produce effects on pupillary response and consciousness, which may obscure neurologic signs of further increases in intracranial pressure. ■ Use with caution in patients in circulatory shock. May further reduce cardiac output or BP. ■ Use with caution in acute alcoholism, adrenocortical insufficiency (e.g., Addison's disease), CNS depression, delirium tremens, prostatic hypertrophy, or urethral stricture. ■ Symptoms of acute abdominal conditions may be masked. Can cause spasm of the sphincter of Oddi. Use with caution in patients with biliary tract disease, including acute pancreatitis. ■ May increase ventricular response rate in presence of supraventricular tachycardias. ■ Cough reflex is suppressed. ■ Tolerance to oxymorphone gradually increases. A marked increase in dose may precipitate seizures. ■ Concerns about abuse, addiction, and diversion should not prevent proper management of pain.

Monitor: Oxygen, controlled respiratory equipment, and naloxone (Narcan) must be available. ■ Assess baseline pain, then assess pain with vital signs and/or more frequently if needed. Reassess after administration of oxymorphone and adjust dose or interval as required. ■ Keep patient supine; orthostatic hypotension and fainting may occur. Uncontrolled pain causes sleep deprivation, decreases pain threshold, and increases pain; when pain is finally controlled, expect the patient to sleep more until recovery from sleep deprivation. ■ Adhere to prescribed bowel care regimen to avoid constipation and/or impaction. Maintain adequate hydration.

Patient Education: Avoid alcohol or other CNS depressants (e.g., barbiturates, benzodiazepines [e.g., diazepam (Valium)]). ■ May cause blurred vision, dizziness, or drowsiness; use caution in tasks that require alertness. ■ Request assistance with ambulation. ■ May be habit forming.

Maternal/Child: Category C: safety for use in pregnancy or breast-feeding not established; see [Contraindications](#). ■ Use with caution during labor. May cause respiratory depression in the newborn. ■ Safety for use in pediatric patients under 18 years of age not established.

Elderly: See [Dose Adjustments](#) and [Precautions](#). ■ May be more sensitive to effects (e.g., respiratory depression, constipation, urinary retention). Adverse effects more commonly observed in the elderly include confusion, dizziness, nausea, and somnolence. ■ Lower doses may provide effective analgesia. ■ Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

Potentiated by **phenothiazines and other CNS depressants** such as narcotic analgesics, alcohol, antihistamines, barbiturates, cimetidine (Tagamet), hypnotics, sedatives, MAO inhibitors (e.g., selegiline [Eldepryl]), neuromuscular blocking agents (e.g., atracurium [Tracrium]), and psychotropic agents. Interactive effects resulting in respiratory depression, hypotension, profound sedation, or coma may result with concomitant use. Reduced dosages of both drugs may be indicated. ■ Administration of **agonist/antagonist analgesics** (e.g., butorphanol [Stadol], buprenorphine [Buprenex]) to an opiate-dependent patient receiving a pure opiate may reduce the analgesic effect of the pure opiate and/or precipitate withdrawal symptoms. ■ Concomitant use with **anticholinergics or medications with anticholinergic activity** (e.g., diphenhydramine [Benadryl]) may result in an increased risk of urinary retention and/or severe constipation, which may lead to paralytic ileus. ■ Concomitant use with **propofol** (Diprivan) for the induction of anesthesia may increase the incidence of bradycardia. ■ Plasma **amylase and lipase determinations** may be unreliable for 24 hours following opioid administration.

SIDE EFFECTS

At equianalgesic doses, may cause more nausea, vomiting, and euphoria than morphine.

Abdominal pain, anorexia, biliary colic, blurred vision, bradycardia, bronchospasm, confusion, constipation, diplopia, dizziness, dry mouth, flushing, hallucinations, miosis, paralytic ileus, pruritus, skin rash, urinary retention, urticaria.

Major: Anaphylaxis, hypotension, respiratory depression, somnolence.

ANTIDOTE

Notify the physician of any side effect. If minor side effects progress or any major side effect occurs, discontinue the drug and notify the physician. Treat anaphylaxis as indicated or resuscitate as necessary. Naloxone hydrochloride (Narcan) will reverse serious reactions.

OXYTOCIN INJECTION **BBW**

(ox-eh-TOE-sin in-JEK-shun)

Oxytocic
Antihemorrhagic**Pitocin****pH 2.5 to 4.5****USUAL DOSE**

Determined by uterine response and intended use, dilution, and rate of administration. Oxytocins must be administered by only one route at a time. For instance, do not combine oral and IV routes. Piggyback oxytocin into a physiologic electrolyte IV solution (e.g., NS) without oxytocins; see **Precautions**.

Induction of labor: 0.5 to 1 milliunit/min (mU/min) will deliver 3 to 6 mL/hr of properly diluted solution. See **Dilution** and **Rate of Administration**.

Control of postpartum bleeding: A total dose of 10 units delivered at 10 to 40 mU/min, following delivery of the infant(s) and preferably the placenta(s). See **Dilution** and **Rate of Administration**.

Incomplete or inevitable abortion: A total of 10 units delivered at 10 to 20 mU/min; a second source says 10 to 40 mU/min. See **Dilution** and **Rate of Administration**.

Postabortion hemorrhage (unlabeled): A total of 10 units delivered at 20 to 100 mU/min. See **Dilution** and **Rate of Administration**.

Oxytocin challenge test (unlabeled): Infuse properly diluted oxytocin (10 mU/mL) at an initial rate of 0.5 mU/min. Rate may be gradually increased at 15- to 30-minute intervals to a maximum of 20 mU/min. Discontinue infusion when 3 moderate contractions occur in a 10-minute interval and compare baseline and oxytocin-induced fetal HR. Monitor fetal HR concurrently. Observe signs of fetal distress with contractions. Distress indicates inadequate fetal respiratory capabilities and placental reserve. Stop infusion.

DILUTION

In all situations rotate gently to distribute medication through solution.

Induction of labor: Dilute 1 mL (10 units) in 1 liter of NS, D5W, LR, or D5NS for infusion (10 mU/mL). This dilution is also used for the **oxytocin challenge test**.

Control of postpartum bleeding: Dilute 1 to 4 mL (10 to 40 units) in 1 liter of above infusion fluids (10 to 40 mU/mL).

Incomplete or inevitable abortion/postabortion hemorrhage: Dilute 1 mL (10 units) in 500 mL of above infusion fluids (20 mU/mL).

Storage: Check package insert. Some preparations may require refrigeration; others can be stored at RT.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Rapidly decomposes in the presence of sodium bisulfate.

One source suggests the following **compatibilities**:

Additive: Chloramphenicol (Chloromycetin), sodium bicarbonate, verapamil.

Y-site: Heparin, hydrocortisone sodium succinate (Solu-Cortef), insulin (regular), meperidine (Demerol), morphine, potassium chloride (KCl), warfarin (Coumadin), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Given only as an IV infusion. Use of an infusion pump or other accurate control device is required. In all situations, use the minimum effective rate and monitor strength, frequency, and duration of contractions; resting uterine tone, fetal HR (in induction of labor), and maternal BP at least every 15 minutes or more often if indicated.

Induction of labor: Begin with 0.5 to 1 mU/min (0.05 to 0.1 mL), increase in increments of 1 to 2 mU/min at 30- to 60-minute intervals until contractions simulate normal labor. Maximum dose rarely exceeds 9 to 10 mU/min at term, average is 2 to 5 mU/min. Re-

duce by similar increments when desired frequency of contractions is reached and labor has progressed to 5 to 6 cm. 6 mU/min provides oxytocin levels similar to spontaneous labor. Preterm inductions may require somewhat higher doses (one source suggests a maximum of 20 mU/min); use caution.

Control of postpartum bleeding: Adjust rate of infusion to sustain contractions and control uterine atony. Begin with 10 to 40 mU/min. Increase or decrease rate as indicated. Proceed quickly but with caution because of strength of solution.

Incomplete or inevitable abortion: 10 to 40 mU/min.

Postabortion hemorrhage: 20 to 100 mU/min.

ACTIONS

A synthetic posterior pituitary hormone that will produce rhythmic contraction of uterine smooth muscle. Its effectiveness depends on the level of uterine excitability, which usually increases as a pregnancy progresses. Very rapid acting, it has a shorter duration of action than ergot derivatives (half-life of 1 to 6 minutes). Duration of action is approximately 1 hour. Is the drug of choice for induction of delivery. Probably detoxified in the liver and through enzymatic processes and excreted in the urine. May exhibit antidiuretic and pressor effects at higher doses. Probably crosses the placental barrier in small amounts.

INDICATIONS AND USES

After selective patient evaluation by the physician, it is used to induce or stimulate labor at term or before. ■ Control of postpartum bleeding. ■ Adjunctive therapy in the management of incomplete or inevitable abortion. ■ Treatment of post-abortion hemorrhage. ■ Not indicated for elective induction of labor (i.e., no medical indication for induction).

Unlabeled uses: Oxytocin challenge test.

CONTRAINDICATIONS

Cephalopelvic disproportion, fetal malpresentation, hypersensitivity, hypertonic uterine contractions, lack of satisfactory progress with adequate uterine activity, obstetrical emergencies (e.g., abruptio placentae), prolonged use in uterine inertia, serious medical or obstetric conditions (past or present), toxemia (severe), vaginal delivery contraindicated (e.g., active herpes genitalis, cord presentation or prolapse, invasive cervical carcinoma, total placenta previa and vasa previa). See [Precautions](#).

PRECAUTIONS

A NS IV without oxytocins must be hung, connected by Y-tube or three-way stopcock, and ready for use in adverse reactions. ■ Should be administered only in the hospital; the physician must be immediately available. ■ The use of oxytocin for fetal distress, hydramnios, partial placenta previa, prematurity, borderline cephalopelvic disproportion, or any condition that may cause uterine rupture (e.g., cesarean section [previous], uterine surgery, uterine overdistention, past history of uterine sepsis) is not recommended except in unusual circumstances. ■ Maternal deaths due to hypertensive episodes, subarachnoid hemorrhage, and uterine rupture, as well as fetal deaths due to various causes, have been reported. ■ When used for induction or reinforcement of already existing labor, patients should be carefully selected. Evaluate pelvic adequacy and maternal and fetal conditions before use. ■ Oxytocin challenge test is an antepartum test of uteroplacental insufficiency in high-risk pregnancy. Test done only by a qualified physician.

Monitor: When properly administered, oxytocin should stimulate uterine contractions comparable to normal labor. Monitor BP, fetal heart tones, strength and timing of contractions, and resting uterine tone at least every 15 minutes or more often if indicated. Continuous observation of patient required. ■ Electronic fetal monitoring provides the best means of early detection of overdose. A fetal scalp electrode provides a more accurate recording of fetal HR than external monitoring. ■ Monitor oral fluid intake and observe for signs of fluid retention. Water intoxication has caused maternal death. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Maternal/Child: Has no use before induction of labor; see [Contraindications](#).

DRUG/LAB INTERACTIONS

Severe hypertension can result in the presence of **local anesthesia, regional anesthesia** (caudal or spinal), **and with dopamine, ephedrine, epinephrine, and other vasopressors. Chlorpromazine** (Thorazine) IV will reduce this hypertension. ■ Concurrent use with **cyclopropane anesthesia** may cause hypotension and/or sinus bradycardia with abnormal atrioventricular rhythms.

SIDE EFFECTS

Maternal: Anaphylaxis, cardiac arrhythmias, fatal afibrinogenemia, fluid retention leading to water intoxication and coma, convulsion, and death; hypertension, increased blood loss, nausea, pelvic hematoma, PVCs, postpartum hemorrhage, severe uterine hypertonicity, spasm or contraction; subarachnoid hemorrhage, uterine rupture, vomiting.

Fetal: Bradycardia, brain damage, CNS damage, death, low Apgar scores, neonatal jaundice, retinal hemorrhage, seizures.

ANTIDOTE

Nausea and vomiting are tolerable and can be treated symptomatically. Immediately call the physician's attention to any side effect noted or suspected; many can be fatal. Discontinue the drug immediately for any signs of fetal distress, uterine hyperactivity, tetanic contractions, uterine resting tone exceeding 15 to 20 mm H₂O, or water intoxication. Use of a Y-connection or three-way stopcock, allowing the oxytocin drip to be discontinued while the vein is kept open, is required. Turn mother on side (to prevent fetal anoxia) and administer oxygen. Restriction of fluids, diuresis, hypertonic saline solutions IV, correction of electrolyte imbalance, control of convulsions with cautious use of barbiturates, or the use of magnesium sulfate may be required. These side effects can occur during labor and delivery and into the postpartum period. Careful evaluation and selection of patients eliminate many hazards, but be prepared for an emergency.

PACLITAXEL ■ PACLITAXEL PROTEIN-BOUND PARTICLES FOR INJECTABLE SUSPENSION (ALBUMIN-BOUND) **BBW**

Antineoplastic
(taxane)

(PACK-lih-tax-el)

Onxol, Taxol ■ Abraxane

pH 4.4 to 5.6 ■ not available

USUAL DOSE

Assessment required before dosing: see [Precautions](#), [Monitor](#), and [Dose Adjustments](#).

CONVENTIONAL PACLITAXEL

Several regimens of paclitaxel, alone or in combination with other antineoplastics, are in use. Doses vary, depending on the regimen used. Consult literature. ■ For all uses, premedication, specific parameters, and specific equipment are required before or during administration; see [Premedication](#), [Dose Adjustments](#), and [Precautions/Monitor](#).

Premedication: Must be premedicated before each dose to prevent severe hypersensitivity reactions. Usual regimen includes oral dexamethasone (Decadron) 20 mg 12 and 6 hours before; IV diphenhydramine (Benadryl) 50 mg 30 to 60 minutes before; and an H₂ antagonist (e.g., ranitidine [Zantac] 50 mg or famotidine [Pepcid IV] 20 mg) 30 to 60 minutes before dosing with paclitaxel. When premedicating patients with AIDS-related Kaposi's sarcoma, reduce the dose of dexamethasone to 10 mg at 12 and 6 hours before paclitaxel. The doses of IV diphenhydramine and IV H₂ antagonists remain as above.

Ovarian cancer in previously untreated patients: 135 mg/M² as an infusion over 24 hours. Follow with cisplatin 75 mg/M² as an infusion over 6 to 8 hours. Repeat every 3 weeks. An alternative regimen is paclitaxel 175 mg/M² as an infusion over 3 hours. Follow with cisplatin 75 mg/M² (one source suggests an infusion over 24 hours; another suggests 6 to 8 hours, which would allow for outpatient therapy). Repeat every 3 weeks. See [comments under Usual Dose](#).

Ovarian cancer in patients previously treated with chemotherapy: 135 or 175 mg/M² as an infusion over 3 hours. An alternate regimen suggests the same dose given as a 24-hour infusion. Repeat every 3 weeks. Larger doses, with or without filgrastim (G-CSF, Neupogen), have produced similar responses. See [comments under Usual Dose](#).

Adjuvant treatment of node-positive breast cancer: 175 mg/M² as an infusion over 3 hours. Repeat every 3 weeks for four courses. Administered sequentially to doxorubicin-containing combination therapy. Clinical trials used four courses of doxorubicin and cyclophosphamide. Administer filgrastim (G-CSF) 5 mcg/kg/dose on Days 3 through 10. See [comments under Usual Dose](#).

Breast cancer in patients previously treated with chemotherapy: 175 mg/M² as an infusion over 3 hours. Repeat every 3 weeks. An alternate regimen suggests 175 to 250 mg/M² over 3 hours every 3 weeks. See [comments under Usual Dose](#).

First-line treatment of non-small-cell lung cancer: 135 mg/M² as an infusion over 24 hours. Follow with cisplatin 75 mg/M² over 6 to 8 hours. Repeat every 3 weeks. See [comments under Usual Dose](#). A Canadian source recommends 175 mg/M² as an infusion over 3 hours followed with cisplatin 75 mg/M² over 6 to 8 hours and repeated every 3 weeks.

AIDS-related Kaposi's sarcoma: 135 mg/M² as an infusion over 3 hours. An alternate regimen suggests the same dose given as a 24-hour infusion. Repeat every 3 weeks. Another regimen is 100 mg/M² as an infusion over 3 hours repeated every 2 weeks. Toxicity somewhat increased with 135 mg/M² dose in clinical studies. See [comments under Usual Dose](#).

ABRAXANE

Premedication: Not required.

Metastatic breast cancer (MBC): 260 mg/M² as an infusion over 30 minutes every 3 weeks.

Continued

Non-small cell lung cancer (NSCLC): 100 mg/M² as an infusion over 30 minutes on Days 1, 8, and 15 of each 21-day cycle. Given in combination with carboplatin to an AUC = 6 mg • min/mL on Day 1 only of each 21-day cycle, beginning immediately after the completion of Abraxane administration.

DOSE ADJUSTMENTS

CONVENTIONAL PACLITAXEL

Reduce dose by 20% for subsequent courses in patients who experience severe peripheral neuropathy or severe neutropenia (neutrophils less than 500 cells/mm³) for 1 week or longer. ■ Withhold therapy if neutrophils below 1,500/mm³ or platelets below 100,000/mm³. ■ Dose reduction not required in impaired renal function. ■ In AIDS-related Kaposi's sarcoma the parameters are slightly different. Initiate or repeat paclitaxel only if neutrophil count is equal to or greater than 1,000/mm³; reduce dose of dexamethasone to 10 mg/dose; reduce dose of paclitaxel by 20% in patients who experience severe neutropenia (neutrophils less than 500/mm³ for a week or longer); use concomitant filgrastim (G-CSF) as clinically indicated. ■ Recommendations for dose adjustment of the initial course of therapy in patients with impaired hepatic function are listed in the following chart.

Guidelines for Dose Adjustment of Paclitaxel in Impaired Hepatic Function*			
Degree of Hepatic Impairment			Recommended TAXOL Dose‡
Transaminase Levels		Bilirubin Levels†	
24-Hour Infusion			
<2 × ULN	and	≤1.5 mg/dL	135 mg/M ²
2 to <10 × ULN	and	≤1.5 mg/dL	100 mg/M ²
<10 × ULN	and	1.6-7.5 mg/dL	50 mg/M ²
≥10 × ULN	or	>7.5 mg/dL	Not recommended
3-Hour Infusion			
<10 × ULN	and	≤1.25 × ULN	175 mg/M ²
<10 × ULN	and	1.26-2 × ULN	135 mg/M ²
<10 × ULN	and	2.01-5 × ULN	90 mg/M ²
≥10 × ULN	or	>5 × ULN	Not recommended

*These recommendations are based on clinical trials of dosages for patients without hepatic impairment of 135 mg/M² over 24 hours or 175 mg/M² over 3 hours; data are not available to make dose adjustment recommendations for other regimens (e.g., for AIDS-related Kaposi's sarcoma).

†Differences in criteria for bilirubin levels between the 3- and 24-hour infusion are due to differences in clinical trial design.

‡Dosage recommendations are for the first course of therapy; further dose reduction in subsequent courses should be based on individual tolerance.

ABRAXANE

Withhold therapy if neutrophils below 1,500/mm³ or platelets below 100,000/mm³. For MBC, reduce dose to 220 mg/M² in patients who experience severe neutropenia (neutrophils less than 500 cells/mm³ for 7 days or more) or severe sensory neuropathy. Further reduce dose to 180 mg/M² for subsequent courses if severe neutropenia (less than 500 cells/mm³ for 7 days or more) or severe sensory neuropathy recur. ■ If Grade 3 sensory neuropathy occurs, withhold treatment until resolution to Grade 1 or 2 for **MBC** or until resolution to less than or equal to Grade 1 for **NSCLC**, followed by a dose reduction for all subsequent courses. ■ No dose adjustment is necessary for patients with mild hepatic impairment. Recommendations for a starting dose in patients with hepatic impairment are shown in the following table. Doses for subsequent cycles should be based on patient tolerance.

Abraxane Starting Dose Recommendations for Patients with Hepatic Impairment					
Degree of Hepatic Impairment	SGOT (AST) Levels		Bilirubin Levels	Abraxane Dose*	
				MBC	NSCLC
Mild	<10 × ULN	and	>ULN to ≤1.25 × ULN	260 mg/M ²	100 mg/M ²
Moderate	<10 × ULN	and	1.26 to 2 × ULN	200 mg/M ²	75 mg/M ²
Severe	<10 × ULN	and	2.01 to 5 × ULN	130 mg/M ² †	50 mg/M ² ‡
	>10 × ULN	or	>5 × ULN	Not eligible	Not eligible

MBC, Metastatic breast cancer; NSCLC, non–small cell lung cancer.

*Dose recommendations are for the first course of therapy. The need for further dose adjustments in subsequent courses should be based on individual tolerance.

†A dose increase to 200 mg/M² in subsequent courses should be considered based on individual tolerance.

‡Increase dose to 75 mg/M² in subsequent courses, as tolerated.

- In patients with NSCLC who develop severe neutropenia or thrombocytopenia, withhold therapy until counts recover to an ANC of at least 1,500 cells/mm³ and platelets of at least 100,000 cells/mm³ on Day 1 or to an ANC of at least 500 cells/mm³ and platelets of at least 50,000 cells/mm³ on Day 8 or 15 of the cycle. Upon resumption of dosing, follow dose reduction outlined in the following chart.

Permanent Abraxane Dose Reductions for Hematologic and Neurologic Adverse Drug Reactions in NSCLC			
Adverse Drug Reaction	Occurrence	Weekly Abraxane Dose (mg/M ²)	Every-3-Week Carboplatin Dose (AUC mg•min/mL)
Neutropenic fever (ANC less than 500/mm ³ with fever >38° C) OR Delay of next cycle by more than 7 days for ANC less than 1,500/mm ³ OR ANC less than 500/mm ³ for more than 7 days	First	75 mg/M ²	4.5 mg•min/mL
	Second	50 mg/M ²	3 mg•min/mL
	Third	Discontinue treatment	Discontinue treatment
Platelet count less than 50,000/mm ³	First	75 mg/M ²	4.5 mg•min/mL
	Second	Discontinue treatment	Discontinue treatment
Severe sensory neuropathy (Grade 3 or 4)	First	75 mg/M ²	4.5 mg•min/mL
	Second	50 mg/M ²	3 mg•min/mL
	Third	Discontinue treatment	Discontinue treatment

DILUTION

Specific techniques required; see Precautions.

CONVENTIONAL PACLITAXEL

Must be diluted and given as an infusion. May leach the toxic plasticizer DEHP from PVC infusion bags or sets; prepare and store in bottles (glass, polypropylene) or plastic bags (polypropylene, polyolefin) and administer through polyethylene-lined administration sets. **Compatible** with NS, D5W, D5NS, or D5R. Final concentration of 0.3 to 1.2 mg/mL required. For a 135 mg/M² dose, a large adult (body surface about 2 M²) will receive 270 mg (45 mL of paclitaxel at 6 mg/mL). Will require dilution in an additional 180 mL to make a 1.2 mg/mL concentration or 855 mL to make a 0.3 mg/mL concentra-

tion. Solution may appear hazy. Do not use a chemo-dispensing pin; can cause the stopper to collapse and result in loss of sterility.

ABRAXANE

Available in single-use vials, each containing 100 mg (5 mg/mL after reconstitution with 20 mL of NS). Calculate the exact number of vials needed to achieve the total dosing volume of suspension required.

$$\text{Total \# of vials required} = \text{Total dose (mg)} \div 100 \text{ mg}$$

$$\text{Dosing volume (mL)} = \text{Total dose (mg)} \div 5 \text{ (mg/mL)}$$

For example, a MBC patient with a body surface area (BSA) of 1.73 M² would need a dose of 449.8 mg of Abraxane. 449.8 mg divided by 100 mg equals 4.498 vials, so 5 vials of Abraxane would be needed. 449.8 mg divided by 5 (mg/mL) equals a dosing volume of 90 mL of reconstituted solution.

Reconstitute each 100-mg vial with 20 mL of NS. A specific process is required to avoid foaming or clumping. Over a minimum of 1 minute, slowly inject the NS, directing it to the inside wall of the vial. Do not allow the NS to flow directly onto the lyophilized cake (will cause foaming). Allow each vial to sit for a minimum of 5 minutes while the NS wets the cake. Gently swirl and/or invert each vial slowly for at least 2 minutes until complete dissolution. Avoid generation of foam. If foaming or clumping occurs, allow solution to stand for at least 15 minutes until foam subsides. Solution should be milky and homogenous without visible particulates. If particulates are visible, gently invert to ensure complete resuspension before use.

Inject the calculated volume from each vial into an empty and sterile polyvinyl chloride (PVC) container or a PVC or non-PVC-type infusion bag (a total dosing volume of 90 mL in the previous example).

Filters: *Conventional paclitaxel:* Use of an in-line filter not greater than 0.22 microns required for administration. *Abraxane:* Use of an in-line filter not required or recommended.

Storage: *Conventional paclitaxel:* May be stored at CRT or refrigerated before dilution (may appear precipitated under refrigeration; will redissolve at room temperature). Diluted for infusion, it is stable at room temperature for up to 27 hours. *Abraxane:* Store vials in original package at 20° to 25° C (68° to 77° F). Protect from light. Refrigeration or freezing does not affect stability of the product. Immediate use of reconstituted solution is preferred, but reconstituted vial may be refrigerated at 2° to 8° C (36° to 46° F) for a maximum of 8 hours if necessary. If refrigeration required, return to original carton to protect from light. Ensure complete resuspension after removing from refrigerator by gently inverting. Reconstituted solution in an infusion bag should be used immediately; however, it is stable at 25° C with ambient lighting conditions for up to 4 hours. Discard unused portions of the vial.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

CONVENTIONAL PACLITAXEL

Leaches out plasticizers; see [Dilution](#).

One source suggests the following **compatibilities**:

CONVENTIONAL PACLITAXEL

Additive: Carboplatin (Paraplatin), cisplatin (Platinol), doxorubicin (Adriamycin); see [Drug/Lab Interactions](#).

Y-site: Acyclovir (Zovirax), amikacin (Amikin), aminophylline, ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), bleomycin (Blenoxane), butorphanol (Stadol), calcium chloride, carboplatin (Paraplatin), cefotetan, ceftazidime (Fortaz), ceftriaxone (Rocephin), cisplatin (Platinol), cladribine (Leustatin), cyclophosphamide (Cytosan), cytarabine (ARA-C), dacarbazine (DTIC), dexamethasone (Decadron), diphenhydramine (Benadryl), doripenem (Doribax), doxorubicin (Adriamycin), droperidol (Inapsine), etoposide (VePesid), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fluconazole (Diflucan), fluorouracil (5-FU), furosemide (Lasix), ganciclovir (Cytovene), gemcitabine

(Gemzar), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, mannitol, meperidine (Demerol), mesna (Mesnex), methotrexate, metoclopramide (Reglan), morphine, nalbuphine, ondansetron (Zofran), oxaliplatin (Eloxatin), **palonosetron (Aloxi)**, pemetrexed (Alimta), pentostatin (Nipent), potassium chloride (KCl), prochlorperazine (Compazine), propofol (Diprivan), ranitidine (Zantac), sodium bicarbonate, thiotepa, topotecan (Hycamtin), vancomycin, vinblastine, vincristine, zidovudine (AZT, Retrovir).

ABRAXANE

Manufacturer states, “Use of specialized DEHP-free solution containers or administration sets is not necessary.” Additional specific information not available.

RATE OF ADMINISTRATION

CONVENTIONAL PACLITAXEL

A single dose properly diluted must be equally distributed over 3 hours or as indicated in Usual Dose. Use of an in-line filter not greater than 0.22 microns required. Use of a metriset (60 gtt/mL) or an infusion pump appropriate to control flow. Rate extended to 24 hours in some regimens.

ABRAXANE

A single dose properly reconstituted and equally distributed over 30 minutes. Volume is small; use of an infusion pump or syringe pump is indicated. Use of an in-line filter is not recommended.

ACTIONS

ALL FORMULATIONS

An antineoplastic. A novel antimicrotubule inhibitor. Paclitaxel derived from the bark of pacific yew has now been replaced by paclitaxel produced semisynthetically from a renewable source (needles and twigs of the Himalayan yew). Both are chemically identical. Through specific processes it stabilizes microtubules by preventing depolymerization. This action inhibits the normal dynamic reorganization of the microtubule network essential for vital interphase and mitotic cellular functions. Also induces abnormal bundles of microtubules throughout the cell cycle and multiple asters of microtubules during mitosis. Distribution and/or tissue binding is extensive. Evidence suggests metabolism in the liver via the cytochrome P₄₅₀ isoenzyme system (CYP2C8 and CYP3A4). Terminal half-life ranges from 13.1 to 52.7 hours and is tied to dose and duration of infusion. Excreted primarily as metabolites in feces and, to a lesser extent, in urine.

CONVENTIONAL PACLITAXEL

More active in patients who have not received previous chemotherapy.

ABRAXANE

Consists of albumin-bound paclitaxel nanoparticles. Highly bound to serum proteins; metabolized in the liver, primarily by CYP2C8 and, to a lesser extent, by CYP3A4. Terminal half-life approximately 27 hours. Minimal excretion in urine and feces.

INDICATIONS AND USES

CONVENTIONAL PACLITAXEL

First-line and subsequent therapy for the treatment of advanced carcinoma of the ovary.

- First-line treatment for ovarian cancer in combination with cisplatin.
- Adjuvant treatment of node-positive breast cancer administered sequentially to standard doxorubicin-containing combination chemotherapy. Most effective in estrogen- and progesterone-receptor-negative tumors.
- Metastatic breast cancer refractory to initial chemotherapy or for a relapse within 6 months.
- First-line treatment, in combination with cisplatin, for non-small-cell lung cancer in patients who are not candidates for potentially curative surgery or radiation therapy.
- Second-line treatment of AIDS-related Kaposi’s sarcoma.

ABRAXANE

Treatment of breast cancer after failure of combination chemotherapy for metastatic disease or relapse within 6 months of adjuvant chemotherapy. Prior therapy should have included an anthracycline unless clinically contraindicated.

- First-line treatment of lo-

cally advanced or metastatic non–small cell lung cancer (NSCLC) (in combination with carboplatin) in patients who are not candidates for curative surgery or radiation therapy. **Unlabeled uses: Conventional paclitaxel:** Advanced head and neck cancer. ■ Cancers of the bladder and cervix. ■ Small-cell lung cancer. ■ In combination with other agents for treatment of metastatic breast cancer. ■ Relapsed or refractory testicular cancer and testicular germ cell tumors. ■ Treatment of (unknown primary) adenocarcinoma. **Abraxane:** Recurrent ovarian, fallopian, primary peritoneal cancers, and metastatic pancreatic cancer.

CONTRAINDICATIONS

CONVENTIONAL PACLITAXEL

Baseline neutropenia less than 1,500 cells/mm³ in patients with solid tumors or baseline neutropenia less than 1,000 cells/mm³ in patients with AIDS-related Kaposi's sarcoma. History of prior severe hypersensitivity reactions to paclitaxel or other drugs formulated in polyoxyethylated castor oil (Cremophor EL [e.g., cyclosporine, teniposide]).

ABRAXANE

Baseline neutrophil count less than 1,500 cells/mm³. ■ Patients who experience a severe hypersensitivity reaction to Abraxane should not be re-challenged with the drug.

PRECAUTIONS

ALL FORMULATIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Usually administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency.

CONVENTIONAL PACLITAXEL

Use caution in patients with cardiac conduction abnormalities, CHF, and MI within previous 6 months. ■ Bradycardia, hypertension, and hypotension have been observed but rarely required treatment. Occasionally the infusion must be interrupted or discontinued because of initial or recurrent hypertension; see **Monitor**. ■ Pre-existing neuropathies resulting from prior therapies are not a contraindication for paclitaxel therapy. ■ Various studies show that incidence and severity of neurotoxicity and hematologic toxicity increase with dose, especially above 190 mg/M². ■ Use with caution in patients with a total bilirubin greater than 2 times the ULN. May be at increased risk of toxicity, especially profound myelosuppression; see **Dose Adjustments**. ■ See **Drug/Lab Interactions**.

ABRAXANE

Do not substitute for or with other paclitaxel formulations. ■ Use of gloves recommended. Wash skin immediately if contact occurs. Flush mucous membranes thoroughly with water if contact occurs. Topical exposure may result in tingling, burning, and redness. ■ Premedication to prevent hypersensitivity reactions is not required but may be needed in patients who have had a prior hypersensitivity reaction to Abraxane. Reports of severe and sometimes fatal hypersensitivity reactions have occurred; see **Contraindications**; do not re-challenge patients who have had a severe reaction. ■ Neutropenia is dose dependent and is a dose-limiting toxicity. Do not administer Abraxane to patients with an absolute neutrophil count (ANC) of less than 1,500 cells/mm³. In patients with MBC, resume treatment with every-3-week cycles after ANC recovers to a level greater than 1,500 cells/mm³ and platelets recover to a level greater than 100,000 cells/mm³. In patients with NSCLC, resume treatment (if recommended) at permanently reduced doses for both weekly Abraxane and every-3-week carboplatin after ANC recovers to at least 1,500 cells/mm³ and platelet count recovers to at least 100,000 cells/mm³ on Day 1 or to an ANC of at least 500 cells/mm³ and a platelet count of at least 50,000 cells/mm³ on Days 8 or 15 of the cycle; see **Dose Adjustments**. ■ Sensory neuropathy is dose and schedule dependent and occurs frequently; see **Dose Adjustments**. ■ Has not been studied in patients with renal dysfunction. ■ Use with caution in patients with hepatic impairment; see **Dose Adjustments**. ■ Derived from human albumin; may carry a risk of viral disease or Creutzfeldt-Jakob disease; risk considered extremely remote. ■ Use with concurrent radiotherapy has not been studied. ■ Has not been studied in patients who have had a hypersensitivity reaction to conventional paclitaxel.

Monitor: ALL FORMULATIONS: Neutropenia is dose dependent and is the dose-limiting toxicity. Obtain baseline CBC with differential and platelet count. Monitor frequently during therapy and before each dose. ■ Monitor injection site carefully; avoid extravasation. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

CONVENTIONAL PACLITAXEL: Neutrophil nadir occurs around Day 11; see [Dose Adjustments](#). ■ Monitor VS frequently, particularly during the first hour of the infusion. ■ Consider obtaining a baseline ECG; arrhythmias have occurred. Continuous cardiac monitoring required for all patients with an abnormal baseline ECG or for those who experienced conduction arrhythmias during administration of a previous dose. ■ Monitoring of cardiac function is recommended when paclitaxel is used in combination with doxorubicin; see doxorubicin monograph. ■ Anaphylaxis and severe hypersensitivity reactions characterized by dyspnea, hypotension requiring treatment, angioedema, and generalized urticaria have been reported. Fatal reactions have occurred despite premedication. ■ Most severe hypersensitivity reactions occur in the first hour; chest pain, dyspnea, flushing, and tachycardia were the most frequent initial symptoms; abdominal pain, diaphoresis, extremity pain, and hypertension also occurred. Monitor all vital signs, including BP continuously for the first 30 minutes of the infusion and at frequent intervals after that. Incidence seems to decrease with subsequent doses. ■ Treatment can often be continued in patients with mild hypersensitivity reactions if proper premedication is given. ■ Monitor injection site carefully; avoid extravasation. Incidence of inflammation increased with 24-hour infusions. Injection site reactions may occur during administration or be delayed by 7 to 10 days. Recurrence of skin reactions at a site of previous extravasation following administration of paclitaxel (“recall”) has been reported.

ABRAXANE: Limited infusion time (30 minutes) reduces the likelihood of infusion-related reactions; however, they have been reported; monitor for S/S; see [Precautions](#). ■ Based on patient history, a baseline ECG may be indicated.

Patient Education: ALL FORMULATIONS: Males and females should avoid conception; nonhormonal birth control recommended. ■ Review of monitoring requirements and adverse events before therapy imperative. ■ Report any unusual or unexpected symptoms, side effects, pain or burning at injection site, S/S of a hypersensitivity reaction (e.g., bronchospasm, difficulty breathing, rash, urticaria), signs of infection (e.g., chills, fever, night sweats), signs of sensory neuropathy (e.g., numbness, tingling, or burning in hands and/or feet), or signs of bleeding (e.g., bruising, tarry stools, blood in urine, pinpoint red spots on skin) as soon as possible. ■ Avoid tasks that require mental alertness (e.g., driving, operating machinery) until the effect of the medication is known. Side effects such as fatigue, lethargy, and malaise may affect the ability to perform these tasks. ■ See Appendix D, p. 1255. ■ Obtain name and telephone number of a contact person for emergencies, questions, or problems. ■ Seek resources for counseling or supportive therapy. ■ Manufacturer provides a patient information booklet.

Maternal/Child: ALL FORMULATIONS: Category D: females should avoid pregnancy, and males should avoid fathering a child. May cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

CONVENTIONAL PACLITAXEL: CNS toxicity (rarely associated with death) was reported in one pediatric trial using high-dose paclitaxel. Use of antihistamines and the ethanol contained in the paclitaxel may have contributed to toxicity noted.

Elderly: ALL FORMULATIONS: Studies suggest response is similar to that seen in younger patients.

CONVENTIONAL PACLITAXEL: Incidence of side effects, including myelosuppression, neuropathy, and cardiovascular events, may be increased in the elderly.

ABRAXANE: Incidence of myelosuppression, neuropathy, and arthralgia may be increased.

DRUG/LAB INTERACTIONS**ALL FORMULATIONS**

Do not administer **chloroquine or live virus vaccines** to patients receiving antineoplastic agents.

CONVENTIONAL PACLITAXEL

Formal drug interaction studies have not been conducted. To reduce potential for profound myelosuppression when using paclitaxel and **cisplatin** concurrently, give paclitaxel first, then cisplatin. ■ Neurotoxicity and symptomatic motor dysfunction occurring with higher doses (greater than 250 mg/M²) may be potentiated by **cisplatin and filgrastim** (G-CSF). ■ May cause additive effects with **bone marrow-suppressing agents, radiation therapy, or agents that cause blood dyscrasias** (e.g., amphotericin B, antithyroid agents [methimazole (Tapazole)], azathioprine [Imuran], chloramphenicol, ganciclovir [Cytovene], interferon, plicamycin [Mithracin], zidovudine [AZT, Retrovir]). Reduced doses may be required. ■ May increase levels of **doxorubicin** and its active metabolite when drugs are used in combination. ■ Metabolized by **cytochrome P₄₅₀ isoenzymes CYP3A4 and CYP2C8**. Use caution when administered concomitantly with known **substrates** (e.g., buspirone [BuSpar], eletriptan [Relpax], felodipine [Plendil], lovastatin [Mevacor], midazolam [Versed], sildenafil [Viagra, Revatio], simvastatin [Zocor], and triazolam [Halcion]), **inhibitors** (e.g., atazanavir [Reyataz], clarithromycin [Biaxin], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase], and telithromycin [Ketek]), and **inducers** (e.g., rifampin [Rifadin] and carbamazepine [Tegretol]) of **CYP3A4**. ■ **Other medications that are substrates and/or inducers of CYP3A4** (e.g., ritonavir [Norvir], saquinavir [Invirase], indinavir [Crixivan], and nelfinavir [Viracept]) may alter the metabolism of paclitaxel but have not been evaluated in clinical trials. ■ Use caution when administered concomitantly with known **substrates** (e.g., repaglinide [Prandin], rosiglitazone [Avandia]), **inhibitors** (e.g., gemfibrozil [Lopid]), and **inducers** (e.g., rifampin [Rifadin]) of **CYP2C8**. ■ Dexamethasone (Decadron), diphenhydramine (Benadryl), cimetidine (Tagamet), and ranitidine (Zantac) do not affect the protein binding of paclitaxel.

ABRAXANE

Drug interaction studies have not been conducted. See **All Formulations** above. ■ Use caution when administering with medicines **known to inhibit or induce CYP2C8 or CYP3A4**. Drugs that may inhibit these enzymes include ketoconazole (Nizoral) and other imidazole antifungals, erythromycin, fluoxetine (Prozac), gemfibrozil (Lopid), cimetidine (Tagamet), ritonavir (Norvir), saquinavir (Invirase), indinavir (Crixivan), and nelfinavir (Viracept). Drugs that may induce these enzymes include rifampin (Rifadin), carbamazepine (Tegretol), phenytoin (Dilantin), efavirenz (Sustiva), nevirapine (Viramune).

SIDE EFFECTS**CONVENTIONAL PACLITAXEL**

Dose dependent and generally reversible, but may be fatal. All patients were premedicated to prevent hypersensitivity reactions. Abnormal ECG, alopecia, arthralgia/myalgia, asthenia, autonomic neuropathy resulting in paralytic ileus, bleeding, bone marrow suppression (anemia, leukopenia, neutropenia, thrombocytopenia), bradycardia, CHF (including cardiac dysfunction and reduction in left ventricular ejection fraction or ventricular failure [more common in patients receiving combination therapy with antiracryclines]), diarrhea, elevated bilirubin, elevated alkaline phosphatase, elevated AST, febrile neutropenia, fever, fluid retention and edema, hypersensitivity reactions (moderate, [e.g., dyspnea, flushing, hypotension, rash, tachycardia]; severe [e.g., chest pain, dyspnea requiring bronchodilators, hypotension requiring treatment, generalized urticaria]), hypertension, hypotension, infections including opportunistic infections (chills, fever, night sweats), injection site reactions (cellulitis, fibrosis, induration, necrosis, phlebitis, skin exfoliation), mucositis, nausea and vomiting, numbness, peripheral neuropathy, optic nerve and/or visual disturbances, respiratory reactions (interstitial pneumonia, lung fibrosis, pleural effusions, pulmonary embolism, respiratory failure), Stevens-Johnson syndrome, toxic epidermal necrolysis, and visual disturbances. A grand

mal seizure occurred in one patient. Other side effects (e.g., cardiac arrest, cardiac ischemia/infarction, CVA, hepatic necrosis, and hepatic encephalopathy leading to death, intestinal obstruction, intestinal perforation, ischemic colitis, pancreatitis, thrombosis/embolism) and many others have been reported rarely. A higher incidence of elevated liver function tests and renal toxicity is seen in Kaposi's sarcoma patients.

Post-Marketing: Diffuse edema, thickening, and sclerosing of the skin; exacerbation of S/S of scleroderma; ototoxicity.

ABRAXANE

Single-agent use in patients with MBC: Abnormal ECG, alopecia, anemia, diarrhea, fatigue/asthenia, elevation of alkaline phosphate and AST, infections (oral candidiasis, pneumonia, and respiratory tract), myalgia/arthritis, nausea, neutropenia, and sensory neuropathy are most common.

Combination use in patients with NSCLC: Alopecia, anemia, fatigue, nausea, neutropenia, peripheral neuropathy, and thrombocytopenia are most common. Most serious side effects reported are anemia and pneumonia. Most common side effects that result in dose reduction or withholding or a delay in dosing are anemia, neutropenia, and thrombocytopenia. Neutropenia, peripheral neuropathy, and thrombocytopenia sometimes resulted in permanent discontinuation of Abraxane.

All diagnoses with Abraxane: Hypersensitivity reactions have occurred but are not usually severe; premedication is not indicated. Other side effects have been reported and include bradycardia, cardiovascular events (e.g., cardiac ischemia/infarction, SVT), dehydration, extravasation, fever, hypotension, pancytopenia, pneumothorax, Stevens-Johnson syndrome, toxic epidermal necrolysis, and many others. Frequency of sensory neuropathy may increase with cumulative dose.

Post-Marketing: Many of these side effects occur with paclitaxel and Abraxane and include CHF and left ventricular dysfunction, cranial nerve palsies, hepatic necrosis and hepatic encephalopathy, injection site reactions, interstitial pneumonia, intestinal obstruction or perforation, ischemic colitis, pancreatitis, paralytic ileus, pneumonitis, pulmonary embolism, visual disorders (reduced visual acuity), vocal cord paresis. Rare reports of severe hypersensitivity reactions have occurred with Abraxane.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. Most hypersensitivity reactions will subside with temporary discontinuation of paclitaxel, and incidence seems to decrease with subsequent doses. Moderate reactions such as dyspnea, flushing, hypotension, skin reactions, or tachycardia do not usually require interruption of treatment. Severe reactions may require epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., dexamethasone [Decadron]), or bronchodilators (e.g., albuterol [Ventolin], theophylline [aminophylline]). Most severe reactions should not be rechallenged, but some patients tolerated subsequent doses of **conventional paclitaxel**; see **Contraindications**. Neutropenia can be profound, and the nadir usually occurs about Day 11 with **conventional paclitaxel**. Recovery is generally rapid and spontaneous but may be treated with filgrastim (G-CSF, Neupogen, pegfilgrastim [Neulasta]). Severe thrombocytopenia (nadir Day 8 or 9 with **conventional paclitaxel**) may require platelet transfusions. Severe anemia (less than 8 Gm/dL) may require packed cell transfusions; moderate anemia (less than 11 Gm/dL) may be treated with darbepoetin alfa (Aranesp) or epoetin alfa (Epogen). Hypotension and bradycardia do not usually occur at the same time except in hypersensitivity. Treat only if symptomatic. Some arrhythmias (e.g., nonspecific repolarization abnormalities, sinus tachycardia, and PVCs) are common and may not require intervention. Treat any serious or symptomatic arrhythmia (e.g., conduction abnormalities, ventricular tachycardia) promptly and monitor continuously during subsequent doses. Neurologic symptoms tend to worsen with each course; see **Dose Adjustments**. Usually improve within several months. Severe peripheral neuropathies or seizure may necessitate discontinuation of paclitaxel. There is no specific antidote for overdose. Supportive therapy will help sustain the patient in toxicity. Resuscitate if indicated.

PALIFERMIN

(PAL-lih-fur-min)

Kevivance, KGF

Growth factor

pH 6.5

USUAL DOSE

Administered as an IV bolus injection for 3 consecutive days before and 3 consecutive days after myelotoxic therapy (a total of 6 doses). Do not administer within 24 hours before, during infusion of, or within 24 hours after administration of myelotoxic chemotherapy. Has resulted in increased severity and duration of oral mucositis. Myelotoxic therapy is high-dose chemotherapy, with or without radiation, that is destructive to bone marrow or any of its components. Followed by bone marrow transplant/hematopoietic stem cell support.

Pre-myelotoxic therapy (first 3 doses): Administer 60 mcg/kg/day for 3 consecutive days before beginning myelotoxic therapy, with the third dose 24 to 48 hours before myelotoxic therapy.

Post-myelotoxic therapy (last 3 doses): Administer 60 mcg/kg/day for 3 consecutive days after myelotoxic therapy is complete; the first of these doses should be administered after, but on the same day of, hematopoietic stem cell infusion and at least 4 days after the most recent administration of palifermin. See [Precautions](#).

DOSE ADJUSTMENTS

None indicated. Gender-related differences were not observed. ■ No dose adjustment is recommended in impaired renal function. ■ Pharmacokinetic studies have not been performed for pediatric patients or for patients with hepatic insufficiency.

DILUTION

Available as a lyophilized powder in a 6.25-mg single vial. Reconstitute by slowly injecting 1.2 mL SWFI into vial. Final concentration is 5 mg/mL. Swirl contents gently. **Do not shake.** Dissolution should take less than 3 minutes. Solution is clear and colorless. Do not use if particulates are present or if solution is discolored.

Filters: Manufacturer states, "Do not filter the reconstituted solution during preparation or administration."

Storage: Keep vials in carton until use. Store at 2° to 8° C (36° to 46° F). Protect from light. Do not use beyond expiration date on vial. Reconstituted product should be used immediately but can be stored up to 24 hours if refrigerated and stored in its carton. Do not freeze. Solution may be warmed to RT before injection but should not be left at RT for more than 1 hour and must be protected from light.

COMPATIBILITY

Specific information not available; however, manufacturer states, "If heparin is used to maintain an IV line, saline should be used to flush the line before and after administration since palifermin has been shown to bind to heparin in vitro."

RATE OF ADMINISTRATION

A single dose administered as an IV bolus injection. If heparin is used to maintain an IV line, flush the line with NS before and after administration.

ACTIONS

Human keratinocyte growth factor (KGF) produced by recombinant DNA technology. Binding of KGF to its receptor results in proliferation, differentiation, and migration of epithelial cells. KGF receptors are present on the epithelial cells in many tissues, including the tongue, buccal mucosa, esophagus, stomach, intestine, salivary gland, lung, liver, pancreas, kidney, bladder, mammary gland, skin (hair follicles and sebaceous gland), and the lens of the eye. The KGF receptor is not present on the cells of the hematopoietic lineage. KGF stimulates the growth of cells in tissues such as the skin and the epithelial layer of the mouth, stomach, and colon. Protects the epithelial cells that line the mouth and GI tract from the damage caused by chemotherapy and radiation and stimulates the

growth and development of new epithelial cells. Average half-life is 4.5 hours (range: 3.3 to 5.7 hours).

INDICATIONS AND USES

To decrease the incidence and duration of severe oral mucositis in patients with hematologic malignancies who are receiving myelotoxic therapy (high-dose chemotherapy), with or without radiation therapy, and who require hematopoietic stem cell support. Indicated as supportive care for preparative regimens predicted to result in equal to or greater than WHO Grade 3 mucositis in the majority of patients.

Limitation of use: Safety and efficacy for use in patients with nonhematologic malignancies not established; see **Precautions**. ■ Not recommended for use with melphalan 200 mg/M² as a conditioning regimen.

Investigational uses: Studies to determine whether palifermin can be used safely in other types of cancer are in progress.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Safety and efficacy has not been established in patients with nonhematologic malignancies. Effect of palifermin on stimulation of KGF receptor-expressing, non-hematopoietic tumors in patients is not known. There is some evidence of tumor growth and stimulation in cell cultures and in animal models of non-hematopoietic human tumors.

Monitor: Monitor improvement in symptoms of oral mucositis. ■ Monitor for the appearance of mucocutaneous adverse effects (e.g., edema, erythema, oral/perioral dysesthesia [impairment of sensitivity to touch], rash, taste alteration, tongue discoloration, tongue thickening).

Patient Education: Review possible side effects. ■ Promptly report side effects (e.g., edema, impairment of sensitivity to touch [especially around the mouth], rash, taste alteration, tongue discoloration, tongue thickening). ■ Inform patient of the evidence of tumor growth and stimulation in cell cultures and animal models of non-hematopoietic human tumors.

Maternal/Child: Category C: potential benefit to mother must justify potential risk to fetus. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Age-related differences have not been observed.

DRUG/LAB INTERACTIONS

Formal studies have not been conducted. ■ Interacts with **unfractionated as well as low-molecular-weight heparins** (e.g., enoxaparin [Lovenox]). Avoid coadministration; it results in increased palifermin levels. If heparin is used to maintain an IV line, NS should be used to flush the line before and after palifermin administration. ■ Do not administer within 24 hours before, during infusion of, or within 24 hours after administration of **myelotoxic chemotherapy**. Has resulted in increased severity and duration of oral mucositis.

SIDE EFFECTS

The most common serious side effects are fever, GI events, respiratory events, and skin rash. Other commonly reported reactions include arthralgia, edema, elevated serum amylase and lipase, hypertension, oral toxicities (alteration of taste, oral/perioral dysesthesia, tongue discoloration, tongue thickening), pain, paresthesia, proteinuria, and skin toxicities (erythema, pruritus, rash). Has the potential for immunogenicity, but the clinical significance is unknown.

Post-Marketing: Anaphylaxis, cataracts, edema of the face and mouth, palmar-plantar erythrodysesthesia syndrome (dysesthesia, edema on the palms and soles, erythema), tongue disorders (e.g., bumps, edema, redness), transient hyperpigmentation of the skin, vaginal edema and erythema.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically.

PALONOSETRON

(pal-oh-NOH-seh-tron)

Antiemetic
(5HT₃ receptor antagonist)

Aloxi

pH 4.5 to 5.5

USUAL DOSE

Chemotherapy-induced nausea and vomiting: A single dose of 0.25 mg approximately 30 minutes before the start of chemotherapy. Safety and effectiveness of consecutive or alternate-day dosing has not been evaluated. Has been coadministered with corticosteroids (e.g., dexamethasone [Decadron]) and metoclopramide (Reglan); see [Drug/Lab Interactions](#).

Postoperative nausea and vomiting: A single dose of 0.075 mg immediately before induction of anesthesia.

DOSE ADJUSTMENTS

No dose adjustment required based on age or race or in patients with any degree of renal or hepatic impairment.

DILUTION

Available in 0.25 mg/5 mL and 0.075 mg/1.5 mL single-use vials. May be given undiluted.

Filters: No data available from manufacturer.

Storage: Before use, store at CRT. Protect from freezing and light.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be mixed with other drugs. Flush the infusion line with NS before and after administration."

One source suggests the following **compatibilities**:

Additive: Not recommended by manufacturer. Dexamethasone (Decadron).

Y-site: Ampicillin/sulbactam (Unasyn), atropine, carboplatin (Paraplatin), cefazolin (Ancef), cefotetan, cisatracurium (Nimbex), cisplatin (Platinol), cyclophosphamide (Cytoxan), dacarbazine (DTIC), docetaxel (Taxotere), famotidine (Pepcid IV), fentanyl (Sublimaze), fluorouracil (5-FU), gemcitabine (Gemzar), gentamicin, glycopyrrolate (Robinul), heparin, hetastarch in lactated electrolyte (Hextend), hydromorphone (Dilaudid), ifosfamide (Ifex), irinotecan (Camptosar), lidocaine, lorazepam (Ativan), mannitol (Osmitrol), meperidine (Demerol), metoclopramide (Reglan), metronidazole (Flagyl IV), midazolam (Versed), morphine, neostigmine, oxaliplatin (Eloxatin), paclitaxel (Taxol), potassium chloride, promethazine (Phenergan), rocuronium (Zemuron), succinylcholine (Anectine), sufentanil (Sufenta), topotecan (Hycamtin), vancomycin, vecuronium.

RATE OF ADMINISTRATION

Flush the infusion line with NS before and after administration.

Chemotherapy-induced nausea and vomiting: A single dose as an IV injection equally distributed over 30 seconds.

Postoperative nausea and vomiting: A single dose as an IV injection equally distributed over 10 seconds.

ACTIONS

A long-acting (up to 120 hours [5 days]) antinauseant and antiemetic agent. A selective antagonist of specific serotonin (5HT₃) receptors. Has a strong binding affinity for this receptor and little or no affinity for other receptors. Chemotherapeutic agents such as cisplatin increase the release of serotonin from specific cells in the GI tract, causing emesis. By antagonizing these receptors, the incidence and severity of chemotherapy-induced nausea and vomiting are decreased. 62% bound to plasma protein. Partially

metabolized to selected metabolites. These metabolic pathways are mediated by multiple CYP enzymes; however, it is not an inhibitor or an inducer of CYP enzyme activity. Eliminated slowly from the body through both metabolic pathways and renal excretion. Has a prolonged half-life of approximately 40 hours. 80% of a single dose was recovered in urine within 144 hours.

INDICATIONS AND USES

Prevention of acute nausea and vomiting associated with initial and repeat courses of *moderately and highly emetogenic* cancer chemotherapy. ■ Prevention of delayed nausea and vomiting associated with initial and repeat courses of *moderately emetogenic* cancer chemotherapy. Studies identified cisplatin (Platinol) in doses equal to or greater than 70 mg/M² and cyclophosphamide (Cytoxan) in doses equal to or greater than 1,100 mg/M² as *highly emetogenic*. Studies identified cisplatin in doses equal to or less than 50 mg/M², cyclophosphamide in doses less than 1,100 mg/M², doxorubicin (Adriamycin) in doses greater than 25 mg/M², methotrexate in doses greater than 250 mg/M², and carboplatin (Paraplatin), epirubicin (Ellence), and irinotecan (Camptosar) in standard doses as *moderately emetogenic*. ■ Prevention of postoperative nausea and vomiting (PONV) for up to 24 hours following surgery. Efficacy beyond 24 hours has not been demonstrated.

CONTRAINDICATIONS

Known hypersensitivity to palonosetron or any of its components. ■ See **Precautions**.

PRECAUTIONS

Cross-sensitivity may occur with other selective 5HT₃ receptor antagonists (e.g., dolasetron [Anzemet], granisetron [Kytril], ondansetron [Zofran]). ■ Routine prophylaxis is not recommended for patients in whom there is little expectation of PONV. However, for patients in whom nausea and vomiting must be avoided during the postoperative period, prophylaxis is recommended even when the incidence of PONV is low. ■ Palonosetron does not appear to have any effect on ECG intervals, including QT_C duration.

Monitor: Observe closely. Monitor VS. ■ Ambulate slowly to avoid orthostatic hypotension. ■ Stool softeners or laxatives may be required to prevent constipation.

Patient Education: Request assistance with ambulation. ■ Used to prevent and/or treat both early and late N/V caused by chemotherapy. Report persistent N/V promptly. ■ Maintain adequate hydration. ■ Review prescription and nonprescription medications with health care provider. Drug interactions are possible, especially with diuretics or antiarrhythmics. ■ Review other medical conditions with health care provider.

Maternal/Child: Category B: use during pregnancy only if clearly needed. Animal studies did not identify evidence of impaired fertility or harm to rat or rabbit fetuses. ■ Safety for use during breast-feeding not established; effects unknown, but potential for tumorigenicity is a concern. Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly: Safety and effectiveness similar to younger adults; however, greater sensitivity in some elderly cannot be ruled out. No dose adjustment or special monitoring required.

DRUG/LAB INTERACTIONS

Eliminated through both renal excretion and metabolic pathways; potential for clinically significant drug interactions is considered to be low. ■ Does not induce or inhibit the cytochrome P₄₅₀ drug metabolizing system. ■ Has been safely administered with analgesics, antiemetics/antinauseants, antispasmodics, anticholinergic agents, and corticosteroids. ■ Has been safely administered with PO metoclopramide (10 mg 4 times daily). ■ Has been administered with oral aprepitant (Emend). ■ Does not appear to inhibit the anti-tumor activity of emetogenic cancer chemotherapies. ■ See **Precautions**.

SIDE EFFECTS

Abdominal pain, constipation, diarrhea, dizziness, fatigue, headache, and insomnia occur in 2% or more patients. Among other reported side effects in 1% or more patients were anxiety, hyperkalemia, and nonsustained tachycardia, bradycardia, or hypotension.

Overdose: Doses more than 20 times the recommended dose did not cause significant problems. Collapse, convulsions, cyanosis, gasping, and pallor occurred in animal studies with rats and mice.

Post-Marketing: Hypersensitivity reactions, including anaphylaxis and injection site reactions (burning, induration, pain) (rare).

ANTIDOTE

Most side effects will be treated symptomatically. Keep physician informed. There is no specific antidote. Has a large volume of distribution; dialysis not likely to be effective in overdose. Treat hypersensitivity reactions and resuscitate as indicated.

PAMIDRONATE DISODIUM

(pah-MIH-droh-nayt DYE-so-dee-um)

Bone resorption inhibitor
Antihypercalcemic
(bisphosphonate)

APD, Aredia

pH 6 to 7.4

USUAL DOSE

Prehydration required. Do not exceed a 90-mg dose. See [Precautions](#) and [Monitor](#).

Moderate hypercalcemia (corrected serum calcium of 12 to 13.5 mg/dL): One dose of 60 to 90 mg as an infusion.

Severe hypercalcemia (corrected serum calcium greater than 13.5 mg/dL): One dose of 90 mg as an infusion. Serum calcium levels should fall into the normal range (8.5 to 10.5 mg/100 mL [1 dL], corrected for serum albumin).

Experience is limited, but retreatment with the same dose may be considered if hypercalcemia is not fully corrected or recurs; wait at least 7 days from completion of first infusion to allow full response. Always used in conjunction with adequate hydration and appropriate testing. See [Precautions/Monitor](#).

Paget's disease: 30 mg/day as an infusion for 3 consecutive days (total dose is 90 mg over 3 days). Selected patients have been retreated with the same dose when indicated. Experience limited. Prehydration required; see [Precautions](#) and [Monitor](#).

Osteolytic bone lesions of multiple myeloma: 90 mg as an infusion once every 30 days. Optimal duration of therapy not known. Withhold dose if renal function has deteriorated; see [Dose Adjustments](#), [Precautions](#), and [Monitor](#).

Osteolytic bone metastases of breast cancer: 90 mg as an infusion every 3 to 4 weeks. Optimum duration of therapy not known. Withhold dose if renal function has deteriorated; see [Dose Adjustments](#), [Precautions](#), and [Monitor](#).

DOSE ADJUSTMENTS

Accumulation of pamidronate in renally impaired patients is not anticipated if dosed on a monthly schedule. No experience with creatinine above 5 mg/100 mL (1 dL) or in severe hepatic disease. ■ See [Precautions](#) and [Elderly](#).

Osteolytic bone lesions of multiple myeloma and osteolytic bone metastases of breast cancer: Withhold dose if renal function has deteriorated. Renal deterioration is defined as an increase of 0.5 mg/dL in patients with a *normal* baseline creatinine or an increase of 1 mg/dL in patients with *abnormal* baseline creatinine. One study suggests that treatment should not be resumed until SCr has returned to within 10% of baseline value.

DILUTION

Reconstitute each 30- or 90-mg vial with 10 mL SWFI. Dissolve completely (3 or 9 mg/mL).

Hypercalcemia of malignancy: Further dilute a single dose in 1,000 mL NS, ½NS, or D5W. A minimum of 500 mL diluent may be used if absolutely necessary in patients with compromised cardiovascular status.

Paget's disease: Further dilute a single daily dose in 500 mL NS, $\frac{1}{2}$ NS, or D5W.

Osteolytic bone lesions of multiple myeloma: Further dilute each 90-mg dose in 500 mL NS, $\frac{1}{2}$ NS, or D5W.

Osteolytic bone metastases of breast cancer: Further dilute each 90-mg dose in 250 mL NS, $\frac{1}{2}$ NS, or D5W.

Storage: Before reconstitution, store at CRT. After reconstitution, may be refrigerated for up to 24 hours. Stable after dilution for 24 hours at room temperature.

COMPATIBILITY

Manufacturer states, "Should be given in a single intravenous solution and line separate from all other drugs, and do not mix with calcium-containing solutions (e.g., Ringer's solutions)."

RATE OF ADMINISTRATION

Use of a microdrip (60 gtt/mL) or an infusion pump recommended for even distribution. Do not exceed recommended rate of infusion. Duration should be no less than 2 hours. Too-rapid infusion rate may lead to overdose, elevated BUN and creatinine levels, and renal tubular necrosis. Rate recommendations vary considerably. They are based on specific clinical trials for each diagnosis. In some trials a rate of up to 1 mg/min has been used with caution.

Hypercalcemia of malignancy: A 60-mg dose or 90-mg dose equally distributed over 2 to 24 hours. Longer infusion times (i.e., greater than 2 hours) may reduce the risk of renal toxicity, particularly in patients with pre-existing renal insufficiency.

Paget's disease: A single dose over 4 hours.

Osteolytic bone lesions of multiple myeloma: A single dose over 4 hours.

Osteolytic bone metastases of breast cancer: A single dose over 2 hours.

ACTIONS

A bisphosphonate hypocalcemic agent. Reduces serum calcium concentrations by inhibiting bone resorption. Binds to preformed bone surfaces and may block bone mineral dissolution. May also inhibit osteoclast activity. Effectively inhibits accelerated bone resorption resulting from osteoclast hyperactivity induced by various tumors. Does not inhibit bone formation and mineralization. Some reduction in calcium levels seen in 24 to 48 hours, and maximum response in 4 to 7 days. Rapidly adsorbed by bone. Is not metabolized. Half-life is approximately 21 to 35 hours. Slowly excreted in urine.

INDICATIONS AND USES

Treatment of moderate to severe hypercalcemia of malignancy in patients with or without bone metastasis, in conjunction with adequate hydration. Symptoms of hypercalcemia may include anorexia, bone pain, confusion, constipation, dehydration, depression, fatigue, lethargy, muscle weakness, nausea and vomiting, and polyuria. Severe dehydration may lead to renal insufficiency. With high levels of serum calcium, cardiac manifestations (e.g., bradycardia, cardiac arrest, ventricular arrhythmias), and neurologic symptoms (e.g., coma, seizures, and death) may occur. ■ Treatment of Paget's disease. ■ Adjunct in treatment of osteolytic lesions of multiple myeloma and osteolytic bone metastases of breast cancer.

Unlabeled uses: Prevention of bone loss associated with androgen deprivation therapy in prostate cancer.

CONTRAINDICATIONS

Hypersensitivity to pamidronate or other bisphosphonates (e.g., alendronate [Fosamax], risedronate [Actonel], zoledronic acid [Reclast, Zometa]).

PRECAUTIONS

Calcium is bound to albumin. Total serum calcium levels in patients who have hypercalcemia of malignancy may not reflect the severity of the hypocalcemia because concomitant hypoalbuminemia is commonly present. Measurement with ionized calcium levels is preferred. If unavailable, all calcium measurement should be corrected for albumin to establish a basis for treatment and evaluation of treatment. ■ Mild or asymptomatic hypercalcemia will be treated with conservative measures (e.g., saline hydration, with or without diuretics [after correcting hypovolemia]). Consider patient's cardiovascular sta-

tus. Corticosteroids may be indicated if the underlying cancer is sensitive (e.g., hematologic cancers). ■ May be used adjunctively with chemotherapy, radiation, or surgery. ■ May cause renal toxicity. Deterioration in renal function progressing to renal failure has been reported and has occurred after the initial or a single dose of pamidronate. Patients with pre-existing renal impairment may be at increased risk for developing toxicity. Do not exceed dose of 90 mg. ■ Osteonecrosis of the jaw (ONJ) has been reported in patients receiving bisphosphonates. The majority of cases have been in cancer patients. Risk factors include cancer, concomitant therapy (e.g., chemotherapy, radiotherapy, corticosteroids), and co-morbid conditions (e.g., anemia, coagulopathies, infection, pre-existing oral disease). Literature and case reports suggest a higher frequency of ONJ based on tumor type (breast cancer, multiple myeloma) and dental status (dental extraction, periodontal disease, local trauma, including poorly fitting dentures). Cancer patients should maintain good oral hygiene. Consider dental exam and appropriate preventive dentistry before beginning therapy with bisphosphonates. Avoid invasive dental procedures during bisphosphonate therapy. Dental surgery may exacerbate ONJ in patients who develop ONJ while on bisphosphonate therapy. ■ Severe and occasionally incapacitating bone, joint, and/or muscle pain has been reported rarely. Onset of symptoms varied from one day to several months after beginning treatment with pamidronate. In most cases, pain resolves when pamidronate is discontinued; however, in some patients symptoms resolved slowly or persisted. ■ Atypical subtrochanteric and diaphyseal femoral fractures have been reported. May occur after minimal or no trauma. Risk may be increased in patients receiving concurrent glucocorticoids (e.g., dexamethasone, prednisone). ■ May be at risk for anemia, leukopenia, or thrombocytopenia; see **Monitor**. ■ Patients with a history of thyroid surgery may have relative hypoparathyroidism that may predispose them to hypocalcemia with pamidronate. **Osteolytic bone lesions of multiple myeloma and osteolytic bone metastases of breast cancer:** Patients being treated for multiple myeloma and bone metastases should have the dose withheld if renal function has deteriorated; see **Dose Adjustments**. Use is not recommended in patients with severe renal impairment being treated for bone metastases. See **Monitor** and **Dose Adjustments**. Limited information available on use in multiple myeloma patients with a CrCl less than 30 mL/min. In clinical trials, patients with a SCR above 3 mg/dL were excluded. ■ In the absence of hypercalcemia, patients with **multiple myeloma** or **Paget's disease of the bone** or patients with **predominantly lytic bone metastases** who are at risk for calcium and vitamin D deficiency should be given oral calcium and vitamin D to reduce the risk of hypocalcemia. **Monitor:** Obtain baseline measurements of serum calcium (corrected for serum albumin), electrolytes, phosphate, magnesium, and creatinine and CBC with differential and hematocrit/hemoglobin. Monitor all closely as indicated by baseline results (may be daily). Serum phosphate levels will decrease and may require treatment. ■ Monitor renal function before each treatment; deterioration in renal function has been reported; see **Precautions**. ■ Monitor serum alkaline phosphatase during therapy for Paget's disease. ■ Patients with cancer-related hypercalcemia are frequently dehydrated. Must be adequately hydrated orally and/or IV before treatment is initiated. Hydration with saline is preferred to facilitate renal excretion of calcium and correct dehydration. A pretreatment urine output of 2 L/day is recommended. Maintain adequate hydration and urine output throughout treatment. ■ Avoid overhydration in patients with compromised cardiovascular status. Observe frequently for signs of fluid overload. Correct hypovolemia before using diuretics. ■ Monitor patients with pre-existing anemia, leukopenia, or thrombocytopenia very carefully during treatment and for the first 2 weeks following treatment. ■ Monitor for S/S of atypical femoral fractures that may occur with minimal or no trauma. Thigh or groin pain may be experienced weeks to months before a fracture appears. Fractures are often bilateral; examine both femurs. **Osteolytic bone lesions of multiple myeloma:** Adequately hydrate patients who have marked Bence-Jones proteinuria and dehydration before pamidronate infusion. **Patient Education:** Regular visits and assessment of lab tests imperative. ■ Dietary restriction of calcium and vitamin D may be required. ■ Take only prescribed meds. ■ Report

abdominal cramps, chills, confusion, fever, muscle spasms, sore throat, and/or any new medical problems promptly. ■ Report development of bone, joint, or muscle pain promptly. Onset of pain is variable. ■ Avoid pregnancy; use of nonhormonal birth control suggested.

Maternal/Child: Category D: should not be used during pregnancy. May cause fetal harm. Avoid pregnancy; use of birth control necessary during treatment and for an undetermined time after treatment; see prescribing information. ■ Discontinue breastfeeding. ■ Safety for use in pediatric patients not established.

Elderly: Response similar to that seen in younger patients. ■ Use with caution based on age-related impaired organ function and concomitant disease or drug therapy; monitor renal function closely. See **Dose Adjustments**. ■ Monitor fluid and electrolyte status carefully to avoid overhydration or electrolyte imbalance. Use of lower fluid volume may be required; see **Dilution**.

DRUG/LAB INTERACTIONS

Use caution when administered with other **potentially nephrotoxic drugs** (e.g., aminoglycosides [tobramycin, gentamicin], cisplatin [Platinol]). ■ Concurrent administration with **furosemide** (Lasix) does not affect calcium-lowering action of pamidronate. ■ Does not interfere with any known primary cancer therapy. ■ Effects may be antagonized by **calcium-containing preparations or vitamin D**; avoid use. ■ Concurrent use with **thalidomide** (Thalomid) may increase risk of renal toxicity in patients with multiple myeloma.

SIDE EFFECTS

Average dose: Abdominal pain, anemia, anorexia, bone pain, confusion and visual hallucinations (sometimes in conjunction with electrolyte imbalance), constipation, fever (mild and transient), generalized pain, hypertension, hypocalcemia (abdominal cramps, confusion, muscle spasms), infusion site reaction (e.g., induration and pain on palpation, redness, swelling), musculoskeletal pain (bone, joint, and/or muscle pain), pruritus, rash, renal toxicity, seizures, urinary tract infections, vomiting. Fluid overload, hypokalemia, hypomagnesemia, and hypophosphatemia occur frequently with use of concurrent fluid and diuretics. Rare instances of hypersensitivity reactions, including anaphylaxis, angioedema, dyspnea, and hypotension, have occurred. Osteonecrosis (primarily of the jaw) has been reported (see **Precautions**). Anemia, leukopenia, and thrombocytopenia may occur.

Overdose: Occurs less frequently with lower dose range (30 to 60 mg). Fever (high), hypocalcemia, hypotension, leukopenia or lymphopenia (fever, chills, sore throat), transient taste perversion. Elevated BUN and CrCl levels and renal tubular necrosis may occur with excessive dose or rate of administration.

Post-Marketing: Adult respiratory distress syndrome (ARDS); atypical subtrochanteric and diaphyseal femoral fractures; bone, joint, and muscle pain (may be severe and incapacitating); conjunctivitis; focal segmental glomerulosclerosis (including the collapsing variant); glomerulonephropathies; hematuria; hypernatremia; influenza-like symptoms; interstitial lung disease; nephrotic syndrome; orbital inflammation; reactivation of herpes simplex and herpes zoster; renal tubular disorders; tubulointerstitial nephritis.

ANTIDOTE

Keep physician informed of side effects. Some may respond to symptomatic treatment. Magnesium, phosphorus, and potassium may require replacement if depletion too severe. If mild, all will probably return toward normal in 7 to 10 days. For asymptomatic or mild to moderate hypocalcemia (6.5 to 8 mg/100 mL [1 dL] corrected for serum albumin), short-term calcium therapy (e.g., calcium gluconate) may be indicated. Consider discontinuing pamidronate in patients who develop atypical fractures of the femur. Unknown if risk continues after stopping treatment. Discontinue drug for any symptoms of overdose. Monitor serum calcium and use vigorous IV hydration, with or without diuretics, for 2 to 3 days. Monitor intake and output to ensure adequacy and balance. Use short-term IV calcium therapy if indicated. High fever may respond to steroids. RBC transfusions may be required in anemia. Treat anaphylaxis and resuscitate as indicated.

PANCURONIUM BROMIDE **BBW**

(pan-kyou-ROH-nee-um BRO-myd)

Neuromuscular blocking agent
(nondepolarizing)
Anesthesia adjunct

pH 4

USUAL DOSE

Adjunct to general anesthesia for adults and pediatric patients: Must be individualized, depending on previous drugs administered and degree and length of muscle relaxation required. Must be used with adequate anesthesia and/or sedation and after unconsciousness induced. Succinylcholine must show signs of wearing off before pancuronium is given. 0.04 to 0.1 mg/kg of body weight initially. 0.01 mg/kg in increments as required to maintain muscle relaxation; usually 25- to 60-minute intervals.

Endotracheal intubation: 0.06 to 0.1 mg/kg.

Support of intubated mechanically ventilated or respiratory-controlled adult ICU patients (unlabeled): **IV bolus injection:** 0.1 to 0.2 mg/kg every 1 to 3 hours. **Continuous infusion:** Begin with a **loading dose** of 0.03 to 0.1 mg/kg followed by a **maintenance dose** of 0.06 to 0.1 mg/kg/hr. A lower-end or reduced dose may be indicated if administered more than 5 minutes after the start of an inhalation agent, when steady-state has been achieved, or in patients with organ dysfunction (e.g., impaired renal function). Adjust dose according to clinical assessment of the patient's response. Use of a peripheral nerve stimulator is recommended.

NEONATAL DOSE

Adjunct to general anesthesia: Extreme sensitivity to pancuronium exists during the first month of life. Begin with a test dose of 0.02 mg/kg and assess responsiveness. See *Maternal/Child*.

DOSE ADJUSTMENTS

See *Drug/Lab Interactions*; marked reduction of pancuronium dose may be required. ■ A higher total dose may be required in biliary or hepatic disease, but onset is slower and neuromuscular block is prolonged. ■ Clearance decreased and half-life increased in renal insufficiency. One source recommends administering 50% of a dose if CrCl is between 10 and 50 mL/min; do not use if CrCl is less than 10 mL/min.

DILUTION

May be given undiluted or diluted in D5W, D5^{1/2}NS, D5NS, NS, or LR for use as an infusion.

Storage: Best if stored in refrigerator. Will maintain potency at room temperature for up to 6 months.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Ciprofloxacin (Cipro IV), verapamil.

Y-site: Aminophylline, cefazolin (Ancef), cefuroxime (Zinacef), dexmedetomidine (Precedex), dobutamine, dopamine, epinephrine (Adrenalin), esmolol (Brevibloc), etomidate (Amidate), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), gentamicin, heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), isoproterenol (Isuprel), levofloxacin (Levaquin), lorazepam (Ativan), midazolam (Versed), milrinone (Primacor), morphine, nitroglycerin IV, nitroprusside sodium, propofol (Diprivan), ranitidine (Zantac), sulfamethoxazole/trimethoprim, vancomycin.

RATE OF ADMINISTRATION

Adjunct to general anesthesia: A single dose over 60 to 90 seconds.

Mechanical ventilation support in ICU: See *Usual Dose* for specific rates and criteria.

ACTIONS

A skeletal muscle relaxant. Causes paralysis by interfering with neural transmission at the myoneural junction. Onset of action is dose dependent. Peak effect occurs in 3 to 4 minutes and lasts 30 to 45 minutes. It may take another 30 minutes or up to several hours before complete recovery occurs. Excreted in the urine.

INDICATIONS AND USES

Adjunctive to general anesthesia to facilitate endotracheal intubation and to relax skeletal muscles during surgery or mechanical ventilation.

Unlabeled uses: Support of intubated, mechanically ventilated, or respiratory-controlled patients in ICU.

CONTRAINDICATIONS

Known hypersensitivity to pancuronium or bromides; first trimester of pregnancy.

PRECAUTIONS

Usually administered by or under the direct observation of the anesthesiologist. Appropriate emergency drugs and equipment for monitoring the patient and responding to any medical emergency must be readily available. ■ Severe anaphylactic reactions have been reported with neuromuscular blocking agents; some have been fatal. Use caution in patients who have had an anaphylactic reaction to another neuromuscular blocking agent (depolarizing or nondepolarizing); cross-reactivity has occurred. ■ Repeated doses may produce a cumulative effect. ■ Impaired pulmonary function or respiratory deficiencies can cause critical reactions. ■ Use caution in impaired liver or kidney function, in patients with tachycardia, and in any patient who might develop adverse effects from an increase in HR. ■ Myasthenia gravis increases sensitivity to drug. ■ Long-term use (i.e., intensive care) may result in prolonged paralysis or skeletal muscle weakness. ■ Acid base and/or electrolyte imbalance, debilitation, hypoxic episodes, and/or the use of other drugs (e.g., broad-spectrum antibiotics, narcotics, steroids) may prolong the effects of pancuronium.

Monitor: All uses: This drug produces apnea. Controlled artificial ventilation with oxygen must be continuous and under direct observation at all times. Maintain a patent airway. ■ Use a peripheral nerve stimulator to monitor response to pancuronium and avoid overdose. ■ Patient may be conscious and completely unable to communicate by any means. Pancuronium has no analgesic or sedative properties. ■ Action is altered by dehydration, electrolyte imbalance, body temperatures, and acid-base imbalance. ■ Hyperkalemia may cause cardiac arrhythmias and increased paralysis. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Mechanical ventilation support in ICU: Physical therapy is recommended to prevent muscular weakness, atrophy, and joint contracture. Muscular weakness may first be noticed during attempts to wean patients from the ventilator.

Maternal/Child: Category C: unknown potential hazards to fetus. Benefits must outweigh risks. Not recommended in first trimester. ■ Has caused rare severe skeletal muscle weakness in neonates undergoing mechanical ventilation.

Elderly: Delay in onset time may be caused by slower circulation time in cardiovascular disease, old age, or edematous states; allow more time for drug to achieve maximum effect.

DRUG/LAB INTERACTIONS

May cause severe arrhythmias with **inhalant anesthetics** (e.g., enflurane, halothane) and in patients on chronic **tricyclic antidepressant therapy** (e.g., amitriptyline [Elavil]). ■ Potentiated by **hypokalemia, some carcinomas, many antibiotics** (e.g., aminoglycosides [kanamycin, gentamicin], bacitracin, colistin [Coly-Mycin S], colistimethate [Coly-Mycin M], polymyxin-B [Aerosporin], tetracyclines, piperacillin), **calcium salts, CO₂, diuretics, diazepam (Valium) and other muscle relaxants, digoxin, magnesium sulfate, quinidine, morphine, lidocaine, meperidine, propranolol (Inderal), succinylcholine, and others.** May need to reduce dose of pancuronium; use with caution. ■ Recurrent paralysis may occur with **quinidine**. ■ Effects may be decreased by **acetylcholine, anticholinesterases, aminophylline, azathioprine, carbamazepine, and potassium**. ■ **Succinylcholine** must show signs of wearing off before pancuronium is given. Use caution.

SIDE EFFECTS

Increased HR, decrease in mean arterial pressure, prolonged action resulting in respiratory insufficiency or apnea and tachycardia. Airway closure caused by relaxation of epiglottis, pharynx, and tongue muscles. Hypersensitivity reactions are possible. Anaphylaxis, histamine release (e.g., bronchospasm, vasodilation, hypotension, cutaneous flushing), and shock may occur. Muscular weakness and atrophy may occur with long-term use (1 to 3 weeks).

ANTIDOTE

All side effects are medical emergencies. Treat symptomatically. Controlled artificial ventilation must be continuous. Pyridostigmine (Regonol) or neostigmine given with atropine will probably reverse the muscle relaxation. Not effective in all situations; may aggravate severe overdose. Resuscitate as necessary.

PANITUMUMAB **BBW**

(pan-i-TUE-moo-mab)

Antineoplastic
Immunosuppressant
Monoclonal antibody

Vectibix

pH 5.6 to 6

USUAL DOSE

6 mg/kg as an infusion once every 14 days.

DOSE ADJUSTMENTS

Hold panitumumab for dermatologic or soft tissue toxicities that are Grade 3 or higher or are considered intolerable. If toxicity does not improve to less than or equal to Grade 2 within a month, permanently discontinue therapy. If dermatologic or soft tissue toxicity improves to less than or equal to Grade 2 and the patient is symptomatically improved after withholding no more than 2 doses of panitumumab, treatment may be resumed at 50% of the original dose. If toxicity recurs, permanently discontinue therapy. If toxicity does not recur, subsequent doses may be increased by increments of 25% of the original dose until the recommended dose of 6 mg/kg is reached. ■ No dose adjustment indicated based on age (21 to 88 years), gender, race, mild-to-moderate renal or hepatic dysfunction, and EGFR (epidermal growth factor receptor) membrane-staining intensity (1+, 2+, 3+).

DILUTION

Solution may contain a small amount of visible, translucent-to-white, amorphous, and proteinaceous panitumumab particulates (will be removed by in-line filter). Do not use if solution is discolored. **Do not shake.** Withdraw calculated dose from vial. Dilute to a total volume of 100 mL with NS. Doses higher than 1,000 mg should be diluted to a volume of 150 mL. (Withdraw a volume of NS equal to the volume of the calculated dose from the infusion bag.) Final concentration should not exceed 10 mg/mL. Mix diluted solution by gentle inversion. **Do not shake.**

Filters: Must be administered through a low-protein binding, 0.2- or 0.22-micron, in-line filter.

Storage: Store unopened vials in refrigerator (2° to 8° C [36° to 46° F]). Protect from direct sunlight. Do not freeze. Diluted solutions should be discarded within 6 hours of preparation if stored at RT and within 24 hours if stored in refrigerator. Do not freeze. Single-dose vial; discard any unused product after entry into vial.

COMPATIBILITY

Manufacturer states, "Should not be mixed with, or administered as an infusion, with other medicinal products. No other medications should be added to solutions containing panitumumab."

RATE OF ADMINISTRATION

Flush line before and after panitumumab administration with NS. **Do not administer as an IV push or bolus.** Administer with an IV infusion pump using a low-protein binding, 0.2- or 0.22-micron, in-line filter.

A single dose equally distributed over 60 minutes. Doses over 1,000 mg should be administered over 90 minutes. Reduce rate of infusion by 50% in patients experiencing a Grade 1 or 2 infusion reaction.

ACTIONS

A genetically engineered recombinant, human IgG2 kappa monoclonal antibody that binds specifically to the human epidermal growth factor receptor (EGFR). EGFR is a transmembrane glycoprotein that is expressed in many normal epithelial tissues, including skin and hair follicles. Overexpression of EGFR is detected in many human cancers, including those of the colon and rectum. Interaction of EGFR with its normal ligands leads to a series of reactions that regulate the transcription of molecules involved with cellular growth and survival, motility, proliferation, and transformation. Panitumumab binds to EGFR on both normal and tumor cells, inhibiting the binding of normal ligands to EGFR. This competitive binding results in inhibition of cell growth, induction of apoptosis, decreased proinflammatory cytokine and vascular growth factor production, and internalization of EGFR. The end result is inhibition of growth and survival of selected human tumor cells that express EGFR. Half-life is approximately 7.5 days (range 3.6 to 10.9 days).

INDICATIONS AND USES

As a single agent in the treatment of EGFR-expressing, metastatic colorectal carcinoma with disease progression on or following chemotherapy regimens that contain fluoropyrimidine (fluorouracil [5-FU]), oxaliplatin (Eloxatin), and irinotecan (Camptosar). ■ Not indicated for use in combination with fluorouracil (5-FU), oxaliplatin (Eloxatin), irinotecan (Camptosar), or any other chemotherapy agent with or without bevacizumab (Avastin). Combination use resulted in decreased progression-free survival and increased incidence of CTCAE Grade 3 to 5 adverse reactions.

Limitation of use: Not indicated for the treatment of patients with KRAS mutation-positive metastatic colorectal cancer (mCRC) or for patients whose KRAS mCRC status is unknown.

CONTRAINDICATIONS

None known. See [Precautions](#).

PRECAUTIONS

Panitumumab should be used only in patients whose tumor shows EGFR expression. Immunohistochemical evidence of EGFR expression should be obtained using specific test kits. Assessment of EGFR expression should be performed by qualified laboratories with demonstrated proficiency in the technology required for testing. ■ Dermatologic toxicities were reported in 89% of patients and were severe (CTCAE Grade 3 or higher) in 12% of patients. Manifestations included dermatitis acneiform, dry skin, erythema, paronychia, pruritus, rash, skin exfoliation, and skin fissures. Severe dermatologic toxicities were complicated by infection. Life-threatening and fatal infectious complications, including necrotizing fasciitis, abscesses requiring incision and drainage, and sepsis, have been observed. See [Dose Adjustments](#) and [Antidote](#). ■ Sunlight may exacerbate dermatologic toxicity. Protection from sun is advised; see [Patient Education](#). ■ Infusion reactions, some severe, have been reported. Fatal reactions have been reported. Administer in a facility with adequate emergency medical equipment and medications for treating these reactions and for responding to any medical emergency; see [Rate of Administration](#) and [Antidote](#). ■ Panitumumab is not indicated for use in combination with chemotherapy. Shortened overall survival time (increased mortality) and increased toxicities were observed in studies exploring combination therapy. See prescribing information. ■ Pulmonary fibrosis has been reported (rare); see [Monitor](#). Interstitial lung disease (ILD), including fatalities, has been reported. ■ Keratitis and

ulcerative keratitis, known risk factors for corneal perforation, have been reported. ■ A protein substance. Potential for immunogenicity exists. Anti-panitumumab antibodies have been detected in a small number of patients. No evidence of altered safety profiles has been confirmed.

Monitor: Monitor vital signs before, during (as needed), and at the completion of the infusion. ■ Monitor for S/S of hypersensitivity or infusion-related reactions. Severe reactions may include anaphylaxis, bronchospasm, chills, fever, and hypotension; see [Side Effects](#). Mild to moderate infusion reactions may respond to a reduction in the rate of infusion; see [Rate of Administration](#). Utility of premedication to minimize or prevent infusion-related reactions has not been determined. ■ Monitor skin integrity. Monitor patients who develop dermatologic or soft tissue toxicities for the development of inflammatory or infectious sequelae. ■ Monitor lung function. Discontinue therapy in patients who develop interstitial lung disease, pneumonitis, or lung infiltrates. ■ Obtain baseline and monitor electrolytes periodically during and for 8 weeks after completion of therapy. Hypomagnesemia and hypocalcemia have been reported. Oral or IV electrolyte replacement may be required. ■ Monitor for evidence of keratitis or ulcerative keratitis.

Patient Education: Avoid pregnancy. Nonhormonal birth control recommended for both men and women during and for 6 months following completion of therapy. ■ Review side effects, including dermatologic toxicity, infusion reactions, pulmonary fibrosis, and potential for fetal harm. ■ Report skin or ocular changes, cough, dehydration, diarrhea, dyspnea, or infusion-related reactions promptly. ■ Limit sun exposure during and for 2 months after the last dose of panitumumab. Use of sunscreen and hats recommended. ■ Compliance with periodic lab work required.

Maternal/Child: Category C: safety for use in pregnancy has not been established. EGFR has been implicated in the control of prenatal development and may be essential for normal organogenesis, proliferation, and differentiation in the developing embryo. Human IgG crosses the placental barrier. Therefore, it is possible that panitumumab may be transmitted from the mother to the developing fetus. Appropriate contraceptive measures must be used during treatment with panitumumab; see [Patient Education](#). ■ Women who become pregnant during panitumumab therapy are encouraged to enroll in Amgen's Pregnancy Surveillance Program. ■ Discontinue breast-feeding during and for 2 months after the completion of therapy. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Specific differences in safety and effectiveness compared to younger adults not noted.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted.

SIDE EFFECTS

The most commonly reported side effects are abdominal pain, constipation, diarrhea (including diarrhea resulting in dehydration), fatigue, hypomagnesemia, nausea, paronychia, and skin toxicity (e.g., dermatitis acneiform, erythema, exfoliation fissures, pruritus, rash). The most serious side effects reported include abdominal pain, constipation, hypomagnesemia, infusion reactions (e.g., anaphylaxis, bronchospasm, chills, dyspnea, fever, hypotension), nausea, pulmonary embolism, pulmonary fibrosis, severe dermatologic toxicity complicated by infectious sequelae and septic death, and vomiting. Other reported side effects include cough, fatigue, mucosal inflammation, ocular toxicity (conjunctivitis, eyelid/eye irritation, increased lacrimation, ocular hyperemia), peripheral edema, and stomatitis. Reactions requiring discontinuation of therapy included infusion reactions, paronychia, pulmonary fibrosis, and severe dermatologic toxicity.

Post-Marketing: Hypersensitivity reactions, including anaphylaxis; angioedema; infusion reactions (fatal); keratitis/ulcerative keratitis; and necrotizing fasciitis.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Replace electrolytes parenterally or orally as indicated. Reduce infusion rate by 50% if a mild or moderate (Grade 1 or 2) infusion reaction occurs. Discontinue panitumumab for a serious infusion reaction (Grade 3 or 4). Depending on the severity and/or persistence of the reaction, discontinue permanently. Hold or discontinue panitumumab if dermatologic or soft tissue toxicities Grade 3 or higher occur, if they are considered intolerable, or if severe or life-threatening inflammatory or infectious complications occur. See [Dose Adjustments](#) for criteria to resume or permanently discontinue treatment. Discontinue if ILD is confirmed. Treat hypersensitivity or infusion reaction as indicated (e.g., oxygen, antihistamines [e.g., diphenhydramine (Benadryl)], epinephrine (Adrenalin), corticosteroids, vasopressors [e.g., dopamine], ventilation equipment, and/or fluids). Interrupt or discontinue panitumumab infusion for acute or worsening keratitis. Resuscitate as necessary.

PANTOPRAZOLE SODIUM

(pan-TOH-prah-zohl SO-dee-um)

Proton pump inhibitor
(Gastric acid inhibitor)

Protonix IV

pH 9 to 10.5

USUAL DOSE

Given as an alternative to continued oral therapy. Resume oral therapy as soon as practical.

Treatment of gastroesophageal reflux disease (GERD): 40 mg as an infusion once daily for 7 to 10 days.

Treatment of Zollinger-Ellison syndrome (ZES): 80 mg as an infusion every 12 hours. Adjust to patient needs based on acid output measurements. If an increased dose is required, 80 mg every 8 hours is expected to maintain gastric acid output at less than 10 mEq/hr. Daily doses in excess of 240 mg or for more than 6 days have not been studied.

Recurrent gastrointestinal bleeding, prophylaxis (unlabeled): 80 mg as an IV injection followed by a continuous infusion of 8 mg/hr for 72 hours.

DOSE ADJUSTMENTS

No dose adjustments are necessary based on race or gender, in the elderly, or in patients with mild, moderate, or severe renal insufficiency, on hemodialysis; or with mild to severe impaired hepatic function. Doses higher than 40 mg/day have not been studied in patients with hepatic impairment.

DILUTION

40-mg dose: Reconstitute each single dose with 10 mL NS. May be further diluted with 100 mL D5W, NS, or LR to achieve a final concentration of approximately 0.4 mg/mL for infusion.

80-mg dose: Combining of two 40-mg vials is required; reconstitute each 40-mg vial with 10 mL NS. This total 80-mg dose may be further diluted with 80 mL D5W, NS, or LR (a total volume of 100 mL) to achieve a final concentration of approximately 0.8 mg/mL for infusion.

Filters: No longer required.

Storage: Store unopened vials at CRT. Protect from light. Do not freeze reconstituted product. Vials reconstituted for the 2-minute infusion may be stored for up to 24 hours at RT. Vials reconstituted for the 15-minute infusion may be stored for up to 6 hours at RT prior to further dilution. Fully diluted solution may then be stored at RT but must be used within 24 hours of initial reconstitution. Protection from light is not required for reconstituted or fully diluted solutions.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug **NOT** listed as compatible to be **INCOMPATIBLE** until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Administer through a dedicated line, should not be simultaneously administered through the same line with other intravenous solutions." See **Rate of Administration**. Manufacturer lists as **incompatible** at the **Y-site** with midazolam (Versed) and states, "May not be **compatible** with products containing zinc." **Discontinue if discoloration or precipitation occurs with any drug at the Y-site.**

One source suggests the following **compatibilities**:

Y-site: Ampicillin, anidulafungin (Eraxis), caspofungin (Cancidas), cefazolin (Ancef), ceftaroline (Teflaro), ceftriaxone (Rocephin), dimenhydrinate, dopamine, doripenem (Doribax), epinephrine (Adrenalin), furosemide (Lasix), insulin (regular), morphine, nitroglycerin IV, norepinephrine (Levophed), octreotide (Sandostatin), potassium chloride (KCl), telavancin (Vibativ), vasopressin.

RATE OF ADMINISTRATION

A dedicated line is preferred, but a **Y-site** may be used. In all situations the IV line must be flushed before and after administration of pantoprazole with **compatible** infusion solutions (D5W, NS, or LR).

Concentration determines the rate of administration.

40 mg/10 mL or 80 mg/20 mL: As an injection evenly distributed over at least 2 minutes.

40 mg/100 mL or 80 mg/100 mL: As an infusion evenly distributed over at least 15 minutes (approximately 7 mL/min).

ACTIONS

A proton pump inhibitor (PPI) that suppresses the final step in gastric acid production. Acts at the secretory surface of the gastric parietal cell. Inhibits both basal and stimulated gastric acid secretion irrespective of the stimulus. Does not accumulate and pharmacokinetics are not altered with multiple daily dosing. Half-life is approximately one hour. Duration of antisecretory effect persists longer than 24 hours. Distributed mainly in extracellular fluid. Highly bound by serum protein (primarily albumin). Extensively metabolized in the liver through the cytochrome P₄₅₀ system (primarily through CYP2C19 and, to a lesser extent, through CYP3A4). Metabolism is independent of the route of administration (intravenous or oral). Primarily excreted in urine with some excretion in feces. Secreted in breast milk.

INDICATIONS AND USES

Short-term treatment (7 to 10 days) of gastroesophageal reflux disease (GERD) with a history of erosive esophagitis, as an alternative to oral therapy. ■ Treatment of pathological hypersecretion associated with Zollinger-Ellison syndrome or other pathologic hypersecretory conditions.

Unlabeled uses: Prophylaxis against recurrent GI bleed (peptic ulcer bleed).

CONTRAINDICATIONS

Known hypersensitivity to pantoprazole or its components or to other substituted benzimidazoles (e.g., lansoprazole [Prevacid]).

PRECAUTIONS

For IV use only; do not give IM or SC. ■ Gastric malignancy may be present even though patient's symptoms improve with pantoprazole therapy. ■ Formulation contains edetate disodium, which can chelate zinc; see **Monitor**. ■ Should be discontinued as soon as the patient is able to resume treatment with pantoprazole delayed-release tablets or oral suspension. ■ Data on safe and effective dosing for other conditions (including life-threatening upper GI bleeds) not available. 40 mg IV of pantoprazole daily does not raise gastric pH levels sufficiently to treat such life-threatening conditions. ■ Hypersensitivity reactions, including anaphylaxis and severe skin reactions (e.g., erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis), have been reported. ■ May be associated with an increased risk for osteoporosis-related fractures of the hip, wrist, or spine. Risk increased in patients receiving high-dose (multiple daily

doses) and long-term therapy (a year or longer). Use lowest dose and shortest duration of therapy appropriate for the condition being treated. ■ In patients treated with proton pump inhibitors (PPIs) for at least 3 months and, in most cases, after a year of treatment, hypomagnesemia (symptomatic and asymptomatic) has been reported. Serious adverse events, including arrhythmias, seizures, and tetany, have occurred. Discontinuation of the PPI and magnesium replacement have been required. ■ May be associated with an increased risk of *Clostridium difficile*-associated diarrhea (CDAD), especially in hospitalized patients. Consider in patients who develop diarrhea that does not improve. ■ See [Drug/Lab Interactions](#).

Monitor: Observe for S/S of a hypersensitivity and/or severe skin reactions. ■ Monitor vital signs and pain levels. ■ Concomitant use of antacids may be indicated. ■ In hypersecretory states, acid output measurements may be indicated to guide dose adjustment. ■ Monitor injection site. Thrombophlebitis has been reported. ■ Zinc supplementation may be indicated in patients who are prone to zinc deficiency; see [Precautions](#). ■ Monitoring of magnesium levels may be indicated with prolonged PPI therapy; see [Precautions](#) and [Drug/Lab Interactions](#). ■ Change to oral dosing when appropriate. ■ See [Drug/Lab Interactions](#).

Patient Education: Review prescription and non-prescription drugs with your physician. ■ Oral route preferred.

Maternal/Child: Category B: use during pregnancy only when clearly needed. ■ Has potential for serious harm to nursing infants; discontinue breast-feeding. ■ Safety and effectiveness for pediatric patients under 18 years of age not established.

Elderly: Safety and effectiveness similar to that of younger patients.

DRUG/LAB INTERACTIONS

Because of profound and long lasting inhibition of gastric acid secretion, pantoprazole may interfere with the **absorption of drugs in which gastric pH is an important determinant of their bioavailability** (e.g., ampicillin esters, digoxin, iron salts [ferrous sulfate], ketoconazole [Nizoral]). ■ Increases in INR and PT have been reported when administered concurrently with **warfarin** (Coumadin); monitoring of INR and PT indicated. ■ Concurrent use with **atazanavir** (Reyataz) or **nelfinavir** (Viracept) is not recommended. Coadministration of proton pump inhibitors (e.g., esomeprazole [Nexium], pantoprazole [Protonix]) results in a significant reduction in **atazanavir** or **nelfinavir** plasma concentrations, thereby inhibiting atazanavir's therapeutic effect and increasing development of drug resistance. ■ Long-term use may increase the risk of **digoxin** toxicity secondary to hypomagnesemia. ■ Patients on long-term therapy receiving concomitant **diuretic therapy** may be at increased risk for hypomagnesemia. ■ Concomitant use of proton pump inhibitors with high-dose **methotrexate** may elevate and prolong serum levels of methotrexate and/or its metabolite. May lead to methotrexate toxicity; consider withdrawal of pantoprazole. ■ Concomitant administration of pantoprazole and clopidogrel (Plavix) had no clinically significant effect on clopidogrel-induced platelet aggregation. No dose adjustment of clopidogrel is necessary when administered with approved doses of pantoprazole. ■ Studies suggest that with concurrent use the metabolism and serum concentrations of pantoprazole are not significantly altered by other drugs metabolized by the cytochrome P₄₅₀ system (e.g., clarithromycin [Biaxin], diazepam [Valium], diclofenac [Apo-Diclo], metoprolol [Lopressor], midazolam [Versed], naproxen [Aleve], nifedipine [ProCardia XL], phenytoin [Dilantin], piroxicam [Feldene], theophylline). ■ Studies also suggest that concurrent use with pantoprazole has not been found to significantly alter the metabolism and serum concentrations of the above agents as well as other drugs metabolized by a similar process (e.g., carbamazepine [Tegretol], cisapride [Propulsid], oral contraceptives). Concurrent administration should not require dose adjustment of either drug. ■ Amoxicillin, caffeine, digoxin (Lanoxin), ethanol, glyburide (DiaBeta), and metronidazole (Flagyl IV) had no clinically relevant interactions during clinical studies. ■ May cause false-positive **urine screening test for tetrahydrocannabinol (THC)**.

SIDE EFFECTS

The most frequently occurring side effects are abdominal pain, arthralgias, diarrhea, dizziness, flatulence, headache, nausea, and vomiting. Abscess, blurred vision, chest pain, confusion, dyspnea, gastroenteritis, hemorrhage, hyperglycemia, hypokinesia, increased salivation, injection site reactions including thrombophlebitis, pruritus, rash, speech disorder, tinnitus, transient elevations of serum transaminase, urinary tract infection, and vertigo are reported. Numerous other side effects have been associated with oral pantoprazole.

Post-Marketing: Anterior ischemic optic neuropathy, asthenia, bone fracture, CDAD, elevated creatine phosphokinase (CPK), fatigue, hallucinations, hepatocellular damage leading to jaundice and hepatic failure, hypersensitivity reactions (e.g., anaphylaxis, angioedema), hypomagnesemia, hyponatremia, insomnia, interstitial nephritis, malaise, pancreatitis, pancytopenia, rhabdomyolysis, severe dermatologic reactions (e.g., erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis [some fatal]), somnolence, weight gain.

ANTIDOTE

Keep physician informed of all side effects. May be treated symptomatically. Discontinue and initiate appropriate treatment if S/S associated with post-marketing reports occur; see [Side Effects](#). Adverse effects from overdose (up to 240 mg/day in healthy subjects) did not occur during clinical trials. Not removed by hemodialysis.

PAPAVERINE HYDROCHLORIDE

(pah-PAV-er-een hy-droh-KLOR-eyed)

Vasodilator
(peripheral)

pH 3 to 4.5

USUAL DOSE

1 to 4 mL (30 to 120 mg) every 3 hours as indicated. Second dose may be given in 10 minutes only when treating extrasystoles.

PEDIATRIC DOSE

1.5 mg/kg of body weight every 6 hours; see [Maternal/Child](#).

DOSE ADJUSTMENTS

See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted or may be diluted in an equal amount of SWFI. Usually not added to IV solutions. May be given through Y-tube or three-way stopcock of infusion set.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Will form a precipitate with LR.

One source suggests the following **compatibilities**:

Additive: Theophylline.

RATE OF ADMINISTRATION

1 mL (30 mg) or fraction thereof over 2 minutes. Rapid IV injection may cause death.

ACTIONS

A non-narcotic opium alkaloid, it is a direct smooth muscle relaxant and antispasmodic. Relaxation is noted in vascular system and bronchial musculature and in GI, biliary, and urinary tracts. More effective on muscle in spasm, it has an affinity for the smooth muscle of blood vessels. Affects cardiac muscle to depress conduction and increase re-

fractory period. Improved circulation and muscle relaxation decrease pain. Metabolized in the liver and excreted in the urine.

INDICATIONS AND USES

Vascular spasm associated with an acute myocardial infarction. ■ Peripheral or pulmonary embolism. ■ Peripheral vascular disease and cerebral angiospastic states. ■ Visceral spasm of ureteral, biliary, or GI colic. ■ Angina pectoris.

CONTRAINDICATIONS

Complete AV heart block.

PRECAUTIONS

Rarely used; active therapeutic value is questioned. ■ Rapid IV injection may cause death. ■ IM injection is preferred. ■ Use with caution in glaucoma and impaired liver function. ■ Large doses can depress AV and intraventricular conduction, resulting in arrhythmias.

Monitor: Observe patient continuously; monitor vital signs. ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid alcohol and other CNS depressants. ■ May cause dizziness and drowsiness; request assistance for ambulation. ■ Use caution in any task requiring alertness.

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding and in pediatric patients not established.

Elderly: Risk of hypothermia may be increased.

DRUG/LAB INTERACTIONS

May be used with **narcotics** if the relaxant effect is not adequate to relieve discomfort. Narcotic dosage should be reduced. ■ Antagonizes effects of **levodopa**.

SIDE EFFECTS

Blurred or double vision, diaphoresis, discomfort (generalized), flushing, hypertension (slight), hypotension, respiratory depth increase, scleral jaundice, sedation, tachycardia.

Major: Respiratory depression, seizures, ventricular ectopic rhythms, sudden death.

ANTIDOTE

Notify the physician of any minor side effects. If minor symptoms progress or any major side effect appears, discontinue the drug immediately and notify the physician. Treatment of toxicity will be symptomatic and supportive. Consider diazepam (Valium) or phenytoin (Dilantin) for convulsions. Anesthesia with thiopental and paralysis with a neuromuscular blocking agent may be required. Use dopamine for hypotension. Calcium gluconate may reduce toxic cardiovascular effects. Monitor ECG. Resuscitate as necessary.

PARICALCITOL

(pair-ee-KAL-sih-tohl)

Vitamin D analog

Zemlar

USUAL DOSE

The currently accepted target range for intact parathyroid hormone (iPTH) in chronic kidney disease (CKD) Stage 5 patients is no more than 1.5 to 3 times the non-uremic upper limit of normal.

Recommended initial dose is 0.04 to 0.1 mcg/kg administered no more frequently than every other day at any time during dialysis. Doses as high as 0.24 mcg/kg have been safely administered.

Information supplied by the manufacturer suggests that the relative dosing of paricalcitol to calcitriol is 4:1. When converting a patient from calcitriol to paricalcitol, the initial dose of paricalcitol should be four times greater than the patient's dose of calcitriol.

PEDIATRIC DOSE

Dose recommendations are based on severity of disease in addition to body weight. A dose is administered at any time during dialysis.

Pediatric patients 5 to 19 years of age (unlabeled): Doses used in clinical trials were:

Baseline iPTH level less than 500 pg/mL: 0.04 mcg/kg 3 times a week.

Baseline iPTH level equal to or greater than 500 pg/mL: 0.08 mcg/kg 3 times a week.

See [Dose Adjustments](#).

DOSE ADJUSTMENTS

Adults: Adjust dosing based on patient response. If a satisfactory response is not observed, dose may be increased by 2 to 4 mcg at 2- to 4-week intervals. Monitor serum calcium, phosphorus, and calcium \times phosphorus product (Ca \times P) frequently during any dose adjustment period. See [Monitor](#).

Pediatric patients: Adjust dose in 0.04-mcg/kg increments based on the levels of serum iPTH, calcium, and Ca \times P (from clinical trials).

Adults and pediatric patients: Reduce dose or interrupt therapy if elevated calcium level or a Ca \times P product of greater than 75 is noted. Reinitiate therapy at a lower dose when parameters have normalized. ■ Paricalcitol dose may need to be reduced as parathyroid hormone (PTH) levels decrease in response to therapy. The currently accepted target range for intact parathyroid hormone (iPTH) in patients with chronic kidney disease (CKD) is no more than 1.5 to 3 times the non-uremic upper limit of normal. Incremental dosing must be individualized and commensurate with PTH, serum calcium, and phosphorus levels. The following chart is a suggested approach to dose titration.

Paricalcitol Suggested Dosing Guidelines	
PTH Level	Paricalcitol Dose
The same or increasing	Increase
Decreasing by <30%	Increase
Decreasing by >30%, <60%	Maintain
Decreasing by >60%	Decrease
One and one-half to three times upper limit of normal	Maintain

DILUTION

May be given undiluted. Available as a 2 mg/mL and a 5 mcg/mL solution in 1- and 2-mL vials.

Filters: Not required by manufacturer; no further data available.

Storage: Store single- and multi-dose vials at CRT before use. Discard unused portions of single-dose vials. Multi-dose vial is stable for up to 7 days at CRT after entry into vial.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Administer as a bolus dose at any time during dialysis.

ACTIONS

A synthetic analog of calcitriol, the metabolically active form of vitamin D indicated for the prevention and treatment of secondary hyperparathyroidism associated with chronic kidney disease (CKD) Stage 5. In the diseased kidney, activation of vitamin D is diminished, resulting in a rise in parathyroid hormone (PTH), subsequently leading to secondary hyperparathyroidism and disturbances in calcium and phosphorus homeostasis. Paricalcitol binds to vitamin D receptors present in the parathyroid gland, intestine, kidney, and bone to maintain parathyroid function and calcium and phosphorus homeostasis. Studies suggest that paricalcitol may cause less hypercalcemia and hyperphosphatemia than calcitriol. Serum paricalcitol levels decrease rapidly after a bolus injection. Extensively bound to plasma proteins. Extensively metabolized by multiple hepatic and non-hepatic enzymes. Mean half-life is approximately 15 hours. Eliminated primarily by hepatobiliary excretion in feces and, to a much smaller extent, by the kidneys.

INDICATIONS AND USES

Prevention and treatment of secondary hyperparathyroidism associated with chronic kidney disease (CKD) Stage 5.

CONTRAINDICATIONS

Patients with evidence of vitamin D toxicity, hypercalcemia, or hypersensitivity to any ingredient in this product; see [Precautions](#).

PRECAUTIONS

Acute overdose may cause hypercalcemia and require emergency attention. If clinically significant hypercalcemia develops, dose should be reduced or held. Chronic administration may place patient at risk of hypercalcemia, elevated $\text{Ca} \times \text{P}$ product, and metastatic calcification. Chronic hypercalcemia can lead to generalized vascular calcification and other soft tissue calcification. See [Side Effects](#) and [Antidote](#). ■ Phosphate or vitamin D–related compounds should not be taken concomitantly with paricalcitol. High intake of calcium and phosphate concomitant with vitamin D compounds (paricalcitol) may lead to serum abnormalities and require more frequent monitoring and individualized dose titration. ■ Adynamic bone lesions may develop if PTH levels are suppressed to abnormal levels. ■ Avoid chronic administration of aluminum-containing preparations (e.g., antacids, phosphate binders); may increase blood levels of aluminum and cause aluminum bone toxicity.

Monitor: During initiation of therapy, obtain baseline serum calcium and phosphorus levels and determine levels at least twice a week. Once dosage has been established, serum calcium and phosphorus should be monitored at least monthly. See [Dose Adjustments](#). ■ Calculate $\text{Ca} \times \text{P}$ (should be less than 75). ■ Measurements of serum or plasma PTH are recommended every 3 months. ■ Monitor for signs and symptoms of hypercalcemia. See [Side Effects](#).

Patient Education: Report symptoms of hypercalcemia promptly (e.g., constipation, difficulty thinking clearly, fatigue, increased thirst, increased urination, loss of appetite, nausea or vomiting, weight loss). Dose adjustment or treatment may be required. Strict adherence to dietary supplementation of calcium and restriction of phosphorus is required to ensure optimal effectiveness of therapy. Phosphate-binding compounds (e.g., calcium acetate [Phos-*lo*], sevelamer [Renagel]) may be needed to control serum phosphorus levels in patients with CKD, but excessive use of aluminum-containing products (e.g., aluminum hydroxide gel [Alternagel]) should be avoided.

Maternal/Child: Category C: safety for use in pregnancy not established. Benefits must outweigh risks. ■ Discontinue breast-feeding. ■ Has not been studied in pediatric patients under 5 years of age.

Elderly: No overall differences in effectiveness or safety have been observed in the elderly.

DRUG/LAB INTERACTIONS

Specific interaction studies have not been performed. ■ Paricalcitol is partially metabolized by the **cytochrome P₄₅₀ enzyme CYP3A**. Use with caution when administered concomitantly **with known inhibitors of this enzyme** (e.g., atazanavir [Reyataz], clarithromycin [Biaxin], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase], telithromycin [Ketek], voriconazole [VFEND]). ■ Digitalis toxicity is potentiated by hypercalcemia. Use caution when paricalcitol is prescribed concomitantly with **digoxin** compounds. ■ **Phosphate or vitamin D-related compounds** should not be taken concomitantly with paricalcitol; see **Precautions**. ■ May reduce **serum total alkaline phosphatase** levels.

SIDE EFFECTS

Most commonly reported side effects include arthralgia, chills, dry mouth, edema, fever, gastrointestinal hemorrhage, influenza, malaise, nausea, palpitations, pneumonia, sepsis, and vomiting. Many other side effects occurred in fewer than 2% of patients. Overdose or chronic administration may lead to hypercalcemia. Signs and symptoms of vitamin D intoxication associated with hypercalcemia include: **Early:** bone pain, constipation, dry mouth, headache, metallic taste, muscle pain, nausea, somnolence, vomiting, and weakness. **Late:** Anorexia, cardiac arrhythmias, conjunctivitis (calcific), death, decreased libido, ectopic calcification, elevated AST and ALT, elevated BUN, hypercholesterolemia, hypertension, hyperthermia, overt psychosis (rare), pancreatitis, photophobia, pruritus, rhinorrhea, somnolence, and weight loss.

Post-Marketing: Hypersensitivity reactions (e.g., angioedema [including laryngeal edema]), rash, urticaria.

ANTIDOTE

Notify physician of any side effects. Treatment should consist of general supportive measures and serial serum electrolyte determinations (especially calcium). Monitor rate of urinary calcium excretion. Treatment of patients with clinically significant hypercalcemia consists of immediate dose reduction or interruption of the therapy and includes a low-calcium diet, withdrawal of calcium supplements, patient mobilization, attention to fluid and electrolyte imbalances, assessment of electrocardiographic abnormalities (critical in patients receiving digoxin), and hemodialysis or peritoneal dialysis against a calcium-free dialysate, as warranted. Monitor serum calcium levels frequently until calcium levels return to within normal limits. Paricalcitol may be restarted at a lower dose when serum calcium levels return to within normal limits. Not significantly removed by dialysis.

PEGASPARGASE

(peg-ASS-pair-gays)

Antineoplastic
(miscellaneous)

Oncaspar, PEG-L-Asparaginase

pH 7.3

USUAL DOSE

2,500 International units (IU)/M² every 14 days as an infusion. Most frequently used as a component of a multiple agent protocol. (International units [IU])

PEDIATRIC DOSE

Over 1 year of age with body surface area less than 0.6 M²: 82.5 IU/kg of body weight every 14 days. (International units [IU])

Body surface area greater than 0.6 M²: Same as adult dose.

DOSE ADJUSTMENTS

Adjust dose based on patient response and toxicity.

DILUTION

Available preservative free in 5-mL vials containing 750 IU/mL. Must be further diluted with 100 mL of NS or D5W and administered through the Y-tube or three-way stopcock of a free-flowing infusion of similar solutions. Do not shake; mix gently. Use only clear solutions. (International units [IU])

Storage: Appearance the same but activity is destroyed if accidentally frozen. **Do not administer!** Refrigerate before dilution. For single-dose use only. Do not reenter vial; discard unused portions. Discard any time solution is cloudy or after 48 hours at room temperature.

COMPATIBILITY

Specific information not available. Consider specific use and toxicity; consult pharmacist.

RATE OF ADMINISTRATION

A single dose evenly distributed over 1 to 2 hours. Slow rate of infusion as indicated by side effects.

ACTIONS

An oncolytic agent. A modified version of L-asparaginase (native asparaginase derived from *Escherichia coli*) that rapidly depletes asparagine from cells. Some malignant cells have a metabolic defect that makes them unable to synthesize asparagine as normal cells do. They are dependent on exogenous asparagine for survival. Depletion of asparagine kills the leukemic cells without affecting normal cells that synthesize their own asparagine. Plasma half-life range is from 2.5 to 8.5 days and does not appear to be influenced by dose levels, nor does it correlate with age, sex, surface area, renal or hepatic function, diagnosis, or extent of disease. Measurable for up to 15 days. Cannot be detected in urine.

INDICATIONS AND USES

First-line treatment of patients with acute lymphoblastic leukemia (ALL). ■ Treatment of patients with ALL and hypersensitivity to native forms of L-asparaginase. Used as a component of a multi-agent regimen for both indications. Occasionally used as a single agent when multiagent chemotherapy is considered inappropriate. Safety and effectiveness have been established in patients between 1 and 21 years of age with known previous hypersensitivity to native L-asparaginase.

Unlabeled uses: Treatment of acute lymphocytic leukemia.

CONTRAINDICATIONS

Pancreatitis, history of pancreatitis, serious thrombosis, or significant hemorrhagic events associated with prior L-asparaginase therapy, and patients who have had previous serious hypersensitivity reactions (e.g., bronchospasm, generalized urticaria, hypotension, laryngeal edema, hypotension) or other unacceptable adverse reactions to pegaspargase (Oncaspar).

PRECAUTIONS

Must be administered by or under the direction of the physician specialist (e.g., medical oncologist). ■ Incidence of hypersensitivity reactions, hepatotoxicity, coagulopathy, and gastrointestinal and renal disorders are lower if given by intramuscular injection. ■ Serious hypersensitivity reactions can occur. Risk increased in patients with known hypersensitivity to other forms of L-asparaginase. ■ Serious thrombotic events have occurred. ■ Pancreatitis has been reported. Evaluate patients with abdominal pain for evidence of pancreatitis. ■ Glucose intolerance has occurred; may be irreversible. ■ Increased PT, PTT, or hypofibrinogenemia are possible. ■ See **Monitor, Drug/Lab Interactions**, and **Antidote**.

Monitor: Observe patient carefully during and for at least 1 hour after infusion. ■ Appropriate treatment for resuscitation and/or anaphylaxis must always be available. Risk may be increased if patient has had reactions to native asparaginase. ■ Frequent monitoring of blood cell counts, bone marrow evaluation, serum amylase, blood sugar, uric acid, and liver and kidney function are necessary. ■ Monitoring of fibrinogen, PT, and PTT may be indicated to determine effects on coagulation. ■ Allopurinol, increased fluid intake, and alkalization of the urine may be required to reduce uric acid levels. ■ Nausea and vomiting can be severe. Prophylactic administration of antiemetics recommended to increase patient comfort. ■ Predisposition to infection probable. ■ Prophylactic antibiotics may be indicated pending results of C/S in febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Report all side effects promptly, especially abdominal pain, allergic reactions, bleeding, increased thirst, or S/S of thrombosis (chest pain, headache, shortness of breath, swelling); incidence of hypersensitivity reactions is significant and risk of bleeding is increased. ■ All meds including nonprescription drugs must be evaluated. Contact physician before changing any meds. ■ Verbalize all questions. ■ Assess birth control requirements. ■ See Appendix D, p. 1255.

Maternal/Child: Category C: effect on fetus unknown. Evaluation of benefit versus risk is necessary for anyone who is pregnant or may become pregnant. ■ Discontinue breastfeeding.

Elderly: Consider age-related organ toxicity.

DRUG/LAB INTERACTIONS

Manufacturer states that specific drug interaction studies have not been performed; other sources suggest that the combination regimen used may have the following effects:

Potential for increased risk of bleeding or thrombosis; may be exacerbated with concurrent administration of **drugs with anticoagulant effects** (e.g., heparin, coumadin, dipyridamole [Persantine], aspirin, or NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]). ■ Use caution with **hepatotoxic agents** (e.g., other chemotherapeutic agents, alcohol, NSAIDs, phenytoin [Dilantin]), especially in the presence of liver dysfunction. May cause hepatic and CNS toxicity. ■ May inhibit action of **drugs dependent on protein synthesis or cell replication** (e.g., methotrexate). One source suggests administering pegaspargase 24 hours after **methotrexate**. ■ May **interfere with the enzymatic detoxification** of other drugs, particularly in the liver. ■ **Depletes serum protein**; may increase the toxicity of protein-bound drugs.

SIDE EFFECTS

May be more toxic in adults than in pediatric patients. Hypersensitivity reactions, including anaphylaxis, occur more frequently in patients hypersensitive to native asparaginase (60% versus 12% in nonsensitized patients) and may be dose limiting. CNS thrombosis, coagulopathy, fever, hepatotoxicity, hyperbilirubinemia, hyperglycemia requiring insulin

therapy (3%), hypersensitivity reactions (e.g., anaphylaxis, bronchospasm, chills, dyspnea, edema, erythema, fever, hypotension, laryngeal edema, pain, rash, urticaria), increased ALT, malaise, nausea and vomiting (over 5%), pancreatitis (clinical) (1%), thrombosis (4%). Has caused fatal fulminating pancreatitis. Capable of causing numerous other side effects in 1% to 5% of all patients.

ANTIDOTE

Notify physician of all side effects. Reduced rate of administration may be helpful. Pegaspargase may have to be discontinued until recovery or permanently discontinued. Discontinue pegaspargase in patients who experience severe hypersensitivity reactions, thrombosis, or coagulopathies. Symptomatic and supportive treatment is indicated. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Consider administration of fresh frozen plasma (FFP) to patients with severe or symptomatic coagulopathy. There is no specific antidote.

PEGINESATIDE **BBW**

(PEG-in-ES-a-tide)

Antianemic agent

Omontys

pH 4.9 to 6.3

The manufacturer has voluntarily recalled peginesatide (Omontys) following serious hypersensitivity reactions, including life-threatening and fatal events, reported in patients using this drug.

USUAL DOSE

Evaluate iron stores before and during treatment and maintain iron repletion. Correct or exclude other causes of anemia (e.g., vitamin deficiency, metabolic or chronic inflammatory conditions, bleeding). Availability of iron stores, baseline hemoglobin, and concurrent medical problems affect the rate and extent of response. In controlled clinical trials, patients experienced greater risks for death, serious adverse cardiovascular reactions, and stroke when administered erythropoiesis-stimulating agents (ESAs) to target a hemoglobin level of greater than 11 Gm/dL. Individualize dosing using the lowest dose for each patient that will gradually increase the hemoglobin concentration to avoid the need for RBC transfusion. Initiate peginesatide when the hemoglobin level is less than 10 Gm/dL. **Starting dose:** 0.04 mg/kg of body weight administered as a single IV or SC injection once monthly. See Monitor and Precautions.

Conversion from epoetin alfa or darbepoetin alfa to peginesatide: Estimate starting monthly dose of peginesatide based on the weekly dose of epoetin alfa or darbepoetin alfa at the time of substitution as shown in the following chart. The route of administration (IV or SC) should remain the same. For patients previously receiving epoetin alfa, the first dose of peginesatide should be administered 1 week after the last epoetin dose. For patients previously receiving darbepoetin alfa, the first dose of peginesatide should be administered at the next scheduled dose in place of darbepoetin alfa.

Estimated Peginesatide Starting Dose Based on Previous Weekly ESA Dose		
Previous Total Weekly Epoetin Alfa Dose (units/week)	Previous Weekly Darbepoetin Alfa Dose (mcg/week)	Peginesatide Dose Once Monthly (mg/month)
Less than 2,500	Less than 12	2
2,500 to less than 4,300	12 to less than 18	3
4,300 to less than 6,500	18 to less than 25	4
6,500 to less than 8,900	25 to less than 35	5
8,900 to less than 13,000	35 to less than 45	6
13,000 to less than 19,000	45 to less than 60	8
19,000 to less than 33,000	60 to less than 95	10
33,000 to less than 68,000	95 to less than 175	15
Greater than or equal to 68,000	Greater than or equal to 175	20

DOSE ADJUSTMENTS

When adjusting therapy, consider hemoglobin rate of rise, hemoglobin rate of decline, ESA responsiveness, and hemoglobin variability. A single hemoglobin excursion may not require a dose adjustment. ■ Do not increase the dose more frequently than once every 4 weeks. ■ If the hemoglobin rises rapidly (e.g., more than 1 Gm/dL in any 2-week period or more than 2 Gm/dL in 4 weeks), reduce the dose by 25% or more as needed to reduce rapid responses. ■ If the hemoglobin level approaches or exceeds 11 Gm/dL, reduce or interrupt the dose of peginesatide. After the dose has been held and once the hemoglobin begins to decrease, peginesatide may be restarted at a dose approximately 25% below the previously administered dose. ■ For patients who do not

respond adequately (e.g., the hemoglobin has not increased by more than 1 Gm/dL after 4 weeks of therapy), increase the dose by 25%. ■ For patients who do not respond adequately over a 12-week escalation period, increasing the dose further is unlikely to improve response and may increase the risks. Discontinue peginesatide if responsiveness does not improve, and evaluate other causes of anemia. ■ If a dose of peginesatide is missed, administer the missed dose as soon as possible and resume once-monthly dosing frequency.

DILUTION

Available in numerous concentrations. Supplied in single-use or multiple-use vials or prefilled syringes with needle guards (needle cover contains a derivative of latex). Solution should be clear to slightly yellow. Must be given undiluted as an IV or SC injection. Do not administer in conjunction with other drug solutions. Single-use vial and prefilled syringes contain no preservatives. Use only one time, then discard.

Filters: No data available from the manufacturer.

Storage: Store all preparations in carton protected from light until use at 2° to 8° C (36° to 46° F). May be stored at temperatures up to 77° F (25° C) for up to 30 days. Refrigerate multi-use vials after first use and discard after 28 days.

COMPATIBILITY

Manufacturer states, “Do not administer in conjunction with other drug solutions.”

RATE OF ADMINISTRATION

A single dose over at least 1 minute.

ACTIONS

An erythropoiesis-stimulating agent that is a synthetic, pegylated dimeric peptide. Production of endogenous erythropoietin is impaired in patients with chronic renal failure, and erythropoietin deficiency is the primary cause of their anemia. Peginesatide binds to and activates the human erythropoietin receptor and stimulates erythropoiesis in human red cell precursors. Increases reticulocyte count, followed by hemoglobin. Does not appear to be metabolized. Urinary excretion is the predominant route of elimination. Half-life is 31.4 to 64.4 hours following IV administration.

INDICATIONS AND USES

Treatment of anemia associated with chronic kidney disease (CKD) in adult patients undergoing dialysis.

Limitations of Use: Peginesatide is not indicated and is not recommended for use in patients with CKD who are not on dialysis. ■ Not indicated and not recommended for use in patients receiving treatment for cancer whose anemia is not due to CKD. ■ Not indicated and not recommended for use as a substitute for RBC transfusions in patients who require immediate correction of anemia. ■ It has not been shown to improve symptoms, physical functioning, or health-related quality of life.

CONTRAINDICATIONS

Uncontrolled hypertension.

PRECAUTIONS

Erythropoiesis-stimulating agents (ESAs) increase the risk of death, MI, stroke, CHF, venous thromboembolism, and thrombosis of vascular access. Patients experienced greater risks of these adverse events when ESAs were administered to target a hemoglobin of greater than 11 Gm/dL. No trial has identified a hemoglobin target level, a peginesatide dose, or a dosing strategy that does not increase these risks. Use the lowest peginesatide dose sufficient to reduce the need for RBC transfusions. ■ Use with caution in patients with coexistent cardiovascular disease and stroke. Patients with CKD and an insufficient hemoglobin response to ESA therapy may be at even greater risk for cardiovascular reactions and mortality than other patients. ■ In clinical trials, ESAs increased the risk of death in patients undergoing CABG surgery and increased the risk of deep venous thrombosis in patients undergoing orthopedic procedures. ■ Increases in hemoglobin of greater than 1 Gm/dL during any 2-week period have been associated with an increased incidence of cardiac arrest, neurologic events (e.g., seizures, stroke), exacerbations of hypertension, congestive heart failure (CHF),

vascular thrombosis/ischemia/infarction, acute MI, deep vein thrombosis (DVT), pulmonary embolus, hemodialysis graft occlusion, and fluid overload/edema. See [Dose Adjustments](#). ■ Administration of erythropoiesis-stimulating agents (ESAs) to cancer patients shortened the overall survival time and/or increased the risk of tumor progression or recurrence in clinical studies of some patients with breast, cervical, head and neck, lymphoid, and non–small cell lung malignancies. Increased risk of death and serious adverse cardiovascular reactions, including MI and stroke, were observed in clinical trials of ESAs in patients with cancer. Peginesatide is not indicated for the reduction of RBC transfusion in patients receiving treatment for cancer whose anemia is not a result of CKD. The risk-benefit ratio for this patient population has not been evaluated. ■ BP may increase during therapy with peginesatide. Patients with uncontrolled hypertension should not be treated with peginesatide until BP has been adequately controlled. ■ In addition to low baseline hemoglobin and inadequate iron stores, delayed or diminished response may result from concurrent medical problems (e.g., infections, inflammatory or malignant processes, occult blood loss, underlying hematologic disease, folic acid or vitamin B₁₂ deficiency, hemolysis, aluminum intoxication, osteofibrosis cystica, bone marrow fibrosis, pure red cell aplasia [PRCA], or anti-erythropoietin antibody-associated anemia). Correct or exclude other causes of anemia before initiating therapy. If typical causes of lack or loss of hemoglobin response are excluded, evaluate the patient for the presence of antibodies. Contact manufacturer to perform assays for binding and neutralizing antibodies. ■ Therapy results in an increase in RBCs and a decrease in plasma volume, which could reduce dialysis efficiency; adjustment of dialysis prescription and anticoagulation with heparin may be necessary. ■ As with all proteins, there is a potential for immunogenicity.

Monitor: Monitor hemoglobin levels at least every 2 weeks until stable, then monitor at least monthly. ■ Monitor BP routinely. Initiation or intensification of antihypertensive therapy and dietary restrictions may be necessary. If BP is difficult to control by pharmacologic or dietary measures, the dose of peginesatide should be reduced or withheld. ■ Normal iron stores are required to support peginesatide-stimulated erythropoiesis. Transferrin saturation should be at least 20% and ferritin at least 100 ng/mL (100 mcg/L). Monitor before and during therapy. Supplemental iron is usually required to increase and maintain transferrin saturation. Administration of parenteral iron may be necessary in some patients.

Patient Education: Risk of seizures, especially for the first several months of therapy. Do not drive or operate heavy equipment. Report new-onset seizures, premonitory symptoms, or changes in seizure frequency to a health care professional. ■ Stress the importance of compliance with diet, iron and vitamin (e.g., folic acid, B₁₂) supplementation, BP control, and dialysis regimen. ■ Close monitoring of BP and hemoglobin is imperative. ■ Promptly report S/S of a hypersensitivity reaction, pain or swelling in the legs, shortness of breath (SOB), increase in BP, dizziness, or loss of consciousness. ■ Additional instruction (e.g., equipment, techniques) is required in patients who will self-administer (manufacturer supplies brochure). ■ Increased risk of mortality, serious cardiovascular events, thromboembolic events, and tumor progression or recurrence. ■ Read Medication Guide carefully. All patients should discuss the risks of using an ESA with a health care professional.

Maternal/Child:

Category C: may present risk to fetus; benefits must justify risk. ■ Use caution in nursing mothers. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response similar to that found in younger patients.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

The most common adverse events are arteriovenous fistula site complications, cough, diarrhea, dyspnea, and nausea. Other commonly reported side effects are arthralgias, back pain, fever, headache, hyperkalemia, hypertension, hypotension, muscle spasms,

pain in extremities, upper respiratory tract infection, and vomiting. Seizures and hypersensitivity reactions have also been reported.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Excessive hypertension may require discontinuation of peginesatide until BP is controlled or may respond to a reduction in the dose of peginesatide or to an increase in antihypertensive therapy. Reduce the dose of peginesatide in patients with an increase in hemoglobin of more than 1 Gm/dL in 2 weeks. May need to withhold peginesatide until hemoglobin falls to the desired goal. Consider phlebotomy in the event of overdose or polycythemia. If overdose or polycythemia does occur, monitor closely for cardiovascular events and hematologic abnormalities. When resuming therapy, monitor closely for evidence of rapid increases in hemoglobin concentration (greater than 1 Gm/dL within 14 days) and reduce dose as indicated. Adjustments in dialysis prescription may be required during dialysis to prevent clotting. Permanently discontinue therapy in patients with antibody-mediated anemia. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary.

PEGLOTICASE **BBW**

(peg-LOE-ti-kase)

Anti-gout agent

Krystexxa

USUAL DOSE

Discontinue oral urate-lowering medications before beginning therapy; see [Precautions](#) and [Drug/Lab Interactions](#).

Gout flare prophylaxis: Use of an NSAID or colchicine is recommended beginning at least 1 week before the start of pegloticase therapy and lasting at least 6 months unless medically contraindicated or not tolerated.

Premedication: Patients should be premedicated before each dose with antihistamines and corticosteroids to reduce the risk of infusion reactions, including anaphylaxis or other hypersensitivity reactions. An oral antihistamine and an IV corticosteroid and acetaminophen have been used.

Pegloticase: 8 mg as an IV infusion every 2 weeks. Optimum treatment duration not established.

DOSE ADJUSTMENTS

No dose adjustment is required based on age, gender, race, or renal impairment.

DILUTION

Withdraw 1 mL (8 mg) from the 2-mL vial. A clear, colorless solution that must be further diluted by injecting it into a 250-mL bag of NS or 1/2NS for infusion. Ensure thorough mixing by inverting the infusion bag a number of times. Do not shake. If diluted solution has been refrigerated, bring to RT before administration (do not subject to artificial heating [e.g., hot water, microwave]).

Filters: No study data available; if filtering is necessary, contact manufacturer.

Storage: Before use, refrigerate in carton at 2° to 8° C (36° to 46° F). Protect from light. Do not shake or freeze. Do not use beyond the expiration date stamped. Diluted infusion bags are stable for 4 hours refrigerated or at RT (20° to 25° C [68° to 77° F]). Manufacturer recommends storing under refrigeration, not frozen, protected from light, and used within 4 hours of dilution. Discard unused product remaining in the 2-mL vial.

COMPATIBILITY

Manufacturer states, “Do not mix or dilute with other drugs.”

RATE OF ADMINISTRATION

A single dose properly diluted as an infusion over no less than 2 hours; see [Antidote](#).

Do not administer by IV push or as a bolus. Administer by gravity feed with a syringe-type pump or infusion pump.

ACTIONS

A uric acid-specific enzyme; a PEGylated product that consists of recombinant modified mammalian urate oxidase (uricase) produced by a genetically modified strain of *Escherichia coli*. Achieves its therapeutic effect by catalyzing the oxidation of uric acid to allantoin, thereby lowering serum uric acid. Duration of suppression of plasma uric acid appears to be dose related. Allantoin is an inert and water-soluble purine metabolite that is readily eliminated, primarily by renal excretion.

INDICATIONS AND USES

Treatment of chronic gout in adult patients refractory to conventional therapy.

Limitation of use: Not recommended for the treatment of asymptomatic hyperuricemia.

CONTRAINDICATIONS

Patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency due to risk of hemolysis and methemoglobinemia.

PRECAUTIONS

Administer under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Anaphylaxis and infusion reactions have been reported to occur during and after administration of pegloticase. ■ Anaphylaxis may occur with any infusion, including a first infusion, and generally manifests within 2 hours of the infusion. However, delayed-type hypersensitivity reactions have also been reported. ■ Infusion reactions, including anaphylaxis, occurred in patients premedicated with one or more doses of an oral antihistamine and an IV corticosteroid and/or acetaminophen. ■ Risk of infusion reaction, including anaphylaxis, is higher in patients who have lost therapeutic response (e.g., uric acid levels increase to above 6 mg/dL). ■ Concomitant use of oral urate-lowering agents (e.g., allopurinol [Aloprim], febuxostat [Uloric]) and pegloticase may blunt the rise of serum uric acid levels. Discontinue oral urate-lowering medications and do not institute oral urate-lowering agents while taking pegloticase. ■ An increase in gout flares is often observed with the initiation of anti-hyperuricemic therapy because changing serum uric acid levels result in the mobilization of urate from tissue deposits. Gout flare prophylaxis with an NSAID (e.g., indomethacin [Indocin], ketoprofen, naproxen [Aleve, Naprosyn]) or colchicine is recommended. Pegloticase does not need to be discontinued because of a gout flare. ■ Exacerbation of CHF has occurred; use with caution in patients with CHF. ■ Data not available for safety and efficacy of retreatment with pegloticase after stopping treatment for longer than 4 weeks. May increase risk of infusion reactions, including anaphylaxis. ■ Anti-pegloticase antibodies developed in most patients treated. High titers were associated with a failure to maintain pegloticase-induced normalization of uric acid. These patients also had a higher incidence of infusion reactions. Anti-PEG antibodies were also detected; the impact on patients' responses to other PEG-containing therapeutics is unknown. ■ Effects of either renal or hepatic impairment on pegloticase pharmacokinetics were not studied.

Monitor: Before initiating treatment, screening for G6PD deficiency is recommended in patients at higher risk (e.g., African or Mediterranean ancestry); see [Contraindications](#). ■ Monitor serum uric acid levels before each infusion. Consider discontinuing treatment if levels increase to above 6 mg/dL, particularly when two consecutive levels above 6 mg/dL are observed. ■ Closely monitor for S/S of potential anaphylaxis for an appropriate period (e.g., during and for at least 1 hour after administration). Dyspnea, erythema, flushing, and urticaria were most commonly observed. Hemodynamic instability, perioral or lingual edema, and wheezing have been observed. Slow or stop the infusion (depending on the severity) if an infusion reaction occurs. ■ Closely monitor patients with a history of CHF during and after infusion. ■ Patients being restarted on therapy after a drug-free interval longer than 4 weeks should be monitored carefully.

Patient Education: Immediately report S/S of an infusion or hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Review prescription and non-prescription drugs with physician. Report use of oral urate-lowering agents. ■ Report side effects of pegloticase that are bothersome or do not go away (e.g., nausea, vomiting). ■ Patients of African or Mediterranean descent may require testing for G6PD deficiency. ■ Gout flares may increase with initiation of pegloticase; prophylactic medications recommended.

Maternal/Child: Category C: use during pregnancy only if clearly needed. ■ Not recommended for use during breast-feeding. ■ Safety and effectiveness for use in pediatric patients less than 18 years of age not established.

Elderly: Response similar to other age-groups; however, greater sensitivity in the elderly cannot be ruled out.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Concomitant use of oral **urate-lowering agents** (allopurinol [Aloprim], febuxostat [Uloric]) and pegloticase may blunt the rise of serum uric acid levels; discontinue oral urate-lowering medications and do not institute oral urate-lowering agents while taking pegloticase. ■ Anti-pegloticase antibodies appear to bind to the PEG portion of the drug; there may be the potential for binding with other PEGylated products (e.g., interferon alpha [Pegasys, Peg-Intron], L-asparaginase [Oncaspar], recombinant methionyl human granulocyte colony-stimulating factor [Neulasta], liposome-containing doxorubicin [Doxil, Caelyx]). Impact of anti-PEG antibodies on patients' responses to other PEG-containing therapeutics is unknown.

SIDE EFFECTS

Most common side effects include chest pain, contusion or ecchymosis, constipation, gout flares, nausea, nasopharyngitis, and vomiting. Most serious reactions are infusion reactions, including anaphylaxis or other hypersensitivity reactions.

ANTIDOTE

Keep physician informed of all side effects. Some will be tolerated or treated symptomatically. Discontinue immediately for any acute serious infusion or hypersensitivity reaction and treat as appropriate; may require epinephrine (Adrenalin), airway management, oxygen, antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol (Ventolin), IV fluids, and ventilation equipment as indicated. Resuscitate as necessary. Slow or stop the infusion (depending on the severity) if an infusion reaction occurs. May be restarted at a slower rate if symptoms subside. Pegloticase does not need to be discontinued because of a gout flare. No specific antidote; monitor and support as indicated in overdose. Resuscitate as necessary.

PEMETREXED

(peh-meh-TREX-ed)

Alimta

Antineoplastic
(Antifolate)

pH 6.6 to 7.8

USUAL DOSE**PREMEDICATION REQUIRED**

Regimen begins 1 week before the first infusion of pemetrexed.

Folic acid supplementation: Prophylaxis to reduce treatment-related hematologic and GI toxicity (pemetrexed is an antifolate; severe myelosuppression can occur); 400 to 1,000 mcg of folic acid **must** be taken daily for 7 days **before** the first dose of pemetrexed. Must be continued daily throughout the treatment regimen and for 21 days after treatment is complete. May be taken as a folic acid preparation or as a multivitamin with folic acid. The most commonly used dose of oral folic acid in clinical trials was 400 mcg.

Vitamin B₁₂ supplementation: Prophylaxis to reduce treatment-related hematologic and GI toxicity; 1,000 mcg of vitamin B₁₂ **must** be given as an injection 1 week **before** the first dose of pemetrexed. Repeat this dose every 3 cycles (about every 9 weeks) during treatment; subsequent doses may be given on the same day as the pemetrexed infusion. **Do not substitute oral vitamin B₁₂ for intramuscular vitamin B₁₂.**

Corticosteroid: To reduce the incidence and severity of skin rashes, administer dexamethasone (Decadron) 4 mg PO (or equivalent) twice daily the day before, the day of, and the day after the pemetrexed infusion. Repeat with each planned dose of pemetrexed.

Prehydration: Required with cisplatin; see cisplatin monograph.

PRETESTING REQUIRED

See **Monitor**. Do not begin a new cycle of treatment unless the ANC (absolute neutrophil count) is equal to or greater than 1,500 cells/mm³, the platelet count is equal to or greater than 100,000 cells/mm³, and the CrCl is equal to or greater than 45 mL/min.

PEMETREXED

Nonsquamous non–small-cell lung cancer (NSCLC) and malignant pleural mesothelioma: **Pemetrexed:** 500 mg/M² as an infusion over 10 minutes on Day 1 of each 21-day cycle.

Cisplatin: Begin 30 minutes after the end of the pemetrexed infusion. 75 mg/M² as an infusion over 2 hours.

As a single agent in nonsquamous NSCLC: **Pemetrexed:** 500 mg/M² as an infusion over 10 minutes on Day 1 of each 21-day cycle.

DOSE ADJUSTMENTS

Other than those recommended for all patients, no dose adjustments are required based on age, gender, or race or in patients with a CrCl equal to or greater than 45 mL/min. ■ Dose Adjustments are based on the nadir hematologic counts of the previous dose cycle for hematologic toxicities and the common toxicity criteria (CTC) for nonhematologic toxicities and neurotoxicity. Therapy may be delayed to allow sufficient time for recovery; when recovery occurs, reinstate therapy according to the following charts:

Pemetrexed/Cisplatin Dose Reduction (Single Agent or in Combination): Hematologic Toxicities	
ANC and Platelet Count	Dose of Pemetrexed (mg/M²) and Cisplatin (mg/M²)
Nadir ANC <500/mm ³ and nadir platelets ≥50,000/mm ³	75% of previous dose (both drugs)
Nadir platelets <50,000/mm ³ without bleeding, regardless of nadir ANC	75% of previous dose (both drugs)
Nadir platelets <50,000/mm ³ with bleeding, regardless of nadir ANC	50% of previous dose (both drugs)

Pemetrexed and Cisplatin Dose Reduction (Single Agent or in Combination) in Neurotoxicity		
CTC Grade*	Dose of Pemetrexed (mg/M ²)	Dose of Cisplatin (mg/M ²)
0 or 1	100% of previous dose	100% of previous dose
2	100% of previous dose	50% of previous dose
3 or 4	Discontinue therapy	Discontinue therapy

*Common Terminology Criteria for Adverse Events (CTCAE).

Excluding neurotoxicity, if patients develop nonhematologic toxicities equal to or greater than Grade 3, pemetrexed should be withheld until pretherapy values are achieved. Resume treatment according to the following chart.

Pemetrexed and Cisplatin Dose Reduction (Single Agent or in Combination): Nonhematologic Toxicities*		
CTC Grade†	Dose of Pemetrexed (mg/M ²)	Dose of Cisplatin (mg/M ²)
Any Grade 3 or 4 toxicities except mucositis	75% of previous dose	75% of previous dose
Any diarrhea requiring hospitalization or Grade 3 or 4 diarrhea	75% of previous dose	75% of previous dose
Grade 3 or 4 mucositis	50% of previous dose	100% of previous dose

*Excluding neurotoxicity.

†Common Terminology Criteria for Adverse Events (CTCAE).

Discontinue therapy if hematologic or nonhematologic Grade 3 or 4 toxicity occurs after two dose reductions or immediately if Grade 3 or 4 neurotoxicity is observed.

DILUTION

Specific techniques required; see *Precautions*. Calculate the dose and number of vials needed. Reconstitute each 100-mg vial with 4.2 mL of preservative-free NS and each 500-mg vial with 20 mL of preservative-free NS. Concentration equals 25 mg/mL. Gently swirl to completely dissolve the powder. Solution ranges in color from colorless to yellow or green-yellow. Withdraw the required volume to provide the calculated dose of pemetrexed. **Must** be further diluted to a total volume of 100 mL with preservative-free NS.

Filters: No data available from manufacturer.

Storage: Store unopened vials at CRT. Reconstituted and diluted solutions are chemically and physically stable for 24 hours refrigerated. Contains no preservatives; discard unused portions.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Is physically **incompatible** with diluents containing calcium, including lactated Ringer's and Ringer's injection. Coadministration with other diluents has not been studied." **Compatible** with standard PVC administration sets and bags.

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), amifostine (Ethyol), amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), carboplatin (Paraplatin), ceftriaxone (Rocephin), cefuroxime (Zinacef), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cytarabine (ARA-C), dexamethasone (Decadron), dexrazoxane (Zinecard), diphenhydramine (Benadryl), docetaxel (Taxotere), dopamine, enalaprilat (Vasotec IV), famotidine (Pepcid IV), fluconazole (Diflucan), fluorouracil (5-FU), ganciclovir (Cytovene), granisetron (Kytril), heparin, hydromorphone (Dilaudid), ifosfamide (Ifex), leucovorin calcium, lorazepam (Ativan), mannitol (Osmitrol), meperidine (Demerol), mesna (Mesnex), methylprednisolone (Solu-Medrol), metoclopramide (Reglan),

morphine, paclitaxel (Taxol), potassium chloride (KCl), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, sulfamethoxazole/trimethoprim, ticarcillin/clavulanate (Timentin), vancomycin, vinblastine, vincristine, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 10 minutes.

ACTIONS

An antifolate antineoplastic agent. It disrupts folate-dependent metabolic processes essential for cell replication. Transported into cells by both the reduced folate carrier and the membrane folate-binding protein transport systems. Converts to polyglutamate forms, which are inhibitors of folate-dependent enzymes involved in the de novo biosynthesis of thymidine and purine nucleotides. Polyglutamation is a time- and concentration-dependent process that occurs in tumor cells and, to a lesser extent, in normal tissues. Polyglutamated metabolites have an increased intracellular half-life, resulting in prolonged drug action in malignant cells. Inhibited the in vitro growth of mesothelioma cell lines and showed synergistic effects when used concurrently with cisplatin. Folic acid and vitamin B₁₂ supplementation is required during treatment. 81% bound to plasma protein. Not appreciably metabolized. Half-life is 3.5 hours. Primarily eliminated in urine as an unchanged drug. Clearance decreases and exposure (AUC) increases as renal function decreases.

INDICATIONS AND USES

Used in combination with cisplatin (Platinol) for the treatment of malignant pleural mesothelioma in patients whose disease is unresectable or who are not candidates for curative surgery. ■ As a single agent for treatment of patients with locally advanced or metastatic nonsquamous NSCLC after prior chemotherapy. ■ Used in combination with cisplatin for the initial treatment of patients with locally advanced or metastatic nonsquamous NSCLC. ■ Maintenance treatment of patients with locally advanced or metastatic nonsquamous NSCLC whose disease has not progressed after 4 cycles of platinum-based first-line chemotherapy.

Limitation of use: Not indicated for treatment of squamous cell NSCLC.

CONTRAINDICATIONS

History of severe hypersensitivity reaction to pemetrexed or any of its components. ■ Should not be administered to patients with a CrCl less than 45 mL/min.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Use of gloves recommended. If a solution of pemetrexed contacts the skin, wash the skin immediately and thoroughly with soap and water. If there is contact with mucous membrane, flush thoroughly with water. ■ Should be administered by or under the direction of a physician specialist in a facility equipped to monitor the patient and respond to any medical emergency. ■ Use caution in patients with a CrCl less than 80 mL/min if NSAIDs (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]) are administered concurrently. ■ Bone marrow suppression (e.g., anemia, neutropenia, thrombocytopenia) is a dose-limiting toxicity; see [Dose Adjustments](#). ■ Folic acid and vitamin B₁₂ supplementation is required; a prophylactic measure to reduce treatment-related hematologic and GI toxicity. ■ In patients with pleural effusion and/or ascites, consider drainage of third-space fluid before administration; the effects of this fluid accumulation on pemetrexed are not known. ■ Co-administration with cisplatin has not been studied in patients with moderate renal impairment. ■ Cutaneous reactions (skin rash) occur more frequently in patients not pretreated with a corticosteroid. ■ See [Contraindications](#) and [Drug/Lab Interactions](#).

Monitor: Pretreatment with folic acid, vitamin B₁₂, dexamethasone, and adequate hydration required; see [Usual Dose](#). ■ Obtain baseline CBC, including platelet count, CrCl, and liver function tests. Repeat CBC and platelet count before each dose and on days 8 and 15 of each cycle. Do not begin a new cycle of treatment unless the ANC is equal to or greater than 1,500 cells/mm³, the platelet count is equal to or greater than 100,000 cells/mm³, and the CrCl is equal to or greater than 45 mL/min. ■ Monitor CBC and platelets for nadir and recovery. Time to ANC nadir ranged between 8 and 9.6 days.

Return to baseline ANC occurred 4.2 to 7.5 days after the nadir. Has no cumulative effect on ANC nadir over multiple treatment cycles. ■ Repeat CrCl before each dose to evaluate renal function. Plasma clearance of pemetrexed given concurrently with cisplatin decreases as renal function decreases; see [Dose Adjustments](#) and [Contraindications](#). ■ No effect of elevated AST, ALT, or total bilirubin on the pharmacokinetics of pemetrexed was seen. However, formal studies to examine the effects of hepatic impairment on the pharmacokinetics of pemetrexed have not been conducted. ■ Monitor patients who have been or are taking NSAIDs carefully for signs of toxicity, especially myelosuppression and renal or GI toxicity; see [Drug/Lab Interactions](#). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See [Precautions](#), [Drug/Lab Interactions](#), and [Antidote](#).

Patient Education: Avoid pregnancy; use of nonhormonal birth control recommended. See [Maternal/Child](#). Women should report a suspected pregnancy immediately. ■ Adherence to regimen (medication [folic acid, vitamin B₁₂, dexamethasone, avoidance or limiting of aspirin or NSAIDs], required lab work, follow-up visits with health care professional) is imperative. ■ Promptly report S/S of anemia, bleeding, dehydration from diarrhea or vomiting, fatigue, infection (e.g., fever), rash, redness or sores in the mouth, trouble swallowing, or other symptoms. ■ Review manufacturer's supplied patient information guide. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. Fetotoxic and teratogenic in mice. ■ Reduced fertility, hypospermia, and testicular atrophy occurred in mice. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: See [Dose Adjustments](#); required only based on general patient criteria. ■ Incidence of common toxicity criteria (CTC) Grade 3 and 4 for anemia, fatigue, hypertension, neutropenia, and thrombocytopenia were greater in patients 65 years of age or older even though they were fully supplemented with vitamins.

DRUG/LAB INTERACTIONS

Concomitant use with **nephrotoxic agents** (e.g., aminoglycosides [e.g., gentamicin], amphotericin B, cisplatin [Platinol], NSAIDs, vancomycin) and **agents that are tubularly secreted** (e.g., probenecid) may delay clearance of pemetrexed. ■ **NSAIDs** (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]) decrease clearance and increase AUC in patients with normal renal function. Ibuprofen 400 mg four times daily was administered to patients with normal renal function (CrCl equal to or greater than 80 mL/min) who were receiving pemetrexed. Effects of larger doses unknown; see [Precautions](#). All patients taking NSAIDs should avoid taking them for from 2 days (short-acting NSAIDs) to 5 days (long-acting NSAIDs) before, the day of, and at least 2 days after a dose of pemetrexed. Monitoring for hematologic, renal, and GI toxicity required. ■ Pharmacokinetics of both drugs (pemetrexed and cisplatin) are not affected by each other. ■ Co-administration of oral folic acid or IM vitamin B₁₂ does not adversely affect pemetrexed. ■ Is not a clinically significant inhibitor of drugs metabolized by cytochrome P₄₅₀ enzymes. Used as recommended (every 21 days), it would not be expected to cause any significant enzyme induction. ■ May be used concurrently with aspirin in low to moderate doses (325 mg every 6 hours). Effect of higher doses not known.

SIDE EFFECTS

The most common side effects with single-agent use are anorexia, fatigue, and nausea. When used in combination with cisplatin, additional common side effects include constipation, hematologic toxicity (anemia, leukopenia, neutropenia, thrombocytopenia), pharyngitis, stomatitis, and vomiting. Bone marrow suppression (anemia, leukopenia, neutropenia, thrombocytopenia), selected nonhematologic toxicities (e.g., Grade 3 or 4 toxicities, diarrhea requiring hospitalization, mucositis), and neurotoxicity are dose-limiting toxicities. Other frequently occurring side effects include fever, infection (including sepsis), and rash with desquamation. Infections and rash leading to bullous

conditions (e.g., Stevens-Johnson syndrome and toxic epidermal necrolysis) have been fatal. Other side effects may include hypersensitivity reactions, alopecia, anorexia, arthralgia, chest pain, decreased CrCl, dehydration, depression, diarrhea, dysphagia, dyspnea, edema, elevated ALT, elevated AST, embolism or thrombosis, esophagitis, fatigue, febrile neutropenia, mood alteration, myalgia, neuropathy (sensory), odynophagia (pain produced by swallowing), renal failure.

Overdose: Bone marrow suppression (e.g., anemia, neutropenia, thrombocytopenia), diarrhea, infection with or without fever, mucositis, rash.

Post-Marketing: Colitis, edema, esophagitis, interstitial pneumonitis, pancreatitis, radiation recall.

ANTIDOTE

Keep physician informed of dose parameters and other side effects. Pemetrexed may be delayed or discontinued based on the degree of side effects. Symptomatic and supportive therapy is indicated. Death may occur from the progression of some side effects. Begin leucovorin treatment immediately for Grade 4 thrombocytopenia, bleeding associated with Grade 3 thrombocytopenia, or Grade 3 or 4 mucositis. Leucovorin treatment is also indicated if Grade 4 neutropenia or Grade 4 leukopenia lasting 3 or more days occurs. Regimen recommended is leucovorin 100 mg/M² IV as an initial dose followed by 50 mg/M² IV every 6 hours for 8 days. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Effect of hemodialysis on pemetrexed is unknown.

PENICILLIN G AQUEOUS

(pen-ih-SILL-in A-kwe-us)

Antibacterial
(penicillin)

Penicillin G Potassium, Penicillin G Sodium, Pfizerpen

pH 5.5 to 8

USUAL DOSE

Adults and pediatric patients 12 years of age and older: 1 to 20 million units/24 hr equally distributed over 24 hours as a continuous infusion or equally divided in 4 to 6 intermittent infusions (250,000 to 5 million units every 6 hours or 166,000 to 3,333,333 units every 4 hours). Doses up to 80 million units/24 hr have been given in life-threatening infections. (400,000 units equals approximately 250 mg.) See package insert for specific indications.

PEDIATRIC DOSE

Administration by intermittent infusion over 15 to 30 minutes is preferred. Dose is based on age or weight and the severity of the infection.

Serious infections (e.g., pneumonia, endocarditis): 25,000 units/kg every 4 hours or 37,500 units/kg every 6 hours (150,000 units/kg/24 hr).

Meningitis: 41,666 units/kg every 4 hours (250,000 units/kg/24 hr). Continue treatment for 7 to 14 days. Maximum dose is 12 to 20 million units/24 hr.

Disseminated gonococcal infections (arthritis), weight less than 45 kg: 25,000 units/kg every 6 hours (100,000 units/kg/24 hr) for 7 to 10 days.

Disseminated gonococcal infections (meningitis), weight less than 45 kg: 41,666 units/kg every 4 hours (250,000 units/kg/24 hr) for 10 to 14 days.

Disseminated gonococcal infections (endocarditis), weight less than 45 kg: 41,666 units/kg every 4 hours (250,000 units/kg/24 hr) for 4 weeks.

Disseminated gonococcal infections (arthritis, meningitis, endocarditis), weight 45 kg or greater: 2,500,000 units every 6 hours (10,000,000 units/24 hr). Duration of therapy is dependent on diagnosis.

Syphilis (congenital or neurosyphilis) after the newborn period: 50,000 units/kg every 4 to 6 hours (200,000 to 300,000 units/kg/24 hr). Continue treatment for 10 to 14 days.

Diphtheria (adjunctive to antitoxin and prevention of carrier state): 37,500 to 62,500 units/kg every 6 hours (150,000 to 250,000 units/kg/24 hr) for 7 to 10 days.

Rat-bite fever, Haverhill fever (caused by a specific organism): 25,000 to 41,666 units/kg every 4 hours (150,000 to 250,000 units/kg/24 hr) for 4 weeks.

The American Association of Pediatrics (AAP) recommends:

Infants and other pediatric patients from 1 month to less than 12 years of age: Mild to moderate bacterial infections: 6,250 to 12,500 units/kg every 6 hours (25,000 to 50,000 units/kg/24 hr).

Severe bacterial infections and Group B streptococcal meningitis: 62,500 to 100,000 units/kg every 6 hours or 41,666 to 66,666 units/kg every 4 hours (250,000 to 400,000 units/kg/24 hr).

Another source recommends:

Pediatric patients under 12 years of age: 100,000 to 400,000 units/kg/24 hr in equally divided doses every 4 to 6 hours as an intermittent infusion (25,000 to 100,000 units/kg every 6 hours or 16,666 to 66,666 units/kg every 4 hours). Dosage can vary greatly and must be adjusted according to the severity of the infection. Maximum dose is 24,000,000 units/24 hr.

Treatment of congenital syphilis over 4 weeks of age: 50,000 to 75,000 units/kg every 6 hours (200,000 to 300,000 units/kg/24 hr). Total course of treatment is 10 to 14 days.

NEONATAL DOSE

Administration by intermittent infusion over 15 to 30 minutes is preferred. Dose is based on weight and age and the severity of the infection.

The AAP recommends 25,000 to 50,000 units/dose. Adjust interval based on weight and age as follows:

Moderate to severe bacterial infections:

Weight less than 1,200 Gm; 4 weeks of age or younger: Every 12 hours.

Weight 1,200 to 2,000 Gm; less than 7 days of age: Every 12 hours.

Weight 1,200 to 2,000 Gm; 1 to 4 weeks of age: Every 8 hours.

Weight over 2,000 Gm; less than 7 days of age: Every 8 hours.

Weight over 2,000 Gm; 1 to 4 weeks of age: Every 6 hours.

Meningitis caused by beta streptococci:

7 days of age or younger: 83,333 to 133,333 units/kg every 8 hours (250,000 to 400,000 units/kg/24 hr).

Older than 7 days of age: 112,500 units/kg every 6 hours (450,000 units/kg/24 hr).

Treatment of congenital syphilis less than 4 weeks of age: 50,000 units/kg every 12 hours (100,000 units/kg/24 hr) for the first week, then 50,000 units/kg every 8 hours (150,000 units/kg/24 hr) for an additional 3 to 7 days. Total course of treatment is 10 to 14 days.

DOSE ADJUSTMENTS

Reduce dose in severe impaired renal function; additional reductions may be indicated if liver function is also impaired. ■ If CrCl is greater than 10 mL/min in uremic patients, give a full loading dose followed by one-half loading dose every 4 to 5 hours. ■ If CrCl is less than 10 mL/min/1.73 M², administer a full loading dose followed by one half of the loading dose every 8 to 10 hours. Another source recommends giving 75% of a normal dose every 4 to 6 hours to patients with a CrCl of 10 to 50 mL/min and 20% to 50% of a normal dose every 4 to 6 hours to patients with a CrCl less than 10 mL/min. ■ See Drug/Lab Interactions.

DILUTION

Available as a premixed frozen solution, or reconstitute each vial with SWFI or NS. Direct flow of diluent against sides of the vial while gently rotating vial. Shake vigor-

ously. Directions on vial should be followed to provide desired number of units per milliliter. Available with 1, 5, 10, and 20 million units per vial. May be added to NS or dextrose solutions for infusion. See chart on inside back cover.

Storage: Dry powder stored at CRT. Reconstituted solutions of penicillin G potassium are stable for 1 week if refrigerated. Reconstituted solutions of penicillin G sodium are stable for 3 days if refrigerated. Infusion solutions are stable at CRT for 24 hours. Store pre-mixed frozen solution at or below -20°C (-4°F). The thawed solution is stable for 14 days refrigerated or for 24 hours at RT. Do not refreeze.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Penicillins are rapidly inactivated in alkaline carbohydrate solutions, reducing agents, alcohols, and glycols; optimum pH range is 6 to 7. To preserve bactericidal action, consult pharmacist before mixing other agents with penicillin in the infusion solution. May form a precipitate with vancomycin. Inactivated in solution with aminoglycosides (e.g., amikacin [Amikin], gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

PENICILLIN G POTASSIUM

Additive: See [general comments under Compatibility](#). Amikacin (Amikin), ascorbic acid, calcium chloride, calcium gluconate, chloramphenicol (Chloromycetin), colistimethate (Coly-Mycin M), dimenhydrinate, diphenhydramine (Benadryl), ephedrine, erythromycin (Erythrocin), heparin, hydrocortisone sodium succinate (Solu-Cortef), lidocaine, lincomycin (Lincocin), magnesium sulfate, methylprednisolone (Solu-Medrol), metronidazole (Flagyl IV), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, verapamil.

Y-site: Acyclovir (Zovirax), amiodarone (Nexterone), cyclophosphamide (Cytosan), diltiazem (Cardizem), enalaprilat (Vasotec IV), esmolol (Brevibloc), fluconazole (Diflucan), foscarnet (Foscavir), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), labetalol, magnesium sulfate, meperidine (Demerol), morphine, nicardipine (Cardene IV), potassium chloride (KCl), tacrolimus (Prograf), theophylline, verapamil.

PENICILLIN G SODIUM

Additive: See [general comments under Compatibility](#). Calcium chloride, calcium gluconate, chloramphenicol (Chloromycetin), colistimethate (Coly-Mycin M), dextran 40, diphenhydramine (Benadryl), erythromycin (Erythrocin), gentamicin, heparin, hydrocortisone sodium succinate (Solu-Cortef), lincomycin (Lincocin), potassium chloride (KCl), ranitidine (Zantac), verapamil.

Y-site: Levofloxacin (Levaquin).

RATE OF ADMINISTRATION

Penicillin is not given by IV injection. Administer as ordered as continuous IV drip; for example, 5 million units in 1,000 mL of D5W over 12 hours. Is sometimes given by intermittent infusion ($\frac{1}{6}$ or $\frac{1}{4}$ of a daily dose in 100 mL over 1 to 2 hours every 4 to 6 hours). Because of its short half-life, frequent dosing is required to maintain serum concentration above the MIC (minimum inhibitory concentration) for most of the dosing interval. Too-rapid administration or excessive doses may cause electrolyte imbalance and/or seizures. Stable at room temperature for at least 24 hours.

Pediatric rate: Administration by intermittent infusion over 15 to 30 minutes is preferred for infants and children.

ACTIONS

Bactericidal against penicillin-sensitive microorganisms during the stage of active multiplication. Inhibits bacterial cell wall synthesis. Distributed into most body fluids. Distribution into spinal fluid is minimal unless inflammation is present. Half-life is approximately 40 minutes. Crosses the placental barrier. Excreted in the urine via glomerular

filtration and tubular secretion. Secreted in breast milk. Available in a potassium salt containing 1.02 mEq of potassium and 0.3 mEq sodium in 1 million units or a sodium salt containing 2 mEq sodium in 1 million units.

INDICATIONS AND USES

Severe infections caused by penicillin G–sensitive gram-positive, gram-negative, and anaerobic microorganisms (e.g., streptococcal, pneumococcal, Vincent’s gingivitis, spirochetal infections, meningitis, endocarditis).

Unlabeled uses: Arthritis, carditis.

CONTRAINDICATIONS

Known sensitivity to any penicillin or cephalosporin (not absolute; see **Precautions**).

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients undergoing penicillin therapy; most likely to occur in patients with a history of penicillin allergy or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies necessary to determine susceptibility of the causative organism to penicillin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, penicillin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue treatment for 48 to 72 hours after symptoms subside. To reduce the risk of rheumatic fever, patients being treated for Group A beta-hemolytic streptococcal infections should be treated for at least 10 days. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with penicillin. ■ Potassium penicillin most frequently used. Doses over 10,000,000 units may cause fatal hyperkalemia, especially in patients with renal insufficiency.

Monitor: Periodic evaluation of renal, hepatic, and hematopoietic systems is recommended in prolonged therapy. ■ Test patients with gonococcal infections and syphilis for HIV. Test patients with gonococcal infections for syphilis. ■ Electrolyte imbalance from potassium or sodium content is very possible. Monitor closely. Penicillin G potassium contains 1.02 mEq sodium/million units. May aggravate CHF. ■ May cause thrombophlebitis; observe carefully and rotate infusion sites. ■ See **Drug/Lab Interactions**.

Patient Education: May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: use only if clearly needed. ■ May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Elimination rate markedly reduced in neonates.

Elderly: Response similar to that seen in younger adults. ■ Consider age-related organ impairment and concomitant disease or drug therapy. Monitor renal function. ■ See **Dose Adjustments**.

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **aminoglycosides** (e.g., amikacin [Amikin], gentamicin). Synergism may be inconsistent; see **Compatibility**. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ **ASA, ethacrynic acid** (Edecrin), **furosemide** (Lasix), **indomethacin** (Indocin), **sulfonamides** (Bactrim), and **thiazide diuretics** (e.g., chlorothiazide [Diuril]) may interfere with tubular secretion of penicillin, increasing serum concentration and risk of toxicity. ■ Risk of bleeding with **anticoagulants** (e.g., heparin) is increased. ■ **Probenecid** decreases elimination of penicillin resulting in prolonged half-life and increased serum levels. May be desirable or may cause toxicity. ■ May decrease

effectiveness of **oral contraceptives**; breakthrough bleeding or pregnancy could result. ■ Concomitant use with **potassium supplements**, **potassium-sparing diuretics** (e.g., spironolactone [Aldactone]), or **ACE inhibitors** (e.g., enalapril [Vasotec]) may increase risk of hyperkalemia. ■ May decrease clearance and increase toxicity of **methotrexate**. ■ May cause false values in common **lab tests**; see literature.

SIDE EFFECTS

Arthralgia, chills, edema, fever, pain at the injection site, prostration, skin rash, thrombophlebitis, urticaria.

Major: Acute interstitial nephritis, anaphylaxis, convulsions, hemolytic anemia, hyperreflexia, neurotoxicity, potassium poisoning with coma, sodium-induced congestive heart failure. Hypersensitivity myocarditis (fever, eosinophilia, rash, sinus tachycardia, ST-T changes and cardiomegaly) and CDAD can occur. Higher-than-normal doses may cause neurologic adverse effects including convulsions, especially with impaired renal function.

ANTIDOTE

For all side effects, discontinue the drug, treat hypersensitivity reactions or resuscitate as necessary, and notify the physician. Treat minor side effects symptomatically according to physician's order. Mild cases of CDAD may respond to discontinuation of the drug. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Removed by hemodialysis.

PENTAMIDINE ISETHIONATE

(pen-TAM-ih-deen is-ah-THIGH-oh-nayt)

Antiprotozoal

pH 4.09 to 5.4

USUAL DOSE

Treatment of *Pneumocystis jiroveci*: 4 mg/kg of body weight once daily for 14 days. See [Precautions/Monitor](#). Has been used up to 21 days; benefits not defined.

***Pneumocystis* prophylaxis:** 4 mg/kg once each month. May be given every 2 weeks if indicated.

Leishmania, visceral (unlabeled): 2 to 4 mg/kg once daily for up to 15 days.

Leishmania, cutaneous (unlabeled): 2 to 4 mg/kg once or twice a week until lesions heal.

Trypanosoma gambiense (unlabeled): 4 mg/kg once daily for 10 days.

PEDIATRIC DOSE

***Pneumocystis jiroveci*:** 4 mg/kg once daily for 12 to 14 days.

***Pneumocystis* prophylaxis:** See [Usual Dose](#).

Leishmania donovani: 2 to 4 mg/kg once daily for 15 days. Up to 21 days have been suggested, but risks with therapy over 14 days may be increased.

Trypanosoma gambiense: See [Usual Dose](#).

DOSE ADJUSTMENTS

Reduced dose in renal failure may be indicated. One source recommends 4 mg/kg every 24 hours with a CrCl of 10 to 50 mL/min or 4 mg/kg every 24 to 36 hours with a CrCl less than 10 mL/min.

DILUTION

Initially dilute each 300 mg or fraction thereof in 3 to 5 mL SWFI or D5W. A single dose must be further diluted in 50 to 250 mL of D5W and given as an infusion.

Storage: Stable at room temperature for 24 hours. Discard unused portion. Protect dry product and reconstituted solution from light.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Will form a precipitate with NS; do not use for dilution or infusion. Manufacturer states, "Do not mix pentamidine solutions with any other drugs."

One source suggests the following **compatibilities**:

Y-site: Diltiazem (Cardizem), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose should be evenly distributed over 60 minutes.

Leishmania, visceral and cutaneous: A single dose evenly distributed over 1 to 2 hours.

ACTIONS

An antiprotozoal agent. Specifically active against *Pneumocystis jiroveci*. It is thought to interfere with nuclear metabolism and inhibit the synthesis of DNA, RNA, phospholipids, and proteins. Route of metabolism is unknown. Excreted partially in urine. May accumulate in renal failure.

INDICATIONS AND USES

Treatment and prophylaxis of *Pneumocystis jiroveci* pneumonia (PCP).

Unlabeled uses: Treatment of trypanosomiasis and visceral and cutaneous leishmaniasis. Aerosol used prophylactically to prevent PCP in high-risk patients.

CONTRAINDICATIONS

None if the diagnosis of *Pneumocystis jiroveci* pneumonia is confirmed.

PRECAUTIONS

Specific use only; establish correct diagnosis. ■ Sulfamethoxazole/trimethoprim is the drug of choice for treatment of *Pneumocystis* pneumonia. Pentamidine causes numerous and serious side effects and is indicated only if the patient does not respond to or tolerate

SMX-TMP. ■ Use extreme caution in patients with hypertension, hypotension, hypoglycemia, hyperglycemia, hypocalcemia, leukopenia, thrombocytopenia, anemia, hepatic or renal dysfunction, ventricular tachycardia, pancreatitis, and Stevens-Johnson syndrome.

Monitor: Before, during, and after therapy obtain a BUN and SCr (daily), CBC, platelet count, alkaline phosphatase, bilirubin, AST, ALT, serum calcium, and ECG. ■ Has caused fatalities resulting from severe hypotension, hypoglycemia, and cardiac arrhythmias even with the administration of the first dose. Keep patient supine, observe continuously for any sign of adverse reaction, and monitor BP continuously during infusion and afterward until stable. ■ Emergency equipment for resuscitation must be immediately available. ■ Monitor blood glucose levels daily during therapy and several times after therapy is complete. Pancreatic necrosis and very high plasma insulin levels have occurred. May also cause hyperglycemia and diabetes mellitus.

Patient Education: May cause severe hypotension; remain lying down until BP is stable. ■ Report any unusual bleeding or bruising.

Maternal/Child: Category C: use only when clearly needed during pregnancy and breast-feeding. Hazards to fetus or infant are unknown. ■ Discontinue breast-feeding.

DRUG/LAB INTERACTIONS

Nephrotoxic effects may be additive with concomitant use with **other nephrotoxic drugs** (e.g., aminoglycosides [e.g., gentamicin], amphotericin B, cisplatin [Platinol], foscarnet [Foscavir], vancomycin). Monitoring of renal function, dose reductions, and/or dose interval adjustments may be required.

SIDE EFFECTS

Occur in over 50% of patients and may be life threatening. Some occur after course of treatment is completed. Acute renal failure, anemia, anorexia, bad taste in mouth, cardiac arrhythmias including ventricular tachycardia, confusion, dizziness, elevated SCr and liver function tests, fever, hallucinations, hyperglycemia, hyperkalemia, hypocalcemia, hypoglycemia, hypotension, leukopenia, nausea, neuralgia, phlebitis, rash, thrombocytopenia.

ANTIDOTE

Discontinue drug for any life-threatening side effects. Notify physician of all side effects. Symptomatic treatment indicated. Resuscitate as necessary.

PENTAZOCINE (LACTATE)

(pen-TAZ-oh-seen LAK-tayt)

Narcotic analgesic
(agonist-antagonist)
Anesthesia adjunct

Talwin

pH 4 to 5

USUAL DOSE

30 mg. May repeat every 3 to 4 hours or decrease to 5 to 15 mg and repeat every 2 hours. 360 mg equals maximum dose in 24 hours. Use oral form of pentazocine when appropriate.

Patients in labor: 20 mg when contractions become regular. May repeat every 2 to 3 hours as needed for two or three additional doses.

DOSE ADJUSTMENTS

Reduced dose may be required in the elderly or debilitated, in impaired hepatic or renal function, in patients with limited pulmonary reserve, and in the presence of other CNS depressants; use caution. ■ Increased dose may be required in smokers. ■ See [Precautions](#), [Drug/Lab Interactions](#), and [Elderly](#).

DILUTION

May be given undiluted. It is preferable to dilute each 5 mg with at least 1 mL of SWFI. **Storage:** Store at CRT. Avoid freezing.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not mix in the same syringe with soluble barbiturates (e.g., phenobarbital [Luminal]); precipitation will occur."

One source suggests the following **compatibilities:**

Y-site: Heparin, hydrocortisone sodium succinate (Solu-Cortef), potassium chloride (KCl).

RATE OF ADMINISTRATION

Each 5 mg or fraction thereof over 1 minute.

ACTIONS

A synthetic narcotic agonist-antagonist with a potent analgesic action, pentazocine is somewhat less effective than morphine and meperidine in equivalent doses. May produce respiratory depression, but does not increase markedly with increased doses. Onset of action is prompt, 2 to 3 minutes, and lasts about 2 to 3 hours. Metabolized in the liver. Excreted in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Relief of moderate to severe pain. ■ Preoperative medication. ■ Support of anesthesia. ■ Obstetric analgesia.

CONTRAINDICATIONS

Hypersensitivity to pentazocine or its components (contains sulfites); pathologic brain conditions.

PRECAUTIONS

Use with caution in bronchial asthma, relief of biliary pain, history of drug abuse, decreased renal or hepatic function, respiratory depression from any cause, a history of seizures, and in patients with head injury or increased intracranial pressure. ■ Some formulations contain sulfites; use caution in patients with allergies; see [Contraindications](#). ■ Use with caution in patients with acute MI accompanied by hypertension or left ventricular failure. May increase systemic and pulmonary arterial pressure and systemic vascular resistance. ■ Mild narcotic antagonist. May precipitate withdrawal symptoms in patients accustomed to narcotics. ■ May provide less effective analgesia in heavy smokers.

Monitor: Naloxone (Narcan), oxygen, and controlled respiratory equipment must always be available. ■ Observe patient continuously during injection and frequently thereafter. Monitor vital signs. Keep patient supine to minimize side effects; orthostatic hypotension and fainting may occur. Observe closely during ambulation. ■ Pain control usually more effective with routinely administered doses. Determine appropriate interval through clinical assessment. ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid use of alcohol or other CNS depressants (e.g., antihistamines, diazepam [Valium]). ■ Request assistance for ambulation. ■ May be habit forming.

Maternal/Child: Category C: safety for use in pregnancy, (other than labor) and breastfeeding not established. ■ Respiratory depression, dyspnea, and transient apnea have been reported in a small number of newborn infants whose mothers received pentazocine during labor. ■ Use extreme caution if necessary during delivery of premature infants. ■ Safety and effectiveness for IV use in pediatric patients under 12 years of age not established.

Elderly: May be more sensitive to effects (e.g., respiratory depression, confusion, constipation, dizziness, oversedation, urinary retention). ■ Analgesia should be effective with lower doses. ■ Consider age-related organ impairment, monitoring of renal function may be indicated. ■ Half-life longer and clearance lower compared to younger patients. ■ See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Potentiated by **cimetidine** (Tagamet), and other CNS depressants such as narcotic analgesics, general anesthetics, alcohol, anticholinergics, antihistamines, barbiturates, hypnotics, sedatives, psychotropic agents, MAO inhibitors, and neuromuscular blocking agents (e.g., atracurium [Tracrium]). Reduced doses of both drugs may be indicated. ■ May decrease analgesic effects of **other narcotics**; avoid concurrent use. ■ Metabolism and clearance increased in **smokers**; analgesic effects may be decreased.

SIDE EFFECTS

Apprehension, blurred vision, circulatory depression, confusion, constipation, cramps, depression, diarrhea, disorientation, dizziness, double vision, dreams, drug dependence, dry mouth, dyspnea, euphoria, facial edema, floating feeling, flushing, hallucinations, headache, hypersensitivity reactions, hypertension, injection site reactions, insomnia, muscle tremor, nausea, neonatal apnea, nervousness, nystagmus, paresthesias, perspiration, pruritus, respiratory depression, sedation, seizures, shock, tachycardia, taste alteration, urinary retention, uterine contraction depression.

ANTIDOTE

For any side effect, discontinue the drug and notify the physician. Treat side effects symptomatically. For overdose or respiratory depression, naloxone hydrochloride (Narcan) is the antidote of choice. If naloxone is not available, methylphenidate (Ritalin) may be of value in respiratory depression (only available in oral form).

PENTETATE CALCIUM TRISODIUM INJECTION ▪ PENTETATE ZINC TRISODIUM INJECTION **BBW**

Antidote

(PEN-teh-tayt **KAL**-see-um try-**SO**-dee-um in-**JEK**-shun ▪ PEN-teh-tayt **ZINK** try-**SO**-dee-um in-**JEK**-shun)

Ca-DTPA ▪ Zn-DTPA

pH 7.3 to 8.3 ▪
pH 6.5 to 7.5

USUAL DOSE

Chelation therapy with either pentetate calcium trisodium (Ca-DTPA) or pentetate zinc trisodium (Zn-DTPA) is most effective when administered within the first 24 hours after internal contamination; however, it should be started as soon as possible after suspected or known internal contamination, even if more than 24 hours have passed. **Initiation of therapy with a single dose of pentetate calcium trisodium (Ca-DTPA) is preferred because it is more effective than pentetate zinc trisodium (Zn-DTPA) in the first 24 hours.** Only a single dose of Ca-DTPA is recommended. Use Zn-DTPA if additional chelation therapy is indicated. **If Ca-DTPA is not available, initiate therapy with pentetate zinc trisodium (Zn-DTPA).** Preliminary lab tests desired; see [Monitor](#). See [Maternal/Child](#). **Do not administer more than one dose of either agent in a 24-hour period.**

Adults and pediatric patients 12 years of age or older: Initial dose: 1 Gm IV (dose is the same for either agent).

After the initial dose, **maintenance treatment is recommended with pentetate zinc trisodium (Zn-DTPA).** If Zn-DTPA is not available, therapy may be continued with Ca-DTPA. Ca-DTPA has more toxicity (e.g., depletion of more trace metals, higher rate of mortality, the presence of kidney and liver vacuolization [air or fluid in the tissues], and small bowel hemorrhagic lesions), and concomitant mineral supplements containing zinc are required. Zn-DTPA results in minimal depletion of manganese and magnesium.

Maintenance dose: 1 Gm IV daily (dose is the same for either agent; however, Zn-DTPA is preferred). If Ca-DTPA is used for maintenance doses, transfer to Zn-DTPA as soon as it is available. Zn-DTPA may be administered for days, months, or years depending on the extent of internal contamination and individual response to therapy.

PEDIATRIC DOSE

Pediatric patients less than 12 years of age: Initial dose: 14 mg/kg IV (dose is the same for either agent). Do not exceed 1 Gm. See [all comments under Usual Dose](#).

Maintenance dose: 14 mg/kg IV daily. See [all comments under Usual Dose](#).

DOSE ADJUSTMENTS

No dose adjustment is required in patients with impaired renal function; however, renal impairment may reduce the rate at which the chelators remove radiocontaminants from the body. Hemodialysis may be used to increase the rate of elimination in heavily contaminated patients with renal impairment. The use of high flux dialysis is recommended. The dialysis fluid requires handling with radiation precautions.

DILUTION

Both agents: IV: A single dose may be given undiluted as an IV injection or diluted in 100 to 250 mL of D5W, NS, or LR and given as an infusion. To open the ampule, face the point upward and break off the neck with a downward movement.

Nebulized inhalation: Dilute in a 1:1 ratio with SWFI or NS (equal amounts of drug and diluent).

Filters: Manufacturer states product may be filtered.

Storage: Store between 15° to 30° C (59° to 86° F).

COMPATIBILITY

Specific information not available.

RATE OF ADMINISTRATION

Both agents: IV injection: A single dose evenly distributed over 3 to 4 minutes.

IV infusion: A single dose properly diluted and infused over 30 minutes.

ACTIONS

Both agents: Hyperosmolar solutions. Form stable chelates with radioactive contaminants (metal ions) found in the circulation, interstitial fluid, and tissues by exchanging calcium or zinc for a metal of greater binding capacity. Most effective with plutonium, americium, or curium. Chelating capacity is greatest immediately and up to approximately 24 hours after internal contamination, when the radiocontaminant is still circulating and readily available for chelation. The ability to chelate decreases with time as the radioactive contaminants incorporate into tissues and become sequestered in the liver and bone. Rapidly distributed throughout the extracellular fluid space. Significant amounts do not penetrate into erythrocytes or other cells. Accumulation in specific organs has not been observed. Metabolism is minimal. Cleared by glomerular filtration. Activity in plasma was not detectable 24 hours after injection. Excreted in urine.

Pentetate calcium trisodium (Ca-DTPA): More effective than pentetate zinc trisodium (Zn-DTPA) in the first 24 hours. After 24 hours, both drugs are equally effective, but Ca-DTPA is not recommended for continued use.

INDICATIONS AND USES

Treatment of individuals with known or suspected internal contamination with radiocontaminants (e.g., plutonium, americium, or curium) to increase the rates of elimination. ■ If Ca-DTPA is not available, initiate therapy with Zn-DTPA. ■ May also be inhaled as treatment for inhalation contamination; it is absorbed, and inhalation results in comparable elimination of the radiocontaminants.

CONTRAINDICATIONS

None known when used for primary indication.

PRECAUTIONS

Both agents: For IV use, safety of IM injection not established. ■ Begin chelation treatment as soon as possible after known or suspected internal contamination with radiocontaminants. The ability of both agents to chelate decreases with time as the radioactive contaminants incorporate into tissues. ■ Radioactive iodine is not bound by DTPA. ■ Not expected to be effective for uranium and neptunium because less stable chelates are formed, which results in the deposition of these elements in tissues (including the bone). ■ Studies in patients with impaired renal or hepatic function have not been conducted. Impaired renal function is expected to increase the half-life of Ca-DTPA and Zn-DTPA and decrease the rate of elimination of the radiocontaminants; see *Dose Adjustments*. ■ Nebulized chelation therapy may exacerbate asthma; use caution. ■ Contamination with multiple or unknown radiocontaminants may require additional therapies (e.g., Prussian blue, potassium iodide). ■ Manufacturer requests collection of patient treatment data; see prescribing information.

Pentetate calcium trisodium (Ca-DTPA): Ca-DTPA is associated with depletion of trace metals such as zinc. Loss of zinc, manganese, and magnesium from the small intestine, skeleton, pancreas, and testes is significant; see *Monitor*. The rate and amount of endogenous metal depletion has been shown to increase with split daily dosing, increased doses, and/or duration of treatment. Depletion of these endogenous metals can interfere with necessary mitotic cellular processes and has resulted in transient inhibition of a metalloenzyme-D-aminolevulinic acid dehydrase (ALAD) in the blood and suppressed hematopoiesis (formation of blood cells). Concomitant supplements containing zinc are required. ■ Use with caution in patients with severe hemochromatosis (a disorder of iron metabolism); deaths have been reported with the use of Ca-DTPA for more than 1 day. ■ Monitor for S/S of asthma exacerbation when administered by the inhalation route.

Pentetate zinc trisodium (Zn-DTPA): Results in minimal depletion of manganese and magnesium.

Monitor: Both agents: If possible, obtain baseline CBC with differential, BUN, serum chemistries and electrolytes, urinalysis, and blood and urine radioassays before initiating

treatment. ■ Monitor serum zinc levels, serum creatinine, BUN, electrolytes, urinalysis, and blood cell counts during Ca-DTPA or Zn-DTPA therapy. Give mineral or vitamin plus mineral supplements that contain zinc as appropriate. ■ Measure the radioactivity in blood, urine, and fecal samples weekly to monitor the radioactive contaminant elimination rate. ■ When possible, establish an elimination curve. A quantitative baseline estimate of total internalized transuranium elements(s) and measures of elimination of radioactivity should be obtained by appropriate whole-body counting, bioassay (e.g., biodosimetry), or fecal/urine sample. ■ Care should be taken to minimize radiation exposure to patients and to medical personnel from patients' contaminated excrement (e.g., blood, sputum, urine); this is consistent with institutional good radiation safety practices and patient management procedures. Contact the radiation safety officer. ■ Encourage fluid intake and frequent voiding. Promotes dilution of the radiocontaminant in urine and minimizes radiation exposure to the bladder. ■ Document adverse reactions. ■ See [Precautions](#), [Maternal/Child](#), and [Drug/Lab Interactions](#).

Pentetate calcium trisodium (Ca-DTPA): If more than one dose of Ca-DTPA is used, monitor lab tests more frequently (with specific attention to serum zinc), and initiate vitamin or mineral supplements containing zinc when appropriate.

Pentetate zinc trisodium (Zn-DTPA): Based on lab tests, initiate mineral or vitamin plus mineral supplements as appropriate.

Patient Education: Both agents: The following steps are required to minimize contamination of others by the radiocontaminants. Use a toilet instead of a urinal and flush several times after each voiding, because treatment increases excretion of radioactivity in the urine. Completely clean up spilled urine or feces, and wash hands thoroughly. Wash clothes that come in contact with blood or urine separately. Drink plenty of fluids; fluid intake is important to aid in flushing radiocontaminants from the system. Void frequently to limit the time that radiocontaminants remain in the bladder. Carefully dispose of expectorant from coughing; do not swallow expectorant. ■ Parents and caregivers need to take extra precautions in handling the urine, feces, and expectorants of children to avoid additional exposure to the caregiver or child.

Maternal/Child: Both agents: Discontinue breast-feeding whether or not chelation therapy is received. Radiocontaminants are secreted in breast milk. Take precautions when disposing of breast milk. ■ Safety and effectiveness of the nebulized route of administration in pediatric patients has not been established.

Pentetate calcium trisodium (Ca-DTPA): Category C: use during pregnancy only if potential benefit justifies the potential risk to the fetus. Teratogenicity in humans cannot be ruled out. Birth defects in animals increased with dose, and incidences were higher in early and mid gestation. ■ Treatment of pregnant women with pentetate zinc trisodium (if available) is preferred, except in cases of high internal radioactive contamination. The risk of immediate and delayed radiation-induced toxicity to both the mother and the fetus should be considered in comparison to the risk of pentetate calcium trisodium because it is more effective than pentetate zinc trisodium in the first 24 hours after internal contamination. The use of a single dose of Ca-DTPA with vitamin or mineral supplements containing zinc may be considered as the initial treatment.

Pentetate zinc trisodium (Zn-DTPA): Category B: treatment of pregnant women should begin and continue with Zn-DTPA. Use only if clearly needed; however, animal studies revealed no evidence of impaired fertility or harm to the fetus.

Elderly: Specific information not available.

DRUG/LAB INTERACTIONS

Specific drug interactions have not been studied. ■ Contamination with **multiple or unknown radiocontaminants** may require the use of additional therapies (e.g., Prussian blue, potassium iodide).

SIDE EFFECTS

Pentetate calcium trisodium (Ca-DTPA): Allergic reactions, chest pain, dermatitis, diarrhea, headache, injection site reactions, light-headedness, metallic taste, and nausea have occurred. Prolonged treatment may result in depletion of manganese, magnesium, zinc

and, possibly, metalloproteinases. Cough and/or wheezing occurred with nebulized Ca-DTPA.

Pentetate zinc trisodium (Zn-DTPA): Headache, light-headedness, and pelvic pain have been reported. Exacerbation of asthma may occur with nebulized chelation therapy. Allergic reactions may occur.

ANTIDOTE

Keep physician informed of side effects; symptomatic treatment is indicated. Treat a hypersensitivity reaction as indicated (oxygen, antihistamines [e.g., diphenhydramine (Benadryl)], epinephrine [Adrenalin], and corticosteroids [e.g., methylprednisolone (Solu-Medrol)]). Maintain a patent airway. Resuscitate as necessary.

PENTOBARBITAL SODIUM

(PEN-toh-bar-bih-tal SO-dee-um)

Barbiturate
Sedative-hypnotic
Anticonvulsant

Nembutal Sodium

pH 9 to 10.5

USUAL DOSE

100 mg initially. Wait 1 full minute between each dose to determine drug effect. Additional doses in increments of 25 to 50 mg may be given as indicated. Maximum dosage ranges from 200 to 500 mg.

Barbiturate coma: Loading dose: 3 to 10 mg/kg over 30 minutes to 3 hours.

Maintenance dose: 1.5 to 2 mg/kg every 1 to 2 hours or an infusion of 0.5 to 3 mg/kg/hr. Adjust to maintain pentobarbital blood level between 110 and 177 mm/L (25 to 40 mg/dL) or ICP below 25 Torr.

PEDIATRIC DOSE

See *Maternal/Child*.

1 to 3 mg/kg slowly until asleep. Maximum dose 100 mg/24 hr.

Barbiturate coma: See *Usual Dose*. An alternate source suggests **Loading dose:** 10 to 15 mg/kg over 1 to 2 hours. **Maintenance dose:** Begin with 1 mg/kg/hr; increase to 2 to 3 mg/kg/hr to maintain EEG burst suppression.

DOSE ADJUSTMENTS

Reduce dose in impaired renal or hepatic function; usually required in the debilitated or elderly. ■ See *Drug/Lab Interactions*.

DILUTION

May be given undiluted or, preferably, may be further diluted in SWFI, NS, or Ringer's injection. Any desired amount of diluent may be used. 9 mL of diluent with 1 mL of pentobarbital (50 mg) equals 5 mg/mL. Use only absolutely clear solutions.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be admixed with any other medication or solution." Do not mix in a syringe with pentazocine (Talwin); precipitation will occur. May precipitate in acidic solutions.

One source suggests the following **compatibilities:**

Additive: Not recommended by manufacturer. Amikacin (Amikin), aminophylline, calcium chloride, chloramphenicol (Chloromycetin), dimenhydrinate, erythromycin (Erythrocin), lidocaine, verapamil.

Y-site: Acyclovir (Zovirax), insulin (regular), linezolid (Zyvox), propofol (Diprivan).

RATE OF ADMINISTRATION

50 mg or fraction thereof over 1 minute. Titrate slowly to desired effect. Rapid injection rate may cause symptoms of overdose (e.g., serious respiratory depression).

Barbiturate coma: See specific dose recommendations.

ACTIONS

A sedative, hypnotic barbiturate of short duration with anticonvulsant effects. Pentobarbital is a CNS depressant. Onset of action is prompt by the IV route and lasts about 3 to 4 hours. Will effectively depress the motor cortex if adequate doses are administered. Pain perception is unimpaired. Reportedly reduces cerebral blood flow and thus reduces cerebral edema and intracranial pressure. Detoxified in the liver and excreted fairly quickly in the urine in changed form. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Preanesthetic sedation. ■ Dental and minor surgical sedation. ■ Control of convulsions caused by disease and drug poisoning. ■ Short-term hypnotic. ■ Sedation in psychotic states.

Unlabeled uses: High doses have been used to induce coma in the management of cerebral ischemia and increased intracranial pressure. Has been most effective in patients under 35 years of age or in closed head injuries.

CONTRAINDICATIONS

Acute or chronic pain, delivery (when maximum drug effect would be at the time of delivery), history of porphyria, known hypersensitivity to barbiturates, severely impaired liver function especially with any signs of hepatic coma, severe respiratory disease or depression.

PRECAUTIONS

IV route usually reserved for critical situations. ■ Use caution in status asthmaticus, shock, severe renal or liver disease, depressive states after convulsions, shock, and in the elderly. ■ Use caution in acute or chronic pain. ■ Status epilepticus can occur from too-rapid withdrawal. ■ May be habit forming. Use caution in the presence of fever, diabetes, hyperthyroidism, or severe anemia; may increase side effects. ■ Benzodiazepines (diazepam [Valium], midazolam [Versed]) generally preferred for sedation.

Monitor: Record BP, pulse, and respirations every 3 to 5 minutes. Keep patient under constant observation. ■ Maintain a patent airway. ■ Treat the cause of a convulsion. ■ Highly alkaline; determine absolute patency of vein; use of large veins preferred to prevent thrombosis. Avoid extravasation. Intra-arterial injection will cause gangrene. ■ Monitor phenytoin and barbiturate levels when both drugs are used concurrently. ■ Monitor hematopoietic, renal, and hepatic systems in extended therapy. ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid alcohol and other CNS depressants (e.g., antihistamines, diazepam [Valium]). ■ May be habit forming. ■ May require alternate birth control.

Maternal/Child: Category D: avoid pregnancy; will cause birth defects. ■ May cause drowsiness in the nursing infant. ■ See [Contraindications](#). ■ May cause paradoxical excitement in pediatric patients.

Elderly: Often have increased sensitivity to barbiturates; may cause marked excitement, depression, confusion, and increased risk of barbiturate-induced hypothermia. ■ See [Dose Adjustments](#) and [Precautions](#). ■ Consider age-related hepatic or renal impairment and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

Use extreme caution if any **other CNS depressants** have been given, such as alcohol, narcotic analgesics, anesthetics, antidepressants, antihistamines, hypnotics, MAO inhibitors, phenothiazines, sedatives, aminoglycoside antibiotics, or tranquilizers; potentiation with respiratory depression may occur. ■ Inhibits effectiveness of **propranolol, corticosteroids, doxycycline, oral anticoagulants, oral contraceptives, quinidine, and theophylline**. Capable of innumerable interactions with many drugs. ■ May increase orthostatic hypotension with

furosemide (Lasix). ■ Monitor **phenytoin** and barbiturate levels when both drugs are used concurrently. ■ May inhibit **vitamin D** metabolism with extended use.

SIDE EFFECTS

Average dose: Depression, dermatitis, facial edema, fever, hypotension, neonatal apnea, pain at or below injection site, respiratory depression (hypoventilation), thrombocytopenic purpura.

Overdose: Apnea, coma, cough reflex depression, flat EEG (reversible unless hypoxic damage has occurred), hypotension, laryngospasm, lowered body temperature, pulmonary edema, renal shutdown, respiratory depression, sluggish or absent reflexes.

ANTIDOTE

Discontinue drug immediately for pain at or below injection site. Notify the physician of any side effects. Symptomatic and supportive treatment are most important in overdose. Maintain an adequate airway with artificial ventilation if indicated. Keep the patient warm. IV volume expanders (dextran) and IV fluids will help maintain adequate circulation. Diuretics or hemodialysis will promote the elimination of the drug. Vasopressors (dopamine) will maintain BP.

PENTOSTATIN **BBW**

(PEN-toh-stah-tin)

Antineoplastic
(antibiotic)

2-Deoxycofomycin, Nipent

pH 7 to 8.5

USUAL DOSE

Evaluation and prehydration is required before administration; see [Monitor](#).

4 mg/M² every other week. Do not exceed recommended dose; see [Precautions](#). If there is no major toxicity and improvement is continuous, treat until a complete response is achieved, then administer two additional doses. Do not treat beyond 12 months.

DOSE ADJUSTMENTS

Reduced dose and benefit-versus-risk assessment may be required with impaired renal function (CrCl below 60 mL/min); insufficient data available. Two patients with impaired renal function (CrCl 50 to 60 mL/min) achieved complete response without unusual adverse events when treated with 2 mg/M². ■ Withhold dose if SCr elevated; obtain CrCl. ■ Withhold dose if the absolute neutrophil count falls from a baseline of greater than 500 cells/mm³ before therapy to less than 200 cells/mm³ during treatment. Resume treatment when count returns to predose levels.

DILUTION

Specific techniques required; see [Precautions](#). Diluent (5 mL SWFI) provided; dissolve completely; will yield 2 mg/mL. May be given by IV injection or further diluted in 25 to 50 mL NS or D5W; 25 mL yields 0.33 mg/mL, 50 mL yields 0.18 mg/mL. Treat spills or waste with a 5% sodium hypochlorite solution before disposal.

Storage: Refrigerate before initial reconstitution. Store at room temperature and use within 8 hours after initial reconstitution or dilution for infusion.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Does not interact with PVC infusion containers or administration sets at concentrations specified for dilution.

One source suggests the following **compatibilities**:

Y-site: Melphalan (Alkeran), ondansetron (Zofran), paclitaxel (Taxol), sargramostim (Leukine). Physically **compatible** at the **Y-site** with fludarabine (Fludara); however, the two drugs are not recommended for concurrent use; see [Drug/Lab Interactions](#).

RATE OF ADMINISTRATION

Follow each dose with an additional 500 mL of prehydration infusion fluids.

IV injection: A single dose over 1 minute.

Infusion: A single dose over 20 to 30 minutes.

ACTIONS

Mechanism of action is not known, but it is cytotoxic as a result of its potent inhibition of the enzyme adenosine deaminase (ADA). Blocks DNA and RNA synthesis and causes DNA damage. Average terminal half-life of 6 hours is extended to 18 hours in patients with impaired renal function (CrCl less than 50 mL/min). Inhibits ADA for up to 1 week; actual response may not occur for months. Primarily excreted in urine.

INDICATIONS AND USES

Single-agent treatment of both untreated patients and alpha-interferon–refractory hairy cell leukemia (HCL) patients with active disease as defined by clinically significant anemia, neutropenia, thrombocytopenia, or disease-related symptoms.

Unlabeled uses: Treatment of chronic lymphocytic leukemia, prolymphocytic leukemia, non-Hodgkin's lymphoma, cutaneous T-cell lymphoma, and peripheral T-cell lymphomas.

CONTRAINDICATIONS

Hypersensitivity to pentostatin; see [Drug/Lab Interactions](#).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Assess drug profile before administration. ■ Severe renal, liver, pulmonary, and CNS toxicities have occurred at higher doses; do not exceed recommended dose. ■ Usually administered by or under the supervision of a physician specialist. ■ Myelosuppression, especially neutropenia, is most severe during the first few courses of treatment. ■ Must consider risk/benefit in patients with some bone marrow suppression, the possibility of chickenpox or herpes zoster, a history of gout or urate renal stones, renal function impairment, or previous cytotoxic drug or radiation therapy. Use extreme caution. ■ After 6 months of treatment, assess for response; if partial or complete response is not evident, discontinue treatment. If partial response is evident, reevaluate as indicated but do not treat beyond 12 months.

Monitor: Monitor CBC (including differential and platelet count) and SCr before each dose and as indicated. Blood chemistries including serum uric acid, and a CrCl assay is required before and during treatment. ■ Prehydration with 500 to 1,000 mL D5^{1/2}NS or an equivalent is required. An additional 500 mL is required postadministration. ■ Treatment of patients with infection may exacerbate symptoms and cause death. Control infection before treatment initiated. Withhold treatment if an active infection occurs; resume when infection is controlled. ■ Prophylactic antiemetics recommended (e.g., prochlorperazine [Compazine], ondansetron [Zofran]); continue for 48 to 72 hours. ■ Observe closely for severe rashes, nervous system toxicity, and myelosuppression (especially after initial cycles); pentostatin may have to be withheld or discontinued. ■ For severe neutropenia beyond the initial cycles, evaluate for disease status, including a bone marrow examination. ■ Assess response to treatment with periodic monitoring of peripheral blood for hairy cells. Bone marrow aspirates and biopsies may be required at 2- to 3-month intervals. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Consider birth control options; nonhormonal birth control recommended. ■ Report rashes, symptoms of infection, or bruising and bleeding immediately. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; can cause fetal harm. ■ Discontinue breastfeeding. ■ Safety for use in pediatric patients under 18 years of age not established.

Elderly: Consider decreased renal function.

DRUG/LAB INTERACTIONS

Assess drug profile before administration. ■ Do not use with **fludarabine** (Fludara); may increase risk of fatal pulmonary toxicity. ■ Combination therapy with **carmustine** (BiCNU), **etoposide** (VePesid), and **high-dose cyclophosphamide** as part of the ablative regimen for bone marrow transplant has caused acute pulmonary edema and hypotension. Deaths have occurred. ■ Pentostatin enhances the effects of **vidarabine** (Ara-A). Combined use of these agents may result in an increase in adverse reactions associated with each drug. The therapeutic benefit of this drug combination has not been established. ■ May cause skin rash with **allopurinol**. ■ Elevates **liver function tests**; usually reversible. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Uric acid levels may increase, increased dose of **gout agents** (e.g., colchicine, probenecid, sulfapyrazone [Anturane]) may be indicated. ■ Leukopenia and thrombocytopenia increased by **agents causing blood dyscrasias** (e.g., anticonvulsants [phenytoin (Dilantin)], penicillins, phenothiazines, and many others).

SIDE EFFECTS

Anemia, anorexia, chills, cough, diarrhea, fatigue, fever, GU disorders, headache, hepatic disorders/elevated liver function tests, hypersensitivity reactions, infection, leukopenia, lung disorders, myalgia, nausea, neurologic disorders/CNS, pain, rashes, skin disorders, thrombocytopenia, upper respiratory infections, and vomiting occur in 10% of patients and may require discontinuation of treatment. Abdominal pain, abnormal thinking, abnormal vision, abnormal ECG, anxiety, arthralgia, asthenia, back pain, bronchitis, cardiac arrhythmias, chest pain, confusion, conjunctivitis, constipation, depression, dizziness, dry skin, dyspnea, dysuria, ear pain, ecchymosis, eczema; elevated BUN, creatinine, and LDH; epistaxis, eye pain, flatulence, flu syndrome, hematuria, hemorrhage, herpes simplex, herpes zoster, insomnia, lung edema, lymphadenopathy, maculopapular rash, malaise, neoplasm, nervousness, paresthesia, peripheral edema, petechia, pharyngitis, pneumonia, pruritus, rhinitis, seborrhea, sinusitis, skin discoloration, somnolence, stomatitis, sweating, thrombophlebitis, vesiculobullous rash, weight loss, and death have occurred in 3% to 10% or more of patients.

ANTIDOTE

Keep physician informed of all side effects; most will be treated symptomatically if indicated. Withhold dose and notify physician for elevated SCr, absolute neutrophil count below 200 cells/mm³, myelosuppression, infection, CNS toxicity, or severe rash. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Overdose may cause death due to severe renal, hepatic, pulmonary, or CNS toxicity. There is no specific antidote. Supportive therapy as indicated will help sustain the patient.

PERTUZUMAB **BBW**

(per-TOOZ-ue-mab)

Recombinant monoclonal antibody
Antineoplastic

Perjeta

pH 6

USUAL DOSE

Preassessment is required; see **Monitor**. Pertuzumab is given in combination with trastuzumab (Herceptin) and docetaxel (Taxotere). See docetaxel and trastuzumab monographs; pre-assessment and premedication indicated. Pertuzumab, trastuzumab, and docetaxel should be administered sequentially. Pertuzumab and trastuzumab can be given in any order. Docetaxel should be administered after pertuzumab and trastuzumab infusions are complete. An observation period of 30 to 60 minutes is recommended after each pertuzumab infusion and before beginning any subsequent infusion of trastuzumab or docetaxel.

Initial doses: *Pertuzumab:* 840 mg as an infusion over 60 minutes; see **Monitor**; preassessment required.

Trastuzumab: 8 mg/kg as an infusion over 90 minutes.

Docetaxel: 75 mg/M² as an infusion over 60 minutes.

Subsequent doses: Begin 3 weeks after initial doses.

Pertuzumab: 420 mg administered as an infusion over 30 to 60 minutes and repeated every 3 weeks.

Trastuzumab: 6 mg/kg as an infusion over 30 to 90 minutes and repeated every 3 weeks.

Docetaxel: If the initial dose is well tolerated, the dose may be escalated to 100 mg/M² and repeated every 3 weeks.

DOSE ADJUSTMENTS

If a dose is delayed or missed and the time between two infusions is less than 6 weeks, administer the 420-mg dose. Do not wait until the next planned dose. ■ If the time between two infusions is 6 weeks or more, re-administer the initial dose of 840 mg and follow with the subsequent dose regimen of 420 mg beginning in 3 weeks. ■ Discontinue immediately for a serious hypersensitivity reaction. ■ Withhold pertuzumab and trastuzumab for at least 3 weeks if there is a drop in left ventricular ejection fraction (LVEF) to less than 40% or a LVEF of 40% to 45% with a 10% or greater absolute decrease below pretreatment values, and reassess LVEF in 3 weeks. Pertuzumab may be resumed if the LVEF recovers to greater than 45%, or to 40% to 45% if associated with less than a 10% absolute decrease below pretreatment values. ■ Pertuzumab should be withheld or discontinued if trastuzumab treatment is withheld or discontinued. ■ Treatment with pertuzumab and trastuzumab may continue if docetaxel is discontinued. ■ Dose reductions are not recommended for pertuzumab. ■ See docetaxel monograph for docetaxel dose adjustments. ■ No dose adjustment is indicated in patients with mild or moderate renal impairment. In patients with severe renal impairment (CrCl less than 30 mL/min), no dose adjustments can be recommended because of the limited pharmacokinetic data available. ■ See **Rate of Administration**, **Precautions**, **Monitor**, and **Antidote**.

DILUTION

Withdraw the calculated dose of pertuzumab from the vial(s) and inject into a 250-mL PVC or non-PVC polyolefin infusion bag of NS. Invert diluted solution gently to mix. **Do not shake**. Dilute only with NS. Do not use D5W. Immediate use is preferred.

Filters: Not required by manufacturer; additional data not available.

Storage: Store vials in carton in refrigerator at 2° to 8° C (36° to 46° F). Do not freeze. Do not shake. Protect from light. Immediate use preferred; if the diluted solution is not used immediately, however, it can be refrigerated for 24 hours.

COMPATIBILITY

Manufacturer states, “Do not mix pertuzumab with other drugs” and lists as **incompatible** with D5W.

RATE OF ADMINISTRATION

For IV infusion only; do not administer as an IV push or IV bolus. The rate of infusion may be slowed or interrupted if the patient develops an infusion-associated reaction. Discontinue immediately for a serious hypersensitivity reaction.

Pertuzumab: Administer the *initial dose* over 60 minutes. Administer *subsequent doses* over 30 to 60 minutes. An observation period of 30 to 60 minutes is recommended after each pertuzumab infusion and before beginning any subsequent infusion of trastuzumab or docetaxel.

Trastuzumab: Administer the *initial dose* over 90 minutes. Administer *subsequent doses* over 30 to 90 minutes. May be administered before or after pertuzumab.

Docetaxel: Each dose equally distributed over 60 minutes. Administer after pertuzumab and trastuzumab infusions have been completed.

ACTIONS

A recombinant humanized monoclonal antibody. It targets the human epidermal growth factor receptor 2 protein (HER2) and blocks ligand-dependent heterodimerization of HER2 with other HER family members, including EGFR, HER3, and HER4. By inhibiting specific pathways, cell growth arrest and apoptosis can occur. Pertuzumab also mediates antibody-dependent, cell-mediated cytotoxicity. Using pertuzumab alone inhibits the proliferation of human tumor cells, whereas the combination of pertuzumab and trastuzumab greatly augments anti-tumor activity in HER2-overexpressing xenograft models. Steady-state concentration can be reached after the first maintenance dose.

INDICATIONS AND USES

Pertuzumab in combination with trastuzumab and docetaxel is indicated for the treatment of patients with HER2-positive metastatic breast cancer who have not received prior anti-HER2 therapy or chemotherapy for metastatic disease.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For IV infusion only; do not administer as an IV push or IV bolus. ■ Assess HER2 status before beginning pertuzumab therapy. Testing should be done by a laboratory with demonstrated proficiency in the testing process. ■ Embryo-fetal toxicity (oligohydramnios, delayed fetal kidney development, and embryo-fetal death) have been reported; see [Patient Education](#) and [Maternal/Child](#). ■ In clinical studies, the only patients who have received benefit from pertuzumab therapy are those with HER2 protein overexpression. ■ Administered by or under the direction of a physician specialist. ■ Adequate laboratory and supportive medical resources must be available. ■ Decreases in LVEF with drugs that block HER2 activity, including pertuzumab, have been reported. Patients who have received prior anthracyclines or radiotherapy to the chest wall may be at higher risk for decreased LVEF. ■ Hypersensitivity reactions, including anaphylaxis, and infusion reactions have occurred. ■ Emergency equipment and drugs for treatment of left ventricular dysfunction and/or hypersensitivity or infusion reactions must be immediately available; see [Antidote](#). ■ Trastuzumab and docetaxel also have extensive precautions and monitoring requirements; a review of their monographs is imperative. ■ Effects on patients with severe renal impairment and/or hepatic impairment have not been studied. ■ A protein substance; has the potential for immunogenicity.

Monitor: Verify non-pregnancy status before beginning pertuzumab therapy ■ Assess LVEF before beginning therapy and at regular intervals (e.g., every 3 months) during treatment to verify that it remains within expected parameters. ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, chills, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, urticaria) or infusion reaction (e.g., asthenia, chills, fatigue, fever, vomiting). Observe closely for 60 minutes after the first infusion and for

at least 30 minutes after subsequent infusions. ■ Trastuzumab and docetaxel have additional monitoring requirements.

Patient Education: Avoid pregnancy; effective contraception required while receiving therapy and for 6 months following the last dose. ■ During infusion, promptly report chills and/or fever and other S/S of an infusion or hypersensitivity reaction (e.g., chest pain, dizziness, feeling faint, flushing, hives, itching, nausea, pruritus, rash, shortness of breath). ■ Report a suspected pregnancy immediately. If a pregnancy occurs during therapy or if pertuzumab is administered during a pregnancy, report exposure immediately to the Genentech Adverse Event Line ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. Exposure can result in embryo-fetal death and birth defects. Studies in animals have resulted in oligohydramnios, delayed fetal kidney development, and embryo-fetal deaths. ■ Encourage patients who are exposed during pregnancy to enroll in the MoTHER Pregnancy Registry. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: No differences in safety and effectiveness noted compared with younger adults.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been done. ■ No drug-to-drug interactions observed between pertuzumab and trastuzumab or between pertuzumab and docetaxel.

SIDE EFFECTS

The most common side effects when pertuzumab was administered in combination with trastuzumab and docetaxel were alopecia, diarrhea, fatigue, nausea, neutropenia, peripheral neuropathy, and rash. The most common Grade 3 and 4 adverse reactions were anemia, asthenia, diarrhea, fatigue, febrile neutropenia, leukopenia, neutropenia, and peripheral neuropathy. The most serious side effects reported include left ventricular dysfunction, including symptomatic left ventricular systolic dysfunction; hypersensitivity and/or infusion reactions; paronychia; and pleural effusion. Arthralgia, constipation, decreased appetite, dizziness, dry skin, dysgeusia, dyspnea, headache, increased lacrimation, insomnia, itching, mucosal inflammation, myalgia, nail disorders, nasopharyngitis, stomatitis, upper respiratory tract infections, and vomiting have been reported. Adverse reactions were reported less frequently after discontinuation of docetaxel treatment.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. If signs of an infusion reaction occur, slow or interrupt the infusion and treat appropriately. Monitor patients carefully until symptoms resolve. Discontinue immediately for a serious hypersensitivity reaction. Strongly consider discontinuing pertuzumab and trastuzumab if LVEF does not improve or has declined further upon repeat assessment. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epoen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity from concurrent antineoplastics. Treat hypersensitivity reactions with epinephrine, antihistamines, corticosteroids, bronchodilators, and oxygen. Resuscitate as indicated.

PHENOBARBITAL SODIUM

(fee-no-BAR-bih-tal SO-dee-um)

Barbiturate
Sedative-hypnotic
Anticonvulsant

Luminal Sodium

pH 8.5 to 10.5

USUAL DOSE

Use only enough medication to achieve the desired effect. May take up to 15 minutes to reach peak levels in the brain; guard against overdose and excessive respiratory depression.

Hypnotic: 100 to 325 mg.

Sedative: 30 to 120 mg/day in 2 or 3 divided doses (15 to 60 mg every 12 hours or 10 to 40 mg every 8 hours).

Anticonvulsant: 200 to 320 mg. May be repeated if necessary. Maximum dose usually does not exceed 600 mg.

Status epilepticus: Loading dose: 10 to 20 mg/kg in single or divided doses. May give an additional 5 mg/kg every 15 to 30 minutes up to a maximum dose of 30 mg/kg.

Maintenance dose: 1 to 3 mg/kg/24 hr or 0.5 to 1.5 mg/kg every 12 hours.

PEDIATRIC DOSE

See [comments under Usual Dose](#).

Preoperative sedation: 1 to 3 mg/kg of body weight 60 to 90 minutes before procedure.

Status epilepticus: Loading dose: 15 to 18 mg/kg as a single dose or in divided doses. May give an additional 5 mg/kg every 15 to 30 minutes up to a maximum total dose of 30 mg/kg.

Maintenance dose: Infants: 2.5 to 3 mg/kg every 12 hours.

Ages 1 to 5: 3 to 4 mg/kg every 12 hours.

Ages 6 to 12: 2 to 3 mg/kg every 12 hours.

Over 12 years of age: 0.5 to 1.5 mg/kg every 12 hours. Up to 12 mg/kg/24 hours has been used in maintenance doses.

NEONATAL DOSE

See [comments under Usual Dose](#).

Status epilepticus: Loading dose: 15 to 20 mg/kg as a single dose or in divided doses.

Maintenance dose: 1.5 to 2 mg/kg every 12 hours; may be increased to 2.5 mg/kg every 12 hours if needed. Therapeutic range is 15 to 40 mg/L. Because of its long half-life, it may take 2 to 3 weeks to reach steady-state levels.

DOSE ADJUSTMENTS

Reduce dose in impaired renal or hepatic function; usually required in the debilitated or elderly. ■ See [Drug/Lab Interactions](#).

DILUTION

Sterile powder must be slowly diluted with SWFI. Use a minimum of 3 mL of diluent. Also available in sterile vials and tubexes. Best if further diluted up to 10 mL with SWFI. Solutions from powder form must be freshly prepared. Use only absolutely clear solutions. Discard powder or solution exposed to air for 30 minutes.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug **NOT** listed as compatible to be **INCOMPATIBLE** until consulting a pharmacist; specific conditions may apply.

One source suggests the following compatibilities:

Additive: Amikacin (Amikin), aminophylline, calcium chloride, calcium gluconate, colistimethate (Coly-Mycin M), dimenhydrinate, meropenem (Merrem IV), verapamil.

Y-site: Doripenem (Doribax), doxapram (Dopram), enalaprilat (Vasotec IV), fentanyl (Sublimaze), fosphenytoin (Cerebryx), hydromorphone (Dilaudid), levofloxacin (Leva-

quin), linezolid (Zyvox), meropenem (Merrem IV), methadone (Dolophine), morphine, propofol (Diprivan).

RATE OF ADMINISTRATION

60 mg (gr 1) or fraction thereof over 1 minute. Titrate slowly to desired effect. Rapid injection rate may cause symptoms of overdose (e.g., serious respiratory depression).

Status epilepticus: A single loading dose over 10 to 15 minutes.

ACTIONS

A sedative, hypnotic barbiturate of long duration with potent anticonvulsant effects. Phenobarbital is a CNS depressant. Onset of action is prompt by the IV route and becomes rapidly more intense. Effects last from 6 to 10 hours. Will effectively depress the motor cortex with small doses. Pain perception is unimpaired. Rapidly absorbed by all body tissues and excreted in changed form in the urine. Excreted more readily in alkaline urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Prolonged sedation (medical and psychiatric). ■ Anticonvulsant.

CONTRAINDICATIONS

History of porphyria, impaired renal function, impaired hepatic function especially with any signs of hepatic coma, known hypersensitivity to barbiturates, previous addiction, severe respiratory depression including dyspnea, obstruction, or cor pulmonale.

PRECAUTIONS

IV route usually reserved for critical situations. ■ Use caution in elderly and debilitated patients and those with asthma, pulmonary disease, shock, and impaired renal or hepatic function. ■ Status epilepticus can occur from too-rapid withdrawal. ■ May be habit forming. Use caution in acute or chronic pain. ■ Benzodiazepines (diazepam [Valium], midazolam [Versed]) generally preferred for sedation.

Monitor: Keep patient under constant observation. Record vital signs every hour, or more often if indicated. ■ Maintain a patent airway. ■ Monitor hematopoietic, renal and hepatic systems in any extended therapy. ■ Treat the cause of a convulsion. ■ Keep equipment for artificial ventilation available. ■ Highly alkaline. Determine absolute patency of vein; use of large veins preferred to prevent thrombosis. Avoid extravasation. Intra-arterial injection will cause gangrene. ■ Monitor serum levels as indicated; the therapeutic range in adults is 20 to 40 mcg/mL (15 to 40 mcg/mL in pediatric patients). Because of its long half-life, it may take 2 to 3 weeks to reach steady-state levels. ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid alcohol or other CNS depressants (e.g., antihistamines, diazepam [Valium]). May be habit forming. ■ May require alternate birth control.

Maternal/Child: Category D: avoid pregnancy; will cause birth defects. ■ May cause drowsiness in the nursing infant. ■ See [Precautions](#).

Elderly: See [Dose Adjustments](#) and [Precautions](#). ■ Often have increased sensitivity to barbiturates; may cause marked excitement, depression, confusion, and increased risk of barbiturate-induced hypothermia. ■ Consider age-related hepatic or renal impairment and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

Use extreme caution if any other **CNS depressants** have been given, such as alcohol, aminoglycoside antibiotics, narcotic analgesics, anesthetics, antidepressants, antihistamines, hypnotics, MAO inhibitors, phenothiazines, sedatives, tranquilizers. Potentiation with respiratory depression may occur. ■ Inhibits effectiveness of **corticosteroids, doxycycline, oral anticoagulants, oral contraceptives, propranolol, quinidine, and theophylline**. Capable of innumerable interactions with many drugs. ■ May increase orthostatic hypotension with **furosemide** (Lasix). ■ Monitor **phenytoin** (Dilantin), **felbamate** (Felbatol), **carbamazepine** (Tegretol), **valproic acid** and **phenobarbital** levels when any combination of these drugs is used concurrently. ■ May decrease the pharmacologic effect of **vitamin D**. ■ May decrease plasma concentrations and effectiveness of **triazole antifungals** (e.g., itraconazole [Sporanox]).

SIDE EFFECTS

Rarely occur with slow injection of average doses.

Average dose: Depression, dermatitis, facial edema, fever, headache, hypotension, nausea, neonatal apnea, respiratory depression (hypoventilation), thrombocytopenic purpura, vertigo.

Overdose: Apnea, coma, cough reflex depression, delirium, flat EEG (reversible unless hypoxic damage has occurred), hypotension, laryngospasm, lowered body temperature, pulmonary edema, renal shutdown, respiratory depression, sluggish or absent reflexes, stupor.

ANTIDOTE

Notify the physician of any side effects. Symptomatic and supportive treatment is most important in overdose. Maintain an adequate airway with artificial ventilation if indicated. Keep the patient warm. IV volume expanders (dextran) and other IV fluids will help maintain adequate circulation. Diuretics may promote the elimination of the drug. Vasopressors (e.g., dopamine) will maintain BP.

PHENTOLAMINE MESYLATE

(fen-TOLL-ah-meen **MES**-ih-layt)

Alpha-adrenergic blocking agent
Antihypertensive
Vasodilator

Regitine

pH 4.5 to 6.5

USUAL DOSE

Preoperative: 5 mg 1 to 2 hours before surgery. If necessary during surgery, the same doses are administered as needed to control epinephrine intoxication.

Prevent necrosis caused by norepinephrine (Levophed): Add 10 mg to each 1,000 mL of IV solution containing norepinephrine or dopamine.

Test dose for diagnosis of pheochromocytoma: 2.5 to 5 mg.

Treatment of congestive heart failure (unlabeled): 5 to 10 mg in 500 mL of D5W given at a rate of 0.17 to 0.4 mg/min.

PEDIATRIC DOSE

Preoperative: 1 mg, 0.1 mg/kg of body weight, or 3 mg/M² 1 to 2 hours before surgery. Repeat as indicated; see [Usual Dose](#).

Prevent necrosis caused by norepinephrine (Levophed): Add 0.1 to 0.2 mg/kg up to a maximum of 10 mg to each 1,000 mL of IV solution containing norepinephrine.

Test dose for diagnosis of pheochromocytoma: 1 mg.

DILUTION

Each 5 mg should be reconstituted with 1 mL of SWFI. May be further diluted with 5 to 10 mL of SWFI or NS. Use only freshly prepared solutions.

Storage: Store below 40° C.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Additive: Dobutamine, verapamil.

Y-site: Amiodarone (Nexterone).

RATE OF ADMINISTRATION

Each 5 mg or fraction thereof over 1 minute.

Test dose: Inject rapidly after pressor response to venipuncture has subsided.

ACTIONS

An alpha-blocking agent that competitively antagonizes endogenous and exogenous alpha agents (e.g., epinephrine and norepinephrine). Has positive chronotropic and inotropic effects on cardiac muscle, as well as vasodilator effects on vascular smooth muscle. Onset of action is prompt. Half-life is approximately 19 minutes. Metabolic fate is undetermined.

INDICATIONS AND USES

Prevention and treatment of hypertensive episodes of pheochromocytoma preoperatively and during surgery. ■ Prevention and treatment of necrosis and sloughing occurring with dopamine and norepinephrine (Levophed). ■ Definitive diagnosis of pheochromocytoma.

Unlabeled uses: Treatment of congestive heart failure, hypertensive crisis due to MAO inhibitor/sympathomimetic amine interactions, and rebound hypertension after discontinuation of clonidine, propranolol, or other hypertensive agents.

CONTRAINDICATIONS

Coronary artery disease, coronary insufficiency, hypersensitivity to phentolamine, myocardial infarction (previous or present).

PRECAUTIONS

Use caution in gastritis or peptic ulcer disease. ■ Use care in the presence of any arrhythmia. It is preferable to have a normal sinus rhythm. ■ MI, cerebrovascular spasm, and cerebrovascular occlusion have occurred following administration, usually in association with marked hypotensive episodes. ■ For diagnosis of pheochromocytoma, urinary tests such as vanillylmandelic acid (VMA) are safer and more accurate. Phentolamine is used only when absolutely necessary. Specific procedure must be followed. Consult with physician and pharmacist.

Monitor: Monitor vital signs every 2 minutes.

Maternal/Child: Category C: safety for use during pregnancy and breast-feeding not established. Use with extreme caution and only when clearly indicated.

Elderly: Risk of phentolamine-induced hypothermia may be increased.

DRUG/LAB INTERACTIONS

Antagonizes effects of **epinephrine** and **ephedrine**.

SIDE EFFECTS

Abdominal pain, diarrhea, dizziness, hypotension, nasal stuffiness, nausea, tachycardia, tingling of skin, weakness, vomiting.

Major: Cardiac arrhythmias, cerebrovascular occlusion, cerebrovascular spasm, hypotension (severe), myocardial infarction, shock, tachycardia, vomiting under anesthesia.

ANTIDOTE

For minor side effects, notify the physician. If symptoms progress or any major side effect occurs, discontinue drug and notify the physician immediately. Elevation of legs, volume expanders (e.g., albumin, hetastarch), and administration of norepinephrine are recommended for treatment of hypotension. Do not use epinephrine. Maintain the patient as indicated. If tachycardia or cardiac arrhythmias occur, defer use of digoxin if possible until rhythm returns to normal.

PHENYLEPHRINE HYDROCHLORIDE **BBW**

Vasopressor

(fen-ill-**EF**-rin hy-droh-**KLOR**-eyed)

Neo-Synephrine

pH 3 to 6.5

USUAL DOSE

Mild to moderate hypotension or hypotensive emergencies during spinal anesthesia: 0.2 mg. From 0.1 to 0.5 mg may be used initially. May be repeated every 10 to 15 minutes. Never exceed 0.5 mg in a single dose. Highly individualized. Start with a small dose, giving only as much of the drug as required to alleviate undesirable symptoms.

Severe hypotension and shock- or drug-related hypotension: Begin infusion at 100 to 180 mcg/min (0.1 to 0.18 mg/min) until BP stabilized at a low normal for specific individual. Maintain with 40 to 60 mcg/min (0.04 to 0.06 mg/min). Titrate to desired effect.

Paroxysmal supraventricular tachycardia: 0.25 to 0.5 mg has been given as a rapid IV bolus. If additional doses are required to achieve adequate response, increase in increments of 0.1 to 0.2 mg and never exceed a total single dose of 1 mg. Adenosine may be the drug of choice. Monitor BP. Systolic BP should not be raised above 160 mm Hg.

PEDIATRIC DOSE

Mild to moderate hypotension: 5 to 20 mcg/kg of body weight per dose. May be repeated every 10 to 15 minutes. Do not exceed adult dose.

Severe hypotension and shock- or drug-related hypotension: Begin an infusion at 0.1 to 0.5 mcg/kg/min. Titrate to desired effect.

DOSE ADJUSTMENTS

Hypotension of powerful peripheral adrenergic blocking agents, chlorpromazine, or pheochromocytectomy may require carefully calculated increased dose therapy.

DILUTION

IV injection: Dilute 1 mL of a 10 mg/mL solution with 9 mL of SWFI to prepare a final concentration of 1 mg/mL.

Infusion: Dilute 10 mg in 500 mL of NS or D5W to provide a 1:50,000 solution (20 mcg/mL). May increase to 20 or 30 mg in 500 mL if necessary (40 to 60 mcg/mL).

Pediatric infusion: Add 0.6 mg/kg to 100 mL diluent. 1 mL/hr equals 0.1 mcg/kg/min.

Storage: Protect from light.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following compatibilities:

Additive: Chloramphenicol (Chloromycetin), dobutamine, lidocaine, potassium chloride (KCl), sodium bicarbonate.

Y-site: Amiodarone (Nexterone), anidulafungin (Eraxis), argatroban, bivalirudin (Angio-max), caspofungin (Cancidas), cisatracurium (Nimbex), dexmedetomidine (Precedex), doripenem (Doribax), etomidate (Amidate), famotidine (Pepcid IV), fenoldopam (Corlopam), hetastarch in electrolytes (Hextend), levofloxacin (Levaquin), micafungin (Mycamine), propofol (Diprivan), remifentanyl (Ultiva), telavancin (Vibativ), vasopressin, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

IV injection: Single dose over 20 to 30 seconds to treat paroxysmal supraventricular tachycardia; over 1 minute in other situations.

Infusion: Regulate drip rate to provide and maintain individual's low normal BP. Use an infusion pump or microdrip (60 gtt/mL) to administer.

ACTIONS

Sympathomimetic, similar to epinephrine. Acts primarily on alpha-adrenergic receptors. Potent, long-lasting vasoconstrictor. Unique in that it slows HR, increases stroke volume,

and does not induce any change in rhythm of the pulse. Renal vessel constriction will occur. Repeated injections produce comparable results. Effective within seconds and lasts about 15 minutes. Metabolic fate and route of excretion not determined. Uptake of drug into tissue and some metabolism by liver have been documented.

INDICATIONS AND USES

Maintain adequate BP in inhalation and spinal anesthesia, shocklike states, drug-induced hypotension, and hypersensitivity reactions. ■ Treat paroxysmal supraventricular tachycardia. ■ Prolong anesthesia.

Unlabeled uses: Specific antidote for hypotension produced by chlorpromazine hydrochloride (Thorazine).

CONTRAINDICATIONS

Hypertension, ventricular tachycardia, hypersensitivity to phenylephrine.

PRECAUTIONS

Usually administered by or under the supervision of a physician knowledgeable in its use. ■ Blood volume depletion should be corrected. May be administered concurrently with blood volume replacement. ■ Use extreme caution in the elderly, hyperthyroidism, bradycardia, partial heart block, myocardial disease, or severe arteriosclerosis. ■ Contains bisulfites; use caution in allergic individuals.

Monitor: Check BP every 2 minutes until stabilized at desired level. ■ Discontinue IV administration if vein infiltrates or is thrombosed; can cause tissue necrosis, sloughing. ■ See [Precautions](#), [Drug/Lab Interactions](#).

Maternal/Child: Category C: safety for use in pregnancy or breast-feeding not established.

Elderly: See [Precautions](#); may have increased sensitivity to effects.

DRUG/LAB INTERACTIONS

Potentiated by **tricyclic antidepressants** (e.g., desipramine [Norpramin]), **guanethidine**, **MAO inhibitors** (e.g., selegiline [Eldepryl]), **other vasopressors** (epinephrine [Adrenalin]); **ergot alkaloids or oxytocic agents** (e.g., methylergonovine, oxytocin); hypertensive crisis and death can result. ■ Use caution with **digoxin or halogenated hydrocarbon anesthetics** (e.g., halothane, isoflurane); arrhythmias may occur.

SIDE EFFECTS

Bradycardia, fullness of head, headache, hypertension, tingling of extremities, tremulousness, ventricular extrasystoles, ventricular tachycardia (short paroxysms), vertigo.

ANTIDOTE

To prevent sloughing and necrosis in areas of extravasation, with a fine hypodermic needle inject 5 to 10 mg of phentolamine (Regitine) diluted in 10 to 15 mL of NS liberally throughout the tissue in the extravasated area. Treatment should be started as soon as extravasation is recognized. Notify the physician of all side effects. IM injection may be preferable. Treat hypertension with phentolamine (Regitine). Treat cardiac arrhythmias as indicated. Treat bradycardia with atropine. Resuscitate as necessary.

PHENYTOIN SODIUM **BBW**

(FEN-ih-toyn SO-dee-um)

Hydantoin
Anticonvulsant
Antiarrhythmic

Dilantin

pH 12

USUAL DOSE

In all situations, transfer to oral therapy 12 to 24 hours after a loading dose or as soon as practical. See **Precautions** and **Monitor**.

Status epilepticus, anticonvulsant: A **loading dose** of 10 to 15 mg/kg. Do not exceed a total dose of 1.5 Gm. Lethal dose estimated at 2 to 5 Gm. Another source suggests that 15 to 20 mg/kg is generally recommended. Follow with **maintenance doses** of 100 mg every 6 to 8 hours. Adjust dose based on phenytoin levels; see **Monitor**. If seizure is not terminated, consider other anticonvulsants, barbiturates, or anesthesia. IV diazepam may be the drug of choice for initial treatment. Concurrent administration of phenytoin in the lesser doses is suggested by clinicians to maintain control.

PEDIATRIC DOSE

Status epilepticus, anticonvulsant: 15 to 20 mg/kg as a **loading dose**. Follow with a **maintenance dose for age** (listed below):

Neonates: Begin with 5 mg/kg/24 hr in equally divided doses every 8 to 12 hours. Range is 5 to 8 mg/kg/24 hr (2.5 to 4 mg/kg every 12 hours or 1.6 to 2.67 mg/kg every 8 hours).

Infants and other pediatric patients: Begin with 5 mg/kg/24 hr in equally divided doses every 8 to 12 hours (2.5 mg/kg every 12 hours or 1.67 mg/kg every 8 hours). Range varies according to age:

6 months to 3 years: 8 to 10 mg/kg/24 hr (4 to 5 mg/kg every 12 hours or 2.67 to 3.33 mg/kg every 8 hours).

4 to 6 years: 7.5 to 9 mg/kg/24 hr (3.75 to 4.5 mg/kg every 12 hours or 2.5 to 3 mg/kg every 8 hours).

7 to 9 years: 7 to 8 mg/kg/24 hr (3.5 to 4 mg/kg every 12 hours or 2.3 to 2.6 mg/kg every 8 hours).

10 to 16 years: 6 to 7 mg/kg/24 hr (3 to 3.5 mg/kg every 12 hours or 2 to 2.3 mg/kg every 8 hours).

DOSE ADJUSTMENTS

Use caution, lower dose, and slower rate of administration in the seriously ill, elderly, and cachetic patients. ■ Lower doses may also be required in patients with renal or hepatic disease or in those with hypoalbuminemia. Monitoring of unbound (free) phenytoin concentrations may be a better dosing guide. ■ In obesity calculate dose on ideal body weight plus 1.33 of excess over ideal; phenytoin preferentially distributes into fat. ■ See **Drug/Lab Interactions**.

DILUTION

Available in 100- or 250-mg ampules or vials and in 100-mg syringes. After verifying patency, may be administered directly into a large peripheral or central vein through a large-gauge catheter. Alternately, may be further diluted in NS to a concentration of no less than 5 mg/mL and administered as an infusion. Use solution only when completely dissolved and clear.

Filters: Manufacturer recommends use of an in-line filter (0.22 to 0.55 microns) when administered as an infusion.

Storage: Store between 15° and 30° C. Infusion solutions should be administered immediately after preparation and must be completed within 1 to 4 hours. Do not refrigerate infusion solutions.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends not adding to IV solutions other than NS or mixing with other medications and states that “the addition of phenytoin to dextrose or dextrose-containing solutions will result in precipitation.” Always flush line with NS before and after administration of any other drug through the same IV line. See *Dilution*.

One source suggests the following **compatibilities**:

Additive: *Not recommended by manufacturer.* Verapamil.

Y-site: Esmolol (Brevibloc), famotidine (Pepcid IV), fluconazole (Diflucan), tacrolimus (Prograf).

RATE OF ADMINISTRATION

Very alkaline; administer slowly and follow each injection with sterile NS to reduce local venous irritation. Best to flush before and after with NS.

Anticonvulsant: **Adults:** 25 to 50 mg or fraction thereof over 1 minute. Do not exceed 50 mg/min.

Pediatric patients: Do not exceed 1 to 3 mg/kg/min. Another source suggests 0.5 mg/kg/min in neonates or 1 mg/kg/min in infants and other pediatric patients not to exceed 50 mg/min.

Elderly: Limit rate to 25 mg/min.

Infusion: Should be completed within 1 to 4 hours. Do not exceed 25 to 50 mg/min rate. Best if piggybacked to a **compatible** primary IV so phenytoin can be discontinued if side effects occur, but IV can be kept open.

ACTIONS

A synthetic anticonvulsant, chemically related to barbiturates. Selectively stabilizes seizure threshold and depresses seizure activity in the motor cortex. Effective control in emergency treatment of seizures may take 15 to 20 minutes because of rate of injection required. Also exerts a depressant effect on the myocardium by selectively elevating the excitability threshold of the cell, reducing the cell’s response to stimuli. Highly protein bound. Metabolized by cytochrome P₄₅₀ enzymes CYP2C9 and CYP2C19 and is excreted in changed form in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Control of generalized tonic-clonic status epilepticus and prevention and treatment of seizures during neurosurgery. Parenteral phenytoin should be used only when oral phenytoin administration is not possible.

CONTRAINDICATIONS

Known hypersensitivity to phenytoin or other hydantoin products. ■ Bradycardia, sinoatrial, second- or third-degree heart block, Stokes-Adams syndrome ■ Coadministration with delavirdine (Rescriptor).

PRECAUTIONS

Because of benefits provided by fosphenytoin (Cerebyx)—e.g., solubility in IV solutions, improved infusion site tolerance, more rapid rate of administration, and well-tolerated IM option—Parke-Davis wants to discontinue injectable phenytoin (Dilantin). Generic products will still be available. ■ Discontinue immediately for hypersensitivity reactions; with caution, substitute a nonhydantoin anticonvulsant (e.g., valproate sodium [Depacon]). ■ Abrupt withdrawal may cause increased seizure activity. Gradually reduce dose, discontinue, or substitute alternative antiepileptic agents. ■ Not effective for petit mal seizures; combined therapy required if both conditions present. ■ Not indicated for seizures due to hypoglycemia or other metabolic causes. ■ Severe hypotension and cardiac arrhythmias have occurred with rapid infusion. Risk increases with increased rates, but adverse cardiac events have been reported at or below the recommended infusion rates. Careful cardiac monitoring is required during and after IV administration. Because of the risks of cardiac and local toxicity associated with IV phenytoin, oral phenytoin should be used whenever possible. ■ Use caution in hypotension and severe myocardial insufficiency. ■ Use caution with low serum albumin level, and adjust dose as indicated. Phenytoin is

90% bound to serum protein, and a reduced albumin causes an increase in free drug availability. ■ May cause acute phenytoin hepatotoxicity (e.g., elevated liver function tests, fever, jaundice, lymphadenopathy, skin eruptions). Discontinue immediately and substitute alternative anticonvulsant therapy. ■ Has caused lymphadenopathy and hematopoietic complications (e.g., agranulocytosis, granulocytopenia, leukopenia, thrombocytopenia, or pancytopenia with or without bone marrow suppression). If lymphadenopathy occurs with or without signs of serum sickness (e.g., fever, hepatotoxicity, rash), substitute alternate anticonvulsant therapy. ■ Drug reaction with eosinophilia and systemic symptoms (DRESS), also known as multi-organ hypersensitivity, has been reported. Usually presents with fever, rash, and/or lymphadenopathy in association with other organ system involvement such as hepatitis, nephritis, hematologic abnormalities, myocarditis, or myositis. Eosinophilia is often present. Deaths have been reported. ■ Serious and sometimes fatal dermatologic reactions, including toxic epidermal necrolysis (TEN) and Stevens-Johnson syndrome (SJS), have been reported. Onset of symptoms is usually within 28 days but can occur later. ■ Discontinue phenytoin if skin rash appears unless the rash is clearly not drug related. ■ Selected patients of Asian ancestry (e.g., Han Chinese, Filipinos, Malaysians, South Asian Indians, and Thais) with a specific human leukocyte antigen allele may have an increased risk of serious skin reactions (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis) from phenytoin therapy. ■ Purple glove syndrome (edema, discoloration, and pain distal to the injection site) has occurred and may or may not be associated with extravasation. ■ Inhibits insulin release and may increase serum glucose; monitoring indicated in patients with diabetes. ■ Psychotic symptoms and other behavioral changes have been reported with antiepileptic drugs and may include aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies. Some resolved without intervention. Others required dose reduction or discontinuation of the antiepileptic agent.

Monitor: Narrow margin of error between therapeutic and toxic dose. Plasma levels above 10 mcg/mL usually control seizure activity. The acceptable range is 5 to 20 mcg/mL. Consider monitoring free phenytoin levels in patients with hypoalbuminemia or renal insufficiency (therapeutic range is 1 to 2 mcg/mL). Toxicity begins with nystagmus and may be seen at levels less than 20 mcg/mL. ■ Periodic monitoring of CBC, platelets, albumin, urinalysis, hepatic and renal function is recommended. ■ Monitor ECG and BP continuously. ■ Closely monitor patients who are gravely ill, have impaired liver function, or are elderly. May show early signs of toxicity. ■ Observation of patient symptoms and effectiveness of all medications is imperative. ■ Observe for rash and discontinue if one appears; see [Precautions](#). ■ Determine absolute patency of vein. Avoid extravasation. Very alkaline; follow each injection with sterile NS to reduce local venous irritation. ■ Patients maintained with phenytoin should be given a dose the morning of surgery to maintain adequate serum levels. ■ Observe patient closely for signs of CNS side effects. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: May cause alterations in mood (e.g., aggression, agitation, anger, anxiety, apathy, decreased ability to cope, depression, hostility, irritability, thoughts of suicide); report these changes promptly. ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry.

Maternal/Child: Category D: avoid pregnancy. Consider risks versus benefit. ■ Alterations in phenytoin kinetics in pregnant women may necessitate periodic monitoring of serum levels. ■ Newborns whose mothers received phenytoin during pregnancy may develop a life-threatening bleeding disorder that can be prevented by giving vitamin K to the mother before delivery and to the neonate after birth. ■ Discontinue breast-feeding.

Elderly: See [Dose Adjustments](#) and [Rate of Administration](#). ■ Clearance tends to decrease with increasing age. ■ Low serum albumin causing a decrease in protein binding may result in increased sensitivity to phenytoin.

DRUG/LAB INTERACTIONS

Interactions are numerous and potentially life threatening. Review of drug profile by pharmacist imperative. ■ Coadministration with **delavirdine** (Rescriptor) is contraindicated. Has potential for loss of virologic response and possible resistance to delavirdine or to the class of non-nucleoside reverse transcriptase inhibitors. ■ Serum levels may be increased by **alcohol** (acute ingestion), **amiodarone** (Nexterone), **anti-epileptic agents** (e.g., ethosuximide [Zarontin], felbamate [Felbatol], methsuximide [Celontin], oxcarbazepine [Trileptal], topiramate [Topamax]), **azoles** (e.g., fluconazole [Diflucan], itraconazole [Sporanox], ketoconazole [Nizoral], voriconazole [VFEND]), **chloramphenicol** (Chloromycetin), **chlordiazepoxide** (Librium), **capecitabine** (Xeloda), **diazepam** (Valium), **disulfiram** (Antabuse), **estrogens**, **fluorouracil** (5-FU), **fluoxetine** (Prozac), **fluvastatin** (Lescol), **fluvoxamine** (Luvox), **H₂ antagonists** (e.g., cimetidine [Tagamet]), **halothane**, **isoniazid** (INH), **methylphenidate** (Ritalin), **omeprazole** (Prilosec), **phenothiazines** (e.g., prochlorperazine [Compazine]), **salicylates** (aspirin), **sertraline** (Zoloft), **succinimides** (e.g., ethosuximide [Zarontin]), **sulfonamides** (e.g., sulfadiazine, sulfamethoxazole/trimethoprim [Bactrim], sulfaphenazole, sulfisoxazole), **ticlopidine** (Ticlid), **tolbutamide** (Orinase), **trazodone** (Desyrel), **and warfarin** (Coumadin). ■ Serum levels and effectiveness may be decreased by **antineoplastics** usually in combination (e.g., bleomycin [Blenoxane], carboplatin [Paraplatin], cisplatin [Platinol], doxorubicin [Adriamycin], methotrexate), **carbamazepine** (Tegretol), **chronic alcohol abuse**, **folic acid**, **fosamprenavir** (Lexiva), **nelfinavir** (Viracept), **reserpine**, **ritonavir** (Norvir), **St. John's wort**, **and vigabatrin** (Sabril). ■ Phenytoin serum levels may be increased or decreased by **phenobarbital** (Luminal), **valproate sodium** (Depacon), **and valproic acid** (Depakene). Similarly, phenytoin may unpredictably affect the levels and efficacy of these drugs. ■ The addition of withdrawal of drugs while patients are undergoing phenytoin therapy may require an adjustment of the phenytoin dose. ■ Phenytoin will inhibit the effects of **azoles** (e.g., fluconazole, itraconazole, ketoconazole, posaconazole [Noxafil], voriconazole), **corticosteroids**, **doxycycline**, **estrogens**, **furosemide** (Lasix), **irinotecan** (Camptosar), **oral contraceptives**, **paclitaxel** (Taxol), **paroxetine** (Paxil), **quinidine**, **rifampin** (Rifadin), **sertraline** (Zoloft), **teniposide** (Vumon), **theophylline**, **and vitamin D**. Dose adjustment of these agents may be indicated. ■ Phenytoin decreases plasma concentrations of **HIV antivirals** (e.g., efavirenz [Sustiva], lopinavir/ritonavir [Kaletra], indinavir [Crixivan], nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase]), **anti-epileptic agents** (e.g., felbamate [Felbatol], oxcarbazepine [Trileptal], quetiapine [Seroquel], topiramate [Topamax]), **atorvastatin** (Lipitor), **cyclosporine** (Sandimmune), **digoxin** (Lanoxin), **fluvastatin** (Lescol), **folic acid**, **mexiletine**, **nisoldipine** (Sular), **praziquantel** (Biltricide), **and simvastatin** (Zocor). Adjust doses of these agents as indicated. ■ Phenytoin when given with **fosamprenavir** alone may decrease the concentration of **amprenavir** (Agenerase), the active metabolite. Phenytoin when given with the combination of **fosamprenavir and ritonavir** may increase the concentration of **amprenavir** (Agenerase). ■ May increase or decrease PT/INR responses when coadministered with **warfarin** (Coumadin). ■ Chronically administered phenytoin may cause resistance to the neuromuscular blocking action of **nondepolarizing neuromuscular blocking agents** (e.g., cisatracurium [Nimbex], pancuronium, rocuronium [Zemuron], and vecuronium). Monitor patients closely; recovery from neuromuscular blockade may be more rapid than expected, and infusion rate requirements may be higher. ■ Alters **some clinical laboratory tests** (e.g., may decrease T₄; may increase glucose, alkaline phosphatase, and GGT; and may produce low results in dexamethasone or metyrapone tests).

SIDE EFFECTS

Ataxia, confusion, dizziness, drowsiness, fever, hyperplasia of gums, nervousness, nystagmus, skin eruptions, tremors, visual disturbances. Psychotic symptoms, including aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies, have occurred with antiepileptic agents.

Major: Bradycardia, cardiac arrest, heart block, hypotension, respiratory arrest, tonic seizures, ventricular fibrillation.

ANTIDOTE

Notify the physician of any side effects. If minor symptoms progress or any major side effect occurs, discontinue the drug and notify the physician; see **Precautions**. Maintain a patent airway and resuscitate as necessary. Symptoms of heart block or bradycardia may be reversed with IV atropine. Epinephrine may also be useful. Decrease rate or discontinue infusion for severe hypotension or cardiac arrhythmias. Hemodialysis may be required in overdose.

PHOSPHATE

(FOS-fayt)

Electrolyte replenisher
Antihypophosphatemic

Potassium Phosphate, Sodium Phosphate

pH 5 to 7.8

USUAL DOSE

Dependent on individual needs of the patient.

TPN, adults and pediatric patients: 10 to 15 mM (310 to 465 mg) of phosphorus/liter of TPN solution should maintain normal serum phosphate. Larger amounts may be required. 1 mM equals 31 mg.

Acute hypophosphatemia: Adults and pediatric patients: 0.08 to 0.32 mM/kg of body weight as a **loading dose** equally distributed over 6 hours. **Maintain pediatric patients** with 0.5 to 1.5 mM/kg/24 hr. **Maintain adults** with 48.4 to 64.5 mM/24 hr.

INFANT DOSE

Infants receiving TPN: 1.5 to 2 mM/kg of body weight/day.

DOSE ADJUSTMENTS

Lower-end initial doses may be indicated in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Must be diluted in a larger volume of suitable IV solution and given as an infusion. Soluble in most commonly used IV solutions (see chart on inside back cover) except protein hydrolysate. Mix thoroughly. See **Compatibility**.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

ALL FORMULATIONS

Mix thoroughly after each addition of supposedly **compatible** drugs or solutions. TPN solutions requiring the addition of phosphates and calcium salts must be mixed by the pharmacist to avoid a precipitate of calcium phosphate. Specific amounts, calculations, order and temperature (precipitate forms more readily at room temperature) are required. Deaths have been reported.

One source suggests the following **compatibilities**:

POTASSIUM PHOSPHATE

Additive: See **comments under All Formulations**. Mix thoroughly. Metoclopramide (Reglan), verapamil.

Y-site: Diltiazem (Cardizem), enalaprilat (Vasotec IV), esmolol (Brevibloc), famotidine (Pepcid IV), 6% hydroxyethyl starch (Voluven), labetalol, miconazole (Mycamine), nifedipine (Cardene IV), nitroprusside sodium, telavancin (Vibativ).

SODIUM PHOSPHATE

Y-site: Doripenem (Doribax), miconazole (Mycamine), telavancin (Vibativ).

RATE OF ADMINISTRATION

A usual dose is usually equally distributed over 6 hours. Other sources suggest administering up to 15 mM over 2 hours, up to 30 mM over 4 hours, and up to 45 mM over 6 hours. Potassium phosphate will be further limited by the maximum rate for potassium. Consider sodium/potassium content. Infuse slowly. Rapid infusion may cause phosphate or potassium intoxication. Serum calcium may be reduced rapidly, causing hypocalcemic tetany.

ACTIONS

Involved in bone deposition. Helps to maintain calcium levels, has a buffering effect on acid-base equilibrium, and influences renal excretion of the hydrogen ion. Normal levels in adults, 3 to 4.5 mg/dL of serum; in pediatric patients, 4 to 7 mg/dL. Excreted in urine.

INDICATIONS AND USES

To prevent or correct hypophosphatemia in patients with restricted or no oral intake.

CONTRAINDICATIONS

Any disease with high phosphate or low calcium levels, hyperkalemia (potassium phosphate), hypernatremia (sodium phosphate).

PRECAUTIONS

Rapid infusion may cause phosphate, sodium, or potassium intoxication. Serum calcium may be reduced, rapidly causing hypocalcemic tetany. ■ Use sodium phosphate with caution in renal impairment, cirrhosis, cardiac failure, or any edematous, sodium-retaining state. ■ Use potassium phosphate with caution in cardiac disease, renal disease, and digitalized patients. ■ See [Compatibility](#).

Monitor: Monitor serum calcium, potassium, phosphate, chlorides, and sodium. Discontinue when serum phosphate exceeds 2 mg/dL. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: safety for use in pregnancy not established.

Elderly: Differences in response between elderly and younger patients have not been identified. Lower end initial doses may be appropriate in the elderly; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

May cause hyperkalemia with **potassium-sparing diuretics** (e.g., amiloride) or **angiotensin-converting enzyme inhibitors** (e.g., enalapril [Vasotec]).

SIDE EFFECTS

Elevated phosphates, reduced calcium levels and hypocalcemic tetany, elevated potassium levels causing cardiac arrhythmias, flaccid paralysis, heaviness of the legs, hypotension, listlessness, mental confusion, paresthesia of the extremities.

ANTIDOTE

For any side effect, discontinue the drug and notify the physician. Restore serum calcium with calcium gluconate or chloride. Shift potassium from serum to cells with 150 mL of ½ M sodium lactate or 10% to 20% dextrose with 10 units regular insulin for each 20 Gm dextrose at 300 to 500 mL/hr. Correct acidosis with sodium bicarbonate. Reduce sodium by restriction, diuretics, or hemodialysis. Resuscitate as necessary.

PHYSOSTIGMINE SALICYLATE

(fye-zoh-**STIG**-meen sah-**LIS**-ah-layt)

Cholinergic
Cholinesterase inhibitor
Antidote

pH 5.8

USUAL DOSE

Postanesthesia: 0.5 to 1 mg initially. Repeat at 10- to 30-minute intervals until desired results obtained.

Anticholinergic toxicity: 0.5 to 2 mg initially. 1 to 4 mg may be repeated as necessary as life-threatening signs recur (arrhythmias, convulsions, deep coma). Maximum dose is 4 mg in 30 minutes.

PEDIATRIC DOSE

To be used in life-threatening situations only. 0.02 mg/kg/dose. May be repeated at 5- to 10-minute intervals only if toxic effects persist and there is no sign of cholinergic effects. Maximum total dose is 2 mg. See [Maternal/Child](#).

DILUTION

May be given undiluted. Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Rapid IV administration may cause bradycardia, hypersalivation, respiratory distress, and convulsions.

1 mg or fraction thereof over 1 to 3 minutes.

Pediatric rate: 0.5 mg or fraction thereof over at least 1 minute.

ACTIONS

An extract of *Physostigma venenosum* seeds. It inhibits the destructive action of acetylcholinesterase and prolongs and exaggerates the effects of acetylcholine. Stimulates parasympathetic nerve stimulation (pupil contraction, increased intestinal musculature tonus, bronchial constriction, salivary and sweat gland stimulation). Does enter the CNS. Onset of action occurs in 5 minutes and lasts about 1 hour. Rapidly hydrolyzed by cholinesterases.

INDICATIONS AND USES

To reverse CNS toxic effects caused by drugs capable of producing anticholinergic poisoning (e.g., atropine), other anticholinergic/antispasmodic agents (e.g., phenothiazines, antihistamines), anticholinergic antiparkinson agents (e.g., bengtropine [Cogentin], trihexyphenidyl [Artane]), and tricyclic antidepressants (e.g., imipramine [Tofranil]).

Unlabeled uses: Treatment of delirium tremens.

CONTRAINDICATIONS

Asthma, cardiovascular disease, diabetes, gangrene, mechanical obstruction of the intestines or urogenital tract, vagotonic states, patients receiving choline esters, depolarizing neuromuscular blocking agents (succinylcholine), or tricyclic antidepressants (e.g., amitriptyline [Elavil]).

PRECAUTIONS

Rapid IV administration may cause bradycardia, hypersalivation, respiratory distress, and convulsions. ■ Contains bisulfites; use caution in allergic individuals.

Monitor: Atropine must always be available. ■ Monitor vital signs. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Safety for use in pregnancy and breast-feeding not established. ■ Has caused muscular weakness in neonates of mothers treated with other cholinesterase inhibitors for myasthenia gravis. ■ May contain benzyl alcohol; do not use in neonates.

DRUG/LAB INTERACTIONS

Potentiates **succinylcholine** and **other choline esters** (e.g., bethanecol). ■ May antagonize CNS depressant effects of **diazepam** (Valium). ■ May cause serious complications, including death, with **tricyclic antidepressants** (e.g., amitriptyline [Elavil]).

SIDE EFFECTS

Anxiety, bradycardia, cholinergic crisis (overdose), coma, convulsions, defecation, delirium, disorientation, emesis, hallucinations, hyperactivity, hypersalivation, hypersensitivity, nausea, respiratory distress, salivation, seizures, sweating, urination.

ANTIDOTE

Keep physician informed of side effects. For excessive nausea or sweating, reduce dose. Discontinue drug for bradycardia; convulsions; excessive defecation, emesis, salivation, or urination; or respiratory distress. Treat cholinergic side effects (e.g., arrhythmias, bronchoconstriction) or hypersensitivity with the specific antagonist atropine sulfate in doses of 0.6 mg IV. May be repeated every 3 to 10 minutes. Endotracheal intubation or tracheostomy are considered prophylactic in anesthesia or crisis. Artificial ventilation, oxygen therapy, cardiac monitoring, adequate suctioning, and treatment of shock or convulsions must be instituted and maintained as necessary.

PHYTONADIONE **BBW**

(fye-toe-nah-DYE-ohn)

Vitamin (prothrombinogenic)
Antidote
Antihemorrhagic

Vitamin K₁

pH 5 to 7

USUAL DOSE

Should be given by the SC or oral route whenever possible; parenteral route administration has caused death; see **Precautions**. A single dose is preferred, but it may be repeated if clinically indicated.

Vitamin K deficiency: Up to 10 mg may be added to TPN solutions as indicated.

Anticoagulant-induced (warfarin or dicumarol) hypoprothrombinemia: 2.5 to 10 mg. Doses up to 25 mg and, rarely, 50 mg may be needed. May repeat in 6 to 8 hours if initial response is not adequate. Doses as low as 1 to 2 mg may be effective. Use the smallest dose that achieves effective results to prevent clotting hazards.

Hypoprothrombinemia from other causes: 2 to 25 mg (rarely 50 mg), depending on the severity of the deficiency and the response obtained.

PEDIATRIC DOSE

See **Usual Dose**, **Precautions**, and **Maternal/Child**.

Vitamin K deficiency: 1 to 2 mg may be added to TPN solutions as indicated.

Anticoagulant-induced (warfarin or dicumarol) hypoprothrombinemia in infants and children: 1 to 2 mg/dose.

Hypoprothrombinemia from other causes in infants and children: A single dose of 1 to 2 mg.

NEWBORN DOSE

See **Usual Dose**, **Precautions**, and **Maternal/Child**. Rarely given IV in the newborn. SC injection preferred.

Prophylaxis of hemorrhagic disease of the newborn: 0.5 to 1 mg IM within 1 hour of birth.

Treatment of hemorrhagic disease of the newborn: 1 to 2 mg/24 hr SC or IM. Higher doses may be necessary if the mother has been receiving oral anticoagulants (e.g., warfarin [Coumadin]) or anticonvulsants (e.g., phenytoin [Dilantin]). Whole blood or blood components may be indicated for excessive bleeding. Give phytonadione concurrently to correct the underlying disorder.

DOSE ADJUSTMENTS

See **Drug/Lab Interactions**.

DILUTION

Use only preservative-free solutions. May be diluted only with NS, D5NS, or D5W. Dilution with at least 10 mL of diluent is recommended to facilitate prescribed rate of administration. Photosensitive; protect from light in all dilutions. Use immediately after preparation.

Filters: Not required by manufacturer; however, there should be no significant loss of potency with the use of a 0.22-micron filter.

Storage: Photosensitive; protect from light before use and in all dilutions. Store unopened ampules below 40° C (104° F), preferably between 15° C and 30° C (59° F and 86° F). Protect from light and freezing. Discard diluted solution and drug remaining in ampule after single use.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Additive: Amikacin (Amikin), chloramphenicol (Chloromycetin), sodium bicarbonate.

Y-site: Ampicillin, epinephrine (Adrenalin), famotidine (Pepcid IV), heparin, hydrocortisone sodium succinate (Solu-Cortef), potassium chloride (KCl).

RATE OF ADMINISTRATION

Each 1 mg or fraction thereof over 1 minute or longer. Too-rapid injection has caused severe reactions, including fatalities.

ACTIONS

Vitamin K, a fat-soluble vitamin, is essential for hepatic production of four blood coagulation factors including prothrombin. These are required for normal blood clotting. Onset of action is within 1 to 2 hours. Usually controls hemorrhage in 3 to 6 hours; normal prothrombin levels should be obtained in 12 to 14 hours. Metabolized by the liver and eliminated in urine and bile.

INDICATIONS AND USES

Coagulation disorders due to faulty formation of factors II, VII, IX, and X when caused by vitamin K deficiency or interference with vitamin K activity. Indicated in anticoagulant-induced prothrombin deficiency (warfarin or dicumarol). ■ Prophylaxis and treatment of hemorrhagic disease of the newborn. ■ Hypoprothrombinemia resulting from antibacterial therapy. ■ Hypoprothrombinemia secondary to factors limiting the absorption or synthesis of vitamin K (e.g., obstructive jaundice, biliary fistula, sprue, ulcerative colitis, celiac disease, intestinal resection, cystic fibrosis of the pancreas, and regional enteritis). ■ Other drug-induced hypoprothrombinemia where it is definitely shown that the result is due to interference with vitamin K metabolism (e.g., salicylates).

CONTRAINDICATIONS

Hypersensitivity to components.

PRECAUTIONS

IV and/or IM is not the route of choice; used only when SC or oral route cannot be used. Use extreme caution; has caused severe reactions, including death, with the first injection, even when the product has been diluted and infused slowly. ■ As an alternative to administering phytonadione, discontinuation or reduction of the doses of drugs interfering with coagulation mechanisms (e.g., antibiotics, salicylates) should be considered. The severity of the coagulation disorder should determine if phytonadione is required in addition to discontinuing or reducing the doses of interfering drugs. To correct excess anticoagulation after the use of warfarin (Coumadin) (e.g., returning an increased INR to the desired range), consider the degree of elevation and the presence of clinically significant bleeding. ■ Supplement with whole blood transfusion or blood components if indicated. ■ Now the only vitamin K product for IV use. ■ Do not use to counteract anticoagulant effects of heparin, not effective; protamine sulfate is indicated. ■ Does not restore abnormal platelet function to normal. ■ Does not correct hypoprothrombinemia due to hepatocellular damage. ■ When phytonadione is used in a patient for whom anticoagulant therapy is indicated, the

same clotting hazards that existed before beginning anticoagulant therapy will recur. Use the smallest dose of phytonadione possible and monitor PT.

Monitor: See **Neonatal Dose**, **Precautions**, and **Drug/Lab Interactions**. ■ Dose and effect determined by PT/INR. Repeat PT/INR 6 to 8 hours after a dose. Keep the physician informed. ■ Pain and swelling at injection site can occur.

Maternal/Child: Category C: safety for use not established. ■ Use caution during breastfeeding. ■ Use extreme caution in premature infants and neonates. Hemolysis, jaundice, and hyperbilirubinemia in newborns may be related to the dose of phytonadione. The recommended dose should not be exceeded. Severe hemolytic anemia, hemoglobinuria, kernicterus, brain damage, and death may occur. ■ Neonates with hemorrhagic disease of the newborn should respond to administration of phytonadione with a shortening of the PT within 2 to 4 hours. If shortening of the PT is not seen, consider other coagulation disorders. ■ May contain benzyl alcohol. When used as recommended, there is no evidence to suggest that this small amount is associated with toxicity.

DRUG/LAB INTERACTIONS

Discontinue drugs **adversely affecting the coagulation mechanism** if possible (e.g., salicylates, antibiotics). ■ May cause temporary resistance to **prothrombin-depressing oral anticoagulants** by increasing amount of phytonadione in the liver and blood. Anticoagulation will require larger doses of same or use of heparin sodium.

SIDE EFFECTS

Cyanosis, diaphoresis, dizziness, dyspnea, hyperbilirubinemia, hypotension, injection site reactions, peculiar taste sensations, rapid and weak pulse, tachycardia, transient flushing sensation. Anaphylaxis, cardiac and/or respiratory arrest, shock, and death have occurred with parenteral route.

ANTIDOTE

Should not be necessary if dosage is accurately calculated before administration. Action can be reversed by warfarin or heparin if indicated. Discontinue the drug and notify the physician of any side effects. For most side effects the physician will probably choose to continue the drug at a decreased rate of administration. Treat hypersensitivity reactions as necessary.

PIPERACILLIN SODIUM AND TAZOBACTAM SODIUM

(pie-**PER**-ah-sill-in **SO**-dee-um and tay-zoh-**BAC**-tam **SO**-dee-um)

Antibacterial
(extended-spectrum penicillin
and beta-lactamase inhibitor)

Zosyn

USUAL DOSE

Measurement of both drugs is included in the total dose; for every 1 Gm of piperacillin there is 0.125 Gm of tazobactam (8:1 ratio).

12 Gm piperacillin/1.5 Gm tazobactam/24 hours given as 3.375 (3 Gm piperacillin/0.375 Gm tazobactam) every 6 hours. Usual duration of therapy is 7 to 10 days, based on severity of infection and patient progress.

Nosocomial pneumonia: 4.5 Gm every 6 hours. Also use an aminoglycoside. Continue aminoglycoside if *P. aeruginosa* is isolated; may be discontinued if it is not isolated. Usual duration of therapy is 7 to 14 days.

PEDIATRIC DOSE

2 months to 9 months of age: 80 mg piperacillin/10 mg tazobactam per kg of body weight every 8 hours.

Over 9 months of age weighing up to 40 kg: 100 mg piperacillin/12.5 mg tazobactam per kg of body weight every 8 hours.

Pediatric patients over 40 kg: See [Usual Dose](#).

DOSE ADJUSTMENTS

No dose adjustment needed in impaired liver function. ■ Dose reduction may be required in the elderly. ■ Adjust dose in adult patients with impaired renal function based on the following chart. Dose recommendations for pediatric patients with impaired renal function are not available.

Piperacillin/Tazobactam Dose Guidelines in Adults with Impaired Renal Function

Renal Function (Creatinine Clearance, mL/min)	All Indications (Except Nosocomial Pneumonia)	Nosocomial Pneumonia
>40 mL/min	3.375 Gm q 6 hr	4.5 Gm q 6 hr
20-40 mL/min*	2.25 Gm q 6 hr	3.375 Gm q 6 hr
<20 mL/min*	2.25 Gm q 8 hr	2.25 Gm q 6 hr
Hemodialysis†	2.25 Gm q 12 hr	2.25 Gm q 8 hr
CAPD	2.25 Gm q 12 hr	2.25 Gm q 8 hr

*Creatinine clearance for patients not receiving hemodialysis.

†Hemodialysis removes 30% to 40% of piperacillin/tazobactam. Give an additional dose of 0.75 Gm following each dialysis session. No additional dose is necessary for CAPD patients.

DILUTION

Available in two different formulations: one with EDTA (edetate disodium dihydrate) and one without. **Compatibility** information differs; consult pharmacist. See [Compatibility](#).

Each 1 Gm of piperacillin content should be reconstituted with at least 5 mL of suitable diluent (e.g., SWFI or NS with or without preservatives, D5W, Dextran 6% in Saline, LR [EDTA containing formulation only]). Swirl until dissolved. Should be further diluted to desired volume (50 to 150 mL) with the **compatible** infusion solutions above and given as an intermittent infusion. If further diluted with SWFI, maximum recommended volume of SWFI per dose is 50 mL. Also available premixed and in ADD-Vantage vials for use with ADD-Vantage infusion containers. May be used in ambulatory IV infusion pumps. Considered stable at RT for 12 hours when reconstituted and

diluted to a final volume of 25 to 37.5 mL. See manufacturer's literature for additional information.

Storage: Store unopened vials at CRT. Use single-dose vials immediately after reconstitution; discard any unused portion after 24 hours at room temperature or 48 hours if refrigerated. Stable for 24 hours at CRT or for up to 7 days after dilution if refrigerated, 3 months if frozen. Do not refrigerate or freeze ADD-Vantage vials after reconstitution.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be mixed with other drugs in a syringe or infusion bottle. Not chemically stable in solutions containing only sodium bicarbonate and/or solutions that significantly alter the pH. **Incompatible** with LR (EDTA-free formulation only) and should not be added to blood products or albumin hydrolysates." One source recommends temporarily discontinuing other solutions infusing at the same site to avoid compatibility problems. May be inactivated in solution with aminoglycosides (e.g., amikacin [Amikin], gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. Formulation containing EDTA **may be compatible** at the **Y-site** with amikacin or gentamicin. Selected doses, specific diluents, and amounts of diluent are required. Consult pharmacist or manufacturer's literature. See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

Y-site: See [general comments under Compatibility](#). Aminophylline, anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), cisatracurium (Nimbex), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cytarabine (ARA-C), dexamethasone (Decadron), dexmedetomidine (Precedex), diphenhydramine (Benadryl), docetaxel (Taxotere), dopamine, enalaprilat (Vasotec IV), etoposide (VePesid), etoposide phosphate (Etopophos), fenoldopam (Corlopam), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gallium nitrate (Ganite), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), leucovorin calcium, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, mannitol, meperidine (Demerol), mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), milrinone (Primacor), morphine, ondansetron (Zofran), potassium chloride (KCl), ranitidine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), sodium bicarbonate, sulfamethoxazole/trimethoprim, telavancin (Vibativ), thiotepa, tigecycline (Tygacil), vancomycin (Vancocin), vasopressin, vinblastine, vincristine, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose over 30 minutes as an intermittent infusion. Discontinue primary IV infusion during administration. Slow infusion rate for pain along venipuncture site. See [Compatibility](#).

ACTIONS

An antimicrobial agent that combines the extended-spectrum penicillin piperacillin with the potent beta-lactamase inhibitor tazobactam. May be used in suspected polymicrobial infections due to its broad spectrum of activity; spectrum is superior to many other agents. Acts by inhibiting septum formation and cell wall synthesis of susceptible bacteria. Bactericidal against all three classes of bacterial pathogens; gram-positive and gram-negative aerobes, and anaerobes that may be resistant to other antibiotics. Well distributed in all body fluids and tissues. Mean tissue concentrations are 50% to 100% of plasma concentrations. Peak levels are achieved immediately at the completion of an infusion. Plasma half-life ranges from 0.7 to 1.2 hours. Extended two-fold (piperacillin) to four-fold (tazobactam), if CrCl less than 20 mL/min. Metabolized and excreted in urine and, to a small extent, in bile. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of infections caused by piperacillin-resistant, piperacillin/tazobactam-susceptible, beta-lactamase-producing strains of specific microorganisms in the following conditions: intra-abdominal (e.g., appendicitis complicated by rupture or abscess and peritonitis), gynecologic (e.g., postpartum endometritis and pelvic inflammatory disease), skin and skin structure (complicated and uncomplicated, e.g., cellulitis, cutaneous abscesses, and ischemic/diabetic foot infection), and pneumonia (moderately severe community-acquired and nosocomial). ■ Used in combination with aminoglycosides for infections in neutropenic patients or nosocomial pneumonia caused by *Pseudomonas aeruginosa*.

Unlabeled uses: Treatment of septicemia.

CONTRAINDICATIONS

History of hypersensitivity reaction to any penicillin, cephalosporin, or beta-lactamase inhibitors (not absolute; see **Precautions**).

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients on penicillin therapy; most likely to occur in patients with a history of penicillin allergy or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies indicated determine susceptibility of the causative organism to piperacillin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, piperacillin/tazobactam should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Bleeding manifestations have been reported and may be associated with abnormal coagulation tests (e.g., clotting time, platelet aggregation, and PT). Patients with impaired renal function may be at increased risk for bleeding tendencies. ■ Use caution in patients with CHF or those with a history of bleeding disorders or GI disease (e.g., colitis). ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with piperacillin/tazobactam. ■ Incidence of side effects (e.g., fever and rash) may be increased in patients with cystic fibrosis. ■ Administration of higher than recommended doses has resulted in neuromuscular excitability and convulsions. Patients with renal impairment are at increased risk. ■ Continue at least 2 days after symptoms of infection disappear.

Monitor: Watch for early symptoms of a hypersensitivity reaction. ■ Periodic evaluation of renal, hepatic, and hematopoietic systems and serum potassium recommended in prolonged therapy. May cause hypokalemia; observe closely. ■ Contains 2.79 mEq (64 mg) of sodium/Gm. At the usual recommended doses, patients would receive 33.5 to 44.6 mEq (768 to 1,024 mg) per day. Observe for electrolyte imbalance and cardiac irregularities. May aggravate CHF. ■ May cause thrombophlebitis; observe carefully, rotate infusion sites. ■ Observe for increased bleeding tendencies in all patients, especially those with impaired renal function. ■ See **Drug/Lab Interactions**.

Patient Education: Report promptly: fever, rash, sore throat, unusual bleeding or bruising, severe stomach cramps, and/or diarrhea, seizures. ■ May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: use during pregnancy only if clearly needed. ■ May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Safety and effectiveness for use in pediatric patients under 2 months of age not established.

Elderly: No problems documented. Consider age-related organ function and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **aminoglycosides** (e.g., amikacin [Amikin], gentamicin). Synergism may be inconsistent; see **Compatibility**. ■ Does not affect pharmacokinetics of vancomycin; may be given without dose adjustment. ■ Concomitant administration with **probenecid** decreases rate of elimination of piperacillin/tazobactam, resulting in higher and more prolonged blood levels. May be desirable or may cause toxicity. ■ Use caution with **anticoagulants** (e.g., heparin, warfarin [Coumadin]), **platelet aggregation inhibitors** (e.g., aspirin, NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], dextran, dipyridamole, glycoprotein GPIIb/IIIa receptor antagonists [e.g., abciximab (ReoPro), eptifibatid (Integrilin), tirofiban (Aggrastat)], plicamycin). Risk of bleeding is increased. Monitoring of coagulation tests may be indicated. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, and tetracyclines); may interfere with bactericidal action. ■ May decrease clearance and increase toxicity of **methotrexate**; monitor methotrexate levels. ■ May inhibit effectiveness of **oral contraceptives**; could result in breakthrough bleeding or pregnancy. ■ May prolong neuromuscular blockade with **vecuronium** or other nondepolarizing muscle relaxants. ■ May cause **false urine protein reactions** with various tests and **false-positive glucose** with Clinitest. ■ **False-positive test results** using the Bio-Rad Laboratories Platelia Aspergillus EIA test in patients receiving piperacillin/tazobactam (Zosyn) have been reported. ■ See **Side Effects**.

SIDE EFFECTS

Hypokalemia, prolonged PTT, prolonged PT, and increased bleeding time. Most other side effects are usually mild or moderate and transient. Abdominal pain; abscess; agitation; anxiety; CDAD; chest pain; cholestatic jaundice; constipation; diarrhea; dizziness; dyspnea; dyspepsia; edema; electrolyte abnormalities; fever; headache; hematuria; hematologic abnormalities (agranulocytosis, anemia, hemolytic anemia, pancytopenia, thrombocytopenia, thrombocytosis); hepatitis; hypertension; increased AST, BUN, and serum creatinine; insomnia; interstitial nephritis; local reactions; moniliasis; nausea; pain; pharyngitis; positive Coombs' test; pruritus; pseudomembranous colitis; rash (e.g., bullous, eczematoid, erythema multiforme, maculopapular, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticarial); rhinitis; seizures; and vomiting have been reported. Anaphylaxis can occur. Transient leukopenia and eosinophilia can occur with prolonged therapy.

ANTIDOTE

Notify the physician immediately of any adverse symptoms. For severe symptoms, discontinue the drug, treat hypersensitivity reactions (antihistamines, epinephrine, corticosteroids, airway management, oxygen), and resuscitate as necessary. Use anticonvulsants (e.g., diazepam [Valium]) or barbiturates (e.g., phenobarbital) for seizures. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Mild cases may respond to drug discontinuation alone. Hemodialysis is effective in overdose.

PLASMA PROTEIN FRACTION

Plasma volume expander

(PLAZ-ma PRO-teen FRAK-shun)

Plasmanate, Plasmatein, Protenate

pH 6.7 to 7.3

USUAL DOSE

Variable, depending on indication for use, condition of patient, and response to therapy. Range is from 250 to 1,500 mL/24 hr. Each 500-mL bottle yields 25 Gm of plasma protein. Suggested initial doses are as follows:

Shock: 250 to 500 mL.

Burns: 500 to 1,000 mL.

Hypoproteinemia: 1,000 to 1,500 mL/24 hr.

PEDIATRIC DOSE

Treatment of acute shock (unlabeled): See [Maternal/Child](#). One source recommends 10 to 30 mL/kg of body weight.

DILUTION

Available as a 5% solution buffered with saline in 250- and 500-mL bottles with injection sets. Plasmanate also available in a 50-mL size. No further dilution is required. Do not use if solution is turbid or a sediment is visible. Use immediately after opening and discard any unused portion. Contains no preservatives.

Storage: Store at CRT.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with solutions containing alcohol, protein hydrolysates, or amino acid products. Manufacturer states, "**Compatible** with the usual carbohydrate and electrolyte solutions."

RATE OF ADMINISTRATION

Variable, depending on indication, present blood volume, and patient response. Adjust or slow rate according to clinical response and rising BP. Averages are:

Normal blood volume: 1 mL/min.

Treatment of shock and burns in adult: 5 to 8 mL/min. Higher rates may be tolerated if necessary. Rapid infusion (over 10 mL/min) may cause hypotension. Decrease flow rate as patient improves.

Treatment of shock in infants and other pediatric patients: 5 to 10 mL/min. Do not exceed 10 mL/min in pediatric patients.

Treatment of hypoproteinemia: Single 500-mL dose over 1 hour. For larger amounts the maximum rate is 100 mL/hr.

ACTIONS

A sterile, natural, plasma protein substance containing at least 83% albumin, no more than 17% alpha and beta globulins, and no more than 1% gamma globulin. Contains 130 to 160 mEq sodium/liter. It expands intravascular volume, prevents marked hemoconcentration, and maintains appropriate electrolyte balance in burns.

INDICATIONS AND USES

Emergency treatment of hypovolemic shock caused by burns, infections, surgery, or trauma (may also be due to dehydration in infants and other pediatric patients). ■ Temporary treatment of hemorrhage when whole blood unavailable. ■ Hypoproteinemia until cause determined and corrected. ■ Prevention of hemoconcentration and maintenance of electrolyte balance in burn patients.

CONTRAINDICATIONS

Cardiac failure, cardiopulmonary bypass, history of hypersensitivity reactions to albumin, normal or increased intravascular volume, severe anemia.

PRECAUTIONS

May be given without regard to blood group or type. ■ Not effective for coagulation mechanism defects. ■ Added protein, fluid, and sodium load requires caution in hepatic or renal impairment. ■ If continuous protein loss occurs or edema is present, normal serum albumin (25%) may be the preferred product.

Monitor: Monitor vital signs (including central venous pressure if possible) and urine output every 5 to 15 minutes for 1 hour and hourly thereafter depending on condition. ■ For treatment of shock, observe carefully for bleeding points that may not have been evident at lower pressures. ■ Whole blood may be indicated for considerable RBC loss or anemia caused by administration of large amounts of plasma protein fraction. ■ Additional fluids are required for dehydrated patients. Tissue dehydration caused by osmotic action of plasma proteins can be acute. ■ May cause vascular overload; monitor for signs of pulmonary edema or heart failure (e.g., dyspnea, fluid in the lungs, abnormal increases in BP or CVP). ■ Hemoglobin, hematocrit, electrolyte, and serum protein evaluations are necessary during therapy.

Maternal/Child: Category C: safety for use in pregnancy not established. ■ Safety and effectiveness for use in pediatric patients not established.

DRUG/LAB INTERACTIONS

May cause an **elevated alkaline phosphatase** level.

SIDE EFFECTS

Hypersensitivity and/or pyrogenic reactions can occur. Incidence of toxicity is low when administered with appropriate caution. Slight nausea can occur. Hypotension can be sudden if administered too rapidly.

ANTIDOTE

Notify the physician of all symptoms and side effects. Discontinue infusion for sudden hypotension. Decrease flow rate if indicated and treat symptomatically. Resuscitate as necessary.

POOLED PLASMA (HUMAN)

(POOLD PLAZ-ma HUE-man)

Plasma replacement and exchange

Octaplas

USUAL DOSE

Administer pooled plasma (Octaplas) based on ABO blood group compatibility.

Pooled Plasma (Octaplas) Dose Guidelines	
Indication	Dose
Replacement of multiple coagulation factors in patients with acquired deficiencies	10 to 15 mL/kg* Adjust dose based on the desired clinical response
Plasma exchange in patients with thrombotic thrombocytopenic purpura (TTP)	1 to 1.5 plasma volumes (40 to 60 mL/kg)†

*Patient's plasma coagulation factor levels should increase by approximately 15% to 25%. If hemostasis is not achieved, use higher doses.

†Completely replace plasma volume removed during plasmapheresis with Octaplas. In general, 1 to 1.5 plasma volumes corresponds to 40 to 60 mL/kg.

DOSE ADJUSTMENTS

Replacement of multiple coagulation factors in patients with acquired deficiencies: Adjust dose based on desired clinical response.

DILUTION

Available as a frozen solution for infusion (specific to blood group A, B, AB, or O) containing 45 to 70 mg human plasma proteins per mL in a 200-mL volume. Administer after thawing using an infusion set with a filter. Avoid shaking.

To thaw in a water bath: Thaw in outer wrapper for up to 30 minutes in a circulating water bath at 30° to 37° C (86° to 98.6° F). An overwrap bag may be used to provide further protection of contents if appropriate. Prevent water from contaminating the entry port. Thawing should not take more than 30 minutes.

To thaw by a dry tempering system: See specific instructions in prescribing information.

Filters: Administration through an in-line filter required.

Storage: Store at -18° C (-0.4° F) or lower, protected from light. Thaw according to manufacturer's instructions. Use thawed product within 12 hours if stored at 2° to 4° C (35.6° to 39.2° F) or within 3 hours if stored at 20° to 25° C (68° to 77° F). Do not re-freeze Octaplas. Discard unused product. Discard after expiration date on container label.

COMPATIBILITY

Manufacturer states, "Do not inject drugs containing calcium in the same IV line with Octaplas because precipitants may block the line."

RATE OF ADMINISTRATION

Infusion rate should not exceed 0.020 to 0.025 mmol citrate/kg/min (i.e., less than 1 mL pooled plasma [Octaplas]/kg/min); see [Precautions](#).

ACTIONS

Octaplas replaces human plasma proteins. It is a sterile, pyrogen-free, frozen solution of octaplas/detergent (S/D) treated, pooled human plasma. It is manufactured from pooled plasma of a single ABO blood group (A, B, AB, or O). The finished product is tested for coagulation factors II, V, VII, VIII, X, and XI; protein C; protein S; alpha 2-antiplasmin (plasmin inhibitor); fibrinogen; and ADAMTS13. The content and distribution of plasma proteins in Octaplas are comparable to reference ranges for healthy blood donors, except for Protein S and alpha 2-antiplasmin, which are labile to S/D treatment and are controlled to ensure levels in the final product of equal to or greater than 0.4 IU/mL. Coagulation factor activities are controlled to obtain levels within the range of normal human plasma.

INDICATIONS AND USES

Replacement of multiple coagulation factors in patients who have acquired deficiencies due to liver disease or are undergoing cardiac surgery or liver transplant. ■ Plasma exchange in patients with thrombotic thrombocytopenic purpura (TTP).

CONTRAINDICATIONS

History of hypersensitivity to fresh frozen plasma (FFP) or plasma-derived products, including any plasma protein. ■ History of hypersensitivity reaction to Octaplas. ■ IgA deficiency. ■ Severe deficiency of Protein S.

PRECAUTIONS

Administration of Octaplas must be based on ABO blood group compatibility. Transfusion reactions can occur with ABO blood group mismatches. ■ Administer in a facility with equipment for monitoring the patient and responding to any medical emergency. ■ High infusion rates can induce hypervolemia with consequent pulmonary edema or cardiac failure. ■ Excessive bleeding due to hyperfibrinolysis can occur due to low levels of alpha 2-antiplasmin (plasmin inhibitor). ■ Thrombosis can occur due to low levels of Protein S. ■ Citrate toxicity can occur with volumes exceeding 1 mL/kg/min. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, hepatitis C). Numerous steps in the manufacturing process are used to make the potential for infection extremely remote. Report suspected infections to manufacturer or FDA.

Monitor: *Replacement of multiple coagulation factors in patients with acquired deficiencies:* Obtain baseline aPTT, PT, and/or specific coagulation factors and monitor response with additional measurements.

All indications: Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, chills, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, urticaria). ■ Monitor for S/S of pulmonary edema or cardiac failure. ■ Monitor for S/S of thrombosis in patients at risk. ■ Monitor for S/S of citrate toxicity (hypocalcemia [e.g., fatigue, muscle spasms, paresthesia]). Potential for citrate toxicity may be increased in patients with impaired hepatic function.

Liver transplant patients: Monitor for S/S of excessive bleeding; may be due to hyperfibrinolysis.

Patient Education: Promptly report S/S of a hypersensitivity reaction (e.g., chest pain, chills, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, urticaria). ■ Report development of edema or volume overload, including shortness of breath and/or difficulty breathing.

Maternal/Child: Category C: use during pregnancy only if clearly needed. ■ Use caution in labor and delivery and during breast-feeding; safety and effectiveness unknown. ■ Safety and effectiveness for use in pediatric patients not evaluated.

Elderly: Safety and effectiveness for use in geriatric patients not evaluated.

DRUG/LAB INTERACTIONS

May form a precipitate with **drugs containing calcium** (e.g., calcium gluconate).

SIDE EFFECTS

Headache, nausea, paresthesia, pruritus, and urticaria are most common. Anaphylactic shock, citrate toxicity, and severe hypotension are the most serious side effects reported.

Post-Marketing: Abdominal pain, alkalosis, bronchospasm, cardiac arrest or failure, chest discomfort or pain, chills, circulatory overload, dyspnea, erythema, fever, hyperfibrinolysis, hypersensitivity reactions (including anaphylaxis), pulmonary edema, rash, respiratory arrest or failure, seroconversions (passive transfer of antibodies), tachycardia, tachypnea, thromboembolism, and vomiting have been reported.

ANTIDOTE

Notify the physician of all side effects. Minor side effects may be tolerated and treated symptomatically. For major side effects (e.g., hypervolemia, hyperfibrinolysis, thrombosis), discontinue Octaplas and treat symptomatically. Treat anaphylaxis immediately with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol (Ventolin), IV fluids, and ventilation equipment as indicated. Treat citrate toxicity with calcium gluconate IV into another vein. Resuscitate as necessary.

PORFIMER SODIUM

(POOR-fih-mer SO-dee-um)

Photosensitizing agent

Antineoplastic

Photofrin

pH 7 to 8

USUAL DOSE

A course is a two-stage process requiring administration of both drug and light.

Stage one: Administration of porfimer: A single IV injection of 2 mg/kg. No further injection of porfimer sodium should be given in any one course of therapy.

Stage two: Illumination: Illumination with nonthermal laser light at 40 to 50 hours post-injection.

ESOPHAGEAL AND ENDOBRONCHIAL CANCER

2 mg/kg of porfimer sodium as an IV injection. Approximately 40 to 50 hours after the injection, standard endoscopic techniques are used for light administration and débridement. The laser system must be approved for delivery of a stable power output at a wavelength of 630 ± 3 nm. Light is delivered to the tumor by cylindrical OPTIGUIDE fiber-optic diffusers passed through the operating channel of an endoscope/bronchoscope. The choice of diffuser tip length depends on the length of the tumor. Diffuser length should be sized to avoid exposure of nonmalignant tissue to light and to prevent overlapping of previously treated malignant tissue. A second laser light application may be given 96 to 120 hours after injection. Before providing a second laser light treatment, the residual tumor should be gently débrided. Vigorous débridement may cause esophageal tumor bleeding; see [Precautions](#).

Up to three courses may be given, but each must be separated by at least 30 days. Evaluate patients with esophageal cancer for the presence of a tracheoesophageal or bronchoesophageal fistula before each course. Evaluate all patients for possible erosion of the tumor into a major blood vessel.

Esophageal cancer: 2 mg/kg of porfimer sodium as an IV injection. A light dose of 300 joules/cm of diffuser length should be delivered by the specific process outlined previously. Light exposure time is set to 12 minutes and 30 seconds. Débridement of tumor may be performed 2 to 3 days later; see [Precautions](#).

Endobronchial non-small-cell lung cancer: 2 mg/kg of porfimer sodium as an IV injection. A light dose of 200 joules/cm of diffuser length should be delivered by the specific process outlined previously. Light exposure time is set to 8 minutes and 20 seconds. Débridement of tumor should be performed 2 to 3 days later; see [Precautions](#).

HIGH-GRADE DYSPLASIA (HGD IN BARRETT'S ESOPHAGUS [BE])

2 mg/kg of porfimer sodium as an IV injection. Approximately 40 to 50 hours after the injection, administration of light should be delivered by an X-cell Photodynamic Therapy (PDT) balloon with a fiber optic diffuser. The choice of fiber optic/balloon diffuser combination will depend on the length of Barrett's mucosa to be treated (see manufacturer's information). The objective of therapy is to expose and treat all areas of HGD and the entire length of Barrett's esophagus. The light dose administered is 130 joules/cm of diffuser length. Acceptable light intensity for the balloon/diffuser combinations ranges from 200 to 270 mW/cm of diffuser. Treatment time is dependent on the fiber optic/balloon diffuser combination used (see manufacturer's information). A maximum of 7 cm of esophageal mucosa may be treated at the first light session. If possible, the area treated should include normal tissue margins of a few millimeters at both the proximal and distal ends. Nodules are pretreated at a light dose of 50 joules/cm of diffuser length with a short (2.5 cm) fiber optic diffuser placed directly against the nodule. A second laser light application may be given to a previously treated segment that shows a "skip" area using a 2.5-cm fiber optic diffuser at a light dose of 50 joules/cm of the diffuser length. Patients with Barrett's esophagus greater than 7 cm should have the remaining untreated length

of Barrett's epithelium treated with a second PDT course at least 90 days later. See **Precautions**.

Up to 3 courses (each separated by 90 days) may be given to a previously treated segment that still shows high-grade dysplasia, low-grade dysplasia, or Barrett's metaplasia, or to a new segment if the initial Barrett's segment was greater than 7 cm in length.

DOSE ADJUSTMENTS

No adjustments required.

DILUTION

Specific techniques required; see Precautions. Prepare immediately before use. Each vial of porfimer sodium must be reconstituted with 31.8 mL of D5W or NS. Concentration will be 2.5 mg/mL. Shake well until dissolved. An opaque solution; detection of particulate matter by visual inspection is difficult. Withdraw desired dose. Must be protected from bright light and used immediately.

Storage: Store unopened vials at CRT in carton to protect from light.

COMPATIBILITY

Manufacturer states, "Do not mix porfimer sodium with other drugs in the same solution."

RATE OF ADMINISTRATION

A single dose equally distributed over 3 to 5 minutes.

ACTIONS

The first light-activated drug (photosensitizing agent) for use in photodynamic therapy (PDT) to be approved in the United States. Treatment consists of a two-step process involving administration of drug and light. Cytotoxic and anti-tumor actions are light and oxygen dependent and are the result of the propagation of radical reactions. PDT with porfimer causes direct intracellular damage by initiating radical chain reactions that damage intracellular membranes and mitochondria. After IV infusion of drug, it is allowed to circulate. It accumulates and is retained in tumors, skin, and organs of the reticuloendothelial system (e.g., liver, spleen) while largely clearing from other tissues. Has no apparent effect on tumors until it is activated by selective delivery of light (usually 40 to 50 hours postinfusion). Light activation induces a photochemical, not a thermal, effect that produces an active form of oxygen and releases thromboxane A₂. This process causes vasoconstriction, activation and aggregation of platelets, and increased clotting that contribute to ischemic necrosis leading to tissue and tumor death. The necrotic reaction and associated inflammatory response may evolve over several days. In patients with esophageal cancer, ability to swallow is improved, as is quality of life. Elimination half-life is very prolonged, up to several weeks. Highly protein bound.

INDICATIONS AND USES

Palliative treatment of patients with completely obstructing esophageal cancer or partially obstructing esophageal cancers that are unsuitable for treatment with thermal laser therapy. ■ Treatment of microinvasive endobronchial non-small-cell lung cancer (NSCLC) in patients for whom surgery and radiotherapy are not indicated. ■ Reduction of obstruction and palliation of symptoms in patients with completely or partially obstructing endobronchial non-small-cell lung cancer. ■ Ablation of high-grade dysplasia (HGD) of Barrett's esophagus patients who do not undergo esophagectomy.

Unlabeled uses: Treatment of AIDS-related cutaneous Kaposi's sarcoma, primary or recurrent basal cell carcinoma, and squamous cell carcinoma.

CONTRAINDICATIONS

Known allergies to porphyrins, an existing tracheoesophageal or bronchoesophageal fistula, porphyria, or tumors eroding into a major blood vessel. ■ Photodynamic therapy (PDT) is not suitable for emergency treatment of patients with severe acute respiratory distress caused by an obstructing endobronchial lesion because 40 to 50 hours are required between injection with porfimer sodium and laser light treatment. ■ PDT is not suitable for patients with esophageal or gastric varices or for patients with esophageal ulcers greater than 1 cm in diameter.

PRECAUTIONS

Use rubber gloves and eye protection during preparation and administration. Avoid any skin or eye contact since that area will become photosensitive. Wipe up spills with a damp cloth. Dispose of all contaminated materials in a polyethylene bag to avoid accidental contact by others. Protection from light will be necessary if accidental exposure or overexposure occurs. See process in [Patient Education](#). ■ Administered by or under the direction of the physician specialist with appropriate knowledge of the selected laser system. Facilities for monitoring the patient and responding to any medical emergency must be available. ■ Requires laser systems and a fiber-optic diffuser to activate. The FDA has approved several photodynamic lasers and the Optiguide fiber-optic diffuser for use with porfimer sodium. ■ Avoid exposure of skin and eyes to direct sunlight or bright indoor light; see [Patient Education](#). ■ Porfimer elimination may be prolonged in patients with hepatic or renal impairment, and they may require longer precautionary measures for photosensitivity. ■ In the original studies for esophageal tumors, some experienced investigators indicated that natural sloughing action in the esophagus might be sufficient and débridement could needlessly traumatize the area. However, débridement may be performed after each light activation to minimize the potential for obstruction caused by necrotic debris. ■ A minimum of 4 weeks after completion of radiation therapy is recommended before treatment with PDT. This allows the acute inflammation produced by radiotherapy to subside. ■ 2 to 4 weeks should be allowed after PDT is complete before beginning any radiotherapy. ■ Thromboembolic events can occur following PDT with porfimer. More common in patients with other risk factors for thromboembolism (e.g., advanced cancer, cardiovascular disease, after a major surgery, or prolonged immobilization).

Esophageal tumors: Not recommended if the esophageal tumor is eroding into the trachea or bronchial tree; tracheoesophageal or bronchoesophageal fistula may result from treatment. Serious and sometimes fatal gastrointestinal and esophageal necrosis and perforation can occur after treatment. ■ Use extreme caution in patients with esophageal varices. Light should not be given directly to the variceal area because of the high risk of bleeding.

Endobronchial cancer: Interstitial fiber placement is preferred to intraluminal activation in noncircumferential endobronchial tumors that are soft enough to penetrate. Results in less exposure of the normal bronchial mucosa to light. ■ Patients with obstructing lung cancer who have received prior radiation therapy or who have tumors that are large, centrally located, cavitating, or extensive and extrinsic to the bronchus have a higher incidence of fatal hemoptysis. ■ An endobronchial tumor that invades deeply into the bronchial wall may create a fistula as the tumor resolves. ■ Use with extreme caution in endobronchial tumors located where treatment-induced inflammation could obstruct the airway (e.g., long or circumferential tumors of the trachea, tumors of the carina that involve both mainstem bronchi circumferentially, or circumferential tumors in the mainstem bronchus in patients with prior pneumonectomy).

HGD in Barrett's esophagus: Before initiating treatment with porfimer PDT, a diagnosis of HGD in Barrett's esophagus should be confirmed by a GI pathologist. ■ Long-term effect of PDT on HGD in Barrett's esophagus is unknown. There may be a risk of leaving cancerous cells behind or of leaving residual abnormal epithelium beneath the new squamous cell epithelium. ■ Esophageal strictures are a common adverse effect seen in patients treated with PDT for HGD in Barrett's esophagus. Nodule pretreatment and retreatment of the same mucosal segment more than once may influence the risk of developing an esophageal stricture. Usually occur within 6 months following PDT. May be managed with esophageal dilation; several dilations may be required.

Monitor: Obtain baseline CBC and monitor for anemia due to tumor bleeding. ■ Prevent extravasation at the injection site. Should extravasation occur, area must be protected from light. ■ Opiates may be required to control pain. ■ Observe patients carefully; most are critically ill, and many complications could occur. Monitor patients with **endobronchial tumors** closely between the laser light therapy and the mandatory débridement

bronchoscopy for any evidence of respiratory distress, inflammation, mucositis, or necrotic debris that may cause obstruction of the airway. Immediate bronchoscopy may be required to remove secretions and debris to open the airway. ■ Monitor for hemoptysis; may be a sign of progressive disease, or may result from resolution of a tumor that has eroded into a pulmonary artery. ■ In patients who have received PDT for **HGD in Barrett's esophagus**, endoscopic biopsy surveillance should be conducted every 3 months until 4 consecutive negative evaluations for HGD have been recorded. Further follow-up should be performed every 6 to 12 months. ■ Photosensitivity not transferable through skin to caregivers. ■ See **Precautions, Patient Education, and Drug/Lab Interactions**.

Patient Education: Must observe precautions to avoid exposure of skin and eyes to direct sunlight or bright indoor light for at least 30 days. Some patients may remain photosensitive for up to 90 or more days. Photosensitivity is due to residual drug, which is present in all parts of the skin. Ambient indoor light is beneficial as it gradually inactivates the remaining drug through a photobleaching reaction. Do not remain in a darkened room. Do expose skin to ambient indoor light. Avoid bright indoor light from examination lamps, dental lamps, operating room lamps, and unshaded light bulbs. Limit time outdoors to necessary excursions and completely cover body with clothing and shade face before going out. Conventional ultraviolet sunscreens are of no value because photoactivation is caused by visible light, not UV rays. Eyes will be sensitive to sun, bright lights, and car headlights; wear dark sunglasses with an average white light transmittance of less than 4%. After several weeks and before exposing any area of skin to direct sunlight or bright indoor light, test a small area of skin (not the face) for residual photosensitivity. Expose the small area of skin for 10 minutes. If no photosensitivity reaction (redness, swelling, or blistering) occurs within 24 hours, gradually resume normal outdoor activities. Exercise caution and increase skin exposure gradually. If some photosensitivity reaction occurs, continue precautions for 2 more weeks and then retest. Retest level of photosensitivity if traveling to a different geographic area with greater sunshine. ■ Report chest pain (caused by inflammatory response within the area of treatment); may require prescription pain medication. ■ Effective contraception necessary for women of childbearing age.

Maternal/Child: Category C: use during pregnancy only if benefits justify potential risk to fetus. Effective contraception necessary for women of childbearing age. Has caused maternal and fetal toxicity in rats and rabbits (increased resorptions, decreased litter size, and reduced fetal body weight). ■ Discontinue breast-feeding; not known if it is secreted in breast milk, but serious reactions could occur in the infant. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Dose modification based on age is not required.

DRUG/LAB INTERACTIONS

No specific studies have been completed, but the following interactions are likely to occur. ■ Use with **other photosensitizing agents** (e.g., griseofulvin, fluoroquinolones [e.g., ciprofloxacin (Cipro IV)], phenothiazines [e.g., prochlorperazine (Compazine)], sulfonamides [sulfisoxazole (Gantrisin), ophthalmic solutions (AK-Sulf)], sulfonyleurea hypoglycemic agents [tolbutamide], tetracyclines [doxycycline], thiazide diuretics [chlorothiazide (Diuril)]) could increase the photosensitivity reaction. ■ Anti-tumor activity may be decreased by **dimethyl sulfoxide, beta-carotene, ethanol, formate, mannitol**. ■ Anti-tumor activity may be decreased by **allopurinol (Aloprim), calcium channel blockers** (e.g., diltiazem [Cardizem]), **prostaglandin synthesis inhibitors** (NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]), **and tissue ischemia**. ■ Effectiveness may be reduced by **drugs that decrease clotting, vasoconstriction** (e.g., nicardipine [Cardene]), **or platelet aggregation** (e.g., dipyridamole [Persantine], ticlopidine [Ticlid]). ■ **Glucocorticoid hormones** (e.g., dexamethasone [Decadron]) given before or with PDT may reduce the effectiveness of porfimer by inhibiting the production of thromboxane A₂.

SIDE EFFECTS

All diagnoses: May cause constipation. Most toxicities are local effects in the region of illumination and occasionally in surrounding tissues. Usually an inflammatory response

induced by the photodynamic effects. Photosensitivity reactions occurred in 20% of patients in clinical studies. Reactions were usually mild to moderate erythema, but also included blisters, burning sensation, itching, and swelling. Less common skin manifestations included increased hair growth, skin discoloration, skin nodules, increased wrinkles, and skin fragility. Cases of fluid imbalance and thromboembolic events have been reported. Cataracts have been reported in one man with a family history of cataracts. Relationship to porfimer sodium unknown.

Post-Marketing: Infusion reactions (bradycardia, dizziness, hypertension, hypotension, urticaria).

Esophageal tumors: Bronchoesophageal or tracheoesophageal fistula can occur as a result of the disease or treatment, including débridement. Abdominal pain, anemia (more prevalent if tumor is located in the lower third of the esophagus), anorexia, arrhythmias (atrial fibrillation [more prevalent if tumor is located in the middle third of the esophagus], tachycardia), candidiasis, chest pain, coughing, dyspepsia, dysphagia, dyspnea, edema, eructation, esophageal edema (more prevalent if tumor is located in the upper third of the esophagus), esophageal tumor bleeding, esophageal stricture, esophagitis, fever, hematemesis, hypertension, hypotension, insomnia, nausea, pleural effusion, and vomiting may occur, as well as numerous others.

Endobronchial tumors: Coughing, dysphagia, dyspnea (may be life threatening), mucositis reaction (e.g., edema, exudate, and mucous plug obstruction), stricture, ulceration. Fatal hemoptysis has occurred (higher incidence in patients who have received radiation therapy).

High-grade dysplasia (HGD in Barrett's esophagus [BE]): Esophageal narrowing and esophageal stricture are common side effects and may require multiple dilations. Other side effects may include abdominal pain, anorexia, anxiety, arthralgia, back pain, chest discomfort or pain, dehydration, depression, diarrhea, dyspepsia, dysphagia, dyspnea, eructation, esophageal pain, fatigue, fever, headache, hiccups, hypertension, infections (bronchitis, sinusitis), insomnia, nausea and vomiting, odynophagia (pain on swallowing), pleural effusion.

ANTIDOTE

If an overdose of porfimer sodium is given, do not give the laser light treatment. Porfimer sodium is not dialyzable. Increased side effects and damage to normal tissue can be expected if an overdose of light is given. Keep physician informed of all side effects; most will be treated symptomatically. Some may be life threatening. Respiratory obstruction may require immediate bronchoscopy and removal of the obstruction with suction or forceps. Stent placement may be required in endobronchial stricture. Chest pain may require the use of opiates.

POTASSIUM ACETATE AND POTASSIUM CHLORIDE

Electrolyte replenisher
Antihypokalemic

(po-TASS-ee-um AS-ah-tayt,
po-TASS-ee-um KLOR-eyed)

pH 4 to 8

USUAL DOSE

Concentrated potassium solutions must be diluted before administration; direct injection of any concentrated solution can be instantly fatal.

Dose and rate of administration are dependent on specific patient condition.

Normal daily requirements: **Adults:** 40 to 80 mEq/24 hr.

Starting dose based on losses, desired replacement, or maintenance. 20 to 60 mEq/24 hr. 200 mEq/24 hr is usually not exceeded. Up to 400 mEq/24 hr has been given in selected situations (e.g., serum potassium less than 2 mEq/L) with extreme caution. Potassium acetate may contain up to 200 mcg/L of aluminum; see **Precautions**.

PEDIATRIC DOSE

Normal daily requirements: **Newborn:** 2 to 6 mEq/kg/24 hr. **Other pediatric patients:** 2 to 3 mEq/kg/24 hr.

1 to 4 mEq/kg of body weight/24 hr. Do not exceed 40 mEq/day. Potassium acetate may contain up to 200 mcg/L of aluminum; see **Precautions** and **Maternal/Child**.

DOSE ADJUSTMENTS

Reduce dose in impaired renal function. ■ Lower-end initial doses may be appropriate in the elderly based on potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Each individual dose must be diluted in a larger volume of suitable IV solution and given as an infusion. Check labels for aluminum content; see **Precautions**. Soluble in commonly used IV solutions; see chart on inside back cover. 40 mEq/L is the preferred dilution. 80 mEq/L is the usual maximum concentration and must be administered with caution. In replacement therapy more concentrated doses may be used and must be administered with extreme caution. 40 mEq/100 mL is commonly used and must be controlled by an infusion pump. *Up to 100 mEq/100 mL has been administered through a central line (to avoid phlebitis); must be controlled by an infusion pump.* **Direct injection of any concentrated solution can be instantly fatal.** Avoid layering of potassium by thoroughly agitating the prepared IV solution. Do not add potassium to an IV bottle in the hanging position; remove from hanger to guarantee dispersion throughout solution. In severe hypokalemia, solutions without dextrose are preferred (dextrose might decrease serum potassium level). Use only clear solutions.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

POTASSIUM ACETATE

Additive: Metoclopramide (Reglan).

Y-site: Ciprofloxacin (Cipro IV).

POTASSIUM CHLORIDE

Additive: Amikacin (Amikin), aminophylline, amiodarone (Nexterone), atracurium (Tracrium), calcium gluconate, cefepime (Maxipime), ceftazidime (Fortaz), chloramphenicol (Chloromycetin), ciprofloxacin (Cipro IV), clindamycin (Cleocin), cytarabine (ARA-C), dimenhydrinate, dobutamine, dopamine, enalaprilat (Vasotec IV), erythromycin (Erythrocin), fluconazole (Diflucan), foscarnet (Foscavir), fosphenytoin (Cerebyx), furosemide (Lasix), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), isoproterenol (Isuprel), lidocaine, magnesium sulfate, methyl dopate, metoclopramide (Reglan), mitoxantrone (Novantrone), nafcillin (Nallpen), nicardipine (Cardene

IV), norepinephrine (Levophed), oxacillin (Bactocill), penicillin G potassium, penicillin G sodium, phenylephrine (Neo-Synephrine), ranitidine (Zantac), sodium bicarbonate, vancomycin, verapamil.

Y-site: Acyclovir (Zovirax), aldesleukin (Proleukin), allopurinol (Aloprim), amifostine (Ethyol), aminophylline, amiodarone (Nexterone), ampicillin, anidulafungin (Eraxis), atropine, aztreonam (Azactam), bivalirudin (Angiomax), calcium gluconate, caspofungin (Cancidas), ceftaroline (Teflaro), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cladribine (Leustatin), dexamethasone (Decadron), dexmedetomidine (Precedex), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), droperidol (Inapsine), edrophonium (Enlon), enalaprilat (Vasotec IV), epinephrine (Adrenalin), ertapenem (Invanz), esmolol (Brevibloc), estrogens, conjugated (Premarin), ethacrynic acid (Edecrin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), filgrastim (Neupogen), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gallium nitrate (Ganite), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hetastarch in electrolytes (Hexend), hydralazine, 6% hydroxyethyl starch (Voluven), idarubicin (Idamycin), indomethacin (Indocin IV), isoproterenol (Isuprel), labetalol, levofloxacin (Levaquin), lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), methyprednisolone (Solu-Medrol), micalofungin (Mycamine), midazolam (Versed), milrinone (Primacor), morphine, neostigmine, nicardipine (Cardene IV), nitroprusside sodium, norepinephrine (Levophed), ondansetron (Zofran), oxacillin (Bactocill), oxaliplatin (Eloxatin), oxytocin (Pitocin), paclitaxel (Taxol), palonosetron (Aloxi), pantoprazole (Protonix IV), pemetrexed (Alimta), penicillin G potassium, pentazocine (Talwin), phytonadione (vitamin K₁), piperacillin/tazobactam (Zosyn), procainamide (Pronestyl), prochlorperazine (Compazine), promethazine (Phenergan), propofol (Diprivan), propranolol, quinupristin/dalfopristin (Synercid in KCl 40 mEq/L), remifentanyl (Ultiva), sargramostim (Leukine), sodium bicarbonate, succinylcholine, tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepa, tigecycline (Tygacil), tirofiban (Aggrastat), vinorelbine (Navelbine), warfarin (Coumadin), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A maximum of 10 mEq/hr of potassium chloride in any given amount of infusion fluid should not be exceeded. With serious potassium depletion (under 2 mEq/L serum), 20 to 40 mEq/hr has been given with extreme caution. Use of an infusion pump is recommended in all situations and required with any dose exceeding 60 mEq/24 hr. Too-rapid infusion of hypertonic solutions may cause local pain and, rarely, vein irritation. Adjust rate of administration according to patient tolerance.

Pediatric rate: 0.5 to 1 mEq/kg/hr. Do not exceed 10 mEq/hr.

ACTIONS

Potassium: Principal cation of intracellular fluid. Important for maintenance of body fluid composition and electrolyte balance. Participates in carbohydrate utilization and protein synthesis. Critical in the regulation of nerve conduction and muscle contraction, particularly in the heart. The normal serum potassium range is 3.5 to 5 mEq/L. The kidney normally regulates potassium balance but does not conserve potassium balance as well or as promptly as it conserves sodium. Excreted in urine.

Chloride: The major extracellular anion. Closely follows the metabolism of sodium. Changes in the acid-base balance of the body are reflected by the changes in chloride concentration.

Acetate: An alternate source of bicarbonate by metabolic conversion in the liver.

INDICATIONS AND USES

Prophylaxis or treatment of potassium deficiency (e.g., hypokalemia due to diuretic therapy, adjunct to treatment of digoxin toxicity, low dietary potassium intake, vomiting and diarrhea, diabetic acidosis, metabolic alkalosis, corticosteroid therapy, increased re-

nal excretion resulting from acidosis, hemodialysis). ■ Utilized when oral replacement therapy is not feasible.

CONTRAINDICATIONS

Any disease or condition in which high potassium levels may occur through potassium retention or other processes (e.g., acute dehydration, adrenocortical insufficiency [untreated Addison's disease]), *adynamica episodica hereditaria* [periodic loss of strength or weakness], anuria, azotemia, crush syndrome, heat cramps, hyperkalemia from any cause, oliguria, patients taking digoxin with severe or complete heart block, postoperative oliguria (early [except during GI drainage]), renal failure, severe hemolytic reactions.

PRECAUTIONS

Impaired renal function or adrenal insufficiency can cause potassium intoxication, which can develop rapidly and without symptoms. ■ Loss of chloride usually accompanies potassium depletion and may cause hypochloremic alkalosis. Treat cause of potassium depletion in addition to giving potassium. ■ Potassium phosphate is preferred for specific intracellular deficiency not caused by alkalosis, since phosphate is the usual ion attached to potassium in the body. Not used in the presence of kidney failure. ■ Alkalyzing potassiums (e.g., acetate, citrate) are preferred for potassium-deficient patients with renal tubular acidosis. Metabolic acidosis and hyperchloremia are most likely present. ■ Use potassium acetate with caution in patients with metabolic or respiratory alkalosis and in patients with severe hepatic insufficiency. ■ Administration of IV solutions can cause fluid and/or solute overload, resulting in dilution of serum electrolyte concentrations, overhydration, congested states, or pulmonary edema. The risk of dilutional states is inversely proportional to the electrolyte concentration (increased fluids may dilute electrolyte concentration). The risk of solute overload causing congested states with peripheral and pulmonary edema is directly proportional to the electrolyte concentration (higher electrolytes pull in fluid, leading to fluid overload). ■ Use solutions containing potassium with caution in patients with cardiac disease, particularly in the presence of renal disease. Cardiac monitoring is recommended. ■ Some solutions of potassium may contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation.

Monitor: Monitor changes in fluid balance, electrolyte concentration, and acid-base balance (e.g., serum potassium, sodium, chloride, bicarbonate, urinary output, pH). Only extracellular potassium can be measured; intracellular potassium equals 98% of total body potassium. Entire clinical picture must be considered. ■ Potassium replacement should be monitored whenever possible by continuous or serial ECG, especially in patients taking digoxin. Serum potassium levels are not necessarily dependable indicators of tissue potassium levels. ■ Continuous cardiac monitoring is preferable for infusion of over 10 mEq of potassium in 1 hour. ■ Confirm absolute patency of vein. Extravasation will cause necrosis. Local pain and phlebitis may occur with concentrations greater than 40 mEq/L. ■ See [Drug/Lab Interactions](#).

Patient Education: Report burning or stinging at IV site promptly.

Maternal/Child: Category C: effect unknown; use caution and only if clearly needed in pregnancy and breast-feeding. ■ Safety and effectiveness for use of KCl in pediatric patients not established. However, use for treatment of potassium deficiency when oral therapy is not feasible is referenced in medical literature. Safety and effectiveness of potassium acetate for use in pediatric patients has been established.

Elderly: See [Dose Adjustments](#). Monitoring of renal function suggested. ■ Increased risk of hyperkalemia.

DRUG/LAB INTERACTIONS

Potentiated by **angiotensin-converting enzyme inhibitors** (e.g., captopril [Capoten], enalapril [Vasotec], lisinopril [Zestril]) and **angiotensin receptor blockers** (e.g., losartan [Cozaar], valsartan [Diovan]); risk of hyperkalemia increased. ■ Digitalis intoxication may occur with hypokalemia. Use caution if discontinuing potassium after stabilization in patients taking **digoxin**. ■ **Potassium-sparing diuretics** (e.g., spironolactone [Aldactone], triamterene [Dyrenium], amiloride [Midamor], and a component of Dyazide and Maxzide) may cause hyperkalemia.

SIDE EFFECTS

Abdominal pain, diarrhea, nausea, and vomiting are common side effects of potassium administration and may progress to potassium intoxication. Extravasation, fever, hyperkalemia, hypervolemia, infection or pain at the site of injection, phlebitis, or venous thrombosis may occur.

Potassium intoxication: Areflexia (absence of reflexes), cardiac arrest, cardiac arrhythmias (e.g., bradycardia, ventricular fibrillation), ECG abnormalities (including increased amplitude of T wave, decreased amplitude of R wave, below-baseline depression of S wave, disappearing P wave, PR prolongation), heart block, hypotension, mental confusion, muscular or respiratory paralysis, paresthesias of the extremities, weakness. Progression of side effects may cause death.

Potassium deficit: Disruption of neuromuscular function, intestinal ileus, and dilatation.

ANTIDOTE

For any side effect, discontinue the drug and notify the physician. Death may result from potassium levels of 8 mEq/L. For severe hyperkalemia (over 6.5 mEq/L plasma), use IV sodium bicarbonate 40 to 160 mEq over 5 minutes to correct acidosis. Repeat in 10 to 15 minutes if ECG still abnormal. Initially, one ampule of 50% dextrose may be given into a large vein. Follow with IV dextrose, 10% to 25%, containing 10 units of regular insulin per 20 Gm of dextrose and infuse at 300 to 500 mL over 1 hour. 150 mL of 1/6 M sodium lactate is rarely used as a substitute. Eliminate potassium-containing foods and medicines. Monitor ECG continuously. If P waves are absent, give calcium gluconate or chloride 0.5 to 1 Gm over 2 minutes (exceeds usual rate of administration). Do not use if patient receiving digoxin. All of these measures cause a shift of potassium into the cells and may be used simultaneously. Sodium polystyrene sulfonate (Kayexalate) orally or as retention enemas is used to actually remove potassium from the body. Hemodialysis or peritoneal dialysis may be useful. Use caution in the digitalized patient; too-rapid removal of potassium may cause digoxin toxicity. Resuscitate as necessary. For extravasation, apply warm, moist compresses.

PRALATREXATE

(pral-a-TREX-ate)

**Antineoplastic
(Antifolate)****Folotyn****pH 7.5 to 8.5****USUAL DOSE**

Premedication: 10 days before starting pralatrexate, begin folic acid 1 to 1.25 mg PO daily. Continue daily throughout the full course of therapy and for 30 days after the last dose of pralatrexate. Administer vitamin B₁₂ (1 mg) IM within the 10 weeks before starting pralatrexate and every 8 to 10 weeks thereafter. Subsequent vitamin B₁₂ injections may be given the same day as pralatrexate.

Pralatrexate: 30 mg/M² by IV push over 3 to 5 minutes via the side port of a free-flowing infusion of NS. Administer once weekly for 6 weeks in 7-week cycles until progressive disease or unacceptable toxicity occurs. Management of severe or intolerable side effects may require dose omission or reduction or interruption of therapy; see [Dose Adjustments](#).

DOSE ADJUSTMENTS

Before administering any dose of pralatrexate, mucositis should be equal to or less than Grade 1, platelet count should be equal to or more than 100,000 cells/mm³ for the first dose and equal to or greater than 50,000 cells/mm³ for all subsequent doses, and the absolute neutrophil count (ANC) should be equal to or greater than 1,000 cells/mm³. Doses may be omitted or reduced based on patient tolerance. Do not make up omitted doses at the end of the cycle, and do not re-escalate once a dose reduction occurs for toxicity. See the following charts for dose modifications based on patient symptoms.

Guidelines for Pralatrexate Dose Modifications for Mucositis		
Mucositis Grade* on Day of Treatment	Action	Dose on Recovery to ≤ Grade 1
Grade 2	Omit dose	Continue prior dose
Grade 2 recurrence	Omit dose	20 mg/M ²
Grade 3	Omit dose	20 mg/M ²
Grade 4	Stop therapy	

*Per National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE), Version 3.

Guidelines for Pralatrexate Dose Modifications for Hematologic Toxicities			
Blood Count on Day of Treatment	Duration of Toxicity	Action	Dose on Restart
Platelets <50,000/mm ³	1 week	Omit dose	Continue prior dose
	2 weeks	Omit dose	20 mg/M ²
	3 weeks	Stop therapy	
ANC 500 to 1,000/mm ³ and no fever	1 week	Omit dose	Continue prior dose
	1 week	Omit dose, give G-CSF or GM-CSF support	Continue prior dose with G-CSF or GM-CSF support
		2 weeks or recurrence	Omit dose, give G-CSF or GM-CSF support
ANC 500 to 1,000/mm ³ with fever or ANC <500/mm ³	3 weeks or 2nd recurrence	Stop therapy	

Continued

Guidelines for Pralatrexate Dose Modifications for All Other Treatment-Related Toxicities		
Toxicity Grade* on Day of Treatment	Action	Dose Upon Recovery to \leq Grade 2
Grade 3	Omit dose	20 mg/M ²
Grade 4	Stop therapy	

*Per National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE), Version 3.

DILUTION

Specific techniques for handling required; see *Precautions*. A clear yellow solution. **Do Not Dilute.** Aseptically withdraw the calculated dose directly into a syringe for immediate use. Available in vials containing 20 mg or 40 mg. Concentration of both is 20 mg/mL.

Filters: Specific information not available.

Storage: Refrigerate vials at 2° to 8° C (36° to 46° F) in original carton to protect from light until use. Unopened vial(s) are stable in original carton at RT for up to 72 hours. Discard if left at RT for more than 72 hours.

COMPATIBILITY

Manufacturer recommends administration via the side port of a free-flowing infusion of NS.

RATE OF ADMINISTRATION

A single dose by IV push over 3 to 5 minutes via the side port of a free-flowing infusion of NS.

ACTIONS

A folate analog metabolic inhibitor. It interferes with the growth of and leads to the destruction of cancer cells. It competitively inhibits dihydrofolate reductase and folypolylglutamyl synthetase. This inhibition results in the depletion of thymidine and other biologic molecules. May also affect healthy cells. Approximately 67% bound to plasma proteins. Half-life is 12 to 18 hours. Some drug excreted unchanged in urine (approximately 31%).

INDICATIONS AND USES

Treatment of patients with relapsed or refractory peripheral T-cell lymphoma (PTCL).

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Follow guidelines for handling cytotoxic agents; see Appendix A, p. 1251. ■ Administered under the direction of a physician knowledgeable in its use and in a facility with adequate diagnostic and treatment facilities to monitor the patients and respond to any medical emergency. ■ Bone marrow suppression can occur (e.g., anemia, neutropenia, and thrombocytopenia). Dose modification based on ANC and platelet count is required before each dose; see *Dose Adjustments*. ■ May cause mucositis; see *Dose Adjustments*. ■ To potentially reduce treatment-related hematologic toxicity and mucositis, folic acid and vitamin B₁₂ supplementation is required. ■ Severe dermatologic reactions, including skin exfoliation, toxic epidermal necrolysis, and ulceration, have been reported. May increase in severity with continued treatment, may involve skin and subcutaneous sites of known lymphoma, and may result in death. ■ Tumor lysis syndrome has been reported. ■ Has not been studied in patients with moderate to severe renal impairment. May be at greater risk for increased exposure and toxicity; administer with caution. ■ Serious drug reactions, including toxic epidermal necrolysis and mucositis, were reported in patients with ESRD undergoing dialysis. ■ Avoid pralatrexate use in patients with ESRD, including those undergoing dialysis, unless the potential benefit justifies the potential risk. ■ Can cause hepatic toxicity and liver function abnormalities. Persistent liver function test abnormalities may be indicators of liver toxicity. Has not been studied in patients with hepatic impairment, and patients with selected liver test elevations were excluded from clinical trials.

Monitor: Obtain baseline CBC and platelets and serum chemistry tests, including renal and hepatic function. Monitor CBC and platelets and severity of mucositis weekly before each dose. Repeat serum chemistry tests, including renal and hepatic function, before the start of the first and fourth dose of a given cycle. ■ Monitor patients with moderate to severe renal function closely. Adjust dose accordingly; see [Dose Adjustments](#). ■ Monitor patients with elevated liver enzymes closely (e.g., AST, ALT, transaminases). If liver functions test abnormalities are greater than or equal to Grade 3, omit or modify dose; see [Dose Adjustments](#). ■ Observe for S/S of skin reactions (e.g., blisters, peeling and loss of skin, rash, sores); see [Antidote](#). ■ Monitor closely for S/S of tumor lysis syndrome (e.g., flank pain, hematuria, hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure) and treat as appropriate. Allopurinol and alkalinization of urine may be indicated for prevention and/or treatment of hyperuricemia. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Use prophylactic antiemetics to reduce nausea and/or vomiting and increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient.

Patient Education: A patient information guide is available from the manufacturer. ■ Avoid pregnancy; nonhormonal birth control is recommended. ■ Blood counts will be required at regular intervals. ■ Take folic acid and vitamin B₁₂ as prescribed to help reduce side effects. ■ Report soreness in the mouth, redness of mucous membranes, difficulty swallowing, or ulcerations in the mouth. Discuss ways to avoid and/or manage mucositis with a health care professional. ■ Promptly report S/S of infection (e.g., fever), S/S of bleeding (e.g., anemia, bruising), and S/S of tumor lysis syndrome (e.g., flank pain, hematuria). ■ Promptly report S/S of skin reactions (e.g., blisters, peeling and loss of skin, rash, sores). ■ Discuss medications (prescription and non-prescription) with a health care professional; see [Drug/Lab Interactions](#). ■ Avoid vaccination with live virus vaccines. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. Can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: No overall differences in effectiveness or safety based on age. ■ No dose adjustment required in elderly patients with normal renal function; however, dose selection should be cautious. Consider age-related organ impairment (e.g., bone marrow reserve, renal, hepatic) and monitor closely.

DRUG/LAB INTERACTIONS

Coadministration with **probenecid** (an inhibitor of multiple transporter systems, including the multidrug resistance–associated protein 2 [MRP2] efflux transporter) resulted in delayed renal clearance and an increase in pralatrexate exposure. ■ Concomitant administration of drugs that are substantially cleared by the renal system (e.g., **NSAIDs** [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)] and **sulfamethoxazole/trimethoprim**) may result in delayed clearance of pralatrexate. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Not a substrate, inhibitor, or inducer of CYP₄₅₀ isoenzymes and has a low potential for drug-drug interactions with drugs metabolized by these isoenzymes.

SIDE EFFECTS

Most common side effects are fatigue, mucositis, nausea, and thrombocytopenia. Most common serious side effects are dehydration, dyspnea, febrile neutropenia, fever, mucositis (stomatitis or mucosal inflammation of the GI and GU tracts), sepsis, and thrombocytopenia. Mucositis and thrombocytopenia were the most common reasons for discontinuing treatment. Other reported side effects include abdominal pain, abnormal liver function tests (e.g., AST, ALT, transaminases), anemia, anorexia, asthenia, back pain, constipation, cough, diarrhea, edema, epistaxis, hypokalemia, leukopenia, neutropenia,

night sweats, pain in extremities, pharyngolaryngeal pain, pruritus, rash, tachycardia, tumor lysis syndrome, upper respiratory infection, vomiting.

Post-Marketing: Dermatologic reactions (e.g., skin exfoliation, toxic epidermal necrolysis, and ulceration).

ANTIDOTE

Treatment of most side effects will be supportive and may require dose adjustment or discontinuation. Discontinue pralatrexate if toxicity from side effects occurs (e.g., dermatologic reactions, Grade 4 treatment-related toxicities [e.g., mucositis], hematologic toxicities [persisting for 3 weeks], uncontrolled tumor lysis syndrome) and notify the physician; see [Dose Adjustments](#). Administration of blood products and/or blood modifiers (e.g., darbepoetin [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Treat hypersensitivity reactions with epinephrine, antihistamines, and corticosteroids as needed. In addition to initiating supportive measures, leucovorin calcium (citrovorum factor, folinic acid) may be given PO, IM, or IV promptly to counteract inadvertent overdose. Resuscitate as indicated.

PRALIDOXIME CHLORIDE

(prah-lih-DOX-eem K-LOR-eyed)

Antidote

(anticholinesterase antagonist)

Protopam Chloride

pH 3.5 to 4.5

USUAL DOSE

In poisonings, correct any existing hypoxemia, then administer atropine as directed in the following paragraphs. After the effects of atropine have become apparent, pralidoxime may be administered. See [Contraindications](#). If IV administration is not possible, may be given IM or SC.

ORGANOPHOSPHATE PESTICIDE POISONING

Atropine: Must be given before pralidoxime and as soon as possible after adequate ventilation has been established (hypoxemia corrected). Ventricular fibrillation can occur if oxygenation is inadequate. Give atropine, 2 to 4 mg IV, after cyanosis disappears, then give initial dose of pralidoxime. Repeat atropine every 10 minutes until atropine toxicity (delirium, dilated pupils, dry mouth, muscle twitching, pulse 140 beats/min). Maintain atropinization for at least 48 hours.

Pralidoxime: 1 to 2 Gm initially after hypoxemia has been corrected, initial dose of atropine has been given, and effects of atropine are apparent (secretions are inhibited). Repeat in 1 hour if indicated. If muscle weakness continues, additional doses can be given with extreme caution, usually every 10 to 12 hours (has been given more frequently). Evidence suggests that a loading dose followed by a continuous infusion may maintain therapeutic levels longer than the traditional short intermittent infusion therapy; see prescribing information for studied regimens.

ORGANOPHOSPHATE CHEMICAL POISONING

Usually administered IM by an autoinjector system (survival technology). Atropine must be given first. After the effects of atropine are apparent (e.g., dry mouth), give pralidoxime 600 mg. Repeat both drugs at 15-minute intervals times 2 if indicated. If muscle weakness persists, seek medical help; IV doses may be required.

ANTICHOLINESTERASE OVERDOSE (E.G., NEOSTIGMINE, PYRIDOSTIGMINE)

1 to 2 Gm followed by 250 mg every 5 minutes.

PEDIATRIC DOSE

See [Maternal/Child](#).

Organophosphate pesticide/chemical poisoning: Give **atropine** 0.05 to 0.1 mg/kg. See **Usual Dose** for order of administration and specific criteria.

Pralidoxime—Loading dose followed by a continuous infusion: Administer a loading dose of 20 to 50 mg/kg (not to exceed 2,000 mg) over 15 to 30 minutes. Follow with a continuous infusion of 10 to 20 mg/kg/hr.

Pralidoxime—Intermittent Infusion: Administer 20 to 50 mg/kg (not to exceed 2,000 mg) over 15 to 30 minutes. May repeat dose in 1 hour if muscle weakness has not been relieved. Repeat every 10 to 12 hours as needed.

DOSE ADJUSTMENTS

Reduce dose in renal impairment. ■ Lower-end initial doses may be indicated in the elderly. Dose selection should be cautious in the elderly. Consider age-related organ impairment and concomitant disease or drug therapy.

DILUTION

Each 1 Gm of sterile powder is diluted with 20 mL of SWFI. Should be further diluted in 100 mL of NS and given as an IV infusion. If reduced fluids are indicated (e.g., pulmonary edema is present) or rapid administration is required, a 5% solution (1 Gm in 20 mL SWFI) given over no less than 5 minutes may be used.

Storage: Store at CRT. Use promptly after reconstitution; discard remaining solution.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Too-rapid injection may cause laryngospasm, muscle rigidity, or tachycardia. Do not exceed a rate of 200 mg/min.

IV injection diluted in 20 mL SWFI: Each 1 Gm or fraction thereof over no less than 5 minutes. Used only if pulmonary edema present or infusion not practical.

Infusion (diluted in 100 mL NS, preferred): A single dose over 15 to 30 minutes.

ACTIONS

An anticholinesterase antagonist that reactivates cholinesterase inhibited by phosphate esters. Slows the conversion of phosphorylated cholinesterase to a nonreactivable form and detoxifies certain organophosphates by direct chemical reaction. Its most critical effect is in relieving paralysis of the respiratory muscles. Because pralidoxime is less effective in relieving depression of the respiratory center, atropine is always required concomitantly to block the effect of accumulated acetylcholine at this site. Rapidly dispersed throughout body fluids. Onset of action is within 10 to 40 minutes; half-life is short (about 1.2 hours), requiring repeated doses as more poison is absorbed. Partially metabolized by the liver. Most of a single dose is excreted within 6 hours in the urine.

INDICATIONS AND USES

Principal indications for the use of pralidoxime are muscle weakness and respiratory depression. In severe poisoning, respiratory depression may be due to muscle weakness. ■ An antidote (treatment adjunct) in organophosphate pesticide or chemical poisoning. Primarily useful for many phosphate ester insecticide poisons with anticholinesterase activity (e.g., diazinon, malathion) or chemicals with anticholinesterase activity (e.g., nerve gas). ■ Control of overdose of anticholinesterase drugs used to treat myasthenia gravis. Confirm diagnosis with edrophonium (Tensilon).

CONTRAINDICATIONS

No known absolute contraindications to use of pralidoxime. Relative contraindications include known hypersensitivity to pralidoxime or any component of the product. ■ See **Precautions**.

PRECAUTIONS

In poisoning: Most effective if administered immediately after poisoning. May be ineffective if more than 36 hours has passed since exposure; some response may be obtained in severe poisoning; see **Contraindications**. ■ Not recommended in carbamate poisoning (increases toxicity of Sevin [carbamate insecticide]). ■ Not effective for treatment of poisoning with phosphorus, inorganic phosphates, or organophosphates not having anticholinesterase activity. ■ Rapid IV administration may lead to temporary worsening of

cholinergic manifestations. Continuous or intermittent infusion is preferred; see [Rate of Administration](#). ■ Caregivers must protect themselves from contamination. Wear gowns and gloves. ■ Remove contaminated clothing and cleanse contaminated skin surfaces, hair, and fingernails with water, sodium bicarbonate solution, or alcohol. ■ Gently flush eyes with water for at least 15 minutes. ■ Diazepam (Valium) may be required to stop convulsions. ■ Use caution in myasthenia gravis; may cause a myasthenic crisis.

Monitor: Before any medication is given, establish and maintain an adequate airway and controlled respiration as indicated. Suctioning of secretions and oxygen usually required. Cardiovascular support, correction of metabolic abnormalities, and seizure control may be necessary. ■ Draw blood samples for baseline RBC acetylcholinesterase and pseudo-cholinesterase concentrations. ■ In suspected poisoning, initiate treatment without waiting for lab confirmation of diagnosis. Combined with a history of possible poisoning, a RBC cholinesterase concentration less than 50% of normal is indicative of organophosphate ester poisoning. ■ Gastric lavage and activated charcoal are indicated if organophosphates are ingested; most effective if started within 30 minutes of ingestion. Avoid emesis as patient may lose consciousness and aspirate. ■ Monitor vital signs and ECG continuously. ■ Maintain adequate urine output. ■ In cases of ingested poison, toxicity may recur as poison is absorbed from bowel; monitor for 48 to 72 hours. ■ In all cases of organophosphate poisoning, patient should be observed for at least 48 to 72 hours. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: effects not known; use only if clearly needed. ■ Safety for breast-feeding not established. ■ Efficacy in pediatric patients is extrapolated from the adult population and is supported by nonclinical studies, pharmacokinetic studies in adults, and experience in pediatric patients. Muscle fasciculations, apnea, and convulsions have been reported; see [Rate of Administration](#).

Elderly: Response similar to younger adults. ■ Dose selection should be cautious; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Used in combination with **atropine**. Signs of atropinization (e.g., dryness of mouth and nose, flushing, mydriasis, tachycardia) may occur earlier than when atropine is used alone. ■ **CNS depressants** (e.g., anticonvulsants, antihistamines, muscle relaxants, narcotics, reserpine compounds, phenothiazines) and xanthines (e.g., aminophylline, caffeine) will intensify the effects of organophosphate poisoning and defeat effectiveness of treatment. ■ **Barbiturates** are potentiated by anticholinesterases; use with caution in treatment of seizures. ■ **Succinylcholine** may cause prolonged respiratory paralysis. ■ **Thiamine** delays excretion of pralidoxime.

SIDE EFFECTS

Blurred vision, diplopia, dizziness, drowsiness, headache, hyperventilation, impaired accommodation, increased diastolic and systolic BP, laryngospasm, muscle rigidity, muscular weakness, nausea, pharyngeal pain, tachycardia, transient elevated AST, ALT, and CPK. Excitement and manic behavior may occur (atropinization) if pralidoxime is delayed after atropine has been given.

ANTIDOTE

Has not been needed. Patient should be observed for atropine intoxication. Artificial ventilation and other supportive therapy should be administered as needed.

PROCAINAMIDE HYDROCHLORIDE

Antiarrhythmic

(proh-KAYN-ah-myd hy-droh-KLOR-eyed)

Pronestyl

pH 4 to 6

USUAL DOSE

Loading dose: 0.2 to 1 Gm (100 mg/mL). 100 mg every 5 minutes or 20 mg every 1 minute may be given as an infusion until arrhythmia is suppressed or 500 mg is administered. Wait 10 minutes to allow adequate distribution, then resume dosing until arrhythmia is suppressed, maximum initial dose of 1 Gm is reached, or side effects appear (e.g., hypotension, QRS complex widening by 50%). Dose cautiously to avoid a hypotensive response. AHA recommends 20 mg/min as an infusion to a maximum total dose of 17 mg/kg. **Maintenance dose:** After arrhythmia is suppressed or maximum dose is reached, follow initial dose with an infusion of 1 to 4 mg/min (may require up to 6 mg/min). Titrate to control arrhythmias. Maintain with oral procainamide as soon as possible but at least 4 hours after last IV dose.

Recurrent VT/VF: AHA recommends 20 mg/min as an infusion. Up to 50 mg/min may be used in urgent situations. Maximum total dose is 17 mg/kg.

PEDIATRIC DOSE

See [Maternal/Child](#); pediatric doses are unlabeled.

2 to 5 mg/kg of body weight. Do not exceed 100 mg/dose. Repeat as indicated every 10 to 30 minutes. Maximum dose in 24 hours is 30 mg/kg or 2 Gm. An alternate dose regimen is 2 to 6 mg/kg as a **loading dose** given over 5 minutes; follow with a **maintenance infusion** of 20 to 80 mcg/kg/min to control arrhythmias.

Supraventricular tachycardia (SVT), atrial flutter, VT with pulse: AHA recommends 15 mg/kg over 30 to 60 minutes.

DOSE ADJUSTMENTS

Maintenance dose may be reduced in impaired or reduced renal function and in individuals over 50 years of age. ■ See [Drug/Lab Interactions](#).

DILUTION

IV injection: Dilute each 100 mg with 5 to 10 mL of D5W.

Infusion: Add 1 Gm of procainamide to 50, 250, or 500 mL of D5W. Yields 20 mg/mL, 4 mg/mL, or 2 mg/mL respectively. 20 mg/mL should only be used as a loading dose. 2 and 4 mg/mL dilutions may be used for loading or maintenance based on fluid restrictions. Solution should be clear; may be light yellow. Discard if darker than light amber.

Pediatric infusion: Loading dose: Add a calculated loading dose (2 to 5 mg/kg) to a minimum of 10 mL D5W for each 100 mg or fraction thereof. More diluent may be used based on size of child and fluid restriction.

Maintenance infusion: See [chart under Rate of Administration \(Pediatric\)](#).

Storage: Photosensitive; protect from light. Store at CRT.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: **Consider individualized rate adjustments necessary to achieve desired effects.** Amiodarone (Nexterone), atracurium (Tracrium), dobutamine, flumazenil (Romazicon), lidocaine, verapamil.

Y-site: Amiodarone (Nexterone), bivalirudin (Angiomax), cisatracurium (Nimbex), dexmedetomidine (Precedex), diltiazem (Cardizem), famotidine (Pepcid IV), fenoldopam (Corlopam), heparin, hetastarch in electrolytes (Hexend), hydrocortisone sodium succinate (Solu-Cortef), metoprolol (Lopressor), nitroprusside sodium, potassium chloride (KCl), ranitidine (Zantac), remifentanyl (Ultiva), vasopressin.

RATE OF ADMINISTRATION

20 mg or fraction thereof over 1 minute. Use an infusion pump or a microdrip (60 gtt/mL) for infusion to deliver a constant rate. Up to 50 mg may be given by IV injection over 1 minute with extreme caution. After stabilized with loading dose, follow with a maintenance infusion at 1 to 6 mg/min.

Procainamide Infusion Rate (Adult)						
Desired Dose	1 Gm in 500 mL D5W 2 mg/mL			1 Gm in 250 mL D5W 4 mg/mL		
mg/min	mg/hr	mL/min	mL/hr	mg/hr	mL/min	mL/hr
1 mg/min	60	0.5	30	60	0.25	15
2 mg/min	120	1	60	120	0.5	30
3 mg/min	180	1.5	90	180	0.75	45
4 mg/min	240	2	120	240	1	60
5 mg/min	300	2.5	150	300	1.25	75
6 mg/min	360	3	180	360	1.5	90

Procainamide Infusion Rate (Pediatric)		
Desired Dose	200 mg in 500 mL D5W 400 mcg/mL	200 mg in 125 mL D5W 1,600 mcg/mL
mcg/kg/min	mL/kg/min × kg = mL/min	mL/kg/min × kg = mL/min
20 mcg/kg/min	$0.05 \times \text{wt in kg}$	$0.0125 \times \text{wt in kg}$
30 mcg/kg/min	$0.075 \times \text{wt in kg}$	$0.01875 \times \text{wt in kg}$
40 mcg/kg/min	$0.1 \times \text{wt in kg}$	$0.025 \times \text{wt in kg}$
50 mcg/kg/min	$0.125 \times \text{wt in kg}$	$0.03125 \times \text{wt in kg}$
60 mcg/kg/min	$0.15 \times \text{wt in kg}$	$0.0375 \times \text{wt in kg}$
70 mcg/kg/min	$0.175 \times \text{wt in kg}$	$0.04375 \times \text{wt in kg}$
80 mcg/kg/min	$0.2 \times \text{wt in kg}$	$0.05 \times \text{wt in kg}$

Example: To deliver 30 mcg/kg/min of a 400 mg/mL solution to a child weighing 20 kg, multiply $0.075 \text{ (mL/kg/min)} \times 20 \text{ (wt in kg)} = \text{an infusion rate of } 1.5 \text{ mL/min}$.

ACTIONS

A procaine derivative. Exerts a depressing antiarrhythmic action on the heart, slowing the rate, slowing conduction, reducing myocardial irritability, and prolonging the refractory period. Decreases membrane permeability of the cell and prevents loss of sodium and potassium ions. Onset of action should occur in 2 to 3 minutes. Half-life is 3 to 4 hours. Crosses the placental barrier. Plasma levels decrease slowly; partially metabolized to the active metabolite NAPA; remaining drug excreted in the urine.

INDICATIONS AND USES

Suppress PVCs and recurrent ventricular tachycardia when lidocaine is contraindicated or has not suppressed ventricular arrhythmias. ■ Treat wide-complex tachycardias difficult to distinguish from VT (lidocaine preferred). ■ Rarely used in atrial fibrillation, paroxysmal atrial tachycardia, or arrhythmias caused by anesthesia. Safer drugs (e.g., verapamil, diltiazem) are readily available.

CONTRAINDICATIONS

Complete atrioventricular heart block, second- and third-degree AV block unless an electrical pacemaker is operative, pre-existing QT prolongation, torsades de pointes, known sensitivity to procainamide or any other local anesthetic of the ester type, myasthenia gravis, systemic lupus erythematosus.

PRECAUTIONS

Oral or IM administration is the route of choice; IV route for emergencies only. ■ Use extreme caution in first- or second-degree blocks, ventricular tachycardia after a myocardial infarction, digoxin intoxication, CHF, any structural heart disease, and impaired liver or reduced kidney function. ■ Predigitalize or cardiovert patients with atrial flutter or fibrillation to reduce incidence of sudden increase in ventricular rate as atrial rate is slowed. Use caution if used concurrently with other drugs that prolong QT interval (e.g., amiodarone [Nexterone]). ■ Some clinicians recommend giving a dose the night before surgery and then discontinuing until after surgery. If an arrhythmia occurs, use lidocaine for ventricular arrhythmias and calcium channel blockers (e.g., diltiazem, verapamil) or beta-blockers (e.g., atenolol, propranolol) for supraventricular arrhythmias. Resume dosing after surgery and utilize oral dosing as soon as possible.

Monitor: Monitor the patient's ECG and BP continuously. Keep patient in a supine position. Avoid a hypotensive response. ■ Discontinue IV use when the cardiac arrhythmia is interrupted or when the ventricular rate slows without regular atrioventricular conduction. ■ Small emboli may be dislodged when atrial fibrillation is corrected. ■ Monitor blood levels of procainamide and NAPA (active metabolite) in patients with renal impairment and in any patient receiving a constant infusion over 3 mg/min for more than 24 hours. ■ Monitor CBC, including WBC, differential, and platelets with continued use; fatal blood dyscrasia have occurred with usual doses. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding and in pediatric patients not established. Consider quinidine as an alternate for use during pregnancy.

Elderly: Half-life of parent drug and active metabolite is prolonged; renal excretion reduced about 25% at age 50 and 50% at age 75. ■ Increased risk of hypotension.

DRUG/LAB INTERACTIONS

Potentiates or is potentiated by **neuromuscular blocking antibiotics** (e.g., kanamycin), **anticholinergics** (e.g., atropine), **thiazide diuretics**, **antihypertensive agents**, **muscle relaxants**, **succinylcholine**, **cimetidine** (Tagamet), and **others**. ■ May cause serious arrhythmias (e.g., prolongation of QT interval or other additive effects) with **other antiarrhythmic agents** (e.g., amiodarone [Nexterone], digoxin, disopyramide [Norpace], lidocaine, quinidine). Lower doses of both drugs may be required. ■ Antagonizes **anticholinesterases** (e.g., neostigmine). ■ **Alcohol** may increase hepatic metabolism. ■ May **elevate AST levels**.

SIDE EFFECTS

Anorexia, bleeding, bruising, chills, dizziness, fever, flushing, giddiness, hallucinations, joint swelling or pain, mental confusion, nausea, skin rash, tremor, vomiting, weakness. May indicate onset of more serious side effects.

Major: Blood dyscrasias (e.g., agranulocytosis, bone marrow suppression, hypoplastic anemia, neutropenia, thrombocytopenia); hypotension with a BP drop over 15 mm Hg, lupus erythematosus-like symptoms, PR interval prolongation, QRS complex widening, QT interval prolongation, ventricular asystole, ventricular fibrillation, ventricular tachycardia.

ANTIDOTE

Notify the physician of any side effect. If minor symptoms progress or any major side effect appears, discontinue the drug immediately and notify the physician. Use dopamine or phenylephrine hydrochloride (Neo-Synephrine) to correct hypotension. Treatment of toxicity is symptomatic and supportive. Infusion of 1/6 M sodium lactate injection may reduce cardiotoxic effects. Hemodialysis may be indicated or urinary acidifiers may increase renal clearance. Resuscitate as necessary. Depending on arrhythmia, quinidine or lidocaine is an effective alternate. Consider insertion of a ventricular pacing electrode as a precautionary measure in case serious AV block develops.

PROCHLORPERAZINE EDISYLATE

(proh-klor-PAIR-ah-zeen eh-DIS-ah-layt)

Phenothiazine
Antiemetic
Antipsychotic

Compazine

pH 4.2 to 6.2

USUAL DOSE

A single IV dose should not exceed 10 mg. The maximum daily IV dose should not exceed 40 mg.

Control of severe nausea and vomiting: 2.5 to 10 mg; may be repeated one time in 1 to 2 hours if indicated.

Control of severe nausea and vomiting in adult surgical patients: 5 to 10 mg 15 to 30 minutes before induction of anesthesia or to control symptoms during or after surgery. Repeat once if necessary. Another source suggests 20 mg diluted in 1 L solution (see [Dilution](#)) during and/or after surgery.

Management of nausea and vomiting in emetic-inducing chemotherapy (unlabeled): One source suggests 10 to 20 mg 30 minutes before and 3 hours after treatment. Another source suggests 30 to 40 mg 30 minutes before and 3 hours after treatment. A third source suggests 0.8 mg/kg 30 minutes before and 3 hours after treatment and cites precipitous hypotension with larger doses; but another source suggests 2 mg/kg for highly emetogenic agents (e.g., cisplatin, dacarbazine) and 1 mg/kg for less emetogenic agents. Begin 30 minutes before chemotherapy, repeat every 2 hours for 2 doses, then every 3 hours for 3 doses. Treat extrapyramidal symptoms with diphenhydramine (Benadryl) IM. These doses have not been recommended by the manufacturer and exceed the recommended maximum daily IV dose of 40 mg/24 hr. In addition, recommended doses of newer agents (e.g., ondansetron [Zofran]) may be more effective.

Control of severe vascular and tension headaches (unlabeled): 10 mg given as an injection over 2 minutes. Sometimes given concurrently with dihydroergotamine 1 mg as an infusion over 30 minutes. Another regimen administers 3.5 mg of prochlorperazine over 5 minutes followed by dexamethasone 20 mg over 10 minutes.

PEDIATRIC DOSE

IV route not recommended for pediatric patients; safety has not been established; see [Contraindications](#), [Precautions](#), and [Maternal/Child](#).

DOSE ADJUSTMENTS

Lower-end initial doses and more gradual adjustments may be indicated in the elderly and in debilitated or emaciated patients. ■ See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted or each 5 mg (1 mL) may be diluted with 9 mL of NS to facilitate titration. 1 mL will equal 0.5 mg. Larger amounts of NS may be used. May add doses over 10 mg to 50 mL to 1 liter of commonly used IV solution (e.g., D5W, NS, D5¹/₂NS, Ringer's or LR), and give as an intermittent or prolonged infusion. Handle carefully; may cause contact dermatitis. Slightly yellow color does not affect potency. Discard if markedly discolored.

Storage: Store below 40° C and protect from light and freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends not mixing with other agents in a syringe.

One source suggests the following **compatibilities:**

Additive: Amikacin (Amikin), ascorbic acid, calcium gluconate, dexamethasone (Decadron), dimenhydrinate, erythromycin (Erythrocin), ethacrynic acid (Edecrin), lidocaine, nafcillin (Nallpen), penicillin G potassium, sodium bicarbonate.

Y-site: Calcium gluconate, cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), docetaxel (Taxotere), doxorubicin liposomal (Doxil), fluconazole (Diflucan), granisetron (Kytrel), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), linezolid (Zyvox), melphalan (Alkeran), ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), potassium chloride (KCl), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), teniposide (Vumon), thiotepa, topotecan (Hycamtin), vinorelbine (Navelbine).

RATE OF ADMINISTRATION

IV injection: Each 5 mg or fraction thereof over 1 minute.

Infusion: May be given at ordered rate, or rate may be increased or decreased as symptoms indicate. Use an infusion pump for infusion.

Management of nausea and vomiting associated with emetic-inducing chemotherapy: A single dose over 15 to 20 minutes as an *intermittent IV*.

ACTIONS

A phenothiazine derivative approximately six times more potent than chlorpromazine (Thorazine), with effects on the central, autonomic, and peripheral nervous systems. Has weak anticholinergic effects, moderate sedative effects, and strong extrapyramidal effects. A potent antiemetic, acting both centrally at the chemoreceptor trigger zone and peripherally by blocking the vagus nerve in the GI tract. Onset of action is prompt and lasting. Metabolized in the liver and excreted in urine and feces. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Control of severe nausea and vomiting. ■ Used IM or PO in the treatment of schizophrenia and nonpsychotic anxiety.

Unlabeled uses: Use of higher doses to control nausea and vomiting associated with emetic-inducing chemotherapy. ■ Treatment of severe vascular and tension headaches.

CONTRAINDICATIONS

Pediatric patients under 2 years or 10 kg (22 lb); pediatric patients with conditions that do not have an established dose; comatose or severely depressed states or in the presence of large amounts of CNS depressants (e.g., alcohol, barbiturates, narcotics); hypersensitivity to phenothiazines; breast-feeding and pregnancy, except labor and delivery; do not use in pediatric surgery.

PRECAUTIONS

Use IV only when absolutely necessary. IV not recommended for pediatric patients. ■ Extrapyramidal symptoms caused by prochlorperazine may be confused with undiagnosed disease (e.g., Reye's syndrome, encephalopathy). ■ May mask diagnosis of other conditions including Reye's syndrome, brain tumor, drug intoxication, and intestinal obstruction. ■ May produce ECG changes (e.g., prolonged QT interval, changes in T waves). ■ Use caution in coronary disease, glaucoma, severe hypertension or hypotension, and in patients with bone marrow suppression. ■ Use caution in patients with epilepsy. May lower the seizure threshold. ■ Neuroleptic malignant syndrome, characterized by hyperpyrexia, muscle rigidity, autonomic instability, and altered mental status has been reported with phenothiazine use. ■ Tardive dyskinesia (potentially irreversible involuntary dyskinetic movements) may develop. Use the smallest doses and shortest duration of therapy to minimize risk. ■ Anticholinergic and cardiac effects may be troublesome during anesthesia. For patients receiving phenothiazines, taper and discontinue preoperatively if they will not be continued after surgery. ■ May discolor urine pink to reddish brown. ■ Photosensitivity of skin is possible. ■ May cause paradoxical excitation in pediatric patients and the elderly. ■ Do not re-expose patients who have experienced jaundice, skin reactions, or blood dyscrasias in reaction to a phenothiazine. Cross-sensitivity may occur. ■ May contain sulfites; use caution in patients with allergies.

Monitor: Keep patient in supine position and monitor BP and pulse before administration and between doses. ■ Cough reflex may be suppressed. Monitor closely if nauseated or vomiting to prevent aspiration. ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid use of alcohol or other CNS depressants (e.g., antihistamines, barbiturates). ■ Request assistance for ambulation; may cause dizziness or fainting. ■ Use caution performing tasks that require alertness. ■ May cause skin and eye photosensitivity. Avoid unprotected exposure to sun.

Maternal/Child: Safety for use in pregnancy, breast-feeding, and pediatric patients not established; see [Contraindications](#). ■ Has been used during pregnancy, for intractable nausea and vomiting; physician must decide if benefit outweighs risk. ■ Use near term may cause maternal hypotension and adverse neonatal effects (e.g., extrapyramidal syndrome, hyperreflexia, hyporeflexia, jaundice). ■ Fetuses and infants have a reduced capacity to metabolize and eliminate. ■ Pediatric patients may metabolize antipsychotic agents more rapidly than adults. ■ Incidence of extrapyramidal reactions is relatively high in pediatric patients, especially in the presence of acute illness (e.g., measles, chickenpox, gastroenteritis).

Elderly: See [Dose Adjustments](#) and [Precautions](#). ■ Have a reduced capacity to metabolize and eliminate and may have increased sensitivity to postural hypotension, anticholinergic and sedative effects. ■ Increased risk of extrapyramidal side effects (e.g., tardive dyskinesia, parkinsonism).

DRUG/LAB INTERACTIONS

Use with **epinephrine** not recommended; may cause precipitous hypotension. ■ Increased CNS respiratory depression and hypotensive effects with **narcotics, alcohol, anesthetics, barbiturates**; reduced doses of these agents usually indicated. ■ Additive effects with **MAO inhibitors** (e.g., selegiline [Eldepryl]), **anticholinergics, antihistamines, antihypertensives, hypnotics, muscle relaxants, phenytoin** (Dilantin), **propranolol, rauwolfia alkaloids, and thiazide diuretics**; dose adjustment may be necessary. ■ Risk of cardiotoxicity increased with **pimozide** (Orap) and **sparfloxacin** (Zagam); concurrent use not recommended. ■ Risk of additive QT interval prolongation, cardiac depressant effects, and cardiac arrhythmias increased with **amiodarone** (Nexterone), **disopyramide** (Norpace), **erythromycin, probucol** (Lorelco), **procainamide** (Pronestyl), and **quinidine**. ■ Concurrent use with **antidepressants** (e.g., fluoxetine [Prozac], paroxetine [Paxil]), **tricyclic antidepressants** (e.g., amitriptyline [Elavil], imipramine [Tofranil]), or **MAO inhibitors** may increase effects of both drugs; risk of neuroleptic malignant syndrome may be increased. ■ Encephalopathic syndrome has been reported with concurrent use of **lithium**; monitor for S/S of neurologic toxicity. ■ May diminish effects of **oral anticoagulants**. ■ May lower seizure threshold. Dose adjustment of **anticonvulsants** may be necessary. ■ Use with **metrizamide** (Amipaque) may lower seizure threshold; discontinue prochlorperazine 48 hours before **myelography**, and do not resume for 24 hours after test is completed. ■ Use caution during anesthesia with **barbiturates** (e.g., methohexital, thiopental); may increase frequency and severity of hypotension and neuromuscular excitation. ■ Capable of innumerable other interactions.

SIDE EFFECTS

Usually transient if drug discontinued but may require treatment if severe: anaphylaxis, blurring of vision, cardiac arrest, dermatitis, dizziness, drowsiness, dryness of mouth, dysphagia, elevated BP, extrapyramidal symptoms (e.g., abnormal positioning, extreme restlessness, pseudoparkinsonism, weakness of extremities), excitement, fever without etiology, hematologic toxicities (e.g., agranulocytosis, aplastic anemia, leukopenia, thrombocytopenia), hypersensitivity reactions, hypotension, photosensitivity, slurred speech, spastic movements (especially about the face), tachycardia, tardive dyskinesia, tightness of the throat, tongue discoloration, tongue protrusion, and many others. Overdose can cause convulsions, hallucinations, and death.

ANTIDOTE

Discontinue the drug at onset of any side effect and notify the physician. Discontinue prochlorperazine and all drugs not essential to concurrent therapy immediately if NMS occurs. Will require intensive symptomatic treatment, medical monitoring, and management of concomitant medical problems. Counteract hypotension with IV fluids and norepinephrine (Levophed) or phenylephrine (Neo-Synephrine) and extrapyramidal symptoms with benztropine mesylate (Cogentin), or diphenhydramine (Benadryl). Maintain a clear airway and adequate hydration. **Epinephrine is contraindicated for hypotension.** Further hypotension will occur. Use diazepam (Valium) for convulsions or hyperactivity. Follow with phenytoin. Phenytoin may be helpful in ventricular arrhythmias. In treating respiratory depression and unconsciousness, avoid analeptics such as doxapram (Dopram); they may cause convulsions. Not removed by dialysis. Resuscitate as necessary.

PROMETHAZINE HYDROCHLORIDE **BBW**

(proh-METH-ah-zeen hy-droh-KLOR-eyed)

Phenothiazine
Antiemetic
Sedative-hypnotic**Phenergan**

pH 4 to 5.5

USUAL DOSE

A vesicant; see Dilution, Rate of Administration, Contraindications, Precautions, Monitor, and Antidote. Deep IM injection is the preferred route of administration.

All uses: The Institute for Safe Medication Practices (ISMP) recommends 6.25 to 12.5 mg as a starting IV dose and suggests considering the use of alternate drugs (e.g., 5-HT₃ receptor antagonists [e.g., dolasetron (Anzemet), granisetron (Kytril), ondansetron (Zofran)]).

Nausea and vomiting: 12.5 to 25 mg every 4 to 6 hours as needed.

Allergic conditions: 25 mg. May repeat in 2 hours if necessary. Change to oral therapy as soon as possible.

Sedation, nighttime: 25 to 50 mg.

Sedation, perioperative: 25 to 50 mg. May combine with a reduced dose of narcotic analgesic and an anticholinergic drug (e.g., atropine).

Sedation, labor and delivery: 50 mg during early stage of labor. When labor fully established, may administer 25 to 75 mg with a reduced dose of a narcotic analgesic. May repeat every 4 hours to a maximum dose of 100 mg in a 24-hour period.

PEDIATRIC DOSE

IV use is rare and is limited to pediatric patients 2 years of age or older; see [Contraindications](#) and [Maternal/Child](#). Adjust dose to the age, weight, and severity of condition. Use the minimum effective dose and avoid concomitant administration with other drugs with respiratory depressant effects. Do not exceed one half of adult dose. One source suggests a maximum dose of 25 mg. If given IV, administer separately from other medications (e.g., appropriately reduced doses of barbiturates or narcotics, and an appropriate dose of an anticholinergic agent).

Adjunct to premedication: 1.1 mg/kg/dose.

Nausea and vomiting (unlabeled): 0.25 to 1 mg/kg/dose every 6 hours as needed.

DOSE ADJUSTMENTS

Reduced dose may be indicated in the elderly. See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted or may dilute with NS. Concentration should never exceed 25 mg/mL. 1 mL (25 to 50 mg) diluted with 9 mL of NS equals 2.5 to 5 mg/mL. The ISMP recommends further dilution with an additional 10 to 20 mL of NS or in a 50-mL

minibag of NS. Slightly yellow color does not alter potency. Discard if greatly discolored. Administer through Y-tube or three-way stopcock of a free-flowing IV.

Storage: Store at CRT. Protect from light.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

May form a precipitate with heparin; flush heparinized infusion sets with SWFI or NS before and after administration.

One source suggests the following **compatibilities:**

Additive: Amikacin (Amikin), ascorbic acid, hydromorphone (Dilaudid), penicillin G potassium.

Y-site: Amifostine (Ethyol), aztreonam (Azactam), bivalirudin (Angiomax), ceftazidime (Teflaro), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), docetaxel (Taxotere), etoposide phosphate (Etopophos), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), gemcitabine (Gemzar), granisetron (Kytrel), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), linezolid (Zyvox), melphalan (Alkeran), ondansetron (Zofran), oxaliplatin (Eloxatin), palonosetron (Aloxi), pemetrexed (Alimta), potassium chloride (KCl), remifentanyl (Ultiva), sargramostim (Leukine), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

The ISMP recommends administration of a single dose over 10 to 15 minutes administered at a port furthest from the patient vein; observe continuously if given in a peripheral vein.

A maximum rate of 25 mg or fraction thereof over 1 minute is suggested by the manufacturer.

ACTIONS

A phenothiazine derivative with effects on the central, autonomic, and peripheral nervous systems. It has antihistaminic, antiemetic, anticholinergic, and sedative effects. As an antihistamine, it competitively blocks the H₁ histamine receptor, antagonizing most of the effects of histamine to at least some degree. Potentiates respiratory depression, sedative, and hypotensive effects of narcotics and other CNS depressants. Has no analgesic effects and does not potentiate analgesic effects of narcotics. Onset of action is prompt. Duration of action is 4 to 6 hours. Half-life ranges from 9 to 16 hours. Primarily metabolized in the liver and excreted in the urine.

INDICATIONS AND USES

Prophylaxis or treatment of minor transfusion reactions. ■ Treatment of or an adjunct to the treatment of hypersensitivity reactions (including anaphylaxis and other immediate-type reactions) after acute symptoms have been controlled with epinephrine and other standard measures. Consider for use if oral administration is impossible or contraindicated. ■ Treatment of acute nausea, vomiting, and motion sickness. ■ Sedation to meet surgical and obstetric needs. ■ Adjunct to analgesics for control of postoperative pain. ■ Sedation and relief of apprehension; production of a light sleep from which a patient can be easily aroused. ■ An adjunct to anesthesia and analgesia in selected surgical situations (e.g., repeated bronchoscopy, ophthalmologic surgery, and poor-risk patients). Given in conjunction with reduced amounts of narcotic analgesics.

CONTRAINDICATIONS

Comatose or severely depressed states, hypersensitivity or an idiosyncratic reaction to phenothiazines, and pediatric patients under 2 years of age. Never inject into an artery; may cause arteriospasm resulting in gangrene. **Do not** administer SC; chemical irritation may result in necrotic lesions.

PRECAUTIONS

Ampule must state “for IV use.” Deep IM injection preferred. ■ Use with extreme caution in pediatric patients and the elderly; see [Maternal/Child](#) and [Elderly](#). ■ Can cause severe chemical irritation and tissue damage regardless of route of administration. Irritation and damage can result from perivascular extravasation, unintentional intra-arterial injection, and intraneuronal or perineuronal infiltration. Adverse event reports include abscesses, burning, erythema, gangrene, pain, palsies, paralysis, sensory loss, severe spasm of the distal vessels, swelling, thrombophlebitis, tissue necrosis, and venous thrombosis. ■ Use should be avoided in patients with compromised respiratory function or in patients at risk for respiratory failure (e.g., COPD, sleep apnea); risk of potentially fatal respiratory depression is increased. ■ May cause paradoxical excitation in pediatric patients and the elderly. ■ Use phenothiazines with extreme caution in pediatric patients with a history of sleep apnea, a family history of sudden infant death syndrome, or in the presence of Reye’s syndrome. ■ Use with caution in patients with asthma, bladder neck obstruction, bone marrow suppression, cardiovascular disease, glaucoma, liver dysfunction, prostatic hypertrophy, pyloroduodenal obstruction, or stenosing peptic ulcer disease. ■ May produce ECG changes (e.g., prolonged QT interval, changes in T waves). ■ May mask diagnosis of other conditions, including Reye’s syndrome, brain tumor, drug intoxication, and intestinal obstruction. ■ May lower seizure threshold; use extreme caution in patients with known seizure disorders and with narcotics or local anesthetics that also lower seizure threshold. ■ May contain sulfites; use caution in patients with allergies. ■ Neuroleptic malignant syndrome (NMS), a rare syndrome manifested by hyperpyrexia, muscle rigidity, irregular BP and HR, and altered mental status, has been reported in association with promethazine alone or in combination with antipsychotic drugs.

Monitor: A vesicant; determine absolute patency of vein; extravasation will cause necrosis; see [Contraindications](#) and [Precautions](#). ISMP suggests administering through large-bore veins but prefers use of a central venous catheter. Administration through hand or wrist veins is strongly discouraged. ■ Monitor frequently for S/S of extravasation (e.g., burning, erythema, pain, palsies, sensory loss, and swelling along IV site), especially along peripheral sites. ■ Keep patient in supine position. Monitor BP and pulse before administration and between doses. ■ Sedative effect may require ambulation to be monitored. ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid use of alcohol or other CNS depressants (e.g., antihistamines, barbiturates). ■ Request assistance for ambulation; may cause dizziness or fainting. ■ Use caution performing tasks that require alertness. ■ May cause skin and eye photosensitivity. Avoid unprotected exposure to sun. ■ Report stinging or burning at IV site promptly. ■ Report any involuntary muscle movements.

Maternal/Child: Category C: safety for use in pregnancy and pediatric patients not established. Use only when clearly needed. ■ Discontinue breast-feeding. ■ Contraindicated in pediatric patients under 2 years of age. Post-marketing cases of respiratory depression and death (not directly related to individualized weight-based dosing) have been reported. Concomitant administration with other respiratory depressants increases this risk. ■ Use caution in pediatric patients 2 years of age or older. Use the minimum effective dose. ■ Do not use for vomiting of unknown etiology in pediatric patients. Antiemetics are not recommended for treatment of uncomplicated vomiting in pediatric patients. Use should be limited to prolonged vomiting of known etiology. Extrapyrimal symptoms that can occur secondary to promethazine administration may be confused with CNS signs of an undiagnosed primary disease (e.g., encephalopathy or Reye’s syndrome). ■ Avoid use in pediatric patients with S/S suggestive of Reye’s syndrome or other hepatic diseases. ■ Excessively large doses of antihistamines in pediatric patients have caused hallucinations, convulsions, and death. ■ Pediatric patients metabolize antipsychotic agents more rapidly than adults. ■ Incidence of extrapyramidal reactions is relatively high in pediatric patients, especially in the presence of acute illness (e.g., measles, chickenpox, gastroenteritis). ■ See [Precautions](#) and [Contraindications](#).

Elderly: See **Dose Adjustments** and **Precautions**. ■ Have a reduced capacity to metabolize and eliminate. ■ May cause confusion, dizziness, hyperexcitability, hypotension, and/or sedation. ■ Increased sensitivity to anticholinergic effects (e.g., dry mouth, urinary retention). ■ Increased risk of extrapyramidal side effects (e.g., tardive dyskinesia, parkinsonism).

DRUG/LAB INTERACTIONS

Increased CNS depression and hypotensive effects with **narcotics, alcohol, anesthetics, and barbiturates**; reduced doses of these agents usually indicated. ■ Additive effects with **MAO inhibitors** (e.g., selegiline [Eldepryl]), **anticholinergics, antihistamines, antihypertensives, hypnotics, muscle relaxants, and propranolol**; dose adjustments may be necessary. ■ Use with **epinephrine** not recommended; may cause precipitous hypotension. ■ Risk of cardiotoxicity increased with **pimozide** (Orap), **quinidine, and sparfloxacin** (Zagam); concurrent use not recommended. ■ Risk of additive QT interval prolongation, cardiac depressant effects, and cardiac arrhythmias increased with **amiodarone** (Nexterone), **disopyramide** (Norpace), **erythromycin, procainamide** (Pronestyl), and **quinidine**. ■ Concurrent use with **antidepressants** (e.g., fluoxetine [Prozac], paroxetine [Paxil]), **tricyclic antidepressants** (e.g., amitriptyline [Elavil]), or **MAO inhibitors** may increase effects of both drugs. ■ Concurrent use with **other neuroleptic agents** (e.g., haloperidol [Haldol]) may increase the risk of NMS. ■ May lower seizure threshold. Dose adjustment of **anticonvulsants** may be necessary. ■ Capable of innumerable other interactions. ■ Selected **pregnancy tests** may show a false-negative or false-positive result. ■ May cause an increase in blood glucose; consider when a **glucose tolerance test** is indicated.

SIDE EFFECTS

Average dose: Blurring of vision, bradycardia, confusion, dizziness, drowsiness, dryness of mouth, extrapyramidal symptoms, faintness, hallucinations, hematologic side effects (e.g., agranulocytosis, leukopenia, thrombocytopenia, thrombocytopenic purpura), hyperexcitability, hypersensitivity reactions, hypertension (rare), hypotension (mild), lassitude, nightmares, photosensitivity, sedation, somnolence, tachycardia, tinnitus, tremors. **Overdose:** Anaphylaxis, cardiac arrest, coma, convulsions, deep sedation, respiratory depression. All side effects of phenothiazines are possible, but rarely occur. See **prochlorperazine** (Compazine).

ANTIDOTE

Discontinue the drug immediately at onset of any side effect and notify the physician. Sympathetic block and heparinization have been used during acute management of promethazine extravasation (unintentional intra-arterial injection or perivascular extravasation). In some cases surgical intervention, including fasciotomy, skin graft, and/or amputation, has been required. Counteract hypotension with IV fluids, Trendelenburg position, norepinephrine (Levophed), or phenylephrine (Neo-Synephrine); extrapyramidal symptoms with benzotropine mesylate (Cogentin) or diphenhydramine (Benadryl). Epinephrine is contraindicated for hypotension; further hypotension will occur. Use diazepam (Valium) or phenobarbital for convulsions or hyperactivity. In treating respiratory depression and unconsciousness, avoid analeptics such as doxapram (Dopram); they may cause convulsions. Treatment of NMS includes discontinuation of all unnecessary drugs and intensive symptomatic treatment and monitoring. Dialysis does not appear to be helpful in overdose situations. Resuscitate as necessary.

PROPOFOL INJECTION

(PROH-poh-fohl in-JEK-shun)

General anesthetic
Anesthesia adjunct
Sedative-hypnotic

Diprivan

pH 7 to 8.5

USUAL DOSE

Lidocaine may be administered to minimize pain on injection of propofol. Administer before propofol injection or add to propofol immediately before administration. Do not exceed more than 20 mg lidocaine to 200 mg propofol.

INDUCTION OF ANESTHESIA

Must be individualized and titrated to desired response. Allow 3 to 5 minutes between dose adjustments to allow for and assess clinical effects.

Healthy adults less than 55 years of age: 40 mg every 10 seconds until induction onset (approximately 2 to 2.5 mg/kg).

Adults over 55 years of age, debilitated, or ASA III or IV risk patients: 20 mg every 10 seconds until induction onset (approximately 1 to 1.5 mg/kg).

Cardiac anesthesia: 20 mg every 10 seconds until induction onset (0.5 to 1.5 mg/kg).

Neurosurgical patients: 20 mg every 10 seconds until induction onset (approximately 1 to 2 mg/kg). Infusion or slow injection (20 mg over 10 seconds) is used to avoid significant hypotension and decrease in cerebral perfusion pressure. If increased intracranial pressure is suspected, hyperventilation and hypocarbia should accompany administration.

MAINTENANCE OF ANESTHESIA

Must be individualized and titrated to desired response. Allow 3 to 5 minutes between dose adjustments to allow for and assess clinical effects.

Adults less than 55 years of age: Immediately follow induction with an infusion of 100 to 200 mcg/kg/min (6 to 12 mg/kg/hr) or an intermittent bolus in increments of 25 to 50 mg as needed.

Adults over 55 years of age, debilitated, or ASA III or IV risk patients: Immediately follow induction with an infusion of 50 to 100 mcg/kg/min (3 to 6 mg/kg/hr). Do NOT use a rapid intermittent bolus in these patients.

Cardiac anesthesia: Most patients require 100 to 150 mcg/kg/min in combination with an opioid (primary propofol with an opioid secondary). An alternate regimen is an opioid primary with low-dose propofol 50 to 100 mcg/kg/min (3 to 6 mg/kg/hr).

Neurosurgical patients: Immediately follow induction with an infusion of 100 to 200 mcg/kg/min (6 to 12 mg/kg/hr). Do NOT use a rapid intermittent bolus in these patients.

INITIATION OF MAC SEDATION

Must be individualized and titrated to desired response. Allow 3 to 5 minutes between dose adjustments to allow for and assess clinical effects. MAC sedation rates are approximately 25% of those used for anesthesia.

Healthy adults less than 55 years of age: An infusion of 100 to 150 mcg/kg/min (6 to 9 mg/kg/hr) over 3 to 5 minutes or a slow injection of 0.5 mg/kg over 3 to 5 minutes. Slow infusion or slow injection techniques are preferable to rapid bolus administration.

Adults over 55 years of age, debilitated, or ASA III or IV risk patients: Most patients require doses similar to healthy adults. Must be given over 3 to 5 minutes as a slow infusion (preferred) or as a slow injection over 3 to 5 minutes. Do NOT give as a rapid bolus.

MAINTENANCE OF MAC SEDATION

Healthy adults less than 55 years of age: Maintain with an infusion (preferred) of 25 to 75 mcg/kg/min (1.5 to 4.5 mg/kg/hr) or incremental bolus doses of 10 to 20 mg.

Continued

Adults over 55 years of age, debilitated, or ASA III or IV risk patients: Reduce dose to 80% of usual dose; an infusion of 20 to 60 mcg/kg/min (1.2 to 3.6 mg/kg/hr). Do NOT use bolus doses.

SEDATION OF INTUBATED, MECHANICALLY VENTILATED ICU PATIENTS

Must be individualized and titrated to desired response. Given as a continuous infusion. Begin with an initial dose of 5 mcg/kg/min (0.3 mg/kg/hr) for 5 minutes. Allow at least 5 minutes between adjustments to reach peak drug effect and to avoid hypotension. Increase slowly over 5 to 10 minutes by 5 to 10 mcg/kg/min (0.3 to 0.6 mg/kg/hr) to desired level of sedation. Individualize to patient condition, response, blood lipid profile, and vital signs. Some clinicians recommend reducing dose by approximately one half for elderly (over 55 years) and debilitated. Check urinalysis and urine sediment before administration of propofol in patients at risk for renal failure; see [Precautions](#) and [Monitor](#).

MAINTENANCE OF SEDATION IN MECHANICALLY VENTILATED OR RESPIRATORY-CONTROLLED ICU PATIENTS

5 to 50 mcg/kg/min (0.3 to 3 mg/kg/hr) or higher as a continuous infusion slowly titrated to desired level of sedation. Use caution with doses higher than 50 mcg/kg/min; may increase risk of hypotension. Bolus doses of 10 to 20 mg may be used to rapidly increase the depth of sedation in patients in whom hypotension is not likely to occur. Temporarily reduce dose once each day to assess neurologic and respiratory function and to determine minimum dose required for desired level of sedation. Average maintenance dose **under 55 years** is 38 mcg/kg/min; **over 55 years**, 20 mcg/kg/min. Average maintenance dose for **post-coronary artery bypass graft (CABG) patients** is usually low (median of 11 mcg/kg/min) because of high intraoperative opiates.

RELIEF OF PRURITUS ASSOCIATED WITH USE OF SPINAL OPIATES OR CHOLESTASIS (UNLABELED)

Subhypnotic doses of 10 to 15 mg as an IV injection or 0.5 to 1.5 mg/kg/hr as an infusion.

MANAGEMENT OF REFRACTORY STATUS EPILEPTICUS (UNLABELED)

Administer doses of 1 to 2 mg/kg as an IV injection over 5 minutes; may be repeated if seizure activity recurs. If indicated, follow with a maintenance infusion of 2 to 10 mg/hr. Adjust to achieve the lowest rate needed to suppress seizure activity. Decrease gradually to prevent withdrawal seizures.

PEDIATRIC DOSE

To minimize pain on injection of propofol in pediatric patients, administer through larger veins or pretreat smaller veins with lidocaine. See [Maternal/Child](#).

INDUCTION OF ANESTHESIA IN HEALTHY PEDIATRIC PATIENTS 3 TO 16 YEARS OF AGE

Must be individualized and titrated to desired response. 2.5 to 3.5 mg/kg administered over 20 to 30 seconds. **Induction with propofol is indicated only in pediatric patients 3 years of age or older. In pediatric patients from 2 months to 3 years of age, induction must be achieved by supplementing with another agent (literature suggests nitrous oxide 60% to 70%).** See [Dose Adjustments](#).

MAINTENANCE OF ANESTHESIA IN HEALTHY PEDIATRIC PATIENTS FROM 2 MONTHS TO 16 YEARS OF AGE

Must be titrated to desired clinical effect. (See statement under induction in healthy pediatric patients in the previous paragraph, and see [Indications and Uses](#).) Administered as a variable-rate infusion supplemented with nitrous oxide 60% to 70% for most pediatric patients.

Pediatric patients 2 months of age and older: Immediately follow induction dose with an infusion of 125 to 300 mcg/kg/min (7.5 to 18 mg/kg/hr). Initially, a rate of 200 to 300 mcg/kg/min may be indicated and can usually be reduced to 125 to 150 mcg/kg/min after the first half-hour. Decrease infusion rate if clinical signs of light anesthesia are not present after 30 minutes of maintenance; see [Rate of Administration](#). Younger pediatric patients may require higher maintenance infusion rates than older pediatric patients. See [Dose Adjustments](#).

DOSE ADJUSTMENTS

All situations: Reduce induction and maintenance doses for pediatric patients classified as ASA III or IV. ■ See [Usual Dose](#) for specific reduced doses required for adults over 55

years of age; debilitated, ASA III, or IV risk patients; or patients with circulatory disorders. ■ Reduced dose required in presence of other CNS depressants. See [Drug/Lab Interactions](#). ■ No dose adjustment required for gender, chronic hepatic cirrhosis, or chronic renal failure.

ICU sedation: Adjust infusion to maintain a light level of sedation through the wake-up assessment or weaning process.

DILUTION

Supplied in ready-to-use vials containing 10 mg/mL. Shake well before use. May be further diluted only with D5W. Do not dilute to a concentration less than 2 mg/mL (4 mL diluent to 1 mL propofol yields 2 mg/mL). More stable in glass than in plastic. Strict aseptic technique imperative; emulsion supports rapid growth of microorganisms. Failure to use strict aseptic technique has been associated with microbial contamination of the product with resultant fever, infection, sepsis, other life-threatening illnesses, and/or death. Do not use with evidence of emulsion separation. Prepare immediately before each use. Flush IV line at end of every 6 hours in extended procedures to remove residual propofol.

Filters: Use filters with caution. The pore size should be equal to or greater than 5 microns. Filters with a pore size less than 5 microns may impede the flow of propofol and/or cause a breakdown of the emulsion.

Storage: Protect from light and store below 22° C (72° F) but do not refrigerate. Discard infusion and tubing every 12 hours or every 6 hours if propofol has been transferred from the original container.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Should not be mixed with other therapeutic agents prior to administration. **Compatibility** with blood/serum/plasma has not been established.”

Y-site: Manufacturer lists as **compatible** at the **Y-site** with the following solutions: D5W, LR, D5LR, D5½NS, D5¼NS. Other sources list acyclovir (Zovirax), alfentanil (Alfenta), aminophylline, ampicillin, atracurium (Tracrium), atropine, aztrenoam (Azactam), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), cefazolin (Ancef), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftaroline (Teflaro), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), cisatracurium (Nimbex), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytosan), cyclosporine (Sandimmune), cytarabine (ARA-C), dexamethasone (Decadron), dexmedetomidine (Precedex), diphenhydramine (Benadryl), dobutamine, dopamine, doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), ephedrine, epinephrine (Adrenalin), esmolol (Brevibloc), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), fluorouracil (5-FU), furosemide (Lasix), ganciclovir (Cytovene), glycopyrrolate (Robinul), granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), insulin (regular), isoproterenol (Isuprel), ketamine (Ketalar), labetalol, lidocaine, lorazepam (Ativan), magnesium sulfate, mannitol, meperidine (Demerol), midazolam (Versed), milrinone (Primacor), morphine, nafcillin (Nallpen), nalbuphine, naloxone (Narcan), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), paclitaxel (Taxol), pancuronium, pentobarbital (Nembutal), phenobarbital (Luminal), phenylephrine (Neo-Synephrine), potassium chloride (KCl), prochlorperazine (Compazine), propranolol, ranitidine (Zantac), sodium bicarbonate, succinylcholine, sufentanil (Sufenta), telavancin (Vibativ), ticarcillin/clavulanate (Timentin), vancomycin, vecuronium.

RATE OF ADMINISTRATION

Use of a syringe pump or volumetric pump recommended to provide controlled infusion rates. See [Usual Dose](#) for specific rates for specific age and/or indication. Decrease rate based on age, debilitation, or calculated risk. Must be individualized and titrated to de-

sired level of sedation and changes in vital signs. Monitor respiratory function continuously. Continuous administration preferable to intermittent to avoid periods of under-sedation or oversedation. Too-rapid administration (bolus dosing, too-rapid increase in infusion rate, overdose) can cause severe cardiorespiratory complications, especially in pediatric patients, adults over 55 years, debilitated or ASA III or IV risk patients. In all anesthesia, higher rates are generally required for the first 15 minutes, then appropriate responses can usually be maintained with a decrease of 30% to 50%. Always titrate rates downward until there is a mild response to surgical stimulation. This avoids administration at rates higher than clinically necessary. Control increased response to surgical stimulation or lightening of anesthesia (increased pulse rate, BP, sweating and/or tearing) with bolus injections of 25 to 50 mg (**adults under 55 years of age only**); slow injection of reduced doses, or by increasing the infusion rate (**adults under or over 55 years of age**) or by increasing the infusion rate (**pediatric patients**). If control not effective within 5 minutes, consider use of an opioid, barbiturate, or inhalation agent.

ACTIONS

A potent emulsified IV sedative hypnotic agent. Action is dose and rate dependent. Can provide conscious (verbal contact maintained) or unconscious sedation, depending on dose. Produces hypnosis rapidly and smoothly with minimal excitation, usually within 40 seconds. Depth of sedation easily and rapidly controlled by adjusting rate of infusion. Rapid onset of action facilitates accurate titration and minimizes oversedation. Due to extensive redistribution from the central nervous system to other tissues and high metabolic clearance, recovery from anesthesia or sedation is rapid. Time to awakening is dependent on duration of infusion. Discontinuation of an infusion after maintenance of anesthesia for 1 hour or sedation in the ICU for 1 day will result in rapid awakening. Prolonged infusions (e.g., 10 days in ICU) will result in drug accumulation and an increased time to awakening. Terminal half-life after a 10-day infusion is 1 to 3 days. Other effects include decreased systemic vascular resistance, myocardial blood flow, and oxygen consumption; a decrease in cerebral blood flow and intracranial pressure; and a decrease in intraocular pressure. Also has antiemetic properties. Has minimal impact on cardiac output, but changes may occur because of assisted or controlled ventilation. Hypotension, oxyhemoglobin desaturation, apnea, and airway obstruction can occur. Addition of an opioid may further decrease cardiac output or respiratory drive. Metabolized in the liver and excreted as metabolites in urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Adults: Induce and/or maintain anesthesia as part of a balanced anesthetic technique for inpatient and outpatient surgery. ■ Initiate and maintain monitored anesthesia care (MAC) during diagnostic procedures (e.g., colonoscopy, dental procedures) and in conjunction with local/regional anesthesia during surgical procedures. ■ Continuous sedation and control of stress responses in intubated, mechanically ventilated ICU patients (e.g., post-CABG, post-surgical, neuro/head trauma, ARDS, COPD, asthma, status epilepticus, tetanus). Continuous infusions of low doses allows controlled recovery of consciousness when required and for assessment.

Pediatric patients: Induction of anesthesia as a part of a balanced anesthetic technique for inpatient and outpatient surgery in pediatric patients over 3 years of age. ■ Maintenance of anesthesia as part of a balanced anesthetic technique for inpatient and outpatient surgery in pediatric patients over 2 months of age. ■ Not recommended for induction of anesthesia below the age of 3 years or for maintenance of anesthesia below the age of 2 months. ■ Not indicated for use in pediatric patients for ICU sedation or for MAC sedation for surgical, nonsurgical, or diagnostic procedures.

Unlabeled uses: Subhypnotic doses used for relief of pruritus associated with use of spinal opiates or cholestasis; treatment of status epilepticus refractory to standard anticonvulsant therapy.

CONTRAINDICATIONS

Known hypersensitivity to propofol or its components (e.g., soybean oil, glycerol, egg lecithin, sodium hydroxide) or any time general anesthesia or sedation is contraindicated.

PRECAUTIONS

All situations: For IV use only. ■ Administered by or under the direct observation of the anesthesiologist. Must have responsibility only for anesthesia during surgery and/or procedures. In the ICU setting, may be administered to intubated, mechanically ventilated patients by persons skilled in medical management of critically ill patients and trained in cardiovascular resuscitation and airway management. Both life-threatening and fatal anaphylactoid and anaphylactic reactions have been reported. ■ Strict aseptic technique required; see [Dilution](#). ■ Use caution in patients with compromised myocardial function, intravascular volume depletion, or abnormally low vascular tone (e.g., sepsis); may be more susceptible to hypotension. ■ Avoid rapid bolus administration in the elderly, debilitated, or ASA-PS III or IV patients. May cause undesirable cardiopulmonary depression, including apnea, airway obstruction, hypotension, and oxygen desaturation. ■ An emulsion; use caution in patients with lipid metabolism disorders (e.g., diabetic hyperlipidemia, pancreatitis, and primary hyperlipoproteinemia). ■ May cause convulsions during recovery phase in patients with epilepsy. ■ Use caution in patients with increased intracranial pressure or impaired cerebral circulation. Decrease in mean arterial pressure may cause decreases in cerebral perfusion. ■ Propofol infusion syndrome has been reported and is characterized by severe metabolic acidosis, hyperkalemia, lipemia, rhabdomyolysis, hepatomegaly, and cardiac and renal failure. Deaths have occurred. Most often associated with prolonged, high-dose infusions in ICU but has been observed following large-dose, short-term infusions during surgical anesthesia. Consider alternative means of sedation when there is a prolonged need for sedation, when large doses of propofol are required to maintain a desired level of sedation, or if a patient develops metabolic acidosis. ■ Has no analgesic properties; provide pain relief or local anesthetic as indicated. Has been used successfully with midazolam (Versed), 1 to 3 mg, for initial induction. Midazolam provides better amnesia and causes less pain on injection, whereas propofol sustains sedation and allows more rapid recovery. ■ May contain sulfites; use caution in patients with allergies.

Monitor: All situations: Correct fluid volume deficiencies before administration. ■ Will cause transient local pain during IV injection; minimize by using larger veins and lidocaine previous to injection. Use with midazolam reduces awareness of this pain. ■ Apnea may occur during induction and last for more than 60 seconds. Intubation equipment, controlled ventilation equipment, oxygen, and facilities for resuscitation and life support must be available. Maintain a patent airway and ascertain adequate ventilation at all times. ■ All vital signs must be monitored continuously. Use of a respiratory monitor required. ■ Hypotension common during first 60 minutes; monitor closely. Significant hypotension or cardiovascular depression can be profound. ■ To prevent profound bradycardia, anticholinergic agents (e.g., atropine, glycopyrrolate) may be required to modify increases in vagal tone due to concomitant agents (e.g., succinylcholine) or surgical stimulation. ■ Bed rest required for a minimum of 3 hours after IV injection, or satisfy specific hospital rules for discharge. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

ICU sedation: Observe for signs and symptoms of pain; may indicate need for opioids or analgesia, not an increase in propofol dose. ■ Benzodiazepines (e.g., diazepam [Valium]) and/or neuromuscular blocking agents (e.g., atracurium [Tracrium], succinylcholine) may also be used. ■ Monitor triglycerides with long-term use (ICU sedation). Adjust if fat is inadequately cleared from body and reduce other lipid administration. 1 mL of propofol contains approximately 0.1 Gm of fat (1.1 kcal). ■ Dose may be reduced carefully to allow patient to awaken to a lighter level of sedation allowing neurologic and respiratory assessment daily. Avoid rapid awakening; will cause anxiety, agita-

tion, and resistance to mechanical ventilation. ■ Monitor urinalysis and urine sediment on alternate days in patients at risk for renal impairment. ■ Some formulations contain EDTA, a trace metal chelator. Formulations containing EDTA should not be infused for longer than 5 days without providing a drug holiday to safely replace estimated or measured zinc losses. Consider zinc supplementation in patients who may be predisposed (e.g., patients with burns, diarrhea, or major sepsis). ■ Discontinue opioids and paralytic agents and optimize respiratory function before weaning from mechanical ventilation. ■ Maintain light sedation until 15 minutes before extubation.

Patient Education: Avoid alcohol or other CNS depressants (e.g., antihistamines, benzodiazepines) for 24 hours following anesthesia. ■ Do not perform tasks requiring mental alertness (e.g., driving, operating hazardous machinery, or signing legal documents) until the day after surgery or longer. All effects must have subsided.

Maternal/Child: Category B: use during pregnancy only if clearly needed. ■ Not recommended for use in obstetric procedures, including cesarean section; no assurance of safety for fetus. ■ Not recommended for use during breast-feeding. ■ Has been approved for induction of anesthesia in pediatric patients 3 years to 16 years of age. Has been approved for maintenance of anesthesia in pediatric patients 2 months to 16 years of age. ■ Distribution and clearance in pediatric patients 3 years to 12 years of age is similar to that seen in adults. ■ Serious bradycardia may result with concomitant administration of fentanyl. ■ Serious adverse effects (e.g., metabolic acidosis) occurred during ICU sedation in pediatric patients with respiratory infections and/or with doses in excess of recommendations for adults. Fatalities have occurred. ■ A recent study identified an increase in deaths with propofol versus standard sedative agents. Manufacturer has issued a warning letter stating that propofol should not be used for sedation of pediatric patients in ICU. ■ See [Side Effects](#).

Elderly: Dose requirements decrease after age 55 due to reduced clearance and volume distribution and higher blood levels. Minimize undesirable cardiorespiratory depression (hypotension, apnea, airway obstruction, and/or oxygen desaturation) by using reduced doses and rates of administration. Avoid rapid single or repeated bolus doses; see [Precautions](#). See [Usual Dose](#) and [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Potentiated by **inhalational anesthetics** (e.g., enflurane, halothane, isoflurane, nitrous oxide), **narcotics** (e.g., morphine, meperidine [Demerol], fentanyl [Sublimaze]), **sedatives** (e.g., barbiturates, benzodiazepines [e.g., diazepam (Valium), midazolam (Versed)], chloral hydrate, droperidol [Inapsine]). Anesthetic and sedative effects increased; systolic, diastolic, mean arterial pressure, and cardiac output are decreased. Dose adjustment may be indicated with concomitant use. ■ No significant adverse interactions noted to date with neuromuscular blocking agents (e.g., atracurium [Tracrium], succinylcholine). ■ Competition for chemoreceptor binding sites may occur if used in combination with **droperidol**; use of propofol as a single agent is suggested to control nausea and vomiting. ■ In pediatric patients, serious bradycardia may result with concomitant administration of **fentanyl**.

SIDE EFFECTS

Adults and pediatric patients: More likely to occur during loading boluses, with supplemental boluses or higher rate of administration. Apnea; bradycardia (profound); cough; dyspnea; headache; hypotension; hypoventilation; injection site burning, pain, stinging; nausea, and upper airway obstruction are most common. Urine may be green. Abdominal cramping, anaphylaxis (including bronchospasm, erythema, and hypotension), bucking/jerking/thrashing, clonic/myoclonic movement (rarely including convulsions and opisthotonus), dizziness, fever, flushing, hiccough, hypertension, tingling/numbness/coldness at injection site, twitching, and vomiting may occur.

Pediatric patients: Increased incidences of agitation, bradycardia, and jitteriness have occurred; apnea has been observed frequently. Abrupt discontinuation following prolonged infusion may result in agitation, flushing of the hands and feet, hyperirritability, and tremulousness.

Overdose: Cardiorespiratory depression (hypotension, apnea, airway obstruction, and/or oxygen desaturation).

ANTIDOTE

Keep physician informed of all side effects. Reduction of dose may be required or will be treated symptomatically. Discontinue the drug for major side effects, paradoxical reactions, or accidental overdose. A short-acting drug, a patent airway, and continuous controlled ventilation with oxygen until normal function assured should be adequate. Treat bradycardia and/or hypotension with increased rate of IV fluids, Trendelenburg position, vasopressors (e.g., dopamine). Anticholinergic agents (e.g., atropine or glycopyrrolate) may be required. Treat hypersensitivity reactions and resuscitate as necessary.

PROPRANOLOL HYDROCHLORIDE

(proh-**PRAN**-oh-lohl hy-droh-**KLOR**-eyed)

Beta-adrenergic blocking agent
Antiarrhythmic

pH 2.8 to 3.5

USUAL DOSE

1 to 3 mg given 1 mg at a time under careful monitoring (e.g., CVP, ECG); see [Monitor](#) and [Rate of Administration](#). Do not give additional propranolol if the desired change in rate or rhythm is achieved. If there is no change in rhythm for at least 2 minutes after the initial dose, cycle may be repeated one time. (AHA recommends 0.5 to 1 mg over 1 minute, repeated as needed up to a total dose of 0.1 mg/kg.) **No further propranolol may be given by any route for at least 4 hours.** Best results achieved if administered within 2 to 4 hours of symptom onset or thrombolytic therapy. Transfer to oral therapy as soon as possible.

PEDIATRIC DOSE (UNLABELED)

0.01 to 0.1 mg/kg/dose over 10 minutes. Maximum dose is 1 mg for infants and 3 mg for other pediatric patients. Repeat at 6- to 8-hour intervals if needed.

Tetralogy spells (hypercyanotic spells): 0.15 to 0.25 mg/kg/dose may be given slowly. May repeat once in 15 minutes. Another source recommends 0.01 to 0.2 mg/kg/dose. Should not exceed 5-mg dose.

DOSE ADJUSTMENTS

Lower-end initial doses may be indicated in the elderly based on potential for decreased organ function and concomitant disease or drug therapy. ■ Consider dose reduction in patients with impaired hepatic function. ■ See [Drug/Lab Interactions](#). ■ Reduce dose gradually to avoid rebound angina, myocardial infarction, or ventricular arrhythmias.

DILUTION

May be given undiluted; however, further dilution of each 1 mg in 10 mL D5W or NS is preferred to facilitate titration of an exact dose while monitoring effect. May be diluted in 50 mL of D5W, D5 $\frac{1}{2}$ NS, D5NS, or NS for infusion.

Storage: Store at CRT. Protect from freezing or excessive heat.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Additive: Dobutamine, verapamil.

Y-site: Alteplase (tPA, Activase), fenoldopam (Corlopam), heparin, hydrocortisone sodium succinate (Solu-Cortef), linezolid (Zyvox), meperidine (Demerol), milrinone (Primacor), morphine, nesiritide (Natrecor), potassium chloride (KCl), propofol (Diprivan), tacrolimus (Prograf), tirofiban (Aggrastat).

RATE OF ADMINISTRATION

Each 1 mg or fraction thereof must be given over 1 minute to avoid excessive hypotension and/or cardiac standstill. A single dose may be given as an infusion over 10 to 15 minutes. Allow adequate time for distribution; consider slow circulation time. Observe monitor and discontinue propranolol as soon as rhythm change occurs.

Pediatric rate: Extend rate of administration of a single dose by injection to a minimum of 5 minutes in pediatric patients.

ACTIONS

Propranolol is a nonselective beta-adrenergic blocker with antiarrhythmic effects. Cardiac response to sympathetic nerve stimulation is inhibited, slowing the HR (especially ventricular rate) by inhibiting atrioventricular conduction. Decreases the force of cardiac contractility, and decreases arterial pressure and cardiac output. Blockade of beta₂-adrenergic receptors found predominantly in smooth muscle (e.g., vascular, bronchial,

gastrointestinal, and genitourinary); leads to constriction in these tissues. Well distributed throughout the body, the onset of action occurs within 1 to 2 minutes and lasts about 4 hours. Half-life is 2 to 5.5 hours. Metabolized in the liver. Excreted primarily in the urine. Secreted in breast milk.

INDICATIONS AND USES

Reserve IV use for life-threatening situations or for those occurring under anesthesia. ■ Short-term treatment to decrease the ventricular rate in supraventricular tachycardia, including Wolff-Parkinson-White syndrome and thyrotoxicosis. ■ Treatment of persistent and symptomatic PVCs that do not respond to conventional measures. ■ Use in patients with atrial flutter or atrial fibrillation should be reserved for arrhythmias unresponsive to standard therapy or when more prolonged control is required. ■ Control of ventricular rate in life-threatening, digoxin-induced arrhythmias (severe bradycardia may occur). ■ Treatment of tachyarrhythmias due to excessive catecholamine action during anesthesia when other measures fail. ■ Not the drug of first choice for treatment of ventricular arrhythmias unless the arrhythmia is induced by catecholamines or digoxin. In critical situations, when cardioversion or other drugs are not indicated or effective, propranolol may be used with caution. (Use a low dose and administer very slowly so the failing heart maintains some sympathetic drive to maintain myocardial tone. May respond with NSR, but a reduction in ventricular rate is more likely.) ■ Numerous other uses PO.

Unlabeled uses: Other beta-blockers (e.g., atenolol, esmolol) have been used in the perioperative period to reduce cardiac morbidity and mortality in patients at risk; propranolol was not used in these studies. ■ Has been used for adjunctive treatment of pheochromocytoma following primary treatment with an alpha-adrenergic blocking agent (e.g., phenoxybenzamine [Dibenzyline], phentolamine [Regitine]) and for treatment of other refractory arrhythmias when benefit outweighs risk.

CONTRAINDICATIONS

Cardiogenic shock, sinus bradycardia, greater than first-degree heart block, bronchial asthma, known hypersensitivity to propranolol.

PRECAUTIONS

Oral administration is preferred. Use IV administration only when necessary. ■ Not considered the drug of choice for arrhythmias in myocardial infarction. ■ Used concurrently with digoxin or alpha-adrenergic blockers as indicated. ■ Use with caution in overt CHF. May precipitate more severe failure. ■ Use with extreme caution in asthmatics, patients with lung disease or bronchospasm; can block bronchodilation produced by endogenous and exogenous catecholamine stimulation of beta receptors. ■ Use with caution in patients with diabetes or in patients with a history of hypoglycemia. May cause hypoglycemia and mask the symptoms. ■ Beta blockade can mask symptoms of hyperthyroidism. Abrupt withdrawal of propranolol may be followed by exacerbation of symptoms, including thyroid storm. ■ Use caution in patients with hepatic or renal impairment. ■ May cause arrhythmia, angina, MI, or death if stopped abruptly. ■ Beta-adrenergic receptor blockade can cause a reduction in intraocular pressure. Withdrawal of propranolol may lead to a return of elevated intraocular pressure. May also interfere with the screening test for glaucoma. ■ IV dose used during surgery to replace an oral dose should be $\frac{1}{10}$ of the oral dose. ■ May cause severe bradycardia in patients with Wolff-Parkinson-White syndrome. See [Drug/Lab Interactions](#).

Monitor: Continuous ECG and BP monitoring is mandatory during administration of IV propranolol. Monitoring of pulmonary wedge pressure or central venous pressure is recommended. Discontinue the drug when a rhythm change is noted and wait to note full effect before giving additional medication if indicated. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Report any breathing difficulty promptly.

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding and in pediatric patients not established. Use only when clearly indicated. ■ Bradycardia, hypoglyce-

mia, and respiratory depression have been seen in neonates whose mothers received propranolol during labor or delivery.

Elderly: Lower-end initial doses may be indicated; see [Dose Adjustments](#). ■ Response of elderly versus younger patients not documented. ■ Use with caution in age-related peripheral vascular disease; risk of hypothermia increased. ■ May exacerbate mental impairment.

DRUG/LAB INTERACTIONS

Metabolism involves multiple pathways in the **cytochrome P₄₅₀ system**. Interactions with inhibitors, inducers, or substrates of this system are documented. ■ Blood levels of propranolol **increased** when administered concurrently **with substrates or inhibitors** such as amiodarone (Nexterone), cimetidine (Tagamet), ciprofloxacin (Cipro IV), delavirdine (Rescriptor), fluconazole (Diflucan), fluoxetine (Prozac), fluvoxamine (Luvox), imipramine (Tofranil), isoniazid (INH), paroxetine (Paxil), quinidine, ritonavir (Norvir), rizatriptan (Maxalt), teniposide (Vumon), theophylline, tolbutamide, zileuton (Zyflo), zolmitriptan (Zomig). ■ Blood levels of propranolol **decreased** when administered concurrently with **inducers** such as cigarette smoke, ethanol, and rifampin (Rifadin). ■ Concurrent use with **propafenone** may produce additive negative inotropic and beta-blocking effects. ■ Concurrent administration with **quinidine** results in additive negative inotropic effects and beta-blockade and postural hypotension. ■ Concurrent use with **disopyramide** (Norpace) has been associated with additive hypotension, severe bradycardia, asystole, and heart failure. ■ Concurrent use with **amiodarone** (Nexterone) results in additive negative chronotropic properties. ■ Decreases **lidocaine** clearance; lidocaine toxicity has been reported with concurrent use. ■ Effects additive when given with **other agents that slow A-V nodal conduction** (e.g., digoxin [Lanoxin], lidocaine). ■ Concurrent use with **calcium channel blockers** that have negative inotropic and/or chronotropic activity (e.g., diltiazem [Cardizem], verapamil) may further depress myocardial contractility and A-V nodal conduction. Bradycardia, heart failure, and cardiovascular collapse have been reported with verapamil and beta-blockers. Bradycardia, hypotension, heart block, and heart failure have been reported with coadministration of diltiazem and beta-blockers. ■ Antihypertensive effects of **clonidine** may be antagonized by propranolol. Use with clonidine may precipitate acute hypertension or aggravate rebound hypertension if clonidine stopped abruptly; discontinue propranolol several days before gradual withdrawal of clonidine. Monitor BP with concurrent use. ■ First-dose hypotension may be prolonged with **prazosin** (Minipress). Postural hypotension has been reported when used concurrently with **doxazosin** (Cardura) and **terazosin** (Hytrin). ■ Coadministration with **reserpine** (a catecholamine-depleting drug) may result in hypotension, bradycardia, vertigo, syncope, or orthostatic hypotension. ■ Avoid concurrent use with **epinephrine**. Beta-blockade may lead to unopposed alpha-receptor stimulation, resulting in uncontrolled hypertension. ■ **Dobutamine or isoproterenol** (Isuprel) may be administered to reverse the effects of propranolol. However, patients may experience protracted, severe hypotension. ■ **Anesthetic agents** (e.g., methoxyflurane and trichloroethylene) may depress myocardial contractility when administered with propranolol. ■ **ACE inhibitors** (enalapril [Vasotec], lisinopril [Zestril]) may increase bronchial hyperactivity when given concurrently with propranolol. ■ Hypotension and cardiac arrest have been reported with concurrent use of **haloperidol** and propranolol. ■ Propranolol may increase serum levels of **theophylline and diazepam** (Valium). ■ Potentiates **ergot alkaloids** (e.g., dihydroergotamine [D.H.E. 45]); monitor for peripheral ischemia; reduce ergot dose or discontinue beta-blocker. ■ Added hypotensive effect with **diuretics** (e.g., furosemide), **other antihypertensive agents** (e.g., enalapril, nitroglycerin), some **phenothiazines** (e.g., chlorpromazine [Thorazine]), and **reserpine**. Reduced dose of one or both drugs may be indicated. ■ May prolong effects of **nondepolarizing muscle relaxants** (e.g., pancuronium). ■ May increase anticoagulant effects of **warfarin**. ■ May mask symptoms of hypoglycemia with **insulin and sulfonyleureas** and result in prolonged hypoglycemia. ■ Can interfere with

numerous diagnostic and physiologic tests. Consult literature. ■ May alter **thyroid function tests** and cause **elevations in BUN, serum potassium, triglycerides, serum transaminases, and alkaline phosphatase**. ■ Metabolism and release of catecholamines increased in **smokers**; increased doses may be required. May also interfere with therapeutic effects in **treatment of angina**. ■ Patients taking beta-blockers who are exposed to a potential allergen may be unresponsive to the usual dose of **epinephrine** used to treat a hypersensitivity reaction.

SIDE EFFECTS

AV conduction delays, bradyarrhythmias, bronchospasm, cardiac failure, cardiac standstill, erythematous rash, hallucination, hypotension, laryngospasm, nausea, paresthesia of the hands, respiratory distress, syncopal attacks, vertigo, visual disturbances. Many other side effects have been reported with oral propranolol and could be seen with the IV route; see manufacturer's literature.

ANTIDOTE

For any side effect or excessive dosage, discontinue the drug and notify the physician immediately. Treat bradycardia with atropine 0.25 to 1 mg. Isoproterenol (Isuprel) may be used with caution if no response to vagal blockade. Serious bradycardia may require pacing. Treat cardiac failure with digitalization and diuretics. Treat hypotension or depressed myocardial function with glucagon. Administer 50 to 150 mcg/kg IV followed by an infusion of 1 to 5 mg/hr (see glucagon monograph for correct dilution). Isoproterenol (Isuprel) and dopamine may also be useful; see [Drug/Lab Interactions](#). Treat bronchospasm with isoproterenol and aminophylline. Treat other side effects symptomatically. Monitor ECG, HR, neurobehavioral status, and intake and output until stable. Not significantly removed by hemodialysis or peritoneal dialysis. Resuscitate as necessary.

PROTAMINE SULFATE **BBW**

(PROH-tah-meen SUL-fayt)

Antidote
(heparin antagonist)

pH 6 to 7

USUAL DOSE

Following a serious heparin overdose, discontinue heparin and administer protamine immediately.

Pretreatment: Corticosteroids and antihistamines can be used for patients at risk for protamine hypersensitivity.

IV heparin overdose: 1 mg of IV protamine neutralizes approximately 100 USP units of heparin. May be repeated if needed in 10 to 15 minutes. Never exceed 50 mg in any 10-minute period. Dose adjusted as indicated by coagulation studies. Any dose over 100 mg in 2 hours should be justified by coagulation studies (has its own anticoagulant effect). Because heparin disappears rapidly from the circulation, the dose of protamine required decreases rapidly with the time elapsed after heparin injection (e.g., 30 minutes after IV heparin, 0.5 mg [or one half of the dose] of protamine may be sufficient to neutralize 100 USP units of heparin).

Subcutaneous heparin overdose: 1 to 1.5 mg IV protamine per 100 units of heparin. Some clinicians recommend a loading dose of 25 to 50 mg given slowly over 10 minutes followed by administration of the remainder of the calculated dose as a continuous infusion over 8 to 16 hours (the continuous infusion covers the absorption time seen with administration of SC heparin). See comments under IV heparin overdose.

Low-molecular-weight heparin overdose (unlabeled): 1 mg IV protamine for every 100 antifactor Xa units of LMWH. If PTT remains prolonged 2 to 4 hours after the first dose, or if bleeding continues, consider administration of a second dose of 0.5 mg protamine for every 100 antifactor Xa units. Only 60% to 75% of antifactor Xa activity is neutralized. Excessive protamine doses can worsen bleeding potential. See comments under IV heparin overdose.

DOSE ADJUSTMENTS

Because heparin disappears rapidly from the system, reduce dose of protamine based on length of time elapsed since heparin dose (up to one half if 30 minutes has elapsed). ■ Prompt administration of protamine sulfate may also decrease dose requirements.

DILUTION

May be given undiluted or may be further diluted with NS or D5W.

Storage: Store at CRT. Do not freeze. Discard remaining medication or diluted solution.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends not mixing with other drugs unless **compatibility** is known, and lists as **incompatible** with some antibiotics, including several cephalosporins and penicillins. Consider individualized rate adjustment necessary to produce desired effects.

One source suggests the following **compatibilities**:

Additive: Ranitidine (Zantac), verapamil.

RATE OF ADMINISTRATION

50 mg (5 mL) or fraction thereof over 10 minutes. Do not exceed 50 mg in 10 minutes. As an infusion, may be given over 2 to 3 hours with dosage titrated according to coagulation studies. Increase duration of infusion to 8 to 16 hours for treatment of SC heparin overdose. Use infusion pump or microdrip (60 gtt/mL) to administer. Too-rapid administration, high doses, or repeated doses can cause anaphylaxis, bradycardia, cardiovascular collapse, catastrophic pulmonary vasoconstriction, pulmonary hypertension, dyspnea, flushing, noncardiogenic pulmonary edema, sensation of warmth, or severe hypotension. Hypertension has also occurred.

ACTIONS

An anticoagulant if administered alone. In the presence of heparin, protamine forms a stable salt, neutralizing the anticoagulant effect of both drugs. Does not bind to low-molecular-weight fragments of LMWH preparations, leading to incomplete neutralization of antifactor Xa. Each 1 mg of protamine can neutralize approximately 100 USP units of heparin. Onset of action is within 0.5 to 1 minute. Neutralization of heparin occurs within 5 minutes. Duration of action is about 2 hours.

INDICATIONS AND USES

To neutralize the anticoagulant activity of heparin in severe heparin overdose.

Unlabeled uses: Neutralization of heparin administered during extracorporeal circulation in arterial and cardiac surgery or dialysis procedures. ■ Heparin neutralization in pregnant women near delivery. ■ Treatment of low-molecular-weight heparin (e.g., dalteparin, enoxaparin, tinzaparin) overdose. Neutralization of LMWH is not complete.

CONTRAINDICATIONS

Known hypersensitivity to protamine. ■ Do not use for bleeding that occurs without prior exposure to heparin.

PRECAUTIONS

For IV use only. Serious, life-threatening reactions have been reported. Risk increased in patients with allergies to fish, abnormal pulmonary hemodynamics, previous exposure to protamine or protamine-containing drugs (e.g., protamine insulin), infertile or vasectomized men (may have antiprotamine antibodies), and severe left ventricular dysfunction. Assess risk versus benefit in at-risk patients; see [Rate of Administration](#) and [Usual Dose](#). ■ Must be administered in a facility equipped to monitor the patient and respond to any medical emergency. ■ Pulmonary edema and/or circulatory collapse may occur in patients undergoing cardiac bypass surgery; etiology unknown.

Monitor: Coagulation studies (e.g., aPTT, ACT, heparin titration test with protamine, plasma thrombin time) may be indicated to monitor therapeutic response. ■ Facilities to treat shock must be available; see [Precautions](#). ■ After cardiac surgery or dialysis procedures, even with adequate neutralization, further bleeding may occur any time within 24 hours (heparin “rebound”). Observe the patient continuously. Additional protamine sulfate may be indicated.

Maternal/Child: Category C: safety for use in pregnancy, breast-feeding, or pediatric patients not established.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Occur more frequently with too-rapid injection; anaphylaxis, back pain, bradycardia, dyspnea, feeling of warmth, flushing, lethargy, nausea, vomiting, severe hypertension or hypotension. Acute pulmonary hypertension, noncardiogenic pulmonary edema, catastrophic pulmonary vasoconstriction, circulatory collapse, capillary leak, or pulmonary edema may occur.

ANTIDOTE

Discontinue the drug and notify the physician, who may recommend a decrease in rate of administration or, if side effects are severe, symptomatic treatment such as administration of whole blood, vasopressors (e.g., dopamine) for hypotension, atropine for bradycardia, and oxygen for dyspnea. Resuscitate as necessary.

Clinisol 15% (SF) ▪ **Crystalline amino acid infusions** ▪
FreAmine HBC 6.9% ▪
FreAmine III 8.5%, 10%, and 3% and 8.5% with electrolytes ▪
HepatAmine 8% ▪ **Hepatosol 8%** ▪ **Hyperalimentation** ▪
NephrAmine 5.4% ▪ **Novamine 11.4% and 15%** ▪
Premasol 6% and 10% ▪
ProcalAmine ▪ **ProSol 20% (sulfite free)** ▪
Protein hydrolysates ▪ **RenAmin without electrolytes** ▪
Total parenteral nutrition ▪
Travasol 2.75% and 4.25% in D5, D10, and D25 ▪
Travasol 4.25% (SF) in D25 with electrolytes ▪
Travasol 5.5%, 8.5%, and 10% without electrolytes ▪
Travasol 3.5%, 5.5%, and 8.5% with electrolytes ▪
Travasol (SF) 3.5%, 5.5%, and 8.5% with electrolytes ▪
TrophaAmine 6% and 10%

pH 5 to 7

USUAL DOSE

0.5 to 2 Gm/kg of body weight/24 hr. Actual dose will depend on several factors, including daily protein and calorie requirements, disease state, physical condition, weight, and patient's metabolic and clinical response. Protein amino acid products are available in general, renal failure, hepatic failure/encephalopathy, and metabolic stress formulations. See [Precautions/Monitor](#).

PEDIATRIC DOSE

Consult pharmacist; not all products are approved for use in pediatric patients. Amino acid formulations developed specifically for nutritional support of infants and other pediatric patients are available (e.g., Aminosyn P/F sulfite free). Amino acid concentrations

greater than 2.5% are too concentrated for infants; older pediatric patients may tolerate concentrations up to 5%. See *Maternal/Child*.

Actual dose and total volume will depend on several factors including age, protein requirements, disease state, physical condition, renal function, and weight. Infants and children require different percentages of all components. The primary source of calories is dextrose. IV fat emulsion may be used to supplement energy intake. Kcal requirements may be increased in malnutrition or stress.

One source indicates that normal energy requirements vary according to age and suggests the following:

1 to 7 years: 75 to 90 kcal/kg/day

7 to 12 years: 60 to 75 kcal/kg/day

12 to 18 years: 30 to 60 kcal/kg/day

Another source suggests a Gm/kg/day dose based on age:

1 to 3 years: 2 to 2.5 Gm/kg/day

4 to 12 years: 2 Gm/kg/day

13 to 15 years: 1.7 Gm/kg/day

16 years and older: 1.5 Gm/kg/day

A third source suggests a Gm/kg/day dose based on age and condition:

Pediatric patients from neonates to 10 years of age:

Unstressed and over 1 year of age: 1 to 1.2 Gm/kg/day

Unstressed and 1 year of age or under: 1.6 to 2.2 Gm/kg/day

Low stress or maintenance: 2 to 2.5 Gm/kg/day

Low-stress anabolism: 2.5 to 3 Gm/kg/day

Critically ill or severe burn injury: 2.5 to 3.5 Gm/kg/day

DILUTION

Dilute under strict aseptic techniques according to manufacturer's specific instructions. Some solutions are very concentrated; are for compounding only, not for direct infusion. Check label for aluminum content; see *Precautions*. Most commonly mixed with dextrose (nonprotein calorie source), electrolytes, vitamins, and trace elements to provide total parenteral nutrition (TPN) or peripheral parenteral nutrition (PPN). Intravenous lipids, providing a second nonprotein calorie source and a source of essential fatty acids, may be mixed with the dextrose/amino acid solution or run simultaneously. Use promptly after mixing; laminar flow hood preferred; refrigerate briefly if necessary, and discard any unused portion. Use only clear solutions; observe against adequate light for particulate matter or evidence of container damage.

Filters: Use of in-line filters is recommended. Use of 0.22-micron in-line microfilter for dextrose and amino acids. Use a 1.2-micron in-line microfilter for solutions with lipids (3 in 1). A precipitate is very difficult to detect in solutions that contain lipids.

Storage: Store unopened protein amino acid solutions at 20° to 25° C (68° to 77° F). Protect from freezing or excessive heat. Protect from light until use. Manufacturer recommends refrigeration after any additives (e.g., IV lipids, electrolytes, minerals) are added. Some preparations can be refrigerated for only short periods, preferably no more than 24 hours. When prepared for home use, some preparations have been refrigerated for up to 14 days (dextrose and amino acids) or up to 7 days with lipids added. Leave vitamins (e.g., M.V.I.) out until time of administration. Consult pharmacist. Discard any single bottle after 24 hours at CRT.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Most **incompatibilities** relate to the preparation (chloride as opposed to phosphate), amount of medication added, other additives present, and thoroughness of mixing. Consult with the pharmacist before mixing any drugs in protein (amino acid) products. Many TPN solutions contain some phosphate. The addition of calcium salts may cause a pre-

cipitate. These additives must be mixed by the pharmacist. Specific amounts, calculations, temperature (precipitate forms more readily at room temperature), and order of dilution are required. Do not administer solutions containing calcium through the same administration set as blood; coagulation may occur.

Manufacturers suggest that only required nutritional products should be added, but H₂ receptors (e.g., ranitidine [Zantac]), insulin, and heparin are frequently added to selected products. Other drugs may be **compatible** for specific lengths of time. Mix thoroughly. Do not store.

One source suggests the following **compatibilities**:

Solution: Fat emulsion 10% IV.

Additive: See *general comments under Compatibility*. Amikacin (Amikin), aminophylline, ampicillin, aztreonam (Azactam), cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefoxitin (Mefoxin), ceftazidime (Fortaz), cefuroxime (Zinacef), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cyclosporine (Sandimmune), cytarabine (ARA-C), dopamine, epoetin alfa (Epoen), famotidine (Pepcid IV), fluorouracil (5-FU), folic acid, furosemide (Lasix), gentamicin, heparin, iron dextran, isoproterenol (Isuprel), lidocaine, meperidine (Demerol), methotrexate, methyl dopate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), midazolam (Versed), morphine, multivitamins (M.V.I.), nafcillin (Nallpen), norepinephrine (Levophed), octreotide (Sandostatin), ondansetron (Zofran), oxacillin (Bactocill), penicillin G potassium and sodium, phytonadione (vitamin K₁), ranitidine (Zantac), sodium bicarbonate, tacrolimus (Prograf), tobramycin, vancomycin.

Y-site: Alprostadil, amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), argatroban, ascorbic acid, atracurium (Tracrium), aztreonam (Azactam), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), cefazolin (Ancef), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftaroline (Teflaro), ceftazidime (Fortaz), cefuroxime (Zinacef), chloramphenicol (Chloromycetin), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cyclosporine (Sandimmune), cytarabine (ARA-C), dexamethasone (Decadron), digoxin (Lanoxin), diphenhydramine (Benadryl), dobutamine, dopamine, doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), epinephrine (Adrenalin), erythromycin (Erythrocin), famotidine (Pepcid IV), fentanyl (Sublimaze), fluconazole (Diflucan), fluorouracil (5-FU), folic acid, foscarnet (Foscavir), furosemide (Lasix), ganciclovir (Cytovene), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), ifosfamide (Ifex), imipenem/cilastatin (Primaxin), insulin (regular), isoproterenol (Isuprel), leucovorin calcium, lidocaine, lorazepam (Ativan), magnesium sulfate, mannitol, meperidine (Demerol), meropenem (Merrem IV), mesna (Mesnex), methotrexate, methyl dopate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), micafungin (Mycamine), milrinone (Primacor), mitoxantrone (Novantrone), morphine, multivitamins (M.V.I.), nafcillin (Nallpen), nalbuphine, nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), octreotide (Sandostatin), ondansetron (Zofran), oxacillin (Bactocill), paclitaxel (Taxol), penicillin G, penicillin G potassium, pentobarbital (Nembutal), phenobarbital (Luminal), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), propofol (Diprivan), ranitidine (Zantac), sargramostim (Leukine), sodium bicarbonate, sulfamethoxazole/trimethoprim, tacrolimus (Prograf), thiotepa, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vecuronium, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Begin parenteral nutrition at 0.5 to 2 mL/min and increase gradually as tolerated until the target rate is reached. The rate of a nutrient infusion is governed by the protein requirement and by the patient's glucose tolerance. With the correct parenteral nutrition formulation, fluid, protein, and calorie requirements should be met at the target rate. **Total daily**

dose should be evenly distributed over the 24-hour period. Maintain a constant drip rate. Use of infusion pump and microfilter (0.22 micron for dextrose and amino acids, 1.2 micron for solutions with lipids [3 in 1]) recommended. Precipitate very difficult to detect in solutions that contain lipids. There are specific situations (e.g., cyclic TPN primarily used in home care patients) where a daily dose is given over less than 24 hours. Range is from 10 to 14 hours. Usually administered overnight, allowing individuals requiring prolonged TPN to maintain their daytime activities.

Pediatric rate: Usually begin with a one-half strength nutritional solution at 60 to 70 mL/kg/day. May be gradually increased over 48 hours until full strength and increased to 125 to 150 mL/kg/day. See [all comments under Pediatric Dose, Rate of Administration/Adult, and Maternal/Child.](#)

ACTIONS

Supplies essential and nonessential amino acids and calories with the intent of promoting protein production (anabolism) and preventing protein breakdown (catabolism). Promotes wound healing, and acts as a buffer in intracellular and extracellular body fluids. Various brands supply additional calories with alcohol, fructose, or glucose. These additional calories permit available protein to be used for repair of tissue in addition to meeting basic caloric needs.

INDICATIONS AND USES

To prevent nitrogen loss or to reverse negative nitrogen balance in severe illness when oral alimentation is not practical for prolonged periods; when normal GI absorption is impaired; when metabolic requirements for protein and calories are substantially increased, as with extensive burns; or when morbidity and mortality may be reduced by replacing amino acids lost from tissue breakdown, thereby preserving tissue reserves, as in acute renal failure.

CONTRAINDICATIONS

Hypersensitivity to any component, hepatic coma, or metabolic disorders involving impaired nitrogen utilization. Some manufacturers also list acidosis, anuria, azotemia, decreased circulating blood volume, severe liver disease, and metabolic disorders with impaired amino acid metabolization. ■ Solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Catheter insertion for administration of central parenteral nutrition is a sterile surgical procedure (must be a large vein [subclavian or superior vena cava preferred]; 50% glucose is a sclerosing solution). ■ Peripheral veins are suitable for specific products (peripheral parenteral nutrition) when amino acid products are diluted with 2.5%, 5%, or 10% dextrose. ■ Safe and effective use of central venous nutrition requires knowledge of nutrition as well as clinical expertise in recognition and treatment of the complications that can occur. Frequent clinical evaluation and laboratory determinations are necessary for proper monitoring of central venous nutrition; see [Monitor](#). ■ Amino acids given without carbohydrates may cause ketone accumulation. ■ Use caution in impaired hepatic function; may cause serum amino acid imbalances, metabolic alkalosis, prerenal azotemia, hyperammonemia, stupor, and coma. ■ Use caution in impaired renal function; may further increase BUN. ■ Concentrated dextrose solutions, if administered too rapidly, may result in significant hyperglycemia and possible hyperosmolar syndrome characterized by mental confusion and loss of consciousness. ■ Fatty infiltration of the liver, acute respiratory failure, and difficulty in weaning hypermetabolic patients from the respirator may be caused by excessive carbohydrate calories. ■ Avoid circulatory overload, particularly in patients with cardiac insufficiency. ■ Solutions containing electrolytes should be used with caution in selected patients (e.g., sodium ions, use caution in patients with CHF, renal insufficiency, and clinical states with edema with sodium retention; potassium ions, use caution in patients with hyperkalemia, renal insufficiency, and conditions with potassium retention; acetate ions from inorganic salts, use caution in patients with metabolic or respiratory alkalosis). ■ Some solutions may contain alumi-

num. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive greater than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. ■ Some solutions may contain sulfites; use caution in patients allergic to sulfites. ■ Essential fatty acid deficiency has been observed in patients on long-term TPN (more than 5 days). The use of fat emulsion to provide 4% to 10% of total caloric intake as linoleic acid may help to prevent this deficiency.

Monitor: Specific baseline studies required before administration: CBC, platelet count, PT, BUN, SCr, electrolytes, glucose, triglycerides, cholesterol, albumin, bilirubin, liver function tests (e.g., AST, ALT, LDH), acid-base balance, fluid balance, weight, body length and head circumference (in infants), and immunocompetence. Frequent clinical evaluation and lab tests are indicated during therapy. ■ Monitor intake and output and weight. More frequent monitoring of serum glucose and additional insulin may be indicated in patients with diabetes. After stabilization, measurement of urine glucose and ketones every 8 hours is suggested. ■ Follow a strict, regular aseptic routine to care for insertion site. ■ Single-port central venous catheters to be used only for the nutritional regimen. Do not draw blood samples, transfuse blood, or administer other medications. Pseudoagglutination and thrombosis can occur, risk of contamination is great, and validity of results is compromised. Multiple-port central venous catheters may be used for these additional procedures. Observe specific protocols. ■ Monitor BUN frequently. Discontinue infusion if BUN exceeds normal postprandial limits and continues to rise. ■ Blood ammonia levels important, especially in infants. ■ Check frequently for any signs of extravasation. ■ Observe for any signs of infection. ■ Additional insulin coverage may be required, especially when dosage is increased too rapidly or with maximum doses. ■ To prevent rebound hypoglycemia, may need to decrease rate gradually over 2 to 6 hours. ■ Discard any single bottle after 24 hours. Replace administration set every 24 to 72 hours depending on formulation and facility-specific policies. ■ See **Precautions**.

Maternal/Child: Category C: use during pregnancy only if clearly needed. ■ Safety for use during breast-feeding not established; effects unknown. Use caution; has potential for adverse effects in nursing infants (e.g., hyperammonemia). ■ Use with caution in pediatric patients with renal failure. ■ Monitor neonates and very small infants carefully to maintain fluid and electrolyte balance, including monitoring of blood glucose. ■ Use hypertonic dextrose (component of parenteral nutrition) with extreme caution in low-birth-weight or septic infants. May cause hyperglycemia, hypoglycemia, or increased serum osmolality with possible intracerebral hemorrhage. Monitor serum glucose frequently. Solutions should not exceed 718 mOsm/L. ■ Amino acid concentrations greater than 2.5% are too concentrated for infants. ■ Hyperammonemia is of particular significance in infants. Can cause mental retardation; measure blood ammonia frequently.

Elderly: Differences in responses between elderly and younger patients have not been identified; however, incidence of fluid overload and electrolyte imbalance may be increased. Monitor closely. ■ Lower end initial doses may be appropriate in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy. Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

Tetracycline may reduce protein-sparing effects. ■ **Magnesium-containing solutions** may have an additive CNS depressive effect with barbiturates, hypnotics, narcotics, or systemic anesthetics; dose adjustment of these agents may be indicated.

SIDE EFFECTS

Abdominal pains, anaphylaxis, bone demineralization, changes in levels of consciousness, convulsions, dehydration, edema at the site of injection, electrolyte imbalances,

glycosuria, hyperammonemia, hyperglycemia, hyperpyrexia, hypertension, metabolic acidosis and/or alkalosis, osmotic dehydration, phlebitis and thrombosis, pulmonary edema, rebound hypoglycemia, septicemia, vasodilation, vomiting, weakness.

ANTIDOTE

Notify the physician of all side effects. An alternate brand may cause fewer problems, or amounts of glucose or additives may be adjusted to correct the problem. Many of the side effects listed will respond to a reduced rate. Some will require catheter insertion at a new site. Treat symptomatically and resuscitate as necessary. Stop infusion immediately for any signs of acute respiratory distress. May represent pulmonary embolus or interstitial pneumonitis, which may be caused by a precipitate of electrolytes (e.g., calcium and phosphates) in the solution.

PROTEIN C CONCENTRATE (HUMAN) (PROH-teen C KON-sen-trayt)	Anticoagulant Antithrombotic
Ceprotrin	pH 6.7 to 7.3

USUAL DOSE

(International units [IU])

Dose, administration frequency, and duration of treatment depend on the severity of the protein C deficiency, the patient’s age, the clinical condition of the patient, and the patient’s plasma level of protein C. Initiate therapy as directed in the chart below and adjust the dosage regimen according to the pharmacokinetic profile for each patient. See *Dose Adjustments* and *Monitor*.

Protein C Concentrate Dosing Schedule for Acute Episodes, Short-Term Prophylaxis, and Long-Term Prophylaxis			
	Initial Dose*	Subsequent 3 Doses*	Maintenance Dose*
Acute episodes/ short-term prophylaxis†	100 to 120 IU/kg	60 to 80 IU/kg every 6 hours	45 to 60 IU/kg every 6 or 12 hours
Long-term prophylaxis	N/A	N/A	45 to 60 IU/kg every 12 hours

*Dose regimen should be adjusted according to the pharmacokinetic profile for each individual patient.

†Continue therapy until the desired anticoagulation is achieved.

PEDIATRIC AND NEONATAL DOSE

See *Usual Dose* and *Maternal/Child*.

DOSE ADJUSTMENTS

For treatment of acute episodes or with short-term prophylaxis, adjust dose according to the pharmacokinetic profile of the patient. Adjust to maintain a target peak protein C activity of 100%. After resolution of the acute episode, continue patient on the same dose to maintain a trough protein C activity above 25% for the duration of treatment. ■ Higher peak protein C activity levels may be required for situations in which there is an increased risk of thrombosis (e.g., infection, surgical intervention, trauma). Maintaining trough protein C activity levels above 25% is recommended. ■ Use in renal and hepatic impairment has not been studied. See *Precautions*.

DILUTION

(International units [IU])

Available in single-dose vials that contain 500 or 1,000 International Units (IU) of protein C. Reconstitute the 500-IU vial with 5 mL of SWFI and the 1,000-IU vial with 10 mL of SWFI to provide a single dose of human protein C at a concentration of 100 IU/mL. Vials also contain human albumin, trisodium citrate dihydrate, and sodium

chloride as excipients. Bring the vials of protein C and SWFI (supplied diluent) to room temperature. Remove tops of vials and cleanse stoppers. Insert one end of the manufacturer-supplied double-ended transfer needle through the center of the diluent vial stopper. Invert the diluent vial and insert the free end of the double-ended transfer needle into the protein C vial. The vacuum in the vial should pull in the diluent. If a vacuum is not present, do not use the vial. Remove the double-ended transfer needle from the diluent vial, then from the protein C vial. Gently swirl the protein C vial until the powder is completely dissolved. The powder must be completely dissolved to prevent active materials from being removed by the filter needle during infusion. Solution should be colorless to slightly yellowish and clear to slightly opalescent. Attach manufacturer-supplied filter needle to a disposable syringe. Withdraw plunger to admit air into the syringe and inject air into the protein C vial. Withdraw reconstituted solution from the vial into the syringe. Remove the filter needle and attach a suitable needle or infusion set for administration. The filter needle is intended to filter the contents of a single vial of protein C.

Filters: Filtering required; see [Dilution](#).

Storage: Refrigerate unopened vials in original carton at 2° to 8° C (36° to 46° F); protect from light. Shelf life is 3 years. Do not use beyond expiration date. Do not freeze. Administer reconstituted product within 3 hours of reconstitution. Single-dose vial; discard any unused product after entry into vial.

COMPATIBILITY

Specific information not available. Consider specialized use.

RATE OF ADMINISTRATION

Administer as an infusion.

Adults and pediatric patients over 10 kg: Maximum rate 2 mL/min.

Pediatric patients less than 10 kg: Maximum rate 0.2 mL/kg/min.

ACTIONS

A precursor of the vitamin K–dependent anticoagulant glycoprotein (serine protease) that is synthesized in the liver. Manufactured from human plasma. Numerous processes are used during manufacturing to minimize the risk for viral transmission; see [Precautions](#). Protein C is converted to activated protein C (APC), a serine protease with potent anticoagulant effects. APC exerts its effect by inactivation of the activated forms of factors V and VIII, which leads to a decrease in thrombin formation. APC also has been shown to have profibrinolytic effects. A complete absence of protein C is not compatible with life. A severe deficiency of this protein leads to unchecked coagulation activation, resulting in thrombin generation and intravascular clot formation and thrombosis. An increase in plasma levels of protein C can be seen within ½ hour after administration of protein C concentrate. Replacement of protein C in protein C–deficient patients is expected to control or, if given prophylactically, prevent thrombotic complications. In clinical studies, patients with severe congenital protein C deficiency were treated more effectively with protein C concentrate than those treated with modalities such as fresh frozen plasma or conventional anticoagulants. Half-life ranges from 4.9 to 14.7 hours, with a median of 9.8 hours. In patients with acute thrombosis, purpura fulminans, and skin necrosis, both the half-life and the increase in protein C plasma level may be reduced.

INDICATIONS AND USES

Prevention and treatment of venous thrombosis and purpura fulminans in patients with severe congenital protein C deficiency. A replacement therapy for pediatric and adult patients.

CONTRAINDICATIONS

None known.

PRECAUTIONS

Initiate treatment under the supervision of a physician experienced in replacement therapy with coagulation factors/inhibitors and in a facility where monitoring of protein C activity is available. ■ Half-life of protein C concentrate may be shortened in certain

clinical conditions such as acute thrombosis, purpura fulminans, and skin necrosis. Patients treated during the acute phase of their disease may display much lower increases in protein C activity. ■ May contain trace amounts of mouse protein and heparin due to the manufacturing process. Hypersensitivity reactions are possible; see **Monitor** and **Antidote**. ■ Manufactured from pooled human plasma. Special screening and purification techniques are used to minimize the risk of transmitting infectious agents (e.g., hepatitis A, human parvovirus B19, Creutzfeldt-Jakob disease [CJD]), but transmission cannot be completely ruled out. Appropriate vaccination (hepatitis A and B) should be considered for patients receiving human-derived protein C. ■ Contains heparin. Discontinue if heparin-induced thrombocytopenia (HIT) is suspected; see **Monitor**. ■ Use with caution in patients who may be sensitive to a sodium load (e.g., patients with HTN or CHF); see **Monitor**. ■ Patients being started on anticoagulant therapy with a vitamin K–antagonist anticoagulant (e.g., warfarin) may experience a transient hypercoagulable state before desired anticoagulation is reached. Patients may be at increased risk for warfarin-induced skin necrosis. Initiate warfarin therapy at a low dose and adjust incrementally as indicated by INR monitoring. Continue protein C replacement until stable anticoagulation with warfarin is reached. ■ Bleeding episodes have been reported. Simultaneous administration with alteplase (Activase, tPA) and/or anticoagulants (e.g., warfarin, heparin) may increase the risk of bleeding; see **Drug Interactions**. ■ Use with caution in patients with renal and/or hepatic impairment. Has not been studied.

Monitor: Measure protein C activity using a chromogenic assay before and during treatment. ■ In the case of an acute thrombotic event, it is recommended that protein C activity measurements be obtained immediately before the next injection until the patient is stabilized. Once stabilized, continue monitoring to maintain the trough protein C level above 25%. ■ Coagulation parameters (e.g., INR/PT) should be monitored. However, a correlation between coagulation parameters and protein C activity levels has not been determined. ■ Discontinue therapy and check platelet count if heparin-induced thrombocytopenia is suspected. ■ Contains more than 200 mg of sodium. Monitor fluid and electrolyte status, especially in patients on a low-sodium diet and/or in patients with renal impairment. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, hives, hypotension, generalized itching, tightness of the chest, and/or wheezing).

Patient Education: Manufactured from pooled human plasma. Risk of transmission of infectious agents cannot be ruled out. Discuss risk versus benefit of therapy with physician. ■ Review vaccination status with physician. Vaccination against hepatitis A and B should be considered. ■ Contains sodium. ■ Report S/S of hypersensitivity reaction immediately (e.g., hives, generalized itching, tightness of the chest, wheezing). ■ Consultation with a physician is required if abdominal pain, chills, drowsiness, fever, jaundice, nausea and vomiting, prolonged poor appetite, runny nose, tiredness, or dark urine occur.

Maternal/Child: Category C: safety for use in pregnancy and lactation has not been established. ■ Has been used in patients as young as 2 days of age. ■ Pharmacokinetics in the very young may differ from that of older pediatric patients and adults. Systemic exposure (C_{max} and AUC) may be reduced due to a faster clearance, larger volume of distribution, and/or shorter half-life. Doses must be individualized based on protein C activity levels; see **Dose Adjustments**.

Elderly: Specific differences in safety and efficacy have not been identified.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Simultaneous use with **alteplase** (Activase, tPA) and **anticoagulants** (e.g., warfarin, heparin) may increase the risk of bleeding. ■ Patients being started on anticoagulant therapy with a **vitamin K–antagonist anticoagulant** (e.g., warfarin) may experience a transient hypercoagulable state before desired anticoagulation is reached; see **Precautions**.

SIDE EFFECTS

The most commonly reported side effects are rash, itching, and light-headedness.

Post-Marketing: Fever, hemothorax, hyperhidrosis, hypotension, and restlessness.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Discontinue protein C concentrate for any serious reaction (e.g., HIT, hypersensitivity). Treat hypersensitivity reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Resuscitate as necessary.

PYRIDOXINE HYDROCHLORIDE

(peer-ih-**DOX**-een hy-droh-**KLOR**-eyed)

Nutritional supplement
(vitamin)
Antidote

Vitamin B₆

pH 2 to 3.8

USUAL DOSE

Pyridoxine dependency syndrome: 30 to 600 mg/day.

Drug-induced pyridoxine deficiency: 50 to 200 mg/day for 3 weeks. Follow with 25 to 100 mg/day as needed.

Prophylaxis or treatment of pyridoxine deficiency in patients receiving parenteral nutrition: May be added to parenteral nutrition; dose will depend on patient condition.

INH poisoning (greater than 10 Gm) (unlabeled): 4 Gm IV followed by 1 Gm IM every 30 minutes. Total pyridoxine dose should equal ingested INH dose.

Cycloserine poisoning (unlabeled): 300 mg/day. Higher doses may be required.

Hydrazine poisoning (unlabeled): 25 mg/kg. Give one third of dose IM and remainder as a 3-hour infusion.

Gyrometra mushroom poisoning (unlabeled): 25 mg/kg over 15 to 30 minutes. Repeat as needed.

PEDIATRIC DOSE

See [Maternal/Child](#).

Pyridoxine-dependent seizures: 10 to 100 mg.

DOSE ADJUSTMENTS

Removed by hemodialysis. Dialysis patients may require higher doses.

DILUTION

May be given by IV injection undiluted or added to most IV solutions and given as an infusion. See chart on inside back cover.

Storage: Store below 40° C unless otherwise stated by manufacturer. Deteriorates in excessive heat; protect from heat and light.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with alkaline solutions, iron salts, oxidizing solutions.

RATE OF ADMINISTRATION

50 mg or fraction thereof over 1 minute if given undiluted.

ACTIONS

Vitamin B₆ is water soluble. It is a coenzyme necessary for the metabolism of proteins, carbohydrates, and lipids. Involved in many reactions including the conversion of tryptophan to nicotinamide and serotonin, breakdown to glucose-1-phosphate, synthesis of gamma aminobutyric acid (GABA) in the CNS (energy transformation in brain and nerve cells), and synthesis of heme. Metabolized by the liver, and excreted in the urine.

INDICATIONS AND USES

Prophylaxis and treatment of pyridoxine deficiency. Deficiency may be due to inadequate diet, inborn error of metabolism, or concomitant drug use.

Unlabeled uses: Treatment of INH, hydrazine, and cycloserine poisoning. Treatment of neurologic effects of Gyrometra mushroom poisoning. Nausea and vomiting associated with pregnancy.

CONTRAINDICATIONS

Known sensitivity to pyridoxine.

PRECAUTIONS

Used IV only when oral dosage not acceptable. ■ Deficiency can cause abnormal EEG. ■ Need for pyridoxine increases with amount of protein in diet. Chronic administration of large doses may cause adverse neurologic effects.

Maternal/Child: Category A: requirements are increased in pregnancy and breast-feeding. Do not exceed RDA. ■ Large doses in utero can cause pyridoxine-dependency syndrome in newborn. ■ May inhibit breast-feeding. ■ Safety for use in pediatric patients not established.

DRUG/LAB INTERACTIONS

An antagonist to **levodopa**. Does not antagonize carbidopa/levodopa combination (Sinemet). ■ **Isoniazid** is a vitamin B₆ antagonist and will cause deficiency disease. ■ **Cycloserine, penicillamine, hydralazine, oral contraceptives** may increase pyridoxine requirements. ■ May decrease **phenobarbital and phenytoin** (Dilantin) levels. ■ Excessive doses may elevate AST.

SIDE EFFECTS

Almost nonexistent; some slight flushing or feeling of warmth may occur. With larger doses, ataxia, low folic acid levels, paresthesias, somnolence, and withdrawal seizures in infants with high maternal doses may occur.

ANTIDOTE

No antidote is known or has been needed. Symptomatic treatment of side effects may be indicated.

QUINIDINE GLUCONATE INJECTION **BBW**

Antiarrhythmic

(KWIN-ih-deen GLOO-ko-nayt in-JEK-shun)

pH 5.5 to 7

USUAL DOSE

Cardiac monitoring required with IV administration; see **Monitor**. *All doses are for quinidine gluconate only. See prescribing information for doses by other routes (e.g., quinidine sulfate PO).*

Test dose: 200 mg PO or IM is recommended by some sources to determine the possibility of idiosyncratic reactions.

Symptomatic atrial fibrillation/flutter: Given as an infusion not to exceed a rate of 0.25 mg/kg/min. Most arrhythmias that will respond to IV quinidine will respond to a total dose of less than 5 mg/kg, but some patients may require a total dose of up to 10 mg/kg. If conversion has not occurred after a dose of 10 mg/kg, discontinue infusion and consider other means of conversion (e.g., direct current cardioversion). Maintain with an oral quinidine preparation.

Life-threatening ventricular arrhythmias: Dosing regimens for use in controlling life-threatening ventricular arrhythmias have not been adequately studied. Regimens are usually similar to the regimen for treatment of symptomatic atrial fibrillation/flutter.

Plasmodium falciparum malaria: A loading dose should not be used if the patient has received more than 40 mg/kg of quinine in the previous 48 hours or mefloquine in the previous 12 hours. If appropriate, administer a loading dose of 24 mg/kg of quinidine gluconate in 250 mL NS as an infusion over 4 hours. Follow with a maintenance dose of 12 mg/kg quinidine gluconate in 125 to 250 mL NS over 4 hours. Begin maintenance dose 8 hours after initiation of loading dose. Repeat every 8 hours for 7 days or transfer to oral therapy. An alternate regimen is a loading dose of 10 mg/kg of quinidine gluconate in approximately 5 mL/kg NS over 1 to 2 hours. Follow with a maintenance infusion of 20 mcg/kg/min quinidine gluconate. Transfer to oral therapy if possible. Continue quinidine therapy (IV or oral) for up to 72 hours or until parasitemia is less than 1%, whichever comes first. After completion of quinidine course, therapy is continued with other antimalarial medications.

PEDIATRIC DOSE

Plasmodium falciparum malaria: See **Usual Dose**.

Antiarrhythmic (unlabeled): One source recommends a test dose of 2 mg/kg (60 mg/M²) of quinidine gluconate (up to 200 mg) IM or PO. If no reaction, follow with 2 to 10 mg/kg/dose of quinidine gluconate every 3 to 6 hours. Use IV only when oral routes not possible; see **Maternal/Child**.

DOSE ADJUSTMENTS

Reduce dose in patients with renal or hepatic impairment or in patients with CHF. ■ Another source suggests administering 75% of the normal dose to patients with a CrCl less than 10 mL/min and suggests that a larger initial dose may be indicated in hepatic impairment, but maintenance doses should be reduced by 50% with close monitoring of serum levels. ■ Reduced dose may be indicated in the elderly based on potential for decreased organ function and concomitant disease or drug therapy. ■ See **Drug/Lab Interactions**.

DILUTION

Symptomatic atrial fibrillation/flutter: 800 mg (10 mL) must be diluted with 40 mL of D5W to provide a final concentration of 16 mg/mL.

Plasmodium falciparum malaria: Add loading dose to 250 mL of NS and maintenance dose to 125 to 250 mL of NS. In the alternative regimen, the loading dose is added to 5 mL/kg of NS. The maintenance infusion is prepared by mixing 800 mg (10 mL) with 40 mL of D5W to provide a final concentration of 16 mg/mL. Use only clear, colorless solutions. May be adsorbed to PVC tubing; minimize tubing length.

Storage: Store at CRT. Protect from light. Infusion solution containing 16 mg/mL in D5W is stable for 24 hours at RT or up to 48 hours at 4° C (40° F).

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Additive: Milrinone (Primacor), ranitidine (Zantac), verapamil.

Y-site: Diazepam (Valium), heparin, milrinone (Primacor), nesiritide (Natrecor).

RATE OF ADMINISTRATION

Symptomatic atrial fibrillation/flutter: Do not exceed a rate of 0.25 mg/kg/min (1 mL/kg/hr) of properly diluted solution. Another source suggests not exceeding a rate equal to or less than 10 mg/min.

Plasmodium falciparum malaria: See rates outlined in **Usual Dose**. Use of an infusion pump recommended. Too-rapid administration may cause peripheral vascular collapse and severe hypotension.

For all indications: Decrease rate or interrupt infusion if corrected QT interval exceeds 0.6 seconds, corrected QT interval exceeds baseline by more than 25%, QRS widening exceeds 50% of baseline, or symptomatic hypotension that does not respond to fluid expansion develops.

ACTIONS

An antimalarial schizonticide and an antiarrhythmic with Class 1a activity. A dextro-isomer of quinine. Decreases myocardial excitability and conduction velocity. May suppress atrial fibrillation or flutter by increasing the effective refractory period and increasing the action potential duration in atrial and ventricular muscle and in the His-Purkinje system. Has anticholinergic, vasodilating, and negative inotropic actions. As an antimalarial agent, it acts primarily as an intra-erythrocytic schizonticide, with little effect on sporozoites or pre-erythrocytic parasites. Rapidly distributed into all tissues except the brain. 80% to 88% bound to plasma proteins. Metabolized in the liver by CYP3A4 to several metabolites, some of which have antiarrhythmic activity. Half-life is 6 to 8 hours. Eliminated mainly in urine. Less than 5% of dose excreted in feces. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of life-threatening *Plasmodium falciparum* malaria. ■ Conversion of atrial fibrillation/flutter. Indicated when rapid therapeutic effect is required or when oral therapy is not feasible as a means of restoring normal sinus rhythm in patients with symptomatic atrial fibrillation/flutter. ■ Treatment of ventricular arrhythmias (e.g., sustained ventricular tachycardia) that in the judgment of the physician are life threatening. Because of the proarrhythmic effects of quinidine, its use for treatment of less severe arrhythmias is not recommended. (*The use of quinidine for treatment of arrhythmias has largely been replaced by more effective, safer antiarrhythmics [e.g., amiodarone (Nexterone)] and/or nonpharmacologic therapies [e.g., ablation].*)

CONTRAINDICATIONS

Known hypersensitivity to quinidine or cinchona (e.g., febrile reactions, skin eruption, thrombocytopenia), myasthenia gravis, history of thrombocytopenic purpura with quinidine administration. ■ In the absence of a functioning artificial pacemaker, quinidine is also contraindicated in any patient whose cardiac rhythm is dependent on a junctional or idioventricular pacemaker, including patients in complete atrioventricular block. ■ **Contraindicated with ritonavir (Norvir).**

PRECAUTIONS

A meta-analysis of data from several randomized, controlled studies in patients with atrial flutter and fibrillation indicates that quinidine therapy may be associated with a mortality rate greater than 3 times higher than that associated with placebo. ■ A meta-analysis of patients with various non-life-threatening ventricular arrhythmias showed that mortality associated with quinidine was consistently greater than that associated with various other antiarrhythmic agents (e.g., flecainide, mexiletine,

propafenone, tocainide). ■ Risk associated with antiarrhythmic drug therapy probably is greatest in patients with structural heart disease. ■ IM injection of quinidine is not recommended; the kinetics of absorption may vary with the patient's peripheral perfusion. ■ Causes prolongation of the QTc interval, which can lead to torsades de pointes. Risk increased in patients with bradycardia, hypokalemia, hypomagnesemia, and high serum quinidine levels. Best predictor of this arrhythmia appears to be the length of the QTc interval. Use quinidine with extreme caution in patients who have pre-existing long QT syndromes, who have a history of torsades de pointes, or who have previously responded to quinidine (or other antiarrhythmics) with marked lengthening of the QTc. ■ Other ventricular arrhythmias (e.g., frequent extrasystoles, ventricular tachycardia, ventricular flutter, and ventricular fibrillation) have been reported. ■ Has been associated with marked sinus node depression and bradycardia in patients with sick sinus syndrome. ■ Use extreme caution with first- or second-degree blocks, extensive myocardial damage, digoxin intoxication, impaired liver or kidney function, and CHF. ■ Use caution in atrial flutter or fibrillation; may require pretreatment with conduction-reducing drugs such as digoxin, verapamil, diltiazem, or beta-blockers to prevent progressive reduction of AV block and an extremely rapid ventricular rate. ■ Even in patients without pre-existing cardiac disease, antimalarial use of quinidine has caused hypotension, increased QRS and QT intervals, and cinchonism (e.g., dizziness, ringing in ears). ■ Because quinidine opposes the atrial and AV nodal effects of vagal stimulation, physical or pharmacologic vagal maneuvers used to terminate paroxysmal supraventricular tachycardia may be ineffective in patients taking quinidine. ■ See [Drug/Lab Interactions](#).

Monitor: Monitor patient's ECG and BP continuously (plus parasitemia in malaria). Too-rapid administration may cause marked hypotension or peripheral vascular collapse. ■ Keep patient in supine position. ■ Discontinue IV use when the normal sinus rhythm returns, HR falls to 120 beats/min, or any signs of cardiac toxicity occur (QRS complex widens to 130% of its pretreatment duration, QTc interval widens to 130% of its pretreatment duration and is then longer than 500 msec, P waves disappear, or patient develops significant tachycardia, symptomatic bradycardia, or hypotension). ■ Monitor serum levels if quinidine is used over 48 hours. ■ See [Drug/Lab Interactions](#).

Patient Education: Promptly report breathing difficulty, dizziness, headache, nausea, ringing in the ears, skin rash, or visual disturbances.

Maternal/Child: Category C: safety for use in pregnancy not established. ■ Safety for use in breast-feeding not established. Present in breast milk. Avoid breast-feeding if possible. ■ Safety and effectiveness for antiarrhythmic use in pediatric patients not established. ■ In antimalarial trials, was as safe and effective in pediatric patients as in adults. ■ Half-life in pediatric patients is 3 to 4 hours.

Elderly: Reduced dose may be indicated; see [Dose Adjustments](#). ■ Half-life prolonged; frequency and severity of side effects may be increased. ■ Response of elderly versus younger patients not documented.

DRUG/LAB INTERACTIONS

Interacts with many medications. Consult pharmacist. ■ Drugs that alkalinize urine (e.g., **sodium bicarbonate**, **carbonic-anhydrase inhibitors**, **thiazide diuretics**) reduce renal elimination of quinidine. ■ Quinidine levels increased with coadministration of **cimetidine** (Tagamet) or **amiodarone** (Nexterone). ■ Quinidine levels decreased with coadministration of **nifedipine** (Procardia). ■ Hepatic elimination increased with coadministration of **phenobarbital** (Luminal), **phenytoin** (Dilantin), and **rifampin** (Rifadin). ■ Hepatic clearance reduced when coadministered with **diltiazem** (Cardizem) or **verapamil**. ■ Metabolism may be decreased and serum levels increased with concurrent use of **ketoconazole** (Nizoral) and **itraconazole** (Sporanox); monitoring of quinidine levels suggested. Causes marked increase in **digoxin** (Lanoxin) levels. Digoxin dose reduction and monitoring required. ■ Potentiates **warfarin** (Coumadin). Warfarin dose reduction and monitoring required. ■ Increases serum levels of **haloperidol** (Haldol) and **procainamide** (Pronestyl). ■ Causes variable slowing of the metabolism of **nifedipine** (Procardia) and most likely of **felodipine** (Plendil), **nicardipine** (Cardene), and **nimodipine**. ■ Potentiates the

action of **depolarizing and nondepolarizing neuromuscular blockers** (e.g., succinylcholine [Anectine], pancuronium). ■ Therapeutic levels of quinidine inhibit cytochrome P2D6. Use with caution with drugs that are metabolized by this enzyme (e.g., mexiletine, some phenothiazines, most polycyclic antidepressants). ■ **Contraindicated** with **ritonavir** (Norvir); may cause life-threatening arrhythmias. ■ Quinidine does not affect the pharmacokinetics of diltiazem (Cardizem), flecainide (Tambacor), mephenytoin, metoprolol (Lopressor), propafenone (Rhythmol), propranolol, quinine, timolol (Betimol), or tocainide (Tonocard). ■ Pharmacokinetics of quinidine are not affected by caffeine, ciprofloxacin (Cipro), digoxin (Lanoxin), felodipine (Plendil), omeprazole (Prilosec), or quinine. ■ **Grapefruit juice** may affect certain enzymes of the P₄₅₀ enzyme system and should be avoided.

SIDE EFFECTS

Most common side effects include diarrhea, nausea, upper GI distress, and vomiting. Less commonly reported side effects include angina-like pain, apprehension, ataxia, autoimmune syndromes, change in sleep habits, cinchonism (a syndrome that may include blurred vision, confusion, deafness, delirium, diplopia, headache, photophobia, reversible high-frequency hearing loss, tinnitus, and vertigo), diaphoresis, discoordination, fatigue, fever, headache, inflammatory syndromes, nervousness, rash, tremor, urge to defecate, urge to void, vertigo, visual disturbances, weakness.

Major: Potentially fatal arrhythmias (including atrioventricular heart block, cardiac standstill, prolonged PR or QT intervals, or 50% widening of QRS complex; tachycardia; ventricular fibrillation), acidosis, arthralgia, coma, confusion, hypokalemia, hypotension (acute), lethargy, myalgia, paresthesia, respiratory depression or arrest, thrombocytopenia purpura, seizures, urticaria.

Overdose: Blurred vision, confusion, delirium, diarrhea, diplopia, headache, high-frequency hearing loss, hypotension, photophobia, tinnitus, ventricular arrhythmias, vertigo, and vomiting.

ANTIDOTE

Notify the physician of any side effects. If minor symptoms progress or if any major side effect appears, discontinue the drug immediately and notify the physician. Discontinue IV use when the normal sinus rhythm returns, HR falls to 120 beats/min, or any signs of cardiac toxicity occur (QRS complex widens to 130% of its pretreatment duration, QTc interval widens to 130% of its pretreatment duration and is then longer than 500 msec, P waves disappear, or patient develops significant tachycardia, symptomatic bradycardia, or hypotension). Another source suggests decreasing the rate or interrupting the infusion if corrected QT interval exceeds 0.6 seconds, corrected QT interval exceeds baseline by more than 25%, QRS widening exceeds 50% of baseline, or hypotension that does not respond to fluid expansion develops. Treatment of hemodynamically unstable polymorphic ventricular tachycardia (including torsades de pointes) is either immediate cardioversion or, if a cardiac pacemaker is in place or is immediately available, immediate overdrive pacing. After cardioversion or pacing, further management must be guided by the length of the QTc interval. Continuous electrocardiographic monitoring required. Use fluid replacement and Trendelenburg positioning and dopamine or norepinephrine (Levophed) to correct hypotension. In overdose, monitoring of blood gases and electrolytes are indicated. Treatment of toxicity is symptomatic and supportive. Resuscitate as necessary.

QUINUPRISTIN/DALFOPRISTIN

(kwin-oo-PRIS-tin/DAL-foh-pris-tin)

**Antibacterial
(Streptogramin)****Synercid****pH 4.5 to 4.75****USUAL DOSE**

Complicated skin and skin structure infection: 7.5 mg/kg every 12 hours. Minimum recommended duration of therapy is 7 days.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients under 16 years of age not established; however, the manufacturer recommends a dose of 7.5 mg/kg every 12 hours for pediatric patients (12 to less than 18 years of age). Dose recommendations for patients less than 12 years of age are not available. Doses of 7.5 mg/kg every 8 or 12 hours have been used under emergency-use conditions in a limited number of pediatric patients.

DOSE ADJUSTMENTS

No dose adjustments required in the elderly, pediatric patients, patients with renal insufficiency, or patients undergoing hemodialysis or peritoneal dialysis. See [Maternal/Child](#). ■ Dose reduction may be required in patients with hepatic cirrhosis (Child Pugh A or B). Exact recommendations are not currently available, but one source recommends decreasing dose to 5 mg/kg in patients who cannot tolerate the usual dose. ■ Patients experiencing arthralgias and myalgias may respond to a reduction in dose frequency to every 12 hours; see [Precautions](#). ■ See [Drug/Lab Interactions](#).

DILUTION

Reconstitute the 500-mg single-dose vial by slowly adding 5 mL of D5W or SWFI. Swirl gently to limit foam formation. Do not shake. Allow solution to sit until foam has disappeared. Final concentration of reconstituted solution is 100 mg/mL. Must be further diluted, withdraw calculated dose and add to 250 mL of D5W. Desired concentration is approximately 2 mg/mL. If moderate to severe venous irritation occurs following peripheral administration, consideration should be given to increasing infusion volume to 500 to 750 mL of D5W; see [Precautions](#). An infusion volume of 100 mL may be used for central line infusions.

Storage: Store unopened vials in refrigerator at 2° to 8° C (36° to 46° F). Reconstituted solution should be used within 30 minutes. Diluted solution is stable for 5 hours at RT and for 54 hours if refrigerated.

COMPATIBILITY**(Underline Indicates Conflicting Compatibility Information)**

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists saline solutions and heparin as **incompatible** and recommends administering quinupristin/dalfopristin separately. Always flush line with D5W before and after administration of any other drug through the same IV line.

Manufacturer lists **Y-site compatibility** with specific concentrations of aztreonam (Azactam [20 mg/mL]), ciprofloxacin (Cipro IV [1 mg/mL]), fluconazole (Diflucan [2 mg/mL]), metoclopramide (Reglan [5 mg/mL]), and potassium chloride (KCl [40 mEq/L]). Another source adds anidulafungin (Eraxis), caspofungin (Cancidas), and fenoldopam (Corlopan).

RATE OF ADMINISTRATION

Flush IV line with D5W before and after administration. A single dose properly diluted over 60 minutes. Use of an infusion pump or device to control rate of infusion is recommended. In animal studies toxicity was higher when administered as a bolus. Studies in humans have not been performed.

ACTIONS

A streptogramin antimicrobial agent composed of two semi-synthetic pristinamycin derivatives, quinupristin and dalfopristin, in a ratio of 30:70 (w:w). Quinupristin and dal-

fopristin bind to the bacterial ribosome, thereby inhibiting protein synthesis. When combined, the two components act synergistically. The compound is bactericidal against strains of methicillin-susceptible and methicillin-resistant staphylococci. Cross-resistance between quinupristin/dalfopristin and other antibacterial agents such as beta-lactams, aminoglycosides, glycopeptides, quinolones, macrolides, lincosamides and tetracyclines has not been reported. Metabolized in the liver via non-enzymatic processes to several active metabolites. Elimination half-life of quinupristin and dalfopristin is approximately 0.85 and 0.7 hours, respectively. Although the elimination half-life for each component is short, the combination exhibits a prolonged post-antibiotic effect of 10 hours with *Staphylococcus aureus* and 9.1 hours with *Streptococcus pneumoniae*. Fecal excretion is the primary elimination route for both components and their metabolites. Urinary excretion accounts for about 15% of the quinupristin and 19% of the dalfopristin dose.

INDICATIONS AND USES

Treatment of complicated skin and skin structure infections caused by *Staphylococcus aureus* (methicillin susceptible) or *Streptococcus pyogenes*.

CONTRAINDICATIONS

Known hypersensitivity to quinupristin/dalfopristin or to other streptogramins (e.g., pristinamycin or virginiamycin).

PRECAUTIONS

C/S indicated to determine susceptibility of causative organism to quinupristin/dalfopristin. ■ Flush line with D5W after completion of peripheral infusion to minimize vein irritation. If moderate to severe venous irritation occurs with 250-mL infusion, consider increasing volume to 500 or 750 mL of D5W, changing the infusion site, or infusing by a peripherally inserted central catheter (PICC) or a central venous catheter; see **Dilution**. Concomitant administration of hydrocortisone or diphenhydramine does **not** appear to alleviate venous irritation. ■ Episodes of arthralgia and myalgia have been reported. In some patients, improvement was noted with a reduction in dose frequency to every 12 hours; see **Dose Adjustments**. ■ Superinfection caused by the overgrowth of nonsusceptible organisms may occur with antibiotic use. Treat as indicated. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with quinupristin/dalfopristin.

Monitor: Monitor total bilirubin. Levels greater than 5 times the upper limit of normal were reported in approximately 25% of patients. ■ Monitor infusion site for any sign of irritation or inflammation; see **Precautions**.

Patient Education: Report pain at injection site or any other side effect promptly. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: safety for use in pregnancy and breast-feeding not established. Use caution. ■ Safety and effectiveness in pediatric patients under 16 years of age not established. Has been used in a limited number of pediatric patients under emergency-use conditions. Dose adjustment does not appear to be required; see **Pediatric Dose**.

Elderly: No apparent differences in frequency, type, or severity of side effects. Dose adjustment not required.

DRUG/LAB INTERACTIONS

Quinupristin/dalfopristin significantly inhibits cytochrome P₄₅₀ 3A4 metabolism of **cyclosporin A** (Sandimmune), **midazolam** (Versed), **nifedipine** (Procardia), and **tacrolimus** (Prograf) and increases their plasma concentrations, dose adjustments may be indicated. Monitoring of cyclosporine and/or tacrolimus serum levels to determine therapeutic dose should be performed when cyclosporine or tacrolimus must be used concomitantly with quinupristin/dalfopristin. ■ It is reasonable to expect that quinupristin/dalfopristin would **inhibit other drugs that are metabolized by the P₄₅₀ 3A4 enzyme system**. Use caution if being coadministered with **drugs that have a narrow therapeutic index** (e.g., cyclosporine) and are metabolized via this pathway. Effects may be prolonged, side effects may be

increased, dose adjustments may be indicated. Some drugs that are predicted to have elevated plasma concentrations when coadministered with quinupristin/dalfopristin are **carbamazepine** (Tegretol), **cisapride** (Propulsid), **delavirdine** (Rescriptor), **diazepam** (Valium), **dihydropyridines** (e.g., nifedipine [Procardia]), **diltiazem** (Cardizem), **disopyramide** (Norpace), **docetaxel** (Taxotere), **HMA-CoA reductase inhibitors** (e.g., lovastatin [Mevacor], simvastatin [Zocor]), **lidocaine**, **quinidine**, **indinavir** (Crixivan), **methylprednisolone** (Solu-Medrol), **nevirapine** (Viramune), **paclitaxel** (Taxol), **ritonavir** (Norvir), **verapamil**, **vinca alkaloids** (e.g., vinblastine). ■ Concomitant medications metabolized by the P₄₅₀ 3A4 enzyme system that **may prolong the QTc interval** should be avoided. ■ May increase **digoxin** levels. If S/S of digoxin toxicity occur, monitor digoxin levels. ■ In vitro combination testing of quinupristin/dalfopristin with aztreonam, cefotaxime (Claforan), ciprofloxacin, and gentamicin against *Enterobacteriaceae* and *Pseudomonas aeruginosa* did not show antagonism. ■ In vitro combination testing of quinupristin/dalfopristin prototype drugs of the following classes: aminoglycosides (gentamicin), beta-lactams (cefepime, ampicillin, and amoxicillin), glycopeptides (vancomycin), quinolones (ciprofloxacin), tetracyclines (doxycycline), and also chloramphenicol against enterococci and staphylococci did not show antagonism. See **Actions**.

SIDE EFFECTS

Allergic reaction; arthralgia; diarrhea; edema, inflammation, and/or pain at infusion site; edema, elevated total and conjugated bilirubin; headache; myalgia; nausea; pain; pruritus; rash; thrombophlebitis; thrombus; and vomiting are reported most frequently. Numerous other side effects have been reported in fewer than 1% of patients. CDAD has been reported. ■ Numerous laboratory abnormalities were noted during studies but were not significantly different than those seen in the comparator group. See literature.

ANTIDOTE

Notify physician of any side effects. Discontinue drug if indicated. Treat hypersensitivity reactions as indicated. Observation and supportive therapy are indicated in an overdose situation. Is not removed by hemodialysis or peritoneal dialysis. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Resuscitate as necessary.

RANITIDINE

(rah-NIH-tih-deen)

**H₂ antagonist
Antiulcer agent
Gastric acid inhibitor****Zantac****pH 6.7 to 7.3****USUAL DOSE**

IV injection or intermittent infusion: 50 mg (2 mL) every 6 to 8 hours. Increase frequency of dose, not amount, if necessary for pain relief. 50 mg every 8 to 12 hours may be used short term to replace an oral dose of 150 mg every 12 hours in patients unable to take oral meds. Do not exceed 400 mg/day.

Continuous infusion: 150 mg may be given as a continuous infusion equally distributed over 24 hours. To maintain intergastric acid secretion rates at 10 mEq/hr or less, dose range may be higher in patients with pathologic hypersecretory syndrome (Zollinger-Ellison). Literature suggests an initial dose of 1 mg/kg/hr. Measure gastric acid output in 4 hours. If above 10 mEq/hr or symptoms recur, adjust dose upward in 0.5 mg/kg/hr increments. Up to 2.5 mg/kg/hr has been used.

Additive for total parental nutrition (TPN [unlabeled]): 70% to 100% of an average 24-hour dose has been used equally distributed over 24 hours as a continuous infusion. May be supplemented with intermittent doses as needed.

Perioperatively to prevent pulmonary aspiration during anesthesia (unlabeled): 45 to 50 mg 60 minutes before anesthesia.

Prophylaxis and/or control of GI hemorrhage associated with stress ulcers (unlabeled): 150 mg over 24 hours.

PEDIATRIC DOSE

Safety for selective use in pediatric patients from 1 month to 16 years of age established; see **Indications**.

One source suggests:

Infants and other pediatric patients: 2 to 4 mg/kg/24 hr in equally divided doses every 6 to 8 hours (0.5 to 1 mg/kg every 6 hours or 0.67 to 1.3 mg/kg every 8 hours). Do not exceed 50 mg/dose.

NEONATAL DOSE

Safety for use of IV ranitidine in neonates less than 1 month of age not established; see **Maternal/Child**.

2 mg/kg every 12 to 24 hours or as a continuous infusion.

Another source suggests 2 mg/kg/24 hr in equally divided doses every 6 to 8 hours (0.5 mg/kg every 6 hours or 0.67 mg/kg every 8 hours).

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly. ■ If the CrCl is less than 50 mL/min, reduce dose to 50 mg every 18 to 24 hours. Gradually increase to 50 mg every 12 hours, or 6 hours with caution if indicated. Adjust schedule to be given after dialysis.

DILUTION

IV injection: Each vial containing 50 mg (2 mL) must be diluted with 18 mL of NS or other **compatible** infusion solution for injection (D5W, D10W, LR, 5% sodium bicarbonate). Concentration of solution must be no greater than 2.5 mg/mL. Additional diluent may be used.

Intermittent infusion: Available premixed as a 1 mg/mL solution in 50 mL. May be given without further dilution. Or each 50 mg may be diluted in 100 mL (0.5 mg/mL) of D5W or other **compatible** infusion solution and given piggyback. Concentration of solution should be no greater than 0.5 mg/mL. Manufacturer recommends discontinuing primary IV during intermittent infusion to avoid incompatibilities. Do not use premixed plastic containers in series connections; may cause air embolism.

Continuous infusion: Total daily dose may be diluted in 250 mL of D5W or other **compatible** infusion solution. For Zollinger-Ellison patients, concentration of solution must be no greater than 2.5 mg/mL. In all situations, avoid any contact with aluminum during administration (e.g., needles). Inspect for color and clarity. Slight darkening of solution does not affect potency. **Compatible** in selected TPN solutions for 24 hours (consult pharmacist).

Storage: Store at CRT protected from light. Stable at room temperature for 48 hours after dilution.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Additives should not be introduced into the premixed solution, and the primary IV should be discontinued during ranitidine infusion."

Solution: D5½NS, IV fat emulsion 10%, selected TNA and TPN solutions; see **Dilution**.

One source suggests the following **compatibilities**:

Additive: See **previous comments under Compatibility**. Acetazolamide (Diamox), amikacin (Amikin), aminophylline, ampicillin, chloramphenicol (Chloromycetin), chlorothiazide (Diuril), ciprofloxacin (Cipro IV), clindamycin (Cleocin), colistimethate (Coly-Mycin M), dexamethasone (Decadron), digoxin (Lanoxin), dobutamine, dopamine, doxycycline, epinephrine (Adrenalin), erythromycin (Erythrocin), flumazenil (Romazicon), furosemide (Lasix), gentamicin, heparin, isoproterenol (Isuprel), lidocaine, lincomycin (Lincocin), meropenem (Merrem IV), methylprednisolone (Solu-Medrol), midazolam (Versed), nitroprusside sodium, norepinephrine (Levophed), penicillin G potassium and sodium, potassium chloride (KCl), protamine sulfate, quinidine gluconate, tobramycin, vancomycin, zidovudine (AZT, Retrovir).

Y-site: Acyclovir (Zovirax), aldesleukin (Proleukin), allopurinol (Aloprim), amifostine (Ethyol), aminophylline, anidulafungin (Eraxis), atracurium (Tracrium), aztreonam (Azactam), bivalirudin (Angiomax), cefazolin (Ancef), cefoxitin (Mefoxin), ceftazidime (Fortaz), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxapram (Dopram), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), epinephrine (Adrenalin), esmolol (Brevibloc), etoposide phosphate (Etopophos), fenoldopam (Corlopam), fentanyl (Sublimaze), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), furosemide (Lasix), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hexend), hydromorphone (Dilaudid), idarubicin (Idamycin), labetalol, linezolid (Zyvox), lorazepam (Ativan), melphalan (Alkeran), meperidine (Demerol), midazolam (Versed), milrinone (Primacor), morphine, nicardipine (Cardene IV), nitroglycerin IV, norepinephrine (Levophed), ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), pancuronium, pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), procainamide (Pronestyl), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepa, tigecycline (Tygacil), vecuronium, vinorelbine (Navelbine), warfarin (Coumadin), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Too-rapid administration has precipitated rare instances of bradycardia, tachycardia, and PVCs.

IV injection: Each 50 mg or fraction thereof at a rate not to exceed 4 mL/min diluted solution (20 mL over 5 min).

Intermittent infusion: Each 50-mg dose over 15 to 20 minutes.

Continuous infusion: Total daily dose equally distributed over 24 hours. Should not exceed a rate of 6.25 mg/hr (10.7 mL/hr if 150 mg [6 mL ranitidine] is diluted in 250 mL). Use of infusion pump preferred to avoid complications of overdose or too-rapid administration.

ACTIONS

A histamine H₂ antagonist, it inhibits both daytime and nocturnal basal gastric acid secretion. It also inhibits gastric acid secretion stimulated by food, histamine, bentazole, and pentagastrin. Not an anticholinergic agent. Does not lower calcium levels in hypercalcemia. Onset of action is prompt and effective for 6 to 8 hours. 5 to 12 times more potent than cimetidine. Half-life is 2 to 2.5 hours. Metabolized in the liver. Excreted in the urine. 70% of a dose is recovered in urine as unchanged drug. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Short-term treatment of intractable duodenal ulcers and pathologic hypersecretory conditions in the hospitalized patient. ■ Treatment of active benign gastric ulcers in those patients unable to take oral medication. ■ Treatment of duodenal ulcers in pediatric patients from 1 month to 16 years of age. Safety for use in pathologic hypersecretory conditions not established. ■ Oral dosing for treatment of duodenal and gastric ulcers, maintenance of healing of duodenal and gastric ulcers, and treatment of GERD and erosive esophagitis has been approved for pediatric patients from 1 month to 16 years of age; see package insert.

Unlabeled uses: Perioperatively to suppress gastric acid secretion, prevent stress ulcers, and prevent aspiration pneumonitis. ■ Reduce the incidence of GI hemorrhage associated with stress ulcers. ■ Additive to TPN to simplify fluid and electrolyte management (decreases the volume and chloride content of gastric secretions).

CONTRAINDICATIONS

Known hypersensitivity to ranitidine or its components.

PRECAUTIONS

Use antacids concomitantly to relieve pain. ■ Gastric malignancy may be present even though patient's symptoms improve on ranitidine therapy. ■ Use caution in patients with impaired hepatic or renal function. ■ Avoid use in patients with acute porphyria; may precipitate acute porphyric attacks. ■ Gastric pain and ulceration may recur after medication stopped. ■ Effects maintained with oral dosage. Total treatment usually discontinued after 6 weeks.

Monitor: Observe frequently; monitor vital signs and pain levels. ■ Obtain baseline SCr. Monitor periodically during extended course of treatment. ■ Monitor ALT if therapy exceeds 400 mg for over 5 days. ■ Change to oral dose when appropriate. ■ See [Drug/Lab Interactions](#).

Patient Education: Stop smoking or at least avoid smoking after the last dose of the day. ■ May increase blood alcohol levels.

Maternal/Child: Category B; use during pregnancy or breast-feeding only when clearly needed. ■ No significant difference in pharmacokinetic parameter values between pediatric patients over 1 month of age and healthy adults when correction is made for body weight. ■ Safety for use of IV ranitidine in neonates less than 1 month of age not established; however, limited data suggest that ranitidine may be useful and safe in increasing gastric pH for infants at risk of GI hemorrhage. ■ Half-life in neonates averages 6.6 hours.

Elderly: Use caution in dose selection; monitoring of renal function suggested; see [Dose Adjustments](#). ■ Half-life is prolonged (3.1 hours) and total clearance is decreased due to reduced renal function. ■ Differences in response between elderly and younger patients not identified; greater sensitivity of some elderly cannot be ruled out. ■ Agitation, confusion (reversible), depression, and hallucination have been reported.

DRUG/LAB INTERACTIONS

Concurrent use with **warfarin** may result in increased or decreased PT and/or INR. Close monitoring is recommended. ■ High doses of ranitidine may reduce the renal excretion of **procaïnamide**; monitoring for procaïnamide toxicity is suggested if ranitidine doses exceed 300 mg/day. ■ May increase serum concentrations of **sulfonylureas** (e.g., glipizide); monitor blood glucose and adjust dose as indicated. ■ Increased pH may reduce

the antibiotic effectiveness of selected **cephalosporins** (e.g., cefpodoxime [Vantin], cefuroxime [Zinacef]). ■ Increased pH may impair the absorption of **atazanavir** (Reyataz) and **delavirdine** (Rescriptor). ■ Effectiveness of **gefitinib** (Iressa) may be reduced if coadministered with ranitidine and sodium bicarbonate. ■ Reduces the plasma concentrations and antibiotic effectiveness of **enoxacin** (Penetrex). ■ Monitor for excessive sedation with concurrent administration of selected **benzodiazepines** (e.g., midazolam [Versed], triazolam [Halcion]). ■ May potentiate the effects of **alcohol**. ■ May inhibit gastric absorption of **ketoconazole** (Nizoral) and reduce antifungal effects. ■ Clinical effect (inhibition of nocturnal gastric secretions) may be reversed by **cigarette smoking**. ■ **Elevated ALT, slight elevation in Scr, and a false-positive for urine protein** with Multistix may occur.

SIDE EFFECTS

Abdominal discomfort, burning and itching at IV site, constipation, diarrhea, headache (severe), and nausea and vomiting are the most common side effects. Hypersensitivity reactions (bronchospasm, fever, rash, eosinophilia) can occur. Acute interstitial nephritis, agitation, alopecia, arthralgias, bradycardia, confusion, depression, dizziness, elevated ALT, erythema multiforme, galactorrhea (rare), gynecomastia (rare), hallucinations, hepatitis (reversible), impotence, insomnia, malaise, muscular pain, pneumonia, PVCs, somnolence, tachycardia, vasculitis, and vertigo occur rarely. See [Drug/Lab Interactions](#).

ANTIDOTE

Notify physician of all side effects. May be treated symptomatically or may respond to decrease in frequency of dosage. Discontinue ranitidine if S/S of hepatitis with or without jaundice occur. Resuscitate as necessary for overdose. Hemodialysis or peritoneal dialysis may be indicated in overdose.

RASBURICASE **BBW**

Antihyperuricemic

(ras-BYOUR-ih-kase)

Elitek

USUAL DOSE

Prehydration required; see [Monitor](#).

0.2 mg/kg as a single daily dose each day for 5 days. Chemotherapy should be initiated 4 to 24 hours after the first dose. Safety and effectiveness of other schedules have not been evaluated. Dosing beyond 5 days and/or administration of more than one course of rasburicase is not recommended. Alternate unlabeled single- and multiple-dose regimens have been used; see literature.

PEDIATRIC DOSE

Same as adult dose; see [Maternal/Child](#).

DOSE ADJUSTMENTS

No dose adjustments recommended.

DILUTION

Each vial contains 1.5 mg of rasburicase. Determine the number of vials needed to provide the calculated dose. Reconstitute each vial with 1 mL of the diluent provided (SWFI and Poloxamer 188). Mix by swirling gently. **Do not shake**. Withdraw the calculated dose of reconstituted solution and inject into an infusion bag containing the appropriate volume of NS to achieve a final total volume of 50 mL. (For example a 20-kg child would receive a dose of 4 mg [$20 \text{ kg} \times 0.2 \text{ mg/kg} = 4 \text{ mg}$]. Reconstitute 3 vials, each with 1 mL of the diluent provided. Withdraw 2.7 mL of reconstituted solution and add to an infusion bag containing 47.3 mL of NS.)

Filters: No filters should be used for the infusion.

Storage: Refrigerate unopened lyophilized drug product and diluent. Do not freeze; protect from light. Both the reconstituted and diluted product may be stored for 24 hours if refrigerated. Discard any unused product.

COMPATIBILITY

Manufacturer states, "Should be infused through a different line than that used for the infusion of other concomitant medications. If use of a separate line is not possible, the line should be flushed with at least 15 mL of NS prior to and after infusion with rasburicase."

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 minutes.

Do not administer as a bolus infusion. Do not filter infusion.

ACTIONS

A recombinant urate-oxidase enzyme produced by genetic engineering. Catalyzes enzymatic oxidation of uric acid into an inactive and soluble metabolite (allantoin). Half-life is 18 hours.

INDICATIONS AND USES

Initial management of plasma uric acid levels in pediatric patients with leukemia, lymphoma, and solid tumor malignancies who are receiving anti-cancer therapy expected to result in tumor lysis and subsequent elevation of plasma uric acid.

CONTRAINDICATIONS

Glucose-6-phosphatase dehydrogenase (G6PD) deficiency or a history of hypersensitivity, hemolytic reactions, or methemoglobinemia reactions to rasburicase or any of its components.

PRECAUTIONS

May cause severe hypersensitivity reactions, including anaphylaxis. Reactions may occur at any time during treatment, including with the first dose; see [Monitor](#) and [Antidote](#). ■ Is immunogenic in healthy volunteers. May elicit antibodies that inhibit the activity of rasburicase. ■ Has caused severe hemolytic reactions in patients with G6PD deficiency. It is recommended that patients at higher risk for G6PD deficiency (e.g., patients of African or Mediterranean descent) be screened before starting rasburicase therapy. See [Contraindications](#) and [Antidote](#). ■ Methemoglobinemia has been reported. Patients developed serious hypoxemia, requiring intervention and medical support. See [Antidote](#).

Monitor: Monitor serum uric acid levels, electrolytes, and renal function before and during therapy. ■ Patients should be hydrated intravenously according to standard medical practice for the management of plasma uric acid in patients at risk for tumor lysis syndrome (TLS). ■ Maintain urine at neutral or slightly alkaline pH. To increase solubility of uric acid, alkalinity of urine may be increased with sodium bicarbonate. ■ Observe for symptoms of TLS (e.g., hyperuricemia, hyperkalemia, hyperphosphatemia, and hypocalcemia). If untreated, may develop acute uric acid nephropathy, leading to renal failure. ■ Monitor for S/S of a hypersensitivity reaction (e.g., anaphylaxis, bronchospasm, chest pain, dyspnea, hypotension, hypoxia, shock, urticaria). ■ Will cause enzymatic degradation of uric acid within blood samples left at room temperature, resulting in falsely low uric acid levels. To ensure accurate measurement, blood must be collected into prechilled tubes containing heparin anticoagulant and immediately *immersed and maintained* in an ice water bath. Plasma samples must be prepared by centrifugation in a precooled centrifuge (4° C). Plasma samples must be analyzed within 4 hours of sample collection.

Patient Education: Report blood in urine, painful urination, or signs of a hypersensitivity reaction promptly.

Maternal/Child: Category C: studies have not been performed. Potential benefits must justify potential risks to fetus. ■ Discontinue breast-feeding. ■ Studied in pediatric patients from 1 month to 17 years of age. Pediatric patients less than 2 years of age had a higher mean uric acid AUC and a lower rate of success at achieving maintenance uric acid concentrations by 48 hours than older pediatric patients. They also experienced more toxicity (e.g., diarrhea, fever, rash, and vomiting).

Elderly: There are insufficient data to determine whether geriatric subjects, or adults in general, respond differently than pediatric patients.

DRUG/LAB INTERACTIONS

Studies have not been conducted. ■ Does not metabolize allopurinol (Aloprim), cytarabine (ARA-C), methylprednisolone (Solu-Medrol), methotrexate, 6-mercaptopurine (Purinethol), thioguanine, etoposide (VePesid), etoposide phosphate (Etopophos), daunorubicin (Cerubidine), cyclophosphamide, or vincristine *in vitro*. Metabolic-based drug interactions are not anticipated with these agents. ■ Did not affect the activity of P₄₅₀ isoenzymes in preclinical *in vivo* studies. Clinically relevant P₄₅₀-mediated drug-drug interactions are not anticipated. ■ Will cause enzymatic degradation of uric acid within blood samples left at room temperature, resulting in **falsely low uric acid levels**; see [Monitor](#).

SIDE EFFECTS

The most serious adverse reactions observed are hemolysis, hypersensitivity reactions (e.g., anaphylaxis, chest pain, dyspnea, hypotension, urticaria), methemoglobinemia, and severe rash. Other, more commonly observed reactions include abdominal pain, acute renal failure, constipation, diarrhea, fever, headache, mucositis, nausea, neutropenia with or without fever, rash, respiratory distress, sepsis, and vomiting. Several other reactions have been observed in a small number of patients. Causality is uncertain. See product literature.

ANTIDOTE

Notify physician of all side effects. Should be immediately and permanently discontinued in patients who experience severe hypersensitivity reactions, hemolysis, or methemoglobinemia. Do not rechallenge. Treat anaphylaxis with epinephrine, corticosteroids (e.g., dexamethasone [Decadron]), oxygen, and antihistamines (diphenhydramine [Benadryl]). Hemolysis or methemoglobinemia may require transfusion support. Methylene blue may be required for treatment of methemoglobinemia. There is no specific antidote. Resuscitate as indicated.

RAXIBACUMAB

(rack-see-BACK-u-mab)

Monoclonal antibody
Antidote

ABthrax

USUAL DOSE

Premedication in adults: Premedicate with diphenhydramine 25 to 50 mg within 1 hour before raxibacumab infusion to prevent or attenuate infusion reactions. May be given IV or PO depending on proximity to the start of the raxibacumab infusion.

Adults: A single dose of 40 mg/kg as an infusion over 2 hours and 15 minutes.

PEDIATRIC DOSE

Premedication in pediatric patients: Premedicate with an appropriate dose of diphenhydramine within 1 hour before raxibacumab infusion to prevent or attenuate infusion reactions. May be given IV or PO depending on proximity to the start of the raxibacumab infusion.

Dosage for pediatric patients: Weight more than 50 kg: A single dose of 40 mg/kg.

Weight more than 15 kg and up to 50 kg: A single dose of 60 mg/kg.

Weight 15 kg or less: A single dose of 80 mg/kg.

DOSE ADJUSTMENTS

No dose adjustments indicated based on age, gender, or race.

DILUTION

Available as a single-use vial that contains 1700 mg/34 mL (50 mg/mL). The recommended dose is weight-based and is given as an intravenous infusion after appropriate

dilution in a compatible solution. The following table outlines dose, diluent, total infusion volume, and infusion rate based on patient body weight.

Raxibacumab Dose, Diluent, Infusion Volume, and Rate by Body Weight					
		Preparation		Administration	
Body Weight (kg)	Dose (mg/kg)	Total Infusion Volume (mL)	Type of Diluent	Infusion Rate (mL/hr) First 20 Minutes	Infusion Rate (mL/hr) Remaining Infusion
1 kg or less	80 mg/kg	7 mL	½ NS or NS	0.5 mL/hr	3.5 mL/hr
1.1 to 2 kg	80 mg/kg	15 mL	½ NS or NS	1 mL/hr	7 mL/hr
2.1 to 3 kg	80 mg/kg	20 mL	½ NS or NS	1.2 mL/hr	10 mL/hr
3.1 to 4.9 kg	80 mg/kg	25 mL	½ NS or NS	1.5 mL/hr	12 mL/hr
5 to 10 kg	80 mg/kg	50 mL	½ NS or NS	3 mL/hr	25 mL/hr
11 to 15 kg	80 mg/kg	100 mL	NS	6 mL/hr	50 mL/hr
16 to 30 kg	60 mg/kg	100 mL	NS	6 mL/hr	50 mL/hr
31 to 40 kg	60 mg/kg	250 mL	NS	15 mL/hr	125 mL/hr
41 to 50 kg	60 mg/kg	250 mL	NS	15 mL/hr	125 mL/hr
Greater than 50 kg or adult	40 mg/kg	250 mL	NS	15 mL/hr	125 mL/hr

Weight in kg × Dose in mg/kg = Calculated dose of raxibacumab in mg

Calculated dose in mg ÷ Raxibacumab concentration (50 mg/mL) =
Required volume of raxibacumab in mL

Based on total infusion volume from the table above, prepare either a syringe or infusion bag as appropriate.

Bag preparation: Select the appropriate size bag of compatible solution. Withdraw a volume of solution from the bag equal to the calculated volume in milliliters of raxibacumab and discard. Withdraw the calculated dose of raxibacumab from the vial and transfer into the prepared infusion bag. Gently invert bag to mix. **Do not shake.**

Syringe preparation: Select an appropriate size syringe for the total volume of infusion to be administered. Using this syringe, withdraw the calculated raxibacumab dose. Then withdraw an appropriate amount of compatible solution to prepare a total volume infusion syringe as specified in the table. Gently mix. **Do not shake.**

Filters: Not required by manufacturer; additional data not available.

Storage: Store in original carton until time of use to protect from light. Refrigerate at 2° to 8° C (36° to 46° F). Do not freeze. Discard unused raxibacumab. Prepared solution stable for 8 hours at RT.

COMPATIBILITY

Specific information not available; consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Administer as outlined in the chart under **Dilution**. Total infusion time is 2 hours and 15 minutes. Slow or interrupt the infusion for infusion-related symptoms or other side effects.

ACTIONS

A human IgG1λ monoclonal antibody. Produced by recombinant DNA technology in a murine cell expression system. It does not have direct antibacterial activity but binds to the protective antigen (PA) of *B. anthracis* toxin. Raxibacumab inhibits the binding of the PA to its cellular receptor. This prevents the intracellular entry of the anthrax lethal factor and edema factor, the enzymatic toxin components responsible for the pathogenic

effects of the anthrax toxin. Mean steady-state volume of distribution was greater than plasma volume, suggesting some tissue distribution. Virtually no renal clearance occurs.

INDICATIONS AND USES

Treatment of adult and pediatric patients with inhalation anthrax due to *Bacillus anthracis* in combination with the appropriate antibacterial drugs. ■ Prophylaxis of inhalation anthrax when alternative therapies are not appropriate or available for use.

Limitations of use: Effectiveness based solely on efficacy studies in animal models of inhalational anthrax. ■ Does not cross the blood-brain barrier and does not prevent or treat meningitis. ■ Does not have direct antibacterial activity. Should be used in combination with appropriate antibacterial drugs. ■ See [Maternal/Child](#).

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Infusion-related reactions have been reported; see [Monitor](#) and [Antidote](#). ■ A protein product; has the potential for immunogenicity. ■ Adequate laboratory and supportive medical resources must be available.

MONITOR

Premedication required; see [Usual Dose](#). ■ Monitor for infusion-related reactions during administration (e.g., dyspnea, pruritus, rash, urticaria) and slow or interrupt infusion as indicated.

Patient Education: Promptly report S/S of an infusion reaction (e.g., hives, itching, rash, shortness of breath). ■ The effectiveness of raxibacumab is based on studies done in animals and has not been tested in humans with anthrax.

Maternal/Child: Category B: safety for use in pregnancy, breast-feeding, and pediatric patients not established. Use raxibacumab only if clearly needed. ■ As in adults, effectiveness in pediatric patients is based solely on efficacy studies in animal models. There are no studies of safety or pharmacokinetics in pediatric patients.

Elderly: Numbers in clinical studies insufficient to determine if the elderly respond differently compared with younger subjects.

DRUG/LAB INTERACTIONS

The pharmacokinetics of ciprofloxacin and raxibacumab were not altered with coadministration of 40 mg/kg raxibacumab IV and either IV or oral ciprofloxacin.

In a study determining the efficacy of the drugs in the treatment of animals with systemic anthrax disease, the pharmacokinetics of levofloxacin and raxibacumab were unaffected by product coadministration.

SIDE EFFECTS

The most frequently reported side effects were pain in extremities, pruritus, rash, and somnolence. Anemia, back pain, dizziness, fatigue, flushing, hypertension, increased blood amylase and blood creatine phosphokinase, infusion site pain, insomnia, leukopenia, lymphadenopathy, muscle spasms, palpitations, peripheral edema, prolonged PT, and vasovagal syncope have been reported.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. If signs of an infusion reaction occur, slow or interrupt the infusion and treat appropriately. No cases of overdose have been observed. If overdose occurs, monitor for any signs or symptoms of adverse effects and apply appropriate medical therapies.

REGADENOSON

(re-ga-DEN-oh-son)

Diagnostic agent

Lexiscan

pH 6.3 to 7.7

USUAL DOSE

0.4 mg (5 mL) as a rapid IV bolus. Given undiluted into a peripheral vein using a 22-gauge or larger catheter or needle. Immediately following dose, flush line with 5 mL of NS. Administer the radionuclide myocardial perfusion imaging agent 10 to 20 seconds after the NS flush. The radionuclide may be injected directly into the same catheter as the regadenoson.

DOSE ADJUSTMENTS

No dose adjustment is indicated based on age, gender, and race or for patients with hepatic or renal insufficiency. Has not been assessed in patients with end-stage renal disease.

DILUTION

Solution must be clear. Do not use if discolored or if particulate matter is present. Available in a single-use 0.4 mg/5 mL vial or syringe. Given undiluted into a peripheral vein using a 22-gauge or larger catheter or needle.

Filter: Information not available.

Storage: Store at CRT.

COMPATIBILITY

Specific information not available; see [Dilution](#).

RATE OF ADMINISTRATION

Administer as a bolus injection over approximately 10 seconds.

ACTIONS

An adenosine receptor agonist that is a coronary vasodilator. It is a low-affinity agonist for the A_{2A} adenosine receptor. Activation of this receptor produces coronary vasodilation and a rapid increase in coronary blood flow that is sustained for a short duration. Mean average peak velocity of coronary blood flow increases to greater than twice the baseline level by 30 seconds and decreases to less than twice the baseline level within 10 minutes. Myocardial uptake of the radiopharmaceutical is proportional to coronary blood flow. Because regadenoson increases blood flow in normal coronary arteries with little or no increase in stenotic arteries, there is relatively less uptake of the radiopharmaceutical in areas of the heart supplied by stenotic arteries. Myocardial perfusion imaging intensity after administration is therefore greater in areas perfused by normal arteries than in areas perfused by stenosed arteries. Additional hemodynamic effects, which may be seen within 45 minutes of administration, include an increase in heart rate and a decrease in blood pressure. Peak plasma concentrations are achieved within 1 to 4 minutes. Half-life is approximately 2 hours. Metabolism is unknown. Excreted primarily as unchanged drug in the urine.

INDICATIONS AND USES

A pharmacologic stress agent indicated for radionuclide myocardial perfusion imaging (MPI) in patients unable to undergo adequate exercise stress.

CONTRAINDICATIONS

Second- or third-degree AV block or sinus node dysfunction unless a functioning artificial pacemaker is in place.

PRECAUTIONS

Pharmaceutical stress agents may induce myocardial ischemia, resulting in myocardial infarction, life-threatening ventricular arrhythmias, or fatal cardiac arrest. Patients with unstable angina may be at increased risk. Emergency resuscitation medications and equipment must be readily available. ■ Hypersensitivity reactions, including anaphy-

laxis, have been reported; see **Monitor**. ■ May produce clinically significant increases in BP. These increases usually occur within minutes of administration and resolve within 10 to 15 minutes. These BP increases have lasted as long as 45 minutes in some patients; more often seen in patients with a history of hypertension and/or when myocardial perfusion imaging includes low-level exercise. ■ Can depress the SA and AV nodes and may cause sinus bradycardia or first-, second-, or third-degree AV block. Most episodes of AV block are asymptomatic and do not require intervention. ■ Induces arterial vasodilation and hypotension. Risk of serious hypotension may be higher in patients with autonomic dysfunction, hypovolemia, left main coronary artery stenosis, stenotic valvular heart disease, pericarditis or pericardial effusions, or stenotic carotid artery disease with cerebrovascular insufficiency. ■ May cause dyspnea, bronchoconstriction, and respiratory compromise. Use with caution in patients with known or suspected bronchoconstrictive disease, COPD, or asthma. Appropriate bronchodilator therapy and resuscitative measures should be readily available.

Monitor: ECG monitoring during administration and imaging is recommended. ■ Monitor BP and HR. ■ Monitor respiratory status. ■ Monitor for S/S of hypersensitivity reactions (e.g., angioedema, cardiac or respiratory arrest, decreased oxygen saturation, hypotension, respiratory distress, throat tightness, rashes, and urticaria).

Patient Education: Avoid consumption of any products containing methylxanthines for at least 12 hours before the study, including caffeinated coffee, tea, or other caffeinated beverages; caffeine-containing drug products; and theophylline. ■ Promptly report side effects such as shortness of breath, headache, and flushing. ■ Patients with COPD or asthma should discuss respiratory history and the administration of pre-study and post-study bronchodilator therapy before scheduling a study.

Maternal/Child: Category C: use in pregnancy only if the potential benefit justifies the risk to the fetus. ■ Consider interrupting breast-feeding for 10 hours after administration of regadenoson. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Older patients have a similar side effect profile compared with younger patients but may have a higher incidence of hypotension.

DRUG/LAB INTERACTIONS

Formal pharmacokinetic drug interaction studies have not been conducted. ■ **Methylxanthines** (e.g., caffeine and theophylline) are nonspecific adenosine receptor antagonists and may interfere with the vasodilation activity of regadenoson. Separate the administration of theophylline preparations or the consumption of any products containing methylxanthines from the administration of regadenoson by at least 12 hours. ■ **Aminophylline** (a methylxanthine) may be used to attenuate severe or persistent adverse reactions to regadenoson. ■ **Dipyridamole** (Persantine) or **aspirin and dipyridamole** (Aggrenox) may change the effects of regadenoson. When possible, hold dipyridamole or aspirin and dipyridamole for at least 2 days before regadenoson administration. ■ Has been administered to patients taking other cardioactive drugs, including beta-blockers (e.g., metoprolol [Lopressor]), calcium channel blockers (e.g., diltiazem [Cardizem]), ACE inhibitors (lisinopril [Zestril]), nitrates (nitroglycerin), cardiac glycosides (e.g., digoxin [Lanoxin]), and angiotensin receptor blockers (e.g., losartan [Cozaar]). ■ Does not appear to alter the pharmacokinetics of drugs metabolized by the cytochrome P₄₅₀ system.

SIDE EFFECTS

Most side effects begin soon after dosing and generally resolve within approximately 15 minutes, except for headache, which resolves in most patients within 30 minutes. Side effects include abdominal discomfort, angina or ST segment depression, chest discomfort, chest pain, dizziness, dysgeusia, dyspnea, ECG abnormalities (e.g., first- or second-degree AV block, conduction abnormalities, PACs, PVCs), feeling hot, flushing, headache, nausea.

Overdose: Dizziness, flushing, increased heart rate.

Post-Marketing: Abdominal pain (may be severe) with myalgias, nausea, and vomiting; diarrhea and fecal incontinence; dyspnea and wheezing; QTc prolongation; heart block

(including third-degree block) and asystole; hypersensitivity reactions; marked hypertension; musculoskeletal pain in the arms, lower back, buttocks, and lower legs; respiratory arrest; seizures; and symptomatic hypotension, transient ischemic attack, and syncope requiring intervention with fluids and/or aminophylline.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Aminophylline (50 to 250 mg IV) may be administered to attenuate severe and/or persistent side effects. Treat conduction abnormalities as indicated. Resuscitate as necessary.

RETEPLASE RECOMBINANT

(REE-teh-place re-KOM-buh-nant)

Thrombolytic agent
(recombinant)

Retavase, r-PA

pH 7 to 7.4

USUAL DOSE

Administered concomitantly with heparin. Give a 5,000-unit IV bolus of heparin before the initial injection of reteplase, then give 10 units (10 mL) of reteplase as an IV injection. Follow with a 1,000 unit/hr continuous IV infusion of heparin for at least 24 hours. Give a second 10-unit bolus of reteplase 30 minutes after the first. See [Dilution](#), [Compatibility](#), and [Rate of Administration](#). Aspirin is also used either during or following heparin treatment; an initial dose of 160 to 350 mg is followed by doses of 75 to 350 mg.

DOSE ADJUSTMENTS

The second bolus should not be given if serious bleeding in a critical location (e.g., intracranial, gastrointestinal, retroperitoneal, pericardial) occurs before it is due to be given.

DILUTION

Supplied in a kit with all components for reconstitution. Each kit contains a package insert and two of each of the following: single-use reteplase vials (10.8 units each), single-use diluent vials of SWFI (10 mL each), sterile 10-mL syringes with 20-gauge needles attached, sterile dispensing pins, sterile 20-gauge needles for administration, and alcohol swabs. Withdraw diluent with 20-gauge needle. Discard needle and put dispensing pin on syringe of diluent. Transfer diluent to vial of reteplase. Pin and syringe should remain in place while vial is swirled to dissolve reteplase. **Do not shake.** When completely dissolved, withdraw 10 mL reconstituted solution into the syringe (vials are 0.7 mL overfilled). Remove dispensing pin and replace with a 20-gauge needle for administration.

Storage: Kit should remain sealed to protect contents from light. Store at 2° to 25° C (36° to 77° F). Do not use beyond expiration date. Contains no preservatives; should be reconstituted immediately before use, but may be stored at room temperature if used within 4 hours. Discard all unused solution and supplies.

COMPATIBILITY

Manufacturer states, "Should be given via an IV line in which no other medication is being simultaneously injected or infused. No other medication should be added to the injection solution containing reteplase. **Incompatible** with heparin; do not administer heparin in the same IV line unless the line is flushed through with NS or D5W before and after reteplase."

RATE OF ADMINISTRATION

Heparin: First 1,000 units over 1 minute. After this test dose, the balance of 4,000 units may be given over 1 minute. Follow with an infusion of 1,000 units/hr.

Retepase: A single dose evenly distributed over 2 minutes. To avoid **incompatibilities** and ensure delivery of both doses, be sure to flush line with a minimum of 30 to 50 mL NS or D5W before and after each injection.

ACTIONS

A recombinant plasminogen activator. Exerts its thrombolytic action by generating plasmin from plasminogen through a specific process. Plasmin then degrades the fibrin matrix of the thrombus. Potency is expressed in units that are specific to reteplase. With therapeutic doses, a decrease in circulating fibrinogen makes the patient susceptible to bleeding. Onset of action is prompt, effecting patency of the vessel within 90 minutes in most patients. The FDA has allowed the manufacturer to claim superiority over alteplase at achieving patency within 90 minutes. Prompt opening of arteries increases probability of improved cardiac function. Half-life is 13 to 16 minutes. Cleared from the plasma by the liver and kidneys. Mean fibrinogen level should return to baseline value within 48 hours.

INDICATIONS AND USES

Management of acute myocardial infarction (AMI) in adults for the improvement of ventricular function following AMI, the reduction of the incidence of congestive failure, and the reduction of mortality associated with AMI. Treatment should begin as soon as possible after the onset of symptoms of AMI. ■ Current AHA and JAMA recommendations identify thrombolytic agents as Class I therapy in patients younger than 70 years with recent onset of chest pain (within 6 hours) consistent with AMI and at least 0.1 mV of ST segment elevation in at least two ECG leads. Use in all other patients based on age, accurate diagnosis, and time from onset of chest pain.

CONTRAINDICATIONS

Active internal bleeding, arteriovenous malformation or aneurysm, bleeding diathesis, history of cerebral vascular accident, intracranial or intraspinal surgery or trauma within 2 months, intracranial neoplasm, severe uncontrolled hypertension.

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use and with appropriate emergency drugs, diagnostic and laboratory facilities available. ■ Reperfusion arrhythmias occur frequently (e.g., sinus bradycardia, accelerated idioventricular rhythm, PVCs, ventricular tachycardia); have antiarrhythmic meds available at bedside. ■ A greater alteration of hemostatic status than with heparin. Strict bed rest indicated to reduce risk of bleeding. Use extreme care with the patient; avoid any excessive or rough handling or pressure (including too-frequent BPs); avoid invasive procedures (e.g., arterial puncture, venipuncture, IM injection). If these procedures are absolutely necessary, use extreme precautionary methods (use radial artery instead of femoral; small-gauge catheters and needles, and sites that are easily observed and compressible where bleeding can be controlled; avoid handling of catheter sites, and use extended pressure application of up to 30 minutes). Minor bleeding occurs often at catheter insertion sites. Avoid use of razors and toothbrushes. ■ Use extreme caution and weigh risks against anticipated benefits in the following situation: recent major surgery (e.g., coronary artery bypass graft, obstetric delivery, organ biopsy), previous puncture of noncompressible vessels (e.g., jugular, subclavian), cerebrovascular disease, recent GI or GU bleeding, recent trauma, hypertension (e.g., systolic BP equal to or greater than 180 mm Hg and/or diastolic BP equal to or greater than 110 mm Hg), high likelihood of left heart thrombus (e.g., mitral stenosis with atrial fibrillation), acute pericarditis, subacute bacterial endocarditis, hemostatic defects including those secondary to severe hepatic or renal disease, severe hepatic or renal dysfunction, pregnancy, diabetic hemorrhagic retinopathy or other hemorrhagic ophthalmic conditions, septic thrombophlebitis or occluded AV cannula at a seriously infected site, advanced age, patients currently receiving oral anticoagulants (e.g., warfarin [Coumadin]), any other condition in which bleeding constitutes a significant hazard or would be particularly difficult to manage because of its location. ■ Simultaneous therapy with continuous infusion of heparin is used to reduce the risk of rethrom-

bosis. Markedly increases risk of bleeding. ■ Standard treatment for myocardial infarction continues simultaneously with reteplase therapy except if temporarily contraindicated (e.g., arterial blood gases) unless absolutely necessary. ■ No experience with patients receiving repeat courses of reteplase. ■ Cholesterol embolization has been reported and may be fatal.

Monitor: Best to establish separate IV lines for reteplase and heparin. If not appropriate, be sure to flush the IV line before and after each injection of reteplase. ■ Baseline ECG, CPK, and clotting studies (TT, PTT, CBC, fibrinogen level, platelets) and baseline assessment (patient condition, pain, hematomas, petechiae, or recent wounds) should be completed before administration. Type and cross-match may also be ordered. ■ Monitor ECG continuously, and record strips with greatest ST segment elevation initially and every 15 minutes for at least 4 hours. A 12-lead ECG is indicated when therapy is complete. ■ Maintain strict bed rest; monitor the patient carefully and frequently for anginal pain and signs of bleeding; observe catheter sites at least every 15 minutes and apply pressure dressings to any recently invaded site; watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, muscle weakness; do neuro checks every hour. Continue until normal clotting function returns. ■ Watch for extravasation. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Compliance with all measures to minimize bleeding (e.g., strict bed rest) is very important. ■ Avoid use of razors, toothbrushes, and other sharp items. ■ Use caution while moving to avoid excessive bumping. ■ Report all episodes of bleeding and apply local pressure if indicated. Expect oozing from IV sites.

Maternal/Child: Category C: has resulted in hemorrhage leading to spontaneous abortions in rabbits. Safety for use in pregnancy, breast-feeding, and pediatric patients not established.

Elderly: See [Indications](#) and [Precautions](#). ■ May have poorer prognosis following AMI and pre-existing conditions that may increase risk of intracranial bleeding. Select patients carefully to maximize benefits.

DRUG/LAB INTERACTIONS

Interaction of reteplase with other cardioactive drugs has not been studied. Risk of bleeding may be increased by **any medicine that affects blood clotting**, including anticoagulants (e.g., heparin, warfarin [Coumadin]); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel [Plavix], dipyridamole [Persantine], glycoprotein GPIIb/IIIa receptor antagonists [e.g., abciximab (ReoPro), eptifibatide (Integrilin), tirofiban (Aggrastat)], plicamycin [Mithracin], sulfipyrazone [Anturane], ticlopidine [Ticlid], valproic acid [Depacon]). Concurrent use not recommended with the exception of heparin and aspirin (in AMI) to reduce the risk of rethrombosis. If concurrent or subsequent use indicated (e.g., management of acute coronary syndrome, percutaneous coronary intervention) monitor PT and aPTT closely. ■ **Coagulation tests will be unreliable**; specific procedures can be used; notify the lab of reteplase use.

SIDE EFFECTS

Bleeding is most common: internal (GI tract, GU tract, intracranial, respiratory, or retroperitoneal sites), epistaxis, gingival, and superficial or surface bleeding (venous cut-downs, arterial punctures, sites of recent surgical intervention). Reperfusion arrhythmias are common; other serious arrhythmias may occur. A few hypersensitivity reactions, as well as fever, hypotension, nausea, and vomiting, have occurred. Cholesterol embolism has been reported and may be fatal. Clinical S/S may include acute renal failure, gangrenous digits, hypertension, infarctions (e.g., bowel, cerebral, myocardial, or spinal cord), pancreatitis, “purple toe” syndrome, renal artery occlusion.

ANTIDOTE

Notify physician of all side effects. Note even the most minute bleeding tendency. Oozing at IV sites is expected. Control minor bleeding by local pressure. For severe bleeding

in a critical location, discontinue second dose of reteplase if it has not been given and any heparin therapy immediately. Whole blood, packed RBCs, cryoprecipitate, fresh-frozen plasma, platelets, desmopressin, tranexamic acid, and aminocaproic acid may all be indicated. Topical preparations of aminocaproic acid may stop minor bleeding. Consider protamine if heparin has been used. Treat bradycardia with atropine, reperfusion arrhythmias with lidocaine or procainamide; VT or VF may require cardioversion. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary. Discontinue therapy if any symptoms of cholesterol embolism occur.

Rh_o(D) IMMUNE GLOBULIN INTRAVENOUS (HUMAN) **BBW**

(ih-MUNE GLAW-byoo-lin IN-trah-ve-nes)

Immunizing agent
(passive)

Platelet count stimulator

Rh_o(D)-IGIV, Rhophylac, WinRho SDF

pH 6.5 to 7.6

USUAL DOSE

(International units [IU])

Pregnancy, predelivery: *Rhophylac* and *WinRho SDF*: Confirm Rh_o(D) negative status of patient. May be given IV or IM. 1,500 IU (300 mcg) at 28 weeks' gestation. If *WinRho SDF* is administered early in the pregnancy, it should be repeated at 12-week intervals to maintain an adequate level of passively acquired anti-Rh.

Pregnancy, postdelivery: Confirm Rh_o(D) negative status of patient. May be given IV or IM. Administer as soon as possible after delivery of a confirmed Rh_o(D)-positive baby. Usually given no later than 72 hours postdelivery. If the Rh status of the infant is unknown at 72 hours, administer to the mother at that time. Should be given as soon as possible up to 28 days after delivery. This second dose postdelivery (first dose given predelivery; see above) can reduce treatment failure.

***Rhophylac*:** 1,500 IU (300 mcg).

***WinRho SDF*:** 600 IU (120 mcg).

Postabortion, amniocentesis (after 34 weeks' gestation), or any other manipulation late in pregnancy (after 34 weeks' gestation): Confirm Rh_o(D) negative status of patient. May be given IV or IM. Administer immediately after abortion or procedure associated with increased risk of Rh isoimmunization. Must be given within 72 hours. One half of a dose (a mini-dose [IM product]) may be given if a pregnancy terminates before 13 weeks' gestation, administration within 3 hours is preferred. According to the literature, this mini-dose can provide 100% effectiveness in preventing Rh immunization.

***Rhophylac*:** 1,500 IU (300 mcg).

***WinRho SDF*:** 600 IU (120 mcg).

Postamniocentesis before 34 weeks' gestation or after chorionic villus sampling: Confirm Rh_o(D) negative status of patient. May be given IV or IM. ***Rhophylac* and *WinRho SDF*:** 1,500 IU (300 mcg) immediately after the procedure. Repeat ***WinRho SDF*** every 12 weeks during the pregnancy.

Threatened abortion: Confirm Rh_o(D) negative status of patient. May be given IV or IM. ***Rhophylac* and *WinRho SDF*:** 1,500 IU (300 mcg) as soon as possible.

Transfusion or fetal hemorrhage: Confirm Rh_o(D) negative status of patient. May be given IV or IM. Administer within 72 hours of an incompatible event involving Rh_o(D) positive blood such as exposure to incompatible blood transfusions (Rh+ whole blood or Rh+ red blood cells) or massive fetal hemorrhage.

***Rhophylac*:** Give 100 IU (20 mcg) per each 2 mL transfused blood or per 1 mL erythrocyte concentrate. In cases of known or suspected excessive fetomaternal hemorrhage, the

number of fetal red blood cells in the maternal circulation should be determined. If testing is not feasible and excessive fetomaternal hemorrhage cannot be excluded, administer a dose of 1,500 IU (300 mcg).

WinRho SDF: Give up to 3,000 IU (600 mcg) every 8 hours IV or 6,000 IU (1,200 mcg) every 12 hours IM until the total dose is administered. Total IV dose is 45 IU (9 mcg) for every milliliter of Rh+ whole blood exposure or 90 IU (18 mcg) for every milliliter of Rh+ red blood cell exposure. Total IM dose is 60 IU (12 mcg) for every milliliter of Rh+ whole blood exposure or 120 IU (24 mcg) for every milliliter of Rh+ red blood cell exposure.

Treatment of immune thrombocytopenic purpura (ITP); Adults and pediatric patients: WinRho SDF: Confirm Rh₀(D)-positive status of patient. Must be given IV. Hemoglobin should be greater than 10 Gm/dL. Give 250 IU/kg (50 mcg/kg) of body weight as the initial dose. May be given as a single dose or divided in half and given on two consecutive days. If response to the initial dose is adequate, maintenance doses of 125 to 300 IU/kg (25 to 60 mcg/kg) may be given. If response to the initial dose is inadequate, see [Dose Adjustments](#). Dose and frequency based on patient's clinical response (e.g., RBC, hemoglobin, reticulocyte levels, and platelet counts); see [Dose Adjustments](#).

PEDIATRIC DOSE

Treatment of ITP: WinRho SDF: See [Usual Dose](#) and [Dose Adjustments](#).

DOSE ADJUSTMENTS

(International units [IU])

Pregnancy and obstetrical conditions: WinRho SDF suggests protection must be maintained throughout pregnancy once Rh₀(D) immune globulin is administered. Level of passively acquired anti-Rh₀(D) should not fall below levels required to prevent an immune response to Rh₀(D)+ blood. Additional doses should be given every 12 weeks during pregnancy and at delivery unless the previous dose was administered within 3 weeks and there is less than 15 mL of fetomaternal red blood cell hemorrhage during delivery.

Suppression of Rh isoimmunization: Rhophylac and WinRho SDF: A large fetomaternal hemorrhage may cause an incorrect evaluation by standard tests of the amount of Rh₀(D) IGIV required. Assess the amount of hemorrhage and adjust dose accordingly.

Treatment of ITP: Adults and pediatric patients: WinRho SDF: If the hemoglobin level is less than 10 Gm/dL before or after the initial dose, reduce the initial dose and/or maintenance doses to 125 to 200 IU (25 to 40 mcg)/kg to minimize the risk of increasing the severity of anemia in the patient. ■ In patients with adequate platelet response to the initial dose, adjust maintenance doses based on platelet and hemoglobin levels. ■ If response to the initial dose is inadequate, adjust subsequent doses as follows:

Hemoglobin above 10 Gm/dL: redose with 250 to 300 IU (50 to 60 mcg)/kg.

Hemoglobin is 8 to 10 Gm/dL: redose with 125 to 200 IU (25 to 40 mcg)/kg.

Hemoglobin below 8 Gm/dL: use with caution; may increase severity of anemia.

DILUTION

(International units [IU])

Rhophylac: Available in a pre-filled 2-mL syringe containing 1,500 IU (300 mcg) for single-dose use. Bring to room or body temperature before use.

WinRho SDF: Available as a ready-to-use liquid. 5 IU equals 1 mcg. Withdraw the entire contents of the vial to obtain the labeled dose. If indicated, calculate a partial dose, then discard the excess from the syringe. The target fill volume of each vial is included in the following chart.

WinRho SDF Target Fill Volumes/Vial	
Vial Size	Target Fill Volume
600 IU (120 mcg)	0.5 mL
1,500 IU (300 mcg)	1.3 mL
2,500 IU (500 mcg)	2.2 mL
5,000 IU (1,000 mcg)	4.4 mL
15,000 IU (3,000 mcg)	13 mL

Storage: *Rhophylac*: Refrigerate syringes before use. Protect from light. Should not be used after expiration date. Discard unused product in syringe. *WinRho SDF*: Store unopened vials in refrigerator. Note expiration date. Do not freeze. Discard unused portion.

COMPATIBILITY

Rhophylac: Specific information not available.

WinRho SDF: Manufacturer states, "Should be administered separately from other drugs." Dilute only with NS.

RATE OF ADMINISTRATION

Rhophylac: A single dose as a slow IV injection.

WinRho SDF: A single dose as an IV injection over 3 to 5 minutes.

ACTIONS

(International units [IU])

Rhophylac and WinRho SDF: Specialty immunoglobulins. A gamma globulin (IgG) fraction containing antibodies to the Rh₀(D) antigen (D Antigen). Reduces the incidence of Rh immunization of an Rh₀(D)-negative mother by an Rh₀(D)-positive infant before, during, and after delivery; reduces the likelihood of hemolytic disease in an Rh₀(D)-positive infant in present and future pregnancies. Has also been shown to increase platelet counts in nonsplenectomized Rh₀(D)-positive patients with immune thrombocytopenic purpura (ITP). A 1,500-IU vial or syringe contains 300 mcg of anti-Rh₀(D), which can effectively suppress the immunizing potential of approximately 15 to 17 mL of Rh₀(D)-positive blood cells, and, in addition, contains 25 to 40 mg of nonspecific gammaglobulin. Pooled from source plasma selected for high titers of Rh₀(D) antibody. Purified and standardized by several methods (e.g., solvent-detergent viral inactivation process to decrease the possibility of transmission of blood-borne pathogens [e.g., HIV, hepatitis]). Similar to native IgG that normally circulates in human plasma.

Rhophylac: Is thiomersol free, mercury free, and latex free. Contains albumin as a stabilizer. Half-life is 12 to 20 days. Anti-D IgG titers were measurable up to 9 weeks after injection.

WinRho SDF: Has also been shown to increase platelet counts in nonsplenectomized Rh₀(D)-positive patients with immune thrombocytopenic purpura (ITP). Platelet counts usually begin to rise in 1 to 2 days with peak effect in 7 to 14 days. Some effects last about 30 days. Contains 25 to 40 mg of nonspecific gammaglobulin. The liquid form contains maltose as a stabilizer; the lyophilized powder is stabilized with glycine, NaCl, and polysorbate 80. Half-life is 24 days. Crosses the blood-brain barrier.

INDICATIONS AND USES

Rhophylac and WinRho SDF: Suppression of Rh isoimmunization in nonsensitized Rh₀(D)-negative women during the normal course of pregnancy, within 72 hours after spontaneous or induced abortions, amniocentesis, chorionic villus sampling, ruptured tubal pregnancy, abdominal trauma or transplacental hemorrhage, unless the blood type of the fetus or father is known to be Rh₀(D)-negative (prophylaxis and Rh hemolytic disease of the newborn). ■ Suppression of Rh isoimmunization in Rh₀(D)-negative female pediatric patients and female adults in their childbearing years transfused with Rh₀(D)-positive red blood cells or blood components containing Rh₀(D)-positive RBCs.

WinRho SDF: Treatment of nonsplenectomized Rh₀(D)-positive pediatric patients with acute or chronic immune thrombocytopenic purpura (ITP), adults with chronic ITP, or pediatric patients and adults with ITP secondary to HIV infection in clinical situations requiring an increase in platelet counts to prevent excessive hemorrhage.

CONTRAINDICATIONS

Rhophylac and WinRho SDF: *All uses:* History of a prior severe hypersensitivity reaction to human immune globulin preparations or their components (*Rhophylac* contains albumin, *WinRho SDF* may contain thiomersol); patients with isolated IgA deficiency or pre-existing IgA antibodies (benefits must outweigh risks; risk of anaphylaxis is greater).

Suppression of Rh isoimmunization in pregnancy: For suppression of Rh isoimmunization in the mother. *Do not administer to the infant.* Not recommended for use in Rh₀(D)-negative individuals shown to be Rh immunized by standard screening tests.

WinRho SDF: Treatment of ITP: Not recommended for use in Rh₀(D)-negative or splenectomized individuals.

PRECAUTIONS

All uses: Confirm vial or syringe label—must state for IV or IV/IM use; several similar products are for IM use only (e.g., RhoGam). ■ May risk transmission of infectious agents (e.g., hepatitis, HIV, possibly the Creutzfeldt-Jakob disease [CJD] agent); see [Actions](#). ■ May contain trace amounts of anti-A, anti-B, anti-C, and anti-E blood group antibodies. ■ Use caution and weigh benefit versus risk in patients with known hypogammaglobulinemia or selective IgA deficiency; risk of severe allergic reactions or anaphylaxis is increased. ■ Not intended for use in Rh+ individuals (with the exception of **WinRho SDF** in the treatment of ITP). ■ Use with caution and monitor renal function in patients at risk for renal insufficiency. IGIV products have been reported to produce renal dysfunction in patients who are predisposed to acute renal failure or in those who have renal insufficiency. Most reports involve products that contain sucrose as a stabilizer. WinRho SDF does not contain sucrose.

Suppression of Rh isoimmunization in pregnancy: More than 1 dose of Rh₀(D) immune globulin may be required. A fetal RBC count can be done on maternal blood to determine the required dose. ■ If a large fetomaternal hemorrhage occurs late in pregnancy or after delivery Rh₀(D) IGIV should be administered in sufficient doses if there is any doubt about the mother's blood type (e.g., presence of passively administered anti-Rh₀(D) in maternal or fetal blood [positive Coombs test]). ■ See [Monitor](#). ■ Manufacturer recommends IM or IV use. Another source recommends IM injection when Rh₀(D) is used as an immunizing agent. ■ Not effective in Rh₀(D)-negative females who have already been sensitized to the Rh₀(D) erythrocyte factor; however, if administered, the risk of side effects is not increased.

Treatment of ITP: IV route required for ITP. ■ Rare cases of intravascular hemolysis have been reported. Usually occurs within 4 hours of administration. Complications may include clinically compromising anemia and multisystem organ failure, including ARDS. Fatalities have occurred. Serious complications, including severe anemia, acute renal insufficiency, renal failure, and DIC, have also been reported. Even if previous infusions have been uneventful, intravascular hemolysis and its complications may occur with subsequent infusions. ■ If the hemoglobin level is less than 8 Gm/dL, use with extreme caution; may increase severity of anemia.

Monitor: All uses: See [Precautions](#). ■ Observe patient for at least 20 to 30 minutes after injection.

Suppression of Rh isoimmunization in pregnancy: Maintain accurate records of Rh factor and Rh₀(D)-IGIV. ■ Obtain CBC and other appropriate lab work based on procedure or situation. ■ Monitor vital signs if indicated.

Treatment of ITP: Obtain baseline RBC, hemoglobin, reticulocyte levels, and platelet counts. Monitor during therapy to determine clinical response. ■ Given to Rh₀(D)-positive patients in this situation, interaction with RBC usually causes some degree of RBC hemolysis; observe carefully. Monitor for S/S of intravascular hemolysis (back pain, chills, fever, hemoglobinuria) for at least 8 hours after infusion. Perform a dipstick urinalysis at baseline, at 2 and 4 hours, and before the end of the monitoring period. ■ Monitor for complications of intravascular hemolysis (IVH), including clinically compromising anemia (decreased hemoglobin, hypotension, pallor, and tachycardia), acute renal insufficiency (anuria, dyspnea, edema, or oliguria), or DIC (increased bruising and prolongation of bleeding or clotting time). ■ If S/S of IVH or its complications occur, lab tests should be performed to confirm the diagnosis. Tests include but are not limited to CBC with platelets, haptoglobin, plasma hemoglobin, urine dipstick, BUN, SCr, LDH, direct and indirect bilirubin, and DIC-specific tests (e.g., D-dimer, fibrin degradation products [FDP], fibrin split products [FSP]). ■ If transfusion is required, use Rh₀(D)-negative RBCs to avoid exacerbating ongoing IVH. Platelet products may contain RBCs; use caution if platelets from an Rh₀(D)+ donor are used.

Patient Education: Report S/S of a hypersensitivity reaction (e.g., feeling of fainting, hives, itching, tightness in the chest, wheezing). ■ Report feelings of dizziness, tiredness,

weakness. **ITP:** May cause a considerable drop in hemoglobin; follow-up testing important. ■ Immediately report symptoms of back pain, chills, decreased urine output, discolored urine or hematuria, fever, sudden weight gain, fluid retention/edema, and/or shortness of breath. May indicate onset of intravascular hemolysis (IVH).

Maternal/Child: Category C: use only if clearly needed. ■ Rhophylac is not secreted in breast milk. Specific information is not available for WinRho SDF on safety during breast-feeding. ■ For the suppression of Rh isoimmunization in the mother; do not administer to the infant.

Elderly: When used for treatment of ITP, fatal outcomes associated with IVH and its complications occurred most frequently in patients over 65 years of age with co-morbid conditions.

DRUG/LAB INTERACTIONS

Interaction with other drugs has not been evaluated. ■ Antibodies contained in Rh₀(D) immune globulin may interfere with the body's immune response to certain **live virus vaccines**. Do not administer live virus vaccines (e.g., measles, mumps, polio, or rubella) for at least 3 months after Rh₀(D) administration. ■ Trace amounts of anti-A, anti-B, anti-C, and anti-E blood group antibodies may be detectable in **direct and indirect anti-globulin (Coombs') tests** following treatment with Rh₀(D). ■ May affect outcomes of **blood typing and antibody testing** in neonates. ■ The liquid formulation of WinRho SDF contains maltose, which may give **falsely high blood glucose levels** with certain types of blood glucose testing systems. Only testing systems that are glucose specific should be used to monitor blood glucose levels in patients receiving maltose-containing parenteral products such as WinRho SDF.

SIDE EFFECTS

All uses: Abdominal or back pain, arthralgias, asthenia, chills, diarrhea, dizziness, fever, headache, hyperkinesia, hypertension, hypotension, increased LDH, pruritus, rash, somnolence, and sweating. Hypersensitivity reactions, including anaphylaxis, have been reported rarely. Made from human plasma donors, transmission of selected diseases possible but not probable; see [Precautions](#).

Suppression of Rh isoimmunization in pregnancy: Side effects are infrequent in Rh₀(D)-negative individuals. Only a few women have had treatment failures resulting in development of Rh₀(D) antibodies.

ITP: Destruction of Rh₀(D) red cells resulting in decreased hemoglobin (range was 0.4 to 6.1 Gm/dL). IVH (back pain, shaking chills, hemoglobinuria), acute onset and exacerbation of anemia, and renal insufficiency have been reported in Rh₀(D)-positive patients. Has rarely resulted in death.

ANTIDOTE

Keep physician informed of side effects; may require symptomatic treatment. Discontinue immediately if an allergic reaction occurs; treat as indicated (e.g., maintain airway, administer fluids, oxygen, epinephrine [Adrenalin], diphenhydramine [Benadryl], corticosteroids [e.g., dexamethasone (Decadron)]). **ITP:** Treatment may have to be discontinued if drop in hemoglobin too severe. Transfusion may be required.

RIFAMPIN(rih-**FAM**-pin)**Rifadin****Antibacterial
(antituberculosis)****pH 7.8 to 8.8****USUAL DOSE**

Dose and schedule may vary depending on treatment regimen selected. IV doses are the same as oral. Use oral dose form as soon as practical.

Tuberculosis (adults and pediatric patients 15 years of age or older): 10 mg/kg once a day when used in conjunction with other antituberculosis agents in a daily regimen, or 10 mg/kg not to exceed 600 mg/dose two or three times a week when used in an intermittent multiple-drug regimen. Do not exceed 600 mg/day. Prescribed concurrently with other antituberculin drugs (e.g., ethambutol [Myambutol], isoniazid [INH], pyrazinamide, or streptomycin). Consult current CDC guidelines for suggested treatment regimens.

Meningococcal carriers: 600 mg every 12 hours for 2 days.

PEDIATRIC DOSE

Tuberculosis: 10 to 20 mg/kg of body weight once a day when used in conjunction with other antituberculosis agents in a daily regimen, or two or three times a week when used in an intermittent multiple-drug regimen. Do not exceed 600 mg. Prescribed concurrently with other antituberculin drugs (e.g., ethambutol [Myambutol], isoniazid [INH], pyrazinamide, or streptomycin).

Meningococcal carriers: Under 1 month of age: 5 mg/kg every 12 hours for 2 days. **Over 1 month of age:** 10 mg/kg every 12 hours for 2 days.

DOSE ADJUSTMENTS

To reduce hepatotoxicity, a reduced dose may be required in impaired hepatic function. ■ No dose adjustment is necessary in impaired renal function; serum concentrations do not change. ■ See [Drug/Lab Interactions](#).

DILUTION

Each 600-mg vial must be initially diluted in 10 mL of SWFI (60 mg/mL). Swirl gently to dissolve. Withdraw desired dose and further dilute in 500 mL or 100 mL of D5W or NS; see [Storage](#).

Storage: Store vials at CRT. Avoid excessive heat (temperatures above 40° C [104° F]). Protect from light. Reconstituted solution stable at RT for 24 hours. Use solution diluted in D5W within 4 hours; solution diluted in NS stable for 24 hours.

COMPATIBILITY

Manufacturer states, “May form a precipitate with diltiazem (Cardizem) at the **Y-site**.” Infusion solutions other than D5W or NS are not recommended.

RATE OF ADMINISTRATION

A single dose equally distributed as an infusion over 3 hours. In selected situations a single dose diluted in 100 mL may be administered over 30 minutes.

ACTIONS

A semi-synthetic antibiotic derivative of rifamycin. Has bactericidal action against slow and intermittently growing *Mycobacterium tuberculosis* organisms. Inhibits bacterial DNA-dependent RNA polymerase activity in susceptible *M. tuberculosis* organisms but does not inhibit the mammalian enzyme. Rapidly distributed throughout the body and present in many organs and body fluids, including CSF. 80% protein bound. Metabolized in the liver. Undergoes enterohepatic circulation. Excreted in bile and urine. Half-life following repeated dosing is 3 to 4 hours. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment or retreatment of tuberculosis when the drug cannot be taken by mouth. ■ Treatment of asymptomatic carriers of *Neisseria meningitidis*. Not indicated for treatment of meningococcal infection because of rapid emergence of resistant meningococci.

Unlabeled uses: Used in combination with other agents in the treatment of certain atypical mycobacterial infections (e.g., *Mycobacterium avium*). ■ Used in combination with other antistaphylococcal agents to treat serious staphylococcal infections.

CONTRAINDICATIONS

Hypersensitivity to rifampin or any of its components or to any rifamycins. Individuals with liver disease are at higher risk for complications. ■ Contraindicated in patients receiving ritonavir-boosted saquinavir; risk for severe hepatocellular toxicity is increased. ■ Concomitant use with atazanavir (Reyataz), darunavir (Prezista), fosamprenavir (Lexiva), saquinavir (Invirase), and tipranavir (Aptivus); see [Drug/Lab Interactions](#).

PRECAUTIONS

For IV use only. Do not administer IM or SC. ■ Obtain cultures before starting therapy to confirm susceptibility of the organism to rifampin. Repeat cultures periodically during therapy to monitor for the emergence of resistance. ■ Resistance can emerge rapidly; appropriate susceptibility tests should be performed in the event of persistent positive cultures. ■ Susceptibility tests also required before use as treatment for asymptomatic carriers of *Neisseria meningitidis*. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, rifampin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Organisms resistant to rifampin are likely to be resistant to other rifamycins. ■ Has been shown to produce liver dysfunction. Risk of liver damage is markedly increased if impaired liver function is present. Hepatotoxicity, hepatic encephalopathy, and death associated with jaundice have occurred in patients with liver disease and when rifampin is given with other hepatotoxic agents (e.g., isoniazid [INH], halothane). Discontinue one or both drugs if signs of hepatocellular damage occur. ■ May exacerbate porphyria. ■ Use with caution in patients with diabetes; diabetes management may be more difficult. ■ Not recommended for intermittent therapy; interruption of daily dosage regimen has resulted in rare renal hypersensitivity reactions when therapy was resumed. ■ Urine, feces, sputum, sweat, and tears may be colored red-orange. Soft contact lenses may be permanently stained. CSF may be light yellow. ■ Pseudomembranous colitis has been reported. May range from mild to life threatening. Consider in patients that present with diarrhea during or after treatment with rifampin.

Monitor: Obtain baseline measurements of hepatic enzymes (e.g., ALT and AST), bilirubin, SCr, CBC, and platelet count. Routine lab monitoring in patients with normal baseline labs is generally not necessary. However, patients should be seen monthly and questioned about symptoms that may indicate adverse reactions. ■ Monitor liver function every 2 to 4 weeks in patients with pre-existing liver impairment. ■ Monitor blood glucose closely in patients with diabetes. ■ Notify physician immediately if flu-like symptoms develop; may be due to hepatotoxicity. ■ Thrombocytopenia has occurred. Reversible if rifampin is discontinued as soon as purpura occurs. Cerebral hemorrhage has occurred when rifampin has been continued or resumed after the appearance of purpura. Contact physician immediately if purpura occurs. ■ Confirm patency of IV; avoid extravasation. Restart IV at a new site for any signs of inflammation or irritation. ■ Do all lab tests and affected radiology studies before daily dose of medication. ■ See [Drug/Lab Interactions](#).

Patient Education: Reliability of hormonal contraceptives may be affected; use of nonhormonal contraceptives recommended. ■ Avoid use of alcohol or other hepatotoxic agents (e.g., acetaminophen [Anacin-3, Tylenol], NSAIDs [ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], phenothiazines [e.g., promethazine (Phenergan)], some antineoplastic agents, sulfonamides). ■ Review side effects with health care professional and promptly report darkened urine, fever, loss of appetite, malaise, nausea and vomiting, pain or swelling of the joints, or yellowish discoloration of the skin and eyes. ■ May

cause reddish-orange discoloration of feces, sputum, sweat, urine, and tears. ■ May discolor soft contact lenses. ■ Do not interrupt daily dosage regimen.

Maternal/Child: Category C: has teratogenic potential. Safety for use during pregnancy not established. Benefit must outweigh risk. See literature for best combinations with least known risk. ■ Administration during the last few weeks of pregnancy may cause post-natal hemorrhages in mother and infant; treatment with vitamin K may be required. ■ Closely monitor neonates of rifampin-treated mothers for adverse effects. ■ Discontinue breast-feeding if mother requires treatment.

Elderly: Differences in response between elderly and younger patients have not been identified. ■ See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Interactions are numerous and potentially life threatening. Review of drug profile by pharmacist imperative. ■ Hepatotoxicity, hepatic encephalopathy, and death associated with jaundice have occurred when rifampin is given with **other hepatotoxic agents** (e.g., alcohol, isoniazid [INH], halothane). Discontinue one or both drugs for signs of hepatocellular damage. ■ Concurrent use of rifampin with **saquinavir/ritonavir** (ritonavir-boosted saquinavir) is **contraindicated**; significant hepatocellular toxicity with markedly increased transaminase elevations have been reported. ■ Concurrent administration with **atazanavir** (Reyataz), **darunavir** (Prezista), **fosamprenavir** (Lexiva), **saquinavir** (Invirase), and **tipranavir** (Aptivus) is **contraindicated**; rifampin may substantially decrease plasma concentrations of these antiviral agents. Loss of antiviral effectiveness and/or development of viral resistance may result. ■ Rifampin increases metabolism and clearance and decreases serum levels and effectiveness of numerous drugs. Manufacturer lists **antiarrhythmics** (e.g., disopyramide [Norpace], mexiletine, quinidine, tocainide [Tonocard]), **anticonvulsants** (e.g., phenytoin [Dilantin]), **antifungals** (e.g., fluconazole [Diflucan], itraconazole [Sporanox], ketoconazole [Nizoral]), **barbiturates** (e.g., phenobarbital), **beta-blockers** (e.g., propranolol), **calcium channel blockers** (e.g., diltiazem [Cardizem], nifedipine [Procardia], verapamil), **cardiac glycoside preparations** (e.g., digoxin [Lanoxin], digitoxin), **chloramphenicol** (Chloromycetin), **clarithromycin** (Biaxin), **clofibrate** (Atromid-S), **corticosteroids** (e.g., prednisone), **cyclosporine** (Sandimmune), **dapsone**, **diazepam** (Valium), **doxycycline**, **fluoroquinolones** (e.g., ciprofloxacin [Cipro IV]), **haloperidol** (Haldol), **levothyroxine** (Synthroid), **methadone**, **narcotic analgesics**, **oral anticoagulants** (e.g., warfarin [Coumadin]), **oral hypoglycemic agents** (e.g., sulfonylureas [e.g., glyburide (DiaBeta), tolbutamide]), **oral or other systemic hormonal contraceptives**, progestins (e.g., progesterone), **quinine**, **tacrolimus** (Prograf), **theophylline** (aminophylline), **tricyclic antidepressants** (e.g., amitriptyline [Elavil], nortriptyline [Aventyl]), **zidovudine**. Other sources add **amiodarone** (Nexterone), **amprenavir** (Agenerase), **benzodiazepines** (e.g., midazolam [Versed], in addition to diazepam), **buspirone** (BuSpar), **estrogens**, **lamotrigine** (Lamictal), **losartan** (Cozaar), **ondansetron** (Zofran), and **zolpidem** (Ambien). Increased doses of these drugs may be required. Monitor carefully; obtain prothrombin daily when used with **anticoagulants** (e.g., warfarin); use of **nonhormonal contraceptives** recommended during rifampin therapy; and **diabetes** may be more difficult to control. ■ May reduce analgesic effects of **morphine and methadone**. Monitor carefully; an alternate analgesic may be required (see earlier statement). ■ Treatment failure of **ketoconazole** (Nizoral) or **rifampin** may occur when given concomitantly. ■ Concomitant use of rifampin and **macrolide antibiotics** (e.g., clarithromycin) may decrease the metabolism of rifampin and increase the metabolism of the macrolide antibiotic. ■ Potentiated by **probenecid** and **cotrimoxazole**. ■ May decrease concentrations of enalaprilat, the active metabolite of **enalapril** (Vasotec), resulting in hypertension. Adjust dose as required. ■ When taken concomitantly, decreased concentrations of **atovaquone** (Mepro) and increased concentration of rifampin have been observed. ■ May induce metabolism of endogenous substrates including **adrenal hormones**, **thyroid hormones**, and **vitamin D**. Reduced levels of vitamin D may be accompanied by decreased serum calcium and phosphate and increased parathyroid hormone. ■ Concomitant administration with **sulfasalazine** may cause a decrease in sulfapyridine levels. ■ Cross-reactivity and false-positive urine screening **tests for opiates** have been reported

when using certain assays. Gas chromatography or mass spectrometry will distinguish rifampin from opiates. ■ May cause an early rise in bilirubin during initial days of treatment; should subside. Throughout treatment transient abnormalities in **liver function tests** will occur. Monitor laboratory trends and patient's clinical condition. ■ Therapeutic levels inhibit microbiologic assays of **serum folate and vitamin B₁₂**. ■ Reduced biliary excretion of contrast media for **gallbladder studies** may occur. Perform test prior to dose of rifampin.

SIDE EFFECTS

Average dose: Anaphylaxis may occur even with repeat doses. Abnormal liver function tests, anorexia, ataxia, behavioral changes, conjunctivitis (exudative), cramps, diarrhea, DIC, dizziness, edema of face and extremities, epigastric distress, eosinophilia, fatigue, flushing, flu-like symptoms (e.g., chills, fever, headache, malaise, muscle and bone pain), gas, heartburn, hematuria, hemolytic anemia, hepatic reactions, hepatitis or a shocklike syndrome and abnormal liver function tests (rare), hypersensitivity reactions (e.g., pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria), hypotension, jaundice, leukopenia, menstrual disturbances, mental confusion, myopathy (rare), muscle weakness, nausea, numbness (generalized), pain in extremities, pseudomembranous colitis, psychosis purpura, renal failure (acute), shortness of breath, sore mouth and tongue, thrombocytopenia, visual disturbances, vomiting, wheezing.

Overdose: Abdominal pain, bilirubin levels and/or liver enzymes may increase rapidly; brown-red discoloration of feces, skin, sweat, tears, and urine is proportional to amount of overdose; headache, lethargy, nausea, and vomiting are immediate; pruritus, unconsciousness. Liver enlargement, possibly with tenderness, can develop within a few hours after severe overdose; bilirubin levels may increase and jaundice may develop rapidly. Arrhythmias, cardiac arrest, hypotension, and seizures have been reported in fatal overdoses.

ANTIDOTE

With increasing severity of any side effect, alterations in liver function tests, flu-like symptoms, purpura, thrombocytopenia, or symptoms of overdose, discontinue the drug and notify the physician immediately. Antiemetics (e.g., ondansetron [Zofran], prochlorperazine [Compazine]) may be required to control nausea and vomiting. Forced diuresis will promote excretion. Hemodialysis may be indicated. If hemodialysis is not available, peritoneal dialysis can be used along with forced diuresis. In severe overdose or acute toxicity, maintain an adequate airway and confirm adequate respiratory exchange. Treat anaphylaxis and resuscitate as necessary.

RITUXIMAB **BBW**

(rih-TUK-sih-mab)

Recombinant monoclonal antibody

Antineoplastic

Rituxan

pH 6.5

USUAL DOSE

Premedication: Use recommended for all indications. Acetaminophen (Tylenol) and diphenhydramine (Benadryl) are recommended before each dose to prevent or attenuate severe hypersensitivity and/or infusion reactions. Additional premedication (e.g., methylprednisolone 100 mg IV or equivalent) is required for patients with rheumatoid arthritis (RA). Patients with granulomatosis with polyangiitis (GPA [Wegener's granulomatosis (WG)]) and microscopic polyangiitis (MPA) require additional premedication with methylprednisolone IV 1,000 mg. Transient hypotension may occur during rituximab infusion; consider withholding antihypertensive medications 12 hours before rituximab infusion. See **Precautions** for PCP prophylaxis and/or antiherpetic viral prophylaxis required in specific indications.

Relapsed or refractory, low-grade or follicular, CD20-positive, B-cell non-Hodgkin's lymphoma (NHL): Single agent: Initial therapy: 375 mg/M² as an infusion once a week for 4 or 8 doses. See [Drug/Lab Interactions](#). Risk of Grade 3 or 4 adverse events increased with treatment with 8 doses as compared to treatment with 4 doses. **Retreatment therapy:** Patients who subsequently develop progressive disease may be retreated with 375 mg/M² as an IV infusion once each week for 4 doses. Incidence of adverse events similar to initial therapy. Data on more than 2 courses are limited.

Previously untreated follicular, CD20-positive, B-cell NHL: 375 mg/M² as an infusion, given on Day 1 of each cycle of CVP chemotherapy for up to 8 doses. In patients with complete or partial response, initiate rituximab maintenance 8 weeks after completion of rituximab in combination with chemotherapy. Administer rituximab as a single agent every 8 weeks for 12 doses.

Non-progressing, low-grade, CD20-positive, B-cell NHL (after first-line CVP chemotherapy): In patients who have not progressed following 6 to 8 cycles of CVP chemotherapy (stable disease), 375 mg/M² may be administered as an infusion once a week for 4 doses every 6 months for up to 16 doses.

Diffuse large B-cell, CD20-positive NHL: 375 mg/M² as an infusion on Day 1 of each cycle of chemotherapy for up to 8 doses.

Chronic lymphocytic leukemia (CLL): 375 mg/M² the day before the initiation of FC chemotherapy (fludarabine [Fludara] and cyclophosphamide [Cytoxan]) in the first cycle, then 500 mg/M² on Day 1 of Cycles 2 through 6 (every 28 days); see [Precautions](#).

Rheumatoid arthritis: Administer **glucocorticoids** (e.g., methylprednisolone [Solu-Medrol] 100 mg IV) 30 minutes before each infusion of rituximab to reduce the incidence and severity of infusion reactions. Follow with a **rituximab** infusion of 1,000 mg. Repeat entire sequence one time in 2 weeks. Given in combination with methotrexate. Subsequent courses should be administered every 24 weeks or based on clinical evaluation, but not sooner than every 16 weeks.

Granulomatosis with polyangiitis (GPA [Wegener's granulomatosis (WG)]) and microscopic polyangiitis (MPA):

Methylprednisolone: 1,000 mg/day IV for 1 to 3 days followed by oral prednisone 1 mg/kg/day (not to exceed 80 mg/day and tapered per clinical need) is recommended to treat severe vasculitis symptoms. This regimen should begin within 14 days before or with the initiation of rituximab and may continue during and after the 4-week course of treatment.

Rituximab: 375 mg/M² as an infusion once weekly for 4 weeks. Safety and effectiveness of subsequent courses not established. See [Precautions](#).

Therapeutic regimen with ibritumomab tiuxetan: 250 mg/M² as an IV infusion. Given in a specific protocol in combination with Y-90 ibritumomab tiuxetan (Zevalin); see ibritumomab monograph.

DOSE ADJUSTMENTS

No dose adjustments recommended. Has not been formally studied in patients with renal or hepatic impairment. See [Rate of Administration](#). ■ Interrupt or slow infusion rate for infusion reactions. Continue the infusion at one-half the previous rate when symptoms subside.

DILUTION

Each single dose must be further diluted to a final concentration of 1 to 4 mg/mL with NS or D5W. 500 mg (50 mL) in 450 mL will yield 1 mg/mL; 500 mg (50 mL) in 75 mL will yield 4 mg/mL. Gently invert to mix solution. Contains no preservatives; discard any unused portion left in vial.

Storage: Refrigerate vials at 2° to 8° C (36° to 46° F); protect from light and freezing. Do not shake. Do not use beyond expiration date. Diluted solutions may be refrigerated for 24 hours and are stable at room temperature for an additional 24 hours.

COMPATIBILITY

Manufacturer states, "Rituximab should not be mixed or diluted with other drugs." No **incompatibilities** with polyvinylchloride or polyethylene bags have been observed.

RATE OF ADMINISTRATION

Must be given as an infusion. **Do not administer as an IV push or bolus.** Hypersensitivity (non-IgE-mediated) and/or infusion reactions are a common occurrence and may be prevented or lessened with premedication and a reduced rate of infusion.

First infusion: Begin with an initial rate of 50 mg/hr (at this rate a 500-mg dose would be infused over 10 hours). If no discomfort or adverse effects occur, may be gradually increased by 50-mg/hr increments at 30-minute intervals to a maximum rate of 400 mg/hr. At any time that discomfort or adverse effects occur, reduce the rate of infusion. Discontinue the infusion for severe reactions and treat as indicated; see [Antidote](#). When symptoms have completely resolved, the infusion can be restarted at half the previous rate.

Subsequent infusions: If the patient did not tolerate the first infusion well, follow instructions under first infusion. If no discomfort or adverse effects occurred with the first infusion,

Standard infusion: Subsequent infusions may begin with an initial rate of 100 mg/hr and increased by 100-mg/hr increments at 30-minute intervals to a maximum rate of 400 mg/hr. See all precautionary measures under [First Infusion](#) (see above).

Previously untreated follicular NHL and diffuse large B-cell lymphoma (DLBCL) patients: If a Grade 3 or 4 infusion-related reaction did not occur during the first infusion, a subsequent 90-minute infusion can be administered with a glucocorticoid-containing chemotherapy regimen. Administer the corticosteroid, acetaminophen, and diphenhydramine; follow with rituximab. Administer 20% of rituximab dose equally distributed over the first 30 minutes and the remaining 80% of the dose equally distributed over 60 minutes. If this initial subsequent 90-minute infusion is tolerated, it can be repeated in the remaining infusions of the protocol. ■ Patients who have clinically significant cardiovascular disease or who have a circulating lymphocyte count equal to or greater than 5,000/mm³ before Cycle 2 should not be administered the 90-minute infusion.

ACTIONS

An antineoplastic agent. A humanized (Ig)G₁ monoclonal antibody produced by recombinant DNA technology. Designed to bind to the CD20 antigen found on the surface of normal and malignant B lymphocytes. CD20 is also expressed on more than 90% of B-cell non-Hodgkin's lymphomas but is not expressed on hematopoietic stem cells. CD20 regulates an early step(s) in the activation process for cell cycle initiation and differentiation. Rituximab binds to lymphoid cells in the thymus, the white pulp of the spleen, and a majority of B lymphocytes in peripheral blood and lymph nodes. There is little or no binding to nonlymphoid tissue. Results in a rapid and sustained depletion (cytotoxicity) of circulating and tissue-based B cells. Cell lysis may be the result of complement-dependent cytotoxicity and antibody-dependent cellular cytotoxicity. May sensitize drug-resistant human B-cell lymphoma cell lines to cytotoxic chemotherapy. Detected in serum for 3 to 6 months after completion of therapy. B-cell depletion was sustained for 6 to 9 months posttreatment in 83% of patients. B-cell recovery begins at approximately 6 months, and most levels return to normal by 12 months following completion of treatment. B-cells are believed to play a role in the pathogenesis of RA and associated chronic synovitis. In this setting, B-cells may act at multiple sites in the autoimmune/inflammatory process, including through production of rheumatoid factor and other auto-antibodies, antigen presentation, T-cell activation, and/or pro-inflammatory cytokine production. In RA it induces depletion of peripheral B-lymphocytes, with near-complete depletion occurring in most patients within 2 weeks of the first dose. This B-lymphocyte depletion lasted for at least 6 months, followed by a gradual recovery. Treatment with rituximab in patients with RA was associated with a reduction of certain biologic markers for inflammation. A few patients had prolonged peripheral B-cell depletion lasting more than 3 years after a single course of treatment. Median half-life ranged from 18 to 32 days depending on diagnosis. Crosses the placental barrier. May be secreted in breast milk.

INDICATIONS AND USES

As a single agent in the treatment of patients with relapsed or refractory low-grade or follicular CD20-positive, B-cell NHL. ■ In combination with CHOP (cyclophosphamide, doxorubicin [hydroxydaunorubicin], vincristine, and prednisone) or other anthracycline-based chemotherapy regimens for treatment in previously untreated diffuse large B-cell, CD20-positive NHL. ■ Treatment of previously untreated follicular, CD20-positive, B-cell NHL in combination with first-line chemotherapy and as a single-agent maintenance therapy in patients achieving a complete or partial response to rituximab in combination with chemotherapy. ■ Treatment of non-progressing (including stable disease), low-grade, CD20-positive, B-cell NHL as a single agent after first-line CVP chemotherapy. ■ Treatment of patients with previously untreated and previously treated CD20-positive CLL. Used in combination with FC chemotherapy (fludarabine and cyclophosphamide). ■ In combination with glucocorticoids for the treatment of adult patients with granulomatosis with polyangiitis (GPA [Wegener's granulomatosis (WG)]) and microscopic polyangiitis (MPA). ■ In combination with ibritumomab tiuxetan as part of a therapeutic regimen for the treatment of patients with relapsed or refractory low-grade, follicular, or transformed B-cell NHL, including patients with rituximab-refractory follicular NHL. ■ In combination with methotrexate to reduce S/S and to slow the progression of structural damage in adult patients with moderate to severe RA who have had an inadequate response to one or more TNF (tumor necrosis factor) antagonist therapies.

Limitation of use: Not recommended for patients with severe active infections.

Unlabeled uses: To postpone relapses in patients with NHL.

CONTRAINDICATIONS

Manufacturer states, "None." Known IgE-mediated hypersensitivity or anaphylactic reactions to murine proteins, rituximab, or any of its components.

PRECAUTIONS

Has been given on an outpatient basis; however, rituximab should be administered by or under the direction of the physician specialist in facilities equipped to monitor the patient and respond to any medical emergency. ■ Severe infusion reactions and hypersensitivity reactions have occurred for up to 24 hours after initiating rituximab infusions, and some have been fatal. Most severe reactions occur within 30 minutes to 2 hours of beginning the first infusion. S/S of severe reactions may include hypotension, angioedema, hypoxia, urticaria, or bronchospasm. More severe manifestations may include anaphylactic and anaphylactoid events, pulmonary infiltrates, acute respiratory distress syndrome, myocardial infarction, ventricular fibrillation, and cardiogenic shock. ■ Use caution in patients who either have or develop HAMA/HACA titers. Clinical relevance of HACA formation in rituximab-treated patients is unclear. ■ Tumor lysis syndrome (TLS) has been reported within 12 to 24 hours after the first rituximab infusion in patients with NHL. S/S are rapid reduction in tumor volume, renal insufficiency, hyperkalemia, hypocalcemia, hyperuricemia, or hyperphosphatemia. May cause acute renal failure requiring dialysis and has been fatal. ■ TLS occurs more often in patients with high numbers of circulating malignant cells or high tumor burden. Consider prophylactic measures; see **Monitor**. ■ Renal toxicity occurs more frequently in patients with high numbers of circulating malignant cells, high tumor burden, and/or TLS. Severe, including fatal, renal toxicity has occurred in patients with NHL. ■ Safety of immunization with vaccines, particularly live virus vaccines, and the ability of the patient to respond to vaccines following rituximab therapy has not been studied. Review vaccination status. Administration of live virus vaccines is not recommended. Weigh benefit versus risk in NHL patients if a delay in treatment may occur for vaccination. ■ Administer any CDC-recommended, non-live virus vaccinations to RA patients at least 4 weeks before initiating treatment with rituximab. ■ In CLL patients, *Pneumocystis jiroveci* pneumonia (PCP) and antiherpetic viral prophylaxis is recommended during treatment and for up to 12 months following treatment. ■ In GPA (WG) and MPA patients, *Pneumocystis jiroveci* pneumonia (PCP) prophylaxis is recommended during treatment and

for at least 6 months following the last rituximab infusion. ■ Mucocutaneous reactions (including lichenoid dermatitis, paraneoplastic pemphigus, Stevens-Johnson syndrome, toxic epidermal necrolysis, and vesiculobullous dermatitis), some with fatal outcomes, have been reported. Onset of reaction has been variable and includes reports of onset on the first day of rituximab exposure. ■ Hepatitis B virus reactivation with fulminant hepatitis, hepatic failure, and death has been reported. Persons at high risk for hepatitis B virus infections should be screened before initiation of rituximab. ■ Carriers of hepatitis B should be closely monitored for clinical and laboratory S/S of hepatitis and/or active hepatitis B virus infection during and for several months following discontinuation of rituximab. ■ Not recommended for use in patients with severe active infections. ■ Serious (including fatal) bacterial, fungal, and new or reactivated viral infections can occur during and following rituximab therapy. Infections have been reported in some patients with prolonged hypogammaglobulinemia (defined as hypogammaglobulinemia more than 11 months after rituximab exposure). New or reactivated viral infections have included JC virus (progressive multifocal leukoencephalopathy [PML], cytomegalovirus, herpes simplex virus, parvovirus B19, varicella zoster virus, West Nile virus, and hepatitis B and C). Deaths have occurred. ■ PML is a rare, progressive, demyelinating disease of the CNS caused by infection of the JC virus. Usually leads to death or severe disability, and there is no effective treatment. Has been reported in patients receiving rituximab for both approved and unlabeled indications. Most of these patients received rituximab in combination with chemotherapy, prior to or concurrent with immunosuppressive therapy, or as part of a hematopoietic stem cell transplant. However, PML has also been reported in patients with autoimmune diseases (e.g., rheumatoid arthritis) who have been treated previously or concurrently with immunosuppressive therapy. ■ RA patients may have an increased risk of cardiovascular events. ■ Not indicated for use in patients with RA who have responded to treatment with TNF antagonists (e.g., adalimumab [Humira], etanercept [Enbrel]). ■ Abdominal pain, bowel obstruction, and perforation have been reported in patients receiving rituximab in combination with chemotherapy. Death has occurred. ■ Use of concomitant immunosuppressants other than corticosteroids has not been studied in GPA (WG) or MPA patients exhibiting peripheral B-cell depletion following treatment with rituximab. ■ See [Rate of Administration](#), [Drug/Lab Interactions](#), and [Antidote](#).

Monitor: In patients with lymphoid malignancies who are receiving rituximab monotherapy, obtain a baseline CBC and platelet count and repeat before each course of therapy. In patients treated with rituximab and chemotherapy, obtain baseline CBC and platelet count at weekly to monthly intervals. Repeat more frequently in patients who develop cytopenias (e.g., leukopenia, neutropenia, thrombocytopenia). Duration of cytopenias may extend months beyond the treatment period. In RA, GPA (WG), or MPA patients, obtain a baseline CBC and platelet count and repeat at 2- to 4-month intervals during therapy. Prolonged and late-onset neutropenia have been observed; see [Post-Marketing](#). Prolonged neutropenia is defined as Grade 3 to 4 neutropenia that has not resolved between 24 and 42 days after the last dose of treatment. Late-onset neutropenia is defined as Grade 3 to 4 neutropenia starting at least 42 days after the last treatment dose. ■ Observe patient continuously for symptoms of hypersensitivity and/or infusion reactions, which are more common during the first infusion but can occur at any time; see [Antidote](#). ■ Monitor HR and BP frequently. ■ ECG and pulmonary monitoring required during and in the immediate posttreatment period in patients with pre-existing cardiac or pulmonary conditions, in any patient who develops or has previously developed a clinically significant cardiopulmonary adverse event during treatment, and in patients with RA. ■ Monitor patients with high numbers of circulating malignant cells (greater than or equal to 25,000/mm³) with or without other evidence of high tumor burden for infusion reaction and tumor lysis syndrome. Monitoring of serum electrolytes and renal function indicated. ■ Prevention and treatment of hyperuricemia due to TLS may be accomplished with adequate hydration and, if necessary, allopurinol (Aloprim) and alkalization of urine; see [Drug/Lab Interactions](#). ■ Prevention and/or treatment of hyperphosphatemia,

hyperkalemia, and hypocalcemia due to TLS is also indicated. ■ Monitor closely for signs of renal failure, and discontinue rituximab in patients with a rising SCr or oliguria. ■ Assess neurologic status frequently. Consider PML in patients with new-onset neurologic manifestations; consultation with a neurologist, brain MRI, and lumbar puncture may be required for diagnosis. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for signs of mucocutaneous reactions. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor patients with diffuse large B-cell, CD20-positive NHL treated with R-CHOP closely for abdominal pain, especially early in the course of treatment. A thorough diagnostic evaluation is indicated; treat appropriately to prevent bowel obstruction and perforation. ■ See [Premedication in Usual Dose, Rate of Administration, Precautions, Drug/Lab Interactions, and Antidote](#).

Patient Education: Avoid pregnancy; nonhormonal birth control recommended; report a suspected pregnancy immediately. See [Maternal/Child](#). ■ Read manufacturer's patient information sheet before each infusion. ■ Discuss health history (e.g., presence of an infection, carrier of or had a previous hepatitis B virus infection, heart or lung problems, recent or scheduled vaccinations, scheduled surgeries) and prescription and non-prescription medications with the health care provider administering the rituximab. ■ Review monitoring requirements and potential side effects before therapy. ■ Promptly report S/S of infection (e.g., fever), blisters, cough, difficulty breathing, dizziness, drowsiness, headache, hives, peeling skin, painful sores, ulcers, swelling, or wheezing; immediate medical treatment may be indicated. ■ New neurologic S/S (e.g., changes in vision, loss of balance or coordination, disorientation, or confusion); could be warning signs of PML. Report them promptly. ■ See Appendix D, p. 1255.

Maternal/Child: Category C: avoid pregnancy; women of childbearing age should use birth control during treatment and for up to 12 months after completion of treatment. B-cell lymphocytopenia generally lasting less than 6 months has occurred in infants exposed to rituximab in utero. Use only if clearly needed. ■ Use caution if breast-feeding; weigh risk versus benefit. ■ Safety and effectiveness for use in pediatric patients not established. Hypogammaglobulinemia has been observed in pediatric patients treated with rituximab.

Elderly: No overall differences in effectiveness were observed between different age-groups of patients treated for diffuse large B-cell NHL. Cardiac and pulmonary adverse reactions (e.g., supraventricular arrhythmia, pneumonia, pneumonitis) occurred more frequently in the elderly. ■ The numbers of elderly treated for low-grade or follicular NHL were insufficient to determine differences. ■ The incidence of Grade 3 and 4 adverse reactions was higher in patients over 70 years of age treated for CLL with R-FC. No observed benefit was seen with the addition of rituximab to FC in patients over 70 years of age. ■ In older patients being treated for RA, GPA, or MPA, the incidence of side effects was similar to younger adults; however, the rates of serious side effects, including serious infection, malignancies, and cardiovascular events, was higher.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. ■ Transient hypotension may occur during rituximab infusion; **consider withholding antihypertensive medications** 12 hours before rituximab infusion. ■ May inhibit the generation of an anamnestic (immunologic memory) or humoral (development of antibodies in the blood) response to any **vaccine**. ■ Pharmacokinetics of rituximab remained similar to rituximab alone when given in combination with CHOP chemotherapy (cyclophosphamide, doxorubicin, vincristine, prednisone). ■ Risk of renal toxicity increased in patients receiving concomitant therapy with **cisplatin** (the combination of cisplatin and rituximab is not an approved treatment regimen). ■ Concurrent use with **CHOP chemotherapy** has resulted in an in-

crease in fatal infections in HIV-related lymphoma patients. ■ Data on the safety of the use of biologic agents or **disease-modifying antirheumatic drugs** (DMARDs) other than methotrexate in RA patients are limited. Monitor patients closely for signs of infection with concurrent use of biologic agents or DMARDs other than methotrexate.

SIDE EFFECTS

CD20-positive, B-cell NHL: The most common side effects are asthenia, chills, fever, infection, infusion reactions, and lymphopenia.

Diffuse large B-cell, CD20-positive NHL: In addition to the previously listed side effects, anemia, neutropenia, viral infection, and Grade 3 or 4 respiratory symptoms and thrombocytopenia occurred more frequently among patients on the R-CHOP regimen. Patients on this regimen 60 years of age and over reported increased incidences of cardiac events (e.g., supraventricular arrhythmias, tachycardia), chills, fever, and respiratory symptoms.

CLL: The most common side effects during clinical trials were infusion reactions and neutropenia.

Major side effects for the previously listed indications include angina, bowel obstruction and perforation, cardiac arrhythmias (e.g., supraventricular and ventricular tachycardia, ventricular fibrillation), hepatitis B reactivation with fulminant hepatitis and other viral infections (including JC virus infection resulting in PML), hypersensitivity reactions (e.g., hypotension, bronchospasm, and angioedema), infusion reactions, mucocutaneous reactions (e.g., lichenoid dermatitis, paraneoplastic pemphigus, Stevens-Johnson syndrome, toxic epidermal necrolysis, and vesiculobullous dermatitis), renal failure, and tumor lysis syndrome (may occur within 12 to 24 hours). Hypersensitivity or infusion-related side effects generally occur within 30 minutes to 2 hours of beginning of first infusion. Other side effects include abdominal pain, angioedema, anorexia, anxiety, arthralgia, back pain, bone marrow suppression (e.g., anemia, leukopenia, neutropenia, thrombocytopenia, prolonged pancytopenia, and marrow hypoplasia), cough, diarrhea, dizziness, dyspnea, elevated LDH, flushing, headache, hyperglycemia, hypertension, hypotension, infections (with or without neutropenia), myalgia, nausea, night sweats, pain at disease sites, peripheral edema, pruritus, rash, respiratory symptoms (e.g., acute infusion-related bronchospasm, acute pneumonitis 1 to 4 weeks post-rituximab infusion, bronchiolitis obliterans [one case ended in death]), rhinitis, sinusitis, tachycardia, throat irritation, urticaria, and vomiting. Incidence of abdominal pain, anemia, dyspnea, hypotension, and neutropenia is higher in patients with bulky disease lesions equal to or greater than 10 cm.

Rheumatoid arthritis: Similar to those seen in patients with NHL. Major side effects include infusion reactions, cardiac events, immunogenicity, and infections (e.g., bronchitis, nasopharyngitis, sinusitis, URI, UTI). Other more frequently reported side effects include abdominal pain (upper), anxiety, arthralgia, asthenia, chills, dyspepsia, fever, hypercholesterolemia, hypertension, migraine headache, nausea, paresthesia, pruritus, rhinitis, throat irritation, urticaria.

GPA (WG) and MPA: Most common side effects reported include anemia, diarrhea, headache, infections, muscle spasm, and peripheral edema. Other commonly reported side effects include arthralgia, cough, dyspnea, epistaxis, fatigue, hypertension, hypogammaglobulinemia, increased ALT, insomnia, leukopenia, nausea, and rash. All major side effects associated with rituximab (e.g., infusion reactions, infections) may occur.

Post-Marketing: Bowel obstruction and perforation, bronchiolitis obliterans (fatal), cardiac failure (fatal), disease progression of Kaposi's sarcoma, Grade 3 to 4 prolonged or late-onset neutropenia, hyperviscosity syndrome in Waldenström's macroglobulinemia, hypogammaglobulinemia (prolonged), increase in fatal infections in HIV-associated lymphoma and a reported increased incidence of Grade 3 and 4 infections in patients with previously treated lymphoma without known HIV infection, lupus-like syndrome, marrow hyperplasia, mucocutaneous reactions (severe), neutropenia (late onset), optic neuritis, pancytopenia (prolonged), pleuritis, pneumonitis (including interstitial pneumonitis), polyarticular arthritis, serum sickness, systemic vasculitis, uveitis, vasculitis with rash, and viral infections, including PML.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Hypersensitivity or infusion-related side effects generally resolve with slowing or interruption of the rituximab infusion and with supportive care (IV saline; diphenhydramine; bronchodilators such as albuterol [Ventolin] or aminophylline; and acetaminophen). Most patients who have had non-life-threatening reactions have been able to complete the full course of therapy. Restart the infusion at half the previous rate after symptoms have resolved completely. Discontinue the infusion immediately for any life-threatening side effect (e.g., clinically significant bronchospasm, cardiac arrhythmias, Grade 3 or 4 infusion reactions, hypersensitivity reactions, hypotension, tumor lysis syndrome, or severe mucocutaneous reaction). Discontinue rituximab in any patient who develops a serious infection. Initiate appropriate antiviral/anti-infective therapy as indicated. Discontinue treatment in patients who develop severe mucocutaneous reactions. Skin biopsy may be required to diagnose mucocutaneous reaction and guide treatment. Safety of readministration of rituximab to patients with severe mucocutaneous reactions has not been determined. Discontinue treatment in patients who develop PML; consider reduction or discontinuation of concomitant chemotherapy or immunosuppressive therapy. Discontinue treatment in patients with a rising SCr or oliguria. Treat anaphylaxis with oxygen, antihistamines (diphenhydramine), epinephrine, and corticosteroids. Maintain a patent airway. Treat arrhythmias if indicated and monitor ECG until recovery and with subsequent doses. Treat hypotension with IV fluids, Trendelenburg position, and, if necessary, vasopressors (e.g., norepinephrine [Levophed], dopamine). Blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Tumor lysis syndrome requires correction of electrolyte abnormalities and monitoring of renal function and fluid balance. Supportive care, including dialysis, may be required. Resuscitate if indicated.

ROMIDEPSIN

(ROE-mi-DEP-sin)

Antineoplastic
(HDAC inhibitor)

Istodax

USUAL DOSE

14 mg/M² as an infusion over 4 hours. Administer on Days 1, 8, and 15 of a 28-day cycle; see **Monitor**. Cycles may be repeated every 28 days provided the patient continues to benefit from and tolerates the drug. Discontinuation or interruption with or without dose reduction to 10 mg/M² may be needed to manage adverse drug reactions; see **Dose Adjustments**.

DOSE ADJUSTMENTS

Romidepsin Dose Modification for Nonhematologic Toxicities Except Alopecia		
CTCAE* Grade on Day of Treatment	Action	Dose on Recovery
Grade 2 or 3 toxicity	Delay dose until toxicity returns to ≤ Grade 1 or baseline	14 mg/M ²
Grade 3 toxicity recurrence	Delay dose until toxicity returns to ≤ Grade 1 or baseline	Permanently reduce dose to 10 mg/M ²
Grade 4 toxicity	Delay dose until toxicity returns to ≤ Grade 1 or baseline	Permanently reduce dose to 10 mg/M ²
Grade 3 or 4 toxicities recur after dose reduction	Discontinue therapy	

*Per Common Terminology Criteria for Adverse Events (CTCAE), Version 3.

Romidepsin Dose Modification for Hematologic Toxicities		
CTCAE* Grade on Day of Treatment	Action	Dose on Recovery
Grade 3 or 4 neutropenia or thrombocytopenia	Delay dose until ANC ≥1,500/mm ³ and/or platelet count ≥75,000/mm ³	14 mg/M ²
Grade 4 febrile (≥38.5° C) neutropenia or thrombocytopenia that requires platelet transfusion	Delay dose until the specific cytopenia returns to ≤ Grade 1 or baseline	Permanently reduce dose to 10 mg/M ²

*Per Common Terminology Criteria for Adverse Events (CTCAE), Version 3.

No dose adjustments required based on age, gender, race, mild or moderate renal impairment, or mild hepatic impairment.

DILUTION

Special techniques required; see Precautions: Reconstitute each 10-mg vial with 2 mL of the supplied diluent. Inject diluent slowly into the vial of romidepsin and swirl contents until there are no visible particles. Concentration equals 5 mg/mL. Withdraw the calculated dose and further dilute in 500 mL NS.

Filters: Specific information not available.

Storage: Store vials in carton at CRT. Reconstituted solution is stable for 8 hours at RT. Diluted solutions are stable at RT for 24 hours, but use soon after dilution is recommended.

COMPATIBILITY

Manufacturer states, “The diluted solution is **compatible** with polyvinyl chloride (PVC), ethylene vinyl acetate (EVA), polyethylene (PE) infusion bags as well as glass bottles.” No additional information available; consider specific use and consult pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 4 hours.

ACTIONS

A histone deacetylase (HDAC) inhibitor. HDACs catalyze the removal of acetyl groups from acetylated lysine residues in histones, resulting in the modulation of gene expression. Induces cell cycle arrest and apoptosis of some cancer cell lines. Mechanism of antineoplastic effect not fully characterized. Highly protein bound. It undergoes extensive metabolism *in vitro* by CYP3A4 with minor contributions from other cytochrome P₄₅₀ isoenzymes. Half-life is approximately 3 hours. No accumulation of plasma concentrations observed after repeated dosing.

INDICATIONS AND USES

Treatment of cutaneous T-cell lymphoma (CTCL) and peripheral T-cell lymphoma (PTCL) in patients who have received at least one prior systemic therapy. These indications are based on response rates. Improvement in overall survival has not been demonstrated.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patients and respond to any medical emergency. ■ Bone marrow suppression can occur (e.g., anemia, lymphopenia, neutropenia, and thrombocytopenia). Dose modification based on ANC, and platelet count is required; see [Dose Adjustments](#). ■ Serious and sometimes fatal infections, including pneumonia and sepsis, have been reported during or within 30 days of therapy. ■ ECG changes have been reported (e.g., T-wave and ST-segment changes, QT prolongation). Use caution in patients with congenital long QT syndrome or a history of significant CV disease or in patients taking antiarrhythmic medicines that lead to significant QT prolongation; see [Drug/Lab Interactions](#). ■ Tumor lysis syndrome has been reported. ■ Use with caution in patients with moderate or severe hepatic impairment. ■ Renal impairment is not expected to influence romidepsin exposure. Effect on end-stage renal disease (ESRD) has not been studied; use with caution in patients with ESRD.

Monitor: Due to the risk of QT prolongation, potassium and magnesium should be within the normal range before administration of romidepsin. ■ Obtain baseline CBC, platelets, and electrolytes. Baseline CrCl or SCr and liver function tests may be indicated. ■ Monitor CBC, platelets, and electrolytes during treatment and modify dose as indicated; see [Dose Adjustments](#). ■ Consider ECG monitoring and more frequent monitoring of electrolytes in at-risk cardiac patients; see [Precautions](#). ■ Monitor for signs of tumor lysis syndrome. Prevention and treatment of hyperuricemia may be accomplished with adequate hydration and, if necessary, allopurinol and alkalization of urine. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Use prophylactic antiemetics to reduce nausea and/or vomiting and increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient.

Patient Education: Read patient insert carefully. ■ Avoid pregnancy; nonhormonal birth control recommended; see [Drug/Lab Interactions](#). ■ Blood counts will be required at regular intervals. ■ Promptly report unusual bleeding, excessive nausea or vomiting, abnormal heartbeat, chest pain, or shortness of breath. ■ Report burning on urination, cough, fever, flulike symptoms, muscle aches, or worsening of skin problems. ■ Discuss medications (prescription, non-prescription, and herbal) with a health care professional; see [Drug/Lab Interactions](#). ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. If the drug is used during pregnancy or the patient becomes pregnant during therapy, inform the patient of the potential hazard to the fetus. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: No differences in safety and effectiveness compared with younger patients were noted; however, greater sensitivity of some older patients cannot be ruled out.

DRUG/LAB INTERACTIONS

Concurrent use with **warfarin** (Coumadin) may prolong PT and elevate INR. Monitoring of PT and INR recommended. ■ **Strong CYP3A4 inhibitors** (e.g., atazanavir [Reyataz], clarithromycin [Biaxin], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase], telithromycin [Ketek], and voriconazole [VFEND]) may increase concentrations of romidepsin; avoid concurrent use if possible. Use caution with concomitant use of **moderate CYP3A4 inhibitors** (aprepitant [Emed], verapamil). ■ **Potent CYP3A4 inducers** (e.g., carbamazepine [Tegretol], dexamethasone [Decadron], phenobarbital [Luminal], phenytoin [Dilantin], rifabutin [Mycobutin], rifapentine [Priftin], rifampin [Rifadin], and St. John's wort) may decrease concentrations of romidepsin and should be avoided. ■ Use caution with other **drugs that inhibit the efflux transporter P-glycoprotein (P-gp, ABCB1)** (e.g., protease inhibitors [e.g., nelfinavir (Viracept)]); may increase concentrations of romidepsin. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Concurrent use with other **drugs that prolong the QT interval** (e.g., antiarrhythmics [e.g., amiodarone (Nexterone), disopyramide (Norpace), ibutilide (Corvert), mexiletine, procainamide (Pronestyl), quinidine], antihistamines, azole antifungals [e.g., itraconazole (Sporanox)], fluoroquinolones [e.g., levofloxacin (Levaquin)], phenothiazines [e.g., thioridazine (Mellaril)], and tricyclic antidepressants [e.g., amitriptyline (Elavil), imipramine (Tofranil)]) may cause torsades de pointes and could be fatal.

SIDE EFFECTS

Most common side effects are anorexia, bone marrow suppression (e.g., anemia, lymphopenia, neutropenia, thrombocytopenia), ECG T-wave changes, fatigue, infections, nausea, and vomiting. Serious adverse reactions reported included central line infection, edema, fatigue, fever, infection, leukopenia, nausea, neutropenia, sepsis, supraventricular arrhythmia, thrombocytopenia, and ventricular arrhythmia. Dyspnea, fatigue, infection, and QT prolongation were the most common reasons for discontinuing therapy. Other side effects reported include asthenia, constipation, dermatitis, diarrhea, dysgeusia, exfoliative dermatitis, elevated AST and ALT, hyperglycemia, hypermagnesemia, hyperuricemia, hypoalbuminemia, hypocalcemia, hypokalemia, hypomagnesemia, hypophosphatemia, hyponatremia, hypotension, and pruritus.

ANTIDOTE

Treatment of most side effects will be supportive and may require dose adjustment or discontinuation. Discontinue if Grade 3 or 4 toxicities recur after dose reduction. Keep physician informed. Administration of blood products and/or blood modifiers (e.g., darbepoetin [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Treat hypersensitivity reactions with epinephrine, antihistamines, and corticosteroids as needed. No known antidote. Discontinue romidepsin and provide supportive therapy in overdose. Not known if romidepsin is dialyzable. Resuscitate if indicated.

SARGRAMOSTIM

(sar-GRAM-oh-stim)

Colony-stimulating factor
Antineutropenic**GM-CSF, Human Granulocyte-Macrophage
Colony-Stimulating Factor, Leukine**

pH 7.1 to 7.7

USUAL DOSE

Myeloid reconstitution after allogeneic or autologous bone marrow transplantation: 250 mcg/M²/day as a 2-hour infusion daily for 21 days. Initial infusion must begin 2 to 4 hours after bone marrow infusion and not less than 24 hours after the last dose of chemotherapy and 12 hours after the last dose of radiation. Post-marrow infusion absolute neutrophil count (ANC) should be less than 500 cells/mm³.

Engraftment delay or failure of bone marrow transplantation: 250 mcg/M²/day as a 2-hour infusion daily for 14 days. Wait for 7 days; if engraftment has not occurred, repeat 14-day course of 250 mcg/M²/day. Wait an additional 7 days; if engraftment has still not occurred, give a 14-day course of 500 mcg/M²/day. If engraftment does not occur, further courses or dose increases are not indicated. Note time restrictions on chemotherapy and radiation above and in Drug/Lab Interactions.

Neutrophil recovery following chemotherapy in acute myelogenous leukemia (AML) in adults 55 years of age or older: 250 mcg/M²/day as an infusion over 4 hours. Begin on Day 11 or 4 days after induction chemotherapy is complete. Day 10 bone marrow should be hypoplastic with fewer than 5% blasts. Repeat sargramostim daily until absolute neutrophil count (ANC) is greater than 1,500/mm³ for three consecutive days or a maximum of 42 days. Use same criteria if a second cycle of induction chemotherapy is indicated.

Mobilization of peripheral blood progenitor cells: 250 mcg/M²/day as a 24-hour continuous infusion (or give SC once daily). Continue at the same dose until adequate numbers of progenitor stem cells are collected. Collection of progenitor cells (apheresis) usually begins about Day 5 and is repeated daily. All cells are stored until predetermined targets are achieved. After immunosuppression with selected antineoplastic bone marrow suppressant agents to neutralize remaining tumor cells or ineffective leukocytes, the collected progenitor stem cells are reinfused into the patient by IV infusion. This process has been used primarily in patients who were not candidates for bone marrow transplant; however, it is increasingly being used instead of bone marrow transplant.

Post-peripheral blood progenitor cell transplantation: 250 mcg/M²/day as a 24-hour continuous infusion (or give SC once daily). Begin immediately following infusion of harvested progenitor cells and continue until an ANC is greater than 1,500/mm³ for three consecutive days. Neutrophil recovery occurs somewhat sooner in patients receiving sargramostim stimulation. Results in a shorter time to platelet and RBC transfusion independence.

DOSE ADJUSTMENTS

May require reduced dose in impaired renal or hepatic function. Based on individual patient response. ■ For an ANC above 20,000 cells/mm³, WBC above 50,000 cells/mm³, or a platelet count above 500,000/mm³, reduce dose by one half or temporarily discontinue. ■ See *Antidote*.

DILUTION

Now available in liquid form (reconstituted) or each 250- or 500-mcg vial of the dry product must be reconstituted with 1 mL SWFI with or without preservative. Confirm expiration date to ensure valid product. Direct diluent to the side of the vial and swirl gently. Avoid foaming or vigorous agitation. Do not shake. Either product must be further diluted in NS for infusion. If the final concentration of sargramostim will be below 10 mcg/mL, albumin (human) must be added to the NS before addition of the sargramostim (1 mL of 5% albumin to each 50 mL NS). This will prevent adsorption of the drug into

the components of the IV delivery system. Liquefied product contains benzyl alcohol. Use sterile technique; enter vial only to dilute and/or to withdraw a single dose. Discard any unused portion. Should be clear and colorless.

Filters: Manufacturer states, "**An in-line membrane filter should not be used for IV infusion of sargramostim.**"

Storage: Must be refrigerated in all forms; do not freeze or shake. Reconstituted with SWFI without preservatives or any diluted solution should be used within 6 hours. Reconstituted with bacteriostatic SWFI (benzyl alcohol preservative) or the new liquid preparation can be refrigerated for up to 20 days.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends that no medication other than albumin be added to the infusion solution and that only NS be used to prepare IV solutions until specific **compatibility** data are available.

One source suggests the following **compatibilities**:

Y-site: Amikacin (Amikin), aminophylline, amphotericin B (conventional), aztreonam (Azactam), bleomycin (Blenoxane), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), cefazolin (Ancef), cefotaxime (Claforan), cefotetan, ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cyclosporine (Sandimmune), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), dexamethasone (Decadron), diphenhydramine (Benadryl), dopamine, doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), etoposide (VePesid), famotidine (Pepcid IV), fentanyl (Sublimaze), fluconazole (Diflucan), fluorouracil (5-FU), furosemide (Lasix), gentamicin, granisetron (Kytril), heparin, idarubicin (Idamycin), ifosfamide (Ifex), immune globulin IV (e.g., Gamunex-C), magnesium sulfate, mannitol, mechlorethamine (nitrogen mustard), meperidine (Demerol), mesna (Mesnex), methotrexate, metoclopramide (Reglan), metronidazole (Flagyl IV), mitoxantrone (Novantrone), pentostatin (Nipent), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), sulfamethoxazole/trimethoprim, teniposide (Vumon), ticarcillin/clavulanate (Timentin), vancomycin, vincristine, vincristine, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

See **Usual Dose**. Each single dose must be evenly distributed over 2, 4, or 24 hours. Do not use an in-line membrane filter. Reduce rate or temporarily discontinue for onset of any side effects that cause concern (e.g., hypersensitivity reactions).

ACTIONS

Colony-stimulating factors are glycoproteins that bind to specific hematopoietic cell surface receptors and stimulate proliferation, differentiation commitment, and some end-cell functional activation. Utilizing recombinant DNA technology, sargramostim is produced in a yeast (*Saccharomyces cerevisiae*). It differs slightly from endogenous G-CSF. It induces partially committed progenitor cells to divide and differentiate in the granulocyte-macrophage pathways. Can also activate mature granulocytes and macrophages. It is a multilineage factor and has dose-dependent effects. It increases the cytotoxicity of monocytes toward certain neoplastic cell lines and activates polymorphonuclear neutrophils to inhibit the growth of tumor cells. It significantly improves the time to neutrophil recovery (engraftment), decreases length of hospitalization, shortens the duration of infectious episodes, and decreases antibiotic usage. Patients with fewer impaired organs have the best opportunity for improvement in survival. Detected in the serum in 5 minutes; peak levels are reached 2 hours after injection and last at least 6 hours.

INDICATIONS AND USES

Acceleration of hematopoietic recovery (myeloid engraftment) in patients undergoing allogeneic or autologous bone marrow transplantation. ■ Bone marrow transplantation failure or engraftment delay. ■ Neutrophil recovery following chemotherapy in acute myelogenous leukemia (AML); safety for use in adults under 55 years not established. ■ Mobilization of peripheral blood progenitor cells. ■ Stimulate neutrophil recovery post-peripheral blood progenitor cell transplantation.

Unlabeled uses: Increase WBC in myelodysplastic syndromes and in AIDS patients receiving zidovudine. ■ Correct neutropenia in aplastic anemia. ■ Decrease transplantation-associated organ system damage, especially in kidney and liver transplants.

CONTRAINDICATIONS

Hypersensitivity to any components of sargramostim or yeast products; patients with leukemic myeloid blasts in the bone marrow or peripheral blood equal to 10% or more.

PRECAUTIONS

Should be administered under the direction of a physician knowledgeable about appropriate use. ■ Use caution if considered for use in any malignancy with myeloid characteristics. Can act as a growth factor for any tumor type, particularly myeloid malignancies. ■ Can be effective in patients receiving purged bone marrow if the purging process preserves a sufficient number of progenitors. ■ Effects may be limited in patients previously exposed to intensive chemotherapy or radiation therapy. ■ Neutralizing antibodies may form after receiving sargramostim and may inhibit therapeutic effect.

Monitor: Obtain a CBC with differential before administration and twice weekly thereafter to monitor for excessive leukocytosis (WBC above 50,000 cells/mm³; or an absolute neutrophil count [ANC] above 20,000 cells/mm³). ■ If blast cells appear or disease progression occurs, treatment should be discontinued. ■ Anemia, leukocytopenia, and thrombocytopenia occur as side effects of various procedures; monitor carefully. ■ Observe for fluid retention; may cause peripheral edema, pleural effusion, and/or pericardial effusion. May occur more frequently in individuals with pre-existing lung disease or cardiac disease, including a history of arrhythmias. Use with caution. ■ Use with caution in patients with pre-existing renal or hepatic dysfunction; an increased SCr or increased bilirubin and hepatic enzymes may occur. Reversible if drug discontinued. Monitor renal and hepatic function biweekly. ■ Flushing, hypotension, and syncope may occur, especially with the initial dose. Reduce rate or stop temporarily.

Patient Education: Promptly report any symptoms of infection (e.g., fever) or hypersensitivity reactions (e.g., itching, swelling, redness at the injection site).

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding not established; use only if clearly needed. ■ Has been used in more than 100 pediatric patients from 4 months to 18 years of age with similar experience to the adult population, even though literature says safety not established. ■ Liquefied product contains benzyl alcohol; do not use in neonates.

DRUG/LAB INTERACTIONS

Do not administer within 24 hours preceding or following **chemotherapy** or within 12 hours preceding or following **radiotherapy**. Rapidly dividing cells and the success of the treatment would be adversely affected by chemotherapy and radiation. ■ Myeloproliferative effects may be potentiated by **lithium or corticosteroids**; use with caution.

SIDE EFFECTS

Asthenia, diarrhea, malaise, peripheral edema, rash, and urinary tract disorders are most common. Hypersensitivity reactions, including anaphylaxis, are possible; arthralgia, capillary leak syndrome, dyspnea, fever, headache, hypoxia, local injection site reactions, myalgia, pericardial effusion, peripheral edema, pleural effusion, and supraventricular arrhythmias have been reported.

ANTIDOTE

Discontinue sargramostim for anaphylaxis, if blast cells appear, or there is progression of underlying disease. A maximum dose limit has not been determined; for accidental overdose, discontinue and monitor for WBC increase and respiratory symptoms. For an ANC above 20,000 cells/mm³, WBC above 50,000 cells/mm³, or a platelet count above 500,000/mm³, reduce dose by one half or temporarily discontinue. Blood cell count should return to baseline level in 3 to 7 days. For any side effect that causes concern, reduce dose or temporarily discontinue. Keep physician informed. Treat anaphylaxis and resuscitate as necessary.

SILDENAFIL **BBW***

(sil-DEN-a-fil)

Vasodilating agent

Antihypertensive (pulmonary)

Revatio

*This drug is on the Black Box Warning list; however, a BBW is not provided in the parenteral prescribing information.

USUAL DOSE

10 mg (12.5 mL) as an IV bolus 3 times daily. Administer doses 4 to 6 hours apart. A 10-mg IV dose of sildenafil is equivalent to a 20-mg oral dose. Resume oral therapy as soon as tolerated.

DOSE ADJUSTMENTS

No dose adjustments required for age, gender, race, weight, renal impairment (mild, moderate, or severe), or hepatic impairment (mild or moderate). Has not been studied in patients with severe hepatic impairment.

DILUTION

May be given undiluted. Aseptically withdraw the dose directly into a syringe for immediate use.

Filters: Specific information not available.

Storage: Store vials at CRT.

COMPATIBILITY

Specific information not available. Manufacturer made no recommendations.

RATE OF ADMINISTRATION

A single dose as an IV bolus.

ACTIONS

An inhibitor of cGMP-specific phosphodiesterase type 5 (PDE-5) in the smooth muscle of the pulmonary vasculature where PDE5 is responsible for degradation of cGMP. Sildenafil increases cGMP within pulmonary vascular smooth muscle cells, resulting in relaxation. In patients with pulmonary hypertension, this can lead to vasodilation of the pulmonary vascular bed and, to a lesser degree, vasodilation in the systemic circulation. PDE5 is also found in other tissues, including vascular and visceral smooth muscle, and in platelets. Sildenafil and its major metabolite are approximately 96% protein bound. Metabolized in the liver predominantly by CYP3A4 and other hepatic microsomal isoenzymes. Terminal half-life is about 4 hours. Findings suggest a lower clearance and/or a higher bioavailability of sildenafil in patients with pulmonary hypertension compared with healthy volunteers. Primarily excreted in feces and approximately 13% in urine.

INDICATIONS AND USES

Treatment of pulmonary arterial hypertension (PAH) (WHO Group 1) in patients who are currently prescribed oral sildenafil and are temporarily unable to take oral medications. Intended to improve exercise ability and delay clinical worsening. Delay in clinical worsening demonstrated with concurrent use of epoprostenol (Flolan). Studies establishing

effectiveness included predominantly patients with NYHA Functional Class II-III symptoms and idiopathic etiology or associated with connective tissue disease.

Limitation of use: Effectiveness in the treatment of PAH in patients taking bosentan (Tracleer) has not been adequately evaluated.

CONTRAINDICATIONS

Known hypersensitivity to sildenafil or any component of the product. ■ Potentiates the hypotensive effects of nitrates. Do not use with organic nitrates in any form (medicines that treat chest pain [angina], nitroglycerin in any form, isosorbide mononitrate [Monoket, Imdur], or isosorbide dinitrate [Isordil, Dilatrate-SR], street drugs called “poppers” [amyl nitrate or nitrite]). ■ See [Drug/Lab Interactions](#).

PRECAUTIONS

Has vasodilatory properties, resulting in mild and transient decreases in BP. Use with caution in patients with resting hypotension (BP less than 90/50 mm Hg), fluid depletion, severe left ventricular outflow obstruction, autonomic dysfunction, and in patients undergoing antihypertensive therapy. ■ Mortality increase with increasing dose noted in pediatric patients; see [Maternal/Child](#). ■ Not recommended for use in patients with pulmonary veno-occlusive disease (PVOD); it may significantly worsen their cardiac status. Consider the possibility of associated PVOD if signs of pulmonary edema occur. ■ Epistaxis has been reported in patients with PAH secondary to connective tissue disease (CTD) and in patients treated with a concomitant oral vitamin K antagonist (warfarin [Coumadin]). ■ Safety for use in patients with bleeding disorders or active peptic ulceration is unknown. ■ Sudden loss of vision in one or both eyes has been reported and may lead to permanent loss of vision. Use with caution in patients with retinitis pigmentosa. ■ Retinal hemorrhage has occurred in patients with risk factors for hemorrhage, including concurrent **anticoagulant** therapy. ■ Sudden decrease or loss of hearing has been reported; may be accompanied by dizziness and tinnitus. ■ Use with caution in patients with an anatomic deformation of the penis (e.g., angulation, cavernosal fibrosis, or Peyronie’s disease) or in patients with conditions that may predispose them to priapism (e.g., sickle cell anemia, multiple myeloma, or leukemia). Penile tissue damage and permanent loss of potency can result from priapism lasting more than 6 hours. ■ Effectiveness and safety of sildenafil in pulmonary hypertension secondary to sickle cell anemia has not been established. Increased incidence of vaso-occlusive crisis requiring hospitalization has been reported in this patient population. ■ See [Drug/Lab Interactions](#).

Monitor: Obtain baseline studies as indicated by specific patient history. ■ Monitor VS closely to note unsafe drops in BP. Monitoring of BP is especially important when sildenafil is coadministered with other BP-lowering drugs. ■ Monitor for cardiovascular and cerebrovascular events, especially in patients with risk factors. ■ Monitor for vision and/or hearing loss. ■ See [Precautions](#), [Patient Education](#), and [Drug/Lab Interactions](#).

Patient Education: Read manufacturers patient education booklet carefully. ■ Never take sildenafil with nitrate medicines; may cause a sudden and unsafe drop in BP. ■ Do not take Viagra or other similar medications for erectile dysfunction with sildenafil. ■ Seek immediate medical attention with a sudden loss of vision in one or both eyes. ■ Seek prompt medical attention in the event of a sudden decrease or loss of hearing. ■ Seek emergency help if an erection lasts for more than 4 hours. ■ Discuss medications (prescription, non-prescription, and herbal) with a health care professional; see [Drug/Lab Interactions](#).

Maternal/Child: Category B: use during pregnancy only if clearly needed. ■ Use during labor and delivery has not been studied. ■ Not known if sildenafil is secreted in human milk; use caution if required during breast-feeding. ■ Use in pediatric patients, particularly chronic use, is not recommended. In a long-term study, mortality increased; deaths were first observed after about 1 year.

Elderly: Major differences in response compared with younger adults have not been identified; however, healthy elderly volunteers had a reduced clearance resulting in higher

plasma concentrations. Dosing should be cautious. Consider age-related organ impairment and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

Sildenafil is also marketed as Viagra. Do not take **Viagra or other PDE5 inhibitors** (e.g., tadalafil [Cialis], vardenafil [Levitra]) concurrently with sildenafil (Revatio). ■ Concurrent use with **nitrates** (e.g., amyl nitrate, nitroglycerin, nitroprusside) in any form (regularly or intermittently) is **contraindicated**. May result in an unsafe drop in BP. ■ Concurrent use with **alpha-adrenergic blocking agents** (e.g., alfuzosin [Uroxatral], doxazosin [Cardura], phentolamine, prazosin [Minipress], tamsulosin [Flomax], terazosin [Hytrin]) can lower BP significantly and lead to symptomatic hypotension. BP may be lowered further with this combined use of vasodilators by other variables, including intravascular volume depletion and concomitant use of **antihypertensive drugs** (e.g., calcium channel blockers [amlodipine (Norvasc), diltiazem (Cardizem)]). ■ Concomitant use of sildenafil with **ritonavir** (Norvir) **and other potent CYP3A4 inhibitors** (e.g., atazanavir [Reyataz], clarithromycin [Biaxin], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], saquinavir [Invirase], telithromycin [Ketek], and voriconazole [VFEND]) **is not recommended**. ■ **Cimetidine** (Tagamet) and **erythromycin** may cause an increase in sildenafil plasma concentrations. ■ **Potent CYP3A4 inducers** (e.g., carbamazepine [Tegretol], dexamethasone [Decadron], phenytoin [Dilantin], phenobarbital [Luminal], rifabutin [Mycobutin], rifapentine [Prifitin], rifampin [Rifadin], and St. John's wort) may increase sildenafil clearance and reduce its effectiveness. ■ **Bosentan** (Tracleer) may also increase sildenafil clearance. ■ Concurrent use with epoprostenol (Flolan) did not have a significant effect on sildenafil pharmacokinetics, effect on epoprostenol not known. ■ Does not potentiate the increase in bleeding time caused by aspirin. ■ Did not potentiate hypotensive effects with alcohol in healthy volunteers. ■ Has been given with atorvastatin [Lipitor], oral contraceptives, and tolbutamide without effect.

SIDE EFFECTS

Manufacturer does not distinguish between side effects caused by oral dosing versus injectable dosing. Most common side effects are dyspepsia, dyspnea, epistaxis, erythema, flushing, headache, insomnia, and rhinitis. Serious side effects include hearing loss, hypotension, indigestion, priapism, vaso-occlusive crisis, and vision loss. Other side effects reported include diarrhea, fever, gastritis, myalgia, paresthesia, and sinusitis. Sildenafil combined with epoprostenol (Flolan) added edema (including peripheral edema), nasal congestion, nausea, and pain in extremities. Retinal hemorrhage occurred in patients with risk factors for hemorrhage, including concurrent anticoagulant therapy. Most hypersensitivity reactions have been nonserious. Serious hypersensitivity reactions (e.g., anaphylaxis, shock) have been rare.

Post-Marketing: Serious cardiovascular, cerebrovascular, and vascular events, including MI, cerebrovascular hemorrhage, hypertension, pulmonary hemorrhage, subarachnoid and intracerebral hemorrhages, TIA, ventricular arrhythmia, and sudden cardiac death; sudden decrease or loss of hearing; seizure; and seizure recurrence.

ANTIDOTE

Treatment of most side effects will be supportive. Notify physician immediately if a serious side effect occurs (e.g., hearing loss, hypotension, hypersensitivity, priapism, vision loss). Treat hypersensitivity reactions with epinephrine, antihistamines, and corticosteroids as needed. Hemodialysis is not expected to be effective in overdose.

SIPULEUCEL-T

Provence

Autologous cellular immunotherapy
Antineoplastic

USUAL DOSE

An autologous (derived from the same individual) cellular immunotherapy. Each infusion of sipuleucel-T is preceded by a leukapheresis procedure and a specific preparation procedure by the manufacturer; see [Dilution](#) and [Actions](#). Three complete doses are administered at approximately 2-week intervals (range of 1 to 15 weeks in clinical trials).

Approximately 3 days before the desired infusion date: Leukapheresis: Peripheral blood mononuclear cells are obtained via a standard leukapheresis procedure. These cells are then sent to the manufacturer (Dendreon) to be prepared for reinfusion into the patient.

Day of infusion: Premedication: Administer oral acetaminophen and an antihistamine (e.g., diphenhydramine [Benadryl]) 30 minutes before administration to minimize potential acute infusion reactions (e.g., chills, fever).

Sipuleucel-T: For autologous IV use only. Do **not** use a cell filter. Confirm that the patient's identity matches the patient identifiers on the infusion bag and the Cell Product Disposition Form (CPDF). Each dose contains a minimum of 50,000,000 autologous CD54+ cells activated with PAP-GM-CSF and suspended in 250 mL of LR in a sealed, patient-specific infusion bag. Do **not** infuse until confirmation of product release has been received from Dendreon; see [Dilution](#). Infusion must begin before the expiration date and time on the Cell Product Disposition Form (CPDF).

DILUTION

Will be shipped directly to the infusing provider in packaging intended to protect the infusion bag and maintain storage temperatures until infusion. Verify the product and patient-specific labels located on top of the insulated container. Do **not** remove from the shipping box or open the lid of the insulated container until the patient is ready for infusion. The manufacturer will send to the infusion site a CPDF that contains the patient identifiers, expiration date and time, and disposition status (approved for infusion or rejected). When all preparations have been made for infusion and the CPDF has been received and verified, remove the sipuleucel-T infusion bag from the insulated container and inspect for signs of leakage. Contents will be slightly cloudy and a cream-to-pink color. Gently mix and resuspend contents, inspecting for clumps and clots. Small clumps of cellular material should disperse with gentle manual mixing. Do **not** administer if the bag leaks during handling or if clumps remain in the bag.

Filters: Do not use a cell filter.

Storage: After removal from the insulated container, the infusion must be complete within 3 hours at RT. Do not return to the shipping container. Do not initiate infusion of expired sipuleucel-T.

COMPATIBILITY

Specific information not available; however, specific use indicates it should be administered separately; consult pharmacist.

RATE OF ADMINISTRATION

A single dose of 250 mL as an infusion equally distributed over 1 hour. Do **not** use a cell filter. If an infusion reaction occurs, decrease rate or interrupt infusion depending on the severity of the reaction; see [Antidote](#).

ACTIONS

An autologous cellular immunotherapy. The patient's own immune cells are obtained through leukapheresis. Active components of sipuleucel-T are autologous peripheral blood mononuclear cells, including antigen-presenting cells (APCs) and PAP-GM-CSF (prostatic acid phosphatase [PAP], an antigen expressed in prostate cancer tissue, linked to granulocyte-macrophage colony-stimulating factor [GM-CSF], an immune cell activator). The recombinant antigen can bind to and be processed by APCs into smaller protein

fragments. The recombinant antigen is designed to target APCs and may help direct the immune response to PAP. The final product contains T-cells, B cells, natural killer (NK) cells and other cells.

INDICATIONS AND USES

Treatment of asymptomatic or minimally symptomatic metastatic hormone refractory prostate cancer.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Intended solely for autologous use. For IV use only. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Concurrent use of immunosuppressive agents may alter the effectiveness and/or safety of sipuleucel-T; see [Drug/Lab Interactions](#). ■ Health care professionals must use universal precautions when handling leukapheresis material and sipuleucel-T. Neither is routinely tested for transmissible infectious diseases and thus may carry the risk of infectious disease transmission to health professionals during handling of the products. ■ Acute infusion reactions (reported within 1 day of infusion) occur frequently and range from mild to serious; see [Monitor](#). Incidence increased with the second infusion and decreased after the third infusion.

Monitor: Obtain baseline vital signs and repeat as indicated. ■ Observe the patient for S/S of an acute infusion reaction (e.g., bronchospasm, chills, fatigue, fever, hypertension, joint aches, nausea, tachycardia) during the infusion and for at least 30 minutes after the infusion. If an acute infusion reaction occurs, the infusion may be interrupted or slowed depending on the severity of the reaction. Do not resume the infusion if the bag will be held at RT for more than 3 hours. ■ Closely monitor patients with cardiac or pulmonary conditions. ■ If the patient is unable to receive a scheduled infusion, the patient will need to undergo an additional leukapheresis procedure. ■ Monitor for extravasation.

Patient Education: Maintain all scheduled appointments. ■ An additional leukapheresis procedure will be required if a scheduled infusion cannot be completed. ■ A central venous line may be required if peripheral venous access is not adequate to accommodate the leukapheresis procedure and/or the infusion. ■ Promptly report S/S of an infusion reaction (e.g., breathing problems, chills, dizziness, fatigue, fever, headache, hypertension, muscle aches, nausea, or vomiting). ■ Report S/S that may indicate a cardiac arrhythmia (e.g., very slow or rapid pulse). ■ Review prescription and non-prescription drug profile with a physician; see [Drug/Lab Interactions](#).

Maternal/Child: Not indicated for use in these populations.

Elderly: Safety similar to that seen in younger adults.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been performed. ■ Use of either **chemotherapy or immunosuppressive agents** (such as systemic corticosteroids) given concurrently with the leukapheresis procedure or sipuleucel-T has not been studied. ■ Sipuleucel-T is designed to stimulate the immune system, and concurrent use of **immunosuppressive agents** may alter the effectiveness and/or safety of sipuleucel-T. Evaluate patients carefully for the medical appropriateness of reducing or discontinuing immunosuppressive agents before treatment.

SIDE EFFECTS

The most common events of backache, chills, fatigue, fever, headache, joint aches, and nausea are usually mild or moderate and generally resolve within 2 days. Other side effects included anemia, anorexia, citrate toxicity, constipation, cough, diarrhea, hematuria, hot flush, influenza-like illness, insomnia, muscle aches and spasms, pain (bone, extremity, musculoskeletal, musculoskeletal chest, and neck), paresthesia (oral, extremity), peripheral edema, rash, sweating, tremor, URIs, UTIs, weight loss. Acute infusion reactions (mild to moderate) occur frequently. Severe acute infusion reactions (Grade 3) add asthenia, bronchospasm, dizziness, dyspnea, hypertension, hypoxia, and vomiting.

Cerebrovascular events (e.g., hemorrhagic and ischemic strokes) and single reports of eosinophilia, myasthenia gravis, myositis, rhabdomyolysis, and tumor flare have been reported.

ANTIDOTE

Keep the physician informed of significant side effects and treat as appropriate. For acute infusion reactions, the infusion may be interrupted or slowed depending on the severity of the reaction. Do not resume the infusion if the bag will be held at RT for more than 3 hours. In controlled clinical trials, acute infusion reactions were treated with acetaminophen, IV antihistamines (e.g., diphenhydramine [Benadryl]) and/or H₂ blockers (e.g., ranitidine [Zantac]) and low-dose IV meperidine. Resuscitate as indicated.

SODIUM ACETATE

(SO-dee-um AS-ah-tayt)

Electrolyte replenisher
Anti hyponatremic
Alkalinizing agent

pH 6 to 7

USUAL DOSE

Determined by nutritional needs, evaluation of electrolytes, and degree of hyponatremia. Some solutions may contain aluminum; see [Precautions](#). Available in 2 mEq and 4 mEq/mL concentrations. Each mL provides 2 or 4 mEq each of sodium and acetate.

DOSE ADJUSTMENTS

Lower-end initial doses may be appropriate in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Must be added to larger volumes of IV infusion solutions including total parenteral nutrition. Use only clear solutions. Check labels for aluminum content; see [Precautions](#).

Storage: Store at room temperature. Discard unused portion.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Enalaprilat (Vasotec IV), esmolol (Brevibloc), labetalol, nicardipine (Cardene IV), ondansetron (Zofran).

RATE OF ADMINISTRATION

Administer at prescribed rate for infusion solutions. Rapid or excessive administration may produce sodium overload, water retention, alkalosis, or hypokalemia.

ACTIONS

An alkalinizing agent and sodium salt. Sodium is the predominant cation of extracellular fluid. It controls water distribution throughout the body. Hypothalamus osmoreceptors, sensitive to osmolarity changes in the blood, control serum sodium concentration (142 mEq/L). Body fluid is lost when sodium content decreases and retained when sodium content increases. Sodium is excreted by the kidney. The acetate ion is metabolized to bicarbonate, thus providing a source of bicarbonate. It also acts as a hydrogen ion receptor.

INDICATIONS AND USES

To prevent or correct hyponatremia in patients with restricted intake, especially in individualized IV formulations when basic needs are not met by standard solutions. ■ Treatment of mild to moderate acidotic states. ■ Source of sodium ions in hemodialysis and peritoneal dialysis.

CONTRAINDICATIONS

Patients with hypernatremia or water retention.

PRECAUTIONS

Use with caution in impaired renal function, congestive heart failure, hypertension, peripheral or pulmonary edema, any condition resulting in salt retention, and in patients receiving corticosteroids. ■ Use acetate-containing solutions with extreme caution in patients with metabolic or respiratory alkalosis and/or impaired hepatic function. ■ Temporary therapy in acidosis. Treatment of primary condition must be instituted. ■ Sodium bicarbonate is the drug of choice for use in severe acidosis that requires immediate correction. ■ Some solutions of sodium acetate contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation.

Monitor: Evaluate electrolytes frequently during treatment. ■ Evaluate fluid balance. ■ Rapid or excessive administration may produce alkalosis or hypokalemia. Cardiac arrhythmias may result from an intracellular shift of potassium. Many other complications may arise from electrolyte imbalance.

Maternal/Child: Category C: safety not established; use only if clearly needed.

Elderly: Differences in response between elderly and younger patients have not been identified. Lower-end initial doses may be appropriate in the elderly; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Alkalinization of urine may increase the renal elimination and decrease the effects of many drugs, including **tetracyclines**, **chlorpropamide**, **lithium carbonate**, **methotrexate**, **salicylates**, and may decrease the renal elimination and prolong the effects of others, including **anorexiant**s (e.g., amphetamines), **flecainide**, **mecamylamine**, **quinidine**, **sympathomimetics** (e.g., ephedrine, dopamine).

SIDE EFFECTS

Hypernatremia, sodium level over 147 mEq/L, is most common (congestive heart failure, delirium, dizziness, edema, fever, flushing, headache, hypotension, oliguria, pulmonary edema, reduced salivation and lacrimation, respiratory arrest, restlessness, swollen tongue, tachycardia, thirst, weakness). Alkalosis and fluid or solute overload can occur.

ANTIDOTE

Notify the physician of any side effect. Reduce rate and notify physician at first sign of congestion or fluid overload. May be treated by sodium restriction and/or use of diuretics (e.g., furosemide [Lasix]) or dialysis. Resuscitate as necessary.

SODIUM BICARBONATE

(SO-dee-um bye-KAR-bon-ayt)

Electrolyte replenisher
Alkalinizing agent

pH 7 to 8.5

USUAL DOSE

Adjusted according to pH, P_{aCO_2} , calculated base deficit, clinical response, and fluid limitations of the patient. In the presence of a low CO_2 content, adjust gradually to avoid unrecognized alkalosis. Correction to a CO_2 of 20 mEq/L within 24 hours will most likely result in a normal pH if the cause of acidosis is controlled and normal kidney function is present. Average dose for most indications is 2 to 5 mEq/kg/24 hr in adults and pediatric patients.

Cardiac arrest: 1 mEq/kg of body weight, only when appropriate (see **Precautions**; evidence supports little benefit and use may be detrimental). Repeat half dose in 10 minutes if indicated by blood pH and P_{aCO_2} .

PEDIATRIC DOSE

0.5 to 1 mEq/kg. For neonates and children up to 2 years of age, dose must never exceed 8 mEq/kg/24 hr of a 4.2% or more dilute solution; see **Usual Dose**, **Monitor**, and **Maternal/Child**.

DILUTION

4.2% sodium bicarbonate solution: 5 mEq/10 mL (0.5 mEq/mL).

5% sodium bicarbonate solution: 297.5 mEq/500 mL (0.595 mEq/mL).

7.5% sodium bicarbonate solution: 44.6 mEq/50 mL (0.892 mEq/mL).

8.4% sodium bicarbonate solution: 50 mEq/50 mL (1 mEq/mL).

neut (4% sodium bicarbonate solution): 2.4 mEq/5 mL (0.48 mEq/mL). Use limited to a buffering solution. Will raise pH of IV fluids and medications. Never used as a systemic alkalinizer.

May be given in prepared solutions. 7.5% and 8.4% solutions should be diluted with equal amount of water for injection, or diluted with **compatible** IV solutions, depending on desired dosage and desired rate of administration. 4.2% or a more dilute solution is preferred for infants and children. Use only clear solutions.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Will form a precipitate with many drugs, including epinephrine. **If coadministration with epinephrine is indicated, give at separate sites.**

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), aminophylline, amphotericin B (conventional), atropine, calcium chloride, cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), chloramphenicol (Chloromycetin), clindamycin (Cleocin), cytarabine (ARA-C), erythromycin (Erythrocin), esmolol (Brevibloc), furosemide (Lasix), heparin, levofloxacin (Levaquin), lidocaine, magnesium sulfate, mannitol, meperidine (Demerol), methotrexate, methyl dopate, multivitamins (M.V.I.), nafcillin (Nallpen), oxytocin (Pitocin), penicillin G potassium, phenylephrine (Neo-Synephrine), phytonadione (vitamin K_1), potassium chloride (KCl), prochlorperazine (Compazine), verapamil.

Y-site: Acyclovir (Zovirax), amifostine (Ethyol), asparaginase (Elspar), aztreonam (Azactam), bivalirudin (Angiomax), ceftaroline (Teflaro), ceftriaxone (Rocephin), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cladribine (Leustatin), cyclophosphamide (Cytosan), cytarabine (ARA-C), daunorubicin (Cerubidine), dexamethasone (Decadron), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doripenem (Doribax), doxorubicin (Adriamycin), etoposide (VePesid), etoposide phosphate (Etopophos), famotidine (Pepcid IV), filgrastim (Neupogen), fludarabine (Fludara), gallium

nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), 6% hydroxyethyl starch (Voluven), ifosfamide (Ifex), indomethacin (Indocin IV), insulin (regular), levofloxacin (Levaquin), linezolid (Zyvox), melphalan (Alkeran), mesna (Mesnex), methylprednisolone (Solu-Medrol), milrinone (Primacor), morphine, paclitaxel (Taxol), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), remifentanyl (Ultiva), tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), thiotepa, vancomycin, vasopressin.

RATE OF ADMINISTRATION

Flush IV line thoroughly before and after administration. Usual rate of administration of any solution is 2 to 5 mEq/kg over 4 to 8 hours. Do not exceed 50 mEq/hr. Decrease rate for pediatric patients. See **Pediatric Dose**. Rapid or excessive administration may produce alkalosis, hypernatremia, hypokalemia, and hypocalcemia. Cardiac arrhythmias may result from an intracellular shift of potassium. Will also produce pain and irritation along injection site.

Cardiac arrest: Up to 1 mEq/kg properly diluted over 1 to 3 minutes.

ACTIONS

An alkalizing agent and sodium salt. Helps to maintain osmotic pressure and ion balance. It is the buffering agent in blood. Bicarbonate ion elevates blood pH promptly. 99% reabsorbed with normal kidney function. Only 1% is excreted in the urine.

INDICATIONS AND USES

Metabolic acidosis (blood pH below 7.2 or plasma bicarbonate of 8 mEq/L or less) caused by circulatory insufficiency resulting from shock or severe dehydration, extracorporeal circulation of blood, severe renal disease, cardiac arrest (see **Precautions**), uncontrolled diabetes with ketoacidosis (low-dose insulin preferred), and primary lactic acidosis. ■ Hyperkalemia. ■ Hemolytic reactions requiring alkalization of urine to reduce nephrotoxicity. ■ Severe diarrhea. ■ Barbiturate, methyl alcohol, or salicylate intoxication. ■ Buffering solution to raise pH of IV fluids and medications.

CONTRAINDICATIONS

Diuretics known to produce hypochloremic alkalosis (e.g., thiazides), edema, hypertension, hypocalcemia (alkalosis may produce CHF, convulsions, hypertension, and tetany), hypochloremia (from vomiting, GI suction, or diuretics), hypernatremia, impaired renal function, metabolic alkalosis, respiratory alkalosis or acidosis, and any situation in which the administration of sodium could be clinically detrimental.

PRECAUTIONS

Temporary therapy in metabolic acidosis. Treatment of primary condition must be instituted. Best to partially correct acidosis and allow compensatory mechanisms to complete the correction. ■ Use with caution in cardiac, liver, or renal disease; CHF, fluid/solute overload, elderly and postoperative patients with renal or cardiovascular insufficiency, and in patients receiving corticosteroids. ■ Use in cardiac arrest indicated only if prolonged resuscitation with effective ventilation or after return of spontaneous circulation after a long arrest interval. ■ Adequate alveolar ventilation should control acid-base balance in most arrest situations except prolonged cardiac arrest, arrested patients with pre-existing metabolic acidosis, hyperkalemia, or tricyclic or barbiturate overdose.

Monitor: Confirm absolute patency of vein. Extravasation may cause chemical cellulitis, necrosis, ulceration, or sloughing. ■ Flush IV line thoroughly before and after administration; many incompatibilities. ■ Determine blood pH, PO₂, PCO₂, and electrolytes several times daily during intensive treatment and daily in most other situations. Determine base excess or deficit in infants and children (dose = 0.3 × kg × base deficit). Notify physician of all results. ■ Rapid or excessive administration may produce alkalosis, hypokalemia, and hypocalcemia. Cardiac arrhythmias may result from an intracellular shift of potassium. Many other complications may arise from electrolyte imbalance. ■ Use only 50-mL ampules in cardiac arrest to prevent accidental overdose. Recent practice indicates smaller doses may be appropriate when indicated in cardiac

arrest and may prevent secondary alkalosis. Adequate alveolar ventilation is imperative. Evaluate patient response and blood gases.

Maternal/Child: Category C: safety for use in pregnancy not established; use only if clearly needed. ■ Use caution in breast-feeding. ■ Doses in excess of 8 mEq/kg/24 hr and/or given too rapidly (10 mL/min) may cause intracranial hemorrhage, hypernatremia, and decrease in cerebrospinal fluid pressure in neonates and children under 2 years.

Elderly: Contains sodium; use caution in the elderly with renal or cardiovascular insufficiency with or without CHF; see [Precautions](#).

DRUG/LAB INTERACTIONS

Alkalinization of urine may increase the renal elimination and decrease the effects of many drugs, including **tetracyclines**, **chlorpropamide**, **lithium carbonate**, **methotrexate**, **salicylates**, and may decrease the renal elimination and prolong the effects of others, including **anorexiant**s (e.g., amphetamines), **flecainide**, **mecamylamine**, **quinidine**, **sympathomimetics** (e.g., ephedrine, dopamine).

SIDE EFFECTS

Rare when used with caution: alkalosis (hyperirritability and tetany), hypernatremia (edema, CHF), hypokalemia, local site venous irritation.

ANTIDOTE

Discontinue the drug and notify the physician of any side effect. Hypokalemia usually occurs with alkalosis. Sodium and potassium chloride must be supplemented as indicated for correction. Treatment of alkalosis often results in more alkalosis. Rebreathing expired air from a paper bag may help to control beginning symptoms of alkalosis. Calcium gluconate may help in severe alkalosis. Administration of a balanced hypotonic electrolyte solution (Isolyte H, Normosol-M, Plasma-lyte 56) with sodium and potassium chloride added may help to excrete the bicarbonate ion in the urine. Ammonium chloride may be indicated. Treat tetany as indicated (calcium gluconate). For extravasation, discontinue infusion; aspirate fluid, drug, and/or 3 to 5 mL of blood through the in-place needle, then remove the needle. Elevate the extremity and apply warm moist compresses. Resuscitate as necessary.

SODIUM CHLORIDE

(SO-dee-um KLOOR-eyed)

Electrolyte replenisher
Antihyponatremic

pH 4.5 to 7

USUAL DOSE

Highly individualized and dependent on age, weight, clinical condition of patient, concentration of salts in the plasma, and/or loss of body fluids.

Hypotonic: (0.45% [$\frac{1}{2}$ NS], 4.5 Gm of sodium chloride/L or 77 mEq of sodium and 77 mEq of chloride [approximately 155 mOsm/L]) 2 to 4 L/24 hr.

Isotonic: (0.9% [NS], 9 Gm of sodium chloride/L or 154 mEq of sodium and 154 mEq of chloride [approximately 310 mOsm/L]), 1.5 to 3 L/24 hr.

Bacteriostatic isotonic NS contains benzyl alcohol as a preservative. It is used in small amounts (usually 1 to 2 mL) as a diluent for injectable drugs (IV, IM, SC) or to flush IV lines. One study suggests that up to 30 mL/dose may be used in adults. However, the amount of benzyl alcohol that is tolerated within 24 hours in adults without toxic effects has not been determined. **Use only preservative-free sodium chloride in newborns for all indications.**

Hypertonic: Calculate sodium deficit. Total body water (TBW) is 45% to 50% in females and 50% to 60% in males.

$$\text{Na deficit in mEq} = \text{TBW} [\text{desired} - \text{observed plasma Na}]$$

Hypertonic (3%, 30 Gm of sodium chloride/L or 513 mEq of sodium and 513 mEq of chloride [approximately 1,030 mOsm/L] or 5%, 50 Gm of sodium chloride/L or 855 mEq of sodium and 855 mEq of chloride [approximately 1,710 mOsm/L]), 200 to 400 mL/24 hr. To correct **acute serious hyponatremia**, hypertonic sodium chloride is used to correct the serum sodium in 5 mEq/L/dose increments at a rate of no more than 0.5 mEq/hr until serum sodium is 125 mEq/L or neurologic symptoms improve. In the first 3 to 4 hours, an increase of plasma sodium at rates up to 1 mEq/L/hr may be tolerated in patients with distressing symptoms. To prevent an overly rapid correction, an increase in plasma sodium of less than 10 mEq/L in the first 24 hours and an increase of less than 18 mEq/L in the first 48 hours is desired. See [Precautions](#).

Concentrated: To be used only as an additive in parenteral fluid therapy (14.6% contains 2.5 mEq of sodium and chloride/mL; 23.4% contains 4 mEq of sodium and chloride/mL).

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly, especially with hypertonic or concentrated solutions. Start at the lower end of the desired dosing range; consider the greater frequency of decreased organ function and of concomitant disease or drug therapy.

DILUTION

Available as **hypotonic** 25 mL, 50 mL, 150 mL, 250 mL, 500 mL, 1 L; **isotonic** (2 mL, 3 mL, 5 mL, 10 mL, 20 mL, 25 mL, 30 mL, 50 mL, 100 mL, 150 mL, 250 mL, 500 mL, 1 L); or **hypertonic** (500 mL) solution in vials and/or bottles for injection or infusion and ready for use. Isotonic and hypotonic sodium chloride are frequently combined with 5% or 10% dextrose. **Concentrated** must be diluted before use. Used only as an additive in parenteral fluids. Permits specific mEq for mEq replacement of sodium and chloride without contributing to fluid overload. Available in 14.6% strength in 20 mL, 40 mL, and 200 mL; 23.4% strength in 30 mL, 50 mL, 100 mL, and 200 mL.

Bacteriostatic isotonic available in 2-mL, 10-mL, and 30-mL vials ready for use as a diluent. Never use in neonates.

Storage: Store at CRT. Do not freeze.

COMPATIBILITY

Consider any drug **NOT** listed as compatible to be **INCOMPATIBLE** until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibility** for concentrations of 14.6% and 23.4%:
Y-site: Ciprofloxacin (Cipro IV).

RATE OF ADMINISTRATION

Isotonic and hypotonic: A single daily dose equally distributed over 24 hours. Rate is dependent on age, weight, and clinical condition of the patient.

Hypertonic: One-half the calculated dose over at least 8 hours. Do not exceed 100 mL over 1 hour. Too-rapid infusion may cause local pain and venous irritation; reduce rate for tolerance.

Concentrated: Properly diluted in parenteral fluids and equally distributed over 24 hours. Never exceed hypertonic rate (see above) based on actual mEq of sodium chloride.

ACTIONS

Sodium: The predominant cation of extracellular fluid. It controls water distribution throughout the body. Hypothalamus osmoreceptors, sensitive to osmolarity changes in the blood, control serum sodium concentration (142 mEq/L). Body fluid is lost when sodium content decreases and retained when sodium content increases.

Chloride: The major extracellular anion. Closely follows the metabolism of sodium. Changes in the acid-base balance of the body are reflected by the changes in chloride concentration.

Distribution and excretion of sodium and chloride are largely under control of the kidney, which maintains a balance between intake and output.

INDICATIONS AND USES

Replace lost fluid or sodium and chloride ions in the body (e.g., hyponatremia, low salt syndrome, dehydration). ■ Maintain fluid and electrolyte balance.

Hypotonic: Water replacement without increase of osmotic pressure or serum sodium levels; treatment of hyperosmolar diabetes requiring considerable fluid without excess sodium.

Isotonic: To replace sodium and chloride lost from vomiting because of obstructions and/or aspiration of GI fluids; treatment of metabolic alkalosis with fluid loss and sodium depletion. ■ Diluent in parenteral preparations. ■ To initiate and terminate blood transfusions without hemolyzing RBCs. ■ Maintain patency and perform routine irrigations of many types of intravascular devices (e.g., catheters, implanted ports). ■ Antidote for drug-induced hypercalcemia. Given concurrently with furosemide (Lasix). ■ Priming solution in hemodialysis procedures.

Hypertonic: Used only when high sodium and/or chloride content without large amounts of fluid is required (e.g., electrolyte and fluid loss replaced with sodium-free fluids, excessive water intake resulting in drastic dilution of body water, emergency treatment of severe salt depletion, Addisonian crisis, diabetic coma).

Concentrated: Used to meet the specific requirements of patients with unusual fluid and electrolyte needs (e.g., special problems of sodium electrolyte intake or excretion).

CONTRAINDICATIONS

Hypernatremia; fluid retention; situations where sodium or chloride could be detrimental. 3% and 5% sodium chloride solutions are contraindicated with elevated, normal, or slightly decreased serum sodium and chloride levels. Bacteriostatic sodium chloride is contraindicated in newborns.

PRECAUTIONS

Use caution in circulatory insufficiency, congestive heart failure, edema with sodium retention, kidney dysfunction, hepatic disease, hypoproteinemia, in the elderly or debilitated individuals, and in patients receiving corticosteroids. ■ Use with caution in surgical patients; see **Monitor**. ■ More than 1 liter of NS may cause hypernatremia, which can result in loss of bicarbonate ions and acidosis. ■ All uses require preservative-free solutions except the limited use of bacteriostatic NS as a diluent or flushing agent. ■ Inadvertent direct injection or absorption of concentrated sodium chloride may cause sud-

den hyponatremia, cardiovascular shock, CNS disorders, extensive hemolysis, cortical necrosis of the kidneys, and severe local tissue necrosis with extravasation. Use extreme caution; see [Dilution](#). ■ Administration of IV solutions can cause fluid and/or solute overload, resulting in dilution of serum electrolyte concentrations, overhydration, congested states, or pulmonary edema. The risk of dilutional states is inversely proportional to the electrolyte concentration (increased fluids may dilute electrolyte concentration). The risk of solute overload causing congested states with peripheral and pulmonary edema is directly proportional to the electrolyte concentration (higher electrolytes pull in fluid, leading to fluid overload). ■ Overly rapid correction of severe hyponatremia (plasma sodium less than 110 to 115 mEq/L) may lead to a neurologic disorder (osmotic demyelination syndrome [central pontine myelinolysis]), which may be irreversible.

Monitor: Maintain accurate intake and output; monitor electrolytes and acid-base balance, especially in prolonged therapy. ■ Monitor vital signs as indicated. ■ Monitor for signs of hyponatremia (sodium less than 135 mEq/L [e.g., disorientation, headache, lethargy, nausea, weakness]). May progress to coma and seizures. ■ Excessive administration of potassium-free solutions may cause hypokalemia. ■ Before and during use of hypertonic or concentrated sodium chloride, determine osmolar concentrations and chloride and bicarbonate content of the serum. Observe patient continuously to prevent pulmonary edema. ■ Hypertonic solutions can cause vein damage; use a small needle and a large vein to reduce venous irritation and avoid extravasation; see [Precautions](#).

Maternal/Child: Category C: safety for use during pregnancy not established; use only if clearly needed. ■ Use caution in breast-feeding. ■ Benzyl alcohol preservative in bacteriostatic sodium chloride has caused toxicity in newborns. Do not use. ■ Is used in pediatric patients. Safety and effectiveness based on similarity of clinical conditions of pediatric and adult populations. Use caution in neonates or very small infants; the volume of fluid may affect fluid and electrolyte balance.

Elderly: Lower-end initial doses may be indicated in the elderly; see [Dose Adjustments](#). ■ Incidence of adverse reactions may be increased; monitor carefully, especially with renal or cardiac insufficiency with or without CHF. ■ See [Precautions](#).

DRUG/LAB INTERACTIONS

High sodium intake may reduce serum **lithium** concentrations.

SIDE EFFECTS

Fever, hypovolemia, and injection site reactions may occur.

Osmotic demyelination syndrome (central pontine myelinolysis) secondary to too-rapid correction with hypertonic solutions.

Due to sodium excess: Aggravation of existing acidosis, anorexia, cellular dehydration, deep respiration, disorientation, distention, edema, hydrogen loss, hyperchloremic acidosis, hypertension, increased BUN, nausea, oliguria, potassium loss, pulmonary edema, water retention, weakness. Excessive excretion of crystalloids to maintain normal osmotic pressure will increase excretion of potassium and bicarbonate and further increase acidosis. Other salts (e.g., iodide and bromide) used for therapy will also be excreted rapidly.

ANTIDOTE

Discontinue or decrease rate of infusion; notify the physician of side effects. Sodium excess can be treated by sodium restriction and/or use of diuretics or hemodialysis to remove excessive amounts. Observe patient carefully and treat symptomatically. Save balance of fluid for examination.

SODIUM FERRIC GLUCONATE COMPLEX

(SO-dee-um FAIR-ick GLUE-koh-nayt KOM-pleks)

Ferlecit

Antianemic
Iron supplement

pH 7.7 to 9.7

USUAL DOSE

Dose is represented in terms of mg of elemental iron. Given as an infusion and may be administered during the dialysis session.

Treatment of iron deficiency in hemodialysis patients: 125 mg (10 mL)/dose. Doses above 125 mg may be associated with a higher incidence and/or severity of adverse events; see [Side Effects](#). A minimum cumulative dose of 1 Gm of elemental iron is required by most patients. May be administered over eight sessions at sequential dialysis treatments to achieve a favorable hemoglobin or hematocrit response. Additional doses as necessary are indicated to maintain target levels of hemoglobin, hematocrit, and laboratory parameters of iron storage within acceptable limits. Use the lowest dose that achieves this goal.

PEDIATRIC DOSE

1.5 mg/kg (0.12 mL/kg) of elemental iron as a 1-hour infusion. Do not exceed 125-mg dose. Administer at 8 sequential dialysis sessions. See [Maternal/Child](#).

DOSE ADJUSTMENTS

Begin at the low end of the dosing range in elderly patients. Consider decreased cardiac, hepatic, or renal function, and concomitant disease or other drug therapy.

DILUTION

Available in ampules or vials containing 62.5 mg/5 mL (12.5 mg/mL) of elemental iron.

Therapeutic dose: 125-mg (10-mL) dose may be diluted in 100 mL NS or may be given undiluted; see [Rate of Administration](#).

Pediatric therapeutic dose: Dilute calculated dose in 25 mL of NS.

Filters: Specific studies not available from manufacturer. Filter needle not required by FDA for drug approval; however, use of a filter needle to withdraw it from an ampule should not have an adverse effect.

Storage: Store ampules at CRT. Do not freeze. Use immediately after dilution in NS.

COMPATIBILITY

Manufacturer states, "Do not mix with other medications or add to parenteral nutrition solutions." Known to be **compatible** only with NS.

RATE OF ADMINISTRATION

Too-rapid administration may cause hypotension associated with fatigue; light-headedness; malaise; severe pain in the chest, back, flanks, or groin; and weakness.

Therapeutic dose: Injection (adults only): A single dose (undiluted) as a slow IV injection. May be given at a rate up to 12.5 mg/min (1 mL/min).

Infusion (adults and pediatric patients): A single dose as an infusion properly diluted and equally distributed over 60 minutes.

ACTIONS

A stable macromolecular complex in sucrose injection. Contains elemental iron as the sodium salt of a ferric ion carbohydrate complex. Used to replete the total body content of iron. Iron is critical for normal hemoglobin synthesis to maintain oxygen transport and necessary for metabolism and synthesis of DNA and various other processes. Half-life is approximately 1 hour. Doses of 1 mg/day are adequate to replenish losses in healthy non-menstruating adults. Iron complex is not dialyzable.

INDICATIONS AND USES

Treatment of iron deficiency anemia in adult patients and pediatric patients 6 years of age or older with chronic kidney disease who are receiving hemodialysis and supplemental erythropoietin therapy (e.g., EPO, Epogen, Procrit); see [Maternal/Child](#).

CONTRAINDICATIONS

All anemias not associated with iron deficiency. Hypersensitivity to sodium ferric gluconate complex or any of its components.

PRECAUTIONS

Use only when truly indicated to avoid excess storage of iron. Not recommended for use in patients with iron overload. ■ Too-rapid administration may cause clinically significant hypotension; see [Rate of Administration](#) and [Side Effects](#). ■ Studies have included patients who have had prior iron dextran exposure with hypersensitivity reactions to at least one form of iron dextran (InFeD or DexFerrum). The majority of these patients tolerated Ferrlecit therapy without a subsequent hypersensitivity reaction. ■ There have been rare occurrences of severe hypersensitivity reactions, including anaphylactic-type reactions, some of which have been life threatening and fatal. Administer in a facility equipped to monitor the patient and respond to any medical emergency. ■ Serum iron levels greater than 300 mcg/dL combined with transferrin oversaturation may indicate iron poisoning; see [Side Effects](#).

Monitor: Recumbent position during and after injection may help to prevent postural hypotension. Hypotensive effects may be additive to transient hypotension during dialysis and/or from too-rapid rate of infusion; monitor closely. Hypotensive reactions associated with fatigue; light-headedness; malaise; severe pain in the back, chest, flanks, or groin; and weakness may occur with IV iron. These symptoms may or may not be indicative of a hypersensitivity reaction and usually resolve within 1 or 2 hours. ■ Observe continuously for a hypersensitivity reaction during an infusion and after administration for at least 30 minutes and until clinically stable. Monitor vital signs. ■ Periodic monitoring of hemoglobin and hematocrit and iron storage levels recommended. Doses in excess of iron needs may lead to accumulation of iron in iron storage sites and iatrogenic hemosiderosis.

Patient Education: Report S/S of a hypersensitivity reaction (e.g., difficulty breathing, rash, shortness of breath) promptly. Report pain at injection site.

Maternal/Child: Category B: use during pregnancy only if potential benefit justifies potential risk to fetus. ■ Safety for use during breast-feeding and in pediatric patients under 6 years of age not established. ■ Contains benzyl alcohol; should not be used in neonates. Benzyl alcohol present in maternal serum may cross into human milk and may be orally absorbed by a breast-feeding infant.

Elderly: No age differences identified. Caution in the elderly suggested; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

May reduce absorption of concomitantly administered **oral iron preparations**. ■ Concurrent administration of iron therapy with **dimercaprol** (BAL in Oil) will result in the formation of a toxic complex. Either postpone iron therapy to at least 24 hours after dimercaprol or consider transfusions.

SIDE EFFECTS

Hypotension associated with fatigue; light-headedness; malaise; severe pain in the chest, back, flanks, or groin; and weakness may be caused by too-rapid infusion. Severe hypersensitivity reactions (e.g., angioedema, bronchospasm, cardiac arrest, cardiovascular collapse, dyspnea, edema [oral or pharyngeal], muscle spasm, pain [back or chest], pruritus, urticaria) have been reported rarely. Most commonly reported side effects include abdominal pain, back pain, chest pain, cramps, diarrhea, dizziness, dyspnea, fever, headache, hypersensitivity reactions, hypertension, hypotension, infection, injection site reactions, nausea and vomiting, pain, pharyngitis, pruritus, rhinitis, tachycardia, and thrombosis. Many other side effects occurred in less than 1% of patients and may or may not be attributable to sodium ferric gluconate complex.

Post-Marketing: Anaphylaxis, convulsions, dysgeusia, hypoesthesia, loss of consciousness, pallor, phlebitis, skin discoloration, and shock have been identified. In addition,

post-marketing reports have identified that individual doses exceeding 125 mg may result in a higher incidence and/or severity of side effects, including abdominal pain, chest pain, diarrhea, dizziness, dyspnea, hypotension, nausea, paresthesia, peripheral swelling, and urticaria.

Overdose: Serum iron levels greater than 300 mcg/dL may indicate iron poisoning. May result in hemosiderosis, and excess iron may increase susceptibility to infection. If acute toxicity is seen, it may present as abdominal pain, diarrhea, or vomiting progressing to pallor or cyanosis, lassitude, drowsiness, hyperventilation due to acidosis, iatrogenic hemosiderosis, and cardiovascular collapse.

ANTIDOTE

Reduce rate or temporarily discontinue infusion for hypotension; volume expanders (e.g., albumin, hetastarch [Hespan]) may be indicated. Restart when resolved. Discontinue drug and treat hypersensitivity reactions or resuscitate as necessary; notify physician. Epinephrine (Adrenalin) and diphenhydramine (Benadryl) should always be available. In overdose, monitor CBC, iron studies, vital signs, blood gases, and glucose and electrolytes. Maintain fluid and electrolyte balance. Correct acidosis with sodium bicarbonate. Iron complex is not dialyzable.

SODIUM PHENYLACETATE AND SODIUM BENZOATE

Ammonia detoxicant

(SO-dee-um fen-ill-**AH**-seh-tate and SO-dee-um **BEN**-zoh-ate)

Ammonul

pH 6 to 8

USUAL DOSE

Must be diluted and administered through a central line. Administration through a peripheral line may cause burns. Given in combination with arginine (dose is dependent on the specific urea cycle disorder [UCD] and is contraindicated in patients with arginase deficiency); see [Dilution, Rate of Administration, Precautions, and Monitor](#). Urea cycle disorders can result from decreased activity of any of the following enzymes: *N*-acetylglutamate synthetase (NAGS), carbamyl phosphate synthetase (CPS), argininosuccinate synthetase (ASS), ornithine transcarbamylase (OTC), argininosuccinate lyase (ASL), or arginase (ARG); dose and treatment may vary for each. Sodium phenylacetate and sodium benzoate (AMMONUL) infusion should be started as soon as the diagnosis of hyperammonemia is made.

Discontinue analogous oral drugs (e.g., sodium phenylbutyrate [Buphenyl]) before sodium phenylacetate and sodium benzoate (AMMONUL) infusion.

A **loading dose** as an infusion is administered over 90 to 120 minutes, followed by an **equivalent maintenance dose** as an infusion administered over 24 hours. Treatment also requires caloric supplementation and restriction of dietary protein. Non-protein calories should be supplied principally as glucose (8 to 10 mg/kg/min), with intravenous fat (e.g., Intralipid) added to maintain a caloric intake of greater than 80 cal/kg/day.

The dose of sodium phenylacetate and sodium benzoate (AMMONUL) is based on mg/kg in neonates, infants, and younger pediatric patients weighing up to 20 kg and on body surface area for older pediatric patients, adolescents, and adults weighing more than 20 kg as described in the following chart.

Dose and Administration Guidelines for Sodium Phenylacetate and Sodium Benzoate (AMMONUL)					
Patient Population	Components of Infusion Solution AMMONUL must be diluted with D10W at equal to or greater than 25 mL/kg before administration		Dosage Provided		
	Ammonul	Arginine HCl Injection, 10%	Sodium Phenylacetate	Sodium Benzoate	Arginine HCl
WEIGHT EQUAL TO OR LESS THAN 20 KG:					
CPS and OTC Deficiency					
Dose Loading: Over 90 to 120 minutes Maintenance: Over 24 hours	2.5 mL/kg	2 mL/kg	250 mg/kg	250 mg/kg	200 mg/kg
ASS and ASL Deficiency					
Dose Loading: Over 90 to 120 minutes Maintenance: Over 24 hours	2.5 mL/kg	6 mL/kg	250 mg/kg	250 mg/kg	600 mg/kg

Dose and Administration Guidelines for Sodium Phenylacetate and Sodium Benzoate (AMMONUL)—cont'd					
Patient Population	Components of Infusion Solution AMMONUL must be diluted with D10W at equal to or greater than 25 mL/kg before administration		Dosage Provided		
	Ammonul	Arginine HCl Injection, 10%	Sodium Phenylacetate	Sodium Benzoate	Arginine HCl
WEIGHT MORE THAN 20 KG:					
CPS and OTC Deficiency					
Dose Loading: Over 90 to 120 minutes Maintenance: Over 24 hours	55 mL/M ²	2 mL/kg	5.5 Gm/M ²	5.5 Gm/M ²	200 mg/kg
ASS and ASL Deficiency					
Dose Loading: Over 90 to 120 minutes Maintenance: Over 24 hours	55 mL/M ²	6 mL/kg	5.5 Gm/M ²	5.5 Gm/M ²	600 mg/kg

Repeat loading doses should not be administered because plasma levels achieved by phenylacetate are prolonged. Continue maintenance infusions until elevated plasma ammonia levels have been normalized or oral nutrition and medications can be tolerated. Mean duration of treatment was 4.6 days per episode and ranged from 1 to 72 days.

DOSE ADJUSTMENTS

No specific recommendations; see [Precautions](#).

DILUTION

Must be diluted with D10W. Do not administer undiluted product.

Loading dose: Dilute with an amount of D10W equal to or more than 25 mL/kg of body weight per dose.

Equivalent maintenance dose: Also requires dilution with an amount of D10W equal to or more than 25 mL/kg of body weight per dose.

A 4-kg neonate would require a minimum of 100 mL of D10W for dilution of the loading dose given over 90 to 120 minutes and a minimum of 100 mL of D10W for dilution of the maintenance dose given over 24 hours. An 80-kg adult would require a minimum of 2,000 mL of D10W for dilution of the loading dose over 90 to 120 minutes and a minimum of 2,000 mL D10W for dilution of the maintenance dose given over 24 hours.

Filters: Use of a 0.22-micron filter has been used to inject Ammonul into D10W.

Storage: Store unopened vials at CRT. Diluted solutions are stable at CRT and room lighting conditions for up to 24 hours.

COMPATIBILITY

May be mixed in the same container with 10% arginine HCl injection. Manufacturer states, “Other infusion solutions and drug products should not be administered together with sodium phenylacetate and sodium benzoate.” May be prepared in glass or PVC containers.

RATE OF ADMINISTRATION

Loading dose infusion rates are relatively high, especially for infants; monitor closely.

Loading dose: A single dose properly diluted as an infusion and equally distributed over 90 to 120 minutes.

Maintenance dose: Each single dose properly diluted as an infusion and equally distributed over 24 hours.

ACTIONS

Sodium phenylacetate and sodium benzoate are metabolically active compounds that can provide an alternative pathway for nitrogen disposal in patients without a fully functioning urea cycle. Two moles of nitrogen are removed per mole of phenylacetate when it is conjugated with glutamine, and one mole of nitrogen is removed per mole of benzoate when it is conjugated with glycine. Has been shown to decrease elevated plasma ammonia levels. Considered to be the result of the reduction in nitrogen overload through glutamine and glycine scavenging by sodium phenylacetate and sodium benzoate (AMMONUL) in combination with appropriate dietary and other supportive measures.

Phenylacetate: Conjugates with glutamine in the liver and kidneys to form phenylacetylglutamine. It is then excreted by the kidneys via glomerular filtration and tubular secretion. Each mole of phenylacetylglutamine contains two moles of waste nitrogen. The nitrogen content of phenylacetylglutamine per mole is identical to that of urea (2 moles of nitrogen). Plasma levels remain higher and are present for a longer period of time than plasma levels of benzoate.

Benzoate: Conjugates with glycine to form hippuric acid, which is rapidly excreted by the kidneys by glomerular filtration and tubular secretion. One mole of hippuric acid contains one mole of waste nitrogen. The formation of hippurate from benzoate occurs more rapidly than that of phenylacetylglutamine from phenylacetate, and the rate of elimination of hippurate appears to be more rapid than that of phenylacetylglutamine.

INDICATIONS AND USES

Adjunctive therapy for the treatment of acute hyperammonemia and associated encephalopathy in adult and pediatric patients with deficiencies in enzymes of the urea cycle. UCDs can result from decreased activity of any of the following enzymes: *N*-acetylglutamate synthetase (NAGS), carbamyl phosphate synthetase (CPS), argininosuccinate synthetase (ASS), ornithine transcarbamylase (OTC), argininosuccinate lyase (ASL), or arginase (ARG). In acute hyperammonemic episodes, arginine supplementation, caloric supplementation, dietary protein restriction, hemodialysis, and other ammonia-lowering therapies should be considered.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

For IV infusion only. Must be infused through a central line. Administration through a peripheral line may cause burns. ■ Acute symptomatic hyperammonemia should be treated as a life-threatening emergency. Treatment may require hemodialysis to remove a large burden of ammonia. Uncontrolled hyperammonemia can rapidly result in brain damage or death, and prompt use of all therapies necessary to reduce ammonia levels is essential. ■ Administered under the direction of a physician knowledgeable in its use and in the treatment of diseases resulting from inborn errors in metabolism. Should be administered in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. In addition, facilities for hemodialysis, nutritional support, and medical support are required. ■ Patients with a large ammonia burden or patients who are not responsive to sodium phenylacetate and sodium benzoate (AMMONUL) require aggressive therapy, including hemodialysis. ■ Metabolized in the liver and kidneys and excreted by the kidneys. Use caution in patients with impaired renal or hepatic function. ■ Use with extreme caution, if at all, in patients with CHF or severe renal insufficiency and in clinical states where there is sodium retention with edema; contains 30.5 mg of sodium/mL of undiluted product; see [Antidote](#). ■ Bioavailability of both benzoate and phenylacetate may be slightly higher in females than in males. ■ See [Monitor](#), [Maternal/Child](#), and [Drug/Lab Interactions](#).

Monitor: Plasma and urine amino acid analyses are used to diagnose ASS and ASL and to provide a preliminary diagnosis of CPS, OTC, or ARG. Blood citrulline levels are very low or absent in OTC and CPS, very high in ASS, and normal to moderately high in ASL and ARG. High urine levels of an unusual amino acid (argininosuccinic acid [ASA]) may distinguish ASL; however, ASA may be difficult to detect on initial examination. Specific

studies are required to separate it from other amino acids. ARG is characterized by high urine levels of arginine. A liver biopsy is indicated for definitive diagnosis of CPS and OTC. RBC enzyme analysis is needed to confirm a diagnosis of ARG. ■ Monitor catheter infusion site closely. Extravasation may lead to skin necrosis. If extravasation is suspected, discontinue the infusion and, if necessary, resume at a different site. ■ Monitor plasma ammonia, glutamine, quantitative plasma amino acids, blood glucose, ABGs, AST, and ALT during and after infusion. ■ Ongoing assessment of clinical response includes monitoring of neurologic status, Glasgow Coma Scale, tachypnea, CT or MRI scan or fundoscopic evidence of cerebral edema, and/or gray matter and white matter damage. In patients responding to therapy, mean ammonia levels decreased significantly within 4 hours of initiation of therapy. ■ May be used in combination with dialysis. Hemodialysis is the most commonly used and can either be instituted immediately while waiting for a more definitive diagnosis or used as a recommended addition to treatment for those patients who fail to have a significant reduction in plasma ammonia levels within 4 to 8 hours after receiving sodium phenylacetate and sodium benzoate (AMMONUL). High levels of ammonia can be reduced quickly when sodium phenylacetate and sodium benzoate (AMMONUL) is used with dialysis. The ammonia scavenging of sodium phenylacetate and sodium benzoate (AMMONUL) suppresses the production of ammonia from catabolism of endogenous protein, and dialysis eliminates the ammonia and ammonia conjugates. ■ Monitor serum electrolytes and maintain within normal range. Monitor plasma potassium levels carefully and treat as indicated; urine potassium loss is enhanced by excretion of the non-resorbable anions phenylacetylglutamine and hippurate. ■ May cause side effects associated with salicylate overdose (e.g., hyperventilation, metabolic acidosis). Obtain baseline and monitor blood chemistry profiles, blood pH, and PCO_2 . ■ Use with high-dose arginine may cause hyperchloremic acidosis. Obtain baseline and monitor chloride and bicarbonate levels; administer bicarbonate as indicated. ■ Use prophylactic antiemetics to reduce nausea and vomiting. ■ Neurotoxicity has been reported (e.g., disorientation, exacerbation of a pre-existing neuropathy, fatigue, headaches, hypoacusis [partial loss of hearing], impaired memory, light-headedness, somnolence). Onset may be acute, and symptoms should improve when therapy is discontinued. ■ Closely monitor patients with impaired renal function; drug therapy may be less effective due to poor clearance of drug metabolites and, subsequently, ammonia. ■ See [Precautions](#), [Maternal/Child](#), and [Drug/Lab Interactions](#).

Patient Education: Compliance with dietary restrictions and supplemental medications is imperative. ■ Obtain identification (e.g., a bracelet) with UCD diagnosis.

Maternal/Child: Category C: use during pregnancy and/or labor and delivery only if clearly needed. Effects on fetus unknown. ■ Not known if it is secreted in human milk; use caution if required during breast-feeding. Has the potential for serious harm to infant. ■ Is used as a treatment for acute hyperammonemia in pediatric patients, including patients in the early neonatal period. ■ The most commonly presented symptoms of UCD in neonates include edema, lethargy, neurologic changes, poor feeding, respiratory distress, and seizures. Milder forms of UCDS may not present until late childhood, adolescence, or adulthood. Symptoms, including hyperammonemic crisis with coma, delirium, and/or lethargy, are often precipitated by viral illness, high-protein diet, stress, or trauma.

Elderly: Relevant information not available. Oldest patient in studies was 53 years of age. Average age in studies was 8.54 years. ■ Monitoring of renal and hepatic function is suggested.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. ■ Concurrent use with **corticosteroids** (e.g., dexamethasone [Decadron]) may cause the breakdown of body protein and increase plasma ammonia levels in patients with an impaired ability to form urea. ■ Some **antibiotics** (e.g., penicillin) may compete with phenylacetylglutamine and hippurate for active secretion by renal tubules. This competition may affect the overall disposition of

either of the infused drugs. ■ **Probenecid** is known to inhibit the renal transport of many drugs and may inhibit the renal excretion of phenylacetylglutamine and hippurate, reducing its effectiveness. ■ **Valproic acid** has been reported to induce hyperammonemia. Administration to patients with UCD may exacerbate their condition and antagonize the effectiveness of sodium phenylacetate and sodium benzoate (AMMONUL).

SIDE EFFECTS

The most commonly reported side effects include convulsions, hyperglycemia, hypokalemia, mental impairment, and vomiting. Acidosis, agitation, anemia, coma, diarrhea, DIC, edema of the brain, fever, hyperammonemia, hypocalcemia, hypotension, injection site reactions, metabolic acidosis, nausea, respiratory distress, and urinary tract infections were also reported frequently. Injection site reactions and metabolic acidosis were dose-limiting reactions in several patients. Incidence and severity of side effects tends to be increased in patients with enzyme deficiencies occurring earlier in the urea cycle (i.e., OTC and CPS). Incidence of side effects were also specific to age and diagnosis as follows.

Pediatric patients 30 days of age or less: Blood and lymphatic system disorders (e.g., anemia, DIC) and hypotension.

Patients more than 30 days of age: GI disorders (e.g., diarrhea, nausea, and vomiting).

Patients with OTC, ASS, CPS, and diagnoses characterized as other: Side effects were primarily the ones most frequently reported.

Patients with OTC and CPS: Nervous system disorders (e.g., coma, convulsions, edema of the brain, mental impairment) were most common.

Overdose: Cardiovascular collapse, encephalopathy (progressive), hypernatremia, hyperosmolarity, hyperventilation, large anion gap, metabolic acidosis (severe and compensated) with a respiratory component, obtundation (in the absence of hyperammonemia), and death. Causes of death from overdose were cardiorespiratory failure/arrest, error in dialysis procedure, hyperammonemia, hypotension (intractable) with probable sepsis, increased intracranial pressure, pneumonitis with septic shock and coagulopathy.

ANTIDOTE

Keep physician informed of all side effects. Many may be life threatening and immediate, and appropriate treatment is required. If an adverse reaction occurs due to sodium content, discontinue infusion, evaluate the patient, and treat as indicated. If extravasation is suspected, discontinue the infusion and, if necessary, resume at a different site. Treat extravasation by aspirating the residual drug from the catheter, elevating the limb (if a limb is involved), and applying intermittent cold packs. If overdose occurs, discontinue the drug, and monitor and treat as indicated by symptoms. In severe cases, hemodialysis (procedure of choice) and/or peritoneal dialysis (when hemodialysis is not available) may be indicated. Resuscitate as indicated.

SOTALOL HYDROCHLORIDE **BBW**

(SO-tuh-lol hy-droh-KLOR-eyed)

Beta-adrenergic blocking agent
Antiarrhythmic

pH 6 to 7

USUAL DOSE

To minimize the risk of induced arrhythmia, patients initiated or reinitiated on sotalol and patients who are converted from IV to oral administration should be hospitalized in a facility that can provide cardiac resuscitation and continuous ECG monitoring. CrCl must be greater than 60 mL/min. Baseline studies and correction of electrolyte abnormalities required before initiating therapy; see [Precautions](#), [Monitor](#), and [Dose Adjustments](#).

Initial dose: 75 mg twice daily. If symptomatic arrhythmia is not controlled and dose is tolerated without excessive QTc prolongation (i.e., greater than 500 msec), may increase dose to 112.5 mg twice daily after 3 days. Continuous ECG monitoring required during dose escalation.

Dose for ventricular arrhythmias: 75 mg twice daily. Dose may be increased in increments of 75 mg/day every 3 days. Usual therapeutic effect is seen with doses of 75 to 150 mg twice daily. However, doses as high as 225 to 300 mg have been required in patients with refractory life-threatening arrhythmias.

Dose for symptomatic atrial fibrillation/atrial flutter (AFIB/AFL): 112.5 mg twice daily was found to be the most effective dose in studies. If symptomatic arrhythmia is not controlled and this dose is tolerated without excessive QTc prolongation (i.e., greater than 520 msec), increase dose to 150 mg twice daily.

Conversion from oral to intravenous sotalol: Patients who have been stabilized on oral sotalol and are unable to take oral medications may be converted to IV sotalol using the following conversion table.

Conversion from Oral Sotalol to IV Sotalol	
Oral Dose	Intravenous Dose
80 mg	75 mg (5 mL sotalol injection)
120 mg	112.5 mg (7.5 mL sotalol injection)
160 mg	150 mg (10 mL sotalol injection)

DOSE ADJUSTMENTS

Increase dosing interval to every 24 hours in patients with a CrCl between 40 and 60 mL/min. Sotalol is not recommended in patients with a CrCl less than 40 mL/min. ■ Titrate dose upward or downward as needed based on clinical effect, QT interval, or adverse reactions as described in Usual Dose.

DILUTION

Available in vials containing 150 mg/10 mL. Dilute required dose with NS, D5W, or LR as described in the following table.

Sotalol Infusion Preparation to Compensate for Dead Space in the Infusion Set				
Target Dose	Sotalol Injection	Diluent	Volume Prepared	Volume to Infuse
75 mg	6 mL	114 mL	120 mL	100 mL
112.5 mg	9 mL	111 mL		
150 mg	12 mL	108 mL		
75 mg	6 mL	294 mL	300 mL	250 mL
112.5 mg	9 mL	291 mL		
150 mg	12 mL	288 mL		

Storage: Store at CRT. Protect from light and freezing.

COMPATIBILITY

Specific information not available. Consult pharmacist; specific conditions may apply.

RATE OF ADMINISTRATION

A single dose equally distributed over 5 hours. Use of an infusion pump recommended.

ACTIONS

An antiarrhythmic with Class II (beta-adrenoreceptor blocking) and Class III (cardiac action potential duration prolongation) properties. The beta-blocking effect is noncardio-selective. Slows heart rate, decreases AV nodal conduction, and increases AV nodal refractoriness. ECG shows dose-related increase in QT and QTc. Produces a reduction in systolic and diastolic blood pressures and cardiac index and an increase in pulmonary capillary wedge pressure. Does not bind to plasma proteins and is not metabolized. Half-life is 12 hours. Excreted predominantly via the kidney in unchanged form. Crosses the placenta. Secreted in breast milk.

INDICATIONS AND USES

A substitute for oral sotalol in patients who are unable to take oral medications. ■ Maintenance of normal sinus rhythm in patients with a history of highly symptomatic AFIB/AFL. ■ Treatment of documented life-threatening ventricular arrhythmias.

CONTRAINDICATIONS

Bradycardia (HR below 50 beats/min), sick sinus syndrome, or second- or third-degree AV block unless a functioning pacemaker is present. ■ Congenital or acquired long QT syndromes, QT interval greater than 450 msec. ■ Cardiogenic shock, uncontrolled heart failure. ■ CrCl less than 40 mL/min. ■ Serum potassium less than 4 mEq/L. ■ Bronchial asthma or related bronchospastic conditions. ■ Known hypersensitivity to sotalol.

PRECAUTIONS

To minimize the risk of induced arrhythmia, patients initiated or reinitiated on sotalol and patients who are converted from IV to oral administration should be hospitalized for at least 3 days (or until steady-state drug levels are reached) in a facility that can provide cardiac resuscitation and continuous ECG monitoring. Personnel trained in the management of serious ventricular arrhythmias must be present. ■ Can cause serious ventricular arrhythmias, primarily torsades de pointes (TdP), a polymorphic ventricular tachycardia associated with QTc prolongation. QTc prolongation is directly related to the concentration of sotalol. Factors that may increase the risk of TdP include a reduced CrCl, larger doses, female gender, sustained VT, and a history of cardiomegaly or CHF. ■ The use of sotalol in conjunction with other drugs that prolong the QT interval has not been studied and is not recommended; see [Drug/Lab Interactions](#). ■ May cause bradycardia, which increases risk of TdP. ■ Increased risk of TdP in patients with AFIB and sinus node dysfunction, especially after cardioversion. Sotalol increases bradycardia and QTc following cardioversion. ■ Produces significant reductions in both systolic and diastolic BP. May cause deterioration in cardiac performance in patients with marginal cardiac compensation. ■ Use caution in CHF. Beta blockade may depress myocardial contractility and precipitate or exacerbate heart failure. ■ Use caution in the presence of heart failure controlled by digoxin. Both drugs slow AV conduction. ■ Experience with use following acute MI is limited. Use caution, titrate dose carefully, and

monitor patient closely. ■ May cause angina, arrhythmia, or MI if discontinued abruptly; gradually reduce over 1 to 2 weeks if possible. ■ May mask tachycardia occurring with hypoglycemia in diabetes and tachycardia of hyperthyroidism. ■ In general, patients with bronchospastic disease should not receive beta-blockers. If sotalol is to be administered, use the smallest effective dose; see [Contraindications](#). ■ Use caution in patients with renal impairment; see [Dose Adjustments](#). ■ Patients with atrial fibrillation should be anticoagulated according to usual medical practice.

Monitor: Obtain baseline ECG to determine the QT interval. If baseline QT interval is greater than 450 msec, sotalol is not recommended. Monitor QT interval after the completion of each infusion. If the QT interval increases to 500 msec or greater, reduce the dose, decrease the infusion rate, or discontinue therapy. ■ Measure and normalize serum potassium and magnesium levels before initiating therapy and as required during therapy. Pay special attention to electrolytes and acid-base status in patients with prolonged diarrhea or in patients receiving concomitant diuretics. ■ Obtain baseline SCr and calculate CrCl to establish dosing interval. ■ Monitor HR and BP. Monitor hemodynamics in patients with marginal cardiac compensation. ■ In patients with life-threatening ventricular arrhythmias, the response to treatment should be evaluated by a suitable method (e.g., programmed electrical stimulation [PES] or Holter monitoring) at steady-state blood levels of the drug before continuing the patient on chronic therapy.

Patient Education: Do not discontinue therapy abruptly. ■ Promptly report any breathing difficulty, syncope, or pain at injection site.

Maternal/Child: Category B; use during pregnancy only if clearly needed. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established. See prescribing information for unlabeled suggested oral doses for use in pediatric patients.

Elderly: Age-related differences in safety and effectiveness not identified; however, greater sensitivity of some elderly cannot be ruled out. Dose with caution, taking into account decreased renal function: See [Dose Adjustment](#).

DRUG/LAB INTERACTIONS

Proarrhythmic events were more common in sotalol-treated patients also receiving **digoxin**. Unclear as to whether this is a drug interaction or is related to the presence of heart failure, which is a known risk factor for arrhythmias. ■ Concurrent use with **calcium channel blockers** (e.g., diltiazem [Cardizem], verapamil) is expected to have additive effects on AV conduction, ventricular function, and BP. ■ Beta-adrenergic blocking agents may be continued during the perioperative period in most patients; however, use caution with **selected anesthetic agents** that may depress the myocardium. Protracted severe hypotension and difficulty in restoring and maintaining normal cardiac rhythm after anesthesia has been reported. ■ Concurrent use with **clonidine** may precipitate acute hypertension if one or both agents is stopped abruptly. ■ Coadministration with **catecholamine-depleting drugs** (e.g., reserpine and guanethidine) may result in hypotension, bradycardia, vertigo, syncope, or orthostatic hypotension. ■ Hyperglycemia may occur. Dosage of **insulin and other antidiabetic drugs** may require adjustment. ■ Symptoms of **hypoglycemia may be masked**. ■ Increased doses of **beta-agonists** such as albuterol, terbutaline, and isoproterenol may be required when administered concomitantly with sotalol. ■ Patients taking **beta-blockers** who are exposed to a potential allergen may be unresponsive to the usual dose of epinephrine used to treat a hypersensitivity reaction. ■ The use of sotalol in conjunction with other **drugs that prolong the QT interval** has not been studied and is not recommended. Such drugs include some phenothiazines (e.g., prochlorperazine [Compazine], promethazine [Phenergan]), tricyclic antidepressants (e.g., amitriptyline [Elavil], imipramine [Tofranil]), certain oral macrolides (e.g., erythromycin [E-Mycin], clarithromycin [Biaxin]), Class I antiarrhythmic (e.g., disopyramide [Norpace], procainamide [Pronestyl], quinidine), and Class III antiarrhythmics (e.g., amiodarone [Nexterone]). **Class I and III antiarrhythmic agents** should be withheld for at least three half-lives before dosing with sotalol. In studies, sotalol was not administered to patients who had been previously treated with **oral amiodarone** (Nexterone) for a more than 1 month in the previous 3 months. ■ Interactions with hydrochlorothiazide and

warfarin were not observed. ■ The presence of sotalol in the urine may result in **falsely elevated levels of urinary metanephrine** by certain methods.

SIDE EFFECTS

There is no clinical experience with IV sotalol. Side effects should be similar to those seen with oral sotalol therapy. The most common side effects (dose related) are asthenia, bradycardia, chest pain, dizziness, dyspnea, fatigue, headache, light-headedness, nausea, QT prolongation, and palpitations. Ventricular arrhythmia, primarily TdP, is the most common serious side effect. Other reported side effects include abdominal distention and pain, abnormal ECG, angina, bradycardia, cough, decreased appetite, diarrhea, dyspepsia, edema, fever, heart failure, hyperhidrosis, hypotension, infection, insomnia, musculoskeletal pain, tracheobronchitis, upper respiratory infection, visual disturbance, vomiting, and weakness. Other reactions have been reported.

Overdose: Bradycardia, bronchospasm, cardiac asystole, CHF, hypoglycemia, hypotension, premature ventricular complexes, prolongation of the QT interval, TdP, and ventricular arrhythmia.

ANTIDOTE

Notify physician of any side effects. If the QT interval increases to 500 msec or greater, reduce the dose, decrease the infusion rate, or discontinue therapy. Atropine, another anticholinergic drug, a beta-adrenergic agonist, or transvenous cardiac pacing may be used to treat bradycardia or cardiac asystole. A transvenous cardiac pacemaker may be required for second- or third-degree heart block. Epinephrine may be useful for treatment of hypotension. Aminophylline or aerosol beta-2-receptor stimulants (e.g., albuterol [Ventolin]) may be useful for treatment of bronchospasm. DC cardioversion, magnesium sulfate, and potassium replacement may be required for treatment of TdP. Once TdP is terminated, transvenous cardiac pacing or an isoproterenol infusion may be used to increase heart rate.

STREPTOMYCIN SULFATE **BBW**(strep-toe-**MY**-sin **SUL**-fayt)Antibacterial
(aminoglycoside)
Antituberculosis

pH 5 to 8

USUAL DOSE**ALL IV DOSES AND USES ARE UNLABELED.**

***Mycobacterium tuberculosis* (unlabeled):** 12 to 15 mg/kg daily. Calculation based on ideal body weight, not actual weight. 12 to 27 mg/kg has been used safely. Doses over 20 mg/kg are usually given every other day. Used in combination with isoniazid (INH), rifampin (Rifadin), and pyrazinamide. Maximum suggested total cumulative dose over course of therapy is 120 Gm.

***Mycobacterium avium* complex (unlabeled):** 11 to 13 mg/kg daily. Part of a multiple drug regimen of three to five agents.

DOSE ADJUSTMENTS

Reduced dose required in renal impairment and/or nitrogen retention. ■ Reduce dose in patients over 60 years based on age, renal function, and eighth nerve impairment. ■ Elevated peak drug concentrations require a reduced dose. ■ See [Drug/Lab Interactions](#).

DILUTION

Prepared solution equals 400 mg/mL. Further dilute total daily dose to a volume of 100 mL with D5W or D5NS.

Storage: Refrigerate undiluted ampules. Diluted solution is stable for 24 hours at room temperature. According to the National Jewish Center guidelines, the current formulation from Pfizer is stable for up to 30 days after dilution if refrigerated.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Inactivated in solution with beta-lactam antibiotics (e.g., cephalosporins, penicillins) and vancomycin. Do not mix in the same solution. Appropriate spacing required because of physical **incompatibilities**. See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

Additive: Bleomycin (Blenoxane).

Y-site: Esmolol (Brevibloc).

RATE OF ADMINISTRATION

Total daily dose, properly diluted, as an infusion over 30 minutes. Slow rate to 60 minutes if any tingling or dizziness occurs during administration or if elevated peak drug concentrations occur.

ACTIONS

An aminoglycoside antibiotic with potential neuromuscular blocking action. Inhibits protein synthesis in bacterial cells. Bactericidal against specific gram-negative organisms and bacilli. Well distributed through all organ tissues except the brain (unless meninges inflamed). Peak serum levels of 25 to 50 mcg/mL occur promptly and gradually decrease to 12.5 to 25 mcg/mL over 5 to 6 hours. Usual half-life is 2.5 hours. Half-life is prolonged in infants, postpartum females, liver disease and ascites, spinal cord injury, cystic fibrosis, and the elderly. May be prolonged up to 100 hours in end-stage renal disease. Half-life is shorter in anemia, severe burns, and fever. Crosses the placental barrier. 30% to 90% excreted in urine within 24 hours.

INDICATIONS AND USES

All IV uses are unlabeled. Treatment of *Mycobacterium tuberculosis* when one or more of the following drugs (ethambutol [Myambutol], isoniazid [INH], rifampin [Rifadin], or pyrazinamide) is contraindicated because of toxicity, intolerance, or drug resistance. Increased rates of drug resistance and/or concomitant HIV infection are more common

than in previous times. Usual four-drug regimen is either ethambutol or streptomycin with isoniazid, rifampin, and pyrazinamide. IV administration is especially useful in cachectic patients or those needing prolonged streptomycin therapy. ■ *Mycobacterium avium* complex, a common infection in AIDS patients.

CONTRAINDICATIONS

Known streptomycin sensitivity. Known aminoglycoside sensitivity may be a contraindication due to cross-sensitivity.

PRECAUTIONS

Labeled for IM use only; probably due to impurities in early preparations. New formulations are being given IV safely; check your hospital's policy in case an informed consent or release is required. ■ Handle with care; may cause skin sensitivity reactions. ■ Used only when other, less hazardous agents are ineffective or contraindicated. ■ Adequate laboratory and audiometric testing facilities must be available. ■ Sensitivity studies necessary to determine susceptibility of causative organism to streptomycin. ■ Potentially nephrotoxic, ototoxic, and neurotoxic. Risk for neurotoxicity is sharply increased in patients with pre-existing renal damage or pre-renal azotemia. Manifestations include disturbances of vestibular and cochlear function. Arachnoiditis, encephalopathy, optic nerve dysfunction, and peripheral neuritis may also occur. Partial or total irreversible deafness may continue to develop after streptomycin is discontinued. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with streptomycin. ■ May contain sulfites; use caution in patients with asthma. ■ For additional questions, consultations may be obtained from the Division of Infectious Disease at National Jewish Center.

Monitor: Monitor serum BUN, creatinine, calcium, magnesium, potassium, and sodium before therapy and weekly. ■ Calcium, magnesium, potassium, and sodium levels may decline and require replacement. ■ Observe for any adverse effects including at the infusion site. ■ High serum levels increase risk of ototoxicity and neurotoxicity. Assess adequacy of dose and clearance of drug with serum streptomycin concentrations (2 to 6 hours after a timed dose) initially and every 2 to 4 weeks. Peak therapeutic levels are between 20 and 30 mcg/mL. Serum levels over 50 mcg/mL may be toxic. ■ Watch for decrease in urine output, rising BUN and SCr, and declining CrCl levels. A decrease in dose may be indicated; serum levels should not exceed 25 mcg/mL if any kidney damage is present. ■ Assess vestibular function toxicity weekly (Romberg test, past point, heel-to-toe, and lateral nystagmus). ■ Assess ototoxicity with audiograms every 2 to 4 weeks. ■ All of the above monitoring may be done more frequently if indicated. Permanently implanted central venous catheters allow treatment on an outpatient basis. Blood work may be done every 2 weeks and all other tests every 4 weeks when stable enough to be treated as an outpatient. ■ Maintain good hydration. Dehydration may increase risk of nephrotoxicity; monitor closely if vomiting, diarrhea, or other events that may cause dehydration occur. ■ Closely monitor patients with impaired renal function for nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity); nephrotoxicity may be reversible. ■ National Jewish Center uses chromatographic assay to determine streptomycin serum levels; concomitantly administered antibiotics do not have to be withheld when collecting samples for analysis. ■ Usual length of treatment for tuberculosis is 1 year. Discontinue streptomycin therapy whenever toxic symptoms appear, impending toxicity is feared, organisms become resistant, or full therapeutic effect is achieved. ■ In long-term therapy, alkalization of urine may minimize renal irritation. ■ See [Drug/Lab Interactions](#).

Patient Education: Report promptly any changes in balance, dizziness, hearing loss or weakness. ■ Consider birth control options. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category D: avoid pregnancy; has caused total, irreversible, bilateral deafness in infants whose mothers received streptomycin during pregnancy. ■ Discontinue

breast-feeding. ■ Has caused CNS depression, including stupor, flaccidity, coma, and deep respiratory depression in very young infants.

Elderly: Risk of toxicity increased; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **beta-lactam antibiotics** (e.g., cephalosporins, penicillins) and **vancomycin**. Synergism may be inconsistent; see [Compatibility](#). ■ Concurrent or sequential use with any **other neurotoxic, ototoxic, or nephrotoxic agents** should be avoided. May have dangerous additive effects with **other aminoglycosides** (e.g., gentamicin, tobramycin), **diuretics** (e.g., furosemide [Lasix], mannitol), **beta-lactam antibiotics** (e.g., cephalosporins), **colistin** (Coly-Mycin S), **polymyxin B**, **vancomycin**, **cyclosporine**, and **many others**. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, and tetracycline); bactericidal action may be affected. ■ **Magnesium sulfate** may reduce antibiotic activity of streptomycin. ■ **Anesthetics** (e.g., enflurane) and **neuromuscular blocking muscle relaxants** (e.g., atracurium [Tracrium], succinylcholine) are potentiated by aminoglycosides. Respiratory paralysis and **apnea can occur**. ■ Aminoglycosides are potentiated by **anticholinesterases** (e.g., edrophonium), **antineoplastics** (e.g., nitrogen mustard, cisplatin). ■ See [Side Effects](#).

SIDE EFFECTS

Occur more frequently with impaired renal function, higher doses, prolonged administration, dehydration, in the elderly, and in patients receiving other ototoxic or nephrotoxic drugs. Apnea, azotemia, CDAD, cochlear ototoxicity (hearing loss and deafness), eosinophilia, exfoliative dermatitis, facial paresthesias, fever, hemolytic anemia, hypersensitivity reactions (e.g., angioneurotic edema, anaphylaxis, itching, rash, urticaria), leukopenia, muscular weakness, neuromuscular blockade, pancytopenia, roaring in the ears, seizures, thrombocytopenia, tinnitus, vestibular ototoxicity (nausea and vomiting, vertigo). Least nephrotic of the aminoglycosides but nephrotoxicity does occur. Has caused severe chilling (rigors) with penicillins if spacing is not adequate.

ANTIDOTE

Notify the physician of all side effects. Discontinue streptomycin with any evidence of renal impairment, ototoxicity, or vestibular toxicity. Tinnitus, roaring noises, or a sense of fullness in the ears indicate a need for audiometric examination. Auditory changes are usually irreversible and bilateral and may be partial or total. Vestibular symptoms are reversible if detected early. A reduction in dose may be required or an alternate drug used. In overdose hemodialysis may be indicated. Monitor fluid balance, CrCl, and plasma levels carefully. Complexation with ticarcillin may be as effective as hemodialysis. Calcium salts or neostigmine may reverse neuromuscular blockade. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Resuscitate as necessary.

STREPTOZOCIN **BBW**

(strep-toe-ZOH-sin)

Antineoplastic
(alkylating agent/nitrosurea)**Zanosar****pH 3.5 to 4.5****USUAL DOSE**

500 mg/M² for 5 consecutive days; see **Monitor**. Repeat every 6 weeks until maximum benefit or treatment-limiting toxicity observed. May also give 1,000 mg/M² weekly for 2 doses. May then increase up to 1,500 mg/M² to achieve therapeutic response if significant toxicity not observed. Overall cumulative dose to onset of response is 2,000 mg/M². Maximum response is usually achieved with 4,000 mg/M² total cumulative dose.

DOSE ADJUSTMENTS

Reduce dose in impaired renal function; see **Precautions/Monitor**. ■ Reduce dose or discontinue drug if mild proteinuria occurs. Lower-end initial doses may be appropriate in the elderly; consider the potential for decreased organ function and concomitant disease or drug therapy. ■ Can be used with other antineoplastic drugs in reduced doses to achieve tumor remission.

DILUTION

Specific techniques required; see Precautions. Each 1-Gm vial must be diluted with 9.5 mL NS or D5W (100 mg/mL). Usually further diluted in larger amounts (50 to 250 mL) of the same solutions.

Storage: Store in refrigerator before and after dilution. Discard within 12 hours of dilution. Contains no preservatives. Protect from light.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Amifostine (Ethylol), etoposide phosphate (Etopophos), filgrastim (Neupogen), gemcitabine (Gemzar), granisetron (Kytril), melphalan (Alkeran), ondansetron (Zofran), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

A single dose in minimum diluent given over 5 to 15 minutes is recommended. Increase injection time somewhat if additional diluent used or if indicated for patient comfort. Has been given as a continuous infusion over 5 days. Some side effects may be reduced, but CNS side effects (e.g., confusion, depression, lethargy) may be increased.

ACTIONS

An alkylating agent of the nitrosurea group with anti-tumor activity, cell cycle phase nonspecific. Has a diabetogenic (hyperglycemic) effect resulting from selective uptake into and toxicity to pancreatic islet beta cells. Disappears from the blood rapidly. Concentrates in the liver and kidneys. Excreted primarily in urine.

INDICATIONS AND USES

Suppress or retard neoplastic growth in metastatic pancreatic islet cell carcinoma. Use limited by renal toxicity to those with symptomatic or progressive metastatic disease.

Unlabeled uses: Treatment of adrenocortical and colon cancers and Hodgkin's lymphoma.

CONTRAINDICATIONS

Hypersensitivity to streptozocin. Severely impaired liver or renal function may be a contraindication.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be readily available. ■ Consider risk of known toxic effects versus benefit before initiating therapy. ■ Marked decrease in leukocyte and platelet counts has occurred and may be fatal. ■ Risk of nephrotoxicity may be reduced by decreasing renal and urinary concentration of strep-

tozocin and its metabolites with adequate hydration. ■ Avoid concomitant use with other potential nephrotoxins (e.g., aminoglycosides [e.g., gentamicin], amphotericin B). ■ Liver dysfunction and diarrhea have been observed in some patients.

Monitor: Renal toxicity is dose related, cumulative, and can be fatal. Monitor renal function before, weekly, and for 4 weeks after each course of therapy (serial urinalysis, BUN, plasma creatinine, serum electrolytes, CrCl). Reduce dose or discontinue drug if mild proteinuria occurs. Further deterioration of renal function may occur; see [Precautions](#). ■ Determine absolute patency and quality of vein and adequate circulation of extremity. Local inflammation (e.g., burning, edema, erythema, tenderness), severe cellulitis, and/or necrosis may result from extravasation. If extravasation occurs, discontinue injection; use another vein. ■ Have IV dextrose available especially with the first dose. Sudden release of insulin may precipitate hypoglycemia. Monitor serum glucose at periodic intervals. ■ Monitor CBC and liver function tests weekly. ■ Nausea and vomiting have occurred in all patients and can be severe. Prophylactic administration of antiemetics recommended. ■ Observe for any signs of infection. Use of prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Maintain hydration; see [Precautions](#). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See [Drug/Lab Interactions](#).

Patient Education: Avoid pregnancy; nonhormonal birth control recommended. ■ Report IV site burning or stinging promptly. ■ Use caution in tasks that require alertness, such as driving or using complex machinery. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. Produces teratogenic effects in rats. Has mutagenic potential. ■ Discontinue breast-feeding.

Elderly: Differences in response compared to younger adults not observed. Lower-end initial doses may be appropriate; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Concurrent use with **hepatotoxic or nephrotoxic medications and radiation therapy** may increase toxicity and could be fatal. ■ Toxicity may be additive when used in combination with **other cytotoxic drugs** (e.g., cyclophosphamide [Cytosan], doxorubicin [Adriamycin, Doxil]). ■ May prolong the elimination half-life of **doxorubicin** and lead to severe bone marrow suppression. A reduced dose of doxorubicin may be indicated. ■ Concurrent use with **phenytoin** (Dilantin) may decrease therapeutic effects of streptozocin.

SIDE EFFECTS

Anemia, decreased platelet count (precipitous), diarrhea, elevated AST and LDH, hepatic toxicity (usually reversible), hypoalbuminemia, hypoglycemia, insulin shock, leukopenia (precipitous), nausea and vomiting (severe), proteinuria, thrombocytopenia. Two cases of diabetes insipidus have been reported.

ANTIDOTE

Notify physician of all side effects. Nausea and vomiting, hematologic changes, and renal toxicity (proteinuria) may require dose reduction or discontinuation of the drug. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. For extravasation, elevate extremity, consider injection of long-acting dexamethasone (Decadron LA) throughout extravasated tissue. Use a 27- or 25-gauge needle. Apply warm, moist compresses.

SULFAMETHOXAZOLE AND TRIMETHOPRIM

(sul-fah-meh-**THOX**-ah-zohl and try-**METH**-oh-prim)

Antibacterial
Antiprotozoal

SMZ-TMP, TMP-SMZ

pH 10

USUAL DOSE

Doses listed are based on the trimethoprim component of the drug.

Severe urinary tract infections and shigellosis in adults and pediatric patients over 2 months of age: 8 to 10 mg/kg/24 hr in equally divided doses every 6, 8, or 12 hours (2 to 2.5 mg/kg every 6 hours, 2.67 to 3.33 mg/kg every 8 hours, or 4 to 5 mg/kg every 12 hours). Administer for 14 days (urinary tract infections) or 5 days (shigellosis). Maximum recommended dose is 960 mg trimethoprim and 4,800 mg sulfamethoxazole/24 hr (60 mL/24 hr).

***Pneumocystis jiroveci* pneumonitis in adults and pediatric patients over 2 months of age:** 15 to 20 mg/kg/24 hr in equally divided doses every 6 or 8 hours (3.75 to 5 mg/kg every 6 hours or 5 to 6.67 mg/kg every 8 hours) for up to 14 days.

DOSE ADJUSTMENTS

Reduce dose by one half for CrCl between 15 and 30 mL/min; see [Contraindications](#). ■ Reduced dose may be indicated in the elderly. ■ See [Monitor](#) and [Drug/Lab Interactions](#).

DILUTION

Each 5-mL ampule (16 mg trimethoprim/mL [80 mg/5 mL], 80 mg sulfamethoxazole/mL [400 mg/5 mL]) must be diluted in 125 mL D5W and given as an infusion. Reduce diluent to 75 mL for each ampule only if fluid restriction required. Standard dilution must be used within 6 hours; fluid restriction dilution must be used within 2 hours. Available in 5-, 10-, 20-, and 30-mL vials. Concentration per mL same as 5-mL ampule. Discard if cloudiness or crystallization is present.

Storage: Store at room temperature; do not refrigerate.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not mix with other drugs or solutions."

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), aldesleukin (Proleukin), allopurinol (Aloprim), amifostine (Ethyol), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), atracurium (Tracrium), aztreonam (Azactam), bivalirudin (Angiomax), ceftazoline (Teflaro), cisatracurium (Nimbex), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), fenoldopam (Corlopam), filgrastim (Neupogen), fludarabine (Fludara), foscarnet (Foscavir), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hex-tend), hydromorphone (Dilaudid), labetalol, lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), morphine, nifedipine (Cardene IV), pancuronium, pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), teniposide (Vumon), thiotepa, vecuronium, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose must be infused over 60 to 90 minutes. When administered by an infusion device, thoroughly flush all lines used to remove any residual sulfamethoxazole/trimethoprim. Avoid rapid infusion or bolus injection.

ACTIONS

A broad-spectrum antibacterial and antiprotozoal combination agent with bactericidal action effective against gram-positive and gram-negative organisms. Blocks sequential steps in the folic acid pathway, preventing the synthesis of nucleic acids and proteins essential to many bacteria. Combination contains 400 mg sulfamethoxazole and 80 mg trimethoprim per each 5 mL. Widely distributed in all body fluids and tissues, including cerebrospinal fluid, sputum, and bile. Onset of action is prompt and serum levels are maintained up to 10 hours. Metabolized in the liver and up to 60% is excreted in urine in 24 hours. Crosses placental barrier. Secreted in breast milk. Partially removed by hemodialysis.

INDICATIONS AND USES

Severe urinary tract infections. ■ *Pneumocystis jiroveci* pneumonia. ■ Shigellosis. ■ Prophylaxis in neutropenic patients. ■ Used orally in HIV and other immunocompromised patients to prevent pneumonia.

Unlabeled uses: Treatment of cholera and salmonella type infections. ■ An alternative agent in the treatment of meningitis caused by susceptible organisms.

CONTRAINDICATIONS

CrCl less than 15 mL/min, hypersensitivity to trimethoprim or sulfonamides, megaloblastic anemia resulting from folate deficiency, nursing mothers, pregnancy at term and infants less than 2 months of age (may cause hemolytic anemia, jaundice, and kernicterus), streptococcal pharyngitis.

PRECAUTIONS

Sensitivity studies indicated to determine susceptibility of the causative organism to sulfamethoxazole/trimethoprim. ■ Not for IM use. ■ Use caution in impaired liver or renal function, possible folate deficiency, allergic individuals, bronchial asthma, porphyria, glucose 6-phosphate dehydrogenase (G-6PD) deficiency, and in the elderly. ■ A sulfonamide drug; hypersensitivity reactions can occur. Use caution in patients with a history of hypersensitivity to furosemide (Lasix), thiazide diuretics (e.g., chlorothiazide), sulfonylureas (e.g., tolbutamide), or carbonic anhydrase inhibitors (e.g., acetazolamide). ■ Some products contain bisulfites; use caution in patients with allergies. ■ Incidence of side effects markedly increased in AIDS patients. May not tolerate or respond to this drug. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with sulfamethoxazole/trimethoprim.

Monitor: Maintain adequate hydration to prevent crystalluria and stone formation. ■ CBC required before and during therapy. Discontinue for any significant reduction in a blood-forming element. Urinalysis and renal function tests also indicated. ■ If extravasation occurs, discontinue and restart at a new site. May cause phlebitis. ■ Monitor closely if any signs of rash appear or have appeared in previous infusions. Several cases of life-threatening reactions have occurred. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Maintain adequate hydration. ■ Report bruising or bleeding, fever, rash, or sore throat promptly. ■ Possible skin photosensitivity. Avoid unprotected exposure to sunlight. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category C: no adequate studies. May interfere with folic acid metabolism in mother and fetus. Benefits must outweigh risks. ■ May contain benzyl alcohol. ■ See [Contraindications](#). ■ Discontinue breast-feeding. ■ Two infants who developed a rash had life-threatening reactions when sulfamethoxazole/trimethoprim was restarted.

Elderly: See [Dose Adjustments](#). ■ Increased risk of severe side effects (e.g., bone marrow suppression, decrease in platelets with or without purpura, skin reactions), especially in impaired renal or liver function or with other drugs (e.g., diuretics).

DRUG/LAB INTERACTIONS

May be potentiated by **probenecid**. ■ May inhibit **cyclosporine** (Sandimmune) and increase nephrotoxicity. ■ May potentiate **warfarin** (Coumadin), **phenytoin** (Dilantin), **oral**

hypoglycemics, dapsone, and zidovudine (AZT, Retrovir). ■ The sulfa component may displace **methotrexate** from its binding sites, increasing free fraction of methotrexate and its potential for toxicity. The trimethoprim component inhibits methotrexate metabolism and increases toxicity. ■ May decrease effectiveness of **tricyclic antidepressants** (e.g., amitriptyline [Elavil]). ■ Concurrent use with **folate antagonists** (e.g., hydantoins [e.g., phenytoin], methotrexate), is not recommended. May increase possibility of megaloblastic anemia. ■ Concurrent use with **leucovorin calcium** may cause treatment failure and increased morbidity in HIV-infected patients being treated for *Pneumocystis jiroveci* pneumonia. ■ Concurrent use with **bone marrow suppressants** (e.g., antineoplastics [e.g., busulfan, cisplatin], amphotericin B [all formulations], ganciclovir [Cytovene]) may increase leukopenic or thrombocytopenic effects. Monitor differential blood count. ■ Serum levels of **digoxin** may be increased with concurrent use; monitor digoxin levels. ■ Concurrent use with **hemolytics** (e.g., doxapram [Dopram], methyl dopate, procainamide [Pronestyl], quinidine) may increase potential for toxic side effects. ■ Concurrent use with **hepatotoxic agents** (e.g., amiodarone [Nexterone], erythromycins, flucanazole [Diflucan]) may increase incidence of hepatotoxicity. Risk increased with prolonged use or in patients with a history of liver disease. ■ May form an insoluble precipitate in acid urine or cause crystalluria with **methenamine** (Mandelamine); concurrent use not recommended. ■ May decrease clearance and increase serum concentrations of **N-acetylprocainamide** (NAPA) and **procainamide** (Pronestyl). ■ Concurrent use with **rifampin** (Rifadin) will increase elimination, reduce serum concentrations, and shorten half-life of trimethoprim. ■ Concurrent use with **thiazide diuretics** (e.g., chlorothiazide) in the elderly may result in an increased incidence of thrombocytopenia with purpura. ■ May interfere with **serum methotrexate assay and Jaffe assay for creatinine**. ■ See **Precautions**.

SIDE EFFECTS

All side effects of sulfonamides, including hypersensitivity reactions are possible. Nausea, vomiting, and rash occur most frequently. Ataxia, convulsions, tremors, and respiratory depression are symptoms of major toxicity. With high doses or administration over an extended period of time, bone marrow suppression (leukopenia, megaloblastic anemia, thrombocytopenia) may occur. CDAD has been reported.

ANTIDOTE

Notify the physician of any side effect. Discontinue the drug at any sign of major toxicity or bone marrow suppression. Some sources recommend leucovorin calcium 5 to 15 mg daily for treatment of bone marrow suppression. Peritoneal dialysis is not effective in toxicity; hemodialysis may be moderately effective in reducing serum levels. Acidification of urine may increase excretion. Treat anaphylaxis with epinephrine, corticosteroids, antihistamines, and vasopressors. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated.

TACROLIMUS **BBW**

(tah-KROH-lih-mus)

Immunosuppressant

Prograf**USUAL DOSE**

See **Precautions**. IV route used for patients unable to take oral medications; risk of anaphylaxis increased with IV administration. Transfer to oral therapy as soon as tolerated, usually within 2 to 3 days.

For all indications: Dose regimens vary among transplant centers and approved or investigational use (range 0.01 to 0.05 mg/kg/day). Begin no sooner than 6 hours after transplantation in liver and heart transplant patients. In kidney transplant patients, initial dose may be administered within 24 hours of transplantation but should be delayed until renal function has recovered. Adults usually receive doses at the lower end of the range. Pediatric patients may require doses at the upper end of the range. Individualized adjustment based on clinical assessment of rejection (e.g., trough blood concentrations) or patients' tolerance is imperative and may be required on a daily basis. Adjunctive adrenal corticosteroid therapy early post-transplant is recommended. Initiate oral tacrolimus therapy as soon as feasible. Oral doses vary with specific organ transplant and in adults and pediatric patients (see literature). Total dose in mg/kg/day is given in equally divided doses every 12 hours. Begin 8 to 12 hours after IV tacrolimus is discontinued. Lower doses may be sufficient for maintenance therapy.

Prophylaxis of organ rejection in heart transplant: The recommended starting dose is 0.01 mg/kg/day as a continuous infusion. Used in combination with azathioprine (Imuran) or mycophenolate (CellCept) in addition to adrenal corticosteroids. See all comments and protocol under **For All Indications** above.

Prophylaxis of organ rejection in kidney transplant: The recommended starting dose is 0.03 to 0.05 mg/kg/day as a continuous infusion. Used in combination with azathioprine (Imuran) or mycophenolate (CellCept) in addition to adrenal corticosteroids. See all comments and protocol under **For All Indications** above.

Prophylaxis of organ rejection in liver transplant: The recommended starting dose is 0.03 to 0.05 mg/kg/day as a continuous infusion. Used in combination with adrenal corticosteroids. See all comments and protocol under **For All Indications** above.

PEDIATRIC DOSE

Has been used successfully in pediatric patients up to 16 years of age in liver transplants. See **Usual Dose** for mg/kg/day dose recommendations. Studies indicate that higher doses may be required to maintain blood trough concentrations similar to adults. Experience in pediatric heart and kidney transplant patients is limited. See **Dilution** and **Maternal/Child**.

DOSE ADJUSTMENTS

Dosing should be titrated based on clinical assessments of rejection and tolerability. ■ Use lowest dosing range initially for patients with impaired renal or hepatic function (pre-transplant or post-transplant). Nephrotoxicity may be increased and further reductions may be required. Half-life prolonged and clearance decreased in patients with severe hepatic impairment (Child-Pugh greater than or equal to 10). Dose reduction may be required. ■ In kidney transplant patients with postoperative oliguria, the initial dose of tacrolimus should be administered no sooner than 6 hours and within 24 hours of transplantation, but it may be delayed until renal function shows evidence of recovery. ■ Lower doses may be appropriate for maintenance. ■ Black patients who have undergone a kidney transplant may require a higher dose to obtain trough concentrations comparable to those seen in white patients. ■ See **Monitor** and **Drug/Lab Interactions**.

DILUTION

Specific techniques required; see Precautions. A 24-hour dose must be diluted with an appropriate amount of NS or D5W. Desired concentration is between 4 and 20 mcg/mL.

May leach phthalate from polyvinylchloride containers; mix in glass or polyethylene infusion bottles. Use PVC-free IV tubing in pediatric patients. The following chart provides some dose and dilution examples.

Tacrolimus Dose and Dilution Examples				
Desired Dose	Weight	Total Dose	Amount of Diluent	mcg/mL
0.01 mg/kg	70 kg	0.7 mg/24 hr	100 mL	7 mcg/mL
0.03 mg/kg	100 kg	3 mg/24 hr	250 mL	12 mcg/mL
0.05 mg/kg	60 kg	3 mg/24 hr	500 mL	6 mcg/mL
			250 mL	12 mcg/mL

Storage: Store between 5° and 25° C (41° and 77° F) before dilution. Discard diluted solution in 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be mixed with solutions of pH 9 or greater (e.g., acyclovir [Zovirax], ganciclovir [Cytovene]." See **Dilution**.

One source suggests the following **compatibilities**:

Y-site: Aminophylline, amphotericin B (conventional), ampicillin, ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), benzotropine (Cogentin), calcium gluconate, caspofungin (Cancidas), cefazolin (Ancef), cefotetan, ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chloramphenicol (Chloromycetin), ciprofloxacin (Cipro IV), clindamycin (Cleocin), dexamethasone (Decadron), digoxin (Lanoxin), diphenhydramine (Benadryl), dobutamine, dopamine, doripenem (Doribax), doxycycline, erythromycin (Erythrocin), esmolol (Brevibloc), fluconazole (Diflucan), furosemide (Lasix), gentamicin, heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), imipenem-cilastatin (Primaxin), insulin (regular), isoproterenol (Isuprel), leucovorin calcium, lorazepam (Ativan), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), micafungin (Mycamine), morphine, multivitamins (M.V.I.), mycophenolate (CellCept IV), nitroglycerin IV, nitroprusside sodium, oxacillin (Bactocill), penicillin G potassium, phenytoin (Dilantin), potassium chloride (KCl), propranolol, ranitidine (Zantac), sodium bicarbonate, sulfamethoxazole/trimethoprim, tobramycin, vancomycin.

RATE OF ADMINISTRATION

A single dose properly diluted and equally distributed over 24 hours as a continuous infusion. Use of a metriset (60 gtt/min) or infusion pump suggested.

ACTIONS

A potent immunosuppressive agent. Prolongs survival of allogeneic heart, kidney, and liver transplants. Inhibition of T-lymphocyte activation results in immunosuppression. Highly protein bound. Metabolized primarily by the P₄₅₀ enzyme system (CYP3A). Half-life ranges from 21 to 36 hours. Primarily excreted in feces. Minimal excretion in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Prophylaxis of organ rejection in allogeneic heart, kidney, and liver transplants in conjunction with adrenal corticosteroids. In heart and kidney transplant patients, concomitant use with azathioprine or mycophenolate is recommended in addition to the adrenal corticosteroids.

Limitations of use: Should not be used simultaneously with cyclosporine. ■ Should be reserved for patients unable to take oral tacrolimus. ■ Use with sirolimus (Rapamune) is not recommended in liver and heart transplant patients. Safety and effectiveness of tacrolimus with sirolimus in kidney transplant patients has not been established.

Unlabeled uses: Treatment of autoimmune diseases (i.e., rheumatoid arthritis). ■ Prevention and treatment of acute graft-versus-host disease.

CONTRAINDICATIONS

Hypersensitivity to tacrolimus or polyoxyl 60 hydrogenated castor oil.

PRECAUTIONS

Follow guidelines for handling hazardous agents. See Appendix A, p. 1251. ■ For IV use only. ■ Oral dosing preferred; begin as soon as feasible. Risk of anaphylaxis is increased by IV route versus oral route; use caution. **Reserve for patients unable to take oral medication.** ■ Usually administered in the hospital by or under the direction of a physician experienced in immunosuppressive therapy and management of organ transplant patients. ■ Adequate laboratory and supportive medical resources must be available. ■ Use caution in impaired renal function; increases in SCr may require dose reduction or use of an alternate immunosuppressant. ■ Use caution in severe hepatic dysfunction (mean Pugh score: greater than 10), clearance decreased. ■ Can cause nephrotoxicity and neurotoxicity, particularly at higher doses; see **Monitor**. ■ Posterior reversible encephalopathy syndrome (PRES), delirium, and coma have been reported; see **Monitor**. ■ Use combination immunosuppressant therapy with caution; may oversuppress the immune system and increase susceptibility to infection. ■ Immunosuppressed patients are at increased risk for bacterial, viral, fungal, and protozoal infections. ■ Opportunistic infections may include latent viral infections such as polyoma virus infections. Polyoma virus infections may result in polyoma virus-associated nephropathy (PVAN) and JC virus-associated progressive multifocal leukoencephalopathy (PML). PVAN is associated with serious outcomes, including deteriorating renal function and kidney graft loss. PML is a serious progressive neurologic disorder caused by infection of the CNS by JC virus, a member of the papovavirus family. It typically occurs in immunocompromised patients. PML is rare but may result in irreversible neurologic deterioration and death, and there is no known effective treatment. Hemiparesis, apathy, confusion, cognitive deficiencies, and ataxia are the most commonly observed clinical signs. ■ Patients receiving immunosuppression are at increased risk for developing cytomegalovirus (CMV) viremia and CMV disease. ■ Antiviral prophylaxis (e.g., acyclovir, ganciclovir, immune globulin) may be advisable in some patients. ■ Concurrent use with sirolimus (Rapamune) is not recommended in liver or heart transplant patients. Regimen is associated with an increased risk of wound healing complications, renal function impairment, and insulin-dependent, post-transplant diabetes mellitus in heart transplant patients; regimen is associated with excess mortality, graft loss, and hepatic artery thrombosis in liver transplant patients. The safety and efficacy of tacrolimus and sirolimus have not been established in kidney transplant patients. ■ Post-liver transplant patients experiencing hepatic impairment may be at increased risk of developing renal insufficiency related to elevated tacrolimus concentrations. ■ **May cause lymphomas and other malignancies (especially of skin).** Risk appears to be related to intensity and duration of immunosuppression. Has been associated with a post-transplant lymphoproliferative disorder (PTLD) related to Epstein-Barr virus infection. ■ New-onset diabetes mellitus has been reported in tacrolimus-treated heart, kidney, and liver transplant patients. May be reversible over 1 to 2 years in some patients. Black and Hispanic kidney transplant patients may be at an increased risk; see **Monitor**. ■ Myocardial hypertrophy has been reported in pediatric patients and adults. Reversible in most cases with dose reduction or discontinuation of tacrolimus. ■ Pure red cell aplasia (PRCA) has been reported. ■ See **Drug/Lab Interactions**.

Monitor: Obtain baseline CBC, differential, platelets, electrolytes, fasting glucose, BUN, SCr, and liver function tests. Monitor regularly during therapy. ■ Contains a castor oil derivative and alcohol; observe continuously for signs of a hypersensitivity reaction (e.g., acute respiratory distress syndrome [ARDS], dyspnea, pruritus, rash) for the first 30 minutes of the infusion and frequently thereafter. A source of oxygen and epinephrine must always be available. ■ Monitor urine output and SCr carefully. Overt nephrotoxicity occurs more frequently early after transplant. Nephrotoxicity may be acute or chronic. Acute nephrotoxicity is characterized by increasing SCr, hyperkalemia, and/or a decrease

in urine output and is usually reversible. Chronic nephrotoxicity is usually progressive and is associated with increased SCr, decreased kidney graft life, and characteristic histologic changes on renal biopsy. Consider changing to another immunosuppressive therapy in patients with persistent elevations of SCr who are unresponsive to dose adjustments. ■ Monitor for S/S of neurotoxicity (e.g., changes in motor or sensory function, changes in mental status, coma, delirium, headache, tremor, seizures). ■ Monitor for S/S of PRES (e.g., altered mental status, headache, hypertension, seizures, and visual disturbances). Diagnosis may be confirmed by MRI. Maintain BP control, and an immediate decrease of immunosuppression is advised. Symptoms have reversed when immunosuppression is reduced or discontinued. ■ Monitor for S/S of PML; apathy, ataxia, cognitive deficiencies, confusion, and hemiparesis are the most commonly observed clinical signs. ■ Tacrolimus whole blood trough concentrations are used to evaluate rejection, toxicity, need for dose reduction, and patient compliance. Risk of toxicity (e.g., nephrotoxicity, neurotoxicity, post-transplant diabetes mellitus) is increased with higher trough concentrations. Whole blood median trough concentrations may vary considerably during the first week but then stabilize. Most patients are stable when trough whole blood concentrations are between 5 and 20 ng/mL depending on indication and length of time since the transplant. The trough concentrations described above and in the manufacturer's prescribing information pertain only to oral administration of tacrolimus. Monitoring tacrolimus concentrations during a continuous IV infusion of tacrolimus may have some utility; however, the observed concentrations will not represent exposures comparable to those estimated by the trough concentrations observed in patients on oral therapy. ■ Monitor all parameters to evaluate possibility of organ rejection. ■ Monitor BP; antihypertensives may be indicated; see [Drug/Lab Interactions](#). ■ Monitor serum potassium and magnesium levels. May cause hyperkalemia or hypomagnesemia. ■ May cause hyperglycemia. Monitor carefully; treatment may be required. ■ Observe for signs of infection (e.g., fever, sore throat, tiredness) or unusual bleeding or bruising. ■ Consider echocardiographic evaluation in patients who develop renal failure or clinical manifestations of ventricular dysfunction. Consider dose reduction or discontinuation of tacrolimus if myocardial hypertrophy is diagnosed. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Review manufacturer's medication guide. ■ Nonhormonal birth control preferred to oral contraceptives to reduce complications of drug interactions. ■ Emphasize need for frequent routine lab work; compliance imperative. ■ Interacts with many medications. Discuss any changes in drug regimen (prescription or nonprescription) with doctor or pharmacist. ■ Promptly report any side effects (e.g., hypertension, neurotoxicity, nephrotoxicity, S/S of infection). ■ Review S/S of diabetes mellitus. ■ Inform patient of increased risk of neoplasia, including malignant skin changes. Limit exposure to sunlight and ultraviolet light. ■ See Appendix D, p. 1255.

Maternal/Child: Category C: use only if necessary; benefits must outweigh risk to fetus. Has been associated with hyperkalemia and renal dysfunction in the fetus. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric kidney and heart transplant patients not established. ■ Appears to be an increased risk for LPD and primary Epstein-Barr virus infection in immunosuppressed pediatric patients.

Elderly: Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

Used concurrently with **adrenocorticosteroids** and **azathioprine (Imuran)** or **mycophenolate (CellCept)**. **Do not use simultaneously with cyclosporine (Sandimmune)**. If a change of immunosuppressants is indicated (tacrolimus to cyclosporine or cyclosporine to tacrolimus), avoid additive nephrotoxicity by waiting for at least 24 hours before starting the alternate drug. If elevated blood concentrations are present, further extend the interval between the two drugs. ■ Concurrent use with **sirolimus (Rapamune)** is not recommended; see [Precautions](#). ■ Coadministration with **strong CYP3A4 inhibitors** (e.g., azole antifungal agents [e.g., itraconazole (Sporanox), ketoconazole (Nizoral), voriconazole (VFEND)], boceprevir [Victrelis], clarithromycin [Biaxin], ritonavir [Norvir], telaprevir

[Incivek]) and strong inducers (e.g., rifampin [Rifadin], rifabutin [Mycobutin]), including those that prolong the QT interval (e.g., azole antifungals, clarithromycin), is not recommended without adjustments in tacrolimus dosing and close monitoring of tacrolimus whole blood trough concentration and associated side effects. ■ Concurrent use with other drugs that prolong the QT interval may require dose adjustment and monitoring of trough concentrations. **Amiodarone** (Nexterone) has been reported to increase tacrolimus whole blood concentration with or without concurrent QT prolongation. ■ Use extreme caution with **other nephrotoxic agents** (e.g., aminoglycosides [gentamicin, tobramycin], amphotericin B [conventional], cisplatin [Platinol], ganciclovir [Cytovene], nucleotide reverse transcriptase inhibitors [e.g., tenofovir (Viread)], and protease inhibitors [e.g., ritonavir (Norvir), indinavir (Crixivan)]). ■ Do not use **potassium-sparing diuretics** (e.g., spironolactone [Aldactone]); increases risk of hyperkalemia. Other agents associated with hyperkalemia (e.g., **ACE inhibitors** [enalapril (Vasotec)] and **angiotension receptor blockers** [e.g., losartan (Cozaar)]) should be used with caution. ■ **Calcium channel blockers** (e.g., diltiazem [Cardizem], nifedipine [Cardene], nifedipine [Procardia], verapamil), **bromocriptine** (Parlodel), **chloramphenicol** (Chloromycetin), **cimetidine** (Tagamet), **cyclosporine** (Sandimmune), **danazol** (Cyclomen), **erythromycin**, **estradiol** (Estrace), **lansoprazole** (Prevacid), **methylprednisone** (Solu-Medrol), **metoclopramide** (Reglan), **metronidazole** (Flagyl), **omeprazole** (Prilosec), **protease inhibitors** (e.g., ritonavir [Norvir], saquinavir [Invirase]), **theophylline**, and **troleandomycin** (TAO) may inhibit the P₄₅₀ enzyme system and increase tacrolimus blood levels, increasing toxicity potential. Tacrolimus toxicity may also be increased if given concurrently with **nefazodone**. ■ Avoid concomitant use with **nelfinavir** unless benefits outweigh risks. ■ When initiating therapy with **posaconazole** or **voriconazole** in patients already receiving tacrolimus, decrease tacrolimus dose to one third of the original dose. Adjust subsequent tacrolimus doses based on tacrolimus whole blood concentrations. ■ **Anticonvulsants** (e.g., carbamazepine [Tegretol], phenobarbital, phenytoin [Dilantin]), **caspofungin** (Cancidas), **rifamycins** (e.g., rifabutin [Mycobutin], rifampin [Rifadin]), **sirolimus** (Rapamune), and **St. John's wort** may induce the P₄₅₀ enzyme system, decreasing effectiveness and leading to decreased tacrolimus blood levels and organ rejection. ■ Tacrolimus may increase serum concentrations of **phenytoin** (Dilantin). ■ **Grapefruit juice** may affect certain enzymes of the P₄₅₀ system and should be avoided. ■ **Do not use live virus vaccines** in patients receiving tacrolimus.

SIDE EFFECTS

Heart transplant: Abnormal renal function, anemia, bronchitis, CMV infection, diabetes mellitus, hyperglycemia, hyperlipidemia, hypertension, infection, leukopenia, pericardial effusion, tremor, and urinary tract infection are most common.

Kidney transplant: Abdominal pain, abnormal renal function, constipation, diarrhea, headache, hypertension, insomnia, and nausea are most common.

Liver transplant: Abdominal pain, abnormal renal function, anemia, asthenia, diarrhea, fever, headache, hyperglycemia, hyperkalemia, hyperlipidemia, hypertension, hypomagnesemia, insomnia, nausea, pain, paresthesia, and tremor are most common. The above side effects are most common by diagnosis, but any of them may occur with any patient receiving a heart, liver, or kidney transplant. Side effects occur in a majority of patients and are more pronounced at higher doses. May improve somewhat over time. Nephrotoxicity (abnormal renal function with increased SCr and BUN, oliguria), and neurotoxicity (delirium, headache, insomnia, paresthesia, tremor, seizures) may be dose limiting. Abnormal ECG, abnormal liver function tests, acute kidney failure, albuminuria, anorexia, arrhythmias, ascites, atelectasis, back pain, blood dyscrasias, CHF, coma, cushingoid features, dyspnea, gastroenteritis, glycosuria, hearing loss (including deafness), hemolytic-uremic syndrome, hypokalemia, hypophosphatemia, impaired wound healing, leukocytosis, leukoencephalopathy, myocardial hypertrophy, neuralgia, pancreatitis, peripheral edema, peritonitis, photosensitivity, plural effusion, pruritus, pulmonary edema, QT prolongation, rash, seizures, Stevens-Johnson syndrome, thrombocytopenia, thrombophlebitis, torsades de pointes, vertigo, and vomiting have also been reported. Many other side effects have occurred in fewer than 3% of patients.

Post-Marketing: Acute respiratory distress syndrome, agranulocytosis, PVAN nephropathy, cardiac arrhythmia, cerebral infarction, DIC, enterocolitis, gastroesophageal reflux disease, hemolytic anemia, hepatotoxicity, interstitial lung disease, posterior reversible encephalopathy syndrome (PRES), PRCA, primary graft dysfunction, and progressive multifocal leukoencephalopathy (PML) are some of the many additional side effects reported.

ANTIDOTE

Notify the physician of all side effects. Most will be treated symptomatically. Tacrolimus may be decreased or discontinued or alternate immunosuppressive agents substituted. Nephrotoxicity, neurotoxicity, or hematopoietic depression may require temporary reduction of dose or discontinuation of therapy. Reduction in immunosuppression should be considered for patients who develop evidence of PVAN or PML. However, the risk that reduced immunosuppression represents to the functioning allograft must also be considered. If S/S of PRES occur, maintain BP control, and an immediate decrease of immunosuppression is advised. Consider discontinuing tacrolimus if PRCA is diagnosed. Dialysis is not effective in overdose. Discontinue immediately if anaphylaxis occurs and treat with oxygen, epinephrine, corticosteroids, and/or antihistamines (e.g., diphenhydramine [Benadryl]). Resuscitate as necessary.

TALIGLUCERASE ALFA

(tal-e-**GLUE**-sir-ace **AL**-fa)

Enzyme replenisher
(glucocerebrosidase)

Elelyso

pH 6

USUAL DOSE

60 units/kg of body weight administered once every 2 weeks as a 60- to 120-minute IV infusion. Adult patients currently being treated with imiglucerase for Type 1 Gaucher disease can be switched to taliglucerase alfa. Patients on a stable dose of imiglucerase may transfer to the same dose of taliglucerase alfa.

DOSE ADJUSTMENTS

Dose may increase or decrease based on achievement of each patient's therapeutic goals. Optimal goal is to establish the lowest dose that is effective in maintaining control of the disease and preventing a recurrence of symptoms for each patient. Clinical studies evaluated dose ranges from 11 units/kg to 73 units/kg.

DILUTION

Available as a lyophilized powder in 200-unit vials. Should be prepared using low-protein-binding containers; see Filters. Determine the number of vials required using the following calculations:

$$\text{Weight in kg} \times \text{Dose/kg desired} \div 200 \text{ (units/vial)} = \# \text{ of vials required}$$

A 60-kg man requiring 60 units/kg would require 3,600 units. The number of vials required would be 18. If necessary, round up to the next whole vial. After patient is weighed and appropriate dose is calculated, remove sufficient vials from refrigerator.

Each 200-unit vial must be reconstituted with 5.1 mL of SWFI (yields 5.3 mL). Gently swirl to mix the solution. **Do not shake.** Let stand for several minutes to allow product to dissolve. Withdraw exactly 5 mL (40 units/mL) from each 200-unit vial. A total dose must be further diluted with NS to a total volume of 100 to 200 mL. Mix gently; **do not shake.** Do not use if discolored or opaque or if particulate matter is present. After dilution, slight flocculation (thin translucent fibers) may occur.

Filters: Should be prepared using low-protein-binding containers and administered with a low-protein-binding infusion set with an in-line, low-protein-binding, 0.2-micron filter.

Storage: Before use, refrigerate at 2° to 8° C (36° to 46° F). Protect from light. Do not use after expiration date on bottle. Contains no preservative; do not leave vials at RT for longer than 24 hours before reconstitution, and do not heat or microwave. Should be used promptly after reconstitution but has been shown to be stable after reconstitution or further dilution for up to 24 hours under refrigeration. Do not freeze; protect from light and discard any unused product.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Use of a low-protein-binding infusion set with an in-line, low-protein binding, 0.2-micron filter is required. Use of an infusion pump is helpful. Flush the IV line with NS at the end of the infusion to ensure the total dose is received.

Begin with a rate of 1.3 mL/min. If the patient tolerates the initial infusion rate, it may be increased to 2.3 mL/min. Total time of the infusion should be no less than 1 hour. Reduction in the rate of infusion may be helpful in the event of side effects or infusion reactions.

ACTIONS

A hydrolytic lysosomal glucocerebroside-specific enzyme. It is produced by recombinant DNA technology using plant cell culture (carrot). An active form of the lysosomal enzyme β -glucocerebrosidase. It catalyzes the hydrolysis of glucocerebroside to glucose and ceramide. In clinical trials, spleen and liver size were reduced, and anemia and thrombocytopenia were improved. Median terminal half-life is 18.9 to 28.7 minutes. No significant accumulation was noted with repeated dosing.

INDICATIONS AND USES

Long-term enzyme replacement therapy (ERT) for adults with a confirmed diagnosis of Type 1 Gaucher disease.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Should be used under the direction of a physician knowledgeable in the management of Gaucher disease and administered in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions (including anaphylaxis) and infusion reactions (defined as occurring within 24 hours of the infusion) have occurred; see [Monitor](#) and [Antidote](#). ■ A therapeutic protein product, patients have developed IgG anti-drug antibodies (ADA) to taliglucerase alfa. The relevance of ADA to therapeutic response and adverse events is currently unclear.

Monitor: Monitor weight before each dose (used to calculate dose) and monitor vital signs. ■ Monitor for S/S of a hypersensitivity reaction (e.g., angioedema, coughing, cyanosis, dyspnea, hypotension, wheezing). Discontinue the infusion immediately if anaphylaxis occurs; rechallenge is not recommended. ■ Monitor for S/S of an infusion reaction (e.g., arthralgia, asthenia, back pain, chest pain or discomfort, erythema, fatigue, flushing, headache, increased BP, urticaria). Decreasing the infusion rate, temporarily stopping the infusion, or administering antihistamines and/or antipyretics is recommended. Pretreatment with antihistamines and/or corticosteroids may prevent subsequent reactions in these patients. ■ Closely monitor patients who develop infusion or immune reactions with taliglucerase alfa treatment and patients transferring to taliglucerase alfa treatment who have had an immune reaction to other enzyme replacement therapies for ADA. ■ Observe patient closely for signs of improvement (e.g., improvement in hemoglobin and platelet counts, reduction in size of liver and/or spleen).

Patient Education: Treatment required for life. ■ Promptly report S/S of a hypersensitivity or infusion reaction (e.g., chills, dizziness, fatigue, fever, headache, itching, nausea, rash,

shortness of breath, wheezing). ■ Pretreatment with antihistamines or corticosteroids may be used to prevent reactions.

Maternal/Child: Category B: use in pregnancy only if clearly needed. ■ Safety for use during breast-feeding not established. Not known if taliglucerase alfa is secreted in breast milk. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Numbers in clinical studies insufficient to determine if the elderly respond differently than do younger adults.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Infusion reactions are the most common side effect. Other commonly reported side effects include arthralgia, back pain, extremity pain, headache, influenza, nasopharyngitis, pharyngitis/throat infection, upper respiratory tract infections, and urinary tract infections/pyelonephritis. Abdominal pain, asthenia, bone pain, chest discomfort, diarrhea, dizziness, dyspnea, erythema, fatigue, flushing, increased ALT, infusion site pain, insomnia, muscle spasms, musculoskeletal discomfort/pain, nausea, pain, paresthesia, peripheral edema, pharyngolaryngeal pain, pruritus, rash, skin irritation, and throat irritation have also been reported.

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. Based on the severity of the reaction, temporarily interrupt or discontinue infusion for clinical evidence of hypersensitivity or an infusion reaction. Patients have successfully continued therapy after mild hypersensitivity or infusion reactions with a reduction in rate of administration and/or treatment or pretreatment with antipyretics, antihistamines (e.g., diphenhydramine [Benadryl]), and/or corticosteroids (e.g., dexamethasone [Decadron]). Discontinue infusion immediately for anaphylaxis and treat with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol (Ventolin), IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

TELAVANCIN **BBW**

(tel-a-VAN-sin)

Antibacterial
(lipoglycopeptide)**Vibativ****pH 4 to 5****USUAL DOSE**

10 mg/kg as an infusion once every 24 hours for 7 to 14 days. Duration of therapy is dependent on severity and site of infection and on the patient's clinical and bacteriologic progress.

DOSE ADJUSTMENTS

Dose adjustment required in renal impairment as outlined in the following chart.

Telavancin Dosage Adjustment in Adult Patients with Renal Impairment	
Creatinine Clearance (mL/min)	Telavancin Dosage Regimen
>50 mL/min	10 mg/kg every 24 hours
30 to 50 mL/min	7.5 mg/kg every 24 hours
10 to ≤30 mL/min	10 mg/kg every 48 hours

There is insufficient information to make specific dose recommendations for patients with end-stage renal disease (CrCl less than 10 mL/min), including patients undergoing hemodialysis. ■ Reduced doses may be indicated in the elderly based on age-related renal impairment. ■ No dose adjustment is recommended based on gender or in patients with mild or moderate hepatic impairment. Has not been studied in patients with severe hepatic impairment.

DILUTION

Reconstitute each 250-mg vial with 15 mL of D5W, SWFI, or NS (45 mL for a 750-mg vial). Resultant solution has a final concentration of 15 mg/mL. Reconstitution time is generally under 2 minutes but can occasionally take as long as 20 minutes. Mix thoroughly to dissolve contents completely. Discard vial if vacuum does not pull diluent into vial. Doses of 150 to 800 mg must be further diluted in 100 to 250 mL of D5W, NS, or LR. Doses less than 150 mg or greater than 800 mg must be diluted in a sufficient volume to provide a final concentration of 0.6 to 8 mg/mL.

Storage: Store unopened vials in refrigerator at 2° to 8° C (36° to 46° F). Excursions up to 25° C (77° F) are acceptable. Reconstituted and diluted solutions are stable for 4 hours at RT and for 72 hours refrigerated. Total time in the vial plus the time in the infusion bag should not exceed 4 hours at RT and 72 hours under refrigeration.

COMPATIBILITY**(Underline Indicates Conflicting Compatibility Information)**

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Additives or other medications should not be added to telavancin single-use vials or infused simultaneously through the same IV line. If the same IV line is used for sequential infusion of additional medications, the line should be flushed before and after infusions of telavancin with D5W, NS, or LR."

One source suggests the following **compatibilities:**

Y-site: Not recommended by manufacturer. Amphotericin B lipid complex (Abelcet), ampicillin/sulbactam (Unasyn), azithromycin (Zithromax), calcium gluconate, caspofungin (Cancidas), cefepime (Maxipime), ceftazidime (Fortaz), ceftriaxone (Rocephin), ciprofloxacin (Cipro IV), colistimethate (Coly-Mycin M), cyclosporine (Sandimmune), dexamethasone (Decadron), diltiazem (Cardizem), dobutamine, dopamine, doripenem (Doribax), doxycycline, ertapenem (Invanz), famotidine (Pepcid IV), fluconazole (Diflucan), gentamicin, heparin, hydrocortisone sodium succinate (Solu-Cortef), imipenem-cilastatin (Primaxin), labetalol, magnesium sulfate, mannitol (Osmitrol), meropenem

(Merrem IV), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), milrinone (Primacor), norepinephrine (Levophed), ondansetron (Zofran), pantoprazole (Protonix IV), phenylephrine (Neo-Synephrine), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), potassium phosphates, propofol (Diprivan), ranitidine (Zantac), sodium bicarbonate, sodium phosphates, tigecycline (Tygacil), tobramycin, vasopressin.

RATE OF ADMINISTRATION

A single dose equally distributed as an infusion over 60 minutes. Rapid IV infusions can cause “red man syndrome”-like infusion-related reactions, including flushing of the upper body, urticaria, pruritus, or rash.

ACTIONS

A lipoglycopeptide antibacterial that is a synthetic derivative of vancomycin. Bactericidal against gram-positive organisms, including susceptible strains of staphylococci, streptococci, and vancomycin-susceptible enterococci. Exerts bactericidal action through inhibition of cell wall synthesis. Highly protein bound, primarily to albumin. The metabolic pathway for telavancin has not been identified. Half-life is 6.6 to 9.6 hours. Primarily excreted by the kidney.

INDICATIONS AND USES

Treatment of adult patients with complicated skin and skin structure infections caused by susceptible isolates of Gram-positive microorganisms, including *Staphylococcus aureus* (including methicillin-susceptible and methicillin-resistant isolates), *Streptococcus pyogenes*, *Streptococcus agalactiae*, *Streptococcus anginosus* group, or *Enterococcus faecalis* (vancomycin-susceptible isolates only). Combination therapy may be clinically indicated if the documented or presumed pathogens include Gram-negative organisms.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, telavancin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies are necessary to determine susceptibility of the causative organism to telavancin. ■ Prolonged use of drug may result in superinfection caused by overgrowth of nonsusceptible organisms. ■ New-onset or worsening renal impairment has been reported. Patients with underlying renal dysfunction or risk factors for renal dysfunction (diabetes mellitus, CHF, or hypertension) may be at increased risk. Patients who received concomitant medications known to affect kidney function (e.g., NSAIDs, ACE inhibitors, and loop diuretics) may also be at higher risk; see [Drug Interactions](#). ■ Data from clinical studies suggest that clinical cure rates were lower in patients with baseline CrCl less than or equal to 50 mL/min. These data should be considered when selecting antibacterial therapy for use in patients with baseline moderate/severe renal impairment. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with telavancin. ■ Infusion-related reactions have been reported; see [Rate of Administration](#) and [Monitor](#). ■ Has caused prolongation of the QTc interval. Use with caution in patients who are taking drugs known to prolong the QTc interval. Avoid use in patients with congenital long QT syndrome, known prolongation of the QTc interval, uncompensated heart failure, or severe left ventricular hypertrophy. ■ Does not interfere with coagulation. Increased risk of bleeding and effects on platelet aggregation have not been observed. However, has been shown to affect certain anticoagulation tests; see [Drug/Lab Interactions](#). ■ There is no known cross-resistance between telavancin and other classes of antibiotics. Some vancomycin-resistant enterococci have a reduced susceptibility to telavancin. ■ See [Maternal/Child](#).

Monitor: Obtain baseline CBC with differential and SCr. Monitor SCr every 48 to 72 hours, or more frequently if indicated, and at the end of therapy. If renal function deteriorates, the risk versus benefit of continuing therapy should be assessed. ■ Monitor for possible infusion-related reactions.

Patient Education: Women of childbearing potential should have a pregnancy test before initiating therapy. Effective birth control should be used throughout therapy. A pregnancy registry has been established to monitor the outcomes of women who become pregnant while receiving telavancin. ■ Report all side effects promptly. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after telavancin has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category C: adverse developmental outcomes in three animal species at clinically relevant doses raise concerns about potential adverse developmental outcomes in humans. Avoid use during pregnancy unless potential benefit justifies potential risk. ■ Women with childbearing potential should have a serum pregnancy test before receiving telavancin. A pregnancy registry has been established to monitor pregnancy outcomes in women exposed to telavancin during pregnancy. ■ Safety for use in breast-feeding not established and effects unknown; use caution. ■ Safety and effectiveness for use in pediatric patients has not been studied.

Elderly: Lower clinical cure rates were seen in patients over 65 years of age. Overall, treatment-emergent adverse events occurred with similar frequencies in patients of all age-groups studied. However, adverse events indicative of renal impairment occurred more frequently in the elderly. Consider age-related renal impairment; see **Dose Adjustments**.

DRUG/LAB INTERACTIONS

Use with caution in patients taking **medications known to prolong the QTc interval** (e.g., amiodarone [Nexterone], diphenhydramine [Benadryl], fosphenytoin [Cerebyx], furosemide [Lasix], itraconazole [Sporanox]). Effects may be additive. ■ Concomitant use with **other agents that can affect renal function** (e.g., NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Naprosyn, Aleve)], diuretics [e.g., furosemide (Lasix)], and ACE inhibitors [e.g., lisinopril (Zestril), enalapril (Vasotec)]) may increase risk of renal toxicity. ■ Telavancin clearance should not be affected by drugs that inhibit or induce the P₄₅₀ system and should not affect the pharmacokinetics of drugs metabolized by the P₄₅₀ system. ■ Has been administered with aztreonam (Azactam) and piperacillin/tazobactam (Zosyn). There was no effect on the pharmacokinetics of either drug. ■ Antagonism between telavancin and amikacin (Amikin), aztreonam (Azactam), cefepime (Maxipime), ceftriaxone (Rocephin), ciprofloxacin (Cipro), gentamicin, imipenem-cilastatin (Primaxin), meropenem (Merrem), oxacillin (Bactocil), rifampin (Rifadin), and sulfamethoxazole/trimethoprim has not been seen in *in vitro* studies. ■ May affect **certain anticoagulation tests**. Increases in PT, INR, aPTT, ACT and coagulation-based factor Xa tests have been observed. Effects dissipate over time. Interference seen when using samples drawn between 0 and 18 hours after telavancin administration. Collect blood samples for these coagulation tests immediately before a patient's next telavancin dose to minimize interaction. ■ Interferes with **urine qualitative dipstick protein assays and quantitative dye methods** (e.g., pyrogallol red-molybdate). However, microalbumin assays are not affected and can be used to monitor urinary protein excretion.

SIDE EFFECTS

The most common side effects include foamy urine, nausea, taste disturbances, and vomiting. Most serious side effects include CDAD, infusion-related reactions, and renal impairment (increased SCr, renal insufficiency, renal failure). The most common events leading to discontinuation of therapy were nausea and rash. Other reported side effects include abdominal pain, decreased appetite, diarrhea, dizziness, infusion site pain and erythema, pruritus, QT prolongation, and rigors.

ANTIDOTE

Notify the physician of all side effects. Initiate supportive care as indicated. Infusion-related reactions may respond to temporarily discontinuing or slowing the rate of infusion. Consider alternative antimicrobial therapy in patients who develop renal toxicity. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. There is no information on the use of hemodialysis or continuous venovenous hemofiltration in toxicity.

TEMOZOLOMIDE

(te-moe-ZOE-loe-mide)

Antineoplastic
(alkylating agent)

Temodar

USUAL DOSE

IV and oral doses are therapeutically equivalent if the IV dose is administered equally distributed over 90 minutes. The oral form should be used as soon as tolerated by the patient.

Newly diagnosed glioblastoma multiforme (GBM): Concomitant phase: 75 mg/M² for 42 days. Given concomitantly with focal radiotherapy. No dose reductions are recommended during the concomitant phase; however, dose interruptions or discontinuation may occur based on toxicity. The temozolomide dose should be continued throughout the 42-day concomitant period up to 49 days if all of the following conditions are met:

- Absolute neutrophil count must be equal to or greater than $1.5 \times 10^9/L$ (1,500/mm³).
- Platelet count must be equal to or greater than $100 \times 10^9/L$ (100,000/mm³).
- Nonhematologic toxicity must be equal to or less than Grade 1 (except for alopecia, nausea, and vomiting).
- CBC and platelet count should be obtained weekly.
- Interrupt or discontinue temozolomide dosing based on the hematologic and non-hematologic criteria in the following chart.

Temozolomide (TMZ) Dosing Interruption or Discontinuation During Concomitant Radiotherapy		
Toxicity	TMZ Interruption*	TMZ Discontinuation
Absolute neutrophil count	≥ 0.5 and $< 1.5 \times 10^9/L$	$< 0.5 \times 10^9/L$
Platelet count	≥ 10 and $< 100 \times 10^9/L$	$< 10 \times 10^9/L$
CTCAE nonhematologic toxicity (except for alopecia, nausea, vomiting)	CTCAE Grade 2	CTCAE Grade 3 or 4

TMZ, Temozolomide; CTCAE, Common Terminology Criteria for Adverse Events.

*Treatment with concomitant TMZ could be continued when all of the following conditions are met: ANC $\geq 1.5 \times 10^9/L$, platelet count $\geq 100 \times 10^9/L$, CTCAE nonhematologic toxicity Grade ≤ 1 (except for alopecia, nausea, vomiting).

Prophylaxis against *Pneumocystis jiroveci* pneumonia (PCP): Required for all patients during this concomitant therapy. PCP prophylaxis should be continued in patients who develop lymphocytopenia until they recover from lymphocytopenia (CTCAE Grade ≤ 1).

Newly diagnosed glioblastoma multiforme (GBM): Maintenance phase: 4 weeks after completing the temozolomide plus focal radiotherapy phase, temozolomide is administered for an additional 6 cycles of maintenance.

Cycle 1: The initial dose is 150 mg/M² once daily for 5 days followed by 23 days without treatment (a 28-day cycle).

Cycles 2 through 6: The dose can be increased to 200 mg/M² if the following conditions are met:

- Absolute neutrophil count is equal to or greater than $1.5 \times 10^9/L$ (1,500/mm³)
- Platelet count is equal to or greater than $100 \times 10^9/L$ (100,000/mm³)
- Nonhematologic toxicity is equal to or less than Grade 2 (except for alopecia, nausea, and vomiting).

The dose remains at 200 mg/M² per day for the first 5 days of each subsequent cycle except if toxicity occurs. If the dose was not increased at Cycle 2, it should not be in-

creased for subsequent cycles. See [Dose Adjustments](#) for dose reduction or discontinuation during maintenance.

Refractory anaplastic astrocytoma: 150 mg/M² once daily for 5 consecutive days for each 28-day treatment cycle. This dose may be increased to 200 mg/M²/day if both the nadir and day of dosing (Day 29, Day 1 of next cycle) ANC is equal to or greater than 1.5 × 10⁹/L (1,500/mm³) and the nadir and day of dosing (Day 29, Day 1 of next cycle) platelet count is equal to or greater than 100 × 10⁹/L (100,000/mm³). During treatment, a CBC should be obtained on Day 22 (21 days after the Day 1 dose of temozolomide) or within 48 hours of that day for each cycle. Repeat weekly until the ANC is above 1.5 × 10⁹/L (1,500/mm³) and the platelet count exceeds 100 × 10⁹/L (100,000/mm³). The next cycle of temozolomide should not be started until the ANC and platelet count exceed these levels. If the ANC falls to <1 × 10⁹/L (1,000/mm³) or the platelet count is <50 × 10⁹/L (50,000/mm³) during any cycle, reduce the next cycle by 50 mg/M² but not below 100 mg/M² (the lowest recommended dose). Therapy can be continued until disease progression. See the flow chart in [Dose Adjustments](#).

DOSE ADJUSTMENTS

Newly diagnosed glioblastoma multiforme (GBM): Temozolomide dose must be adjusted according to the nadir ANC and platelet counts in the previous cycle and the ANC and platelet counts at the time of initiating the next cycle. Obtain a CBC and platelet count weekly during the concomitant phase and as indicated during the 4-week interim before beginning the maintenance phase. Obtain a baseline CBC and platelet count before beginning a cycle and repeat on Day 22 (21 days after the first dose of temozolomide in the cycle or within 48 hours of that day). Repeat weekly until the ANC is above 1.5 × 10⁹/L (1,500/mm³) and the platelet count exceeds 100 × 10⁹/L (100,000/mm³). The next cycle of temozolomide should not be started until the ANC and platelet count exceed these levels. This sequence is repeated for Cycles 1 through 6 of maintenance dosing. Base dose reductions during the next cycle on the lowest blood counts and worst nonhematologic toxicity during the previous cycle. Dose reductions or discontinuations during maintenance should be applied according to the following two charts.

Temozolomide Dose Levels for Maintenance Treatment		
Dose Level	Dose (mg/M ² /day)	Remarks
-1	100 mg/M ² /day	Reduction for prior toxicity
0	150 mg/M ² /day	Dose during Cycle 1
1	200 mg/M ² /day	Dose during Cycles 2 through 6 in absence of toxicity

Temozolomide Dose Reduction or Discontinuation During Maintenance Treatment		
Toxicity	Reduce TMZ by 1 Dose Level*	Discontinue TMZ
ANC	<1 × 10 ⁹ /L	See † in footnote
Platelet count	<50 × 10 ⁹ /L	See † in footnote
CTCAE nonhematologic toxicity (except for alopecia, nausea, vomiting)	CTCAE Grade 3	CTCAE Grade 4

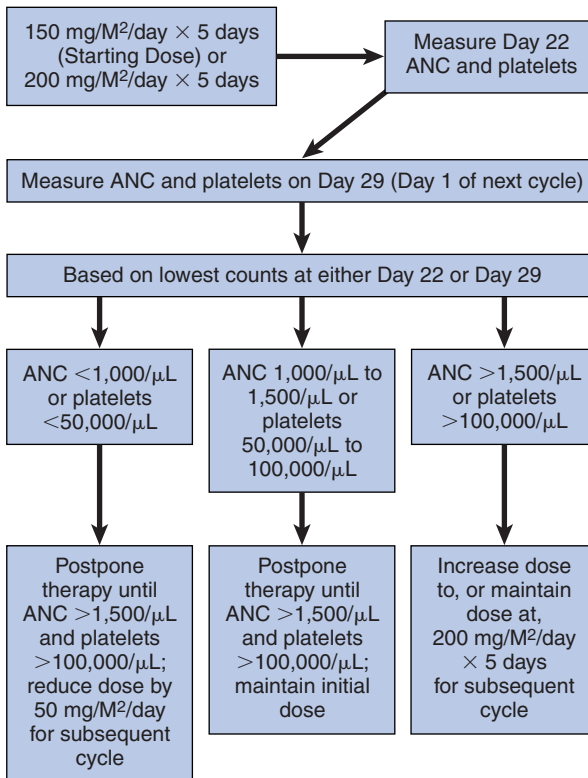

TMZ, Temozolomide; CTCAE, Common Terminology Criteria for Adverse Events.

*See preceding chart for temozolomide dose levels for maintenance treatment.

†TMZ is to be discontinued if a dose reduction to <100 mg/M² is required or if the same Grade 3 nonhematologic toxicity (except for alopecia, nausea, vomiting) recurs after dose reduction.

Continued

Temozolomide Dose Modification Table for Refractory Anaplastic Astrocytoma:

DILUTION

Specific techniques required; see Precautions. Bring vial(s) to room temperature before reconstitution. Reconstitute each 100-mg vial with 41 mL of SWFI. Swirl gently to dissolve; **do not shake**; will yield a concentration of 2.5 mg/mL of temozolomide. **Do not further dilute** the reconstituted solution. Withdraw up to 40 mL from each vial(s) and transfer into an empty 250-mL PVC infusion bag for delivery with an infusion pump.

Filters: Specific information not available.

Storage: Refrigerate single-use vials at 2° to 8° C (36° to 46° F). Store reconstituted product at RT. Reconstituted solution must be used within 14 hours, including infusion time.

COMPATIBILITY

No **compatibility** data available. Manufacturer states, “Other medications should not be infused simultaneously through the same IV line.” May be administered only in the same infusion line as NS.

RATE OF ADMINISTRATION

A single dose equally distributed over 90 minutes. Use of an infusion pump is recommended. Flush IV lines before and after temozolomide infusion. Infusion must be complete within 14 hours of reconstitution.

ACTIONS

An imidazotetrazine derivative and alkylating agent. It is not directly active but undergoes rapid nonenzymatic conversion, as dacarbazine does, to the reactive compound 5-(3-methyl triazen-1-yl)-imidazole-4-carboxamide (MTIC) and to temozolomide acid metabolite. Cytotoxicity is thought to be due primarily to alkylation of DNA. Weakly bound to plasma proteins. Rapidly eliminated with a mean elimination half-life of 1.8 hours. Some excretion in urine and a very small amount in feces.

INDICATIONS AND USES

Treatment of adults with newly diagnosed glioblastoma multiforme. Initially given concomitantly with radiotherapy and then continued as maintenance treatment. ■ Treatment of adults with refractory anaplastic astrocytoma (i.e., adults who have experienced disease progression on a drug regimen containing nitrosourea and procarbazine).

CONTRAINDICATIONS

Known history of hypersensitivity to dacarbazine. ■ Known history of hypersensitivity reaction to temozolomide or any of its components (e.g., urticaria, allergic reaction including anaphylaxis, toxic epidermal necrolysis, and Stevens-Johnson syndrome).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Usually administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Myelosuppression may be severe and dose limiting. May include prolonged pancytopenia, which may result in aplastic anemia. Deaths have been reported. Risk may be increased with concomitant use of other medications associated with aplastic anemia (e.g., carbamazepine [Tegretol], phenytoin [Dilantin], sulfamethoxazole/trimethoprim [Bactrim]). ■ Risk of myelosuppression increased in women and the elderly. ■ Cases of myelodysplastic syndrome and secondary malignancies, including myeloid leukemia, have been observed. ■ Prophylaxis against *Pneumocystis jiroveci* pneumonia (PCP) is required for all patients being treated for newly diagnosed glioblastoma multiforme (a 42-day regimen). The longer dosing regimen may increase the risk of PCP; however, all patients, particularly those receiving steroids, should be monitored for symptoms of PCP regardless of the regimen. ■ Use caution in patients with severe renal or hepatic impairment.

Monitor: Obtain a baseline CBC and platelet count. See [Usual Dose](#) for minimum levels required before administration of temozolomide.

Patients with newly diagnosed GBM: Obtain a CBC and platelet count weekly during the concomitant phase and as indicated during the 4-week interim before beginning the maintenance phase. Obtain a baseline CBC and platelet count before beginning a maintenance dose (28-day cycles) and repeat on Day 22 (21 days after the first maintenance dose of temozolomide or within 48 hours of that day). Repeat weekly until the ANC is above $1.5 \times 10^9/L$ ($1,500/mm^3$) and the platelet count exceeds $100 \times 10^9/L$ ($100,000/mm^3$). This sequence is repeated for Cycles 1 through 6 of maintenance dosing.

Patients with refractory anaplastic astrocytoma: Obtain a CBC and platelet count on Day 1 of each cycle. During treatment (28-day cycles), a CBC should be obtained on Day 22 (21 days after the Day 1 dose of temozolomide or within 48 hours of that day for each cycle). Repeat weekly until the ANC is above $1.5 \times 10^9/L$ ($1,500/mm^3$) and the platelet count exceeds $100 \times 10^9/L$ ($100,000/mm^3$).

All indications: Nausea and vomiting may be severe. Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than $50,000/mm^3$). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Regardless of the regimen, monitor all patients, particularly those receiving steroids, for symptoms of PCP (dyspnea; fever; dry, nonproductive cough; characteristic x-ray).

Patient Education: Avoid pregnancy; use of nonhormonal birth control is recommended. ■ Promptly report a rash; swelling of the face, throat, or tongue; severe skin reaction; or troubled breathing. ■ Report IV site burning or stinging promptly. ■ Secondary malignancies have been reported. ■ See Appendix D, p. 1255. ■ Additional precautions are required with the capsule form.

Maternal/Child: Category D: avoid pregnancy; can cause fetal harm. ■ Discontinue breastfeeding. ■ Safety and effectiveness for use in pediatric patients not established. A 5-day

regimen every 28 days using the oral formulation has been studied in selected pediatric patients from 3 to 18 years of age. Toxicity profile was similar to that seen in adults.

Elderly: Numbers in clinical studies are insufficient to determine if the elderly respond differently than younger subjects. Dose selection should be cautious based on the potential for decreased organ function and concomitant disease or drug therapy. **In newly diagnosed patients with glioblastoma multiforme**, side effects were similar to those seen in younger patients. In the **anaplastic astrocytoma study**, patients 70 years or older had a higher incidence of Grade 4 neutropenia and Grade 4 thrombocytopenia in the first cycle of therapy.

DRUG/LAB INTERACTIONS

Valproic acid decreases the oral clearance of temozolomide by about 5%; clinical significance is not known. Another source suggests the following interactions. ■ Temozolomide may increase the effects of **leflunomide** (Arava), **natalizumab** (Tysabri), and **live vaccines** (may also decrease the effects of **live vaccines**); one source recommends that concomitant use be avoided. ■ May decrease the effects of **BCG and inactivated vaccines**. ■ The effects of temozolomide may be decreased by **echinacea**.

SIDE EFFECTS

Newly diagnosed glioblastoma multiforme: Myelosuppression may be severe and dose limiting. May include prolonged pancytopenia, which may result in aplastic anemia; deaths have been reported. Alopecia, anorexia, constipation, headache, nausea and vomiting, and thrombocytopenia were the most frequently reported side effects. Abdominal pain, blurred vision, confusion, convulsions, coughing, diarrhea, dizziness, dry skin, dyspnea, erythema, fatigue, hypersensitivity reactions including anaphylaxis, insomnia, memory impairment, radiation injury, pruritus, rash, stomatitis, taste perversion, thrombocytopenia, and weakness have been reported.

Refractory anaplastic astrocytoma: Fatigue, headache, myelosuppression, and nausea and vomiting were the most frequently reported side effects. Abdominal pain, abnormal coordination, abnormal gait, abnormal vision (blurred vision, vision changes, visual deficit), adrenal hypercorticism, amnesia, anorexia, anxiety, asthenia, ataxia, back pain, breast pain (female), confusion, convulsions (local and general), coughing, depression, diarrhea, diplopia, dizziness, dysphasia, fever, hemiparesis, insomnia, myalgia, paresis, paresthesia, peripheral edema, pharyngitis, pruritus, rash, sinusitis, URI, urinary incontinence, UTI, viral infection, and weight increase have been reported.

Injection site reactions: Erythema, irritation, pain, pruritus, swelling, and warmth at the infusion site; hematoma; and petechiae.

Post-Marketing: The oral formulation has had reports of hypersensitivity reactions, including anaphylaxis; alveolitis; hepatotoxicity, including elevations in liver function tests, hyperbilirubinemia, cholestasis, and hepatitis; interstitial pneumonitis/pneumonitis; opportunistic infections, including *Pneumocystis jiroveci* pneumonia (PCP); prolonged pancytopenia, which may result in aplastic anemia with fatal outcomes; pulmonary fibrosis; and skin reactions (e.g., erythema multiforme, toxic epidermal necrolysis, and Stevens-Johnson syndrome).

ANTIDOTE

Keep physician informed of all side effects and CBC results. Temozolomide may need to be reduced or discontinued. Symptomatic and supportive treatment is indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Precautions are indicated for cancer patients with erythropoietin-stimulating agents (ESAs); see darbepoetin alfa and epoetin alfa monographs. Treat hypersensitivity reactions and/or anaphylaxis as indicated (e.g., epinephrine, corticosteroids, oxygen, and antihistamines [diphenhydramine]). There is no specific antidote. Resuscitate as indicated.

TEMSIROLIMUS

(TEM-sir-OH-li-mus)

Antineoplastic
(kinase inhibitor)

Torisel

USUAL DOSE

Premedication: To minimize the incidence of hypersensitivity reactions, administer diphenhydramine (Benadryl) 25 to 50 mg IV (or similar antihistamine) 30 minutes before the start of each dose of temsirolimus; see [Precautions](#) and [Monitor](#).

Temsirolimus: 25 mg as an infusion once a week until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

Hold for absolute neutrophil count (ANC) less than $1,000/\text{mm}^3$, platelet count less than $75,000/\text{mm}^3$, or CTCAE Grade 3 or greater adverse reactions. Once toxicities have resolved to Grade 2 or less, restart therapy with the dose reduced by 5 mg/week to a dose no lower than 15 mg/week. ■ Consider dose reduction to 12.5 mg/week when coadministered with a strong CYP3A4 inhibitor; see [Drug Interactions](#). If the strong inhibitor is discontinued, wait approximately 1 week before adjusting the temsirolimus dose upward to the indicated dose. ■ Consider a dose increase to 50 mg/week when coadministered with a strong CYP3A4 inducer; see [Drug Interactions](#). If the strong inducer is discontinued, the temsirolimus dose should be returned to the dose used prior to initiation of the strong CYP3A4 inducer. ■ Decrease dose to 15 mg/week in patients with mild hepatic impairment (bilirubin greater than 1 to 1.5 ULN or AST greater than ULN but bilirubin equal to or less than ULN); see [Contraindications](#). ■ No dose adjustment indicated based on age, race, gender, or renal status. Not studied in hemodialysis patients.

DILUTION

Specific techniques required; see [Precautions and Compatibility](#). Available as a kit containing a vial of temsirolimus and a vial of a manufacturer-supplied diluent. Temsirolimus and diluent vials contain overfill. A two-step dilution process is required. Reconstitute the temsirolimus vial with 1.8 mL of the provided diluent. Invert the vial several times to mix thoroughly. Allow time for foam to subside. Final concentration in temsirolimus vial is 10 mg/mL. Solution will be clear to slightly turbid and colorless to yellow. Withdraw the required amount of reconstituted temsirolimus and inject into a 250-mL container (**glass, polyolefin, or polyethylene**) of NS. Invert bag to mix; see [Compatibility](#). Avoid excessive shaking. Use of non-DEHP, non-polyvinylchloride (PVC) tubing with appropriate filter is recommended. If a PVC administration set must be used, it should not contain DEHP. Temsirolimus contains polysorbate 80 when diluted, which increases the rate of DEHP extraction from PVC.

Filter: Use of an in-line polyethersulfone filter with a pore size not greater than 5 microns is recommended. If an administration set with an in-line filter is not available, a polyethersulfone end-filter should be used. The use of both an in-line and end-filter is not recommended.

Storage: Store unopened vials at 2° to 8° C (36° to 46° F). Protect from light. During handling and preparation, protect from excessive room light or sunlight. The temsirolimus/diluent mixture (10 mg/mL) is stable for up to 24 hours below 25° C (77° F) in the temsirolimus vial. Administration of the final product diluted in NS should be completed within 6 hours of adding the temsirolimus/diluent mixture to the NS.

COMPATIBILITY

Manufacturer states, "Final dilution for infusion should be stored in bottles (glass, polypropylene) or plastic bags (polypropylene, polyolefin) and administered through polyethylene-lined administration sets." Non-DEHP containing materials must be used for administration. Manufacturer also states that undiluted temsirolimus should not be added directly to aqueous infusion solutions. A precipitate will form. In addition, "The

stability of temsirolimus in other infusion solutions has not been evaluated. Addition of other drugs or nutritional agents to admixtures of temsirolimus in NS has not been evaluated and should be avoided. Temsirolimus is degraded by both acids and bases, and thus combinations of temsirolimus with agents capable of modifying solution pH should be avoided.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 to 60 minutes. Use of an infusion pump is recommended. Increase duration of infusion to 60 minutes in patients who experience a hypersensitivity reaction.

ACTIONS

An inhibitor of mTOR (mammalian target of rapamycin). Binds to an intracellular protein (FKBP-12); this protein-drug complex inhibits the activity of mTOR that controls cell division. Results in a cell cycle-specific (G1) growth arrest in treated tumor cells. In *in vitro* studies, temsirolimus inhibited the activity of mTOR and resulted in reduced levels of hypoxia-inducible factors HIF-1 α and HIF-2 α and the vascular endothelial growth factor. Both temsirolimus and sirolimus are extensively partitioned into formed blood elements. Extensively metabolized, primarily by cytochrome P₄₅₀ 3A4. Sirolimus is the principal metabolite and is active. Elimination is primarily via the feces and to a small extent via urine. Mean half-lives of temsirolimus and sirolimus were 17.3 and 54.6 hours, respectively.

INDICATIONS AND USES

Treatment of advanced renal cell carcinoma.

CONTRAINDICATIONS

Bilirubin greater than 1.5 ULN; see [Dose Adjustments](#) and [Precautions](#).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Should be administered by or under the direction of the physician specialist in facilities equipped to monitor the patient and respond to any medical emergency. ■ Hypersensitivity/infusion reactions have been reported. May occur early in the first infusion but may also occur with subsequent infusions. Premedication required to minimize the chance of a reaction; see [Usual Dose](#). Use with caution in patients with known hypersensitivity to temsirolimus or its metabolites (including sirolimus) or to any components of the product. Use caution in patients who cannot receive prophylactic treatment with an antihistamine for medical reasons; see [Monitor](#). ■ Patients with moderate and severe hepatic impairment had increased rates of adverse reactions and deaths. Use caution when treating patients with mild hepatic impairment; see [Dose Adjustments](#) and [Contraindications](#). ■ Hyperglycemia/glucose intolerance is common. Initiation of or an increase in the dose of insulin and/or oral hypoglycemic agent therapy may be required. ■ Elevated cholesterol and triglycerides are common. Initiation or adjustment of existing therapy may be required. ■ May cause immunosuppression, thus increasing the risk of infections, including opportunistic infections. ■ Cases of interstitial lung disease, some resulting in death, have been reported. ■ Cases of fatal bowel perforation have been reported. ■ Rapidly progressive and sometimes fatal acute renal failure has occurred. ■ Has been associated with abnormal wound healing. Exercise caution when temsirolimus is used in the perioperative period. ■ Patients who have CNS tumors and/or are receiving anticoagulation therapy may be at increased risk of intracerebral bleeding. ■ The use of live virus vaccines and close contact with those who have received live virus vaccines should be avoided. See [Drug Interactions](#).

Monitor: Obtain baseline and weekly CBC with differential and platelet count. Obtain a baseline chemistry panel, including bilirubin and liver function tests (ALT, AST), and repeat every 2 weeks. Obtain baseline radiographic assessment by lung CT or chest x-ray. Repeat assessments periodically. ■ Monitor for S/S of a hypersensitivity/infusion reaction (e.g., anaphylaxis, bronchospasm, chest pain, dyspnea, flushing, hypotension, rash). If a reaction occurs, the infusion should be stopped and the patient should be ob-

served for at least 30 to 60 minutes (depending on the severity of the reaction). At the discretion of the physician, and after a benefit-risk assessment, treatment may be resumed with the administration of an H₁-receptor antagonist (such as diphenhydramine [Benadryl]) if not previously administered and/or an H₂-receptor antagonist (e.g., ranitidine [Zantac] 50 mg IV or famotidine [Pepcid] 20 mg IV) approximately 30 minutes before restarting the temsirolimus infusion. The infusion may be resumed at a slower rate; see [Rate of Administration](#). ■ Monitor serum glucose, cholesterol, and triglycerides before and during therapy. ■ Monitor for S/S of infection. ■ Monitor respiratory status. Patients may present with symptoms such as dyspnea, cough, hypoxia, and fever or may be asymptomatic. If clinically significant respiratory symptoms develop, consider withholding temsirolimus until after recovery of symptoms and improvement of radiographic findings related to pneumonitis. Empiric treatment with corticosteroids and/or antibiotics may be considered. ■ Monitor for S/S of bowel perforation (abdominal pain, acute abdomen, bloody stools, diarrhea, fever, metabolic acidosis). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³); see [Dose Adjustments](#) and [Contraindications](#). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Review medical history with health care provider. Temsirolimus may affect existing medical conditions (e.g., diabetes, high cholesterol, hyperlipidemia). Therapy may need to be adjusted. ■ Review medication list (prescription, over-the-counter, and herbal) with health care provider. Interactions are possible. ■ Promptly report any S/S of a hypersensitivity reaction (chest tightness, dyspnea, flushing, pruritus, rash, urticaria). ■ Avoid pregnancy during and for 3 months after completion of therapy. Men with partners of childbearing potential should use reliable contraception during treatment and for 3 months after completion of therapy. ■ Report excessive thirst or any increase in volume or frequency of urination. ■ Promptly report S/S of infection, new or worsening respiratory symptoms, new or worsening abdominal pain, or blood in stools. ■ Wound healing complications may occur while on therapy. ■ The use of live virus vaccines and close contact with those who have received live virus vaccines should be avoided. ■ Increased risk of intracerebral bleed in patients who have CNS tumors and/or are receiving anticoagulants.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. ■ Potential for tumorigenicity. Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Elderly patients may be more likely to experience certain side effects, including diarrhea, edema, and pneumonia.

DRUG/LAB INTERACTIONS

Use of concomitant **strong CYP3A4 inhibitors** (e.g., amprenavir [Agenerase], atazanavir [Reyataz], clarithromycin [Biaxin], delavirdine [Rescriptor], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase], telithromycin [Ketek], or voriconazole [VFEND]) may increase plasma concentrations of the active metabolite sirolimus. Avoid concomitant use if possible. If required, consider a dose reduction of temsirolimus to 12.5 mg/week and monitor closely for acute toxicity. If the strong inhibitor is discontinued, a washout period of approximately 1 week should be allowed before adjusting the temsirolimus dose upward to the indicated dose; see [Dose Adjustments](#). ■ **Grapefruit juice** may increase plasma concentrations of temsirolimus and should be avoided. ■ **CYP3A4/5 inducers** (e.g., carbamazepine [Tegretol], dexamethasone [Decadron], phenobarbital [Luminal], phenytoin [Dilantin], rifabutin [Mycobutin], rifampin [Rifadin]) may decrease plasma concentrations of the active metabolite sirolimus, thus decreasing effectiveness. Avoid concomitant use if possible. If required, consider a dose increase to 50 mg/week. If the strong inducer is discontinued, the temsirolimus dose should be returned to the dose used before initiating the strong CYP3A4 inducer; see [Dose Adjustments](#). ■ Angioneurotic

edema-type reactions (including delayed reactions occurring 2 months after initiation of therapy) have been observed in some patients with concurrent administration of ACE inhibitors (e.g., enalapril [Vasotec]). ■ **St. John's wort** may decrease temsirolimus plasma concentrations, decreasing effectiveness. Avoid use. ■ Use caution with other **drugs that inhibit the efflux transporter P-glycoprotein (P-gp, ABCB1)** (e.g., protease inhibitors [e.g., nelfinavir (Viracept)]); may increase concentrations of temsirolimus. ■ The combination of sunitinib (Sutent) and temsirolimus resulted in dose-limiting toxicity. ■ Do not administer **live virus vaccines** to patients receiving temsirolimus, and avoid close contact with those who have received live virus vaccines. ■ No clinically significant effect is anticipated when temsirolimus is coadministered with agents that are metabolized by CYP2D6 or CYP3A4.

SIDE EFFECTS

The most common side effects include abdominal pain, anemia, anorexia, asthenia, constipation, edema, elevated alkaline phosphatase and AST, elevated SCr, hyperglycemia, hyperlipemia, hypertriglyceridemia, hypophosphatemia, leukopenia, lymphopenia, mucositis, nausea, rash, and thrombocytopenia. Less commonly reported side effects include acne, arthralgia, bowel perforation, chest pain, chills, cough, depression, diarrhea, dry skin, dysgeusia, dyspnea, edema, epistaxis, fever, headache, hypokalemia, increased bilirubin, increased total cholesterol, increased triglycerides, infection, insomnia, nail disorder, neutropenia, pain, pruritus, rash, vomiting, and weight loss. The most serious side effects include bowel perforation, hyperglycemia/glucose intolerance, hyperlipemia, hypersensitivity reactions, hypertension, interstitial lung disease, renal failure, and venous thromboembolism (including DVT and pulmonary embolus [including fatal outcomes]).

Post-Marketing: Complex regional pain syndrome (reflex sympathetic dystrophy); convulsions; extravasation with erythema, pain, swelling, and warmth; injection site reactions; pericardial effusions (hemodynamically significant and requiring intervention); pleural effusions; rhabdomyolysis; Stevens-Johnson syndrome.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. Monitor patient closely. Discontinue temsirolimus at the first sign of a hypersensitivity reaction. Monitor patient for 30 to 60 minutes. Treatment may be resumed at the discretion of the physician; see **Monitor**. Treat severe hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]) and pressor amines (e.g., dopamine). Treat the development of interstitial lung disease as indicated. May require discontinuation of temsirolimus and/or treatment with corticosteroids and/or antibiotics. Some patients have been able to continue therapy without additional intervention.

TENECTEPLASE

(teh-NECK-teh-plays)

Thrombolytic agent
(recombinant)

TNKase

pH 7.3

USUAL DOSE

Initiate therapy as soon as possible after the onset of acute myocardial infarction (AMI) symptoms. Total dose is based on patient weight and should not exceed 50 mg. See the following chart.

Tenecteplase Dosing Guidelines		
Patient Weight (kg)	Tenecteplase (mg)	Volume of Tenecteplase* to Be Administered (mL)
<60 kg	30 mg	6 mL
≥60 to <70 kg	35 mg	7 mL
≥70 to <80 kg	40 mg	8 mL
≥80 to <90 kg	45 mg	9 mL
≥90 kg	50 mg	10 mL

*From one vial of tenecteplase reconstituted with 10 mL of SWFI.

Concurrent administration of heparin and aspirin has been used in MI patients receiving tenecteplase therapy. In the ASSENT-2 trial, the following doses were used.

Aspirin: 150 to 325 mg as soon as possible was followed by 150 to 325 mg daily.

Heparin IV: Was administered based on weight. **Patients weighing 67 kg or less** received a heparin loading dose of 4,000 units followed by an infusion at 800 units/hr. **Patients weighing more than 67 kg** received a heparin loading dose of 5,000 units followed by an infusion at 1,000 units/hr. Heparin was continued for 48 to 72 hours with the infusion rate adjusted to maintain the aPPT at 50 to 75 seconds.

DOSE ADJUSTMENTS

None noted.

DILUTION

Remove the shield assembly from the manufacturer-supplied B-D® 10 mL syringe with TwinPak™ dual Cannula Device. Aseptically withdraw 10 mL of SWFI from the supplied diluent vial using the red hub cannula syringe filling device. Do not use bacteriostatic water for injection. Do not discard the shield assembly. Inject the 10 mL of SWFI into the tenecteplase vial, directing the diluent stream into the powder. Slight foaming may occur. Allow product to stand for several minutes. Gently swirl until contents are completely dissolved. Do not shake. The reconstituted preparation is colorless to pale yellow and contains tenecteplase 50 mg/10 mL. Withdraw the desired dose from the vial using the syringe. Once the appropriate dose is drawn into the syringe, stand the shield vertically on a flat surface with the green side down and passively recap the red hub cannula. Remove the entire shield assembly, including the red hub cannula, by twisting counterclockwise. **Note:** The shield assembly also contains the clear-ended blunt plastic cannula; retain for split septum IV access. The supplied syringe is compatible with a conventional needle and with needleless IV systems. See package insert for complete instructions for administration.

Storage: Store unopened vial at CRT or under refrigeration (at 2° to 8° C [(36° to 46° F)]). Reconstitution immediately before use preferred, or may be refrigerated for up to 8 hours.

COMPATIBILITY

Manufacturer states, "Precipitation may occur when tenecteplase is administered in an IV line containing dextrose. Dextrose-containing lines should be flushed with a saline-containing solution prior to and following single bolus administration of tenecteplase."

RATE OF ADMINISTRATION

A single bolus dose over 5 seconds. Flush line with saline-containing solution to ensure delivery of entire dose.

ACTIONS

A tissue plasminogen activator and enzyme produced by recombinant DNA technology. Binds to fibrin in a thrombus and converts plasminogen to plasmin. Plasmin digests fibrin and dissolves the clot. Onset of action is prompt. Cleared via hepatic metabolism. Terminal half-life is 90 to 130 minutes.

INDICATIONS AND USES

For use in the reduction of mortality associated with acute myocardial infarction (AMI). Treatment should be initiated as soon as possible after the onset of AMI symptoms.

CONTRAINDICATIONS

Active internal bleeding, history of cerebrovascular accident, intracranial or intraspinal surgery or trauma within the past 2 months, intracranial neoplasm, arteriovenous malformation, or aneurysm, known bleeding diathesis, and severe uncontrolled hypertension.

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use and with appropriate emergency drugs and diagnostic and laboratory facilities available. ■ Most common complication is bleeding. May be internal bleeding or superficial or surface bleeding. Strict bed rest indicated to reduce risk of bleeding. Use extreme care with the patient; avoid any excessive or rough handling or pressure; avoid invasive procedures (e.g., arterial puncture, venipuncture, IM injection). If these procedures are absolutely necessary, use extreme precautionary methods (use radial artery instead of femoral; use small-gauge catheters and needles, and sites that are easily observed and compressible where bleeding can be controlled; avoid handling catheter sites; and use extended pressure application of up to 30 minutes). Minor bleeding occurs often at catheter insertion sites. Avoid use of razors and toothbrushes. If serious bleeding (not controlled by local pressure) occurs, discontinue any concomitant heparin or antiplatelet agents immediately. ■ Use extreme caution in the following situations: recent major surgery (e.g., CABG), previous puncture of non-compressible vessels, organ biopsy, or trauma, cerebrovascular disease, recent GI or GU bleeding, hypertension (systolic BP above 180 and/or diastolic BP above 110), high likelihood of left heart thrombus (e.g., mitral stenosis with atrial fibrillation), acute pericarditis, subacute bacterial endocarditis, hemostatic defects (including those secondary to severe hepatic or renal disease), severe hepatic dysfunction, pregnancy or recent childbirth, diabetic hemorrhagic retinopathy, septic thrombophlebitis or occluded AV cannula at a seriously infected site, advanced age, patients currently receiving oral anticoagulants (e.g., warfarin), recent administration of GPIIb/IIIa inhibitors (e.g., abciximab [ReoPro], eptifibatid [Integrilin]), any other condition in which bleeding constitutes a significant hazard or would be particularly difficult to manage because of its location. In the presence of any of these situations, the risk versus benefit of tenecteplase therapy must be evaluated. ■ Cholesterol embolism has been reported rarely in patients treated with all types of thrombolytic agents. See [Side Effects](#). ■ Reperfusion arrhythmias (e.g., sinus bradycardia, accelerated idioventricular rhythm, ventricular premature depolarization, ventricular tachycardia) may occur following coronary thrombolysis. Manage with standard antiarrhythmic measures. Have antiarrhythmic meds readily available. ■ Standard management of MI should be implemented concomitantly with tenecteplase therapy. Simultaneous therapy with heparin and aspirin is used to reduce the risk of rethrombosis. Increases risk of bleeding; see [Usual Dose](#). ■ Readministration of tenecteplase to patients who have received prior plasmino-

gen activator therapy has not been studied. Use caution if deemed necessary, and monitor for signs of hypersensitivity or anaphylactic reactions.

Monitor: Obtain appropriate clotting studies (e.g., PT, PTT, aPTT, fibrinogen levels), CBC, and platelet count. ■ Diagnosis-specific baseline studies (e.g., ECG, CPK with isoenzymes, troponin) are indicated. Baseline assessment (patient condition, pain, hematomas, petechiae, or recent wounds) should be completed before administration. ■ Type and cross-match may also be ordered. ■ Maintain strict bed rest; monitor the patient carefully and frequently for pain and signs of bleeding; observe catheter sites at least every 15 minutes and apply pressure dressings to any recently invaded site; watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, muscle weakness; and do neuro checks every hour (or more frequently if indicated). Continue until normal clotting function returns. ■ Monitor ECG continuously. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Compliance with all measures to minimize bleeding (e.g., strict bed rest) is very important. ■ Avoid use of razors, toothbrushes, and other sharp items. Use caution while moving to avoid excessive bumping. ■ Report all episodes of bleeding and apply local pressure if indicated. Expect oozing from IV sites.

Maternal/Child: Category C: safety for use in pregnancy, breast-feeding and pediatric patients not established.

Elderly: See [Indications](#) and [Precautions](#). May have poorer prognosis following AMI and pre-existing conditions that may increase risk of adverse events, including bleeding. Select patients carefully to maximize benefits.

DRUG/LAB INTERACTIONS

Formal studies have not been performed. ■ Risk of bleeding may be increased by **any medicine that affects blood clotting**, including anticoagulants (e.g., heparin, warfarin [Coumadin]); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel [Plavix], dipyridamole [Persantine], glycoprotein GPIIb/IIIa receptor antagonists [e.g., abciximab (ReoPro), eptifibatid (Integrilin), tirofiban (Aggrastat)], plicamycin [Mithracin], sulfapyrazone [Anturane], ticlopidine [Ticlid], valproic acid [Depacon, Depakene]). Concurrent use not recommended with the exception of heparin and aspirin to reduce the risk of rethrombosis. If concurrent or subsequent use indicated (e.g., management of acute coronary syndrome, percutaneous coronary intervention) monitor PT and aPTT closely. ■ **Coagulation test will be unreliable**; specific procedures can be used; notify the lab of tenecteplase use.

SIDE EFFECTS

Bleeding is most common: internal (GI tract, GU tract, retroperitoneal, or intracranial), epistaxis, gingival, and superficial or surface bleeding (venous cutdowns, arterial punctures, sites of recent surgical intervention). Hypersensitivity reactions (e.g., anaphylaxis, angioedema, laryngeal edema, rash, and urticaria) have been reported rarely. Fever, hypotension, nausea and vomiting, and reperfusion arrhythmias have occurred. Cholesterol embolization can occur with thrombolytic therapy, but has been reported rarely. Clinical features may include livedo reticularis, “purple toe” syndrome, acute renal failure, gangrenous digits, hypertension, pancreatitis, MI, cerebral, spinal cord or bowel infarction, retinal artery occlusion, and rhabdomyolysis. Several other adverse events have been reported. These reactions are frequently sequelae of the underlying disease, and the effect of tenecteplase on the incidence of these events is unknown.

ANTIDOTE

Notify physician of all side effects. Note even the most minute bleeding tendency. Oozing at IV sites is expected. Control minor bleeding by local pressure. For severe bleeding in a critical location or suspected intracranial bleeding, discontinue any heparin therapy immediately. Obtain PT, aPTT, platelet count, and fibrinogen. Draw blood for type and

cross-match. Platelets and cryoprecipitate are most commonly used but whole blood, packed red blood cells, fresh-frozen plasma, desmopressin, tranexamic acid, or aminocaproic acid may be indicated. Topical preparations of aminocaproic acid may stop minor bleeding. Consider protamine if heparin has been used. Treat bradycardia with atropine, reperfusion arrhythmias with lidocaine, procainamide, or other standard antiarrhythmic therapy; VT or VF may require cardioversion. If hypotension occurs, vasopressors (e.g., dopamine), Trendelenburg position, and suitable plasma expanders (e.g., albumin, plasma protein fraction [Plasmanate], or hetastarch) may be indicated. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary.

TENIPOSIDE **BBW**

(teh-NIP-ah-side)

Antineoplastic
(mitotic inhibitor)

VM-26, Vumon

pH 5

USUAL DOSE

Adults: All indications and doses are unlabeled.

Acute lymphoblastic leukemia: 165 mg/M² by IV infusion on Days 1, 4, 8, and 11 during consolidation on the “Linker” regimen.

Refractory non-Hodgkin’s lymphoma: Given as an IV infusion. Dosage schedules include 30 mg/M² for 10 days or 50 to 100 mg/M² weekly as a single agent; or 60 to 70 mg/M² weekly in combination with other chemotherapy agents.

PEDIATRIC DOSE

See [Precautions](#) and [Maternal/Child](#). Optimum dose not established.

Acute lymphocytic leukemia (ALL): 165 mg/M² in combination with cytarabine 300 mg/M². Both drugs are given twice weekly for 8 to 9 doses. An alternate regimen includes teniposide 250 mg/M² and vincristine 1.5 mg/M² once each week for 4 to 8 weeks plus prednisone 40 mg/M² PO daily for 28 days.

DOSE ADJUSTMENTS

Reduce dose by one half in patients with Down syndrome and leukemia (increased sensitivity to myelosuppressive chemotherapy). Higher doses may be used in subsequent courses based on degree of myelosuppression and mucositis. Must be individualized. ■ Reduced dose may be necessary in severe renal or hepatic impairment.

DILUTION

Specific techniques required; see [Precautions](#). Must be diluted and given as an infusion. May leach the toxic plasticizer DEHP from PVC infusion bags or sets; prepare and store in bottles (glass, polypropylene) or plastic bags (polypropylene, polyolefin) and administer through polyethylene-lined administration sets (e.g., lipid administration sets or low DEHP-containing nitroglycerin IV sets). Undiluted teniposide has caused acrylic or ABS plastic devices to crack and leak; handle carefully during dilution process. **Compatible** with NS or D5W. Final concentration of 0.1, 0.2, 0.4, or 1 mg/mL desired. Contains 10 mg/mL. 100 mg (10 mL) in 990 mL yields 0.1 mg/mL, in 490 mL yields 0.2 mg/mL, in 240 mL yields 0.4 mg/mL, in 90 mL yields 1 mg/mL. Precipitation may occur at recommended concentrations, especially with excessive agitation. Avoid contact of diluted solution with any other drugs or fluids; flush IV line with D5W or NS before and after administration.

Storage: Refrigerate unopened ampules in original packaging. Do not refrigerate diluted solutions; 1 mg/mL should be administered within 4 hours; all other dilutions are stable at RT for up to 24 hours.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Heparin solution can cause precipitation of teniposide; flush IV line thoroughly with D5W or NS before and after administration of teniposide. Because of potential for precipitation, **compatibility** with other drugs, infusion materials, or IV pumps cannot be ensured." See *Dilution, Rate of Administration, and Precautions/Monitor*.

One source suggests the following **compatibilities**:

Y-site: Not recommended by manufacturer. Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), aminophylline, amphotericin B (conventional), ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), cisplatin (Platinol), cladribine (Leustatin), clindamycin (Cleocin), cyclophosphamide (Cytosan), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), daunorubicin (Cerubidine), dexamethasone (Decadron), diphenhydramine (Benadryl), doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), etoposide (VePesid), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gallium nitrate (Ganite), ganciclovir (Cytovene), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), leucovorin calcium, lorazepam (Ativan), mannitol, mechlorethamine (nitrogen mustard), melphalan (Alkeran), meperidine (Demerol), mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), mitomycin (Mutamycin), mitoxantrone (Novantrone), morphine, nalbuphine, ondansetron (Zofran), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), sargramostim (Leukine), sodium bicarbonate, streptozocin (Zanosar), sulfamethoxazole/trimethoprim, thiotepea, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vinblastine, vincristine, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Total desired dose, properly diluted and evenly distributed over at least 30 to 60 minutes. Infusion time may be extended. Flush IV line with D5W or NS before and after administration to avoid precipitation of teniposide in IV catheter. Rapid infusion may cause marked hypotension or increased nausea and vomiting.

ACTIONS

An antineoplastic agent. A semi-synthetic derivative of podophyllotoxin related to etoposide. Cell cycle-specific for the late S or early G₂ phase, thus preventing cells from entering mitosis. Cytotoxic effects are related to the relative number of single- and double-strand DNA breaks produced in cells. Has a broad spectrum of in vivo anti-tumor activity against murine tumors, including hematologic malignancies and various solid tumors. Active against certain murine leukemias with acquired resistance to cisplatin, doxorubicin, amsacrine, daunorubicin, mitoxantrone, or vincristine. Highly protein bound; limits distribution within the body (a beneficial effect). Plasma levels increase with dose. Terminal half-life is 5 hours. Metabolized primarily in the liver. Only about 10% excreted as unchanged drug in urine.

INDICATIONS AND USES

Induction therapy in refractory childhood acute lymphoblastic leukemia. Used in combination with other antineoplastic agents.

Unlabeled uses: Has been used as an unlabeled agent in several adult protocols (e.g., refractory non-Hodgkin's lymphoma and neuroblastoma).

CONTRAINDICATIONS

Hypersensitivity to teniposide, etoposide (no cross-sensitivity to date), or a history of prior severe hypersensitivity reactions to other drugs formulated in Cremophor EL (e.g., cyclosporine, paclitaxel).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. Always wear impervious gloves when handling ampules containing teniposide. After contact with skin, wash immediately and thoroughly with soap and water; after contact with mucous membranes, flush immediately and thoroughly with water. ■ Usually administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be readily available. ■ May cause severe myelosuppression with resulting infection or bleeding. ■ Causes severe myelosuppression when used in combination with other chemotherapeutic agents. Sepsis, sometimes fatal, may result. ■ Use caution in patients with impaired hepatic or renal function; may reduce plasma clearance and increase toxicity. ■ Hypersensitivity reactions, including anaphylaxis, may occur with initial dosing or with repeated exposure. ■ Incidence of hypersensitivity may be increased in patients with brain tumors or neuroblastoma. ■ Acute CNS depression, hypotension, and metabolic acidosis occurred in patients receiving high-dose teniposide pretreated with antiemetic drugs; use caution. ■ Pediatric patients with ALL in remission on teniposide maintenance therapy have shown an increased risk of developing secondary acute nonlymphocytic leukemia (ANLL). ■ Reduce dose in patients with Down's syndrome. ■ See [Drug/Lab Interactions](#).

Monitor: Bone marrow suppression; occurs early with indicated doses and can be profound. Obtain baseline hemoglobin, WBC count with differential, and platelet count. Monitor frequently during therapy, before each dose, and after therapy. See [Dose Adjustments](#). ■ Severe hypersensitivity reactions can occur with teniposide and may be life threatening. Epinephrine, oxygen, and other emergency supplies must be at the bedside. Monitor patient continuously and take vital signs very frequently during the first hour and at intervals thereafter. ■ Monitor renal and hepatic function tests before and during therapy. ■ Determine absolute patency and quality of vein and adequate circulation of extremity. Avoid extravasation; can cause local tissue necrosis and thrombophlebitis. ■ Precipitation sufficient to occlude central venous access catheters has occurred; monitor infusion closely, and flush thoroughly before and after administration. ■ Use prophylactic antiemetics to increase patient comfort. ■ Steady-state volume of distribution increases with a decrease in plasma albumin levels; monitor pediatric patients with hypoalbuminemia carefully. ■ If severe myelosuppression occurs, bone marrow examination should be repeated before a decision to continue therapy is made. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient.

Patient Education: Report IV site burning or stinging promptly. ■ Avoid pregnancy; non-hormonal birth control recommended for males and females. ■ Males should consider the possibility of storing sperm for future artificial insemination. ■ Report any signs of hypersensitivity promptly (e.g., chills, difficult breathing, fever, flushing, rapid heartbeat, rash). ■ Secondary acute nonlymphocytic leukemia (ANLL) has been reported (see [Precautions](#)). ■ Interacts with many medications. Discuss all drugs (prescription or non-prescription) with doctor or pharmacist. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. May cause fetal harm; see [Patient Education](#). ■ Potential for serious adverse reactions in nursing infants; discontinue breastfeeding. ■ Contains benzyl alcohol; not recommended for use in premature infants. ■ Intended for use in pediatric patients, but see [Precautions/Monitor](#). ■ When used as a single agent, side effects in pediatric patients from 2 weeks to 20 years of age are similar to other age-groups.

Elderly: Monitor renal, hepatic, and hematologic function closely.

DRUG/LAB INTERACTIONS

Concomitant use with **vincristine sulfate** has resulted in neurotoxicity, including severe cases of neuropathy. ■ **Sodium salicylate, sulfamethizole, and tolbutamide** displace teniposide from protein-binding sites. Can cause substantial increases in free drug levels and increase toxicity of teniposide. ■ May result in clinically significant drug interactions with **other drugs highly bound to protein** (e.g., buprenorphine, calcium channel blocking agents [e.g., diltiazem, verapamil], phenothiazines [e.g., prochlorperazine (Compazine)]). ■ May increase plasma clearance and increase intracellular levels of **methotrexate**. ■ **Phenobarbital, fosphenytoin (Cerebyx), and phenytoin (Dilantin)** increase clearance of teniposide; may reduce effectiveness. ■ Depressant and hypotensive effects of **antiemetics** may be additive with alcohol in teniposide. ■ May cause additive effects with **bone marrow-suppressing agents or agents that cause blood dyscrasias** (e.g., amphotericin B, antithyroid agents [Methimazole (Tapazole)], azathioprine [Imuran], chloramphenicol, ganciclovir [Cytovene], interferon, plicamycin [Mithracin], zidovudine [AZT, Retrovir]) and **radiation therapy**. ■ Do not administer **live virus vaccines**.

SIDE EFFECTS

Most are reversible if detected early. Hypersensitivity reactions (e.g., bronchospasm, chills, confusion, dyspnea, facial flushing, fever, headache, hypertension, hypotension, tachycardia, urticaria) have occurred and can be fatal if not treated promptly. Myelosuppression (anemia, leukopenia, neutropenia, thrombocytopenia) occurs early, can be profound, and recovery can be delayed. Alopecia, asthenia, bleeding, diarrhea, fever, hypotension/cardiovascular, infection, mucositis, nausea and vomiting, rash, thrombophlebitis. Hepatic dysfunctions, metabolic abnormalities, neurotoxicity, and renal dysfunction have occurred in fewer than 1% of patients.

Overdose: Acute CNS depression, hypotension, and metabolic acidosis.

ANTIDOTE

Keep physician informed of all side effects. Symptomatic treatment is often indicated. Discontinue teniposide and treat hypersensitivity reactions immediately (epinephrine [Adrenalin], antihistamines [e.g., diphenhydramine (Benadryl)], cimetidine [Tagamet], corticosteroids [e.g., dexamethasone (Decadron)], bronchodilators [e.g., theophylline (Aminophylline)], IV fluids). Consider risk/benefit before rechallenging any patient who has had a severe hypersensitivity reaction. Pretreatment with corticosteroids and antihistamines and constant observation are imperative. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Consider diazepam (Valium) or phenytoin (Dilantin) for seizures. Hypotension is usually due to a rapid infusion rate; discontinue temporarily. Trendelenburg position and IV fluids should reverse the hypotension; vasopressors (e.g., dopamine) may be required. In addition to antiemetics (e.g., ondansetron [Zofran]), rate reduction may reduce nausea and vomiting. For extravasation, discontinue the drug immediately and administer into another site. Resuscitate as necessary.

THIAMINE HYDROCHLORIDE

(THIGH-ah-min hy-droh-KLOR-eyed)

Nutritional supplement
(vitamin)Vitamin B₁

pH 2.5 to 4.5

USUAL DOSE

Transfer to PO doses when practical; see **Precautions**. Administer before dextrose solutions in the poorly nourished to avoid the development of acute symptoms of thiamine deficiency.

Thiamine deficiency (prophylaxis): Administered as part of a TPN program and based on individual patient needs (average daily requirement in a normal healthy adult is 1 mg). Average supplementation in TPN is 6 mg/day; may be increased to 25 to 50 mg/day in patients with a history of alcohol abuse. In critically ill adults, an initial dose of up to 100 mg has been used. May be followed with 50 to 100 mg daily until a regular balanced diet can be eaten. IV dextrose solutions or high carbohydrate diets increase thiamine requirements and may worsen symptoms in patients who are thiamine deficient.

Beriberi: 5 to 30 mg IV or IM 3 times daily for up to 2 weeks. Continue PO for 1 month.

Alcohol withdrawal syndrome: 100 mg IV or IM daily for several days. Administer concurrently with IV glucose. Follow with 50 to 100 mg/day PO.

Wernicke's encephalopathy: An initial dose of 100 mg IV. Larger doses may be required in the first 24 hours with extreme caution. Follow with 50 to 100 mg daily until a normal diet is resumed.

PEDIATRIC DOSE

Thiamine deficiency (prophylaxis and/or treatment): Administered as part of a TPN program and based on individual patient needs (average daily requirement in a normal healthy infant or child ranges from 0.2 mg in infants to 0.9 mg in 9- to 13-year-olds). Up to 10 to 25 mg/24 hr may be used in critically ill pediatric patients. See comments under **Usual Dose**.

Beriberi: 10 to 25 mg/24 hr. Follow with 10 to 50 mg PO daily for 2 weeks, then 5 to 10 mg PO daily for 1 month.

DILUTION

May be given by IV injection or added to most IV solutions and given as an infusion. See chart on inside back cover.

Storage: Can be refrigerated; protect from freezing and from light.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Unstable in neutral or alkaline solutions. Do not use in combination with alkaline solutions (e.g., acetates, barbiturates [e.g., phenobarbital (Luminal)], carbonates, citrates, copper ions). **Incompatible** with solutions containing sulfites and other oxidizing and reducing agents."

One source suggests the following **compatibilities**:

Y-site: Famotidine (Pepcid IV).

RATE OF ADMINISTRATION

100 mg or fraction thereof over 5 minutes. For 100 mg or larger doses, equal distribution over an extended time as an infusion is preferred.

ACTIONS

A water-soluble vitamin, thiamine is necessary to most metabolic processes in humans, especially carbohydrate metabolism. Widely distributed in all body tissues, metabolized in the liver, and excreted in urine.

INDICATIONS AND USES

Prophylaxis or treatment of thiamine deficiency syndromes including beriberi (wet or dry), Wernicke's encephalopathy, or peripheral neuritis.

CONTRAINDICATIONS

Known hypersensitivity to thiamine hydrochloride.

PRECAUTIONS

Not commonly administered IV; PO or IM is preferred. ■ Rarely used alone, it is more often administered as a multiple B vitamin. ■ In thiamine deficiency, administer thiamine before giving any glucose load to prevent the sudden onset of Wernicke's encephalopathy or add 100 mg to each of the first few liters of IV fluid to avoid precipitating heart failure. ■ Requirements may be increased in certain conditions (e.g., alcoholism, burns, GI disease, or malabsorption). ■ Supplementation is necessary in patients receiving total parenteral nutrition (usually administered as a multivitamin). ■ S/S of thiamine deficiency (e.g., ataxia, edema, heart failure, neuritis, ocular signs) may respond within hours of thiamine administration and disappear within days. Confusion and psychosis may be slower to respond and may not improve if nerve damage has occurred.

Patient Education: Dietary consultation indicated to prevent relapse.

Maternal/Child: Category A: use only if clearly needed. ■ Use caution in breast-feeding.

SIDE EFFECTS

Anaphylaxis and death caused by hypersensitivity reaction can occur with IV administration. Recent studies have shown that hypersensitivity reactions can occur with equal frequency by any route. Incidence after IV administration is less than 0.1%. May increase in frequency with repeat injections. Other reactions include feeling of warmth, nausea, pruritus, pain, sweating, urticaria, and weakness.

ANTIDOTE

Discontinue the drug, treat hypersensitivity reactions or resuscitate as necessary, and notify the physician.

THIOTEPA

(thigh-oh-TEP-ah)

Antineoplastic
(alkylating agent/nitrosurea)**TSPA****pH 7.6****USUAL DOSE**

0.3 to 0.4 mg/kg every 1 to 4 weeks. Maintenance dose and frequency adjusted according to blood cell counts before and after treatment. Dose based on average weight in presence of ascites or edema.

DOSE ADJUSTMENTS

Reduce dose or discontinue if WBC or platelet count falls rapidly. ■ Usually contraindicated but can be used with extreme caution and in low doses in patients with existing hepatic, renal, or bone marrow damage if benefits outweigh risks.

DILUTION

Specific techniques required; see Precautions. Each 15 mg of drug is reconstituted with 1.5 mL of SWFI (10 mg/mL). Shake solution gently and allow to stand until clear. A hypotonic solution; further dilute with NS before administration. Must be filtered through a 0.22-micron filter before administration. May then be given through Y-tube or three-way stopcock of a free-flowing IV infusion. Final solution should be clear; do not use if hazy, opaque, or a precipitate is present.

Filters: Filter through a 0.22-micron filter before administration. See *Dilution*.

Storage: Must be refrigerated before and after reconstitution. Protect from light at all times. Use reconstituted solution within 8 hours. Use diluted solution immediately.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following compatibilities:

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), aminophylline, amphotericin B (conventional), ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), cefazolin (Ancef), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), clindamycin (Cleocin), cyclophosphamide (Cytosan), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), daunorubicin (Cerubidine), dexamethasone (Decadron), diphenhydramine (Benadryl), dobutamine, dopamine, doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), etoposide (VePesid), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gallium nitrate (Ganite), ganciclovir (Cytovene), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), leucovorin calcium, lorazepam (Ativan), magnesium sulfate, mannitol, melphalan (Alkeran), meperidine (Demerol), mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), mitomycin (Mutamycin), mitoxantrone (Novantrone), morphine, nalbuphine, ondansetron (Zofran), paclitaxel (Taxol), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, streptozocin (Zanosar), sulfamethoxazole/trimethoprim, teniposide (Vumon), ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vinblastine, vincristine, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose as a rapid IV injection.

ACTIONS

An alkylating agent of the nitrosurea group with anti-tumor activity. Cell cycle phase-nonspecific. Thought to have a radiomimetic action, which releases ethylenimine radicals that disrupt DNA bonds and destroy actively dividing cells. Well distributed, it is metabolized in the liver and excreted as metabolites in the urine.

INDICATIONS AND USES

To suppress or retard neoplastic growth in adenocarcinomas of the breast and ovary. ■ Treatment of Hodgkin's lymphomas. ■ Also used intracavitary to treat some bladder cancers and to control intracavitary effusions (pericardial or pleural) secondary to neoplastic disease (toxicity still occurs from systemic absorption).

CONTRAINDICATIONS

Hepatic, renal, or bone marrow damage unless need is greater than the risk; known hypersensitivity to thiotepea.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Use caution in leukopenia, thrombocytopenia, recent radiation therapy, and infection. ■ See [Dose Adjustments](#) and [Side Effects](#).

Monitor: Daily blood cell and platelet counts are necessary during initial treatment and weekly thereafter until 3 weeks after therapy is discontinued. Very toxic to hematopoietic system. ■ Obtain baseline SCr, BUN, and/or liver function tests in patients with renal or hepatic impairment and monitor during treatment. ■ Be alert for signs of bone marrow suppression or infection. Use of prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ May induce hyperuricemia, increased doses of antigout agents may be necessary (e.g., allopurinol, probenecid). Allopurinol preferred to reduce risk of uric acid nephropathy associated with uricosuric antigout agents. ■ Prophylactic antiemetics may increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See [Drug/Lab Interactions](#).

Patient Education: Nonhormonal birth control recommended for patient and partner. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. Will produce teratogenic effects on the fetus. Has a mutagenic potential. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients up to 12 years of age not established.

Elderly: Consider possibility of impaired organ function.

DRUG/LAB INTERACTIONS

May cause irreversible bone marrow damage with **other antineoplastic drugs, radiation therapy, or any drugs that cause bone marrow suppression** (e.g., amphotericin B [all formulations], ganciclovir [Cytovene]). Allow complete recovery verified by WBC count before using a second agent. ■ Potentiates **succinylcholine**. May cause prolonged apnea. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs.

SIDE EFFECTS

Alopecia, amenorrhea, anorexia, asthenia, dizziness, fatigue, fever, headache, hives, hyperuricemia, nausea, pain at injection site, skin rash, throat tightness, vomiting.

Major: Anaphylaxis, hemorrhage, intestinal perforation, septicemia. Bone marrow suppression (anemia, leukopenia, thrombocytopenia) may be life threatening, is dose related, and does occur with usual doses.

ANTIDOTE

Minor side effects will be treated symptomatically if necessary. Discontinue the drug and notify the physician of major side effects. If platelet count below 150,000/mm³ or WBCs below 3,000/mm³, discontinue use and notify physician. Administration of whole blood products (e.g., packed RBCs, platelets, or leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Treat hypersensitivity reactions as indicated.

TICARCILLIN DISODIUM AND CLAVULANATE POTASSIUM

(tie-kar-SILL-in dye-SO-dee-um and klav-you-LAN-ate poe-TASS-ee-um)

**Antibacterial
(extended-spectrum penicillin
and β-lactamase inhibitor)**

Timentin

pH 5.5 to 7.5

USUAL DOSE

3.1 Gm of preparation available contains 3 Gm ticarcillin to 0.1 Gm clavulanate. Doses vary depending on the severity of the infection, susceptibility of the organism, and condition of the patient. Dose recommendations are based on the ticarcillin content. Treatment usually continued for 10 to 14 days; may be extended if required. Continue for at least 2 days after signs and symptoms of infection have disappeared.

Systemic and urinary tract infections: 60 kg (130 lb) or more: 3.1 Gm every 4 to 6 hours. Some sources extend interval to 6 to 8 hours.

Under 60 kg: 200 to 300 mg/kg of body weight/24 hr in equally divided doses every 4 to 6 hours (33.3 to 50 mg/kg every 4 hours or 50 to 75 mg/kg every 6 hours).

Moderate gynecologic infections: 200 mg/kg/day in divided doses every 6 hours (50 mg/kg every 6 hours).

Severe gynecologic infections: 300 mg/kg/day in divided doses every 4 hours (50 mg/kg every 4 hours).

Surgical prophylaxis (unlabeled): 3.1 Gm 30 to 60 minutes before start of surgery or as soon as the umbilical cord is clamped in cesarean section. Repeat at 4-hour intervals for 3 doses.

PEDIATRIC DOSE

Dose recommendations are based on the ticarcillin content.

Infants and other pediatric patients 3 months to 12 years of age and less than 60 kg: 50 mg/kg every 6 hours. In serious infections, increase to 50 mg/kg every 4 hours. See [Contraindications](#).

Pediatric patients greater than 60 kg: 3.1 Gm every 6 hours for mild to moderate infections. Increase frequency to every 4 hours for severe infections.

Pediatric patients with cystic fibrosis: 300 to 600 mg/kg/24 hr. Give in equally divided doses every 4 to 6 hours (50 to 100 mg/kg every 4 hours or 75 to 150 mg/kg every 6 hours). Maximum dose is 24 Gm/24 hr.

NEONATAL DOSE

Safety for use in infants under 3 months of age not established but has been used. Base dose on ticarcillin component. See [Contraindications](#).

7 days of age or less and weighing less than 2 kg: 75 mg/kg every 12 hours.

7 days of age or less and weighing 2 kg or more: 75 mg/kg every 8 hours.

Over 7 days of age and weighing less than 1.2 kg: 75 mg/kg every 12 hours.

Over 7 days of age and weighing 1.2 to 2 kg: 75 mg/kg every 8 hours.

Over 7 days of age and weighing more than 2 kg: 100 mg/kg every 8 hours.

Term neonate and/or infant less than 3 months of age: 50 mg/kg every 4 to 6 hours.

DOSE ADJUSTMENTS

After an initial loading dose of 3.1 Gm, reduce dose in impaired renal function according to the following chart.

Ticarcillin/Clavulanate Dose in Impaired Renal Function	
Creatinine Clearance (mL/min)	Dosage Based on Ticarcillin Content
>60 mL/min	3 Gm q 4 hr
30-60 mL/min	2 Gm q 4 hr
10-30 mL/min	2 Gm q 8 hr
<10 mL/min	2 Gm q 12 hr
<10 mL/min with hepatic dysfunction	2 Gm q 24 hr
Patients on peritoneal dialysis	3 Gm q 12 hr
Patients on hemodialysis	2 Gm q 12 hr supplemented with 3 Gm after each dialysis

- Reduce dose in impaired hepatic function. ■ Reduced dose may be indicated in the elderly.

DILUTION

Each 3.1 Gm or fraction thereof is reconstituted with 13 mL of SWFI or NS (200 mg/mL of ticarcillin). Shake well. A single dose must be further diluted to a final concentration between 10 and 100 mg/mL. Dilute in 50 to 100 mL or more of D5W, NS, or LR and given as an intermittent infusion. Also available prediluted and frozen (Galaxy bags), in ADD-Vantage vials for use with ADD-Vantage infusion containers, and in pharmacy bulk packages.

Storage: Store unopened vials at or below 24° C (75° F). Reconstituted solutions (200 mg/mL) and pharmacy bulk packages (300 mg/mL) are stable at room temperature for 6 hours or up to 72 hours under refrigeration (4° C [40° F]). Stability extended after further dilution and with specific diluents (see literature). Store frozen Galaxy containers at or below 20° C (-4° F). Thawed Galaxy containers are stable for 24 hours at RT or for 7 days refrigerated.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

May be inactivated in solution with aminoglycosides (e.g., amikacin [Amikin], gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. Manufacturer recommends temporarily discontinuing the administration of other solutions at the same site during intermittent infusion and lists as **incompatible** with sodium bicarbonate. See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), cisatracurium (Nimbex), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopan), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hexend), insulin (regular), melphalan (Alkeran), meperidine (Demerol), milrinone (Primacor), morphine, ondansetron (Zofran), pemetrexed (Alimta), propofol (Diprivan), remifentanyl (Ultiva), sargramostim

(Leukine), teniposide (Vumon), theophylline, thiotepa, topotecan (Hycamtin), vancomycin, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Intermittent infusion: A single dose over 30 minutes. May be given through Y-tube or three-way stopcock of infusion set. Discontinue primary IV during administration. Too-rapid injection may cause seizures. Slow infusion rate for pain along venipuncture site.

ACTIONS

An extended-spectrum penicillin combined with a β -lactamase inhibitor. Bactericidal for many gram-negative, gram-positive, and anaerobic organisms. Acts by disrupting bacterial cell wall development. This specific formulation extends activity by protecting ticarcillin from degradation by β -lactamase enzymes. Large doses with high blood levels are well tolerated. Widely distributed in body fluids and tissues. Distributes into cerebrospinal fluid only if inflammation is present. Peak serum levels achieved by end of infusion. Half-life is 1.1 hours. Crosses the placental barrier. Primarily excreted in the urine.

INDICATIONS AND USES

Treatment of infections caused by susceptible isolates of specific bacteria in the following conditions caused by β -lactamase-producing organisms: bacterial septicemia; acute and chronic infections of the lower respiratory tract, skin and skin structures, bone and joint, endometrium, urinary tract; and peritonitis. Useful in mixed infections as presumptive therapy before identifying the causative organism, in infections complicated by impaired renal functions, or in patients receiving immunosuppressive or oncolytic drugs.

Unlabeled use: Surgical prophylaxis.

CONTRAINDICATIONS

Known history of a hypersensitivity reaction (e.g., anaphylaxis or erythema multiforme) to ticarcillin or other β -lactam antibacterials (e.g., penicillins and cephalosporins [not absolute]); see [Precautions](#).

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients undergoing penicillin therapy; most likely to occur in patients with a history of penicillin allergy or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Specific sensitivity studies indicated to determine susceptibility of the causative organism to ticarcillin and clavulanate. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ticarcillin/clavulanate should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Superinfection caused by overgrowth of nonsusceptible organisms can occur. ■ Risk of bleeding associated with abnormalities in coagulation tests have occurred; more likely in patients with renal impairment. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ticarcillin/clavulanate. ■ Seizures have been reported. More common when recommended doses are exceeded, especially in patients with impaired renal function.

Monitor: Periodic evaluation of renal, hepatic, and hematopoietic systems and serum potassium is recommended. Observe for electrolyte imbalance and cardiac irregularities. Observe for hypokalemia. Monitor serum potassium in patients with fluid and electrolyte imbalance and in patients receiving prolonged therapy. Contains 4.51 mEq sodium/Gm. May aggravate CHF. ■ Observe for increased bleeding tendencies in all patients but especially those with impaired renal function. Monitor coagulation tests as indicated (bleeding time, INR, PT). ■ May cause thrombophlebitis; observe carefully and rotate infusion sites. ■ Test patients with syphilis for HIV. ■ See [Drug/Lab Interactions](#).

Patient Education: Report promptly: fever, rash, sore throat, unusual bleeding or bruising, seizures. ■ Promptly report diarrhea or bloody stools that occur during treatment or up

to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ May require alternate birth control.

Maternal/Child: Category B: use only if clearly needed. Studies in rats have not shown adverse effects on the fetus. ■ Use with caution in breast-feeding. May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ If meningitis is suspected or documented in pediatric patients, an alternative agent should be used; see literature. ■ Safety and effectiveness established for use in pediatric patients between 3 months and 16 years of age. Has been used in infants under 3 months of age but safety for use not established.

Elderly: Safety and effectiveness similar to that seen in younger adults; however, greater sensitivity of some elderly patients cannot be ruled out. ■ Monitoring of renal function suggested. ■ Use care in dose selection. Consider age-related organ function and concomitant disease or drug therapy; see [Dose Adjustments](#). ■ At the recommended dose, patients may receive 1,285 to 1,927 mg/day (56 to 84 mEq) of sodium. Elderly patients may respond with blunted natriuresis to salt loading. Monitor patients with CHF closely.

DRUG/LAB INTERACTIONS

Probenecid decreases rate of ticarcillin elimination, resulting in higher and more prolonged blood levels of ticarcillin; will not affect clavulanate levels. May be desirable or may cause toxicity. ■ Synergistic when used in combination with **aminoglycosides** (e.g., amikacin [Amikin], gentamicin). Synergism may be inconsistent; see [Compatibility](#). ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Use caution with **anticoagulants** (e.g., heparin), **thrombolytic agents** (e.g., alteplase [tPA]), **platelet aggregation inhibitors** (e.g., aspirin, NSAIDs, dextran, dipyridamole, **glycoprotein GPIIb/IIIa receptor antagonists** [e.g., abciximab (ReoPro), eptifibatid (Integrilin), tirofiban (Aggrastat)], plicamycin). Risk of bleeding may be increased. Monitoring of coagulation tests may be indicated. ■ May inhibit effectiveness of **oral contraceptives**; breakthrough bleeding or pregnancy could result. ■ May decrease clearance and increase toxicity of **methotrexate**. ■ May decrease effectiveness of **live vaccines**. ■ Clavulanic acid may cause a **false-positive Coombs' test**. ■ May cause **false urine protein reactions** with various tests; see [Side Effects](#) and/or literature.

SIDE EFFECTS

Diarrhea, nausea, phlebitis at injection site, and rash are most common. Most common laboratory abnormalities included elevations in eosinophils, AST, and ALT. Other reported side effects include anaphylaxis; anemia; arthralgia; CDAD; chest discomfort; chills; disturbances of taste and smell; elevated alkaline phosphatase, BUN, LDH, serum bilirubin, and serum creatinine; fever; flatulence; epigastric pain; headache; hemorrhagic cystitis; hypernatremia; hypokalemia; increased bleeding time; leukopenia; myalgia; neutropenia; phlebitis; prolonged clotting time or PT; pruritus; skin rash; stomatitis; thrombocytopenia; urticaria; vomiting. Higher than normal doses may cause neurologic adverse reactions, including convulsions, especially with impaired renal function.

Post-Marketing: Stevens-Johnson syndrome, toxic epidermal necrolysis.

ANTIDOTE

Notify the physician immediately of any adverse symptoms. For severe symptoms, discontinue the drug; treat hypersensitivity reactions (epinephrine, antihistamines, corticosteroids), and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of ticarcillin/clavulanate. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Discontinue the drug if symptoms of bleeding manifestations appear, and treat as indicated. Hemodialysis may be indicated in overdose.

TIGECYCLINE FOR INJECTION

(tye-ge-**SYE**-kleen)

Tygacil

Antibacterial
(glycylcycline)

pH 7.8

USUAL DOSE

100 mg as an initial dose. Follow with 50 mg every 12 hours. Recommended duration of treatment is 5 to 14 days for complicated skin and skin structure infections and complicated intra-abdominal infections and 7 to 14 days for community-acquired bacterial pneumonia. Duration of treatment is based on the severity and site of the infection and the patient's clinical and bacteriologic progress.

DOSE ADJUSTMENTS

In patients with severe impaired liver function (Child Pugh C [score 10 to 15]), the initial dose remains the same, but subsequent doses should be reduced to 25 mg every 12 hours. ■ No dose adjustment is indicated for impaired renal function, for mild to moderate impaired liver function (Child Pugh A and Child Pugh B [score 5 to 9]), or in patients undergoing hemodialysis. ■ No dose adjustment is indicated based on age, gender, or race.

DILUTION

Reconstitute each 50-mg vial with 5.3 mL of NS, D5W, or LR (yields 10 mg/mL). Use 2 vials for the 100-mg dose. Swirl gently until lyophilized powder is dissolved. Reconstituted solution should be yellow to orange in color. Immediately withdraw 5 mL from two vials for the 100-mg dose (vials are overfilled) or from one vial for the 50-mg dose and add to a 100-mL IV bag of D5W, NS, or LR for infusion. Maximum concentration should be 1 mg/mL. Reconstituted solution has a pH of 7.8. When fully diluted, tigecycline assumes the pH of its diluent.

Filters: No data available from manufacturer.

Storage: Store unopened vials at CRT. Reconstituted solution may be stored at RT for up to 6 hours. Fully diluted solution in the IV bag may be stored at RT for up to 24 hours or for 6 hours in the vial and the remaining time in the IV bag, or the fully diluted solution in either D5W or NS may be refrigerated at 2° to 8° C (36° to 46° F) for up to 48 hours following immediate transfer of the reconstituted solution into the IV bag.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "The following drugs **should not** be administered simultaneously through the same **Y-site** as tigecycline: amphotericin B (conventional), amphotericin B lipid complex (Abelcet), diazepam (Valium), esomeprazole (Nexium IV), and omeprazole (Prilosec)."

Y-site: Manufacturer lists as **compatible** at the **Y-site** with amikacin (Amikin), dobutamine, dopamine, gentamicin, LR solution, lidocaine, metoclopramide (Reglan), morphine, norepinephrine (Levophed), piperacillin/tazobactam (Zosyn), potassium chloride, propofol (Diprivan), ranitidine (Zantac), theophylline (Aminophylline), and tobramycin.

Another source adds **compatibility** at the **Y-site** with azithromycin (Zithromax), aztreonam (Azactam), cefepime (Maxipime), cefotaxime (Claforan), ceftazidime (Fortaz), ceftriaxone (Rocephin), ciprofloxacin (Cipro IV), doripenem (Doribax), epinephrine (Adrenalin), ertapenem (Invanz), fluconazole (Diflucan), heparin, imipenem-cilastatin (Primaxin), linezolid (Zyvox), metoclopramide (Reglan), telavancin (Vibativ), vancomycin.

RATE OF ADMINISTRATION

Flush IV line with D5W, NS, or LR before and after infusion of tigecycline if other drugs are administered through the same line; see **Compatibility**. Consider **compatibility** of other drugs when flushing the line.

A single dose as an infusion over 30 to 60 minutes.

ACTIONS

A broad-spectrum glycylicycline antibiotic, bacteriostatic against specific aerobic gram-positive and gram-negative microorganisms and specific anaerobic microorganisms; see prescribing information. Inhibits protein translation in bacteria by binding to a specific ribosomal subunit and blocking entry of specific molecules into the A site of the ribosome. Chemical structure has similarities to tetracyclines; however, it is not affected by the two major tetracycline resistance mechanisms of ribosomal protection and efflux. Plasma protein binding is approximately 71% to 89%. Extensively distributed beyond the plasma volume and into tissues. For example, concentrations have been identified in the bone, colon, gallbladder, synovial fluid, and lung. Mean half-life is 42.4 hours. Not extensively metabolized. 59% of a dose is excreted in bile and feces, and 33% is excreted in urine. Crosses the placental barrier in animals.

INDICATIONS AND USES

Treatment of adults with infections caused by susceptible strains of designated microorganisms in complicated skin and skin structure infections, complicated intra-abdominal infections, and community-acquired bacterial pneumonia.

CONTRAINDICATIONS

Known hypersensitivity to tigecycline. Contains no excipients or preservatives.

PRECAUTIONS

Sensitivity studies are indicated to determine susceptibility of the causative organism to tigecycline. Treatment may begin after culture and sensitivity studies are drawn. Re-evaluate after results are known. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, tigecycline should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Cross-resistance and/or antagonism between tigecycline and other antibiotics has not been observed. ■ Not affected by resistance mechanisms seen with other antibiotics (e.g., β -lactamases). ■ Structurally similar to the tetracycline class of antibiotics; may have similar side effects (e.g., anti-anabolic action [which has led to acidosis, azotemia, hypophosphatemia, and increased BUN], pancreatitis, photosensitivity, and pseudotumor cerebri). ■ An increase in all-cause mortality has been observed across Phase 3 and 4 clinical trials in tigecycline-treated patients versus comparator groups. The cause of this increase has not been established and should be considered when selecting among treatment options. ■ Anaphylaxis/anaphylactoid reactions have been reported. Use caution in patients with a history of hypersensitivity to tetracyclines; may have cross-sensitivity. ■ Lower cure rates and higher mortality rates were seen in patients with ventilator-associated pneumonia treated with tigecycline versus comparator groups. Particularly high mortality rates were seen in tigecycline-treated patients with ventilator-associated pneumonia and bacteremia at baseline. ■ Acute pancreatitis, including fatalities, have been reported. ■ Use caution when considering tigecycline monotherapy in patients with complicated intra-abdominal infections secondary to clinically apparent intestinal perforation; sepsis/septic shock has occurred. ■ Abnormalities in total bilirubin, PT, and transaminases have been seen in patients treated with tigecycline. Has also caused isolated cases of significant hepatic dysfunction and hepatic failure; see **Monitor**. ■ May cause permanent discoloration of the teeth during tooth development; see **Maternal/Child**. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with severe liver impairment. Monitoring for treatment response is indicated. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with tigecycline.

Monitor: Monitor vital signs carefully. ■ Obtain baseline CBC with differential, and monitor as indicated. ■ Monitor patients with impaired liver function carefully. If abnormal liver function tests develop, monitor closely for worsening hepatic function and evaluate for risk/benefit of continuing therapy. May occur after tigecycline is discontinued. ■ Observe for signs of hypersensitivity reactions (e.g., chills, fever, hives, rash, shortness of breath). ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Avoid pregnancy; use effective contraceptive measures; see [Drug/Lab Interactions](#). Should pregnancy occur, notify physician immediately and discuss potential hazards. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Promptly report S/S of hypersensitivity (e.g., chills, fever, hives, rash, shortness of breath) and/or S/S of liver dysfunction (e.g., jaundice or yellow sclera).

Maternal/Child: Category D: avoid pregnancy. May cause fetal harm; use of effective contraception required; see [Drug/Lab Interactions](#). Use during pregnancy only if benefits justify potential risk to the fetus. ■ Use during tooth development (the last half of pregnancy, infancy, and childhood to the age of 8 years) may cause permanent discoloration of the teeth. ■ Not known if tigecycline is secreted in breast milk; use caution. Is secreted in the milk of lactating rats. ■ Safety and effectiveness in pediatric patients less than 18 years of age not established.

Elderly: Response similar to that seen in younger adults; however, the potential for greater sensitivity to side effects cannot be disregarded.

DRUG/LAB INTERACTIONS

Digoxin (Lanoxin) and tigecycline do not affect each other's pharmacokinetics; no dose adjustment of either drug is indicated. ■ Concurrent use of tigecycline with **warfarin** (Coumadin) does not significantly affect INR; however, monitoring of PT or other anticoagulation tests is recommended. ■ Inhibits **oral contraceptives**; may result in pregnancy or breakthrough bleeding. ■ Tigecycline does not inhibit the metabolism of any of the following six cytochrome P₄₅₀ (CYP) isoforms: 1A2, 2C8, 2C9, 2C19, 2D6, and 3A4; it is not expected to alter the metabolism of drugs metabolized by these enzymes. In addition, because tigecycline is not extensively metabolized, its clearance is not expected to be affected by drugs that induce or inhibit the activity of these P₄₅₀ isoforms. ■ No reported interactions with lab tests.

SIDE EFFECTS

Nausea and vomiting are the most common side effects and are the primary reason for discontinuing therapy. Other commonly reported side effects include abdominal pain, diarrhea, headache, and increased ALT. Less commonly reported side effects include abnormal healing; abscess; acute pancreatitis; anemia; asthenia; back pain; bilirubine-mia; CDAD; constipation; cough; dizziness; dyspepsia; dyspnea; fever; hyperglycemia; hypertension; hypokalemia; hypoproteinemia; hypotension; increased alkaline phosphatase, amylase, AST, BUN, and lactic dehydrogenase; infection; insomnia; leukocytosis; local injection reaction; pain; peripheral edema; phlebitis; pruritus; pulmonary findings; rash; sweating; thrombocytopenia. Sepsis/septic shock and death occurred in a few patients with complicated infections.

Post-Marketing: Acute pancreatitis, anaphylaxis/anaphylactoid reactions, hepatic cholestasis, jaundice.

Overdose: Increased incidence of nausea and vomiting. Estimated lethal dose in rats was 106 mg/kg.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically; monitor closely. If minor side effects are progressive or if any major side effect occurs, discontinue the drug, treat hypersensitivity reactions, or resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of tigecycline. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Not removed by hemodialysis.

TIROFIBAN HYDROCHLORIDE

(ty-roh-FYE-ban hy-droh-KLOR-eyed)

Platelet aggregation inhibitor

Aggrastat

pH 5.5 to 6.5

USUAL DOSE

Tirofiban: A **loading infusion** of 0.4 mcg/kg/min for 30 minutes, followed by a **maintenance infusion** of 0.1 mcg/kg/min. Unless contraindicated, give in conjunction with **aspirin** and **heparin**. Duration of therapy will vary depending on patient condition and procedures performed. In one major study, infusion was continued for 48 to 108 hours. The infusion should be continued through angiography and for 12 to 24 hours after angioplasty or arthrectomy.

Aspirin: 325 mg/day.

Heparin: Administer a heparin bolus of 5,000 units, followed by an infusion titrated to maintain an aPTT of 2 times control. Heparin and tirofiban may be administered through the same intravenous catheter.

DOSE ADJUSTMENTS

Patients with severe renal insufficiency (CrCl less than 30 mL/min) should receive half the usual rate of infusion. See **Rate of Administration**. ■ Differences in plasma clearance based on age, race, gender, or mild to moderate hepatic insufficiency do not require dose adjustment.

DILUTION

Available premixed in a plastic container in a 50 mcg/mL concentration (5 mg/100 mL and 12.5 mg/250 mL). Remove overwrap. Plastic may be somewhat opaque due to sterilization process. Opacity should diminish. Squeeze inner container to check for leak. Discard if leakage noted; sterility is impaired. Do not use plastic containers in a series connection.

Filters: Studies found no loss of drug potency through most standard 5-micron or larger filters.

Storage: Store unopened or premixed containers at 25° C (77° F). Variations from 15° to 30° C (59° to 86° F) are acceptable for short periods. Protect from light during storage. Do not freeze. Discard unused solution.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not add other drugs or remove solution directly from the bag with a syringe. Should not be administered in the same IV line as diazepam (Valium)."

Manufacturer indicates **compatibility** at the **Y-site** with atropine, dobutamine, dopamine, epinephrine (Adrenalin), famotidine (Pepcid IV), furosemide (Lasix), lidocaine, midazolam (Versed), morphine, nitroglycerin IV, potassium chloride, propranolol. Another source adds amiodarone (Nexterone), argatroban (Acova), bivalirudin (Angiomax), and heparin.

RATE OF ADMINISTRATION

Loading infusion: 0.4 mcg/kg/min for 30 minutes.

Maintenance infusion: 0.1 mcg/kg/min.

Tirofiban Infusion Rates				
Patient Weight (kg)	Most Patients		Severe Renal Impairment	
	30-Min Loading Infusion Rate (mL/hr)	Maintenance Infusion Rate (mL/hr)	30-Min Loading Infusion Rate (mL/hr)	Maintenance Infusion Rate (mL/hr)
30-37	16 mL/hr	4 mL/hr	8 mL/hr	2 mL/hr
38-45	20 mL/hr	5 mL/hr	10 mL/hr	3 mL/hr
46-54	24 mL/hr	6 mL/hr	12 mL/hr	3 mL/hr
55-62	28 mL/hr	7 mL/hr	14 mL/hr	4 mL/hr
63-70	32 mL/hr	8 mL/hr	16 mL/hr	4 mL/hr
71-79	36 mL/hr	9 mL/hr	18 mL/hr	5 mL/hr
80-87	40 mL/hr	10 mL/hr	20 mL/hr	5 mL/hr
88-95	44 mL/hr	11 mL/hr	22 mL/hr	6 mL/hr
96-104	48 mL/hr	12 mL/hr	24 mL/hr	6 mL/hr
105-112	52 mL/hr	13 mL/hr	26 mL/hr	7 mL/hr
113-120	56 mL/hr	14 mL/hr	28 mL/hr	7 mL/hr
121-128	60 mL/hr	15 mL/hr	30 mL/hr	8 mL/hr
129-137	64 mL/hr	16 mL/hr	32 mL/hr	8 mL/hr
138-145	68 mL/hr	17 mL/hr	34 mL/hr	9 mL/hr
146-153	72 mL/hr	18 mL/hr	36 mL/hr	9 mL/hr

ACTIONS

A non-peptide antagonist of the platelet glycoprotein GPIIb/IIIa receptor. It inhibits platelet aggregation by preventing the binding of fibrinogen to the receptor site on activated platelets. Inhibits platelet aggregation in a dose- and concentration-dependent manner. When given according to the recommended regimen, greater than 90% inhibition is attained by the end of the 30-minute infusion. Bleeding time is prolonged. Inhibition is reversible, with aggregation returning to baseline in more than 90% of patients within 4 to 8 hours following cessation of the infusion. Has been shown to decrease the rate of a combined endpoint of death, new myocardial infarction, or refractory ischemia/ repeat cardiac procedure (see literature). Half-life is approximately 2 hours. Cleared from the plasma primarily by renal excretion, with about 65% of the unchanged drug appearing in the urine and about 25% appearing in feces. Metabolism is limited.

INDICATIONS AND USES

Used in combination with heparin and aspirin for the treatment of acute coronary syndrome (characterized by prolonged [more than 10 minutes] or repetitive symptoms of cardiac ischemia occurring at rest or with minimal exertion, associated with either ischemic ST-T wave changes on electrocardiogram [ECG] or elevated cardiac enzymes. Includes “unstable angina” and “non-Q-wave myocardial infarction” but excludes myocardial infarction that is associated with Q-waves or nontransient ST-segment elevation). May be used in patients who are being medically managed and in those undergoing percutaneous transluminal coronary angioplasty (PTCA) or arthroectomy.

CONTRAINDICATIONS

Known hypersensitivity to any component of the product; active internal bleeding or history of bleeding diathesis within the previous 30 days (a second source indicates within the previous year); a history of intracranial hemorrhage, intracranial neoplasm, arteriovenous malformation, or aneurysm; a history of thrombocytopenia following prior exposure to tirofiban; a history of stroke within 30 days or any history of hemorrhagic stroke,

major surgical procedure or severe physical trauma within the previous month; history, symptoms, or findings suggestive of aortic dissection; severe hypertension (systolic BP above 180 mm Hg and/or diastolic BP above 110 mm Hg); concomitant use of another parenteral GPIIb/IIIa inhibitor (e.g., abciximab [ReoPro]); acute pericarditis.

PRECAUTIONS

Use with caution in patients with platelet count less than 150,000/mm³, in patients with hemorrhagic retinopathy, and in chronic hemodialysis patients. ■ Use caution when given with drugs that affect hemostasis (e.g., warfarin [Coumadin]). Safety when used in combination with thrombolytic agents (e.g., alteplase [tPA, Activase], reteplase [Retavase], streptokinase [Streptase]) has not been established. See [Drug/Lab Interactions](#). ■ Use with caution in patients with renal insufficiency. See [Dose Adjustments](#). ■ An analysis during clinical trials showed that women who are medically managed or are undergoing subsequent percutaneous transluminal coronary angioplasty/atherectomy may receive less benefit from tirofiban than men. ■ Bleeding is the most common complication encountered during therapy. Incidence may be slightly higher in females and the elderly. ■ Most major bleeding occurs at the arterial access site for cardiac catheterization. Care should be taken when attempting vascular access that only the anterior wall of the femoral artery is punctured. ■ Hypersensitivity reactions, including anaphylaxis, have been reported in post-marketing. They have occurred during initial infusion and during readministration. Severe thrombocytopenia (platelet count less than 10,000/mm³) has been associated with some cases. Emergency medical equipment and medications for treating these reactions must be readily available.

Monitor: Obtain platelet count, hemoglobin, and hematocrit before therapy, within 6 hours following the loading infusion, and at least daily thereafter. More frequent monitoring may be indicated. Consider earlier monitoring of platelet count in patients who have previously received GPIIb/IIIa receptor antagonists (e.g., abciximab [ReoPro], eptifibatid [Integrilin], tirofiban [Aggrastat]). ■ If platelet count drops to below 90,000/mm³, additional platelet counts should be performed to exclude pseudothrombocytopenia. If thrombocytopenia is confirmed, heparin and tirofiban should be discontinued and appropriate therapy initiated. ■ Obtain an aPTT before treatment and carefully monitor the anticoagulant effects of heparin by repeated determinations of aPTT; adjust heparin dose accordingly. To monitor unfractionated heparin, obtain an aPTT 6 hours after the start of the heparin infusion. Adjust heparin infusion rate to maintain an aPTT 2 times control. ■ Monitor for S/S of hypersensitivity or infusion-related reactions (e.g., anaphylaxis, hypotension, pruritus, rash, urticaria, or wheezing). ■ Monitor the patient for signs of bleeding; take vital signs (avoiding automatic BP cuffs), observe any invaded sites at least every 15 minutes (e.g., sheaths, IV sites, cutdowns, punctures, epidural sites, Foleys, NGs); watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, muscle weakness. Perform neuro checks frequently. If during therapy bleeding cannot be controlled with pressure, tirofiban and heparin infusions should be discontinued. ■ Use care in handling patient; minimize use of urinary catheters, nasotracheal intubation, and nasogastric tubes. Avoid arterial puncture, venipuncture, epidural procedures, and IM injection. Use extreme precautionary methods and only compressible sites if these procedures are absolutely necessary (i.e., avoid subclavian or jugular veins). Apply pressure for 30 minutes to any invaded site and then apply pressure dressings. Saline or heparin locks suggested to facilitate blood draws. ■ Patients receiving percutaneous coronary intervention who have a sheath in place should be maintained on complete bed rest with the head of the bed elevated 30 degrees and the affected limb restrained in a straight position. Monitor sheath insertion site(s) and distal pulses of affected leg(s) frequently while sheath is in place. Measure any hematoma and monitor for enlargement. ■ In patients receiving percutaneous coronary intervention, heparin should be discontinued 3 to 4 hours before pulling the sheath and an activated clotting time (ACT) less than 180 seconds or an aPTT less than 45 seconds should be documented. ■ Care should be taken to obtain proper hemostasis after removal of the sheath using standard

compressive techniques followed by close observation. Sheath hemostasis should be achieved at least 4 hours before hospital discharge.

Patient Education: Compliance with all measures to minimize bleeding (e.g., strict bed rest, positioning) is imperative. ■ Avoid use of razors, toothbrushes, and other sharp items. ■ Use caution while moving to avoid excessive bumping. ■ Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face) and all episodes of bleeding and apply local pressure if indicated. ■ Expect oozing from IV sites.

Maternal/Child: Category B: safety for use in pregnancy not established. Benefits must outweigh risks. ■ Discontinue breast-feeding until 24 hours after completion of tirofiban therapy. ■ Safety and efficacy for use in pediatric patients not established.

Elderly: Clearance is reduced in the elderly, possibly due to age-related renal impairment. Dose adjustment is not necessary unless renal impairment severe; see [Dose Adjustments](#). Incidence of bleeding complications increase somewhat but are similar to use of heparin as a single agent. Incidence of non-bleeding side effects also increased.

DRUG/LAB INTERACTIONS

All studies with tirofiban included the use of **aspirin** and **heparin**. Concomitant use, although indicated, increases the risk of bleeding. ■ Use caution when given with drugs that affect hemostasis (e.g., **anticoagulants** [e.g., warfarin (Coumadin)], **NSAIDs** [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], **platelet aggregation inhibitors** [e.g., dipyridamole (Persantine), ticlopidine (Ticlid)], **glycoprotein GPIIb/IIIa receptor antagonists** [e.g., abciximab (ReoPro), eptifibatide (Integrilin)], or **selected antibiotics** [e.g., cefotetan]). ■ Safety of tirofiban when used in combination with **thrombolytic agents** (e.g., alteplase [tPA, Activase], reteplase [Retavase], streptokinase [Streptase]) has not been established. ■ Patients receiving **omeprazole** (Prilosec) or **levothyroxine** (Synthroid) concurrently with tirofiban had a higher clearance of tirofiban. Clinical significance of this observation is not known. ■ The following drugs were coadministered with tirofiban in clinical trials: acebutolol (Monitan), acetaminophen (Tylenol), alprazolam (Xanax), amlodipine, aspirin, atenolol (Tenormin), bromazepam, captopril (Capoten), diazepam (Valium), digoxin, diltiazem (Cardizem), docusate sodium, enalapril (Vasotec), furosemide (Lasix), glyburide, heparin, insulin, isosorbide, lorazepam (Ativan), lovastatin

(Mevacor), metoclopramide (Reglan), metoprolol (Lopressor), morphine, nifedipine (Procardia), nitrate preparations (e.g., nitroglycerin), oxazepam (Serax), potassium chloride, propranolol, ranitidine (Zantac), simvastatin (Zocor), sucralfate (Sulcrate), and temazepam (Restoril). Plasma clearance of tirofiban was not affected by coadministration.

SIDE EFFECTS

Bleeding is the most frequent adverse event and is usually reported as mild oozing. Laboratory findings related to bleeding include decrease in hemoglobin, hematocrit, and platelet count and occult blood in urine and feces. Decreased platelet count may be associated with chills and fever. Other side effects that occur at an incidence of greater than 1%, regardless of drug relationship, are bradycardia, dissection of the coronary artery, dizziness, edema, fever, headache, hypersensitivity reactions (e.g., hives, rash), leg pain, nausea, pelvic pain, sweating, thrombocytopenia, and vasovagal reflex. Platelet decreases have been observed in patients with no prior history of thrombocytopenia upon readministration of GPIIb/IIIa receptor antagonists.

Post-Marketing: Acute decreases in platelet counts, hypersensitivity reactions (including anaphylaxis), intracranial bleeding, pulmonary (alveolar) hemorrhage, retroperitoneal bleeding, spinal-epidural hematoma, hemopericardium. Fatal bleeding events have been reported.

ANTIDOTE

Keep physician informed of laboratory values and side effects. Discontinue the infusion of tirofiban and heparin if any serious bleeding not controllable with pressure occurs. If platelet count drops to below 90,000 mm³, obtain additional platelet counts to exclude pseudothrombocytopenia. If thrombocytopenia is confirmed, discontinue tirofiban and heparin. Platelet transfusion may be required. If a hypersensitivity reaction should occur, discontinue the infusion and treat as indicated by severity (e.g., epinephrine, dopamine, theophylline, antihistamines [e.g., diphenhydramine (Benadryl)], and/or corticosteroids as necessary).

No specific antidote is available. Overdosage should be treated by assessment of the patient's clinical condition and cessation or adjustment of the drug infusion as appropriate. Hemodialysis may be useful in an overdose situation.

TOBRAMYCIN SULFATE **BBW**(toe-brah-MY-sin **SUL**-fayt)**Antibacterial
(aminoglycoside)****pH 3 to 6.5****USUAL DOSE**

3 mg/kg of body weight/24 hr equally divided into 3 doses and given every 8 hours (1 mg/kg every 8 hours). Up to 5 mg/kg equally divided into 3 or 4 doses may be given in life-threatening infections (1.25 mg/kg every 6 hours or 1.67 mg/kg every 8 hours). Reduce to usual dose as soon as feasible. For obese patients, the dosing weight used to calculate the mg/kg dose is achieved by adding the ideal or lean body weight (IBW) to 40% of the excess over IBW.

$$\text{Dosing weight} = \text{IBW} + 0.4 (\text{Total body weight} - \text{IBW})$$

Do not exceed 5 mg/kg/day unless serum levels are monitored.

Studies suggest that a single daily dose of 5 to 7 mg/kg (instead of divided into 2 to 3 doses) may provide higher peak levels and enhance drug effectiveness while actually reducing or having no adverse effects on risk of toxicity. Various procedures for monitoring blood levels are in use. Some health facilities are monitoring with trough levels; others may draw levels at predetermined times and plot the concentration on nomograms. Depending on the protocol in place, doses or intervals may be adjusted. See **Precautions**. **Patients with cystic fibrosis:** One source suggests 7.5 to 10.5 mg/kg/24 hr equally divided into 3 doses and given every 8 hours for 7 to 21 days (2.5 to 3.5 mg/kg every 8 hours).

PEDIATRIC DOSE

In pediatric and neonatal patients, monitor serum levels. Wide interpatient variability; see **Monitor** and **Maternal/Child**.

Over 1 week of age: 6 to 7.5 mg/kg of body weight/24 hr in 3 or 4 equally divided doses (1.5 to 1.89 mg/kg every 6 hours or 2 to 2.5 mg/kg every 8 hours). Another source suggests the same as adult dose.

A single daily dose is also being used in pediatric patients. See comments under **Usual Dose**.

Severe cystic fibrosis: 10 mg/kg/day in equally divided doses every 6 hours (2.5 mg/kg every 6 hours).

NEONATAL DOSE

1 week of age or less: Up to 4 mg/kg of body weight/24 hr in two equal doses every 12 hours (up to 2 mg/kg every 12 hours). Lower doses may be safer because of immature kidney function. 2.5 mg/kg every 18 hours or 3 mg/kg every 24 hours may provide acceptable peak and trough levels in neonates weighing less than 2,000 Gm. See **Maternal/Child**.

DOSE ADJUSTMENTS

Reduce daily dose commensurate with amount of renal impairment and/or increase intervals between injections. Measurement of serum concentrations following a loading dose of 1 mg/kg is suggested. Adjust subsequent doses accordingly. ■ Reduced doses or extended intervals may be required in the elderly. ■ See **Drug/Lab Interactions**.

DILUTION

Prepared solutions equal 10 or 40 mg/mL. Further dilute each single dose in 50 to 100 mL of NS or D5W and administer through an additive tubing. Also available in ADD-Vantage vials for use with ADD-Vantage infusion containers. Reduce volume of diluent proportionately for pediatric patients.

Storage: Store at CRT.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not physically premix with other drugs; administer separately." Inactivated in solution with beta-lactam antibiotics (e.g., cephalosporins, penicillins) and vancomycin; do not mix in the same solution. Appropriate spacing required because of physical **incompatibilities**. See **Drug/Lab Interactions**.

One source suggests the following **compatibilities**:

Additive: Not recommended by manufacturer. Aztreonam (Azactam), bleomycin (Blenoxane), calcium gluconate, ceftazidime (Maxipime), ciprofloxacin (Cipro IV), clindamycin (Cleocin), dextran 40, furosemide (Lasix), imipenem-cilastatin (Primaxin), linezolid (Zyvox), mannitol (Osmitrol), metronidazole (Flagyl IV), ranitidine (Zantac), verapamil. **Y-site:** Acyclovir (Zovirax), alprostadiol, amifostine (Ethyol), amiodarone (Nexterone), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), caspofungin (Cancidas), cefepime (Maxipime), ceftazidime (Teflaro), ceftazidime (Fortaz), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doripenem (Doribax), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), furosemide (Lasix), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), insulin (regular), labetalol, linezolid (Zyvox), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), midazolam (Versed), milrinone (Primacor), morphine, nifedipine (Cardene IV), remifentanyl (Ultiva), tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepa, tigecycline (Tygacil), vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Each single dose, properly diluted, over a minimum of 20 and a maximum of 60 minutes.

ACTIONS

An aminoglycoside antibiotic with potential neuromuscular blocking action. Inhibits protein synthesis in bacterial cells. Bactericidal against specific gram-negative and bacilli, including *Escherichia coli*, *Klebsiella*, *Proteus*, and *Pseudomonas*. Well distributed through all body fluids. Usual half-life is 2 to 2.5 hours. Half-life is prolonged in infants, postpartum females, fever, liver disease and ascites, spinal cord injury, cystic fibrosis, and the elderly; shorter in severe burns. Crosses the placental barrier. Excreted in the kidneys.

INDICATIONS AND USES

Short-term treatment of serious infections caused by susceptible organisms. Indicated infections include septicemia, lower respiratory tract infections, CNS infections (meningitis), intra-abdominal infections (including peritonitis and skin, bone, and skin structure infections), and complicated and recurrent urinary tract infections. ■ Primarily used when penicillin and other less toxic antibiotics are ineffective or contraindicated. ■ Concurrent therapy with a penicillin or cephalosporin sometimes indicated.

CONTRAINDICATIONS

Known tobramycin or aminoglycoside sensitivity. Sulfite sensitivity may be a contraindication.

PRECAUTIONS

Use extreme caution if therapy is required over 7 to 10 days. ■ Sensitivity studies necessary to determine susceptibility of causative organism to tobramycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, tobramycin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ Use caution in infants, children, the elderly, and patients with congestive heart failure,

extensive burns, or muscular disorders. ■ May contain sulfites; use caution in patients with asthma. ■ Potentially nephrotoxic, ototoxic, and neurotoxic. Risk for neurotoxicity (e.g., auditory and vestibular ototoxicity) increased in patients with pre-existing renal damage or in normal renal function with prolonged use. Partial or total irreversible deafness may continue to develop after tobramycin is discontinued. ■ Aminoglycosides are nephrotoxic; risk for nephrotoxicity increased in patients with impaired renal function and in patients who receive high doses or prolonged therapy. ■ Single daily dosing has been used effectively in abdominal, pelvic inflammatory, and GU infections in patients with normal renal function. Not recommended in bacteremia caused by *Pseudomonas aeruginosa*, endocarditis, meningitis, during pregnancy, or in patients less than 6 weeks postpartum. Limited data available for use in all other situations (e.g., burns, pediatric patients or the elderly, cystic fibrosis, renal impairment). ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with tobramycin.

Monitor: Watch for decrease in urine output, rising BUN and SCr, and declining CrCl levels. Dose may require decreasing. ■ Closely monitor renal and eighth cranial nerve function, especially in patients with known or suspected reduced renal function at onset of therapy and in patients who develop signs of renal dysfunction during therapy. Monitor urine for decreased specific gravity, increased protein, and the presence of cells or casts. Serial audiograms are recommended, particularly in high-risk patients. ■ Closely monitor patients with impaired renal function for nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity, convulsions, muscle twitching, numbness, tingling); nephrotoxicity may be reversible. ■ Routine evaluation of hearing is recommended. ■ Narrow range between toxic and therapeutic levels. Periodically monitor peak and trough concentrations to avoid peak serum concentrations above 12 mcg/mL and trough concentrations above 2 mcg/mL (indicates accumulation). With traditional dosing, therapeutic levels are between 4 and 8 mcg/mL depending on site and severity of infection. Accumulation, excessive peak concentrations, advanced age, cumulative doses, and dehydration may contribute to ototoxicity and nephrotoxicity. ■ Maintain good hydration. ■ Monitor serum calcium, magnesium, potassium, and sodium; levels may decline. ■ Closely monitor patients with impaired renal function for nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity); nephrotoxicity may be reversible. ■ In extended treatment, monitoring of serum levels, electrolytes, renal, auditory, and vestibular functions daily is recommended. ■ See [Drug/Lab Interactions](#).

Patient Education: Report promptly dizziness, hearing loss, weakness, or any changes in balance. ■ Consider birth control options. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category D: avoid pregnancy; use during pregnancy and breast-feeding only when absolutely necessary. Potential hazard to fetus. ■ Peak concentrations are generally lower in infants and young children. ■ Use extreme caution in premature infants and neonates; immature kidney function will result in prolonged half-life. ■ See [Precautions](#).

Elderly: Consider less toxic alternatives. ■ Monitor renal function and drug levels carefully. Measurement of CrCl more useful than BUN or SCr to assess renal function. ■ Half-life prolonged; longer intervals between doses may be more important than reduced doses. ■ See [Precautions](#), [Dose Adjustments](#), and [Side Effects](#).

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **beta-lactam antibiotics** (e.g., cephalosporins, penicillins) and **vancomycin**. Synergism may be inconsistent; see [Compatibility](#). ■ Concurrent and/or sequential use topically or systemically with any other neurotoxic, ototoxic, or nephrotoxic agents should be avoided. May have dangerous additive effects with **anesthetics** (e.g., enflurane), **other neuromuscular blocking antibiotics** (e.g., other aminoglycosides [e.g., kanamycin]), **diuretics** (e.g., furosemide [Lasix]), **beta-lactam antibiotics** (e.g., cephalosporins), **vancomycin**, and **many others**. ■ **Neuromuscular blocking muscle relaxants** (e.g., atracurium [Tracrium], succinylcholine) are potentiated by aminoglycosides. **Apnea can occur**. ■ May be antago-

nized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, and tetracycline); bactericidal action may be affected. ■ **Magnesium sulfate** may reduce the antibiotic activity of tobramycin. ■ Aminoglycosides are potentiated by **anticholinesterases** (e.g., edrophonium), **antineoplastics** (e.g., nitrogen mustard, cisplatin). ■ See *Side Effects*.

SIDE EFFECTS

Occur more frequently with impaired renal function, higher doses, prolonged administration, dehydration, in the elderly, and in patients receiving other ototoxic or nephrotoxic drugs.

Dizziness; fever; headache; increased AST, ALT, and serum bilirubin; itching; lethargy; rash; roaring in the ears; seizures; urticaria; vomiting.

Major: Apnea; blood dyscrasias; CDAD; cylindruria; elevated BUN, nonprotein nitrogen (NPN), and creatinine; hearing loss; leukocytosis; neuromuscular blockade; oliguria; proteinuria; seizures (large doses); tinnitus; vertigo.

ANTIDOTE

Notify the physician of all side effects. If minor side effects persist or any major symptom appears, discontinue the drug and notify the physician. Evidence of impaired renal, vestibular, or auditory function requires discontinuation of tobramycin or a dose adjustment. Treatment is symptomatic or a reduction in dose may be required. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. In overdose hemodialysis may be indicated. Monitor fluid balance, CrCl, and plasma levels carefully. Complexation with ticarcillin may be as effective as hemodialysis. Consider exchange transfusion in the newborn. Calcium salts or neostigmine may reverse neuromuscular blockade. Resuscitate as necessary.

TOCILIZUMAB **BBW**

(TOE-si-LIZ-oo-mab)

**Antirheumatic
Monoclonal antibody****Actemra****pH 6.5****USUAL DOSE**

Before initial use, the absolute neutrophil count (ANC) should be equal to or greater than 2,000/mm³, platelet count should be equal to or greater than 100,000/mm³, and ALT and AST should be no more than 1.5 times the ULN.

Initial adult dose in rheumatoid arthritis: 4 mg/kg as an IV infusion once every 4 weeks. Increase dose to 8 mg/kg every 4 weeks based on clinical response. May be used in combination with disease-modifying anti-rheumatic drugs (DMARDs) such as methotrexate or as monotherapy. Doses above 800 mg per infusion are not recommended.

Systemic juvenile idiopathic arthritis (SJIA): Administer as an IV infusion once every 2 weeks. May be used alone or in combination with methotrexate. Do not adjust dose based on a single-visit body weight; weight may fluctuate.

Weight less than 30 kg: 12 mg/kg.

Weight equal to or more than 30 kg: 8 mg/kg.

DOSE ADJUSTMENTS

There is a trend toward a higher clearance with increasing body weight; see [Usual Dose](#). No specific dose adjustments required based on age, gender, race, or mild renal impairment.

- Withhold therapy in patients with severe infections, an opportunistic infection, or sepsis.
- Dose reduction has not been studied in SJIA. Dose interruptions are recommended for liver enzyme abnormalities, low neutrophil counts, and low platelet counts in patients with SJIA at levels similar to those outlined in the following charts for patients with rheumatoid arthritis (RA). May require interrupting or discontinuing tocilizumab and/or other concomitant medications (e.g., methotrexate) until evaluation of the clinical situation.
- The effects of moderate to severe renal impairment or hepatic impairment have not been studied.
- The following charts outline dose adjustments for adults with RA based on ANC, platelets, and liver function tests.

Tocilizumab Dose Recommendations for Low Absolute Neutrophil Count (ANC)	
Lab Value (cells/mm³)	Recommendation
ANC >1,000/mm ³	Maintain dose.
ANC 500 to 1,000/mm ³	Interrupt tocilizumab dosing. When ANC >1,000/mm ³ , resume tocilizumab at 4 mg/kg and increase to 8 mg/kg as clinically appropriate.
ANC <500/mm ³	Discontinue tocilizumab.

Tocilizumab Dose Recommendations for Low Platelet Count	
Lab Value (cells/mm³)	Recommendation
Platelet count 50,000 to 100,000/mm ³	Interrupt tocilizumab dosing. When platelet count is >100,000/mm ³ , resume tocilizumab at 4 mg/kg and increase to 8 mg/kg as clinically appropriate.
Platelet count <50,000/mm ³	Discontinue tocilizumab.

Tocilizumab Dose Recommendations for Liver Enzyme Abnormalities	
Lab Value	Recommendation
>1 to 3 × ULN	Dose modify concomitant DMARDs if appropriate. For persistent increases in this range, reduce tocilizumab dose to 4 mg/kg or interrupt dosing until ALT and/or AST have normalized.
>3 to 5 × ULN (confirmed by repeat testing)	Interrupt tocilizumab dosing until <3 × ULN, and follow recommendations above for >1 to 3 × ULN. For persistent increases >3 × ULN, discontinue tocilizumab.
>5 × ULN	Discontinue tocilizumab.

DILUTION

Available as a solution for single use (20 mg/mL). For adults and SJIA patients weighing 30 kg or more, the solution must be further diluted to 100 mL in NS. For SJIA patients weighing less than 30 kg, dilute to 50 mL in NS. From a 100-mL (or 50-mL) infusion bag or bottle, withdraw a volume of NS equal to the volume of solution required for the calculated dose. Slowly add tocilizumab and avoid foaming by gently inverting the bag or bottle. Bring fully diluted solution to RT before administration.

Filters: Specific information not available.

Storage: Refrigerate unopened vials in original carton at 2° to 8° C (36° to 46° F). Do not use beyond expiration date. Protect from light. Do not freeze. Fully diluted solution may be refrigerated or stored at RT for up to 24 hours. Protect from light. Discard unused solution.

COMPATIBILITY

Manufacturer states, “Fully diluted solutions are **compatible** with polypropylene, polyethylene, and polyvinyl chloride infusion bags and glass infusion bottles. Tocilizumab should not be infused concomitantly in the same intravenous line with other drugs.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 60 minutes.

ACTIONS

A recombinant humanized anti-human interleukin 6 (IL-6) receptor monoclonal antibody. Binds specifically to both soluble and membrane-bound IL-6 receptors. Inhibits IL-6–mediated signaling through these receptors. IL-6 is a pro-inflammatory cytokine produced by a variety of cell types. IL-6 is also produced by synovial and endothelial cells leading to local production of IL-6 in joints affected by inflammatory processes such as rheumatoid arthritis. IL-6 has been shown to be involved in diverse physiologic processes such as T-cell activation, induction of immunoglobulin secretion, initiation of hepatic acute phase protein synthesis, and stimulation of hematopoietic precursor cell proliferation and differentiation. Following administration, increases in hemoglobin and decreases in C-reactive protein, rheumatoid factor, erythrocyte sedimentation rate, and serum amyloid A were observed. ANC counts decreased to the nadir 3 to 5 days after administration, and neutrophils recovered toward baseline in a dose-dependent manner. Steady state is reached with the first administration. It undergoes biphasic elimination from the circulation. Half-life is concentration dependent and ranges from 11 to 13 days depending on the dose administered. Half-life in patients with SJIA is up to 23 days.

INDICATIONS AND USES

Treatment of adults with moderately to severely active rheumatoid arthritis who have had an inadequate response to one or more disease-modifying anti-rheumatic drugs (DMARDs), such as cyclophosphamide (Cytoxan), cyclosporine (Sandimmune), methotrexate, and biologics (e.g., adalimumab [Humira], etanercept [Enbrel], infliximab [Remicade], rituximab [Rituxan]). ■ Treatment of patients 2 years of age and older with active systemic juvenile idiopathic arthritis (SJIA).

CONTRAINDICATIONS

Known hypersensitivity to tocilizumab.

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patients and respond to any medical emergency. ■ Serious and sometimes fatal infections due to bacterial, mycobacterial, invasive fungal, viral, protozoal, or other opportunistic pathogens have been reported. Deaths have occurred. The most common serious infections included bacterial arthritis, cellulitis, diverticulitis, gastroenteritis, herpes zoster, pneumonia, sepsis, and UTIs. Opportunistic infections reported with tocilizumab include aspergillosis, candidiasis, cryptococcus, pneumocystosis, and tuberculosis (TB). Patients were often taking concomitant immunosuppressants such as methotrexate or corticosteroids, which may have predisposed them to infection. ■ Tocilizumab should not be administered in patients with an active infection, including localized infections. Assess the risks and benefits of tocilizumab before initiating in patients with chronic or recurrent infection, patients who have been exposed to tuberculosis, patients with a history of a serious or an opportunistic infection, patients who have resided or traveled in areas of endemic tuberculosis or endemic mycoses, or patients with underlying conditions that may predispose them to infection. ■ Evaluate patients for TB risk factors and latent TB before initiating therapy; see **Monitor**. ■ Anti-rheumatic therapies have been associated with hepatitis B reactivation. Viral reactivation (e.g., herpes zoster) occurred during clinical studies; patients who screened positive for hepatitis were excluded. ■ Has not been studied in patients with active hepatic disease or hepatic impairment, including patients with positive HBV (hepatitis B virus) or HCV (hepatitis C virus) serology. Use is not recommended. ■ Has not been studied in patients with moderate to severe renal impairment. ■ Use caution in patients who may be at risk for GI perforation (e.g., diverticulitis [primarily in RA patients]) and in patients with pre-existing or recent-onset demyelinating disorders (e.g., multiple sclerosis, chronic inflammatory demyelinating polyneuropathy). ■ Hypersensitivity reactions, including anaphylaxis and death, have been reported. Emergency medical equipment and medications for treating these reactions must be readily available. ■ Tocilizumab is associated with increases in lipids. ■ Infusion-related reactions have occurred; see **Side Effects**. ■ A small number of patients have developed binding antibodies to tocilizumab. Hypersensitivity reactions leading to withdrawal have been reported. ■ Treatment may result in an increased risk of malignancy.

Monitor: Evaluate patients for TB risk factors and latent TB with a TB skin test before tocilizumab use and during therapy. Patients testing positive in TB screening should be treated with a standard TB regimen before initiating therapy with tocilizumab. Include patients with a history of latent or active TB when an adequate course of treatment cannot be confirmed and patients who have a negative test for latent TB but have risk factors for TB. Consultation with a specialist in TB diagnosis and treatment is encouraged. ■ Screening for viral hepatitis may be indicated. ■ In RA patients, obtain baseline CBC, platelets, and liver function tests (e.g., ALT, AST, bilirubin). Consider obtaining a baseline bilirubin. Monitor neutrophils, platelets, ALT, and AST every 4 to 8 weeks. In SJIA patients, obtain baseline CBC, platelets, and liver function tests. Monitor neutrophils, platelets, ALT, and AST before the second infusion and every 2 to 4 weeks. ■ In both RA and SJIA patients, obtain baseline lipid studies (e.g., cholesterol [HDL, LDL, and total], triglycerides). Repeat in 4 to 8 weeks and then at 24-week intervals. Elevated lipids respond to lipid-lowering agents (e.g., simvastatin [Zocor]). ■ Closely monitor for S/S of infection during and after treatment with tocilizumab; patients with invasive fungal infections may present with disseminated, rather than localized, disease; S/S may be lessened due to suppression of the acute phase reactants. Therapy should be interrupted if a serious infection, an opportunistic infection, or sepsis develops, and appropriate evaluation and treatment should be initiated promptly. ■ Monitor for S/S of hypersensitivity or infusion-related reactions (e.g., anaphylaxis, hypotension, pruritus, rash, urticaria, or wheezing); most hypersensitivity reactions have occurred between the second and fourth infusion but can occur at any time, even if they have not occurred with earlier infusions;

see **Side Effects**. ■ Monitor for S/S of GI perforation (e.g., new-onset abdominal pain). ■ Monitor for S/S potentially indicative of demyelinating disorders. ■ Do not administer live virus vaccines. All patients, especially SJIA patients, should be brought up-to-date with all immunizations before beginning therapy. ■ See **Precautions** and **Drug/Lab Interactions**.

Patient Education: Read FDA-approved medication guide before starting therapy. ■ Promptly report S/S of an allergic reaction (e.g., rash, itching, wheezing), infusion reaction (e.g., dizziness, headache), or infection (e.g., chill, cough, fever). Report severe, persistent abdominal pain promptly. ■ Discuss previous infections, current infections, or exposure to TB. ■ Routine laboratory monitoring required.

Maternal/Child: Category C: use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ A pregnancy registry has been established; contact manufacturer. ■ Discontinue breast-feeding. ■ Safety and effectiveness not established for use in pediatric patients with conditions other than SJIA and in SJIA patients less than 2 years of age.

Elderly: Incidence of infection is higher in the elderly. Use caution; see **Precautions**.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. Avoid concurrent use with a **TNF antagonist** (e.g., adalimumab [Humira], etanercept [Enbrel], infliximab [Remicade]); may increase immunosuppression and risk of infection. ■ Methotrexate, NSAIDs (e.g., naproxen [Naprosyn, Aleve], ibuprofen [Advil, Motrin]), and corticosteroids (e.g., prednisone) do not appear to influence tocilizumab clearance. ■ Has no clinically significant effect on methotrexate exposure. ■ Inhibition of IL-6 signaling in patients treated with tocilizumab may restore CYP450 activities to higher levels, resulting in an increased metabolism of drugs that are CYP450 substrates. Concurrent use showed an increase in metabolism and lower serum concentrations of **omeprazole** (Prilosec) and **simvastatin** (Zocor). This effect may be clinically relevant with CYP450 substrates with a narrow therapeutic index, in which the dose is individually adjusted (e.g., **warfarin** [Coumadin], **cyclosporine** [Sandimmune], **theophylline**). Therapeutic monitoring of effect (INR) and/or serum concentrations is indicated to adjust the dose of these drugs with initiation or termination of tocilizumab. Use caution with CYP3A4 substrate drugs in which a decrease in effectiveness is undesirable (e.g., **atorvastatin** [Lipitor], **lovastatin** [Mevacor], **oral contraceptives**). The effect of tocilizumab on CYP450 enzyme activity may persist for several weeks after therapy is discontinued. ■ Do not administer **live virus vaccines**.

SIDE EFFECTS

RA: Most common adverse reactions include headache, hypertension, increased transaminases (ALT, AST), nasopharyngitis, and upper respiratory tract infections. The most common serious infections include bacterial arthritis, cellulitis, diverticulitis, gastroenteritis, herpes zoster, pneumonia, sepsis, and UTIs. Most common side effects that required discontinuation of therapy were increased hepatic transaminase values and serious infections. Infusion-related reactions have been reported. Hypertension frequently occurred during infusion, and headache and skin reactions (e.g., pruritus, rash, urticaria) were reported within the next 24 hours. Hypersensitivity reactions (e.g., anaphylactoid and anaphylactic) did occur in a few patients. Other side effects reported include bronchitis, conjunctivitis, cough, dizziness, dyspnea, elevated lipids, gastric ulcer, gastritis, GI perforation, hypothyroidism, increased total bilirubin, increased weight, leukopenia, mouth ulceration, nephrolithiasis, neutropenia, oral herpes simplex, peripheral edema, stomatitis, thrombocytopenia, and upper abdominal pain.

SJIA: Most common adverse reactions included diarrhea, headache, nasopharyngitis, and upper respiratory tract infections. Anaphylaxis, decreased platelet count, development of anti-tocilizumab antibodies, increased liver function tests and lipids, infections, infusion reactions, macrophage activation syndrome (MAS), and neutropenia have been reported.

Post-Marketing: Fatal anaphylaxis.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. During clinical studies, most infusion-related reactions were mild to moderate. Interrupt therapy for decreases in ANC and platelets and increases in liver function studies as outlined in Dose Adjustments. Therapy may need to be interrupted in patients who develop infections. Discontinue tocilizumab for any serious reaction or infection. Treat infusion and hypersensitivity reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Resuscitate as necessary.

TOPOTECAN HYDROCHLORIDE **BBW**

(toh-poh-TEE-kan hy-droh-KLOR-eyed)

**Antineoplastic
(topoisomerase I inhibitor)****Hycamtin****pH 2.5 to 3.5****USUAL DOSE**

Before giving the initial dose, the baseline neutrophil count must be at least 1,500/mm³ and baseline platelet count must be at least 100,000/mm³.

Ovarian cancer and small-cell lung cancer: 1.5 mg/M²/day as an infusion each day for 5 consecutive days (Days 1 through 5 of a 21-day course). Begin the second course on Day 22. A minimum of four courses is recommended; median time to response has been 9 to 12 weeks for ovarian cancer and 5 to 7 weeks for small-cell lung cancer. See [Dose Adjustments](#).

Cervical cancer: 0.75 mg/M² as an infusion on Days 1, 2, and 3. On Day 1 follow with cisplatin 50 mg/M². Repeat every 21 days. See cisplatin monograph for prehydration requirements.

Non-small-cell lung cancer (unlabeled): 1.5 mg/M²/day as an infusion each day for 5 consecutive days. Repeat every 21 days.

Myelodysplastic syndrome/chronic myelomonocytic leukemia (unlabeled): 2 mg/M²/day as a continuous 24-hour infusion. Repeat every day for 5 consecutive days. Repeat every 3 to 4 weeks until remission, then repeat once a month.

DOSE ADJUSTMENTS

Do not begin subsequent courses of topotecan until neutrophils recover to more than 1,000/mm³, platelets recover to 100,000/mm³, and hemoglobin recovers to 9 mg/dL (with transfusion if necessary). ■ No dose adjustment required in patients with impaired hepatic function (bilirubin between 1.5 and 10 mg/dL). ■ Reduce dose to 0.75 mg/M² in patients with moderate impaired renal function (CrCl 20 to 39 mL/min). There are inadequate data at this time to recommend a dose in severe renal impairment. ■ Dose adjustment may be required in the elderly because of age-related renal impairment.

Ovarian cancer and small-cell lung cancer: If severe neutropenia occurs (neutrophils less than or equal to 500/mm³) during any course, either reduce dose for all subsequent courses by 0.25 mg/M² (to 1.25 mg/M²) or, before resorting to dose reduction, give G-CSF (filgrastim) starting with Day 6 (must be at least 24 hours after the final dose of that course). ■ If platelet count falls below 25,000/mm³, reduce dose for all subsequent courses by 0.25 mg/M² (to 1.25 mg/M²).

Cervical cancer: Dose adjustment in subsequent cycles is drug specific.

Topotecan: If severe febrile neutropenia occurs (neutrophils less than 1,000 cells/mm³, temperature equal to or greater than 38° C [100.4° F]), either reduce the dose of topotecan by 20% to 0.6 mg/M² for subsequent courses or give G-CSF (filgrastim) starting on Day 4 (24 hours after completion of topotecan). If febrile neutropenia occurs despite the

use of filgrastim, further reduce dose to 0.45 mg/M² for subsequent courses. ■ If platelet count falls below 10,000 cells/mm³, reduce dose to 0.6 mg/M².

Cisplatin: See cisplatin monograph for specific dose adjustments. ■ Topotecan in combination with cisplatin for treatment of cervical cancer should be initiated only in patients with a SCr equal to or less than 1.5 mg/dL. Discontinue cisplatin for a SCr greater than 1.5 mg/dL. Insufficient data available regarding continuation of topotecan as monotherapy after discontinuation of cisplatin.

DILUTION

Specific techniques required; see Precautions. Reconstitute each 4-mg vial with 4 mL of SWFI (1 mg/mL). Withdraw the calculated dose and further dilute in 50 to 100 mL of NS or D5W.

Filters: No data available from manufacturer.

Storage: Store unopened vials in cartons protected from light at CRT. Reconstituted solutions contain no preservative; use immediately. Solutions diluted for infusion are stable at room temperature in soft light for 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Y-site: Carboplatin (Paraplatin), cisplatin (Platinol), cyclophosphamide (Cytoxan), doxorubicin (Adriamycin), etoposide (VePesid), gemcitabine (Gemzar), granisetron (Kytril), ifosfamide (Ifex), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), palonosetron (Aloxi), prochlorperazine (Compazine), ticarcillin/clavulanate (Timentin), vincristine.

RATE OF ADMINISTRATION

A single dose as an infusion evenly distributed over 30 minutes.

Myelodysplastic syndrome/chronic myelomonocytic leukemia (unlabeled): See Usual Dose.

ACTIONS

A new class of antineoplastic agent that inhibits the enzyme topoisomerase I required for DNA replication. A topoisomerase I inhibitor, it is a semi-synthetic derivative of camptothecin. Hydrolyzed to its active lactone form. Causes cell death by damaging DNA produced during the S-phase of cell synthesis. Distributes evenly between plasma and blood cells and is found in significant quantities in CSF. Minor additional metabolism occurs in the liver. Terminal half-life is from 2 to 3 hours. Moderately bound to plasma protein (35%). Some excretion in urine and bile.

INDICATIONS AND USES

Treatment of metastatic carcinoma of the ovary after failure of initial or subsequent chemotherapy. ■ Treatment of small-cell lung cancer sensitive disease after failure of first-line chemotherapy. ■ In combination with cisplatin for treatment of stage IV-B, recurrent or persistent cervical cancer not amenable to curative treatment with surgery and/or radiation therapy.

Unlabeled uses: Treatment of non-small-cell lung cancer. ■ Treatment of myelodysplastic syndrome and chronic myelomonocytic leukemia (CMML).

CONTRAINDICATIONS

Severe hypersensitivity reactions (e.g., anaphylactoid) to topotecan or any of its components. Not recommended for use during pregnancy, breast-feeding, or in patients with severe bone marrow suppression.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be available to meet any medical emergency. ■ Must have adequate bone marrow reserves. Bone marrow suppression (primarily neutropenia) is the dose-limiting toxicity. Anemia, Grade 3 and 4 neutropenia, pancytopenia, and thrombo-

cytopenia have been reported; see **Monitor**. ■ Use with caution in patients who have received previous cytotoxic drug therapy or radiation therapy. ■ Use with caution in impaired renal function; clearance decreased. ■ Use caution in patients with a history of allergies. ■ Fatalities have occurred from neutropenia that resulted in neutropenic colitis; see **Monitor**. ■ Fatalities have occurred from interstitial lung disease (ILD); risk increased in patients with a history of ILD, lung cancer, pulmonary fibrosis, thoracic exposure to radiation, and the use of pneumotoxic drugs and/or colony-stimulating factors.

Monitor: Baseline neutrophil count must be at least 1,500 cells/mm³ and platelets at least 100,000 cell/mm³ before the initial dose. ■ Obtain a baseline CBC with differential and platelets. ■ Monitor before each course and frequently during treatment. Platelet count must be 100,000/mm³, neutrophils 1,000/mm³, and hemoglobin 9 mg/dL before a course of therapy can be repeated. Anemia is frequent and transfusion is often indicated. ■ Baseline CrCl and BUN suggested. ■ Monitor vital signs. ■ Maintain adequate hydration. ■ Nausea and vomiting are frequent and may be severe; use prophylactic administration of antiemetics to increase patient comfort. ■ Observe closely for S/S of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile or nonfebrile neutropenic patient. ■ Not a vesicant, but monitor injection site for inflammation and/or extravasation. ■ Median duration of neutropenia is 7 days. Expected nadir for neutrophils is 12 days, 15 days for platelets and hemoglobin. ■ Monitor for S/S of ILD (e.g., cough, dyspnea, fever, and/or hypoxia). ■ Monitor for signs of neutropenic colitis (e.g., fever, neutropenia, and abdominal pain). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Platelet transfusions may be required. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Nonhormonal birth control recommended. ■ Report any unusual or unexpected symptoms or side effects as soon as possible (e.g., signs of infection [e.g., chills, fever, night sweats] or signs of bleeding [e.g., bruising, black tarry stools]). ■ May cause loss of strength or fatigue. Use caution when driving or operating machinery. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; can cause fetal harm. ■ Discontinue breastfeeding. ■ Safety and effectiveness for use in pediatric patients not established. One study showed that severe myelotoxicity may occur at lower doses in pediatric patients than in adults.

Elderly: Safety and effectiveness similar to younger adults; however, greater sensitivity of some older adults cannot be ruled out. ■ Consider age-related renal impairment; see **Dose Adjustments**. Monitoring of renal function may be useful.

DRUG/LAB INTERACTIONS

May cause severe prolonged myelosuppression and Grade 3 or 4 nonhematologic effects (e.g., diarrhea, lethargy, nausea, vomiting) with **cisplatin**. Interaction on myelosuppression is sequence dependent. Coadministration of a platinum agent on Day 1 of topotecan therapy required lower doses of each agent compared to coadministration on Day 5 of topotecan therapy. ■ Concurrent administration of **G-CSF (filgrastim)** can prolong the duration of neutropenia. If used, do not administer before Day 6, at least 24 hours after the final dose of topotecan. ■ Concurrent or consecutive administration of **other bone marrow suppressants** (e.g., cyclophosphamide [Cytosan], paclitaxel [Taxol]), **radiation therapy or agents that cause blood dyscrasias** (e.g., amphotericin B, anticonvulsants [e.g., phenytoin, valproic acid], NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]) may produce additive bone marrow suppression. Dose reduction may be required based on blood cell counts. ■ Concurrent use of **immunosuppressants** (e.g., tacrolimus [Prograf], **corticosteroids**, **muromonab CD-3** [Orthoclone]) may increase the risk of infection. ■ **Probenecid** may decrease renal clearance and increase the risk of toxicity. ■ Do not administer **live or killed virus vaccines**.

SIDE EFFECTS

Bone marrow suppression, primarily neutropenia, is the dose-limiting toxicity of topotecan. Abdominal pain; alopecia; anorexia; asthenia; bone marrow toxicity such as anemia (less than 10 mg/dL [96%], less than 8 mg/dL [40%]), leukopenia (less than 3,000/mm³ [98%], less than 1,000/mm³ [32%]), neutropenia (less than 1,500/mm³ [98%], less than 500/mm³ [81%]), thrombocytopenia (less than 75,000/mm³ [63%], less than 25,000/mm³ [26%]); coagulation; constipation; coughing; diarrhea; dyspnea; fatigue; fever; headache; hemorrhage; infection with neutropenia less than 500/mm³ (26%); nausea (77%); neuropathy; pain; paresthesia; rash; stomatitis; transient increases in AST and ALT; vomiting (58%); weakness.

Post-Marketing: Abdominal pain associated with neutropenic colitis, hypersensitivity reactions (including anaphylaxis), interstitial lung disease, severe bleeding, skin and subcutaneous tissue disorders (e.g., angioedema, severe dermatitis, severe pruritus).

ANTIDOTE

Keep physician informed of all side effects. Withhold topotecan until myelosuppression has improved to minimum requirements. Neutropenia recovery may be aided by G-CSF (filgrastim, pegfilgrastim [Neulasta]) under specific conditions; see [Dose Adjustments](#) or [Drug/Lab Interactions](#). Anemia required RBC or whole blood transfusions in 50% of patients. Thrombocytopenia may require platelet transfusion. Death can result from the progression of many side effects. Discontinue topotecan if a new diagnosis of ILD is confirmed. No known antidote for overdose. Symptomatic and supportive treatment is indicated. Treat hypersensitivity reactions with oxygen, epinephrine, corticosteroids, and antihistamines.

TORSEMIDE INJECTION

(TOR-seh-myd in-JEK-shun)

**Diuretic (loop)
Antihypertensive****Demadex****pH over 8.3****USUAL DOSE**

IV and oral doses are therapeutically equivalent. Oral dose can replace an IV dose at any time. If diuretic response is not adequate, titrate the recommended dose upward by doubling the dose until desired response achieved or maximum suggested dose reached.

Edema of congestive heart failure: 10 to 20 mg once daily. See general instructions above; single doses over 200 mg have not been adequately studied.

Edema of chronic renal failure: 20 mg once daily. See general instructions above; single doses over 200 mg have not been adequately studied.

Hepatic cirrhosis with ascites: 5 to 10 mg once daily. To prevent hypokalemia and metabolic alkalosis give in combination with an aldosterone antagonist (e.g., spironolactone [Aldactone]) or a potassium-sparing diuretic (e.g., dyazide). See general instructions above; single doses over 40 mg have not been adequately studied.

Hypertension: 5 mg once daily. May be increased to 10 mg in 4 to 6 weeks if BP reduction is inadequate. If response is still inadequate, the addition of other antihypertensive agents is recommended instead of larger doses of torsemide. Usually given PO.

Continuous infusion: Studies used a 100-mg dose divided as follows. A **loading dose** of 25 mg (2.5 mL) as an IV injection over 2 minutes (25% of total daily dose). Follow with an infusion at 3.1 mg/hr (10 mL/hr) or 75% of total daily dose equally distributed over 24 hours.

DOSE ADJUSTMENTS

Higher doses may be required in renal failure. See [Drug/Lab Interactions](#).

DILUTION

Available as 10 mg/mL. May be given undiluted. May be given through Y-tube or three-way stopcock of infusion set. May be further diluted in NS, ½NS, or D5W. For a 75-mg dose (75% of the 100-mg total daily dose), dilute 7.5 mL to a total volume of 240 mL. 200 mg in 250 mL diluent yields 0.8 mg/mL. 50 mg in 500 mL diluent yields 0.1 mg/mL.

Storage: Store at CRT. Do not freeze.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends flushing the IV line before and after torsemide injection to avoid **incompatibilities** caused by alkaline pH.

One source suggests the following **compatibilities**:

Y-site: Milrinone (Primacor), nesiritide (Natreacor).

RATE OF ADMINISTRATION

Ototoxicity (usually reversible) has occurred with too-rapid injection and doses over 200 mg. Flush IV line with NS before and after administration.

IV injection: Each 200 mg or fraction thereof over 2 minutes.

Continuous infusion: Balance of daily dose after loading dose equally distributed over 24 hours. For a 75-mg dose, the rate would be 3.1 mg (10 mL/hr) for 24 hours.

ACTIONS

A sulfonamide type loop diuretic. Acts from within the ascending portion of the loop of Henle to excrete water, sodium, chlorides, and some potassium. Diuretic action correlates better with the rate of drug excretion in urine than with plasma concentration. Will produce diuresis in alkalosis or acidosis. Effects begin within 10 minutes and peak within

1 hour. Diuresis lasts 6 to 8 hours. Highly protein bound. Metabolized by the liver (80%). 20% eliminated via urinary excretion. Other loop diuretics cross the placental barrier and are secreted in breast milk; specific information not available for torsemide.

INDICATIONS AND USES

Treatment of edema associated with congestive heart failure, cirrhosis of the liver with ascites, and chronic renal failure. Used when a rapid onset of diuresis is desired or when oral administration is impractical. ■ Treatment of hypertension.

CONTRAINDICATIONS

Known hypersensitivity to torsemide or to sulfonyleureas and in anuric patients.

PRECAUTIONS

Tests to determine serum levels of torsemide not widely available. ■ In patients with congestive heart failure and/or renal failure, a smaller dose is actually delivered to the ascending loop of Henle, resulting in less response at any given dose. ■ Use caution and improve basic condition first in hepatic coma, electrolyte depletion, and advanced cirrhosis of the liver. Initiation of therapy in the hospital is preferred. ■ Use extreme caution in patients sensitive to bumetanide, furosemide (Lasix), or sulfonamides (including thiazide diuretics); may also be sensitive to torsemide. ■ In patients with hepatic disease with cirrhosis and ascites use a potassium-sparing diuretic (e.g., dyazide) or an aldosterone antagonist (e.g., spironolactone) concurrently to prevent hypokalemia and metabolic alkalosis. ■ Use caution in acute MI; excessive diuresis may precipitate shock. ■ In nonanuric renal failure, may cause marked increases in water and sodium excretion without impacting steady-state fluid retention. High doses (500 to 1,200 mg) have caused seizures. ■ May activate or exacerbate systemic lupus erythematosus. Chronic use in renal or hepatic disease has not been adequately studied. ■ Antihypertensive effects greater in black patients.

Monitor: Monitor BP frequently, especially during initial therapy. May precipitate excessive diuresis with water and electrolyte depletion. Dehydration, electrolyte imbalance, hypovolemia, prerenal azotemia, embolism, or thrombosis can occur. Routine checks on electrolyte panel, CO₂, and BUN are necessary during therapy. Potassium chloride and/or magnesium replacement may be required. ■ Risk of hypokalemia greatest in patients with cirrhosis of the liver, during brisk diuresis, with inadequate oral electrolyte intake, or with concurrent administration of corticosteroids (e.g., prednisone). ■ May increase blood glucose, serum cholesterol, and triglycerides. ■ Slight increases in BUN, SCr, and uric acid may occur, usually reverse when therapy discontinued. Sudden changes in fluid and electrolyte balance may precipitate hepatic coma in patients with hepatic disease and ascites. ■ Rarely precipitates an attack of gout. ■ See [Drug/Lab Interactions](#).

Patient Education: Hypotension may cause dizziness; request assistance with ambulation. ■ May cause a decrease in potassium levels and require a supplement. ■ Possible skin photosensitivity. Avoid unprotected exposure to sunlight. ■ Report cramps, dizziness, muscle weakness, or nausea promptly.

Maternal/Child: Category B: use only if clearly needed during pregnancy; safety for use not established. ■ Safety for use during breast-feeding not established; other loop diuretics suggest discontinuing breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established. Administration of other loop diuretics to premature infants with edema due to patent ductus arteriosus and hyaline membrane disease may have caused renal calcifications; also other loop diuretics may have increased the risk of persistent patent ductus arteriosus in premature infants with hyaline membrane disease. Torsemide has not been studied in these situations.

Elderly: No specific age-related differences; dose adjustment not indicated. May be more susceptible to dehydration; observe carefully. ■ Avoid rapid contraction of plasma volume and hemoconcentration. May cause thromboembolic episodes (e.g., CVA, pulmonary emboli).

DRUG/LAB INTERACTIONS

Concurrent administration with **high-dose salicylates** may cause salicylate toxicity. ■ Probenicid decreases the diuretic activity of torsemide. ■ May reduce renal clearance of spironolactone, but dose adjustment not required. ■ Has been administered with beta-blockers (e.g., atenolol), ACE inhibitors (e.g., captopril), calcium-channel blockers (e.g., diltiazem), cimetidine (Tagamet), digoxin, and nitrates (e.g., nitroglycerin) without new or unexpected adverse events; however, torsemide has caused severe hypotension with **ACE inhibitors** in sodium- or volume-depleted patients. ■ Does not affect protein binding of glyburide (DiaBeta) or coumarin derivatives (e.g., warfarin). ■ May cause excessive potassium depletion with **amphotericin B** (Abelcet, conventional), **corticosteroids**, **thiazide diuretics** (e.g., hydrochlorothiazide [HydroDiuril]). Monitor electrolytes closely. ■ May cause cardiac arrhythmias with **digoxin and other antiarrhythmic agents** secondary to potassium and magnesium depletion. ■ **NSAIDs** (e.g., indomethacin [Indocin], ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]) **or salicylates** (e.g., aspirin) may cause retention of sodium and water and may decrease diuretic and antihypertensive effects. ■ Antihypertensive effects may be increased by any **hypotension-producing agent** (e.g., lidocaine, nitroglycerin, nitroprusside sodium, paclitaxel); reduced dose of the antihypertensive agent or both drugs may be indicated. ■ May potentiate **propranolol, salicylates, muscle relaxants** (e.g., atracurium [Tracrium]), and hypotensive effect of **other diuretics**. ■ May increase ototoxicity in doses exceeding the usual or in conjunction with **ototoxic drugs** (e.g., cisplatin, aminoglycosides [e.g., amikacin, streptomycin, gentamicin], ethacrynic acid [Edecrin]). ■ May increase nephrotoxicity if given concurrently with **any other nephrotoxic agent** (e.g., amphotericin B, aminoglycosides [e.g., gentamicin], foscarnet [Foscavir], rifampin [Rifadin]). Concurrent use with **amphotericin B** is not recommended, especially in patients with some impaired renal function. ■ Effects of **warfarin** (Coumadin) are increased; may require dose adjustment. ■ May be inhibited by **phenytoin** (Dilantin). ■ May reduce excretion of **lithium** and cause lithium toxicity. ■ May increase or decrease effectiveness of **theophyllines**.

SIDE EFFECTS

Arthralgia, constipation, cough, diarrhea, dizziness, dyspepsia, ECG abnormalities, edema, electrolyte imbalance, esophageal hemorrhage, excessive thirst, excessive urination, headache, hyperglycemia, hyperuricemia, hypokalemia, impotence, insomnia, myalgia, nervousness, ototoxicity (usually reversible), rhinitis, sore throat, and tinnitus have all been reported. Hypersensitivity reactions can occur. Hypocalcemia and hypomagnesemia have been minimal with usual doses.

Major: Anorexia, dizziness, drowsiness, dryness of the mouth, hypotension, increased BUN, lethargy; mental confusion, muscle cramps, fatigue, or pain; nausea and vomiting, oliguria, restlessness, tachycardia, thirst, or weakness may indicate severe electrolyte imbalance, hypovolemia, or prerenal azotemia.

Overdose: Circulatory collapse, dehydration, excessive diuresis, hemoconcentration, hypochloremic alkalosis, hyperchloremia or hypochloremia, hyperkalemia or hypokalemia, hypomagnesemia, hypernatremia or hyponatremia, hypotension, hypovolemia, vascular thrombosis, and embolism.

ANTIDOTE

Notify the physician of any side effect. Depending on severity the physician may treat the side effects symptomatically and either continue or discontinue torsemide. Fluid and electrolyte replacement may be indicated. If side effects are progressive or any major side effects or signs of overdose appear, discontinue the drug immediately and notify the physician. Treatment of overdose is symptomatic and aggressive. Hemodialysis is not effective in overdose. Resuscitate as necessary. Torsemide may be restarted at a lower dose after the patient is stable.

TOSITUMOMAB AND IODINE-131 TOSITUMOMAB **BBW**

(toes-ih-**TOO**-moh-mab)

Radiopharmaceutical
Monoclonal antibody
Antineoplastic

Bexxar

pH 7.2 and 7

USUAL DOSE

A therapeutic regimen consisting of pretesting and premedication followed by two components (tositumomab and iodine-131 tositumomab) administered in two specific steps: the dosimetric step, followed 7 to 14 days later by a therapeutic step. Each step consists of a sequential infusion of tositumomab followed by I-131 tositumomab. Intended as a single course of treatment; see [Limitations of Use](#).

PRETESTING

Pretesting required; see [Monitor](#). Do not administer to patients with a platelet count less than 100,000 cells/mm³, neutrophils less than 1,500 cells/mm³, or greater than 25% lymphoma marrow involvement and/or impaired bone marrow reserve.

PREMEDICATION

Prophylaxis to reduce the risk of hypothyroidism: Thyroid-protective agents *must be started 24 hours before the dosimetric step begins and continued daily for a minimum of 2 weeks after the therapeutic dose is completed*. May be *one of three* agents: saturated solution of potassium iodide (SSKI) 4 drops PO three times daily, Lugol's solution 20 drops PO three times daily, or potassium iodide tablets 130 mg PO daily. Patients who cannot tolerate these thyroid-blocking agents may not begin the regimen. *Do not give dosimetric dose unless the patient has received at least 3 doses of SSKI, three doses of Lugol's solution, or one 130-mg potassium iodide tablet.*

Prophylaxis to prevent or reduce infusion reactions: Administer 30 minutes before both the dosimetric step and the therapeutic step.

Acetaminophen: 650 mg PO

and

Diphenhydramine: 50 mg PO

DAY BEFORE DOSIMETRIC STEP (DAY -1)

Begin **thyroid-protective regimen** with one of the three agents listed under Premedication. Continue daily for a minimum of 14 days post-therapeutic dose.

DAY OF DOSIMETRIC STEP (DAY 0)

Premedicate with **acetaminophen** 650 mg and **diphenhydramine** 50 mg. Both are given PO 30 minutes before infusion begins.

Tositumomab: 450 mg as an infusion over 60 minutes. Follow with I-131 tositumomab (containing 5 mCi I-131 and 35 mg tositumomab) as an infusion over 20 minutes. **Specific process required;** see [Dilution](#) and [Rate of Administration](#).

Biodistribution: Whole-body dosimetry and biodistribution. The therapeutic dose will be based on information from three scans taken during the dosimetric step:

1st image (scan): Within 1 hour of the end of the infusion of I-131 tositumomab. Do not allow patient to void; must have urine in the bladder when this image is taken.

2nd image (scan): 2 to 4 days after I-131 tositumomab infusion and immediately following patient voiding.

3rd image (scan): 6 to 7 days after I-131 tositumomab infusion and immediately following patient voiding. Verification of expected biodistribution is indicated.

DAY 6 OR 7

Assessment of biodistribution of I-131 tositumomab: *If biodistribution is not acceptable, stop therapy now.* If biodistribution is acceptable, therapy with the therapeutic dose can proceed. On this day the radiation oncologist must calculate the exact dose activity to be ordered based on (1) assessment of dosimetry and biodistribution obtained following the dosimetric dose, and (2) platelet counts obtained within 28 days prior to dosing. May be

given on any day from Day 7 to Day 14. Specific date may be selected based on patient parameters, availability of the radioactive component, or patient or physician convenience.

THERAPEUTIC STEP: DAY 7 TO DAY 14 (SELECT ONE DAY)

Do not administer if biodistribution is altered.

Thyroid-protective agents: Have been administered every day and will continue for a minimum of 14 days following the therapeutic dose.

Premedicate with *acetaminophen* 650 mg and *diphenhydramine* 50 mg. Both are given PO 30 minutes before infusion begins.

Tositumomab: 450 mg as an infusion over 60 minutes. Follow with calculated therapeutic dose of I-131 tositumomab (calculated dose of I-131 and 35 mg tositumomab) as an infusion over 20 minutes. **Specific process required;** see [Dilution](#) and [Rate of Administration](#).

Dose of I-131 is administered based on platelet count as follows:

Platelets equal to or greater than 150,000/mm³: Activity of I-131 calculated to deliver 75 cGy total-body irradiation.

Platelets 100,000/mm³ to 149,000/mm³: Activity of I-131 calculated to deliver 65 cGy total-body irradiation.

Do not treat patients with a platelet count less than 100,000/mm³.

DOSE ADJUSTMENTS

See Usual Dose under Therapeutic Step.

DILUTION

Tositumomab is supplied in a carton containing two single-use 225-mg vials and one single-use 35-mg vial for both the dosimetric and therapeutic steps (14 mg/mL). **I-131 tositumomab** for the dosimetric step is supplied in a package containing one single-use vial (0.61 mCi/mL at calibration). For the therapeutic step, it is supplied in a package containing one or two single-use vials, each containing not less than 20 mL of I-131 tositumomab solution at protein and activity concentrations of not less than 1.1 mg/mL and 5.6 mCi/mL (at calibration). Availability of supplies must be confirmed by the radiation specialist before scheduling therapy.

Tositumomab: To prepare for the dosimetric and therapeutic steps of the 450-mg tositumomab dose, additional supplies needed include 50-mL syringe(s), 18-gauge needle(s), and a 50-mL infusion bag of NS. Withdraw 32 mL of NS from the 50-mL infusion bag of NS and discard (approximately 18 mL will remain). Withdraw entire contents from each of the two 225-mg vials (450 mg tositumomab in 32 mL) and transfer to the infusion bag containing 18 mL of NS. Final volume is 50 mL. Gently mix by inverting and rotating the bag; **do not shake**. Solution may contain some white particles (expected). Additional supplies are needed for administration; see [Rate of Administration](#).

I-131 tositumomab: All supplies, preparation, calibration, confirmation of radiochemical purity, and administration of these doses in both the dosimetric and therapeutic steps will be provided by personnel authorized to handle radiopharmaceuticals and certified to administer this therapeutic regimen. Each requires a specific order and specific timing of preparation. For additional information, see prescribing information.

Filters: Must be administered through a 0.22-micron in-line filter. The same primary IV tubing set and filter must be used throughout the entire dosimetric step. A change in filter during the procedure can result in loss of drug. Another IV tubing and filter must be used throughout the entire therapeutic step.

Storage: Tositumomab: Prior to dilution, refrigerate 35-mg and 225-mg vials at 2° to 8° C (36° to 46° F). Diluted solutions are stable for 24 hours refrigerated or 8 hours at RT. In all concentrations, protect from strong light. **Do not shake**. Do not freeze. Discard any unused portions. **I-131 tositumomab:** Stored in radiation therapy freezer at -20° C or below in original lead pots until removed for thawing before administration. **Do not shake**. Thawed doses are stable for up to 8 hours refrigerated or at room temperature. Do not use beyond expiration date. Do not refreeze. Discard unused portions according to specific regulations.

COMPATIBILITY

A radiopharmaceutical. Use only as directed. Should not be mixed or diluted with other drugs.

RATE OF ADMINISTRATION

Administer the 450-mg component over 60 minutes and the 35-mg component over 20 minutes as described in the following procedure.

Reduce rate by 50% for mild infusion reactions. Discontinue for severe infusion reactions.

Tositumomab 450-mg dose (dosimetric and therapeutic): If unit staff will be administering these doses, correlate timing with the radiation oncologist directing the procedure. Supplies required include the following:

- A. One IV filter set (0.22-micron filter) with injection site (port) and Luer-Lok.
- B. One primary IV infusion set.
- C. One 100-mL bag of NS for infusion.
- D. Two secondary IV infusion sets.
- E. One IV extension set, 30-inch Luer-Lok.
- F. One 3-way stopcock.
- G. One 50-mL bag of NS for infusion.
- H. One infusion pump for tositumomab infusion.
- I. One syringe pump for I-131 tositumomab infusion.
- J. Lead shielding for use in administration of dosimetric dose of I-131.

The procedure is as follows:

Attach the primary IV infusion set (B) to the 0.22-micron in-line filter set (A) and the 100-mL bag of NS for infusion (C).

After priming the primary IV infusion set (B) and IV filter set (A), connect the infusion bag containing 450 mg tositumomab (50 mL) via a secondary IV infusion set (D) to the primary IV infusion set (B) to a port distal to the 0.22-micron in-line filter. Carefully prime this second infusion set from the 50-mL solution of tositumomab so as not to waste any drug. A single dose must be administered evenly distributed over 60 minutes via an infusion pump.

After completion of the infusion, disconnect the secondary IV infusion set (D) and flush the primary IV infusion set (B) and the in-line filter set (A) with NS. Leave the primary line and filter extension intact; the pre-wetted filter must be used for delivery of the radioactive component. Discard the tositumomab bag and secondary IV infusion set.

I-131 tositumomab 35-mg dose: Preparation, calibration, confirmation of radiochemical purity, administration, and disposal of these doses and the equipment used to deliver them in both the dosimetric and therapeutic steps will be provided by personnel authorized to handle radiopharmaceuticals and certified to administer this therapeutic regimen. Administration will be via a syringe pump using an appropriate shield, new secondary IV tubing, and the same primary line and pre-wetted filter used for the previously administered (450-mg) dose. A single dose must be administered evenly distributed over 20 minutes. Actual delivered dose will be calculated by the radiation oncologist. All materials must be discarded according to federal regulations.

ACTIONS

An antineoplastic, radioimmunotherapeutic, monoclonal antibody-based regimen composed of the monoclonal antibody, tositumomab, and the radiolabeled monoclonal antibody (I-131 tositumomab). Tositumomab is a murine IgG_{2a} monoclonal antibody directed against the CD20 antigen found on the surface of normal and malignant B lymphocytes. I-131 tositumomab is tositumomab that has been covalently linked to I-131. Tositumomab binds to the CD20 antigen. This antigen is expressed on pre-B lymphocytes, mature B lymphocytes, and on B-cell non-Hodgkin's lymphomas. Induces cell death by emitting ionizing radiation to CD20-expressing lymphocytes or neighboring cells. In addition to cell death mediated by the radioisotope, other possible mechanisms of action include antibody-dependent cellular cytotoxicity, complement-dependent cytotoxicity, and CD20-mediated apoptosis. Regimen results in sustained depletion of circu-

lating CD20-positive cells. Lymphocyte recovery began at approximately 12 weeks following treatment. Eliminated in urine and through decay. Radioiodine is secreted in breast milk.

INDICATIONS AND USES

Treatment of patients with CD20-positive relapsed or refractory, low-grade, follicular, or transformed non-Hodgkin's lymphoma who have progressed during or after rituximab therapy, including patients with rituximab-refractory non-Hodgkin's lymphoma. Determination of the effectiveness of the regimen is based on overall response rates in patients whose disease is refractory to chemotherapy and rituximab. Effects on survival not known.

Limitations of use: This regimen is indicated only for a single course of treatment. Safety and effectiveness of additional courses not established. ■ Not indicated for the first-line treatment of patients with CD20-positive non-Hodgkin's lymphoma.

CONTRAINDICATIONS

Manufacturer states, "None"; see [Precautions](#).

PRECAUTIONS

Radiopharmaceuticals are administered by or under the direction of the physician specialist whose experience and training in the safe use and handling of radionuclides have been approved by the appropriate government agency. In addition, the specific physician administering I-131 tositumomab should either be participating in a certification program or have been certified in the preparation and administration of this therapeutic regimen. Follow institutional radiation safety practices and applicable federal guidelines to minimize radiation exposure during handling and after administration. ■ Administer in a facility with adequate personnel, equipment, and supplies to monitor the patient and respond to any medical emergency. ■ Serious hypersensitivity reactions, including anaphylaxis, have occurred during or following administration; some have been fatal; premedication required; see [Usual Dose](#), [Monitor](#), [Side Effects](#), and [Antidote](#). ■ Has a potential for immunogenicity. ■ Biodistribution of I-131 tositumomab on the first day occurs mainly in the blood pool (heart and major blood vessels), liver, and spleen. Second and third imaging time points reflect decreased accumulation in the blood pool, liver, and spleen and may show uptake by the thyroid, kidneys, and other organs. Tumors show areas of increased intensity. Altered biodistribution on the first day may be visualized as little or no activity in the blood pool, intense uptake in the liver or spleen, greater uptake in the lungs than in the blood pool, or uptake suggestive of urinary obstruction. Altered biodistribution on the second and third imaging time points may suggest urinary obstruction, diffuse lung uptake greater than the blood pool, or total-body residence times of less than 50 hours and more than 150 hours. ■ Patients with a high tumor burden, splenomegaly, or bone marrow involvement were noted to have a faster clearance, shorter terminal half-life, and larger volume of distribution. ■ May cause prolonged, severe, and life-threatening cytopenias (neutropenia, thrombocytopenia); see [Contraindications](#), [Monitor](#), [Side Effects](#), and [Antidote](#). Should not be administered to patients with greater than 25% lymphoma marrow involvement, a platelet count less than 100,000 cells/mm³, or a neutrophil count less than 1,500 cells/mm³. ■ Safety for use in patients with a platelet count less than 100,000 cells/mm³ or a neutrophil count less than 1,500 cells/mm³ has not been established. ■ Impaired renal function may decrease the rate of excretion of the radiolabeled iodine and increase patient exposure to this radioactive component. Has not been studied in patients with renal impairment. ■ Myelodysplastic syndrome and secondary malignancies have been reported. ■ Do not administer live virus vaccines to patients recently treated with tositumomab regimen. Ability to generate a primary or anamnestic humoral response to any vaccine has not been studied. ■ Tositumomab therapeutic regimen can cause hypothyroidism; risk is likely to be increased in patients who do not complete the recommended thyroid protective regimen. Patients who cannot tolerate the thyroid-blocking agents may not begin the regimen. ■ See [Contraindications](#) and [Maternal/Child](#).

Monitor: Obtain baseline CBC with differential and platelets, thyroid-stimulating hormone (TSH) levels, and SCr. ■ Monitor CBC with differential and platelets weekly for 10 to 12 weeks or more frequently if indicated (e.g., cytopenias, concurrent drugs). Con-

continue until recovery. Cytopenias (e.g., neutropenia and thrombocytopenia) can be severe and may be fatal. Time to nadir was 4 to 7 weeks, and the duration of cytopenias was approximately 30 days. Anemia, neutropenia, and thrombocytopenia may persist for more than 90 days, and some patients died without recovering. ■ Monitor for S/S of hypersensitivity reactions and/or infusion reactions (e.g., bronchospasm, chills, dyspnea, fever, hypotension, injection site hypersensitivity, itching, nausea, rash, serum sickness); see **Precautions** and **Antidote**. Have occurred during or within 48 hours of infusion or up to 2 weeks after infusion. ■ Establish a free-flowing IV line before administration; avoid extravasation. Monitor closely; if any signs of extravasation occur, discontinue immediately and restart in another vein. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³) for up to 3 months. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Observe closely for signs of infection for up to 3 months. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for S/S of hypothyroidism (e.g., cold intolerance, drooping eyelids, facial puffiness, thinning hair). Screen for biochemical evidence of hypothyroidism by monitoring TSH annually. ■ See **Precautions**, **Drug/Lab Interactions**, and **Antidote**.

Patient Education: Avoid pregnancy; effective birth control is recommended for males and females during treatment and for up to 12 months following therapy. Women should report a suspected pregnancy immediately. ■ Promptly report S/S of a hypersensitivity reaction (e.g., chills, fever, difficulty breathing, faintness, itching, rash), S/S of infection (e.g., fever, sore throat), or S/S of bleeding (e.g., bruising, nosebleed, dark stools). ■ Compliance with daily medications for thyroid protection imperative; monitoring for hypothyroidism will continue. ■ Side effects, especially reduced blood counts, may persist for many weeks; close follow-up with physician is imperative. ■ Radiation department should provide instructions for minimizing exposure of family members, friends, and the general public. ■ Review all Precautions before treatment begins.

Maternal/Child: Category D: avoid pregnancy; may cause harm to the fetal thyroid gland, and radioiodide may cause severe, and possibly irreversible, hypothyroidism in neonates. ■ Women of child-bearing potential should avoid becoming pregnant. ■ Could cause toxic effects on testes and ovaries. Effective contraceptive methods are recommended for men and women during treatment and for up to 12 months following therapy. ■ Evaluate infants born to mothers treated with the tositumomab regimen for hypothyroidism at delivery and during the neonatal period. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Numbers in clinical studies insufficient to determine if the elderly respond differently from younger subjects.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been performed. ■ Risk of bleeding may be increased by **any medicine that affects blood clotting**, including anticoagulants (e.g., heparin, warfarin [Coumadin]); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]); **and/or any other medication that inhibits platelet aggregation** (e.g., dipyridamole [Persantine], glycoprotein GPIIb/IIIa receptor antagonists [e.g., abciximab (ReoPro), eptifibatid (Integrilin), tirofiban (Aggrastat)], plicamycin [Mithracin], sulfipyrazone [Anturane], ticlopidine [Ticlid], valproate [Depacon]). ■ Do not administer **live virus vaccines** to patients recently treated with tositumomab regimen. ■ Potential for additive effects with previously administered bone marrow-suppressing agents and/or radiation therapy has not been studied.

SIDE EFFECTS

Anemia, asthenia, fever, infections (including bacteremia, bronchitis, pneumonia, septicemia, and skin infections), infusion reactions, nausea, neutropenia, and thrombocytopenia are most common. The most serious side effects include severe and prolonged cyto-

penias, hypersensitivity reactions (including anaphylaxis, angioedema, and bronchospasm), infections (including bacteremia, bronchitis, pneumonia, septicemia, and skin infections), infusion reactions, myelodysplastic syndrome, and secondary leukemia. Other reported side effects that may be reported within days or be delayed included abdominal pain, anorexia, arthralgia, back pain, chest pain, chills, constipation, cough, diarrhea, dizziness, dyspepsia, dyspnea, fever, headache, hypotension, hypothyroidism, myalgia, nausea and vomiting, neck pain, pain, peripheral edema, pharyngitis, pruritus, rash, rhinitis, somnolence, sweating, vasodilation, weight loss. Abdominal pain and nausea and vomiting often occur days after the infusion. Diarrhea may occur days to weeks after the infusion. Other delayed side effects may include HAMA, hypothyroidism, myelodysplastic syndrome (MDS), secondary leukemia, and secondary malignancies.

Post-Marketing: Axonal neuropathy leading to quadriparesis; hypersensitivity reactions, including fatal anaphylaxis.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Hypersensitivity or infusion-related side effects to any component of the regimen may resolve by slowing the rate of infusion by 50% or interrupting the infusion and by providing supportive care (IV saline; diphenhydramine; bronchodilators such as albuterol [Ventolin], or aminophylline; and acetaminophen). Discontinue entire regimen in patients who develop severe hypersensitivity reactions. Treat anaphylaxis with oxygen, antihistamines (diphenhydramine), epinephrine, and corticosteroids. Maintain a patent airway. If overdose occurs, monitor closely for cytopenias and radiation-related toxicity. Autologous stem cell transplantation has not been studied; consider timing in relation to dosing to minimize the possibility of irradiation of infused hematopoietic stem cells. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity or to treat moderate to severe bleeding. Control minor bleeding by local pressure. For severe bleeding, delay or discontinue therapy and obtain PT, aPTT, platelet count, and fibrinogen. Draw blood for type and cross-match. Antibiotic therapy is indicated for infections and may be indicated prophylactically. Death may occur from the progression of some side effects. Resuscitate as indicated.

TRACE METALS

(tras MET-als)

Chromium	MulTE-PAK-5
Copper	Multiple Trace Element With Selenium
Iodine	Multiple Trace Element With Selenium Concentrated
Manganese	Multitrace-5 Concentrated
Molybdenum	Selenium
M.T.E.-4, 5, 6, & 7	Zinc
M.T.E.-4, 5, & 6 Concentrated	
MulTE-PAK-4	

Multiple Trace Element Neonatal, Neotrace-4, PedTE-PAK-4, P.T.E.-4, P.T.E.-5

USUAL DOSE

Available as single elements, selected combined elements in various strengths, and in combination with electrolytes. Some preparations may contain aluminum; see *Precautions*. Selection of correct product based on minimum daily requirement and individual needs.

Chromium: 10 to 15 mcg/day. Increase to 20 mcg/day with intestinal fluid loss.

Copper: 0.5 to 1.5 mg/day.

Iodine: 1 to 2 mcg/kg of body weight/day. Increase to 2 to 3 mcg/kg/day in growing children, pregnant and lactating women.

Manganese: 0.15 to 0.8 mg/day. May contain up to 100 mcg/L of aluminum; see *Precautions*.

Molybdenum: 20 to 120 mcg/day. Increase to 163 mcg/day for 21 days in deficiency states resulting from prolonged TPN.

Selenium: 20 to 40 mcg/day. Increase to 100 mcg/day for 31 days in deficiency states resulting from prolonged TPN.

Zinc: 2.5 to 4 mg/day; add 2 mg in acute catabolic states. Increase to 12.2 mg/L of total parenteral nutrition (TPN) if there is fluid loss from the small bowel. May contain aluminum.

PEDIATRIC DOSE

Chromium: 0.14 to 0.2 mcg/kg/day.

Copper: 20 mcg/kg/day.

Manganese: 2 to 10 mcg/kg/day. May contain up to 100 mcg/L of aluminum; see *Precautions*.

Molybdenum: Must calculate dosage by extrapolation; consult pharmacist.

Selenium: 3 mcg/kg/day.

Zinc: 100 mcg/kg/day for full-term infants and other pediatric patients up to 5 years of age. 300 mcg/kg/day for premature infants with birth weights from 1,500 Gm to 3 kg. May contain aluminum.

DOSE ADJUSTMENTS

Reduce or omit dose in impaired renal function. ■ Caution and lower-end dosing may be appropriate in the elderly; consider decreased organ function and concomitant disease or drug therapy.

DILUTION

Must be added to daily volume of IV infusion fluids including TPN. Check labels for aluminum content; see *Precautions*.

COMPATIBILITY

Specific trace metals may present **compatibility** problems. Check **incompatibilities** of each agent to be admixed or delivered to the **Y-site**.

RATE OF ADMINISTRATION

Administer properly diluted at rate prescribed for IV infusion fluids or TPN.

ACTIONS

All are basic elements present in the human body. Specific amounts required to initiate, facilitate, or maintain appropriate body systems.

INDICATIONS AND USES

Nutritional supplement to IV solutions given for total parenteral or central nutrition.

CONTRAINDICATIONS

Do not give direct IV; hypersensitivity to any component (especially iodides). Manganese contraindicated in presence of high manganese levels. Molybdenum without copper supplementation contraindicated in copper-deficient patients.

PRECAUTIONS

Selenium enhances vitamin E and decreases the toxicity of mercury, cadmium, and arsenic. ■ Patients with biliary tract obstruction may retain copper and manganese. ■ Avoid copper in patients with Wilson's disease (genetic disorder of copper metabolism). ■ Assess possibility of diabetes mellitus when giving chromium supplements to maintain normal glucose metabolism. ■ Some solutions may contain aluminum (e.g., manganese, zinc). In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation.

Monitor: Monitor serum trace metal concentration to avoid accumulation. Results will also determine use of a single element or a combined product.

Maternal/Child: Category C; use in pregnancy only if clearly indicated. Use manganese with caution in the nursing mother. ■ May contain benzyl alcohol; may cause fatal "gasping" syndrome in premature infants.

Elderly: Differences in response compared to younger adults not identified. ■ Dosing should be cautious; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Therapeutic serum levels of **copper and zinc** will decrease if not given together.

SIDE EFFECTS

Toxicity is rare at recommended doses. Iodine may cause anaphylaxis.

ANTIDOTE

Dosage will be adjusted based on serum levels. Keep physician informed. Resuscitate as necessary.

TRASTUZUMAB **BBW**(traz-**TOO**-zah-mab)Monoclonal antibody
Antineoplastic

Herceptin

pH 6

USUAL DOSE

Premedication: Pretreatment with antihistamines (e.g., diphenhydramine [Benadryl]) and/or corticosteroids (e.g., dexamethasone [Decadron]) may be indicated and is suggested for patients being retreated after a hypersensitivity reaction or a severe infusion reaction; see **Precautions**. Pretreatment may not be successful; hypersensitivity reaction and/or infusion reaction may recur. Preassessment required; see **Monitor**. Combination therapies may require additional premedication; refer to product monographs.

Adjuvant treatment of breast cancer: Administer according to one of the following dose regimens and schedules for a total of 52 weeks of trastuzumab therapy:

1. **During and following paclitaxel, docetaxel, or docetaxel/carboplatin:** Administer an initial dose of **trastuzumab** 4 mg/kg as an infusion over 90 minutes. Follow with a dose of 2 mg/kg as an infusion over 30 minutes at weekly intervals for the first 12 weeks when given in combination with **paclitaxel or docetaxel** or for 18 weeks when given in combination with **docetaxel/carboplatin**. Beginning 1 week after the last 2-mg/kg weekly dose of **trastuzumab**, administer **trastuzumab** 6 mg/kg as an infusion over 30 to 90 minutes every 3 weeks.
2. **As a single agent within 3 weeks of completion of multimodality, anthracycline-based chemotherapy regimens,** administer an initial dose of **trastuzumab** 8 mg/kg as an infusion over 90 minutes. Follow with a dose of 6 mg/kg as an infusion over 30 to 90 minutes every 3 weeks.
3. See clinical studies in prescribing information for different treatment regimens used. In all studies, **trastuzumab** was initiated **after completion of the doxorubicin and cyclophosphamide treatment cycles**.

Metastatic breast cancer: Initial dose: 4 mg/kg as an infusion over 90 minutes. Follow with a **maintenance dose** of 2 mg/kg as an infusion over 30 minutes at weekly intervals. Trastuzumab is administered until tumor progression.

Metastatic breast cancer in combination therapy with paclitaxel: Trastuzumab dose as above. **Paclitaxel dose:** 175 mg/M² over 3 hours every 21 days for at least 6 cycles. See paclitaxel monograph.

Metastatic gastric cancer in combination with cisplatin and capecitabine or 5-fluorouracil: Initial dose: 8 mg/kg as an infusion over 90 minutes. Follow with a dose of 6 mg/kg as an infusion over 30 to 90 minutes every 3 weeks until disease progression. See individual monographs and specific protocol for doses of cisplatin and capecitabine (Xeloda) or 5-fluorouracil (5-FU).

DOSE ADJUSTMENTS

Withhold trastuzumab dose for at least 4 weeks for either of the following:

- Equal to or greater than a 16% absolute decrease in left ventricular ejection fraction (LVEF) from baseline assessment.
- LVEF below institutional limits of normal and equal to or greater than 10% absolute decrease in LVEF from baseline assessment.

May resume trastuzumab if within 4 to 8 weeks the LVEF returns to normal limits and the absolute decrease from baseline is equal to or less than 15%. Discontinue permanently for a persistent (more than 8 weeks) LVEF decline or for suspension of trastuzumab dosing on more than three occasions for cardiomyopathy.

DILUTION

Manufacturer supplies a vial of bacteriostatic water for injection (BWFI). Confirm content of vial; 20 mL is required to obtain the correct concentration. Inject diluent slowly directed at the lyophilized cake. Swirl gently; **do not shake** (is sensitive to agitation or

rapid expulsion from a syringe). Allow vial to stand for 5 minutes, slight foaming is permissible. Will yield a multidose solution containing 21 mg/mL. Label vial immediately with a “do not use after” date 28 days from date of reconstitution. SWFI may be used to reconstitute trastuzumab for patients with a known hypersensitivity to benzyl alcohol, but the calculated dose must be withdrawn, used immediately, and the balance of the reconstituted solution discarded. Reconstituted solution must be further diluted and given as an infusion. Withdraw the calculated dose from the reconstituted vial (21 mg/mL) and add it to an infusion bag containing 250 mL of NS. Gently invert to mix the solution.

Filters: In-line filters are not necessary but may be used (0.2-micron filters were evaluated).

Storage: Refrigerate unopened and reconstituted vials at 2° to 8° C (36° to 46° F). Vials reconstituted in supplied diluent are stable for 28 days after reconstitution. Discard remaining diluent. Discard reconstituted trastuzumab after expiration date written or stamped on vial. Solutions diluted in NS may be refrigerated for 24 hours before use. Do not freeze reconstituted trastuzumab.

COMPATIBILITY

Manufacturer states, “Do not reconstitute with drugs other than BWFI or SWFI. Further dilute infusion with NS. Infusions should not be administered or mixed with dextrose solutions Do not mix with other drugs.” Is **compatible** with polyethylene and polyvinylchloride infusion bags and tubing.

RATE OF ADMINISTRATION

Use of a microdrip (60 gtt/min) or other IV controller suggested. For infusion only, **do not administer** as an IV push or bolus. Decrease rate of infusion for mild or moderate infusion reactions.

Initial dose: A single dose as an infusion over a minimum of 90 minutes. Observe for chills, fever, or other infusion-associated symptoms; see [Precautions/Monitor](#).

Maintenance dose: If the initial dose was well tolerated, administer a single dose as an infusion over 30 to 90 minutes (based on regimen; see [Usual Dose](#)).

ACTIONS

A recombinant DNA–derived humanized monoclonal antibody that selectively binds with high affinity to the extracellular domain of the human epidermal growth factor receptor 2 (HER2) protein. Inhibits proliferation and mediates an antibody-dependent cellular toxicity in cancer cells that overexpress the HER2 protein. Half-life increases and clearance decreases with increasing doses. May cross the placental barrier. May be secreted in breast milk.

INDICATIONS AND USES

Indicated for adjuvant treatment of breast cancer that is HER2-overexpressing, node-positive or node-negative (ER/PR-negative or with one high-risk feature). May be used as part of a treatment regimen that may consist of (1) doxorubicin (Adriamycin), cyclophosphamide (Cytoxan), and either paclitaxel (Taxol) or docetaxel (Taxotere); (2) a regimen with docetaxel and carboplatin (Paraplatin); or (3) a single agent following multimodal anthracycline-based therapy. ■ As a single agent for treatment of patients with metastatic breast cancer whose tumors overexpress the HER2 protein and who have received one or more chemotherapy regimens for their metastatic disease. ■ In combination with paclitaxel (Taxol) for the first-line treatment of patients with metastatic breast cancer whose tumors overexpress the HER2 protein and who have not received chemotherapy for their metastatic disease. ■ In combination with cisplatin and capecitabine (Xeloda) or 5-fluorouracil (5-FU) for treatment of patients with HER2-overexpressing metastatic gastric or gastroesophageal junction adenocarcinoma who have not received prior treatment for metastatic disease. ■ Trastuzumab is not indicated for any other patients, including those with newly diagnosed, operable breast cancer.

CONTRAINDICATIONS

None known when used as indicated; see [Precautions](#).

PRECAUTIONS

Trastuzumab should be used only in patients whose tumors have HER2 overexpression. Beneficial treatment effects were largely limited to patients with the highest level of HER2 protein overexpression (3+). Tumor histology differs; use FDA-approved tests for specific tumor type (breast or gastric/gastroesophageal adenocarcinoma) to assess HER2 overexpression and HER2 gene amplification. HER2 protein overexpression can be determined or inferred using immunohistochemistry (IHC) or fluorescence in situ hybridization (FISH). Must be performed in laboratories with demonstrated proficiency in the specific technology. ■ Administered by or under the direction of the physician specialist. May be given on an outpatient basis. ■ Adequate laboratory and supportive medical resources must be available. ■ Emergency equipment and drugs for treatment of left ventricular dysfunction and/or hypersensitivity reactions must be immediately available; see **Antidote**. ■ Use with caution in patients with known hypersensitivity to trastuzumab, Chinese hamster ovary cell proteins, benzyl alcohol, or any component of this product. ■ Hypersensitivity reactions and infusion reactions (including some with a fatal outcome) and pulmonary toxicity (including ARDS and death) have occurred. Retreatment after full recovery from a hypersensitivity or infusion reaction has been tried following pretreatment with antihistamines and/or corticosteroids. Some tolerated treatment; others had another severe reaction. ■ Can cause subclinical and clinical cardiac failure. Incidence of cardiac dysfunction was highest in patients who received trastuzumab with an anthracycline-containing chemotherapy regimen (e.g., doxorubicin [Adriamycin]) and in the elderly. ■ Can cause left ventricular cardiac dysfunction, arrhythmias, hypertension, disabling cardiac failure, cardiomyopathy, and cardiac death. May also cause asymptomatic decline in left ventricular ejection fraction (LVEF). Congestive heart failure may be severe; has been associated with disabling cardiac failure, mural thrombosis leading to stroke, and death. ■ Use extreme caution in treating patients with pre-existing cardiac dysfunction or pulmonary compromise. Pre-existing cardiac disease or prior cardiotoxic therapy (e.g., anthracyclines), radiation therapy to the chest or pre-existing pulmonary compromise secondary to intrinsic lung disease and/or malignant pulmonary involvement may decrease ability to tolerate trastuzumab. ■ May exacerbate chemotherapy-induced neutropenia. Septic deaths have been reported. ■ Low titers of human anti-human antibodies (HAHA) were detected in one patient who had no symptoms of a hypersensitivity reaction.

Monitor: Obtain baseline CBC with differential and platelet count and repeat as needed. ■ Monitor all vital signs before and during therapy. ■ Treatment with trastuzumab can result in the development of ventricular dysfunction and CHF. For all treatment regimens (monotherapy and/or combination therapies), patients should have a thorough baseline cardiac assessment to evaluate left ventricular function, including a history and physical exam, determination of LVEF, and an echocardiogram or a MUGA scan. Monitoring and assessment may not identify all patients at risk for developing cardiotoxicity. ■ Monitor closely throughout treatment for S/S of deteriorating cardiac function (e.g., cough, dyspnea, paroxysmal nocturnal dyspnea, peripheral edema, S₃ gallop, or reduced ejection fraction [symptomatic or asymptomatic]). Suggested monitoring schedule includes a repeat evaluation of left ventricular function (echocardiogram or MUGA scan) every 3 months during treatment with trastuzumab and at least every 6 months for 2 years after completion of treatment if trastuzumab was used as a component of adjuvant therapy. More frequent monitoring should be used for patients with pre-existing cardiac dysfunction and/or if S/S of deteriorating cardiac function develop. ■ Onset and clinical course of infusion reactions are variable. Most occur during or immediately following the infusion or within 24 hours; however, delayed infusion events (up to 1 week post-infusion) have also been reported. Chills and/or fever occur in 40% of patients during the first infusion. May be treated with acetaminophen (Tylenol), diphenhydramine (Benadryl), and meperidine (Demerol) with or without reduction in the rate of infusion. During infusion, monitor closely; asthenia, bronchospasm, dizziness, dyspnea, headache, hypotension (may be severe), hypoxia, nausea, pain (may be at tumor site), rash, rigors, and

vomiting have also occurred. Recurrence of this syndrome is infrequent with subsequent infusions. Fatal serious infusion reactions have been reported (rare); death occurred within hours to days. ■ Monitor closely; in addition to the symptoms of infusion reaction previously noted, severe and sometimes fatal hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, hypotension, urticaria) and pulmonary reactions (e.g., dyspnea, pulmonary infiltrates, pleural effusions, pneumonitis, non-cardiogenic pulmonary edema, pulmonary fibrosis, pulmonary insufficiency, hypoxia, and ARDS) have occurred during and after the infusion. Monitor until symptoms completely resolve. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Not a vesicant; if extravasation occurs, discontinue infusion and restart using another vein.

Patient Education: During infusion, promptly report chills and/or fever and other S/S of infusion reaction. ■ Promptly report cough, difficulty breathing, weight gain, and swelling of extremities. ■ Avoid pregnancy; nonhormonal birth control is preferred during and for 6 months following treatment. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; can cause fetal harm. Increases the risk for oligohydramnios and oligohydramnios sequence manifesting as pulmonary hypoplasia, skeletal abnormalities, and neonatal death during the second and third trimesters. Pregnant women with breast cancer who receive trastuzumab are encouraged to enroll in the Cancer and Childbirth Registry. ■ Discontinue breast-feeding during trastuzumab therapy. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Advanced age may increase the risk of cardiac dysfunction.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been done. Use with **paclitaxel** may decrease trastuzumab clearance and increase serum levels. Paclitaxel concentration is not affected. ■ Use in combination with capecitabine, cisplatin, docetaxel, doxorubicin, or cyclophosphamide did not suggest any interactions; however, risk of cardiotoxicity increased with concurrent use or previous use of **anthracyclines** (e.g., doxorubicin). ■ Bone marrow toxicity may be additive with **other antineoplastic agents** (e.g., anthracyclines, cyclophosphamide).

SIDE EFFECTS

Cardiomyopathy, pulmonary toxicity, infusion reactions, and febrile neutropenia are the most serious side effects. Anemia, cough, diarrhea, dysgeusia, dyspnea, fatigue, fever, headache, infections, infusion reactions, myalgia, nausea, neutropenia, rash, stomatitis, thrombocytopenia, vomiting, and weight loss are most common. Side effects that cause interruption or discontinuation of therapy include severe infusion reactions, pulmonary toxicity, congestive heart failure, and a decline in left ventricular cardiac function. Abdominal pain, accidental injury, acne, anorexia, arthralgia, asthenia, back pain, bone pain, depression, dizziness, edema, flu syndrome, headache, herpes simplex, hypersensitivity reactions, hypotension, insomnia, neuropathy, pain (may be at tumor site), paresthesia, peripheral edema, peripheral neuritis, pharyngitis, rash, rhinitis, sinusitis, and tachycardia have been reported in more than 5% of patients. Many other serious side effects have been reported in some patients (e.g., cardiac arrest, coagulation disorder, death; hypersensitivity reactions [e.g., angioedema, bronchospasm, dyspnea, urticaria, wheezing]; hypertension, hypotension, non-cardiogenic pulmonary edema, pancytopenia, pericardial or pleural effusion, pulmonary infiltrates, pulmonary insufficiency and hypoxemia requiring O₂ and/or ventilatory support, shock arrhythmia, syncope, vascular thrombosis).

Post-Marketing: Serious adverse events including hypersensitivity reactions and infusion reactions, including some with a fatal outcome; and pulmonary events including ARDS and death. Symptoms occurred most commonly during the infusion, but some occurred 24 hours or more after the infusion. Renal toxicity (glomerulopathy) has also been reported. Cases of oligohydramnios, and oligohydramnios sequence manifesting as pulmo-

nary hypoplasia, skeletal abnormalities, and neonatal death, have been reported when trastuzumab has been administered to pregnant women.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Decrease rate of infusion for mild or moderate infusion reactions. Temporarily discontinue infusion if dyspnea or clinically significant hypotension occurs. Discontinue infusion and strongly consider discontinuing trastuzumab therapy in patients who experience a severe infusion reaction. Discontinue infusion in patients who develop anaphylaxis, angioedema, ARDS, interstitial pneumonitis, and/or a clinically significant decrease in left ventricular function. Strongly consider discontinuation of trastuzumab therapy in patients who develop clinically significant congestive heart failure. Safety of continuation or resumption of therapy has not been studied. Treatment may include diuretics, ACE inhibitors (e.g., lisinopril [Zestril], enalapril [Vasotec]), inotropic agents (e.g., digoxin, inamrinone [Amrinone], isoproterenol [Isuprel]), beta-blockers (e.g., atenolol [Tenormin], propranolol), and/or supplemental oxygen. Infusion reaction is treated with acetaminophen, diphenhydramine, and meperidine. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity from concurrent antineoplastics. Treat hypersensitivity reactions (may be more frequent with coadministration of paclitaxel) with epinephrine, antihistamines, corticosteroids, bronchodilators, and oxygen. To treat extravasation, apply cold compresses and elevate extremity. Resuscitate as indicated.

TROMETHAMINE

(troh-METH-ah-meen)

Alkalizing agent

Tham-E

pH 8.6

USUAL DOSE

Limit dose to amount needed to increase blood pH to normal limits (7.35 to 7.45) and to correct acid-base derangements. Evaluate the need for repeat doses by serial determinations of existing base deficit, pH, and clinical observations. Tham-E contains electrolytes.

Acidosis: Required dose (mL of 0.3 molar solution) equal to body weight in kilograms \times base deficit in mEq/L \times 1.1.

Acidosis in cardiac bypass surgery: 9 mL/kg (324 mg/kg) of body weight. 500 mL (18 Gm) is an average adult dose. Up to 1,000 mL has been used. Never exceed 500 mg/kg in any individual dose over less than 1 hour.

Correct acidity of ACD priming blood: Stored blood has a pH of 6.22 to 6.8. An average of 60 mL (15 to 77 mL) tromethamine to each 500 mL of stored blood is required to correct pH to 7.4.

Acidosis in cardiac arrest: Use only if indicated. Never inject into cardiac muscle. Initial dose in an open chest is 62 to 185 mL (2 to 6 Gm). Additional doses should be based on evaluation of base deficit. If the chest is not open, give 111 to 333 mL (3.6 to 10.8 Gm); use a large peripheral vein. After arrest is reversed, additional amounts may be needed to control persistent acidosis.

PEDIATRIC DOSE

Correction of metabolic acidosis associated with respiratory distress syndrome (RDS) in neonates and infants: 1 mL/kg of body weight for each pH unit below 7.4. Repeat doses may be given according to changes in PaO₂, pH, and Pco₂.

DOSE ADJUSTMENTS

Lower-end initial doses may be appropriate in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Supplied as a 0.3 molar solution. Each 100 mL contains tromethamine 3.6 Gm in water for injection. May be given undiluted as an infusion or added to pump oxygenator blood, other priming fluid, or ACD blood.

Storage: Store at CRT. Single use container, discard unused solution.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Slow IV infusion recommended. 5 mL or less/min would deliver up to 300 mL in 1 hour.

Rate dictated by patient's condition and intended use; see [Usual Dose](#) and [Precautions](#). Reduced rate may control venospasm.

ACTIONS

Acts as a proton acceptor. Prevents or corrects acidosis by actively binding hydrogen ions in metabolic acids and carbonic acid. Releases bicarbonate anions. Rapidly excreted in the urine, it has an osmotic diuretic effect, increases urine output, urine pH, and excretion of fixed acids, CO₂, and electrolytes. Also capable of neutralizing acidic ions of the intracellular fluid.

INDICATIONS AND USES

Prevention and correction of metabolic acidosis; particularly metabolic acidosis associated with cardiac bypass surgery, correction of acidity of ACD blood in cardiac bypass surgery, and cardiac arrest.

CONTRAINDICATIONS

Hypersensitivity to tromethamine, anuria, and uremia. In neonates it is also contraindicated in chronic respiratory acidosis and salicylate intoxication.

PRECAUTIONS

Intended for short-term use only (1 day). ■ Sodium bicarbonate or sodium lactate is effective in most acidotic situations and has fewer side effects. ■ Use extreme caution in impaired renal function or decreased urine output.

Monitor: Determine blood pH, PCO₂, bicarbonate, glucose, and electrolytes before, during, and after administration. ■ Avoid overdose (total drug or too-rapid rate). Severe alkalosis and/or prolonged hypoglycemia may result. ■ May cause fluid and/or solute overload, resulting in dilution of serum electrolyte concentrations, overhydration, congested states, or pulmonary edema. ■ Use a large peripheral vein. Determine absolute patency of vein; necrosis may result from extravasation. ■ May severely depress respiration. Incidence may be increased in patients who have chronic hypoventilation or those who have been treated with drugs that depress respiration. Oxygen and controlled ventilation equipment must always be available. ■ ECG monitoring and frequent serum potassium measurements are required to rule out hyperkalemia in impaired renal function or decreased urine output. Decreased excretion of tromethamine may also occur, resulting in toxicity.

Maternal/Child: Category C: safety for use not established. Benefits must outweigh risks. ■ Use caution or discontinue breast-feeding. ■ Has been used to treat severe cases of metabolic acidosis with concurrent respiratory acidosis because it does not raise PCO₂ as bicarbonate does in neonates and infants with respiratory failure. It has also been used in neonates and infants with hypernatremia and metabolic acidosis to avoid the additional sodium given with the bicarbonate. However, because the osmotic effects of tromethamine are greater and large continuous doses are required, bicarbonate is preferred to tromethamine in the treatment of acidotic neonates and infants with RDS. ■ Severe hypoglycemia may occur in premature or full-term infants. ■ Infusion via low-lying umbilical venous catheters has been associated with hepatocellular necrosis.

Elderly: Lower-end initial doses may be appropriate in the elderly; see [Dose Adjustments](#). Differences in response between elderly and younger patients have not been identified.

DRUG/LAB INTERACTIONS

Potentiates **amphetamines, ephedrine, and quinidine**. ■ Inhibits **lithium, methotrexate, and salicylates**. ■ Incidence of respiratory depression may be increased in patients receiving **drugs that depress respiration** (e.g., narcotic analgesics [morphine]). ■ May **increase coagulation time**.

SIDE EFFECTS

Hyperkalemia, hypoglycemia, phlebitis, respiratory depression, and thrombosis.

Overdose: Alkalosis, overhydration, severe prolonged hypoglycemia, solute overload. May be due to total drug or too-rapid rate of administration.

ANTIDOTE

Notify physician of all side effects. Reduced rate of infusion may prevent hypoglycemia. Use glucose if indicated. Discontinue drug immediately for hyperkalemia or extravasation. Local infiltration with 1% procaine with phentolamine may reduce tissue necrosis. Use a number 25 needle. Symptomatic treatment is indicated. Alternate drugs are indicated (sodium bicarbonate, sodium lactate).

VACCINIA IMMUNE GLOBULIN INTRAVENOUS (HUMAN) **BBW**

Immunizing agent
(passive)

(vack-SIN-ee-ah ih-MUNE GLAW-byoo-lin IV)

VIGIV

USUAL DOSE

100 mg/kg (2 mL/kg) as a single-dose IV infusion; see **Monitor**. May be repeated based on the severity of symptoms and on individual patient response. Higher doses (200 mg/kg or 500 mg/kg) may be considered in patients who do not respond to the initial 100 mg/kg dose; see **Precautions**.

DOSE ADJUSTMENTS

Because of sucrose content, doses higher than 400 mg/kg are not recommended in patients with potential renal problems.

DILUTION

Contains sucrose; see **Precautions**. A ready-to-use liquid preparation supplied in a 50-mL vial containing 50 mg VIGIV/mL or 2,500 mg VIGIV/vial. Solution should be colorless, free of particulate matter, and not turbid. **Do not shake vial; avoid foaming**. Further dilution before or during administration is not recommended. Infusion should begin within 6 hours of entering the vial and be complete within 12 hours of entering the vial. Use of a dedicated IV line, a 0.22-micron in-line filter, and a constant infusion pump is recommended. If necessary, it may be piggybacked into a pre-existing IV line containing NS or D2½W, D5W, D10W, or D20W with or without NaCl added; see **Compatibility**. VIGIV should not be diluted more than 1:2 (v/v) with any of these solutions.

Filters: Use of a 0.22-micron in-line filter is recommended; see **Dilution**.

Storage: Store between 2° and 8° C (35.6° and 46.4° F). Do not use after expiration date. Infusion must begin within 6 hours and be complete within 12 hours of entering the vial. Discard partially used vials. Do not use if turbid or has been frozen.

COMPATIBILITY

Manufacturer states, “Administer separately from other drugs or medications.” If necessary, it may be piggybacked into a pre-existing IV line containing NS or D2½W, D5W, D10W, or D20W with or without NaCl added. Flush line before and after administration. VIGIV should not be diluted more than 1:2 (v/v) with any of these solutions.

RATE OF ADMINISTRATION

Flush line before and after administration.

Administer 1 mL/kg/hr for the first 30 minutes. If no discomfort or adverse effects, it may be increased to 2 mL/kg/hr for the next 30 minutes and then to 3 mL/kg/hr for the remainder of the infusion, as tolerated. Infusion of 100 mg/kg (2 mL/kg) should take approximately 70 minutes in a 70-kg patient. Do not exceed these rates. Too-rapid infusion may cause infusion rate–related reactions (e.g., arthralgia, back pain, chills, fever, flushing, muscle cramps, nausea, vomiting, wheezing). **In patients at risk for developing renal dysfunction, administer at the minimum concentration available and the minimum rate of infusion practicable**. Use of a dedicated IV line, a 0.22-micron in-line filter, and a constant infusion pump (i.e., an IVAC pump or equivalent) is recommended.

ACTIONS

An immunoglobulin (Ig). Obtained from human plasma, purified, and standardized. Donors had received booster immunizations with the Dryvax smallpox vaccine. Specific methods (e.g., cold ethanol fractionation, detergents, nanofiltration, solvents) inactivate bloodborne viruses (e.g., hepatitis, HIV). Tested and found negative for antibodies against HIV, hepatitis, Creutzfeldt-Jakob disease, and others. Contains increased levels of protective antibodies against the vaccinia virus—the live virus used in the currently available smallpox vaccine. When use is necessary, can help to minimize possible risks

associated with this highly effective smallpox vaccine. Half-life is approximately 22 days but may be decreased by fever or infection (increased catabolism or consumption).

INDICATIONS AND USES

Treatment and/or modification of the following conditions: aberrant infections induced by the vaccinia virus that include accidental implantation in the eyes (excluding isolated keratitis; see [Contraindications](#)), mouth, or other areas where vaccinia infection would be hazardous; eczema vaccinatum; progressive vaccinia; severe generalized vaccinia; and vaccinia infections in individuals who have skin conditions such as burns, impetigo, varicella-zoster, or poison ivy or in individuals who have eczematous skin lesions because of the activity or extensiveness of such lesions.

CONTRAINDICATIONS

Presence of isolated vaccinia keratitis. ■ Individuals known to have an allergic response to this or other human immunoglobulin preparations. ■ Contains trace amounts of IgA. Patients with isolated or selective IgA deficiency can develop antibodies to IgA and have an increased risk of anaphylactic reactions with subsequent exposure to blood products that contain IgA. ■ Not considered effective for the treatment of postvaccinal encephalitis.

PRECAUTIONS

For IV infusion only. ■ Hypersensitivity reactions are possible and have occurred with other IGIV preparations; administer in a facility with adequate equipment and supplies to monitor the patient and respond to any medical emergency. ■ Use extreme caution in individuals with a history of prior systemic hypersensitivity reactions. Incidence of anaphylaxis may be increased, especially with repeated injections. ■ Use caution when treating complications that include vaccinia keratitis; may cause increased corneal scarring. ■ IGIV products have been associated with renal dysfunction, acute renal failure, osmotic nephrosis, and death. Use extreme caution in patients with any degree of renal insufficiency; in patients 65 years of age and older; in patients with diabetes mellitus, paraproteinemia, sepsis, or volume depletion; and/or in patients receiving known nephrotoxic drugs. If used, should be administered at the minimum concentration available and at the minimum rate of infusion practicable. **Products containing sucrose as a stabilizer have demonstrated an increased risk of renal dysfunction.** Consider benefit versus risk before use. ■ May cause aseptic meningitis syndrome (AMS), which may begin from 2 hours to 2 days after treatment. Symptoms are drowsiness, fever, headache (severe), nausea and vomiting, nuchal rigidity, painful eye movements, and photophobia. Symptoms resolve if VIGIV is discontinued. A neurologic exam to rule out other causes of meningitis is indicated. ■ IGIV products have been associated with thrombotic events; use caution in patients with a history of cardiovascular disease or thrombotic episodes and in patients with thrombotic risk factors (e.g., cerebrovascular disease, coronary artery disease, diabetes, hypertension). Baseline assessment of blood viscosity should be made in patients at risk for hyperviscosity, including chylomicronemia, markedly high triglycerides, or monoclonal gammopathies. ■ Hemolysis and hemolytic anemia may develop. ■ Non-carcinogenic pulmonary edema (transfusion-related acute lung injury ([TRALI]) has been reported with other IGIV preparations; see [Monitor](#). ■ Interacts with some glucose-monitoring systems; see [Monitor](#) and [Drug/Lab Interactions](#).

Monitor: Use of larger veins may reduce infusion site discomfort. ■ Correct volume depletion before administration. ■ Recording the lot number on vials is helpful. ■ Monitor vital signs and observe patient continuously during infusion. A precipitous drop in BP or anaphylaxis can occur at any time. Emergency equipment and supplies must be at bedside. ■ Monitor renal function (e.g., BUN, SCr) and urine output in patients at increased risk for renal failure. Obtain baseline studies, monitor at intervals, and discontinue future VIGIV therapy if renal function deteriorates. See [Precautions](#). ■ Monitor for S/S of hemolysis (e.g., anemia, lysis of red blood cells, liberation of hemoglobin). ■ Monitor for S/S of TRALI (e.g., fever, hypoxemia, normal left ventricular function, pulmonary edema, severe respiratory distress). Usually occurs within 1 to 6 hours after completion of the transfusion. Manage with oxygen and adequate ventilatory support. If TRALI is suspected, test for the presence of anti-neutrophil antibodies in product

and patient serum. ■ Some types of blood glucose testing systems (e.g., those based on the glucose dehydrogenase pyrroloquinolinequinone [GDH-PQQ] or glucose-dye-oxidoreductase methods) could falsely interpret the maltose contained in VIGIV as glucose. To avoid this interference by maltose contained in VIGIV, blood glucose measurements in patients receiving VIGIV must be done with a glucose-specific method (monitor and test strips); see [Drug/Lab Interactions](#).

Patient Education: Report a burning sensation in the head, chills, cyanosis, diaphoresis, dyspnea, faintness or light-headedness, fatigue, fever, hives, itching or rash, neck pain or difficulty moving neck, tachycardia, wheezing. ■ Report chest pain or tightness, difficulty passing urine, decreased urine output, fluid retention, edema, shortness of breath, or sudden weight gain.

Maternal/Child: Category C: use during pregnancy only if clearly needed. ■ Safety for use in breast-feeding not established. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Not tested for safety and effectiveness in the elderly. Use with caution. Incidence of renal insufficiency and other side effects may be increased due to age, potential for decreased organ function, and pre-existing medical conditions; see [Precautions](#).

DRUG/LAB INTERACTIONS

Defer administration of **live virus vaccines** for approximately 6 months after administration of VIGIV. ■ Concurrent use with **nephrotoxic drugs** (e.g., aminoglycosides [e.g., gentamicin], amphotericin B [Amphotec, conventional], cidofovir [Vistide], rifampin [Rifadin]) may increase the risk of renal insufficiency. ■ Maltose in IVIG products has been shown to give falsely high blood glucose levels. Use could result in inappropriate doses of insulin, resulting in life-threatening hypoglycemia or untreated hypoglycemia masked by falsely elevated glucose readings. Review product information of the blood glucose testing system, including test strips, to determine if the system is appropriate for use with maltose-containing parenteral products. ■ Additional drug/lab interaction studies have not been completed.

SIDE EFFECTS

Headache and mild to moderate urticaria are most frequently observed. A full range of hypersensitivity symptoms, including anaphylaxis, is possible. Backache, dizziness, injection site reaction, nausea, and upper respiratory infections also occur. A precipitous hypotensive reaction can occur and is most commonly associated with a too-rapid rate of injection. Serious side effects reported with other IGIV products should be considered and include acute renal failure, acute tubular necrosis, osmotic nephrosis, and proximal tubular nephropathy (may result in death); aseptic meningitis syndrome; hemolytic anemia (reversible); increased BUN and SCr (may occur as soon as 1 to 2 days following infusion); noncarcinogenic pulmonary edema (transfusion-related acute lung injury [TRALI]); severe reactions (e.g., circulatory collapse, fever, loss of consciousness, nausea and vomiting, sudden onset of dyspnea) are more common in patients with antibody deficiencies; thromboembolism. Made from human plasma; the manufacturing process attempts to eliminate the risk of bloodborne viruses (e.g., hepatitis, HIV infection, Creutzfeldt-Jakob disease), but the potential for infection cannot be ruled out.

ANTIDOTE

Reduce rate or temporarily interrupt infusion for patient discomfort or any sign of adverse reaction. Reduce rate in patients at risk for renal insufficiency. Loop diuretics (e.g., furosemide [Lasix]) may be helpful in the management of fluid overload. If patient continues to experience adverse reactions after rate has been reduced, other IGIV preparations suggest premedicating with hydrocortisone 1 to 2 mg/kg 30 minutes before the immune globulin infusion. Pretreatment with acetaminophen (Tylenol) and diphenhydramine (Benadryl) may also be useful. Discontinue the drug immediately for any signs of a hypersensitivity reaction. Notify the physician. May be treated symptomatically and infusion resumed at slower rate if symptoms subside. Treat anaphylaxis immediately. Epinephrine (Adrenalin), diphenhydramine (Benadryl), oxygen, vasopressors (e.g., dopamine), corticosteroids, and ventilation equipment must always be available. Manage TRALI with oxygen and ventilatory support. Resuscitate as necessary.

VALPROATE SODIUM **BBW**

Anticonvulsant

(val-**PROH**-ayt **SO**-dee-um)

Depacon

pH 7.6

USUAL DOSE

Adults and pediatric patients 10 years of age or older: For all indications optimal clinical response is usually achieved with doses less than 60 mg/kg/24 hr. Usual therapeutic range of plasma levels is 50 to 100 mcg/mL. A total daily dose exceeding 250 mg should be given in divided doses every 6 hours (studies used an every-6-hour regimen). See [Precautions](#), [Monitor](#), and [Drug/Lab Interactions](#). Transfer to oral dosing as soon as practical. Oral and IV doses are considered to be equivalent and should be given at previously established intervals (e.g., every 6 or 8 hours). See [Precautions](#).

Complex partial seizures (monotherapy [initial]): Begin with an initial dose of 10 to 15 mg/kg/24 hr. May be increased by 5 to 10 mg/kg/week until desired clinical response achieved or side effects are dose limiting.

Complex partial seizures (conversion to monotherapy): Begin with an initial dose of 10 to 15 mg/kg/24 hr. May be increased by 5 to 10 mg/kg/week until desired clinical response achieved or side effects are dose limiting. Concomitant antiepilepsy drug (AED) dosage can usually be reduced by 25% every 2 weeks. Dose of AEDs may be decreased at the beginning of valproate therapy or decrease may be delayed for 1 to 2 weeks to avoid unwanted seizures.

Complex partial seizures (adjunctive therapy): Begin with an initial dose of 10 to 15 mg/kg/24 hr. May be increased by 5 to 10 mg/kg/week until desired clinical response achieved. Has been used in combination with either carbamazepine (Tegretol) or phenytoin (Dilantin). Dose adjustment of these drugs is not usually needed; however, drug interactions may occur; monitor plasma concentrations, especially during early therapy.

Simple and complex absence seizures: Begin with an initial dose of 15 mg/kg/24 hr. May be increased by 5 to 10 mg/kg/week until seizures are controlled or side effects are dose limiting.

PEDIATRIC DOSE

No IV dose recommendations available for pediatric patients under 10 years of age. See [Maternal/Child](#).

DOSE ADJUSTMENTS

Monitor plasma concentrations when transferring from oral to IV or IV to oral; dose increases or decreases may be indicated. ■ Reduce initial dose in the elderly; base subsequent doses on clinical response and/or development of side effects. ■ Reduced dose or discontinuation of therapy may be indicated if there is evidence of bruising, hemorrhage, or a disorder of hemostasis/coagulation. ■ No dose adjustments required for impaired renal function, gender, or race. ■ See [Maternal/Child](#).

DILUTION

Each single dose should be diluted with at least 50 mL of D5W, NS, or LR.

Storage: Store vials at CRT. Diluted solutions stable at CRT for 24 hours. No preservative added; discard unused contents of vial.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Cefepime (Maxipime), ceftazidime (Fortaz).

RATE OF ADMINISTRATION

A single dose as an infusion over 60 minutes. Manufacturer has recommended that a rate of 20 mg/min not be exceeded; however, results of a single study suggest that selected

patients tolerated rates from 1.5 to 3 mg/kg/min, allowing administration of up to 15 mg/kg/dose over 5 to 10 minutes. Incidence of side effects may be increased with too-rapid infusion.

ACTIONS

An anticonvulsant. A sodium salt of valproic acid. Therapeutic effect in epilepsy may result from increased brain concentrations of gamma-aminobutyric acid (GABA). Peak effect occurs at the end of a 60-minute infusion or 4 hours after an oral dose. Plasma protein binding is high and is concentration dependent. Concentration in CSF is similar to unbound concentrations in plasma (10%). Half-life range is 13 to 19 hours. The half-life will be in the lower part of the range in patients receiving other enzyme-inducing antiepileptic agents (e.g., carbamazepine [Tegretol], phenobarbital [Luminal], phenytoin [Dilantin]). Metabolized in the liver. 30% to 50% excreted in changed form in urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Use of IV product indicated in the following specific conditions when oral administration of valproate products (e.g., divalproex sodium [Depakote]) is temporarily not feasible. ■ Treatment of complex partial seizures occurring in isolation or with other seizures (monotherapy or adjunctive therapy). ■ Treatment of simple and complex absence seizures (monotherapy or adjunctive therapy). ■ Adjunctive treatment of multiple seizure types that include absence seizures.

Unlabeled uses: Used alone or in combination with other antiepileptic drugs for treatment of absence, myoclonic and grand mal seizures and for treatment of patients with intractable status epilepticus who have not responded to other therapies.

CONTRAINDICATIONS

Known hypersensitivity to valproate products, patients with hepatic disease or significant hepatic dysfunction, and patients with known urea cycle disorders. ■ Not recommended for use in patients with acute head trauma for the prophylaxis of posttraumatic seizures.

PRECAUTIONS

Use of IV valproate for more than 14 days has not been studied. Safety of doses above 60 mg/kg/day is not known. ■ Use caution in patients with a history of hepatic disease. Has caused fatal hepatic failure. Pediatric patients under 2 years of age are at the greatest risk, especially if they are on multiple anticonvulsants or have congenital metabolic disorders, severe seizure disorders with mental retardation, or organic brain disease. If valproate is used in pediatric patients under 2 years of age with or without these increased risk factors, benefits must outweigh risks; use only as a sole agent with extreme caution. Most cases of hepatic failure have occurred during the first 6 months of treatment. Incidence of fatal hepatotoxicity decreases in progressively older patient groups. ■ Cases of life-threatening pancreatitis have been reported in both pediatric patients and adults receiving valproate. Some of the cases have been described as hemorrhagic with rapid progression from initial symptoms to death. May occur at any time from shortly after initiation of therapy to years later. If pancreatitis is diagnosed, valproate should be discontinued. ■ Hyperammonemic encephalopathy has been reported in patients with urea cycle disorders (UCD); has been fatal. Before starting valproate, consider a possible diagnosis of UCD in patients with a history of unexplained encephalopathy or coma, encephalopathy associated with a protein load, pregnancy-related or postpartum encephalopathy, unexplained mental retardation, a history of elevated plasma ammonia or glutamine, cyclical vomiting or lethargy, episodic extreme irritability, ataxia, low BUN, protein avoidance, a family history of UCD or unexplained infant deaths, or any other S/S of UCD. ■ Hyperammonemia may be present even with normal liver function tests. Hyperammonemic encephalopathy should be considered in patients who present with lethargy and vomiting or altered mental status. Hyperammonemia should also be considered in patients who present with hypothermia (unintentional drop in body temperature to less than 35° C [95° F]). Elevation of ammonia may also be asymptomatic. ■ Hyperammonemia with or without encephalopathy has been reported with concomitant administration of valproic acid and topiramate (Topamax). Has occurred in patients who have tolerated either drug alone. S/S in most cases are abated with

discontinuation of either drug. ■ Hypothermia has occurred with valproate therapy both in conjunction with and in the absence of hyperammonemia. Can also occur in patients using concomitant topiramate with valproate after starting topiramate therapy or after increasing the dose of topiramate. ■ Some adverse effects (e.g., elevated liver enzymes and thrombocytopenia) appear to be dose-related. Must weigh benefit of improved therapeutic effect with higher doses against the possibility of an increased incidence of adverse effects. ■ Psychotic symptoms and other behavioral changes have been reported and may include aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies. Some resolved without intervention. Others required dose reduction or discontinuation of valproate. ■ Incidence of thrombocytopenia increases at total trough concentrations greater than 110 mcg/mL in females and greater than 135 mcg/mL in males. ■ Multi-organ hypersensitivity reactions have been reported rarely when beginning valproate therapy. Onset may range from 1 to 40 days (median 21 days), and initial S/S include fever and rash associated with other organ system involvement (e.g., arthralgia, hepatitis, lymphadenopathy, nephritis). Discontinue valproate and use alternative therapy. ■ Plasma protein binding is decreased and free fraction is increased in the elderly, in hyperlipidemic patients, in chronic hepatic disease, in impaired renal function, and in the presence of other drugs; see [Drug/Lab Interactions](#). Total plasma concentrations may be normal, but free concentrations may be substantially elevated in these patients. ■ Reduce AED doses gradually to prevent status epilepticus in patients treated for major seizure activity. ■ Can cause major congenital malformations, particularly neural tube defects (e.g., spina bifida). Do not administer to a woman of childbearing potential unless essential to the management of her medical condition. Consider benefit versus risk to the fetus in women of childbearing age. Do not use to treat non-life-threatening conditions (e.g., migraine); see [Maternal/Child](#). ■ In vitro studies suggest that valproate may stimulate the replication of the HIV and CMV viruses under certain experimental conditions. The clinical significance of this is unknown but should be kept in mind when evaluating patients with HIV or CMV.

Monitor: Thrombocytopenia, inhibition of the secondary phase of platelet aggregation, and abnormal coagulation parameters have been reported. Obtain baseline platelet counts and coagulation tests and monitor during therapy. Repeat before planned surgery. ■ Obtain baseline liver function tests and monitor frequently during therapy, especially during the first 6 months. ■ Observe closely for S/S of hepatotoxicity (e.g., anorexia, facial edema, lethargy, loss of seizure control, malaise, weakness, vomiting). ■ Abdominal pain, anorexia, nausea, and vomiting may be symptoms of pancreatitis and should be evaluated promptly. ■ Therapeutic serum levels for most patients will range from 50 to 100 mcg/mL; however, a good correlation has not been established between daily dose, serum levels, and therapeutic effect. ■ Monitor antiepileptic concentrations more frequently whenever concomitant AEDs are being introduced or withdrawn and observe closely for seizure activity. ■ Monitor plasma ammonia levels more frequently if an asymptomatic elevation of ammonia occurs; may need to discontinue valproate sodium if hyperammonemia appears. ■ Monitor serum concentrations more frequently if any of the risk factors listed in Dose Adjustments or Precautions are present, and when any drugs that affect hepatic enzymes are introduced or discontinued; see [Drug/Lab Interactions](#). ■ Evaluate for S/S of UCD; see [Precautions](#) and [Antidote](#). ■ Consider hyperammonemia encephalopathy in patients who develop unexplained lethargy and vomiting or changes in mental status. Consider hyperammonemia in patients who present with hypothermia. Elevations of ammonia may be asymptomatic; monitor plasma ammonia levels closely; see [Antidote](#). Treat hyperammonemia and assess for underlying UCD. ■ Observe patient closely for signs of CNS side effects; see [Precautions](#). ■ Total serum valproic acid concentration is affected by variable free-fractions of drug; consider hepatic metabolism and protein binding when interpreting valproic acid concentrations. ■ See [Dose Adjustments](#), [Precautions](#), and [Drug/Lab Interactions](#) for additional monitoring requirements.

Patient Education: May cause drowsiness; determine effects before driving or operating any machinery. ■ **Avoid pregnancy;** use effective contraception; see [Maternal/Child](#). ■ Read the patient information leaflet provided by manufacturer, and discuss your medical history and concurrent prescription and non-prescription medications with your health care provider. ■ Report symptoms such as abdominal pain, anorexia, changes in mental state, fever, jaundice, lymphadenopathy, nausea, rash, unexplained lethargy, or vomiting promptly. ■ May cause alterations in mood (e.g., aggression, agitation, anger, anxiety, apathy, decreased ability to cope, depression, hostility, irritability, thoughts of suicide); report these changes promptly. ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry.

Maternal/Child: Category D: avoid pregnancy. There is an increased risk for major congenital malformations, particularly neural tube defects (e.g., spina bifida) and other birth defects, such as craniofacial defects and cardiovascular malformation, in infants exposed to valproate sodium and related products in utero. The incidence of congenital malformations associated with the use of valproate by women with seizure disorders during pregnancy is higher than in women with seizure disorders who use other AEDs. The increased teratogenic risk from valproate in women with epilepsy is expected to be reflected in an increased risk in other indications (e.g., bipolar disorder, migraine). Use during pregnancy only if essential for management of a serious medical condition (e.g., seizures). ■ Evidence suggests that folic acid supplementation before conception and during the first trimester decreases the risk for congenital neural tube defects in the general population. Tests to detect neural tube and other defects should be considered as part of routine prenatal care in pregnant women receiving valproate. To prevent major seizures, do not discontinue valproate abruptly in these patients; can precipitate status epilepticus, resulting in maternal and fetal hypoxia and a threat to life. ■ When used during pregnancy, valproate has caused clotting abnormalities, including afibrinogenemia in a newborn; monitor clotting parameters carefully. Has also caused hepatic failure in a newborn and an infant. ■ Developmental delay, autism, and/or autism spectrum disorder in the offspring of women exposed to valproate during pregnancy have been reported. ■ Use with caution during breast-feeding. ■ Neonates under 2 months have a markedly decreased ability to eliminate valproate compared to older pediatric patients and adults. ■ Pediatric patients 3 months to 10 years of age have 50% higher clearance rates based on weight. ■ Younger pediatric patients, especially those receiving enzyme-inducing drugs (e.g., carbamazepine, phenobarbital, phenytoin) will require larger maintenance doses to achieve therapeutic valproic acid concentrations. ■ IV product has not been studied in pediatric patients under 2 years of age. If used, use as a sole agent with extreme caution. ■ Children under 2 years of age are at an increased risk for developing fatal hepatotoxicity. ■ See [Precautions](#) and [Monitor](#).

Elderly: May be more prone to adverse events. Initial dose should be lower, and dosage should be increased slowly. Rate of clearance decreased, free fraction increased; see [Dose Adjustments](#). ■ Monitor for fluid, nutritional intake, dehydration, somnolence, and other adverse events.

DRUG/LAB INTERACTIONS

Clearance increased and effectiveness reduced by **drugs that induce hepatic enzymes** (e.g., phenytoin [Dilantin], carbamazepine [Tegretol], phenobarbital [Luminal], primidone [Mysoline]); increased monitoring of valproate and concomitant drug concentrations indicated. ■ **Aspirin** decreases protein binding, inhibits metabolism, and increases free concentration of valproate; use caution and monitor valproate concentrations if administered concomitantly. ■ Peak concentrations increased if coadministered with **felbamate** (Felbatol); reduced dose of valproate indicated. ■ Metabolism may be decreased and serum levels increased when given concurrently with **erythromycin**. ■ **Carbapenem antibiotics** (e.g., doripenem [Doribax], ertapenem [Invanz], meropenem [Merrem]) may reduce serum valproic acid concentrations to subtherapeutic levels, resulting in loss of seizure

control. Monitor valproic acid levels. Consider alternative antibacterial therapy. If administration of a carbapenem is necessary, supplemental anticonvulsant therapy should be considered. ■ **Rifampin** (Rifadin) may increase clearance of valproate and require dose adjustment. ■ Inhibits metabolism of **barbiturates** (e.g., phenobarbital) and **primidone**, increasing their effects. Monitor for neurologic toxicity; obtain barbiturate serum levels and reduce barbiturate dose as indicated. ■ May decrease serum levels of carbamazepine. **Carbamazepine** decreases plasma concentrations of valproate, and a loss of seizure control may occur; monitor carefully and increase valproate dose if indicated. ■ Concomitant use with **clonazepam** (Klonopin) may induce absence status in patients with a history of absence-type seizures. ■ **Displaces some protein-bound drugs**, inhibits their metabolism, and increases their effects (e.g., carbamazepine, diazepam [Valium], phenytoin, tolbutamide, warfarin [Coumadin]). Dose adjustments and serum concentrations may be indicated. ■ **Phenytoin** with valproate has caused breakthrough seizures in patients with epilepsy; adjust dose of phenytoin as indicated by serum concentrations. ■ Hyperammonemia with or without encephalopathy has been reported with concomitant administration of valproic acid and **topiramate** (Topamax); see **Precautions**. ■ Monitor coagulation tests if administered with **anticoagulants** (e.g., warfarin). ■ CNS effects may be increased when given concurrently with **CNS depressants** (e.g., benzodiazepines [e.g., diazepam (Valium)] and **tricyclic antidepressants** [e.g., amitriptyline (Elavil)]). ■ May decrease clearance and increase effects of **amitriptyline** (Elavil) and **nortriptyline** (Aventyl). Dose reduction of these drugs may be required. ■ Inhibits metabolism of **ethosuximide** (Zarontin); monitor serum concentrations of both drugs with concomitant administration. ■ Concurrent administration of **lamotrigine** (Lamictal) and valproate may decrease valproate levels and increase lamotrigine levels. Serious skin reactions have been reported. Dose adjustments may be required. ■ Decreases clearance and may increase toxicity of **zidovudine** (AZT, Retrovir). ■ See package insert for additional information about many drugs that do not present significant clinical interactions. ■ May alter **thyroid function tests**. ■ May cause **false-positive urine ketone test**.

SIDE EFFECTS

Abdominal cramps and/or pain; abnormal gait; acute pancreatitis; alopecia; amblyopia/blurred vision; amnesia; anaphylaxis; anorexia with weight loss or increased appetite

with weight gain; asterixis (spots before the eyes); asthenia; ataxia; bronchitis; chest pain; confusion; constipation; diarrhea; diplopia; dizziness; dyspepsia; dyspnea; ecchymosis; elevated serum amylase; euphoria; fever; flu syndrome; headache; hyperesthesia; indigestion; infection; injection site reaction; insomnia; nausea; nervousness; nystagmus; parkinsonism; peripheral edema; pharyngitis; pneumonia; psychiatric symptoms, including aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies; rhinitis; somnolence; taste perversion; thinking abnormally; thrombocytopenia; tinnitus; tremor; vasodilation; vertigo; vomiting. Frequency of elevated liver enzymes and thrombocytopenia may be dose related. Fatal hepatotoxicity (anorexia, facial edema, lethargy, loss of seizure control, malaise, sweating, weakness, vasodilation, vomiting) has occurred. Coma has occurred with or without concurrent phenobarbital. Encephalopathy with or without fever has caused fatalities in patients with hyperammonemic encephalopathy and/or underlying UCD disorder.

Overdose: Somnolence, deep coma, heart block. Some fatalities have been reported.

ANTIDOTE

Keep physician informed of all side effects. Some may respond to a decrease in the rate of administration. Discontinue immediately if signs of suspected or apparent significant hepatic dysfunction appear (e.g., hyperammonemia, elevated liver function tests) or S/S of underlying UCD. Hepatic dysfunction may progress after valproate is discontinued. Discontinue if S/S of multi-organ hypersensitivity reaction occur. Initiate alternate therapy. Reduce dose or discontinue if bruising, hemorrhage, or abnormal coagulation parameters occur (e.g., thrombocytopenia). Discontinue if S/S of pancreatitis occur. All of the above situations may be life threatening and will require immediate symptomatic treatment. Maintain a patent airway and resuscitate as indicated. Support patient as required in treatment of overdose; monitor and maintain adequate urine output. Hemodialysis is effective in overdose. Naloxone (Narcan) may reverse CNS depressant effects in overdose but may also reverse antiepilepsy effects of valproate. Psychotic symptoms may require dose reduction or discontinuation of valproate.

VANCOMYCIN HYDROCHLORIDE(van-koh-**MY**-sin hy-droh-**KLOR**-eyed)**Antibacterial**
(tricyclic-glycopeptide)

pH 2.4 to 5

USUAL DOSE

7.5 mg/kg or 500 mg every 6 hours or 15 mg/kg or 1 Gm every 12 hours for 7 to 10 days. Maximum dosage of 3 to 4 Gm/24 hr used only in extreme situations. Normal renal function required.

Prevention of bacterial endocarditis in selected penicillin-allergic patients having GI, biliary, or GU surgery or instrumentation:

Adults and adolescents: 1 Gm IV before the procedure. Give gentamicin 1.5 mg/kg IV concurrently in high-risk patients (not to exceed 120 mg). Infusion must be administered over at least 60 minutes and should be completed within 30 minutes of starting the procedure. Gentamicin may not be necessary in moderate-risk patients. Both doses may be repeated in 8 to 12 hours for high-risk patients. Vancomycin alone may be indicated in selected patients having dental procedures or upper respiratory tract surgery or instrumentation. Consult recent recommendations of the American Heart Association or the American Dental Association.

Treatment of patients with methicillin-resistant or methicillin-susceptible staphylococcal endocarditis who have a native cardiac valve: 30 mg/kg/24 hr equally divided into 2 doses (15 mg/kg every 12 hours) for 6 weeks or longer. If more than 2 Gm/day are required, monitoring of serum concentrations of vancomycin is recommended.

Treatment of patients with methicillin-resistant or methicillin-susceptible staphylococcal endocarditis who have a prosthetic valve or other prosthetic material: 30 mg/kg/24 hr equally divided into 2 doses (15 mg/kg every 12 hours) or 4 doses (7.5 mg/kg every 6 hours) for 6 weeks or longer. If more than 2 Gm/day are required, monitoring of serum concentrations of vancomycin is recommended. Given in conjunction with oral rifampin 300 mg every 8 hours for 6 weeks or longer and IM or IV gentamicin 1 mg/kg every 8 hours during the first 2 weeks of vancomycin therapy.

Treatment of endocarditis caused by viridans streptococci or *Streptococcus bovis*: 30 mg/kg/24 hr equally divided into 2 doses (15 mg/kg every 12 hours) for 4 weeks. If more than 2 Gm/day are required, monitoring of serum concentrations of vancomycin is recommended.

Treatment of enterococcal endocarditis: 30 mg/kg/24 hr equally divided into 2 doses (15 mg/kg every 12 hours) for 4 to 6 weeks. If more than 2 Gm/day are required, monitoring of serum concentrations of vancomycin is recommended. Given in conjunction with IM or IV gentamicin 1 mg/kg every 8 hours for 4 to 6 weeks.

Perioperative prophylaxis in selected surgeries (e.g., cardiac, prosthetic valve, coronary artery bypass, joint replacement, craniotomy) when a cephalosporin cannot be used or there is a high incidence of methicillin-resistant staphylococci at the institution (unlabeled use): 1 Gm IV over 1 to 2 hours; should be completed within 30 minutes before the start of surgery. May be repeated one or more times if surgery is prolonged or major blood loss occurs. Postoperative doses are considered generally unnecessary and are not recommended.

Prevention of neonatal Group B streptococcal disease: Used for women with penicillin hypersensitivity who should not receive β -lactam anti-infectives or if resistance to clindamycin or erythromycin is known or suspected. 1 Gm every 12 hours until delivery. Initiate at the beginning of labor or rupture of membranes.

PEDIATRIC DOSE

Pediatric patients 1 month of age or older: Mild to moderate infections: 40 mg/kg of body weight/24 hr equally divided and given every 6, 8, or 12 hours (10 mg/kg every 6 hours, 13.33 mg/kg every 8 hours, or 20 mg/kg every 12 hours) for 7 to 10 days.

Severe infections: Up to 60 mg/kg/24 hr (15 mg/kg every 6 hours, 20 mg/kg every 8 hours, or 30 mg/kg every 12 hours) has been used if there is CNS involvement. Do not exceed 2 Gm in 24 hours.

Prevention of bacterial endocarditis in selected penicillin-allergic patients having GI, biliary, or GU surgery or instrumentation: 20 mg/kg before the procedure. Give gentamicin 1.5 mg/kg concurrently in high-risk patients (not to exceed 120 mg). Gentamicin may not be necessary in moderate-risk patients. Infusion must be administered over at least 60 minutes and should be complete within 30 minutes of starting the procedure. Both doses may be repeated in 8 to 12 hours for high-risk patients. Note comments about dental and upper respiratory surgery or instrumentation under Usual Dose.

NEONATAL DOSE

15 mg/kg as an initial dose. See [Maternal/Child](#). Follow with 10 mg/kg. Adjust interval based on age and/or weight as follows:

Infants up to 1 week of age: Give every 12 hours.

Infants 1 week to 1 month of age: Give every 8 hours.

The American Academy of Pediatrics recommends 10 to 15 mg/kg. Adjust dose and interval based on weight and/or age as follows:

Postnatal Weight and Age	Dose and Interval
Less than 1.2 kg and less than 7 days of age	15 mg/kg/dose every 24 hours
Less than 1.2 kg and 7 days of age or older	15 mg/kg/dose every 24 hours
1.2 to 2 kg and less than 7 days of age	10 to 15 mg/kg/dose every 12 to 18 hours
1.2 to 2 kg and 7 days of age or older	10 to 15 mg/kg/dose every 8 to 12 hours
Over 2 kg and less than 7 days of age	10 to 15 mg/kg/dose every 8 to 12 hours
Over 2 kg and 7 days of age or older	15 to 20 mg/kg/dose every 6 to 8 hours

DOSE ADJUSTMENTS

Reduce total daily dose in premature infants and the elderly. Greater dose reductions than expected may be necessary in these patients because of impaired renal function. ■ Dose reduction required in impaired renal function. In all renal impaired patients (including functionally anephric and anuric patients), the initial dose should be no less than 15 mg/kg. **See prescribing information;** dose is reduced for every decrease of 10 mL/min in the CrCl. Subsequent doses of 250 to 1,000 mg every several days are suggested for functionally anephric patients. Subsequent doses of 1,000 mg every 7 to 10 days are suggested for anuric patients. Monitoring of serum levels is recommended.

DILUTION

Available premixed, premixed and frozen, or reconstitute each 500-mg vial with 10 mL of SWFI. Each 500 mg must be further diluted with 100 mL of NS or D5W and given as an intermittent infusion. Also **compatible** in D5NS, LR, D5LR, D5 Normosol-M, Iso-lyte E, and acetated Ringer's injection. Concentrations greater than 5 mg/mL are not recommended. If absolutely necessary, 1 to 2 Gm may be further diluted in sufficient amounts of the same infusion fluids and given over 24 hours. Not recommended. Also available in ADD-Vantage vials for use with ADD-Vantage infusion containers.

Storage: Store in refrigerator after initial dilution. Maintains potency for 2 weeks in D5W or NS, 96 hours for other infusion solutions. Solutions prepared from ADD-Vantage vials stable at room temperature for 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Several sources recommend not admixing with other drugs. They suggest it is **incompatible** with alkaline solutions (e.g., aminophylline, aztreonam [Azactam], barbiturates [e.g., pentobarbital (Nembutal)], chloramphenicol [Chloromycetin], dexamethasone [Decadron], sodium bicarbonate) and may form a precipitate with heavy metals. May inactivate aminoglycosides; should also not be combined in the same solution with albumin, selected cephalosporins, foscarnet (Foscavir), or selected penicillins; if administered concurrently, administer at separate sites or separate intervals (flush IV line with a **compatible** solution before and after administration).

One source suggests the following **compatibilities**:

Additive: See general comments under Compatibility. Amikacin (Amikin), aminophylline, atracurium (Tracrium), aztreonam (Azactam), calcium gluconate, cefepime (Maxipime), dimenhydrinate, famotidine (Pepcid IV), heparin, hydrocortisone sodium succinate (Solu-Cortef), meropenem (Merrem IV), potassium chloride (KCl), ranitidine (Zantac), verapamil.

Y-site: See general comments under Compatibility. Acyclovir (Zovirax), aldesleukin (Proleukin), allopurinol (Aloprim), alprostadil, amifostine (Ethyol), amiodarone (Nexterone), ampicillin, ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), atracurium (Tracrium), aztreonam (Azactam), caspofungin (Cancidas), cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), cisatracurium (Nimbex), cyclophosphamide (Cytoxan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doripenem (Doribax), doxapram (Dopram), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), insulin (regular), labetalol, levofloxacin (Levaquin), linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), methotrexate, midazolam (Versed), milrinone (Primacor), morphine, mycophenolate (CellCept IV), nafcillin (Nallpen), nifedipine (Cardene IV), ondansetron (Zofran), paclitaxel (Taxol), palonosetron (Aloxi), pancuronium, pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), sodium bicarbonate, tacrolimus (Prograf), teniposide (Vumon), theophylline, thiotepa, ticarcillin/clavulanate (Timentin), tigecycline (Tygacil), vecuronium, vinorelbine (Navelbine), warfarin (Coumadin), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Severe hypotension, with or without red blotching of the face, neck, chest, and extremities, and cardiac arrest can occur with too-rapid injection.

A single dose properly diluted (concentration of no more than 5 mg/mL) at a rate not to exceed 10 mg/min or 60 minutes, whichever is longer. Another reference suggests infusion over 1 to 2 hours. This intermittent infusion is the preferred route of administration because of high incidence of thrombophlebitis.

Pediatric rate: A single dose over a minimum of 60 minutes.

ACTIONS

A very potent tricyclic glycopeptide antibiotic, it is bactericidal against gram-positive organisms. Bactericidal action results from the inhibition of cell wall synthesis. Also alters bacterial cell-membrane permeability and RNA synthesis. Well distributed in most body tissues and fluids, including pleural, pericardial, ascitic, and synovial fluids; in urine; in peritoneal dialysis fluid; and in atrial appendage tissue. Penetration into the CSF occurs when the meninges are inflamed. Half-life is 4 to 6 hours in patients with normal renal function. Vancomycin is excreted in biologically active form in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Serious gram-positive infections (e.g., staphylococcal) infections including endocarditis, septicemia, bone, lower respiratory tract, and skin and skin structure infections that do not respond or are resistant to other less toxic antibiotics, such as penicillins or cephalosporins (e.g., methicillin-resistant staphylococci). ■ Penicillin-allergic patients. ■ Treatment of endocarditis caused by *Streptococcus viridans* or *S. bovis* concurrently with an aminoglycoside antibiotic; endocarditis caused by diphtheroids or *S. epidermidis* concurrently with rifampin and/or an aminoglycoside. ■ Parenteral form used orally for pseudomembranous colitis/staphylococcal enterocolitis caused by *C. difficile*.

Unlabeled uses: Prophylaxis against bacterial endocarditis in moderate or high-risk (prosthetic heart valves, congenital or rheumatic heart disease) penicillin-allergic patients undergoing GI, biliary or GU surgery or instrumentation. Given in combination with gentamicin in GI or GU procedures.

CONTRAINDICATIONS

Known hypersensitivity to vancomycin. Solutions containing dextrose may be contraindicated in patients with allergies to corn or corn products.

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, vancomycin should be used only to treat or prevent infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies necessary to determine susceptibility of the causative organism to vancomycin. ■ Prolonged use of drug may result in superinfection caused by overgrowth of nonsusceptible organisms. ■ May be ototoxic and nephrotoxic. Some clinicians feel the risk of ototoxicity and nephrotoxicity is minimal in patients with normal renal function who receive vancomycin as a single agent. ■ Use caution in impaired hearing, impaired renal function, pregnancy, breast-feeding, neonates, and the elderly. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with vancomycin. ■ Oral vancomycin has a local effect only (e.g., in the bowel); not for systemic use. ■ A syndrome of chemical peritonitis has been reported in patients receiving intraperitoneal vancomycin during CAPD.

Monitor: Monitoring of serum levels and SCr may be indicated in patients at increased risk for developing nephrotoxicity and/or ototoxicity (e.g., underlying renal dysfunction, or receiving concomitant aminoglycosides [e.g., gentamicin]). ■ Determine absolute patency of vein. Necrosis and sloughing will result from extravasation. Rotate injection sites every 2 to 3 days. ■ Observe for furry tongue, diarrhea, and foul-smelling stools. ■ Severe hypotension, with or without red blotching of the face, neck, chest, and extremities, and cardiac arrest can occur with too-rapid injection (red man or red neck syndrome). ■ Monitor BP continuously during infusion to prevent a precipitous drop. ■ Auditory testing indicated with prolonged use. ■ Periodic monitoring of leukocyte count recommended in prolonged therapy. ■ See [Drug/Lab Interactions](#).

Patient Education: Report all side effects promptly. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category C: studies not conclusive. Use only if clearly needed. ■ Safety for use in breast-feeding not established; discontinue breast-feeding. ■ Neonates have immature renal function; blood levels may be excessive. Confirmation of desired serum concentrations suggested in premature and full-term neonates.

Elderly: Systemic and renal clearance may be reduced; dosage reduction required.

DRUG/LAB INTERACTIONS

Synergistic with **aminoglycosides** (e.g., amikacin [Amikin], gentamicin, tobramycin) against many strains of *Staphylococcus aureus* and streptococci; see package insert. Combined use may increase risk of ototoxicity and nephrotoxicity. ■ Use caution with **dimenhydrinate**, which can mask ototoxicity. ■ Additive toxicities may occur with **systemic or topical** use of **other nephrotoxic, neurotoxic, or ototoxic drugs** (e.g., aminoglycosides, amphotericin B, bacitracin, cisplatin, colistin, ethacrynic acid [Edecrin], furose-

mide [Lasix], polymyxin B). Use with caution in combination with vancomycin; serial monitoring of renal and auditory systems indicated. ■ May enhance neuromuscular blockade with **nondepolarizing muscle relaxants** (e.g., pancuronium). ■ May cause erythema and histamine-like flushing in pediatric patients with **anesthetics**. Use with anesthetics may also increase the risk of hypersensitivity reactions, including anaphylaxis and infusion reactions. Administration of vancomycin as a 1-hour infusion before anesthetic induction may reduce this interaction. ■ May inhibit **methotrexate** excretion and increase methotrexate toxicity. May occur even if 10 days have elapsed since vancomycin administered. Adjust methotrexate dose as indicated.

SIDE EFFECTS

Chills, dizziness, fever, macular rashes, pain at injection site, pruritus, tinnitus, urticaria. **Major:** Anaphylaxis, cardiac arrest, CDAD, dyspnea, eosinophilia, hearing loss, hypotension, infusion-related events (anaphylactoid reactions, dyspnea, flushing of the upper body, pruritus, urticaria, wheezing), interstitial nephritis, neutropenia, red neck or red man syndrome, renal failure, Stevens-Johnson syndrome (erythema multiforme [flu-like symptoms that can be fatal]), thrombophlebitis, wheezing.

Post-Marketing: Drug Rash with Eosinophilia and Systemic Symptoms (DRESS).

ANTIDOTE

Notify the physician of all side effects. Hearing loss may progress even if drug is discontinued. If minor side effects are progressive or any major side effect occurs, discontinue the drug, treat hypersensitivity reaction, or resuscitate as necessary. Prevent severe hypotension by slowing infusion rate to 2 hours. Fluids, antihistamines, corticosteroids, and vasopressors (e.g., dopamine) may be required. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis or CAPD will not decrease blood levels in toxicity.

VASOPRESSIN INJECTION

(vay-so-PRESS-in in-JEK-shun)

Hormone
Antidiuretic
Vasopressor
(unlabeled)

Pitressin, Pressyn 

pH 2.5 to 4.5

USUAL DOSE

ALL IV DOSES AND USES ARE UNLABELED.

Treatment of shock-resistant VF or pulseless VT during cardiac arrest in adult patients: AHA Emergency Cardiovascular Care recommends 40 units by IV push or through the endotracheal tube for one dose only (may replace the first or second dose of epinephrine).

Hemodynamic support during vasodilatory shock (e.g., septic shock): AHA guidelines recommend a continuous infusion of 0.02 to 0.04 units/min. Other sources in the literature recommend low-dose vasopressin infusions in vasodilatory shock refractory to catecholamines. 0.04 units/min as an infusion (range was 0.01 to 0.1 units/min). Doses greater than 0.08 units/min showed no added benefit. Continue infusion until the patient is stabilized. Mean duration in a study was 18 to 168 hours.

Hypotension unresponsive to norepinephrine following cardiopulmonary bypass: In 2002, Masetti and colleagues conducted an open-label study of vasopressin in 16 adults with hypotension following cardiopulmonary bypass. All had failed to respond to maximum norepinephrine doses (greater than 30 mcg/kg/min). Vasopressin was administered at rates of 0.1 to 1 unit/min for an average of 58.8 ± 37.3 hours. Systolic blood pressure increased from 89.6 ± 7.9 to 119 ± 10.5 mm Hg with treatment, and systemic vascular resistance increased from 688 ± 261.7 to $1,043.3 \pm 337.1$ dynes \cdot sec/cm⁵. Vasopressin use permitted discontinuation of other vasopressors in 13 of the patients within an average of 5.8 ± 7.8 hours. Seven of the 16 patients survived to discharge. (Source: Buck ML [PharmD, FCCP]: Low-dose vasopressin infusions for vasodilatory shock, *Journal of Cardiac Surgery*, 17:485-489, 2002.)

GI hemorrhage: 0.2 units/min as an infusion. Increase each hour by 0.2 units/min until hemorrhage is controlled. Doses up to 1 unit/min are suggested. Another source suggests 0.2 to 0.4 units/min as an infusion. Gradually increase dose as needed to a maximum dose of 0.9 units/min.

PEDIATRIC DOSE

All IV doses and uses are unlabeled; however, studies in pediatric patients have been conducted.

Hemodynamic support during vasodilatory shock: 0.0003 to 0.002 units/kg/min as an infusion (range is 0.018 to 0.12 units/kg/hr). Continue infusion until the patient and concurrently administered catecholamine infusions are stabilized. Mean duration in a study was 6 to 144 hours. AHA guidelines recommend a continuous infusion of 0.0002 to 0.002 units/kg/min (0.2 to 2 milliunits/kg/min).

Treatment of shock-resistant VF or pulseless VT during cardiac arrest: Recommended for use in adult patients only. AHA guidelines recommend 0.4 to 1 unit/kg IV push (maximum dose 40 units).

GI hemorrhage: 0.002 to 0.005 units/kg/min as an infusion. Gradually increase dose as needed to a maximum dose of 0.01 units/kg/min.

DILUTION

AHA Guidelines do not mention the use of a diluent, which suggests that vasopressin may be given undiluted. Another source recommends dilution for IV use to a 0.1 to 1 unit/mL dilution with NS or D5W. 38 mL diluent with 2 mL vasopressin (40 units) yields 1 unit/mL. 398 mL diluent with 2 mL vasopressin (40 units) yields 0.1 unit/mL.

Storage: Store unopened vials at CRT.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Consider specific use and unlabeled IV use.

Sources suggest the following **compatibilities**:

Additive: One source lists it as **compatible** as an additive with verapamil.

Y-site: Another source suggests **Y-site compatibility** with amiodarone (Nexterone), argatroban, caspofungin (Cancidas), ceftazidime (Teflaro), ciprofloxacin (Cipro IV), diltiazem (Cardizem), dobutamine, dopamine, epinephrine (Adrenalin), fluconazole (Diflucan), gentamicin, heparin, 6% hydroxyethyl starch (Voluven), imipenem-cilastatin (Primaxin), insulin (regular), lidocaine, linezolid (Zyvox), meropenem (Merrem IV), metronidazole (Flagyl IV), miconazole (Mycelex CR), milrinone (Primacor), moxifloxacin (Avelox), nitroglycerin IV, norepinephrine (Levophed), pantoprazole (Protonix IV), phenylephrine (Neo-Synephrine), piperacillin/tazobactam (Zosyn), procainamide (Pronestyl), sodium bicarbonate, telavancin (Vibativ), voriconazole (VFEND IV).

RATE OF ADMINISTRATION

Injection: A single dose IV push; see **Precautions**.

Infusion: See **Usual Dose** for recommended rates for each diagnosis. Use of a central venous catheter is recommended. Titrate rate so that perfusion remains adequate while BP is optimized. Do not discontinue abruptly; one source recommends tapering over 2 to 3 hours while monitoring effects.

ACTIONS

Synthetic vasopressin of the posterior pituitary gland standardized to 20 units/mL. An antidiuretic. Also a potent vasoconstrictor. Causes smooth muscle contraction of all parts of the vascular bed (e.g., capillaries, small arterioles, and venules). Has a lesser effect on the smooth muscles of larger arteries and veins. This direct contractile effect on the smooth muscle of the vascular system is not antagonized by adrenergic blocking agents (e.g., atenolol [Tenormin], metoprolol [Lopressor]) and is not prevented by vascular denervation (loss of nerve impulse to the vascular system). Its IV use is as an alternative pressor agent to epinephrine. Not effective in normotensive patients; however, promotes an effective increase in BP in hypotensive patients, even when other agents have failed. Rapidly degraded by enzymes in the liver and kidneys. Plasma half-life is 10 to 35 minutes. A small amount is excreted unchanged in the urine.

INDICATIONS AND USES

Used IM or SC as an antidiuretic in central diabetes insipidus or as a diagnostic aid in diabetes insipidus.

Unlabeled uses: The AHA Handbook of Emergency Cardiovascular Care recommends use in the treatment of adult shock-refractory ventricular fibrillation (class IIb) (an alternative pressor agent to epinephrine) and for hemodynamic support in vasodilatory shock (e.g., septic shock). Has also been used for treatment of GI hemorrhage.

CONTRAINDICATIONS

Hypersensitivity to vasopressin or any of its components; see **Precautions**. AHA Guidelines state "not recommended for responsive patients with coronary heart disease."

PRECAUTIONS

IV uses are unlabeled. ■ May cause ischemia of other organs (e.g., GI tract, kidneys) if fluid intake is not adequate. ■ Use with extreme caution in patients with vascular disease, especially coronary artery disease; may cause cardiac ischemia. Small doses may precipitate anginal pain, and larger doses may cause myocardial infarction. ■ May produce water intoxication; use with caution in patients with asthma, chronic nephritis and nitrogen retention, epilepsy, heart failure, migraine, or any conditions in which a rapid addition to extracellular water could be hazardous.

Monitor: In addition to management of airway, oxygenation, and blood gas determinations, the continuous monitoring of ECG, vital signs, and fluid and electrolyte status is mandatory. ■ Monitor IV site very closely, especially if it is a peripheral site; a central venous catheter is preferred. Produces intense vasoconstriction. Avoid extravasation;

vasoconstriction that may result in severe tissue necrosis and gangrene can occur. ■ Maintain adequate fluid intake to avoid ischemia of other organs. ■ Use of vasopressin in vasodilatory shock may permit reduction or discontinuation of other vasopressors. ■ Use an indwelling urinary catheter to confirm urine output and monitor closely. ■ Fluid restriction may be indicated; initial signs of water intoxication include drowsiness, listlessness, and headache, which can rapidly progress to terminal coma and convulsions. ■ See **Rate of Administration, Precautions, and Drug/Lab Interactions.**

Maternal/Child: Category C: safety for use during pregnancy not established; use only if clearly needed. ■ Safety for use during breast-feeding not established. ■ Safety and effectiveness for use in pediatric patients not established; however, it has been used successfully in selected critically ill pediatric patients with catecholamine-resistant hypotension.

Elderly: See **Precautions;** elderly may be more sensitive to adverse effects.

DRUG/LAB INTERACTIONS

Vasodilators (e.g., nitroglycerin, nitroprusside sodium) counteract the vasoconstrictive effects of vasopressin. ■ Additive pressor response with **ganglionic blocking agents** (e.g., trimethaphan [Arfonad (rarely used antihypertensive)]). ■ Antidiuretic effect may be increased with concurrent use of **carbamazepine** (Tegretol), **chlorpropamide** (Diabinese), **clofibrate** (Atromid-S), **fludrocortisone** (Florinef), **tricyclic antidepressants** (e.g., amitriptyline [Elavil]), **urea**. ■ Antidiuretic effect may be decreased with concurrent use of **alcohol**, **demeclocycline** (Declomycin), **heparin**, **lithium** (Carbolith), **norepinephrine** (Levophed).

SIDE EFFECTS

Arrhythmias, bradycardia, hypertension, and MI have resulted from high doses. Abdominal cramps, angina, arrhythmias, bronchial constriction, cardiac arrest, circumoral pallor, cutaneous gangrene, decreased cardiac output, diaphoresis, flatus, gangrene, headache (pounding), hypersensitivity reactions (including anaphylaxis), hyponatremia, injection site ischemia resulting in severe tissue necrosis and gangrene, ischemic skin and mucous membrane lesions, myocardial ischemia, nausea, organ ischemia (e.g., GI, kidney), peripheral vasoconstriction, shock, sweating, tremor, urticaria, venous thrombosis, vertigo, and vomiting.

Overdose: Water intoxication.

ANTIDOTE

In an emergency cardiac care situation, all side effects can present life-threatening additional problems. Monitor the patient closely and observe all S/S that may indicate further deterioration. Treat symptomatically according to AHA Guidelines. Monitor fluid intake and urine output to ensure adequate hydration. Extravasation and/or ischemia at the injection site should be reported immediately to prevent tissue necrosis and gangrene. If water intoxication should occur, treat with water restriction and discontinue vasopressin. If possible, discontinue gradually as described in Rate of Administration to prevent a rapid fall in BP. If severe, may require osmotic diuresis with mannitol, hypertonic dextrose, or urea alone or with furosemide (Lasix).

VECURONIUM BROMIDE **BBW**(veh-kyour-**OH**-nee-um **BRO**-myd)Neuromuscular blocking agent
(nondepolarizing)
Anesthesia adjunctNorcuron 

pH 4

USUAL DOSE

Adjunct to general anesthesia: Must be individualized, depending on previous drugs administered and degree and length of muscle relaxation required. 0.08 to 0.1 mg/kg (80 to 100 mcg/kg) of body weight initially as an IV bolus. Must be used with adequate anesthesia and/or sedation and after unconsciousness induced. One source suggests using IBW for obese patients (equal to or greater than 30% of IBW). Determine need for **maintenance dose** based on beginning symptoms of neuromuscular blockade reversal determined by a peripheral nerve stimulator. **IV bolus injection:** 0.01 to 0.015 mg/kg (10 to 15 mcg/kg) will be required in approximately 25 to 40 minutes and every 12 to 20 minutes thereafter to maintain muscle relaxation. Higher doses (0.15 to 0.28 mg/kg) at longer intervals have been given with proper ventilation without causing adverse cardiac effects. **Continuous infusion:** 1 mcg/kg/min. Begin in 20 to 40 minutes after initial bolus dose.

Support of intubated, mechanically ventilated, or respiratory-controlled adult ICU patients (unlabeled): **IV bolus injection:** 0.1 to 0.2 mg/kg (100 to 200 mcg/kg) every 1 hour. **Continuous infusion:** Begin with a loading dose of 0.1 mg/kg (100 mcg/kg) followed by a **maintenance dose** of 0.05 to 0.1 mg/kg/hr (50 to 100 mcg/kg/hr). A lower-end or reduced dose may be indicated if administered more than 5 minutes after the start of an inhalation agent, when steady-state has been achieved, or in patients with organ dysfunction (e.g., impaired liver function). Adjust dose according to clinical assessment of the patient's response. Use of a peripheral nerve stimulator is recommended. Vecuronium may be the preferred agent for patients with renal failure.

PEDIATRIC DOSE

Adjunct to general anesthesia: 1 to 10 years of age: May require high end of initial adult dose, and maintenance dose may be required on a more frequent basis.

DOSE ADJUSTMENTS

Reduce dose by 15% if administered more than 5 minutes after inhalation general anesthetics. ■ Reduce dose to 0.04 to 0.06 mg/kg if following succinylcholine administration. Succinylcholine must show signs of wearing off before vecuronium is given. Use caution. ■ Reduced dose required with numerous drugs; see [Drug/Lab Interactions](#). ■ Reduced dose may be required in renal or hepatic impairment. Preparation by dialysis before surgery is recommended for patients with renal failure. In an emergency surgery when dialysis cannot be accomplished, consider a lower initial dose. ■ Infants between 7 weeks and 1 year may require a slightly lower dose, and recovery time will be extended.

DILUTION

Each 10 mg must be diluted with 5 mL SWFI (supplied). May be given by IV injection or 10 (20) mg may be further diluted in up to 100 mL NS, D5W, D5NS, or LR and given as an infusion 0.1 (0.2) mg/mL concentration. Titrated to symptoms of neuromuscular blockade reversal.

Storage: Stable at room temperature before reconstitution. Store under refrigeration. Discard after 24 hours except if reconstituted with bacteriostatic water; stable refrigerated up to 5 days.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Has an acid pH. Reconstituted vecuronium should not be mixed with alkaline solutions (e.g., barbiturates) in the same syringe or administered simultaneously during IV infusion through the same needle or the same IV line."

One source suggests the following **compatibilities**:

Additive: Ciprofloxacin (Cipro IV).

Y-site: Alprostadil, aminophylline, amiodarone (Nexterone), cefazolin (Ancef), cefuroxime (Zinacef), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, dopamine, epinephrine (Adrenalin), esmolol (Brevibloc), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), gentamicin, heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), isoproterenol (Isuprel), labetalol, linezolid (Zyvox), lorazepam (Ativan), midazolam (Versed), milrinone (Primacor), morphine, nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), **palonosetron (Aloxi)**, propofol (Diprivan), ranitidine (Zantac), sulfamethoxazole/trimethoprim, vancomycin.

RATE OF ADMINISTRATION

Adjunct to general anesthesia: A single dose as an IV bolus over 30 to 60 seconds. If maintenance dose is given as an infusion, adjust rate to specific dose desired, usually 1 mcg/kg/min. See the following chart.

Vecuronium Guidelines for Infusion During General Anesthesia		
Desired Vecuronium Delivery Rate (mcg/kg/min)	Vecuronium Infusion Delivery Rate (mL/kg/min)	
	0.1 mg/mL*	0.2 mg/mL†
0.7 mcg/kg/min	0.007 mL/kg/min	0.0035 mL/kg/min
0.8 mcg/kg/min	0.008 mL/kg/min	0.0040 mL/kg/min
0.9 mcg/kg/min	0.009 mL/kg/min	0.0045 mL/kg/min
1.0 mcg/kg/min	0.010 mL/kg/min	0.0050 mL/kg/min
1.1 mcg/kg/min	0.011 mL/kg/min	0.0055 mL/kg/min
1.2 mcg/kg/min	0.012 mL/kg/min	0.0060 mL/kg/min
1.3 mcg/kg/min	0.013 mL/kg/min	0.0065 mL/kg/min

*10 mg of vecuronium in 100 mL solution.

†20 mg of vecuronium in 100 mL solution.

Mechanical ventilation support in ICU: Dose must be calculated; the preceding chart is for use during general anesthesia only. See **Usual Dose** for specific rates and criteria.

ACTIONS

A nondepolarizing skeletal muscle relaxant about one-third more potent than pancuronium with a shorter duration of neuromuscular blockade. Acts by competing for cholinergic receptors at the motor end-plate. Onset of action is within 30 seconds, is dose dependent, produces maximum neuromuscular blockade (paralysis) within 3 to 5 minutes, and lasts about 25 minutes. It may take up to 60 minutes or more before complete recovery occurs. Up to three times the therapeutic dose has been given without significant changes of hemodynamic parameters in good-risk surgical patients. Excreted as metabolites in bile and urine. Crosses the placental barrier.

INDICATIONS AND USES

Adjunctive to general anesthesia, to facilitate endotracheal intubation and to relax skeletal muscles during surgery or mechanical ventilation.

Unlabeled uses: Support of intubated, mechanically ventilated, or respiratory-controlled patients in ICU.

CONTRAINDICATIONS

Known hypersensitivity to vecuronium.

PRECAUTIONS

For IV use only. ■ Administered by or under the direct observation of the anesthesiologist. ■ Appropriate emergency drugs and equipment for monitoring the patient and responding to any medical emergency must be readily available. ■ Repeated doses have no cumulative effect if recovery is allowed to begin before administration. ■ Use extreme caution in patients with cirrhosis, cholestasis, obesity, or circulatory insufficiency. ■ Myasthenia gravis and other neuromuscular diseases increase sensitivity to drug. Can cause critical reactions. ■ Severe anaphylactic reactions have been reported with neuromuscular blocking agents; some have been fatal. Use caution in patients who have had an anaphylactic reaction to another neuromuscular blocking agent (depolarizing or nondepolarizing); cross-reactivity has occurred. ■ Acid base and/or electrolyte imbalance, debilitation, hypoxic episodes, and/or the use of other drugs (e.g., broad-spectrum antibiotics, narcotics, steroids) may prolong the effects of vecuronium.

Monitor: All uses: This drug produces apnea. Controlled artificial ventilation with oxygen must be continuous and under direct observation at all times. Maintain a patent airway. ■ Use a peripheral nerve stimulator to monitor response to vecuronium and avoid overdose. Have reversal agents available (e.g., edrophonium, neostigmine, pyridostigmine with atropine or glycopyrrolate); see [Antidote](#). ■ Patient may be conscious and completely unable to communicate by any means. Has no analgesic or sedative properties. Respiratory depression with morphine may be preferred in some patients requiring mechanical ventilation. ■ Action is altered by dehydration, electrolyte imbalance, body temperatures, and acid-base imbalance. ■ Recovery time extended in infants 7 weeks to 1 year. ■ See [Drug/Lab Interactions](#). **Mechanical ventilation support in ICU:** Physical therapy is recommended to prevent muscular weakness, atrophy, and joint contracture. Muscular weakness may be first noticed during attempts to wean patients from the ventilator.

Maternal/Child: Category C: use in pregnancy only if use justifies potential risk to fetus. Has been used during cesarean section; monitor infant carefully. Action may be enhanced by magnesium administered for the management of toxemia of pregnancy. ■ Use caution during breast-feeding. ■ Safety for use in infants under 7 weeks of age not established. ■ Some preparations contain benzyl alcohol; do not use in premature infants. ■ See [Dose Adjustments](#).

Elderly: Differences in response compared to younger adults not observed. Lower-end initial doses may be appropriate based on the potential for decreased organ function and concomitant disease or drug therapy. ■ Duration of neuromuscular block may be prolonged.

DRUG/LAB INTERACTIONS

Potentiated by **acidosis, hypokalemia, some carcinomas, general anesthetics** (e.g., enflurane, isoflurane, halothane), **many antibiotics** (e.g., clindamycin [Cleocin]), **aminoglycosides** (e.g., kanamycin, gentamicin), **polypeptide antibiotics** (e.g., bacitracin, colistimethate), **tetracyclines, diuretics, diazepam** (Valium) and **other muscle relaxants, magnesium sulfate, quinidine, morphine, meperidine, succinylcholine, verapamil, and others**. May need to reduce dose of vecuronium. Use with caution. ■ Effects may be decreased by **acetylcholine, alkalosis, anticholinesterases, azathioprine, carbamazepine, phenytoin, and theophylline**. ■ **Succinylcholine** must show signs of wearing off before vecuronium is given. Use caution.

SIDE EFFECTS

No side effects have occurred except with overdose: prolonged action resulting in respiratory insufficiency or apnea, airway closure caused by relaxation of epiglottis, pharynx, and tongue muscles. Hypersensitivity reactions including anaphylaxis are possible. Muscular weakness and atrophy may occur with long-term use (1 to 3 weeks).

ANTIDOTE

All side effects are medical emergencies. Treat symptomatically. Controlled artificial ventilation must be continuous until full muscle control returns. Edrophonium (Enlon), pyridostigmine (Regonol) or neostigmine given with atropine or glycopyrrolate will probably reverse the muscle relaxation but should not be required because of short time of effectiveness. Not effective in all situations; may aggravate severe overdose. Resuscitate as necessary.

VERAPAMIL HYDROCHLORIDE

(ver-AP-ah-mil hy-droh-KLOR-eyed)

Calcium channel blocker
Antiarrhythmic

pH 4.1 to 6

USUAL DOSE

5 to 10 mg initially (0.075 to 0.15 mg/kg of body weight). May cause transient bradycardia or hypotension. 10 mg (0.15 mg/kg) may be repeated in 30 minutes if needed to achieve appropriate response. Maximum total dose is 20 mg. AHA recommendation is 2.5 to 5 mg as an initial dose. Repeat 5 to 10 mg if needed every 15 to 30 min. Maximum dose 20 mg. Alternately, give 5 mg every 15 min to a total dose of 30 mg.

PEDIATRIC DOSE

ECG and BP monitoring mandatory. See [Maternal/Child](#).

Infants up to 1 year of age: 0.1 to 0.2 mg/kg of body weight (usually 0.75 to 2 mg). Repeat in 30 minutes if indicated.

1 to 15 years of age: 0.1 to 0.3 mg/kg (usually 2 to 5 mg). Do not exceed 5 mg. Repeat in 30 minutes if response not adequate. Repeat dose should not exceed 10 mg as a single dose.

DOSE ADJUSTMENTS

Reduced dose may be required in hepatic or renal disease, especially with repeat dosing. ■ Dose selection should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy. ■ See [Drug/Lab Interactions](#).

DILUTION

IV injection: May be given undiluted through Y-tube or three-way stopcock of tubing containing D5W, NS, or Ringer's solution for infusion.

Filters: No data available from manufacturer.

Storage: Store between 15° and 30° C (59° and 86° F). Protect from light and freezing. Do not use if discolored or particulate matter present. Discard unused solution.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Not recommended for dilution with sodium lactate in polyvinyl chloride bags. Will precipitate in any solution with a pH greater than 6." Lists as **incompatible** with albumin, amphotericin B (conventional), hydralazine, sulfamethoxazole/trimethoprim.

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), amiodarone (Nexterone), ampicillin, ascorbic acid, atropine, calcium chloride, calcium gluconate, cefazolin (Ancef), cefotaxime (Claforan), cefoxitin (Mefoxin), chloramphenicol (Chloromycetin), clindamycin (Cleocin), dexamethasone (Decadron), dextran 40, diazepam (Valium), digoxin (Lanoxin), dobutamine, dopamine, epinephrine (Adrenalin), erythromycin (Erythrocin), furosemide (Lasix), gentamicin, heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), isoproterenol (Isuprel), lidocaine, magnesium sulfate, mannitol, meperidine (Demerol), methyl dopate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), morphine, multivitamins (M.V.I.), nafcillin (Nallpen), naloxone (Narcan), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), oxacillin (Bactocill), oxytocin (Pitocin), pancuronium, penicillin G potassium and sodium, pentobarbital (Nembutal), phenobarbital (Luminal), phentolamine (Regitine), phenytoin (Dilantin), potassium chloride (KCl), potassium phosphates, procainamide (Pronestyl), propranolol, protamine sulfate, quinidine gluconate, sodium bicarbonate, theophylline, tobramycin, vancomycin, vasopressin.

Y-site: Argatroban, bivalirudin (Angiomax), ciprofloxacin (Cipro IV), dexmedetomidine (Precedex), dobutamine, dopamine, famotidine (Pepcid IV), fenoldopam (Corlopam), hetastarch in electrolytes (Hextend), hydralazine, linezolid (Zyvox), meperidine (Demerol), milrinone (Primacor), nesiritide (Natrecor), oxaliplatin (Eloxatin), penicillin G potassium.

RATE OF ADMINISTRATION

IV injection: A single dose over a minimum of 2 minutes for adults and pediatric patients. Extend to 3 minutes in the elderly.

ACTIONS

A calcium (and possibly sodium) ion inhibitor through slow channels into conductile and contractile myocardial cells and vascular smooth muscle cells. Slows conduction through SA and AV nodes, prolongs effective refractory period in the AV node, and reduces ventricular rates. Prevents reentry phenomena through the AV node. Reduces myocardial contractility, afterload, arterial pressure, vascular tone, and oxygen demand. Effective within 1 to 5 minutes. Hemodynamic effects last about 20 minutes, but antiarrhythmic effects may last up to 6 hours. Does not alter total serum calcium levels. Metabolized in the liver. Half-life range is 2 to 5 hours. Crosses the placental barrier. Excreted in urine and feces. Secreted in breast milk.

INDICATIONS AND USES

Treatment of supraventricular tachyarrhythmias including conversion to normal sinus rhythm of paroxysmal supraventricular tachycardia (includes Wolff-Parkinson-White and Lown-Ganong-Levine syndromes). ■ Temporary control of rapid ventricular rate in atrial flutter or atrial fibrillation.

Unlabeled uses: Alternative drug after adenosine to terminate re-entry SVT with narrow QRS complex and adequate BP and preserved LV function (AHA guidelines).

CONTRAINDICATIONS

SA nodal function impairment or atrial fibrillation or flutter when associated with an accessory bypass tract (e.g., Wolff-Parkinson-White or Lown-Ganong-Levine syndromes), cardiogenic shock, congestive heart failure (severe) unless secondary to supraventricular tachyarrhythmia treatable with verapamil, known hypersensitivity to verapamil, second- or third-degree AV block (unless functioning artificial pacemaker is in place), severe hypotension, sick sinus syndrome (unless functioning artificial pacemaker in place), patients receiving IV beta-adrenergic blocking drugs (e.g., propranolol) within a few hours, and ventricular tachycardia.

PRECAUTIONS

Administer in a facility with adequate personnel, equipment, and supplies to monitor the patient and respond to any medical emergency. ■ Valsalva maneuver recommended before use of verapamil in all paroxysmal supraventricular tachycardias if clinically appropriate. ■ May produce hypotension. Usually transient and asymptomatic, but can cause dizziness. ■ Has rarely caused second- and third-degree AV block and, in extreme cases, asystole. ■ Caution required in hepatic and renal disease, especially if repeated dosing is required. ■ Use extreme caution in patients with hypertrophic cardiomyopathy. ■ May cause ventricular fibrillation in patients with wide-complex ventricular tachycardia. ■ May precipitate respiratory muscle failure in patients with muscular dystrophy or increase intracranial pressure during anesthesia induction in patients with supratentorial tumors. Use caution and monitor closely. ■ Use with caution in patients with severe aortic stenosis and acute MI with pulmonary congestion documented by x-ray. ■ Reduction of myocardial contractility may worsen CHF in patients with severe left ventricular dysfunction. ■ Continue regular dosing on day of surgery and thereafter unless otherwise specified by physician. May cause severe angina or MI if discontinued. ■ Recent studies indicate that verapamil inhibits thrombus formation and platelet aggregation.

Monitor: Continuous ECG and BP monitoring recommended. ■ Document cardiac rhythm before therapy, with any significant change in type or rate, and at least every 4 hours. See PR interval. ■ Monitor BP and HR very closely, every 5 minutes times 3 or

until reasonably stabilized, every 15 minutes times 4 and hourly thereafter. May need more frequent checks with increased drip rate. ■ Emergency resuscitation drugs and equipment must always be available. ■ When heart failure is not severe or rate related, it should be controlled with digoxin and diuretics before using verapamil. ■ Patients with pulmonary wedge pressure above 20 mm Hg and/or ejection fraction below 30% may experience acute worsening of heart failure. ■ Maintain bed rest until effects on HR, BP, and potential dizziness evaluated. ■ Monitor for side effects (AV block) and digoxin levels when used concurrently with digoxin. ■ Monitor for any unusual bleeding or bruising. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: safety for use in pregnancy not yet established; use only when clearly indicated. ■ Discontinue breast-feeding. ■ Controlled studies have not been conducted in pediatric patients. Severe hemodynamic side effects (e.g., bradycardia, hypotension, or a rapid ventricular rate in atrial flutter/fibrillation) can occur in infants and neonates. Use caution and monitor closely.

Elderly: May have an increased hypotensive effect; see [Rate of Administration](#). ■ Half-life may be prolonged; see [Dose Adjustments](#). ■ May cause drug-induced tinnitus.

DRUG/LAB INTERACTIONS

Potentiates **digoxin**; lower dose may be appropriate. Both drugs slow AV conduction. Monitor for AV block and bradycardia. ■ Do not give concomitantly (within a few hours) with **IV beta-adrenergic blocking drugs** (e.g., propranolol); see [Contraindications](#). Use with extreme caution with **oral or ophthalmic beta blockers**. Both drugs depress myocardial contractility and AV node conduction; monitor patient closely. ■ Do not administer **disopyramide** (Norpace) within 48 hours before or 24 hours after verapamil. ■ Use caution with **inhalation anesthetics**. Both depress cardiovascular activity. Titrate each carefully to avoid excessive cardiovascular depression. ■ Coadministration with **amiodarone** (Nexterone) may result in bradycardia and decreased cardiac output. Monitor closely. ■ Potentiates **cyclosporine, carbamazepine, and theophyllines**. Monitor serum levels of these drugs and adjust dose as needed. ■ Potentiates **nondepolarizing muscle relaxants** (e.g., vecuronium); dose reduction of either drug may be required. ■ Metabolism may be decreased and serum concentrations may be increased by **itraconazole** (Sporanox). ■ Verapamil may increase serum concentrations of **dofetilide** (Tikosyn). One source says avoid use; another says concurrent use contraindicated. ■ Verapamil may increase serum concentrations of **HMG-CoA reductase inhibitors** (e.g., atorvastatin [Lipitor], simvastatin [Zocor]), **imipramine** (Tofranil), **prazosin** (Minipress), **sirolimus** (Rapamune), **tacrolimus** (Prograf). Monitor serum levels and/or monitor for S/S of toxicity; adjust dose as needed. ■ Concomitant use of **HMG-CoA reductase inhibitors** (e.g., atorvastatin [Lipitor], lovastatin [Mevacor], simvastatin [Zocor]) has been associated with reports of myopathy and rhabdomyolysis. In patients receiving verapamil, limit dose of simvastatin to 10 mg daily and limit lovastatin dose to 40 mg daily. Dose reductions for other HMG-CoA reductase inhibitors may also be required. ■ May increase effects of certain **benzodiazepines** (e.g., midazolam [Versed], triazolam [Halcion]) and **bupirone** (BuSpar); monitor and adjust doses as indicated. ■ May cause excessive hypotension with **other antihypertensive drugs** (vasodilators and diuretics). ■ Serum concentrations and effectiveness of verapamil may be decreased by **barbiturates** (e.g., phenobarbital), **calcium salts, phenytoin** (Dilantin), **sulfinpyrazone** (Anturane). ■ Concomitant use with **IV dantrolene** (Dantrium) may result in cardiovascular collapse. ■ Use caution with **quinidine**; may cause hypotension. ■ Hypotension and bradycardia have been observed with concurrent **telithromycin** (Ketek). ■ Highly protein bound; use with caution with **other highly protein-bound drugs** (e.g., oral hypoglycemics, warfarin). ■ Variable effects when administered with **lithium**. Has caused decreased effectiveness of lithium and may cause neurotoxicity. ■ Monitor heart rate with concurrent use of verapamil with **clonidine**; has resulted in sinus bradycardia requiring pacemaker insertion. ■ **Grapefruit juice** may affect certain enzymes of the P₄₅₀ enzyme system and increase the serum concentrations of verapamil and should be avoided.

SIDE EFFECTS

Abdominal discomfort, asystole, bradycardia, dizziness, headache, second- and third-degree heart block, heart failure, hypersensitivity reactions including anaphylaxis, hypotension (symptomatic), increased ventricular response in atrial flutter, fibrillation (Wolff-Parkinson-White and Lown-Ganong-Levine syndromes), nausea, PVCs, skin eruptions (including rare reports of erythema multiforme), tachycardia.

ANTIDOTE

Discontinue verapamil and notify physician promptly if hypotension, bradycardia, or second- or third-degree heart block occurs. Keep physician informed of all side effects. Treatment will depend on clinical situation. Calcium chloride may reverse effects of verapamil and can be used in toxicity. Glucagon may also be used in toxicity; see glucagon monograph. Rapid ventricular response in atrial flutter/fibrillation should respond to cardioversion, procainamide, and/or lidocaine. Treat bradycardia, AV block, and asystole with standard AHA protocol (atropine, pacing). Norepinephrine (Levarterenol) or dopamine will reverse hypotension. Treat hypersensitivity reactions or resuscitate as necessary. Not removed by hemodialysis.

VERTEPORFIN(ver-teh-**POR**-fin)**Visudyne**

Photosensitizing agent
Macular degeneration
therapy adjunct

USUAL DOSE

A course is a **two-stage process** requiring administration of both drug and light. Each course may be repeated every 3 months as indicated. Body surface area, lesion size determination, and spot size determination of the choroidal neovascularization (CNV) are used by the retina specialist to calculate dosing of verteporfin. The greatest linear dimension of the lesion is estimated by fluorescein angiography and color fundus photography. The treatment spot size should be 1,000 microns larger than the greatest linear dimension of the lesion on the retina to allow a 500-micron border. The nasal edge of the treatment spot must be positioned at least 200 microns from the temporal edge of the optic disc.

First stage: 6 mg/M² of verteporfin as a single IV infusion.

Second stage: Activation of verteporfin using a recommended light dose of 50 J/cm² of neovascular lesion administered at an intensity of 600 mW/cm² over 83 seconds. Initiate 689 ± 3 nm wavelength laser light delivery 15 minutes after the start of the verteporfin infusion. Light is delivered to the retina as a single circular spot via a fiber optic and a slit lamp, using a suitable ophthalmic magnification lens. Light dose, light intensity, ophthalmic lens magnification factor, and zoom lens setting are important parameters for the appropriate delivery of light to the predetermined treatment spot. Follow the laser system manuals for procedure set up and operation.

Concurrent bilateral treatment: In patients who present with eligible lesions in both eyes without prior verteporfin therapy, treat only one eye (the most aggressive lesion) during the first course. One week after the first course, if no significant safety issues are identified, the second eye can be treated, using the same treatment regimen including a verteporfin infusion and light activation. Approximately 3 months later, both eyes can be evaluated and concurrent treatment following a new verteporfin infusion can be started if both lesions still show evidence of leakage. When treating both eyes concurrently, the more aggressive lesion should be treated first, at 15 minutes after the start of infusion. Immediately at the end of light application to the first eye, the laser settings should be adjusted to introduce the treatment parameters for the second eye, with the same light

dose and intensity as for the first eye, starting no later than 20 minutes from the start of the infusion.

DOSE ADJUSTMENTS

No adjustments required. See *Precautions*.

DILUTION

Specific techniques required; see *Precautions*. Reconstitute each vial of verteporfin with 7 mL of SWFI to provide 7.5 mL of opaque, dark green solution containing 2 mg/mL. Withdraw the desired dose from the vial and further dilute with D5W to a total infusion volume of 30 mL.

Filters: Use of a 1.2-micron in-line filter is required for administration.

Storage: Store between 20° and 25° C (68° and 77° F). Reconstituted and diluted solution must be protected from light and used within 4 hours.

COMPATIBILITY

Manufacturer states, “May precipitate in saline solutions. Do not use NS or other parenteral solutions. Do not mix in same solution with other drugs.” Use only SWFI and D5W as listed under Dilution.

RATE OF ADMINISTRATION

A 30-mL infusion equally distributed over 10 minutes (3 mL/min) using an appropriate syringe pump and a 1.2-micron in-line filter.

ACTIONS

A light activated drug (photosensitizing agent) for use in photodynamic therapy (PDT). Transported in the plasma by lipoproteins. Endothelial cells of the abnormal choroidal blood vessels which have high concentrations of lipoprotein receptors take up the lipoprotein-verteporfin complex. Light activation in the presence of O₂, induces a photochemical reaction, generating highly reactive singlet oxygen and reactive oxygen radicals that cause local damage to the neovascular endothelium. The damaged endothelium releases procoagulant and vasoactive factors through the lipo-oxygenase (leukotriene) and cyclo-oxygenase (eicosanoids such as thromboxane) pathways, resulting in platelet aggregation, fibrin clot formation, vasoconstriction, and ultimately, vessel occlusion. Verteporfin appears to preferentially accumulate in neovasculature, including choroidal neovasculature. However, animal models indicate that the drug is also present in the retina. Therefore, there may be collateral damage to retinal structures following photoactivation. Terminal elimination half-life of verteporfin is 5 to 6 hours. It is metabolized to a small extent by liver and plasma esterases and is eliminated primarily by the fecal route as unchanged drug. May be secreted in breast milk.

INDICATIONS AND USES

Treatment of patients with predominantly classic subfoveal choroidal neovascularization due to age-related macular degeneration, pathologic myopia, or presumed ocular histoplasmosis. Slows retinal damage, does not reverse loss of vision in eyes damaged by AMD. ■ Not recommended for use in treatment of predominantly occult subfoveal choroidal neovascularization; evidence insufficient.

CONTRAINDICATIONS

Patients with porphyria or a known hypersensitivity to any component of this preparation.

PRECAUTIONS

Use rubber gloves and eye protection during preparation and administration. Avoid any skin or eye contact since that area will become photosensitive. Wipe up spills with a damp cloth. Dispose of all contaminated materials in a polyethylene bag to avoid accidental contact by others. Protection from light will be necessary if accidental exposure or overexposure occurs. Note process in Patient Education. ■ Administered by or under the direction of the physician specialist with appropriate knowledge of the selected laser system. Facilities for monitoring the patient and responding to any medical emergency must be available. ■ Requires laser systems and a fiber-optic diffuser to activate. *Coher-*

ent Opal Photoactivator Laser Console and LaserLink Adapter, Zeiss VISULAS 690s laser and VISILINK PDT adapter, Ceralas I laser system and Ceralink Slit Lamp Adapter, and Quantel Activis laser console and the ZSL30 ACTTM, ZSL120 ACTTM, and HSBMBQ ACTTM slit lamp adapters are the laser systems that have been tested for **compatibility** with verteporfin and are approved for delivery of a stable power output at a wavelength of 689 ± 3 nm. Use of **incompatible** lasers that do not provide the required characteristics of light could result in incomplete treatment due to partial photoactivation, overtreatment due to overactivation, or damage to surrounding normal tissue. ■ Following verteporfin administration, care should be taken to avoid exposure of skin or eyes to direct sunlight or bright indoor light for 5 days. If emergency surgery is necessary within 48 hours after treatment, as much of the internal tissue as possible should be protected from intense light. ■ Patients who experience severe decrease of vision of 4 lines or more within 1 week after treatment should not be retreated, at least until their vision completely recovers to pretreatment levels. Potential risk versus benefit of any subsequent treatment should be considered. ■ Use with caution in patients with moderate to severe hepatic impairment or biliary obstruction, and in anesthetized patients. There is no clinical experience with these patient populations. ■ Older patients, patients with dark irides, patients with occult lesions or patients with less than 50% classic CNV may be less likely to benefit from verteporfin therapy. ■ Safety and efficacy of verteporfin beyond 2 years has not been demonstrated; however, it has been used up to 5 years in extension studies.

Monitor: Standard precautions should be taken to avoid extravasation (e.g., establish a free-flowing IV line in a large arm vein, preferably the antecubital vein). If extravasation occurs, the infusion should be stopped immediately and cold compresses applied. The extravasation area must be thoroughly protected from direct light until the swelling and discoloration have faded in order to prevent the occurrence of a local burn, which could be severe. Oral analgesics may be indicated. ■ Monitor patient during infusion. Verteporfin has caused a concentration-dependent increase in complement activation in human blood in vitro. S/S consistent with complement activation (chest pain, dyspnea, flushing, syncope) have been reported. ■ Patient should be reevaluated every 3 months and if choroidal neovascular leakage is detected on fluorescein angiography, therapy should be repeated. ■ See [Usual Dose, Precautions, Patient Education, and Drug/Lab Interactions](#).

Patient Education: ■ Must observe precautions to avoid exposure of skin and eyes to direct sunlight or bright indoor light for 5 days. Photosensitivity is due to residual drug, which is present in all parts of the skin. Ambient indoor light is beneficial as it gradually inactivates the remaining drug through a photobleaching reaction. Do not remain in a darkened room. Do not expose skin to ambient indoor light. Avoid bright indoor light from examination lamps, dental lamps, operating room lamps, bright halogen lighting, and unshaded light bulbs. Limit time outdoors to necessary excursions and completely cover body with clothing and shade face before going out. Ultraviolet sunscreens are of no value because photoactivation is caused by visible light, not UV rays. Eyes will be sensitive to sun, bright lights, and car headlights; wear dark sunglasses with an average white light transmittance of less than 4%. ■ Visual disturbances may develop and interfere with the ability to drive or operate machinery. Avoid these activities as long as visual symptoms persist.

Maternal/Child: Category C: use during pregnancy only if benefits justify potential risk to fetus. Effective contraception necessary for women of childbearing age. Has caused maternal and fetal toxicity in rats and rabbits. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Reduced treatment effect was seen with increasing age (75 years of age or older).

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. Based on the mechanism of action of verteporfin, many drugs used concomitantly could influence the effect of verteporfin therapy. ■ **Calcium channel blockers** (e.g., diltiazem [Cardizem], verapamil, nifedipine [Cardene]), **polymyxin B**, or **radiation therapy** could enhance the rate of verteporfin

uptake by the vascular endothelium. ■ Use with **other photosensitizing agents** (e.g., griseofulvin, phenothiazines [e.g., prochlorperazine (Compazine)], sulfonamides [sulfisoxazole (Gantrisin)], ophthalmic solutions (AK-Sulf), sulfonyleurea hypoglycemic agents [tolbutamide], tetracyclines [doxycycline], thiazide diuretics [chlorothiazide (Diuril)]) could increase the potential for a photosensitivity reaction. ■ Compounds that quench active oxygen species or scavenge radicals (e.g., **dimethyl sulfoxide [DMSO], beta-carotene, ethanol, formate, mannitol**) would be expected to decrease verteporfin activity. ■ Effectiveness may be reduced by **drugs that decrease clotting** (e.g., heparin, alteplase [tPA]), **vasoconstriction** (e.g., nicardipine [Cardene]) or **platelet aggregation** (e.g., clopidogrel [Plavix], dipyridamole [Persantine], ticlopidine [Ticlid]).

SIDE EFFECTS

The most frequently reported side effects are headache, injection site reactions (e.g., edema, extravasation, hemorrhage with discoloration, pain, and rashes), visual disturbances (e.g., blurred vision, decreased visual acuity and visual field defects), and self-resolving photosensitivity. Less frequently reported side effects include abnormal white blood cell count (decreased or increased), albuminuria, anemia, arthralgia, arthrosis, asthenia, atrial fibrillation, back pain (primarily during infusion), blepharitis, cataracts, chest pain, conjunctivitis, constipation, decreased hearing, diplopia, dizziness, dry eyes, dyspnea, elevated liver function tests, eye hemorrhage (subconjunctival, subretinal, or vitreous), eczema, fever, flu-like syndrome, flushing, hypertension, hyperesthesia, hypersensitivity reactions, increased creatinine, lacrimation disorder, malaise, myasthenia, nausea, ocular itching, peripheral vascular disorder, pharyngitis, photosensitivity, pneumonia, prostatic disorder, pruritus, retinal detachment (nonrhegmatogenous), retinal or choroidal vessel nonperfusion, retinal pigment epithelial tear, severe vision loss (may be equivalent of 4 lines or more within 7 days of treatment and occur with or without subretinal/retinal or vitreous hemorrhage), sleep disturbance, sweating, syncope, urticaria, varicose veins, vasovagal reactions, and vertigo.

Overdose: Overdose of drug and/or light may result in nonperfusion of normal retinal vessels with the possibility of severe decrease in vision that could be permanent. May also result in prolongation of the time during which the patient will be photosensitive.

ANTIDOTE

Keep the physician informed of all side effects; most will be treated symptomatically. In the event of an overdose of drug and/or light, extend the photosensitivity precautions for a time proportional to the overdose.

VINBLASTINE SULFATE **BBW**

(vin-BLAS-teen SUL-fayt)

Antineoplastic
(mitotic inhibitor-vinca alkaloid)**VLB****pH 3.5 to 5****USUAL DOSE**

Auxiliary labeling required; see **Precautions**.

3.7 mg/M² initially. Administered once every 7 days, increasing the dose to specific amounts (5.5, 7.4, 9.25, 11.1 mg/M²) a single step each week until the WBC count is decreased to 3,000 cells/mm³, remission is achieved, or a maximum dose of 18.5 mg/M² is reached. Maintenance dose is one step below any dose that causes leukopenia (3,000 cells/mm³ or less), once every 7 to 14 days. Usually 5.5 to 7.4 mg/M². Continue treatment for 4 to 6 weeks. Up to 12 weeks often necessary.

PEDIATRIC DOSE

See **Maternal/Child**.

One source suggests 2.5 mg/M² initially. Use same procedure as for adult dose using steps to 3.75, 5, 6.25, and 7.5 mg/M². Maximum dose is 12.5 mg/M². Maintenance dose is calculated by same parameters as Usual Dose (above). Usually differs with each individual. Other sources suggest that initial doses vary depending on the schedule used, use of vinblastine as a single agent, or in a combination regimen. Some suggested doses are: **Letterer-Siwe disease (unlabeled)**: As a single agent, an initial dose of 6.5 mg/M².

Hodgkin's disease: An initial dose of 6 mg/M² in combination with other chemotherapeutic agents.

Testicular cancer: An initial dose of 3 mg/M² in combination with other chemotherapeutic agents.

DOSE ADJUSTMENTS

Reduce dose by 50% if serum bilirubin above 3 mg/dL. ■ Often used with other antineoplastic drugs and corticosteroids in reduced doses and/or extended intervals to achieve tumor remission.

DILUTION

Specific techniques required; see Precautions. Each 10 mg is diluted with 10 mL of NS for injection. 1 mg equals 1 mL. Also available in liquid form (1 mg/mL). May be given by IV injection or through Y-tube or three-way stopcock of a free-flowing IV infusion.

Storage: Store in refrigerator before and after dilution. Potency maintained for 28 days after dilution if reconstituted with bacteriostatic NS.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer suggests that the pH not be altered from between 3.5 to 5 by an additive or a diluent, and it recommends NS as a diluent and not admixing with other drugs in the same container.

One source suggests the following **compatibilities**:

Additive: **Not recommended by manufacturer.** Bleomycin (Blenoxane).

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), amphotericin B cholesteryl (Amphotec), aztreonam (Azactam), bleomycin (Blenoxane), cisplatin (Platinol), cyclophosphamide (Cytoxan), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), droperidol (Inapsine), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), fluorouracil (5-FU), gemcitabine (Gemzar), granisetron (Kytril), heparin, leucovorin calcium, melphalan (Alkeran), methotrexate, metoclopramide (Reglan), mitomycin (Mutamycin), ondansetron (Zofran), paclitaxel (Taxol), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), sargramostim (Leukine), teniposide (Vumon), thiotepea, vincristine, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

IV injection: Total desired dose, properly diluted, over 1 minute.

ACTIONS

An alkaloid of the periwinkle plant with anti-tumor activity. Cell cycle-specific for M phase. Thought to interfere with the metabolic pathways of amino acids. Sometimes pharmacologically effective without any noticeable improvement in symptoms of malignancy. Cell energy production and synthesis of nucleic acid may also be inhibited. Half-life is 24.8 hours. Metabolism mediated by the hepatic cytochrome P₄₅₀ isoenzymes in the CYP 3A subfamily. Some excretion through bile and urine.

INDICATIONS AND USES

To suppress or retard neoplastic growth. Remission and probable cure has been achieved with bleomycin and cisplatin in testicular malignancies. Response has been noted in Hodgkin's disease, non-Hodgkin's lymphomas, choriocarcinoma, Kaposi's sarcoma, mycosis fungoides, breast and renal cell malignancies. ■ Used to treat many other malignancies.

CONTRAINDICATIONS

Bacterial infection or leukopenia below 3,000 cells/mm³.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Usually administered by or under the direction of the physician specialist. ■ Manufacturer provides an auxillary sticker labeled "Fatal if given intrathecally, for IV use only" and an overwrap labeled "Do not remove covering until moment of injection. Fatal if given intrathecally. For intravenous use only." Each and every syringe(s) containing a specific dose and prepared in advance of actual administration must be labeled with the provided auxiliary sticker and packaged in this overwrap. If intrathecal injection should occur, immediate neurosurgical intervention is required, consult package insert for immediate steps to be taken. ■ May cause corneal ulceration with accidental contact to the eye. ■ Use caution in presence of ulcerated skin areas, cachexia, or impaired liver function. ■ Leukocyte and platelet counts have fallen precipitously in patients with malignant-cell infiltration of the bone marrow following moderate doses of vinblastine. Further administration is not recommended. ■ Acute pulmonary reactions including acute shortness of breath and severe bronchospasm have been reported in patients receiving vinca alkaloids. Occurs most frequently when given in combination with mitomycin C. Onset of reaction may occur minutes to hours after vinca administration and up to 2 weeks following the mitomycin dose.

Monitor: Determine absolute patency, quality of vein, and adequate circulation of extremity. Severe cellulitis may result from extravasation. Rinse syringe and needle with venous blood before withdrawal from the vein; see *Antidote*. ■ Leukopenia is dose-limiting toxicity. Nadir occurs 5 to 10 days after therapy. Recovery occurs within another 7 to 14 days. ■ WBC count must be checked before each dose. Must be above 4,000 cells/mm³. ■ Be alert for signs of bone marrow suppression or infection. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Thrombocytopenia is rare, but may occur in patients whose bone marrow has been impaired by prior radiation therapy or other bone marrow suppressants. If platelet count is less than 50,000/mm³, initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Observe for increased uric acid levels; may require increased doses of antigout agents; allopurinol (Aloprim) preferred. ■ Maintain adequate hydration. ■ Prophylactic antiemetics may increase patient comfort. ■ See *Drug/Lab Interactions*.

Patient Education: Avoid pregnancy; nonhormonal birth control recommended. ■ Report IV site burning or stinging promptly. ■ Report chills, fever, sore mouth, or throat promptly. ■ Maintain adequate hydration; avoid constipation. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. May produce teratogenic effects on the fetus. Has a mutagenic potential. ■ Discontinue breast-feeding. ■ Do not use diluents containing benzyl alcohol in premature infants.

Elderly: Leukopenic response may be increased in malnutrition or with skin ulcers.

DRUG/LAB INTERACTIONS

Inhibited by **some amino acids, glutamic acid, and tryptophan**. ■ Potentiated by **other bone marrow suppressants** (e.g., antineoplastics, radiation therapy). ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Acute pulmonary reactions can occur with **Mitomycin-C**; see **Precautions**. ■ May inhibit effects of **phenytoin** (Dilantin); increased doses of phenytoin may be needed. ■ **Erythromycin** decreases metabolism and increases toxicity of vinblastine. ■ Use caution with **any drug that inhibits P₄₅₀ enzymes** (e.g., calcium channel blockers [e.g., diltiazem (Cardizem), nicardipine (Cardene), verapamil], antifungal agents [e.g., fluconazole (Diflucan), itraconazole (Sporanox), ketoconazole (Nizoral)], bromocriptine [Parlodel], cimetidine [Tagamet], clarithromycin [Biaxin], cyclosporine [Sandimmune], danazol [Medrol], metoclopramide [Reglan]); may increase vinblastine blood levels and increase toxicity. ■ Effect of **bleomycin** is significantly enhanced if vinblastine is administered 6 to 8 hours prior to bleomycin administration.

SIDE EFFECTS

Usually dose related and not always reversible: abdominal pain, alopecia, anorexia, cellulitis, constipation, convulsions, diarrhea, dizziness, extravasation, gonadal suppression, headache, hemorrhage, ileus, leukopenia (severe), malaise, mental depression, myelosuppression, nausea, numbness, oral lesions, paresthesias, peripheral neuritis, pharyngitis, Raynaud's syndrome, reflex depression (deep tendon), skin lesions, thrombophlebitis, tumor site pain, vomiting, weakness.

ANTIDOTE

For extravasation, discontinue the drug immediately and administer into another vein. Hyaluronidase should be injected locally into extravasated area. Use a fine hypodermic needle. Elevate extremity. Moist heat may be helpful. Notify the physician of all side effects; symptomatic treatment is often indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Glutamic acid blocks toxicity of vinblastine but also blocks its antineoplastic activity.

USUAL DOSE

CONVENTIONAL VINCRIStINE

Auxiliary labeling required; see [Precautions](#).

Neurotoxicity appears to be dose related. Use extreme care in calculating and administering vincristine. Overdose may be fatal.

1.4 mg/M² administered once every 7 days. Various dosage schedules have been used with caution.

MARQIBO (LIPOSOMAL VINCRIStINE)

2.25 mg/M² as an IV infusion over 1 hour once every 7 days. Liposomal vincristine has different dosage recommendations than conventional vincristine. Verify drug name and dose before preparation and administration.

PEDIATRIC DOSE

CONVENTIONAL VINCRIStINE

Weight 10 kg or more with a body surface area more than 1 M²: 1.5 to 2 mg/M² once each week.

Weight less than 10 kg (22 lb) or with a body surface area less than 1 M²: 0.05 mg/kg of body weight once a week. See comments under [Usual Dose](#).

MARQIBO (LIPOSOMAL VINCRIStINE)

Safety and effectiveness for use in pediatric patients not established.

DOSE ADJUSTMENTS

CONVENTIONAL VINCRIStINE: In impaired hepatic function, reduce initial doses to 0.05 to 1 mg/M² or by 50% if direct bilirubin above 3 mg/dL. May be increased gradually based on individual response. ■ Usually given with other antineoplastic drugs and corticosteroids in reduced doses to achieve tumor remission. ■ See [Drug/Lab Interactions](#).

MARQIBO (LIPOSOMAL VINCRIStINE)

Recommended Dose Modifications for Marqibo-Related Peripheral Neuropathy	
Severity of Peripheral Neuropathy Signs/Symptoms*	Modification of Marqibo Dose and Regimen
Patient develops Grade 3 (severe symptoms, limiting self-care activities of daily living [ADL]†) or persistent Grade 2 (moderate symptoms, limiting instrumental ADL‡) peripheral neuropathy.	Interrupt Marqibo. If the peripheral neuropathy remains at Grade 3 or 4, discontinue Marqibo. If the peripheral neuropathy recovers to Grade 1 or 2, reduce the Marqibo dose to 2 mg/M ² .
Patient has persistent Grade 2 peripheral neuropathy after the first dose reduction to 2 mg/M ² .	Interrupt Marqibo for up to 7 days. If the peripheral neuropathy increases to Grade 3 or 4, discontinue Marqibo. If peripheral neuropathy recovers to Grade 1, reduce the Marqibo dose to 1.825 mg/M ² .
Patient has persistent Grade 2 peripheral neuropathy after the second dose reduction to 1.825 mg/M ² .	Interrupt Marqibo for up to 7 days. If the peripheral neuropathy increases to Grade 3 or 4, discontinue Marqibo. If the toxicity recovers to Grade 1, reduce the Marqibo dose to 1.5 mg/M ² .

*Grading based on the National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE) v3.0.

†Self-care ADL: Refers to bathing, dressing/undressing, feeding self, using the toilet, taking medications, not bedridden.

‡Instrumental ADL: Refers to preparing meals, shopping for groceries and clothes, using telephone, managing money, etc.

DILUTION

CONVENTIONAL VINCRISTINE: *Specific techniques required; see Precautions.* Available in preservative-free solutions (1 mg/mL). May be given by IV injection or through Y-tube or three-way stopcock of a free-flowing IV infusion. Occasionally further diluted in 50 mL or more NS or D5W and given as an infusion.

MARQIBO (LIPOSOMAL VINCRISTINE): *Specific techniques required; see Precautions.* Marqibo will be prepared in the pharmacy by a very specific process that takes approximately 60 to 90 minutes. Dedicated, uninterrupted time is required due to extensive monitoring of temperature and time required for preparation. When prepared according to directions, each single-dose vial contains 5 mg/31 mL (0.16 mg/mL). Refer to manufacturer's literature for a detailed outline of the preparation procedure. Contact manufacturer if questions arise about preparation.

Items required by the pharmacy to prepare Marqibo include:

- Marqibo kit
- Water bath*
- Calibrated thermometer (0° to 100° C)*
- Calibrated electronic timer*
- Sterile venting needle or other suitable device equipped with a sterile 0.2-micron filter
- 1-mL or 3-mL sterile syringe with needle, and a 5-mL sterile syringe with needle

*Manufacturer will send the water bath, calibrated thermometer, and calibrated electronic timer to the medical facility at the initial order of Marqibo and will replace them every 2 years.

Filters: *Marqibo (liposomal vincristine):* 0.2-micron filter required during preparation; however, **do not use with in-line filters.**

Storage: Conventional vincristine: Store in refrigerator before and after dilution. Potency maintained for 14 days after dilution. Label vial pertaining to mg/mL.

Marqibo (liposomal vincristine): Store Marqibo kit in refrigerator at 2° to 8° C (36° to 46° F). **Do not freeze.** Once prepared, may be stored at CRT for no more than 12 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

CONVENTIONAL VINCRISTINE

Manufacturer suggests that the pH not be altered from between 3.5 to 5.5 by an additive or a diluent, and it recommends NS or D5W as a diluent and not admixing with other drugs in the same container.

One source suggests the following **compatibilities:**

Additive: Not recommended by manufacturer. Bleomycin (Blenoxane), cytarabine (ARA-C), doxorubicin (Adriamycin), fluorouracil (5-FU), methotrexate.

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), aztreonam (Azactam), bleomycin (Blenoxane), caspofungin (Cancidas), cisplatin (Platinol), cladribine (Leustatin), cyclophosphamide (Cytosan), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), droperidol (Inapsine), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), fluorouracil (5-FU), gemcitabine (Gemzar), granisetron (Kytril), heparin, leucovorin calcium, linezolid (Zyvox), melphalan (Alkeran), methotrexate, metoclopramide (Reglan), mitomycin (Mutamycin), ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), sargramostim (Leukine), teniposide (Vumon), thiotepa, topotecan (Hycamtin), vinblastine, vinorelbine (Navelbine).

MARQIBO (LIPOSOMAL VINCRISTINE)

Manufacturer states, "Do not mix with other drugs."

RATE OF ADMINISTRATION**CONVENTIONAL VINCRISTINE**

"Fatal if given intrathecally; for IV use only."

IV injection: Total desired dose, properly diluted, over 1 minute.

Infusion: A single dose over 20 to 30 minutes or as a continuous infusion prolonged over up to 96 hours.

MARQIBO (LIPOSOMAL VINCRISTINE)

For IV use only; fatal if given by other routes. A single dose as an IV infusion equally distributed over 1 hour. Administer through a secure and free-flowing venous access line.

ACTIONS

CONVENTIONAL VINCRISTINE: An alkaloid of the periwinkle plant with anti-tumor activity. Cell cycle-specific for the M phase. It binds to tubulin, altering the tubulin polymerization equilibrium and resulting in altered microtubule structure and function. It stabilizes the spindle apparatus, preventing chromosome segregation and triggering metaphase arrest and inhibition of mitosis. Well distributed except in spinal fluid, it is primarily excreted through bile and feces.

MARQIBO (LIPOSOMAL VINCRISTINE): Vincristine encapsulated in sphingomyelin/cholesterol liposomes. Its mechanism of action, distribution, and elimination is similar to conventional vincristine.

INDICATIONS AND USES

CONVENTIONAL VINCRISTINE: To suppress or retard neoplastic growth; good response experienced in leukemia, Hodgkin's disease, lymphosarcoma, oat cell, Wilms' tumor, and others.

MARQIBO (LIPOSOMAL VINCRISTINE): Treatment of adults with Philadelphia chromosome-negative (Ph-) acute lymphoblastic leukemia (ALL) in second or greater relapse or adults whose disease has progressed following two or more anti-leukemia therapies. Indication based on overall response rate; clinical benefit such as improvement in overall survival not verified.

Unlabeled uses: Conventional vincristine: Treatment of idiopathic thrombocytopenic purpura; treatment of Kaposi's sarcoma, breast and bladder cancer.

CONTRAINDICATIONS

Both formulations: Demyelinating form of Charcot-Marie-Tooth syndrome.

Marqibo (liposomal vincristine): Hypersensitivity to vincristine sulfate or any of the components of Marqibo.

PRECAUTIONS

BOTH FORMULATIONS: Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Sensory and motor neuropathies are common and cumulative. Risk of neurologic toxicity is greater in patients with pre-existing neuromuscular disorders or when other potentially neurotoxic drugs are coadministered; see **Monitor**. ■ Myelosuppression may require dose adjustment. ■ Tumor lysis syndrome leading to acute uric acid nephropathy has occurred; see **Monitor**.

CONVENTIONAL VINCRISTINE: Manufacturer provides an auxiliary sticker labeled "Fatal if given intrathecally, for IV use only" and an overwrap labeled "Do not remove covering until moment of injection. Each and every infusion bag(s) or syringe(s) containing a specific dose and prepared in advance of actual administration must be labeled with the provided auxiliary sticker and packaged in this overwrap. If intrathecal injection should occur, immediate neurosurgical intervention is required, consult package insert for immediate steps to be taken. ■ Use extreme caution in combination with radiation therapy. ■ May cause corneal ulceration with accidental contact to the eye; flush eyes with water immediately. ■ Use caution in pre-existing neuromuscular disease or impaired liver function. ■ Not recommended for use in patients receiving radiation therapy that involves the liver.

MARQIBO (LIPOSOMAL VINCRISTINE): For IV use only; fatal if given by other routes. ■ Death has occurred with intrathecal administration. ■ Has different dose recommendations than conventional vincristine. Verify drug name and dose before preparation and administration to avoid overdose. ■ Constipation and bowel obstruction have occurred. ■ Can cause severe fatigue requiring dose delay, reduction, or discontinuation of therapy. ■ Fatal liver toxicity and elevated AST have occurred. ■ The influence of renal impairment and severe hepatic impairment has not been evaluated.

Monitor: Both Formulations: Determine absolute patency and quality of vein and adequate circulation of extremity. Severe cellulitis may result from extravasation; see Antidote. ■ Monitor CBC and platelets, bilirubin, and liver function tests before therapy and at frequent intervals. ■ Be alert for signs of bone marrow suppression or infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor neurologic status before therapy and at frequent intervals. Symptoms of neuropathy may include areflexia, arthralgia, burning sensation, cranial neuropathy, decreased vibratory sense, hyperesthesia, hypoesthesia, hyporeflexia, ileus, jaw pain, muscle spasm, myalgia, neuralgia, paresthesia, or weakness. ■ Observe for increased uric acid levels; may require increased doses of antigout agents (allopurinol [Aloprim] preferred) and may require alkalization of urine. Monitor for early signs of tumor lysis syndrome (e.g., flank pain and hematuria). ■ Maintain adequate hydration. ■ Prophylactic antiemetics may increase patient comfort. ■ Monitor for hyponatremia and inappropriate secretion of antidiuretic hormone (ADH); may require fluid limitation. ■ Institute a prophylactic bowel regimen to prevent potential constipation, bowel obstruction, and/or paralytic ileus. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See [Drug/Lab Interactions](#).

Patient Education: Both formulations: Avoid pregnancy; nonhormonal birth control recommended. ■ Report IV site burning or stinging promptly. ■ See Appendix D, p. 1255. ■ Use adequate dietary fiber, hydration, stool softeners and, if necessary, laxatives to avoid constipation.

Maternal/Child: Both formulations: Category D: avoid pregnancy. Can cause fetal harm. ■ Discontinue breast-feeding.

Marqibo (liposomal vincristine): Safety and effectiveness for use in pediatric patients not established.

Elderly: Both formulations: Neurotoxicity may be more severe (observe closely for constipation, ileus, and urinary retention). Dose selection should be cautious.

DRUG/LAB INTERACTIONS

Studies have not been conducted for Marqibo, but it is expected to have interactions similar to conventional vincristine. ■ May cause severe bone marrow suppression with **other antineoplastic drugs or radiation therapy**. ■ Use with **asparaginase or doxorubicin** not recommended. Asparaginase inhibits the elimination of vincristine and increases its toxicity. The manufacturer suggests giving vincristine 12 to 24 hours before asparaginase; use caution. ■ Concurrent use with **itraconazole** (Sporanox) may increase vincristine toxicity. ■ Acute pulmonary reactions can occur with **mitomycin-C**. ■ Inhibited by **glutamic acid**. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Inhibits **digoxin and phenytoin**. Monitor serum levels of digoxin and phenytoin; increased doses of these drugs may be required. ■ Use with **filgrastim** may induce a severe atypical neuropathy (foot pain, severe motor weakness). ■ A substrate for cytochrome P₄₅₀ isoenzymes (CYP3A). Avoid concurrent use of **drugs known to inhibit cytochrome P₄₅₀ isoenzymes** (e.g., atazanavir [Reyataz], clarithromycin [Biaxin], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase], telithromycin [Ketek]) and **inducers of cytochrome P₄₅₀ enzymes** (e.g., carbamazepine [Tegretol], dexamethasone [Decadron], phenobarbital [Luminal], phenytoin [Dilantin], rifabutin [Mycobutin], rifampin [Rifadin], St. John's wort). ■ Although not yet studied, it is likely that there will be interactions, and concomitant use should be avoided with **inhibitors of P-gp** (e.g., amiodarone [Nexterone], clarithromycin, diltiazem [Cardizem], erythromycin [Erythrocin], itraconazole, ketoconazole, protease inhibitors [e.g., nelfinavir, ritonavir], quinidine, sirolimus [Rapamune], tacrolimus [Prograf]) and **inducers of P-gp** (e.g., carbamazepine, phenytoin, rifampin, St. John's wort).

SIDE EFFECTS

CONVENTIONAL VINCRISTINE: Frequently dose related and not always reversible: abdominal pain, alopecia, anaphylaxis, ataxia, bronchospasm, cellulitis, constipation, convulsions, cranial nerve damage, diarrhea, dysuria, extravasation, fever, foot-drop, gonadal suppression, headache, hypertension, hypotension, leukopenia (rare), muscle wasting, nausea, neuritic pain, oral lacerations, paralytic ileus, paresthesias, polyuria, reflex changes, sensory impairment, shortness of breath, SIADH, thrombocytopenia (rare), thrombophlebitis, tingling and numbness of extremities, upper colon impaction, uric acid nephropathy, vomiting, weakness, weight loss.

MARGIBO (LIPOSOMAL VINCRISTINE): Anemia, constipation, decreased appetite, diarrhea, fatigue, febrile neutropenia, fever, insomnia, nausea, and peripheral sensory and motor neuropathy are most common. Asthenia, bowel obstruction, cardiac arrest, hypotension, ileus, increased AST, mental status changes, muscle weakness, neutropenia, pain, pneumonia, renal disorders, respiratory distress and/or failure, septic shock, staphylococcal bacteremia, and thrombocytopenia have also been reported. Extravasation, hepatic toxicity, and tumor lysis syndrome have occurred.

ANTIDOTE

For extravasation, discontinue the drug immediately and administer into another vein. Hyaluronidase may be injected locally into extravasated area. Use a fine hypodermic needle. Elevate extremity; moist heat may be helpful. Notify the physician of all side effects; symptomatic treatment is often indicated. Will probably reduce dose at earliest signs of neurologic toxicity (tingling and numbness of extremities). Discontinue for inappropriate ADH secretion or hyponatremia. Treat with fluid restriction and diuretics. Phenobarbital may be needed for convulsions. Use enemas or cathartics to treat constipation or prevent ileus. Glutamic acid blocks toxicity of vincristine, but also blocks its antineoplastic activity. Folinic acid, 100 mg IV every 3 hours for 24 hours and then every 6 hours for at least 48 hours, may be helpful in overdose. Supportive measures still required. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity.

VINORELBINE TARTRATE **BBW**

(vin-OR-el-been TAHR-trayt)

Antineoplastic
(mitotic inhibitor-vinca alkaloid)**Navelbine, NVB****pH 3.5****USUAL DOSE**Auxiliary labeling required; see [Precautions](#).

30 mg/M² administered once each week until disease progression or dose-limiting toxicity. Calculate carefully in presence of edema or ascites. Vinorelbine 25 mg/M² weekly has been used in combination with cisplatin 100 mg/M² every 4 weeks. Vinorelbine 30 mg/M² weekly has also been used in combination with cisplatin 120 mg/M² on Days 1 and 29 and then once every 6 weeks. Premedication with dexamethasone (Decadron) may be beneficial in patients who experience acute or subacute pulmonary reactions. See cisplatin monograph.

DOSE ADJUSTMENTS

Reduce or withhold dose based on hematologic toxicity or hepatic insufficiency (e.g., hyperbilirubinemia) on the day of treatment. For patients with both hematologic toxicity and hepatic insufficiency, administer the lower of the doses determined appropriate from the following charts.

Vinorelbine Dose Adjustments for Hematologic Toxicity	
Granulocytes (cells/mm ³) on Day of Treatment	Dose of Vinorelbine
≥1,500 cells/mm ³	100%
1,000 to 1,499 cells/mm ³	50%
<1,000 cells/mm ³	Do not administer. Repeat count in 1 week. If 3 consecutive weekly doses are held because granulocyte count is <1,000 cells/mm ³ , discontinue vinorelbine.
For patients who during treatment with vinorelbine have experienced fever and/or sepsis while granulocytopenic or had 2 consecutive weekly doses held due to granulocytopenia, subsequent doses of vinorelbine should be:	
≥1,500 cells/mm ³	75%
1,000 to 1,499 cells/mm ³	37.5%
<1,000 cells/mm ³	Same as <1,000 above

Vinorelbine Dose Adjustments for Impaired Hepatic Function	
Total Bilirubin (mg/dL)	Dose of Vinorelbine
≤2 mg/dL	100%
2.1 to 3 mg/dL	50%
>3 mg/dL	25%

Appropriate dose reductions for cisplatin should be made when vinorelbine is used in combination. During studies, most patients required a 50% dose reduction of vinorelbine by Day 15 and a 50% dose reduction of cisplatin by Cycle 3. ■ No dose adjustment is required for impaired renal function. ■ If Grade 2 or greater neurotoxicity develops, discontinue vinorelbine.

DILUTION

Specific techniques required; see Precautions.

IV injection: Each 10 mg (1 mL) must be further diluted with a minimum of 2 to 5 mL NS or D5W. Desired concentration is 1.5 to 3 mg/mL (2 mL diluent yields 3 mg/mL concentration, 5 mL yields 1.5 mg/mL concentration). Must be given into the side-arm port of a free-flowing IV infusion.

Intermittent infusion: Each 10 mg (1 mL) must be further diluted with 4 to 19 mL NS or D5W, ½NS, D5/½NS, R, or LR. Desired concentration is 0.5 to 2 mg/mL (4 mL diluent yields 2 mg/mL concentration, 19 mL yields 0.5 mg/mL concentration). Other references recommend diluting a single dose to a minimum total volume of 100 mL. Must be given into the side-arm port of a free-flowing IV infusion or may be given directly into a large central vein.

Storage: Refrigerate vials and protect from light; are stable at room temperature for up to 72 hours. Diluted solution stable for 24 hours at 5° to 30° C (41° to 86° F).

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends mixing only with solutions listed under Dilution.

One source suggests the following **compatibilities:**

Y-site: Amikacin (Amikin), aztreonam (Azactam), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), cefotaxime (Claforan), ceftazidime (Fortaz), chlorpromazine (Thorazine), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytosan), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), daunorubicin (Cerubidine), dexamethasone (Decadron), diphenhydramine (Benadryl), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), etoposide (VePesid), famotidine (Pepcid IV), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), gallium nitrate (Ganite), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), lorazepam (Ativan), mannitol, mechlorethamine (nitrogen mustard), melphalan (Alkeran), meperidine (Demerol), mesna (Mesnex), methotrexate, metoclopramide (Reglan), metronidazole (Flagyl IV), mitoxantrone (Novantrone), morphine, nalbuphine, ondansetron (Zofran), oxaliplatin (Eloxatin), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), streptozocin (Zanosar), teniposide (Vumon), ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vinblastine, vincristine, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Inadequate flushing of the vein after administration may increase the risk of phlebitis.

IV injection: Total desired dose, properly diluted over 6 to 10 minutes through the side-arm port of a free-flowing IV. After administration, flush with at least 75 to 125 mL of diluent solution over 10 minutes or more. Up to 300 mL has been used as a flush.

Intermittent infusion: Total desired dose, properly diluted over 6 to 10 minutes. Other references recommend over 20 minutes. Must be given into the side-arm port of a free-flowing IV infusion or may be given directly into a large central vein. Flush according to directions for IV injection.

ACTIONS

An antineoplastic agent. A semi-synthetic vinca alkaloid with chemical differences from other vinca alkaloids that may provide unique clinical benefits with a lower incidence of clinical neurotoxicity. Causes depolymerization of microtubules and inhibits microtubule assembly. May be more specific to mitotic microtubules. Cell cycle-specific and produces a blockade in the cell-cycle progression in G₂ and M phase. Widely distributed in

the body. Elimination half-life is 27 to 43 hours. Metabolized in the liver by hepatic cytochrome P₄₅₀ isoenzymes in the CYP3A subfamily. Excreted in bile, feces, and urine.

INDICATIONS AND USES

Treatment of unresectable advanced non–small-cell lung cancer (ANSCLC), in ambulatory patients. Used as a single agent or in combination with cisplatin. ■ Indicated as a single agent or in combination with cisplatin in patients with Stage IV NSCLC and in combination with cisplatin in patients with Stage III NSCLC.

Unlabeled uses: Treatment of breast, cervical, and epithelial ovarian cancers; treatment of desmoid tumors and fibromatosis, and advanced Kaposi's sarcoma.

CONTRAINDICATIONS

Patients with pretreatment granulocyte counts less than 1,000 cells/mm³.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Severe irritation of the eye has been reported with accidental exposure to another vinca alkaloid. If exposure occurs, thoroughly flush eye with water immediately. ■ Administered by or under the direction of the physician specialist. ■ Manufacturer provides an auxiliary sticker labeled "Fatal if given intrathecally, for IV use only" and an overwrap labeled "Do not remove covering until moment of injection. Fatal if given intrathecally. For Intravenous use only." Each and every syringe(s) containing a specific dose and prepared in advance of actual administration must be labeled with the provided auxiliary sticker and packaged in this overwrap. If intrathecal injection should occur, immediate neurosurgical intervention is required, consult package insert for immediate steps to be taken. ■ Adequate diagnostic and treatment facilities must be readily available. ■ May cause severe granulocytopenia resulting in increased susceptibility to infection. ■ Use extreme caution in patients with hepatic impairment, pre-existing neuromuscular disease, pre-existing peripheral neuropathies, or those taking other neurotoxic drugs (e.g., antineoplastics [cisplatin], phenothiazines [prochlorperazine]). ■ Acute SOB and severe bronchospasm have been reported, most commonly when vinorelbine was used with mitomycin. May require treatment with oxygen, bronchodilators (e.g., albuterol), and/or corticosteroids (e.g., hydrocortisone). Incidence may be increased when there is pre-existing pulmonary dysfunction. ■ Prior radiation therapy or treatment with other antineoplastic agents may cause an increase in myelotoxicity; use with extreme caution. ■ Administration to patients with prior radiation therapy may result in radiation recall reactions. ■ See [Monitor](#) and [Drug/Lab Interactions](#).

Monitor: Monitor CBC, differential, platelets, and bilirubin on each day of treatment to determine correct dose and 1 or 2 times weekly, granulocytopenia is dose-limiting. Temporary leukopenia is an expected effect. Maximum depression usually occurs in 7 to 10 days after the dose, and recovery should occur within the following 7 to 14 days. ■ Cases of interstitial pulmonary changes and adult respiratory distress syndrome (ARDS), most of which were fatal, have been reported. Onset of symptoms has occurred in 3 to 8 days. Promptly evaluate patients with alterations in their baseline pulmonary symptoms or with new onset of cough, dyspnea, hypoxia, or other symptoms. ■ Monitor AST frequently. ■ Evaluate neurologic status frequently (e.g., constipation, decreased deep tendon reflexes, paresthesia). ■ Closely monitor patients who have had symptoms of neuropathy with previous drug regimens (e.g., paclitaxel [Taxol]) for new or worsening neuropathy. ■ Determine absolute patency and quality of vein and adequate circulation of extremity. Local tissue necrosis and/or thrombophlebitis can result from extravasation; see [Antidote](#). ■ Be alert for any sign of infection. Infections must be brought under control before beginning therapy with vinorelbine. ■ Use of prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Maintain adequate hydration. ■ Prophylactic antiemetics may increase patient comfort; haloperidol and oral dexamethasone have benefited some patients. ■ May cause severe (Grade 3-4) constipation, paralytic ileus, intestinal obstruction, necrosis, and/or perforation. Use

a laxative to prevent constipation. Monitor bowel sounds. ■ Monitor for hyponatremia and syndrome of inappropriate secretion of antidiuretic hormone (SIADH). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Report burning or stinging at IV site promptly. ■ Report chills, fever, difficulty breathing, or shortness of breath promptly. ■ Avoid pregnancy; nonhormonal birth control recommended. ■ Take laxatives consistently to avoid constipation. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients has not been established but has been investigated. In one study, vinorelbine was considered to be ineffective when used in doses similar to those used in adults in a limited number of pediatric patients with recurrent solid malignant tumors (e.g., rhabdomyosarcoma/undifferentiated sarcoma, neuroblastoma, and CNS tumors). Toxicities were similar to those reported in adults.

Elderly: The pharmacokinetics of vinorelbine in elderly and younger adult patients are similar. No relationship between age, systemic exposure, and hematologic toxicity has been observed.

DRUG/LAB INTERACTIONS

Neurotoxicity may be increased by **other neurotoxic drugs** (e.g., antineoplastics [such as cisplatin, paclitaxel (Taxol)] and phenothiazines [prochlorperazine]); may require dose reduction or discontinuation of vinorelbine. Vestibular and auditory deficits have been observed, usually when vinorelbine is used in combination with cisplatin. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ **Mitomycin-C** may cause or aggravate acute pulmonary reactions (e.g., acute shortness of breath, bronchospasm). May require oxygen, bronchodilators, and/or corticosteroids. ■ Granulocytopenia significantly higher when used in combination with **cisplatin**. ■ Additive bone marrow suppression may occur with **radiation therapy and/or other bone marrow-suppressing agents** (e.g., azathioprine [Imuran], chloramphenicol, melphalan [Alkeran]); dose reductions may be required. ■ Leukopenic effects may be increased by **agents that cause similar blood dyscrasias** (e.g., anticonvulsants, antidepressants, phenothiazines). ■ **Drugs that inhibit the cytochrome P₄₅₀ isoenzymes in the CYP3A subfamily** (e.g., azole antifungals [e.g., itraconazole (Sporanox)], macrolides [e.g., erythromycin (Erythrocin), troleandomycin (TAO)]) may inhibit the metabolism of vinorelbine and increase its toxicity. **Other vinca alkaloids cause interactions with the following drugs; vinorelbine has not been studied.** ■ Use with **asparaginase or doxorubicin** may not be recommended or may require specific scheduling. ■ May be potentiated by **calcium channel blockers** (e.g., verapamil). ■ May inhibit **digoxin and phenytoin**; increased doses of these drugs may be required. ■ See [Precautions](#).

SIDE EFFECTS

Granulocytopenia is the major dose-limiting toxicity and may be significantly greater in combination regimens. Alopecia (12%, mild); anemia (87%, mild to moderate); ARDS, auditory deficits, bronchospasm, chest pain (7%); constipation (35%); diarrhea; dyspnea [2%] (acute and reversible shortness of breath may occur within a few hours); elevated total bilirubin and AST; fatigue; hematologic toxicity [99%] (leukopenia and neutropenia are the most frequent and are dose-limiting); hemorrhagic cystitis (rare); hypertension; hypotension; intestinal obstruction, necrosis, and/or perforation; jaw pain; loss of deep tendon reflexes (5%); nausea and vomiting (50% [23%]); pain and redness at injection site (38%); pancreatitis, paralytic ileus (less than 2%); peripheral neuropathy (31%), mild to moderate paresthesia and hypesthesia, phlebitis (10%); pulmonary edema; radiosensitizing effects in patients with prior or concomitant radiation therapy; SIADH (few);

subacute pulmonary reactions (4%, e.g., cough, dyspnea, hypoxemia, and interstitial infiltrates on chest x-ray); thrombocytopenia (rare), thrombocytosis (asymptomatic), tumor pain, vestibular deficits. Pattern of side effects similar when vinorelbine is used as a single agent or in combination.

ANTIDOTE

For severe reactions, discontinue vinorelbine or reduce subsequent doses. If Grade 2 or greater neurotoxicity develops, discontinue vinorelbine. For extravasation, discontinue the drug immediately and administer into another vein. Elevate the extremity. Moist heat may be helpful. Notify the physician of all side effects; symptomatic treatment is often indicated. Discontinue for hyponatremia or SIADH, may require fluid limitation and diuretics (e.g., furosemide [Lasix]). Bone marrow toxicity is reversible after discontinuing vinorelbine. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) may be indicated. Darbepoetin alfa (Aranesp), epoetin alfa (Epogen), filgrastim (Neupogen), pegfilgrastim (Neulasta), or sargramostim (Leukine) may be used to promote bone marrow recovery but may not be given within 24 hours of a dose of cytotoxic therapy or until 24 hours after a dose of cytotoxic therapy. Acute or chronic pulmonary reactions may be an allergic phenomena, corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), oxygen and bronchodilators (e.g., albuterol [Ventolin, Proventil]) may be helpful. Neurologic toxicity may be reversible.

VON WILLEBRAND FACTOR/COAGULATION FACTOR VIII COMPLEX (HUMAN)

Antihemorrhagic

(von **WILL**-a-brand **FAK**-tor/koh-**AG**-yoo-**LAY**-shun
FAK-tor VIII **KOM**-plex) (**HYOO**-man)

Wilate

USUAL DOSE

(International Units [IU])

Completely individualized. One IU of von Willebrand factor:Ristocetin Cofactor (VWF:RCo) or 1 IU of factor VIII (FVIII) is approximately equal to the level of VWF:RCo or FVIII activity found in 1 mL of fresh pooled human plasma. The ratio between VWF:RCo and FVIII activities in Wilate is approximately 1:1. When using a FVIII-containing VWF product, continued treatment may cause an excessive rise in FVIII activity; see **Monitor**. The following chart provides estimated doses for minor and major hemorrhages.

Guide to Wilate Dosing for Treatment of Minor and Major Hemorrhages			
Type of Hemorrhage	Loading Dose (IU VWF:RCo/kg)	Maintenance Dose (IU VWF:RCo/kg)	Therapeutic Goal
Minor Hemorrhages	20 to 40 IU/kg	20 to 30 IU/kg every 12 to 24 hours*	VWF:RCo and FVIII activity trough levels of >30%
Major Hemorrhages	40 to 60 IU/kg	20 to 40 IU/kg every 12 to 24 hours*	VWF:RCo and FVIII activity trough levels of >50%

*Maintenance doses may need to be continued for up to 3 days for minor hemorrhages and 5 to 7 days for major hemorrhages. Repeat doses may be administered for as long as needed based on repeated monitoring of appropriate clinical and laboratory measures.

PEDIATRIC DOSE

Unlabeled: For immediate control of bleeding, follow the general recommendations for dosing and administration for adults. See **Usual Dose** and **Maternal/Child**.

DOSE ADJUSTMENTS

Adjust dose according to the extent and location of bleeding. Higher doses may be required in von Willebrand (vWD) Type 3 patients, especially those with GI bleeding. ■ If a dose is missed, consider administration of a dose based on the level of coagulation factors measured, extent of the bleeding, and patient's clinical condition.

DILUTION

Provided as a kit containing a single-dose vial of powder, a vial of diluent, a Mix2Vial transfer device, a 10-mL syringe, an infusion set, and 2 alcohol swabs. Consult instructions for reconstitution and injection in the package insert. Warm to room temperature (25° C) before dilution and maintain throughout reconstitution. If a water bath is used for warming (temperature should not exceed 37° C [98° F]), do not allow water to come into contact with the latex-free rubber stopper or vial caps. The total number of IUs available is clearly marked on each vial. Concentration is 90 IU/mL. Record the batch number of each vial. Should be used immediately after reconstitution. Solution should be slightly opalescent. Contents of multiple vials may be pooled in a single administration device. Use a new Mix2Vial transfer set for each vial of drug.

Filters: Incorporated into the Mix2Vial.

Storage: Store in original carton to protect from light. Stable for 36 months from date of manufacture when refrigerated at 2° to 8° C (36° to 46° F). Avoid freezing. May be stored at RT (maximum of 25° C [77° F]) for up to 6 months. Label vial with date removed from refrigeration. Once stored at RT, do not return to refrigeration. Shelf life expires with date of manufacture or 6 months from date of removal from refrigeration, whichever comes

first. Confirm expiration date on vial. Administer immediately after reconstitution. Discard any unused solution.

COMPATIBILITY

Manufacturer states, "Must not be mixed with other medicinal products or administered simultaneously with other IV preparations in the same infusion set."

RATE OF ADMINISTRATION

A single dose as an infusion at 2 to 4 mL/min. Reduce rate of administration or interrupt the infusion if a marked increase in pulse occurs.

ACTIONS

A purified, sterile, lyophilized concentrate of von Willebrand factor (VWF) and antihepophilic factor (factor VIII) that is obtained from pooled human plasma. Multiple methods of purification are used to inactivate infectious agents, including viruses. VWF and FVIII are normal constituents of human plasma. Patients with vWD have a deficiency or abnormality of VWF; this results in low FVIII activity and an abnormal platelet function, which causes excessive bleeding. VWF re-establishes platelet adhesion at the site of vascular damage, providing primary hemostasis (shortening of bleeding time occurs immediately), and stabilizes FVIII by binding to it and preventing its rapid degradation. This latter action is slightly delayed. However, administration of a FVIII-containing VWF preparation rapidly restores FVIII activity to normal. VWF activity is measured with an assay that uses an agglutinating cofactor called Ristocetin (RCo). The VWF:RCo assay provides a quantitative measurement of VWF function by determining how well VWF helps platelets adhere to one another. Reduced VWF:RCo activity indicates a deficiency of VWF. Half-life varies based on type of VWF (1, 2, or 3). Half-life range is 10.9 to 34.7 hours. Clearance may be slightly higher in females; clinical significance unknown.

INDICATIONS AND USES

Treatment of spontaneous and trauma-induced bleeding episodes in patients with severe von Willebrand disease (vWD), as well as patients with mild or moderate vWD in which the use of desmopressin is known or suspected to be ineffective or contraindicated. ■ Not indicated for the prevention of excessive bleeding during and after surgery in vWD patients (see Alphanate [type 1 or 2], Humate-P [type 1, 2, or 3]). ■ Not indicated for hemophilia A (see Alphanate, Humate-P). ■ Studies to determine safety and effectiveness of prophylactic dosing to prevent spontaneous bleeding have not been conducted.

CONTRAINDICATIONS

History of anaphylactic or severe systemic response to plasma-derived products, any ingredient in the formulation, or components of the container.

PRECAUTIONS

For IV use only. ■ Administered under the direction of a physician knowledgeable in the treatment of coagulation disorders in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, have occurred; see **Monitor**. ■ Important to establish that coagulation disorder is caused by vWD. Not useful in treatment of other deficiencies. ■ Manufactured from human plasma. Risk of transmitting infectious agents (e.g., HIV, hepatitis and, theoretically, Creutzfeldt-Jakob disease) has been greatly reduced by screening, testing, and manufacturing techniques. However, risk of transmission cannot be totally eliminated. Health care professionals should use caution during administration; may have risk of exposure to viral infection. ■ Hepatitis A and B vaccines are recommended for patients receiving plasma derivatives. ■ Thrombotic events have been reported. Use caution in patients with known risk factors for thrombosis. ■ Inhibitors may develop with large or frequent doses; see **Monitor**.

Monitor: Monitor BP and pulse during infusion. If a marked increase in pulse occurs, either reduce rate of infusion or interrupt the infusion. ■ Throughout the infusion, monitor for S/S of a hypersensitivity reaction (e.g., angioedema, burning and stinging at injection site, chills, flushing, headache, hives, hypotension, tachycardia, tightness of the chest, urticaria, wheezing). Evaluate for the presence of inhibitors if an anaphylactic reaction

occurs. ■ When using a FVIII-containing VWF product, continued treatment may cause an excessive rise in FVIII activity. Appropriate laboratory tests should be performed on the patient's plasma at suitable intervals to ensure that adequate VWF:RCo and FVIII activity levels have been reached and are maintained. Excessive activity levels may increase the risk of thrombotic events. ■ Monitor for development of VWF and FVIII inhibitors (neutralizing antibodies). Consider formation of inhibitors and perform assays if bleeding is not controlled with usual doses.

Patient Education: Prophylactic hepatitis A and hepatitis B vaccines recommended.

■ Promptly report S/S of a hypersensitivity reaction (e.g., dizziness, hives, itching, rash, tightness of the chest). ■ Frequent blood tests (e.g., monitoring of VWF:RCo and FVIII activity) are required to reduce the risk of thrombotic events. ■ Report symptoms of possibly transmitted viral infections immediately. Symptoms may include anorexia, arthralgias, fatigue, jaundice, low-grade fever, nausea, or vomiting.

Maternal/Child: Category C: use during pregnancy or labor and delivery only if clearly needed. ■ Safety for use during breast-feeding has not been studied. ■ Has been used in pediatric patients between 5 and 16 years of age. No dose adjustment is required.

Elderly: Numbers insufficient to determine differences in response compared with younger adults.

DRUG/LAB INTERACTIONS

Manufacturer states, "No interactions with other medicinal products are known."

SIDE EFFECTS

Most common side effects reported are dizziness, facial edema, headache, paresthesia, pruritus, and urticaria. The most serious effect is a hypersensitivity reaction.

Post-Marketing: Cough, dyspnea, hypersensitivity reactions, nausea, and vomiting.

ANTIDOTE

Keep the physician informed of side effects. Slow or interrupt infusion for a marked increase in pulse rate or mild hypersensitivity reaction. Discontinue the infusion immediately if a severe hypersensitivity reaction or thrombotic event (e.g., chest pain, dyspnea, leg pain, MI) occurs and evaluate for the presence of inhibitors. Treat hypersensitivity as necessary (e.g., antihistamines, epinephrine, corticosteroids), and treat thrombotic events with appropriate measures. Resuscitate as necessary.

VORICONAZOLE

(vor-ih-KOH-nah-zohl)

Antifungal

VFEND IV

USUAL DOSE

Duration of treatment is based on severity of the underlying disease, recovery from immunosuppression, and clinical response. Pretesting required; see [Precautions](#) and [Monitor](#). Obtain baseline electrolytes and correct calcium, magnesium, and potassium deficiencies before initiating voriconazole.

Voriconazole Dose Guidelines			
Infection	Loading Dose	IV Maintenance Dose ^f	Oral Maintenance Dose ^f
Invasive aspergillosis ^{c, g}	6 mg/kg q 12 hr for the first 24 hours	4 mg/kg q 12 hr	200 mg q 12 hr ^c
Candidemia in nonneutropenic patients and in other deep tissue <i>Candida</i> infections	6 mg/kg q 12 hr for the first 24 hours	3 to 4 mg/kg q 12 hr ^{a, b}	200 mg q 12 hr ^{a, b, c}
Esophageal candidiasis			200 mg q 12 hr ^{c, d}
Scedosporiosis and fusariosis ^g	6 mg/kg q 12 hr for the first 24 hours	4 mg/kg q 12 hr	200 mg q 12 hr ^c

^aIn clinical trials, patients with candidemia received 3 mg/kg q 12 hr as primary therapy, and patients with other deep tissue *Candida* infections received 4 mg/kg as salvage therapy. Appropriate dose should be based on the severity and nature of the infection.

^bTreat for at least 14 days following resolution of symptoms or following last positive culture, whichever is longer.

^cPatients who weigh 40 kg or more should receive an oral maintenance dose of 200 mg q 12 hr. Adult patients who weigh less than 40 kg should receive an oral maintenance dose of 100 mg q 12 hr.

^dTreat for a minimum of 14 days and for at least 7 days following the resolution of symptoms.

^eIn a clinical study of invasive aspergillosis, the median duration of IV voriconazole was 10 days (range 2 to 90 days). Median duration of oral therapy was 76 days (range 2 to 232 days).

^fIn healthy volunteer studies, a 200-mg oral dose every 12 hours provided an exposure (AUC) similar to a 3-mg/kg IV dose every 12 hours; a 300-mg oral dose every 12 hours provided an exposure (AUC) similar to a 4-mg/kg IV dose every 12 hours.

^gIV therapy should be continued for at least 7 days.

For all indications: A switch between IV and oral formulations is appropriate because of high bioavailability of oral formulations. Depending on diagnosis, may switch to oral formulation when a patient has shown clinical improvement and can tolerate oral therapy; see [Patient Education](#).

DOSE ADJUSTMENTS

In patients with an inadequate response weighing 40 kg or more, increase the oral maintenance dose from 200 mg every 12 hours (similar to 3 mg/kg IV every 12 hours) to 300 mg every 12 hours (similar to 4 mg/kg every 12 hours). If unable to tolerate the 300-mg oral dose, decrease it by 50-mg increments to a minimum of 200 mg orally every 12 hours. For adult patients with an inadequate response weighing less than 40 kg, increase the oral maintenance dose from 100 mg every 12 hours to 150 mg every 12 hours. If unable to tolerate the 150-mg dose, decrease it to 100 mg orally every 12 hours. ■ Reduce the IV maintenance dose to 3 mg/kg every 12 hours in patients unable to tolerate treatment. ■ If phenytoin (Dilantin) is being administered concurrently, increase the IV maintenance dose of voriconazole to 5 mg/kg every 12 hours or from 200 to 400 mg orally every 12 hours (or 100 mg to 200 mg orally every 12 hours in patients weighing less than 40 kg); see [Drug/Lab Interactions](#). ■ When voriconazole is coadministered

with efavirenz (Sustiva), increase voriconazole oral maintenance dose to 400 mg every 12 hours and decrease efavirenz dose to 300 mg every 24 hours. ■ No dose adjustment is indicated based on age or gender or in patients with baseline liver function tests (ALT, AST) up to 5 times the ULN (see [Precautions](#) and [Monitor](#)). ■ In patients with mild to moderate hepatic cirrhosis (Child-Pugh Class A and B), use the standard loading dose but reduce the maintenance dose by one half and administer every 12 hours based on tolerance of treatment and/or concurrent medication. ■ No dose adjustment is required in patients with a CrCl of 50 mL/min or greater; however, the intravenous vehicle, sulfobutyl ether beta-cyclodextrin sodium (SBECD), accumulates in patients with a CrCl of less than 50 mL/min. Use of oral voriconazole is recommended in these patients; see [Precautions](#) and [Monitor](#). ■ A 4-hour hemodialysis session does not remove a sufficient amount of voriconazole to warrant dose adjustment.

DILUTION

Reconstitute each vial with exactly 19 mL SWFI. Use of a standard 20-mL (nonautomated) syringe is recommended to facilitate exact measurement. Volume will be 20 mL (10 mg/mL). Discard the vial if a vacuum is not present to pull the diluent into the vial. Shake until all powder is dissolved. Calculate the required dose based on patient weight (see the following chart). Must be further diluted for infusion in D5W, D5LR, LR, NS, D5½NS, D5NS, ½NS, or D5W with 20 mEq KCl. Withdraw a volume equal to the calculated dose of voriconazole from an infusion bag or bottle (30 mL in the following example). The volume of diluent left in the infusion bag or bottle should be enough to allow a final concentration of not less than 0.5 mg/mL or greater than 5 mg/mL after voriconazole is added. Withdraw the required volume of reconstituted drug and add to the infusion bag or bottle. For example, a patient weighing 50 kg will require a loading dose of 300 mg (6 mg/kg × 50 kg), which equals 30 mL of reconstituted drug (1½ vials). Withdraw and discard 30 mL of solution from a 100-mL infusion bag and add the 30 mL of reconstituted drug. Final concentration equals 3 mg/mL.

Required Volumes of 10 mg/mL Voriconazole Concentrate			
	Volume of Voriconazole Concentrate (10 mg/mL) required for:		
Body Weight (kg)	3 mg/kg Dose (number of vials)	4 mg/kg Dose (number of vials)	6 mg/kg Dose (number of vials)
30 kg	9 mL (1 vial)	12 mL (1 vial)	18 mL (1 vial)
35 kg	10.5 mL (1 vial)	14 mL (1 vial)	21 mL (2 vials)
40 kg	12 mL (1 vial)	16 mL (1 vial)	24 mL (2 vials)
45 kg	13.5 mL (1 vial)	18 mL (1 vial)	27 mL (2 vials)
50 kg	15 mL (1 vial)	20 mL (1 vial)	30 mL (2 vials)
55 kg	16.5 mL (1 vial)	22 mL (2 vials)	33 mL (2 vials)
60 kg	18 mL (1 vial)	24 mL (2 vials)	36 mL (2 vials)
65 kg	19.5 mL (1 vial)	26 mL (2 vials)	39 mL (2 vials)
70 kg	21 mL (2 vials)	28 mL (2 vials)	42 mL (3 vials)
75 kg	22.5 mL (2 vials)	30 mL (2 vials)	45 mL (3 vials)
80 kg	24 mL (2 vials)	32 mL (2 vials)	48 mL (3 vials)
85 kg	25.5 mL (2 vials)	34 mL (2 vials)	51 mL (3 vials)
90 kg	27 mL (2 vials)	36 mL (2 vials)	54 mL (3 vials)
95 kg	28.5 mL (2 vials)	38 mL (2 vials)	57 mL (3 vials)
100 kg	30 mL (2 vials)	40 mL (2 vials)	60 mL (3 vials)

Filters: No data available from manufacturer.

Storage: Store unopened vials at CRT. Immediate use of reconstituted vials is preferred; however, they may be refrigerated up to 24 hours at 2° to 8° C (37° to 46° F). Discard partially used vials.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Must not be infused concomitantly with any blood product or short-term infusion of concentrated electrolytes, even if the two infusions are running in separate IV lines or cannulas. Electrolyte disturbances such as hypokalemia, hypomagnesemia, and hypocalcemia should be corrected before initiation of voriconazole; see **Precautions.**" Voriconazole can be infused at the same time as other IV solutions containing (non-concentrated) electrolytes but must be infused through a separate line. Voriconazole can be infused at the same time as total parenteral nutrition (TPN) but must be infused in a separate line. If infused through a multiple-lumen catheter, TPN needs to be administered using a different port from the one used for voriconazole. Manufacturer states that voriconazole should not be diluted with 4.2% sodium bicarbonate solution.

Compatibility with other concentrations of sodium bicarbonate is unknown; do not use.

One source suggests the following **compatibilities:**

Y-site: Anidulafungin (Eraxis), caspofungin (Cancidas), ceftaroline (Teflaro), doripenem (Doribax), vasopressin.

RATE OF ADMINISTRATION

A single dose as an infusion over 1 to 2 hours. Do not exceed a rate of 3 mg/kg/hr.

ACTIONS

A triazole antifungal agent. Inhibits a fungal cytochrome P₄₅₀-mediated essential step in fungal ergosterol biosynthesis. With a loading dose regimen, peak and trough plasma concentrations close to steady-state concentrations are achieved within the first 24 hours. Extensively distributed into tissues. Plasma protein binding (estimated at 58%) is not affected by varying degrees of hepatic and renal insufficiency. Metabolized by cytochrome P₄₅₀ enzymes (CYP2C19 is significantly involved). Terminal half-life is dose dependent and is not useful in predicting accumulation or elimination. Eliminated via hepatic metabolism; less than 2% is excreted unchanged in urine.

INDICATIONS AND USES

For use in patients 12 years of age and older in treatment of the following infections: Treatment of invasive aspergillosis caused by *Aspergillus fumigatus* and other species of *Aspergillus*. ■ Treatment of candidemia in nonneutropenic patients and the following *Candida* infections: disseminated infections in the skin and infections in the abdomen, kidney, bladder wall, and wounds. ■ Treatment of serious fungal infections caused by *Scedosporium apiospermum* and *Fusarium* species, including *Fusarium solani*, in patients intolerant of or refractory to other therapy. ■ Treatment of esophageal candidiasis.

CONTRAINDICATIONS

Hypersensitivity to voriconazole or any of its components. Use caution in patients exhibiting hypersensitivity to other azoles (e.g., fluconazole [Diflucan], itraconazole [Sporanox], ketoconazole [Nizoral]); see **Precautions.** ■ Coadministration is specifically **contraindicated** with CYP3A4 substrates (e.g., cisapride [Propulsid], pimozide [Orap], and quinidine [astemizole and terfenadine would be included but are no longer commercially available]); increased plasma concentrations of these drugs may result in QT prolongation and torsades de pointes. ■ Coadministration is **contraindicated** with the following drugs: barbiturates (long-acting [e.g., phenobarbital (Luminal)]), carbamazepine (Tegretol), a *standard dose* of efavirenz (Sustiva) with a *standard dose* of voriconazole, ergot alkaloids (ergotamine and dihydroergotamine [D.H.E. 45]), rifabutin (Mycobutin), rifampin (Rifadin), high-dose (400 mg every 12 hours) ritonavir (Norvir), sirolimus (Rapamune), and St. John's wort; see **Drug Interactions.**

PRECAUTIONS

Do not give as an IV bolus, for infusion only. ■ Specimens for fungal culture, serologic testing, and histopathologic testing should be obtained before therapy to isolate and identify

causative organisms. Therapy may begin as soon as all specimens are obtained and before results are known. Reassess after test results are known. ■ Correct electrolyte disturbances such as hypokalemia, hypomagnesemia, and hypocalcemia before initiation of voriconazole. ■ Infusion-related hypersensitivity reactions, including anaphylaxis, chest tightness, dyspnea, faintness, fever, flushing, nausea, pruritus, rash, sweating, and tachycardia have occurred. Usually appear at the beginning of the infusion. If a hypersensitivity reaction occurs, discontinue the infusion. ■ Consider use in patients with severe hepatic insufficiency only if the benefit outweighs potential risk; monitor carefully for drug toxicity. ■ Serious hepatic reactions (including clinical hepatitis, cholestasis, and fulminant hepatic failure, including fatalities) have occurred. Usually occur in patients with serious underlying medical conditions (e.g., hematologic malignancy); however, hepatic reactions, including hepatitis and jaundice, have occurred in patients with no other identifiable risk factors. Liver function usually improves with discontinuation of voriconazole. ■ Pancreatitis has been reported; see [Monitor](#). ■ Consider use of IV formulation in patients with a CrCl less than 50 mL/min only if the benefit outweighs potential risk. Accumulation of SBECD may occur with the IV formulation; use of the oral formulation is recommended. ■ Acute renal failure has been reported, usually in patients receiving concomitant nephrotoxic drugs or in patients who have concurrent medical conditions that may result in decreased renal function; see [Drug/Lab Interactions](#). ■ May cause prolongation of the QT interval on ECG and rarely torsades de pointes. Use with caution in patients with proarrhythmic conditions (e.g., cardiotoxic chemotherapy, cardiomyopathy, hypokalemia, and concomitant medications that may also prolong the QT interval). ■ Because of the enzymes involved in metabolism, Asian populations may be poor metabolizers, and serum concentrations may be elevated from 2 to 4 times higher than normal metabolizers. Some Caucasians and Blacks are also poor metabolizers. ■ Blurred vision, color vision changes, and/or photophobia are common but may be associated with higher serum concentrations and/or doses. Usually resolves within 2 weeks of the end of voriconazole therapy. If therapy continues beyond 28 days, the effects of voriconazole therapy on visual function is not known. Prolonged visual adverse effects, including optic neuritis and papilledema, have been reported. ■ Fluorosis (mottled enamel of human teeth caused by flouride) and periostitis (inflammation of the periosteum) have been reported during long-term therapy. Discontinue treatment in patients who develop skeletal pain or radiographic findings consistent with either of these diagnoses. ■ Fungi with reduced susceptibility to one azole antifungal agent may also be less susceptible to other azole derivatives. Cross-resistance may occur and may require alternative antifungal therapy. ■ Oral maintenance doses adjusted based on weight (above or below 40 kg); see product literature.

Monitor: Obtain baseline electrolytes and make rigorous attempts to correct calcium, magnesium, and potassium before initiating voriconazole. Monitor electrolytes during therapy; may cause hypocalcemia, hypokalemia, and hypomagnesemia. ■ Obtain baseline liver function tests (e.g., alkaline phosphatase, ALT, AST, bilirubin), serum creatinine, and electrolytes in all patients. Monitor liver function tests during therapy, more frequently in patients with increasing or pre-existing elevated liver function tests and/or impaired hepatic function, and any time S/S suggestive of liver dysfunction develop (e.g., jaundice, lethargy). ■ Monitor pancreatic function (e.g., serum amylase) in adults and children with risk factors for acute pancreatitis (e.g., recent chemotherapy, hematopoietic stem cell transplantation [HSCT]). ■ Monitor serum creatinine during therapy, more frequently in patients with a CrCl less than 50 mL/min. If an increase in serum creatinine occurs, consider changing to the oral formulation. ■ Monitor for S/S of hypersensitivity reactions; see [Precautions](#) and [Antidote](#). ■ Monitor visual acuity, visual field, and color perception if treatment continues beyond 28 days. ■ If a rash develops, serious cutaneous reactions (e.g., Stevens-Johnson syndrome) may develop; see [Side Effects](#) and monitor closely. Consider discontinuing voriconazole. ■ See [Precautions](#), [Drug/Lab Interactions](#), and [Antidote](#).

Patient Education: Review of health history and medication profile is imperative. ■ Avoid pregnancy; nonhormonal birth control recommended; see [Drug/Lab Interactions](#). Should pregnancy occur, notify physician immediately and discuss potential hazards. ■ Do not drive at night; changes to vision, including blurring and/or photophobia, may occur. Ophthalmologic monitoring is required with prolonged use. ■ If a change in vision occurs, avoid hazardous tasks, such as driving or operating machinery. ■ Avoid strong, direct sunlight. ■ Promptly report S/S of a hypersensitivity reaction (e.g., itching, hives, shortness of breath) or a serious skin reaction (e.g., severe sunburn, blistering or peeling of skin). ■ Additional precautions required with transfer to oral voriconazole.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. Teratogenic in rats and embryotoxic in rabbits. Use of effective contraception is required in women of child-bearing age. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients less than 12 years of age not established.

Elderly: Safety profile similar to younger adults. ■ Peak plasma concentrations slightly higher in elderly males; however, dose adjustment is not indicated. ■ Use caution; consider decreased cardiac, hepatic, or renal function and effects of concomitant disease or other drug therapy. ■ Monitor liver and renal function closely.

DRUG/LAB INTERACTIONS

Interactions are numerous and potentially life threatening. Review of drug profile by pharmacist is imperative.

Contraindicated with CYP3A4 substrates (e.g., **cisapride** [Propulsid], **pimozide** [Orap], and **quinidine** [astemizole and terfenadine would be included but are no longer commercially available]); increased plasma concentrations of these drugs may result in QT prolongation and torsades de pointes. ■ **Contraindicated** with **long-acting barbiturates** (e.g., phenobarbital [Luminal]), **carbamazepine** (Tegretol), **rifampin** (Rifadin), and **St. John's wort**; these drugs may significantly increase metabolism and decrease serum concentrations of voriconazole. ■ **Contraindicated** with **high-dose (400 mg every 12 hours) ritonavir** (Norvir); decreases serum concentrations of voriconazole. **Low-dose ritonavir (100 mg every 12 hours)** reduces voriconazole concentration to a lesser extent. Coadministration should be avoided unless assessment of the benefit versus risk to the patient justifies voriconazole use. ■ **Contraindicated** with **sirolimus** (Rapamune); metabolism of sirolimus is decreased, and serum concentrations are significantly increased by voriconazole. ■ **Contraindicated** with **rifabutin** (Mycobutin); voriconazole significantly increases the serum concentrations of rifabutin, and rifabutin significantly decreases voriconazole serum concentrations. ■ **Contraindicated** with **standard doses of efavirenz** (Sustiva); voriconazole increases serum concentrations of efavirenz, and efavirenz decreases serum concentrations of voriconazole. If coadministration is required, dose adjustment of both drugs is indicated. Increase voriconazole to 400 mg every 12 hours and decrease efavirenz to 300 mg every 24 hours. Restore the initial dose of efavirenz when treatment with voriconazole is discontinued. ■ **Contraindicated** with **ergot alkaloids** (e.g., ergotamine and dihydroergotamine [D.H.E. 45]); serum concentrations of ergot alkaloids may be increased and may lead to ergotism. ■ Avoid concomitant use with **fluconazole** (Diflucan). Potential for voriconazole toxicity remains if voriconazole is initiated within 24 hours of the last dose of fluconazole. ■ May decrease the metabolism and increase serum levels of **cyclosporine** (Sandimmune). If concurrent administration with voriconazole is indicated, reduce the dose of cyclosporine by one half and monitor cyclosporine serum levels frequently. When voriconazole is discontinued, monitor cyclosporine levels frequently and increase the dose as necessary. ■ May decrease the metabolism and increase serum levels of **methadone** (Dolophine) and increase risk of QT prolongation. If concurrent administration with voriconazole is indicated, monitor closely and decrease dose of methadone as necessary. ■ Increases concentration and half-life of **alfentanil** (Alfenta), **fentanyl** (Sublimaze), **oxycodone** (ETH-Oxydose), and **sufentanil** (Sufenta). Dose reduction and extended monitoring recommended. ■ May decrease the metabolism and increase serum levels of **tacrolimus** (Prograf). If concurrent administration with voriconazole is indicated, reduce the dose of tacrolimus by one third and monitor tacrolimus serum levels frequently.

When voriconazole is discontinued, monitor tacrolimus levels frequently and increase the dose as necessary. ■ Concurrent use with **warfarin** (Coumadin) or oral coumarin preparations may cause a significant increase in PT or INR. Monitor PT or INR closely and adjust warfarin dose as necessary. ■ May decrease the metabolism and increase serum concentrations of CYP3A4 substrates, such as selected **HMG-CoA reductase inhibitors** (statins such as lovastatin [Mevacor]), **selected benzodiazepines** (e.g., alprazolam [Xanax], midazolam [Versed], triazolam [Halcion]), **selected calcium channel blockers** (e.g., felodipine [Plendil]), **vinca alkaloids** (e.g., vinblastine, vincristine), and CYP2C9 substrates such as **sulfonylureas** (e.g., glipizide [Glucotrol XL], glyburide [DiaBeta], tolbutamide) and **NSAIDs** (e.g., ibuprofen [Motrin], diclofenac [Voltaren]). To reduce the potential for toxic effects that may be caused by these drugs (e.g., rhabdomyolysis, prolonged sedative effect, cardiac toxicity, GI toxicity, neurotoxicity, hypoglycemia), close monitoring for toxic effects of all of these drugs is indicated, and in most cases dose reduction is indicated during concomitant administration of voriconazole. ■ Concurrent use with **phenytoin** (Dilantin) may require dose adjustments of both drugs. Phenytoin increases metabolism and decreases serum concentrations of voriconazole. An increased dose of voriconazole is indicated; see [Dose Adjustments](#). Voriconazole decreases the metabolism of phenytoin and increases serum concentrations. Monitor phenytoin serum concentrations and reduce dose as necessary to avoid toxicity. ■ May decrease the metabolism and increase serum levels of **selected HIV protease inhibitors** (e.g., amprenavir [Agenerase], nelfinavir [Viracept], saquinavir [Invirase]). Selected HIV protease inhibitors (e.g., amprenavir, saquinavir) may decrease the metabolism of voriconazole and increase its serum levels. Monitor frequently for drug toxicity with coadministration of voriconazole and HIV protease inhibitors. No dose adjustment is required with indinavir (Crixivan). ■ May decrease the metabolism and increase serum levels of **omeprazole** (Prilosec). If concurrent administration with voriconazole is indicated, reduce a dose of omeprazole of 40 mg or more by one half. The metabolism of other selected proton pump inhibitors may react similarly. ■ **Non-nucleoside reverse transcriptase inhibitors** (NNRTIs) such as delavirdine (Rescriptor) may decrease the metabolism of voriconazole and increase its serum concentrations. Voriconazole may inhibit the metabolism of the same NNRTIs and increase their serum levels. Monitor frequently for drug toxicity with coadministration of voriconazole and NNRTIs. ■ Concurrent use with **other nephrotoxic drugs** (e.g., aminoglycosides, cyclosporine) may result in decreased renal function or acute renal failure. ■ Concurrent use with **oral contraceptives** may increase concentrations of both drugs. Monitor for adverse events related to each drug. Should not reduce the effectiveness of oral contraception. ■ May have minor interactions with **cimetidine** (Tagamet), **macrolide antibiotics** (e.g., azithromycin, erythromycin), and **ranitidine** (Zantac); however, no dose adjustments are required. ■ No significant interactions have been observed with indinavir (Crixivan), prednisolone, digoxin (Lanoxin), and mycophenolate (CellCept).

SIDE EFFECTS

Abdominal pain, chills, diarrhea, dyspnea, fever, hallucinations, headache, hypokalemia, increases in liver function tests, nausea, peripheral edema, rash, respiratory disorders, sepsis, tachycardia, visual disturbances, and vomiting occur most frequently. Side effects that most often led to discontinuation of therapy include elevated liver function tests, rash, and visual disturbances. Blurred vision, color vision change, and/or photophobia are common but may be associated with higher serum concentrations and/or doses. Hypersensitivity reactions, including anaphylaxis, have been reported. Rarely, Stevens-Johnson syndrome and photosensitivity skin reactions have been reported. In patients with photosensitivity reactions, squamous cell cancer and melanoma have been reported. Numerous other side effects may occur, including QT prolongation and, rarely, torsades de pointes.

Post-Marketing: Pancreatitis in pediatric patients, prolonged visual adverse events, including optic neuritis and papilledema.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. If a hypersensitivity reaction (e.g., an infusion reaction) occurs, discontinue the infusion and treat with oxygen, epinephrine, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., dexamethasone [Decadron]), or bronchodilators (e.g., albuterol [Ventolin]) as indicated. Consider discontinuation of voriconazole if liver function tests are elevated and/or clinical S/S of liver disease attributable to voriconazole develop, if visual disturbances occur, if an increase in serum creatinine occurs, or if a rash develops (may be the first sign of an exfoliative skin disorder). No known specific antidote. Hemodialysis may assist in the removal of some voriconazole in accidental overdose and in the removal of SBECD. Resuscitate as indicated.

WARFARIN SODIUM **BBW**

(WAR-far-in SO-dee-um)

Anticoagulant

Coumadin

pH 8.1 to 8.3

USUAL DOSE

Used primarily for patients on Coumadin when oral dosing is not feasible. IV and oral doses are the same, and administration of the IV formulation should not provide any increased effect or an earlier onset of action. Dose must be individualized and adjusted based on PT/International Normalized Ratio (INR). An INR of greater than 4 appears to provide no additional benefit in most patients and is associated with a higher risk of bleeding. Loading doses may increase the incidence of complications and do not offer greater prompt anticoagulation protection. Heparin is preferred in situations requiring prompt anticoagulation because the anticoagulant actions for warfarin are not effective for at least 60 hours after initial dosing begins (60 hours is the half-life of the last clotting factor [II] to be affected by warfarin). Conversion to warfarin therapy may begin concomitantly with heparin therapy or may be delayed 3 to 6 days. To ensure continuous anticoagulation, overlap therapy until warfarin has produced a therapeutic response as determined by PT/INR. Discontinue heparin when therapeutic response is achieved. Duration of treatment is individualized. In general, it should continue until the danger of thrombosis and embolism has passed. See prescribing information for suggested durations of therapy for different indications and/or risk factors. Aspirin may or may not be a component of therapy depending on indication and risk factors. Not all factors causing warfarin dose variability are known. The maintenance dose needed to achieve a target PT/INR is influenced by clinical factors that include age, race, body weight, gender, concomitant medications, co-morbidities, and genetic factors (CYP2C9 and VKORC1 genotypes). See prescribing information and [Dose Adjustments](#) for dosing related to specific genotypes.

Initial dose: Select the starting dose based on the expected maintenance dose, taking into account the above factors. If the patient's CYP2C9 and VKORC1 genotypes are not known, the initial dose is usually 2 to 5 mg/day. Adjust dose based on patient-specific clinical factors and PT/INR determination. The American College of Chest Physicians (ACCP) suggests 5 to 10 mg/day for the first 1 to 2 days, then adjust dose based on PT/INR determination.

Maintenance dose: 2 to 10 mg/day. Adjust dose to maintain desired INR.

Atrial fibrillation, prophylaxis and treatment of venous thromboembolism, prophylaxis and treatment of pulmonary embolism: Adjust dose to maintain an INR of 2 to 3 (target INR 2.5).

Postmyocardial infarction: Current ACCP guidelines recommend that moderate-risk and low-risk patients be treated with aspirin alone instead of warfarin plus aspirin. High-risk

patients with MI should be treated with low-dose aspirin (100 mg or less/day) and warfarin for 3 months after the MI. Adjust dose to maintain an INR of 2 to 3 (target INR 2.5). **Mechanical heart valves:** Adjust dose to maintain an INR of 2.5 to 3.5 (target INR 3). Maintained long term. Use in combination with aspirin 75 to 100 mg/day may be indicated.

Bioprosthetic heart valves: Adjust dose to maintain an INR of 2 to 3.5 (target INR 3) for 12 weeks after valve insertion. Use in combination with aspirin 75 to 100 mg/day may be indicated. Longer-term therapy may be required in patients with additional risk factors (e.g., atrial fibrillation, prior thromboembolism).

PEDIATRIC DOSE

Safety for use in pediatric patients under 18 years of age not established, but is used. Usually given PO. See *Maternal/Child*.

DOSE ADJUSTMENTS

Use low initial doses in the elderly, debilitated, and those with expected increased PT/INR responses. ■ Patients with genetic factors (CYP2C9 and VKORC1 genotypes) may require a reduced dose because these alleles may be associated with reduced clearance of warfarin. ■ Use lower end of dose range in patients at increased risk of bleeding or those on aspirin therapy. ■ Reduced dose is required in impaired hepatic function. ■ No dose adjustment is required in impaired renal function. ■ Higher doses may be required in selected situations (e.g., patients with recurrent systemic embolism or mechanical prosthetic valves). The ACCP and National Heart, Lung, and Blood Institute (NHLBI) suggest that maintaining an INR of 3 to 4.5 may be indicated.

DILUTION

Reconstitute the 5-mg vial with 2.7 mL of SWFI (2 mg/mL).

Storage: Protect from light by storing in carton at CRT. Store reconstituted solution at room temperature and use within 4 hours. Do not refrigerate; discard any unused solution.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Some adsorption may occur in PVC containers and tubing when diluted in D5W or NS.

One source suggests the following **compatibilities:**

Y-site: Amikacin (Amikin), ammonium chloride, ascorbic acid, bivalirudin (Angiomax), cefazolin (Ancef), ceftriaxone (Rocephin), dopamine, epinephrine (Adrenalin), heparin, lidocaine, morphine, nitroglycerin IV, oxytocin (Pitocin), potassium chloride (KCl), ranitidine (Zantac), vancomycin.

RATE OF ADMINISTRATION

A single dose as an injection over 1 to 2 minutes.

ACTIONS

An anticoagulant that acts by inhibiting vitamin K–dependent coagulation factors (e.g., factor II, VII, IX, and X) and the anticoagulant proteins C and S in the liver, resulting in a depression of their activities. An anticoagulant effect occurs within 24 hours; however, peak anticoagulant effect may be delayed for 72 to 96 hours. Approximately 99% bound to plasma proteins. Effective half-life ranges from 20 to 60 hours. Effects may be more pronounced as daily maintenance doses overlap. Well-established clots are not dissolved, but growth is prevented. Metabolized by hepatic microsomal enzymes (cytochrome P₄₅₀ system) to inactive metabolites and reduced metabolites. Excreted primarily in urine with small amounts excreted in bile. Crosses the placental barrier.

INDICATIONS AND USES

Prophylaxis and/or treatment of venous thrombosis and pulmonary embolism. ■ Prophylaxis and/or treatment of the thromboembolic complications of atrial fibrillation and/or cardiac valve replacement. ■ Reduce the risk of death, recurrent myocardial infarction, and thromboembolic events such as stroke or systemic embolization after myocardial infarction. ■ Treatment of patients receiving oral warfarin who are unable to take oral medication.

CONTRAINDICATIONS

Localized or general physical condition or circumstance in which the hazard of hemorrhage might be greater than the potential clinical benefits of anticoagulation (e.g., bleeding tendencies associated with active ulceration or overt bleeding of GI, GU, or respiratory tracts, CVA, aneurysms [cerebral or aortic], pericarditis, pericardial effusions, bacterial endocarditis; hemorrhagic tendencies or blood dyscrasias, inadequate laboratory facilities; major regional or lumbar block anesthesia; malignant hypertension; pregnancy; spinal puncture or other procedures with potential for uncontrollable bleeding; threatened abortion, eclampsia, preeclampsia; unsupervised patients who would find it difficult to cooperate [e.g., senility, alcoholism, or psychosis]; and recent or contemplated surgery of the CNS, eye, or traumatic surgery resulting in large open surfaces).

PRECAUTIONS

For IV use only; do not administer IM. ■ Hemorrhage in any tissue or organ is one of the most serious risks associated with warfarin therapy. Fatalities have occurred. Bleeding is more likely to occur during initiation of therapy and with higher doses (resulting in a higher INR). Risk factors for hemorrhage include an INR greater than 4 or highly variable INRs, elderly patients age 65 or older, history of GI bleed, hypertension, cerebrovascular disease, serious heart disease, anemia, malignancy, trauma, renal insufficiency, concomitant drugs that affect hemostasis, and a long duration of therapy. Necrosis and/or gangrene is another serious risk associated with warfarin therapy. Necrosis appears to be associated with local thrombosis. In severe cases, débridement or amputation may be required. ■ Limit IM injections of concomitant medications to upper extremities to permit easy access for manual compression, inspection for bleeding, and use of pressure bandages. ■ Anticoagulation with warfarin may enhance the release of atheromatous plaque emboli, increasing the risk of complications from systemic cholesterol microembolization. May present with a variety of S/S, including abdominal, back, or flank pain; abrupt and intense pain in the leg, foot, or toes; cerebral ischemia; foot ulcers; gangrene; hematuria; hypertension; livedo reticularis (reddish blue mottling of skin on exposure to cold); myalgias; pancreatitis, purple toe syndrome; rash; and renal insufficiency. The kidney is the most commonly involved visceral organ, followed by the pancreas, spleen, and liver. Some cases have progressed to necrosis and death. ■ Use with caution in patients with heparin-induced thrombocytopenia and deep vein thrombosis. Cases of venous limb ischemia, necrosis, and gangrene have occurred when heparin was discontinued and warfarin was started. ■ Determinations of whole blood clotting and bleeding times are not an accurate measurement to adjust dose. ■ Warfarin may increase the aPTT, even in the absence of heparin. A severe aPTT elevation (greater than 50 seconds) with a PT/INR in the normal range is an indicator of increased risk of postoperative hemorrhage. ■ Use caution in the elderly or debilitated, severe to moderate impaired hepatic or renal function, severe to moderate hypertension, severe diabetes, with indwelling catheters, infectious diseases or disturbances of intestinal flora (e.g., sprue, antibiotic therapy), surgery or trauma involving large raw surfaces or that may result in internal bleeding, patients with a history of allergic problems, polycythemia vera, vasculitis, and known or suspected deficiency in protein C anticoagulant response. ■ Increased PT/INR response may occur in patients with blood dyscrasias (see [Contraindications](#)), cancer, collagen vascular disease, congestive heart failure, diarrhea, elevated temperature, hyperthyroidism, infectious hepatitis, jaundice, poor nutritional state, steatorrhea, or vitamin K deficiency. ■ Decreased PT/INR response may occur in patients with edema, hereditary coumarin resistance, hyperlipidemia, hypothyroidism, or nephrotic syndrome. Patients who are protein C or S deficient (inherited thrombotic conditions) must be covered with heparin and warfarin. ■ If dental procedures or surgery or other minor surgical procedures are necessary, the PT/INR should be adjusted to the lower end of the therapeutic range. Monitor PT/INR just before treatment. Operative site should be limited so local procedures for hemostasis can be used. Warfarin therapy may have to be interrupted; consider risks versus benefits.

Monitor: PT/INR must be done before initial injection. Frequent monitoring of PT/INR required (very accurate bedside monitoring units are now available). Usually repeated daily during initiation of therapy, every 1 to 4 weeks after PT/INR has stabilized in the therapeutic range. Monitor with any change in patient regimen that may affect treatment (e.g., diet, illness, change in drug regimen). Draw blood for prothrombin just before a heparin dose being given concomitantly. If heparin is given as a continuous infusion, PT/INR may be drawn at any time; see **Precautions**. ■ Because heparin may affect the PT/INR in patients receiving both heparin and warfarin, PT/INR determinations should be drawn 5 hours after the last IV bolus dose of heparin, 4 hours after a heparin infusion has been discontinued, or 24 hours after the last SC injection of heparin. ■ Patients at high risk for bleeding may benefit from more frequent monitoring of INR, careful dose adjustments to desired INR, and a shorter duration of therapy. ■ Monitor for S/S of hemorrhage, necrosis, cholesterol microembolization, and the possible sequelae; see **Precautions**. ■ Has a narrow therapeutic range that can be affected by other drugs and dietary vitamin K. See **Drug/Lab Interactions**.

Patient Education: Nonhormonal birth control recommended. ■ Adhere to dose schedule; do not take or discontinue any prescription or over-the-counter medication, including herbal products, without physician's approval. ■ Confirm procedure for missed dose. ■ Avoid alcohol. Eat a normal balanced diet, maintaining a consistent vitamin K intake. Avoid cranberry products. ■ Avoid any activity or sport that may result in traumatic injury. ■ Regular PT/INR testing and physician visits are imperative. ■ Notify physician of unusual bleeding (e.g., increased menstrual flow, nosebleeds, tarry stools), any illness (e.g., diarrhea, infection, fever), headache, dizziness, or weakness. ■ Carry an ID stating that warfarin is being taken.

Maternal/Child: Category X: avoid pregnancy. May cause fatal hemorrhage, has caused birth deformities, and may cause abortion and/or stillbirth. Low birth weight and growth retardation have also been reported. ■ In mothers requiring warfarin, consider alternative methods of infant feeding, or use extreme caution if decision is made to breast-feed. Prolonged PTs have been reported in breast-fed infants. Careful monitoring of coagulation tests and vitamin K status in the breast-fed infant and the mother's PT/INR is required. ■ Safety and effectiveness for use in pediatric patients not established; however, use is well documented for prevention and treatment of thromboembolic events. Difficulty in achieving and maintaining a therapeutic PT/INR in pediatric patients has been reported. More frequent PT/INR determinations are recommended.

Elderly: Less warfarin is required to produce a therapeutic level of anticoagulation in patients over 60 years of age; may have a greater-than-expected PT/INR response; see **Dose Adjustments** and **Precautions**. ■ Not recommended for use in an unsupervised patient with senility.

DRUG/LAB INTERACTIONS

Monitor PT/INR carefully when drugs are added or discontinued. **Interactions are numerous and potentially life threatening. Review of drug profile by pharmacist is imperative.** ■ Listed are some of the most significant. ■ Not recommended for concurrent use with **streptokinase or urokinase**; may be hazardous. ■ **Increased PT/INR response** (risk of bleeding increased) may occur with numerous drugs, including **amiodarone** (Nexterone), **anticoagulants** (e.g., argatroban, bivalirudin [Angiomax]), **antifungal agents** (e.g., fluconazole [Diflucan], itraconazole [Sporanox], miconazole [Monistat (intravaginal or systemic)]), **aspirin**, **atenolol** (Tenormin), **capecitabine** (Xeloda), **cephalosporins** (e.g., cefazolin [Ancef], cefotetan, cefoxitin [Mefoxin], ceftriaxone [Rocephin]), **cimetidine** (Tagamet), **cisapride** (Propulsid), **clofibrate** (Atromid-S), **cyclophosphamide** (Cytoxan), **ezetimibe** (Zetia), **fenofibrate** (Tricor), **fluoroquinolones** (e.g., ciprofloxacin [Cipro IV], levofloxacin [Levaquin], moxifloxacin [Avelox], norfloxacin [Noroxin]), **fluvastatin** (Lescol), **gefitinib** (Iressa), **heparin**, **herbal medicines** (e.g., bromelains, cranberry products, danshen, dong quai, garlic, ginkgo biloba, and ginseng), **HMG-CoA reductase inhibitors** (e.g., atorvastatin [Lipitor], fluvastatin [Lescol], pravastatin [Pravachol], simvastatin [Zocor]), **isoniazid** (INH), **levothyroxine** (Synthroid), **macrolide antibiotics** (e.g., azithromycin [Zithromax], clarithromycin [Biaxin], erythromycin), **metronidazole** (Flagyl), **NSAIDs** (e.g., celecoxib

[Celebrex], ibuprofen [Advil, Motrin], ketorolac [Toradol], naproxen [Aleve, Naprosyn], rofecoxib [Vioxx]), **oxandrolone** (Oxandrin), **propafenone** (Rhythmol), **propranolol**, **proton pump inhibitors** (e.g., esomeprazole [Nexium], omeprazole [Prilosec], pantoprazole [Protonix], rabeprazole [Aciphex]), **sertraline** (Zoloft), **sulfipyrazone** (Anturane), **sulfonamides** (e.g., sulfamethoxazole/trimethoprim [Bactrim]), **tamoxifen** (Nolvadex), **ticlopidine** (Ticlid), **tolterodine** (Detrol), **tramadol** (Ultram), **zafirlukast** (Accolate). ■ Concomitant treatment with **thrombolytics** (e.g., alteplase [Activase, tPA], reteplase [Retavase, rPA], streptokinase [Streptase]) may increase the risk of bleeding. ■ Concomitant treatment with **drugs that affect platelet function**, such as dipyridamole (Persantine), glycoprotein GPIIb/IIIa receptor antagonists (e.g., abciximab [ReoPro], eptifibatid [Integrilin], tirofiban [Aggrastat]), and NSAIDs (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]), may also increase the risk of bleeding. ■ **Decreased PT/INR response** (anticoagulant effects decreased and risk of blood clots increased) may occur with numerous drugs, including **ascorbic acid** (high-dose vitamin C), **barbiturates** (e.g., phenobarbital), **carbamazepine** (Tegretol), **cholestyramine** (Questran), **griseofulvin** (Fulvicin), **nevirapine** (Viramune), **penicillins** (e.g., nafcillin [Nallpen]), **protease inhibitors** (e.g., ritonavir [Norvir]), **rifampin** (Rifadin), **spironolactone** (Aldactone), **sucralfate** (Carafate), **trazodone** (Desyrel), and increased oral **vitamin K** intake (e.g., leafy greens, supplements). ■ **Atorvastatin** (Lipitor) and **pravastatin** (Pravachol) may increase or decrease PT/INR. ■ May inhibit metabolism and increase effects of **oral antidiabetic agents** (e.g., tolbutamide), and **phenytoin** (Dilantin); may cause toxicity. ■ **Herbal medicines** should be used with caution. May have anticoagulant, coagulant, or fibrinolytic properties; see literature for specific examples.

SIDE EFFECTS

Bleeding when the PT/INR is within the therapeutic range (may unmask an unsuspected lesion [e.g., tumor, ulcer]), hemorrhage in any tissue or organ, necrosis and/or gangrene of skin and other tissues. Complications from systemic cholesterol microembolization (e.g., “purple toes syndrome”) from release of atheromatous plaque emboli. Less frequently reported side effects include anemia, angina, chest pain, coma, hypotension, loss of consciousness, pallor, and syncope. Hypersensitivity reactions, including anaphylaxis, do occur. Protein C deficiency may occur if not covered by heparin long enough.

ANTIDOTE

Keep physician informed of all side effects; some may be life threatening. Discontinue if warfarin is suspected to be the cause of developing necrosis (e.g., “purple toes syndrome”); consider heparin therapy if anticoagulation required. Phytonadione (vitamin K₁) is a specific antagonist and is indicated in overdose or desired warfarin reversal (e.g., severe bleeding). May be given via the parenteral or oral route; the usual dose is 5 to 25 mg (rarely up to 50 mg). In one small study, IV phytonadione (vitamin K₁) decreased the INR more rapidly in 24 hours than SC phytonadione; however, within 72 hours, results were similar. See phytonadione monograph for precautions surrounding IV administration. The use of phytonadione will impede subsequent anticoagulant therapy, and patients are at risk of returning to a pretreatment thrombotic status following rapid reversal of a prolonged PT/INR. Fresh whole blood, fresh frozen plasma, factor IX complex (not purified factor IX preparations, they increase PT levels) may be indicated.

ZIDOVUDINE **BBW**

(zye-DOH-vyou-deen)

Antiviral

Azidothymidine, AZT, Retrovir

pH 5.5

USUAL DOSE

Treatment of HIV infection (symptomatic or asymptomatic): 1 mg/kg every 4 hours (5 or 6 times daily) is the most frequent dose used in the United States. Dose recommendation in Canada is 1 to 2 mg/kg every 4 hours. Initiate oral therapy as soon as possible (100 mg PO approximately equal to 1 mg/kg IV). Impaired renal or hepatic function may increase toxicity. Usually part of a multi-drug regimen; see [Drug/Lab Interactions](#).

Prevention of maternal-fetal HIV transmission: 2 mg/kg of total body weight over 1 hour when labor begins. Follow with an infusion of 1 mg/kg/hr (of total body weight) until umbilical cord is clamped.

PEDIATRIC DOSESee [Maternal/Child](#).

Treatment of HIV infections in pediatric patients 6 weeks to 12 years of age (unlabeled): 120 mg/M²/dose every 6 hours as an intermittent infusion or a continuous infusion of 20 mg/M²/hr. See [Dose Adjustments](#). Follow with oral therapy; see comments in [Usual Dose](#).

Treatment of HIV infections in pediatric patients over 12 years of age (unlabeled): 1 mg/kg/dose every 4 hours. See [Dose Adjustments](#). Follow with oral therapy; see comments in [Usual Dose](#).

NEONATAL DOSESee [Maternal/Child](#).

Prevention of maternal-fetal HIV transmission: Start neonatal dosing within 12 hours after birth and continue through 6 weeks of age. Oral dosing preferred but may be given IV. Consider impaired hepatic or renal function; see [Precautions](#).

Recommended Neonatal Doses of Zidovudine

Route	Total Daily Dose	Dose and Frequency
Oral	8 mg/kg/day	2 mg/kg every 6 hours
IV	6 mg/kg/day	1.5 mg/kg infused over 30 minutes every 6 hours

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy. ■ Reduce dose to 1 mg/kg every 6 to 8 hours in patients with ESRD who are being maintained on hemodialysis or peritoneal dialysis. ■ Dose reduction may be required in patients with hepatic impairment. Monitor for toxicity. ■ Reduce the 120 mg/M² dose to 90 mg/M² in pediatric patients with granulocytopenia. ■ May be required in anemia and/or with other drugs. See [Monitor](#), [Drug/Lab Interactions](#), and [Antidote](#).

DILUTION

Withdraw the calculated dose and add to a sufficient volume of D5W to achieve a final concentration no greater than 4 mg/mL.

Filters: Not required by manufacturer; no further data available from manufacturer.

Storage: Store undiluted vials at 15° to 25° C (59° to 77° F). Protect from light. Chemically and physically stable after dilution for 24 hours at RT or 48 hours refrigerated at 2° to 8° C (36° to 46° F). However, as an added precaution against microbial contamination,

manufacturer recommends use within 8 hours if stored at 25° C (77° F) and 24 hours if refrigerated.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Admixture in biologic or colloidal fluids (e.g., blood products, protein solutions) is not recommended."

One source suggests the following **compatibilities**:

Additive: Dobutamine, meropenem (Merrem IV), ranitidine (Zantac).

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), amphotericin B (conventional), amphotericin B cholesteryl (Amphotec), andulafungin (Eraxis), aztreonam (Azactam), ceftazidime (Fortaz), ceftriaxone (Rocephin), cisatracurium (Nimbex), clindamycin (Cleocin), dexamethasone (Decadron), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), erythromycin (Erythrocin), etoposide phosphate (Etopophos), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, imipenem-cilastatin (Primaxin), linezolid (Zyvox), lorazepam (Ativan), melphalan (Alkeran), meropenem (Merrem IV), metoclopramide (Reglan), morphine, nafcillin (Nallpen), ondansetron (Zofran), oxacillin (Bactocill), oxytocin (Pitocin), paclitaxel (Taxol), pemetrexed (Alimta), pentamidine, phenylephrine (Neo-Synephrine), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), ranitidine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), sulfamethoxazole/trimethoprim, teniposide (Vumon), tiopeta, tobramycin, vancomycin, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Intermittent infusion: Each single dose properly diluted must be delivered at a constant rate over 1 hour. Avoid rapid infusion or IV bolus.

Continuous infusion: Prevention of maternal-fetal HIV transmission: 2 mg/kg equally distributed over 1 hour, followed by 1 mg/kg/hr until umbilical cord clamped.

Pediatric continuous infusion: 20 mg/M²/hr.

Neonatal in prevention of maternal-fetal HIV transmission: A single dose infused over 30 minutes.

ACTIONS

A pyrimidine nucleoside analog active against HIV. Through a specific process this thymidine analog inhibits the viral replication and terminates the DNA chain of some retroviruses, including HIV. Metabolized by glucuronidation in the liver and excreted through the kidneys. Half-life is approximately 1 hour. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of HIV infection in combination with other anti-retroviral agents. ■ Prevention of maternal-fetal HIV transmission. Protocol includes oral zidovudine beginning between week 14 and week 34 of gestation, continuing until labor begins, IV dosing during labor, and zidovudine syrup or IV dosing to the newborn.

CONTRAINDICATIONS

Life-threatening hypersensitivity reactions to any of the components.

PRECAUTIONS

Do not give IM. ■ Antiretroviral products have been shown to reduce the risk of transmission to others when HIV-infected patients or their uninfected partners take antiretroviral medication. ■ Incidence of adverse reactions appears to increase with disease progression. ■ Has been associated with hematologic toxicity, including neutropenia and severe anemia, particularly in patients with advanced HIV. ■ Use with extreme caution in patients with bone marrow compromise as indicated by a granulocyte count of less than 1,000/mm³ or hemoglobin below 9.5/dL. ■ Prolonged use of zidovudine has been associated with myopathy and myositis with pathologic changes similar to those produced by HIV disease. ■ Rare cases of lactic

acidosis (without hypoxemia) and severe hepatomegaly with steatosis have been reported with the use of some antiretroviral nucleoside analogs, including zidovudine when used alone or in combination. Deaths have occurred. Female gender, obesity, and prolonged exposure to antiretroviral nucleoside analogs may increase risk of lactic acidosis. Lactic acidosis should be considered, and therapy suspended, in patients who develop unexplained tachypnea, dyspnea, or a fall in serum sodium bicarbonate. ■ Use with caution in any patient (especially obese women) with hepatomegaly, hepatitis, or other risk factors for liver disease. Suspend therapy with rapidly elevating aminotransferase levels (ALT), progressive hepatomegaly, or metabolic/lactic acidosis of unknown etiology. ■ Use with caution in patients with severe hepatic impairment; may be at increased risk for hematologic toxicity. ■ Hepatic decompensation has occurred in HIV/HCV co-infected patients receiving combination antiretroviral therapy for HIV and interferon alfa with or without ribavirin (Rebetol) for HCV. ■ Use with caution in patients with severely impaired renal function (CrCl less than 15 mL/min); see [Dose Adjustments](#). ■ Immune reconstitution syndrome has been reported in patients treated with combination antiretroviral therapy, including zidovudine. Patients may develop an inflammatory response to indolent opportunistic infections (e.g., *Mycobacterium avium*, CMV, PCP, or tuberculosis). May require further evaluation and treatment. ■ Autoimmune disorders (e.g., Graves' disease, polymyositis, and Guillain-Barré syndrome) have been reported in the setting of immune reconstitution; may occur months after initiation of therapy. ■ See [Drug/Lab Interactions](#).

Monitor: Observe closely; not a cure for HIV infections. Patients may acquire illnesses associated with AIDS or ARC, including opportunistic infections. ■ Frequent blood cell counts are required. Hematologic toxicity, including neutropenia, severe anemia, and occasionally reversible pancytopenia are common. Anemia may occur as early as 2 to 4 weeks. Neutropenia usually occurs after 6 to 8 weeks of therapy; dosage adjustments and/or transfusions may be required. ■ Monitor liver function. ■ Closely monitor patients receiving zidovudine and interferon alfa, with or without ribavirin (Rebetol), for treatment-associated toxicities, especially hepatic decompensation, neutropenia, and anemia. Dose reduction or discontinuation of interferon, ribavirin, or both may be required if worsening clinical toxicities are seen (e.g., hepatic decompensation [e.g., Child-Pugh score greater than 6]). ■ Monitoring of zidovudine serum concentrations has been used to individualize therapy. May increase effectiveness while decreasing toxicity. ■ Monitor CD4 lymphocyte count at diagnosis and every 3 to 6 months. ■ Drug resistance testing and monitoring of (HIV) RNA, an indicator of viral load, are recommended to help guide treatment. ■ See [Drug/Lab Interactions](#).

Patient Education: Zidovudine is not a cure. Remain under the care of a physician when using zidovudine and avoid actions that can spread HIV-1 infection to others. ■ Report abdominal pain, jaundice, muscle weakness, shortness of breath, or rapid breathing promptly. ■ Major side effects are neutropenia and/or anemia. ■ Requires frequent lab work and close follow-up with physician; keep all appointments. ■ Check with physician before taking any other meds.

Maternal/Child: Category C: safety for use during pregnancy has been evaluated. Risk versus benefit appears justified only in HIV-infected mothers. Congenital deformities not increased in studies; however, long-term consequences of in utero and neonatal exposure to zidovudine are unknown. ■ Discontinue breast-feeding to reduce incidence of HIV transmission and potential for serious adverse reactions in nursing infants. ■ Has been studied in HIV-infected pediatric patients over 3 months of age who have HIV-related symptoms or are asymptomatic with abnormal lab values, indicating significant HIV-related immunosuppression. Has also been studied in neonates perinatally exposed to HIV. To monitor maternal-fetal outcomes, an Antiretroviral Pregnancy Registry has been established. See prescribing information.

Elderly: Dose selection should be cautious; see [Dose Adjustments](#). Consider impaired hepatic and renal function.

DRUG/LAB INTERACTIONS

Toxicity may be increased by **nephrotoxic and/or cytotoxic drugs and/or drugs that interfere with RBC or WBC number and function** (e.g., amphotericin B [conventional], dapsone, doxorubicin [Adriamycin], flucytosine, interferons, pentamidine, vinblastine, vincristine). ■ **Do not use in combination with other products that contain zidovudine (e.g., lamivudine/zidovudine [Combivir], abacavir/lamivudine/zidovudine [Trizivir]).** ■ **Probenicid** may inhibit glucuronidation or reduce renal excretion of zidovudine, increasing zidovudine toxicity. ■ Use with **protease inhibitors** (e.g., nelfinavir [Viracept], zidovudine [Norvir]) may decrease serum concentrations of zidovudine; monitoring indicated; dose adjustment of zidovudine is not indicated. ■ Use with **atovaquone** (Mepron), **fluconazole** (Diflucan), **methadone** (Dolophine), or **valproic acid** (Depacon, Depakene) may increase zidovudine serum concentrations; monitoring indicated; dose adjustment of zidovudine is not indicated. ■ **Rifamycins** (e.g., rifampin [Rifadin], rifabutin [Mycobutin]) may increase clearance, reduce zidovudine serum levels, and reduce effectiveness. ■ Antagonized by **doxorubicin** (Adriamycin), **stavudine** (Zerit), and **ribavirin** (Rebetol). Avoid concurrent use. ■ Hematologic toxicity increased with **ganciclovir** (Cytovene), **interferons, or other bone marrow suppressants or cytotoxic agents.** ■ **Phenytoin** levels may increase or decrease; monitor carefully to ensure proper dosing. ■ **Phenytoin** may also increase zidovudine levels by decreasing clearance. ■ Use with **acyclovir** may cause neurotoxicity (drowsiness, lethargy). ■ Combination therapy with zidovudine and **interferon alfa**, with or without **ribavirin** (Rebetol), may increase risk of hepatic decompensation.

SIDE EFFECTS

Frequency and severity of adverse events are greater in patients with more advanced infection at the time of initiation of treatment. Directly related to pretreatment bone marrow reserve, dose and duration and inversely related to T4 lymphocyte numbers. Abdominal pain, anaphylaxis, anemia (severe), anorexia, arthralgia, asthenia, chills, constipation, diaphoresis, diarrhea, dizziness, dyspepsia, dysphagia, dyspnea, fatigue, fever, flatulence, GI pain, granulocytopenia, gynecomastia, headache, hepatomegaly (severe), hyperbilirubinemia, increased liver function tests (e.g., ALT, AST, alkaline phosphatase), injection site reaction (e.g., pain, redness), insomnia, malaise, mouth ulcers, myalgia, myopathy and myositis, nausea, neuropathy, neutropenia, pancytopenia (reversible), paresthesia, pure red cell aplasia, rash, somnolence, taste perversion, thrombocytopenia, vomiting. Suspect lactic acidosis if dyspnea, a fall in serum bicarbonate level, or tachypnea occurs.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Moderate anemia or granulocytopenia may respond to a reduction in dose. Interrupt zidovudine therapy for severe anemia (less than 7.5 Gm/dL or a 25% reduction from baseline) or severe granulocytopenia (less than 750/mm³ or 50% reduction from baseline). Transfusions may be required. If marrow recovery occurs following dose interruption, resumption of therapy may be appropriate using adjunctive measures such as epoetin alfa (Epo-gen). Rash may be the first sign of anaphylaxis; notify physician and treat with diphenhydramine (Benadryl), epinephrine (Adrenalin), and corticosteroids as indicated. Antimicrobial therapy may be indicated to treat opportunistic infections. Not removed by hemodialysis or peritoneal dialysis.

ZIV-AFLIBERCEPT **BBW**

(ZIV-a-FLIB-er-sept)

Recombinant monoclonal antibody
 Angiogenesis inhibitor
 Antineoplastic

Zaltrap

pH 6.2

USUAL DOSE

4 mg/kg as an infusion over 1 hour every 2 weeks. Administer before any component of the FOLFIRI regimen (5-fluorouracil, leucovorin, and irinotecan) on the day of treatment. Continue until disease progression or unacceptable toxicity. See Monographs for 5-fluorouracil, leucovorin, and irinotecan to incorporate all requirements into this regimen.

DOSE ADJUSTMENTS

Ziv-Aflibercept Dose Adjustments*	
Indication	Recommended Dose or Action
Neutrophil count less than 1,500/mm ³ (1.5 × 10 ⁹ /L)	Withhold or delay dosing until neutrophil count is at or above 1.5 × 10 ⁹ /L (1,500/mm ³).
Elective surgery	Withhold for at least 4 weeks before elective surgery.
Recurrent or severe hypertension	Withhold until hypertension is controlled, then resume at a permanently reduced dose of 2 mg/kg.
Proteinuria at or above 2 Gm/24 hr	Withhold ziv-aflibercept. Resume when proteinuria decreases to less than 2 Gm/24 hr.
Recurrent proteinuria	Withhold ziv-aflibercept until proteinuria is less than 2 Gm/24 hr, then resume at a permanently reduced dose of 2 mg/kg.
Severe hemorrhage, GI perforation, compromised wound healing, fistula formation, hypertensive crisis or hypertensive encephalopathy, arterial thromboembolic events, nephrotic syndrome or thrombotic microangiopathy, and/or reversible posterior leukoencephalopathy syndrome (RPLS)	Discontinue ziv-aflibercept.
Age, gender, or race; mild, moderate, or severe renal impairment or mild or moderate hepatic impairment; see Precautions.	No dose adjustment required.

*For toxicities related to irinotecan, 5-FU, or leucovorin, refer to individual monographs.

DILUTION

Available in single-use vials containing 100 mg/4 mL or 200 mg/8 mL (25 mg/mL). A clear, colorless to pale yellow solution. Do not use if the solution is discolored or cloudy or contains particles. Do not re-enter the vial after the initial puncture. Withdraw the prescribed dose from the vial and dilute in NS or D5W to achieve a final concentration of 0.6 to 8 mg/mL. For example, in a 70-kg patient:

$$\text{Weight in kg} \times \text{Dose in mg/kg} = \text{Calculated dose of drug}$$

$$(70 \text{ kg} \times 4 \text{ mg/kg} = 280 \text{ mg})$$

$$\text{Calculated dose in mg} \div \text{Drug concentration (25 mg/mL)} = \text{Volume of drug required}$$

$$(280 \text{ mg} \div 25 \text{ mg/mL} = 11.2 \text{ mL of drug})$$

Dilution in a 50-mL infusion bag plus the 11.2 mL of drug would yield 4.6 mg/mL. Dilution in a 250-mL infusion bag plus the 11.2 mL of drug would yield 1.1 mg/mL. Use PVC infusion bags containing DEHP or polyolefin infusion bags.

Filters: Administer through a 0.2-micron polyethersulfone filter. Do not use filters made of polyvinylidene fluoride (PVDF) or nylon.

Storage: Store vials in refrigerator at 2° to 8° C (36° to 46° F). Keep in original carton to protect from light. Diluted solution may be refrigerated for up to 4 hours. Discard any unused portion left in vial or infusion bag.

COMPATIBILITY

Manufacturer states, “Do not combine ziv-aflibercept with other drugs in the same infusion bag or intravenous line.”

RATE OF ADMINISTRATION

Administer using an infusion set made of PVC containing DEHP, DEHP-free PVC containing trioctyl-trimellitate (TOTM), polypropylene, polyethylene-lined PVC, or polyurethane through a 0.2-micron polyethersulfone filter. Do not use filters made of polyvinylidene fluoride (PVDF) or nylon.

A single dose as an infusion over 1 hour.

ACTIONS

A recombinant fusion protein (monoclonal antibody) consisting of vascular endothelial growth factor (VEGF)-binding portions from the extracellular domains of human VEGF receptors 1 and 2 fused to the Fc portion of the human IgG1. It is a soluble receptor that binds to specific components of human VEGF. Inhibits the binding and activation of the specific receptors, resulting in decreased neovascularization and decreased vascular permeability. In animals ziv-aflibercept was shown to inhibit the proliferation of endothelial cells, thereby inhibiting the growth of new blood vessels. Elimination half-life is approximately 6 days (range 4 to 7 days). Steady-state concentrations reached by the second dose.

INDICATIONS AND USES

Treatment of metastatic colorectal cancer (mCRC) that is resistant to or has progressed following an oxaliplatin-containing regimen. Used in combination with 5-fluorouracil, leucovorin, and irinotecan (FOLFIRI).

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Do not administer as an IV push or bolus. ■ Severe and sometimes fatal hemorrhagic events have been reported. Do not administer to patients with severe hemorrhage. ■ GI perforation, including fatal GI perforation, can occur. ■ Can impair wound healing. Withhold ziv-aflibercept for at least 4 weeks before elective surgery and do not resume for at least 4 weeks after major surgery and until the surgical wound is fully healed. For minor surgery (e.g., CVP access port placement, biopsy, tooth extraction), ziv-aflibercept may be resumed once the surgical wound is fully healed. ■ Incidence of fistula formation is increased. ■ Anal, enterovesical, enterocutaneous, colovaginal, and intestinal site fistulas have been reported. ■ Risk of Grade 3 or 4 hypertension is increased. Grade 3 is defined as requiring an adjustment in existing antihypertensive therapy or treatment with more than one drug. Grade 4 is defined as a hypertensive crisis. ■ Risk of arterial thromboembolic events is increased. ■ Severe proteinuria, nephrotic syndrome, and thrombotic microangiopathy (TMA) have been reported. ■ Risk of neutropenic complications (e.g., febrile neutropenia and neutropenic infection) is increased. ■ Incidence of severe diarrhea and dehydration is increased. ■ Reversible posterior leukoencephalopathy syndrome (RPLS) has been reported. ■ A protein product; has potential for immunogenicity. ■ No data available for patients with severe hepatic impairment. ■ See [Monitor](#) and [Antidote](#).

Monitor: Obtain baseline CBC with differential and repeat every 2 weeks before each dose of ziv-aflibercept. Withhold or delay dosing until neutrophil count is at or above $1.5 \times 10^9/L$ ($1,500/mm^3$). ■ Obtain baseline BP history and monitor BP a minimum of every 2 weeks or more frequently as clinically indicated. ■ Management with antihypertensive

medications is indicated. Closely monitor patients already taking hypertensive medications. ■ Monitor for S/S of bleeding (e.g., GI hemorrhage, hematuria, post-procedural hemorrhage). ■ Monitor for S/S of GI perforation. ■ Monitor for S/S of fistula formation. ■ Monitor for S/S of arterial thromboembolic events (e.g., transient ischemic attack [TIA], cerebrovascular vascular accident [CVA], and angina pectoris). ■ Monitor proteinuria by urine dipstick analysis and urinary protein creatinine ratio (UPCR) for development or worsening of proteinuria. Obtain a 24-hour urine collection in patients with a UPCR greater than 1. ■ Diarrhea may be severe; monitor bowel history and encourage adequate hydration to prevent dehydration. Monitor for neurologic S/S that may be consistent with RPLS (e.g., confusion, headache, seizures, visual changes). Diagnosis confirmed by MRI. ■ See [Dose Adjustments, Precautions, and Antidote](#).

Patient Education: May cause hypertension; monitor BP. ■ Promptly report abdominal pain, bleeding, elevated BP, fever or other signs of infection, light-headedness, neurologic symptoms, severe diarrhea, severe headache, or vomiting. ■ Wound healing is compromised; do not undergo surgery or procedures (including tooth extractions) without the knowledge of a health care provider. ■ Risk of chest pain, TIAs, and CVAs increased. ■ Risk of fetal harm; highly effective contraception required in males and females during and for at least 3 months following the last dose of therapy. If a pregnancy occurs in patient or partner, notify health care provider immediately.

Maternal/Child: Category C. However, ziv-aflibercept was embryotoxic and teratogenic in rabbits at doses lower than required for humans. Use only if potential benefit justifies potential risk to fetus. Highly effective contraception required in both males and females; see Patient Education. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Incidence of asthenia, dehydration, diarrhea, dizziness, and weight loss increased. Monitor closely for dehydration and diarrhea.

DRUG/LAB INTERACTIONS

No drug-drug interaction studies have been conducted. ■ No clinically important pharmacokinetic drug-drug interactions have been found between ziv-aflibercept and **irinotecan/SN-38 or 5-FU**.

SIDE EFFECTS

Abdominal pain, decreased appetite, diarrhea, dysphonia, epistaxis, fatigue, headache, hypertension, increased AST and ALT, increased SCr, leukopenia, neutropenia, proteinuria, stomatitis, thrombocytopenia, and weight loss are most common. Most serious side effects include arterial thrombotic events, compromised wound healing, diarrhea and dehydration, fistula formation, GI perforation, hemorrhage, hypertension, neutropenia and neutropenic complications, proteinuria, and RPLS. Asthenia, dyspnea, hemorrhoids, oropharyngeal pain, palmar-plantar erythrodysesthesia syndrome, proctalgia, rectal hemorrhage, rhinorrhea, skin hyperpigmentation, upper abdominal pain, and urinary tract infections have been reported.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Hypersensitivity or infusion-related side effects may resolve with slowing or interruption of the infusion and with supportive care (IV saline, diphenhydramine, bronchodilators such as albuterol [Ventolin] or aminophylline, and acetaminophen). Discontinue for severe hemorrhage, GI perforation, compromised wound healing, fistula formation, hypertensive crisis or hypertensive encephalopathy, arterial thromboembolic events, nephrotic syndrome or thrombotic microangiopathy, and/or reversible posterior leukoencephalopathy syndrome (RPLS). See [Dose Adjustments](#) for instructions on resuming treatment. Treat anaphylaxis with oxygen, antihistamines (diphenhydramine [Benadryl]), epinephrine (Adrenalin), and corticosteroids. Maintain a patent airway. Resuscitate if indicated.

ZOLEDRONIC ACID

(ZOH-leh-dron-ick AS-id)

Bone resorption inhibitor
Antihypercalcemic
(bisphosphonate)

Reclast ■ Zometa

pH 6 to 7 ■ pH 2

USUAL DOSE

(International Units [IU])

RECLAST AND ZOMETA

Prehydration required. Always used with adequate hydration and appropriate monitoring. See [Dose Adjustments](#), [Precautions](#), and [Monitor](#).

RECLAST

Premedication: Administration of acetaminophen after Reclast administration may reduce the incidence of acute phase reaction symptoms; see [Side Effects](#). In clinical studies, a standard dose of acetaminophen was given with the infusion and for the next 72 hours as needed.

Treatment of Paget's disease: One dose of 5 mg as an infusion over no less than 15 minutes. Supplemental calcium and vitamin D are required, particularly during the 2 weeks following administration.

Calcium: 1,500 mg daily in divided doses (750 mg two times a day or 500 mg three times a day).

Vitamin D: 800 IU/day.

An extended remission period has been observed after a single treatment. Specific retreatment data not available; however, retreatment may be considered for patients who have relapsed based on increases in serum alkaline phosphatase, for patients who did not achieve normalization of their serum alkaline phosphatase, and for patients with symptoms.

Treatment of osteoporosis in men and post-menopausal women and treatment and prevention of glucocorticoid-induced osteoporosis: A single dose of 5 mg given once a year as an infusion over at least 15 minutes. 1,200 mg of calcium and 800 to 1,000 IU of vitamin D daily are recommended. If the calcium and vitamin D are not obtained by dietary means, oral supplementation is indicated.

Prevention of osteoporosis in postmenopausal women: A single dose of 5 mg given every 2 years as an infusion over at least 15 minutes. Postmenopausal women require an average of 1,200 mg of calcium and 800 to 1,000 IU of vitamin D daily.

ZOMETA

Hypercalcemia of malignancy (corrected serum calcium equal to or greater than 12 mg/dL [3 mmol/L]): One dose of 4 mg as an infusion over no less than 15 minutes.

Experience is limited, but retreatment with the same dose may be considered if serum calcium does not return to normal or remain normal after initial treatment. Wait at least 7 days from completion of the first infusion to allow full response.

Multiple myeloma and metastatic bone lesions from solid tumors: 4 mg as an infusion over no less than 15 minutes every 3 to 4 weeks. A CrCl greater than 60 mL is required; see [Dose Adjustments](#). Optimal duration of therapy is unknown. Concurrent daily administration of PO calcium 500 mg and a multivitamin with 400 units vitamin D is recommended.

DOSE ADJUSTMENTS**RECLAST AND ZOMETA**

Dose adjustment is not indicated based on age or race. Studies have not been conducted in patients with hepatic or severe renal impairment; see [Dilution](#), [Precautions](#), and [Elderly](#).

RECLAST

No dose adjustment required in patients with a CrCl greater than 35 mL/min.

ZOMETA

Hypercalcemia of malignancy: Dose adjustments are not necessary in patients with mild to moderate renal impairment before beginning treatment (SCr less than 4.5 mg/dL). If renal function deteriorates, consider if the potential benefit of continued treatment outweighs the possible risk.

Multiple myeloma and metastatic bone lesions from solid tumors: Reduce the initial and following doses in patients with mild to moderate renal impairment based on the following chart:

Zometa Dose Adjustments in Multiple Myeloma and Metastatic Bone Lesions	
Baseline Creatinine Clearance	Zoledronic Acid Recommended Dose
Greater than 60 mL/min	4 mg
50 to 60 mL/min	3.5 mg
40 to 49 mL/min	3.3 mg
30 to 39 mL/min	3 mg

Measure SCr before each Zometa dose and withhold if renal condition deteriorates; see **Monitor**. When the CrCl has returned to within 10% of the baseline value, resume dosing at the same dose administered before treatment interruption.

In patients who experience a decrease in renal function after receiving the initial dose of Zometa, delayed dosing is required before retreatment as follows:

Normal serum creatinine (SCr) before treatment: If SCr has increased 0.5 mg/dL within 2 weeks of planned retreatment, withhold retreatment dose until recovery to within 10% of baseline SCr value.

Abnormal SCr before treatment: If SCr has increased 1 mg/dL within 2 weeks of planned retreatment, withhold retreatment dose until the SCr is within 10% of baseline value.

DILUTION

RECLAST

A 5-mg dose is available prediluted in 100 mL of water for injection for administration as an infusion. If previously refrigerated, allow solution to reach room temperature before administration.

ZOMETA

Available in two formulations: (1) a single-use prediluted solution containing 4 mg in 100-mL solution, and (2) a concentrate containing 4 mg in 5 mL.

Single-use, ready-to-use-bottle: 100 mL of solution equals a 4-mg dose of zoledronic acid and may be administered without further dilution.

Single-Use, Ready-to-Use Bottle Zometa Dilution Recommendations for Reduced Doses in Patients with a CrCl Less Than or Equal to 60 mL/min		
Remove and discard the following Zometa ready-to-use solution (mL)	Replace with the following volume of NS or D5W (mL)	Dose (mg)
12 mL	12 mL	3.5
18 mL	18 mL	3.3
25 mL	25 mL	3

Concentrate with 4 mg in 5 mL for single use: Vials contain overfill; measure accurately. Withdraw desired volume from vial. Must be further diluted immediately in 100 mL of NS or D5W and given as an infusion.

4-mg Concentrate in 5 mL for Single Use Zometa Dilution Recommendations for Reduced Doses in Patients with a CrCl Less Than or Equal to 60 mL/min	
Recommended Dose (mg)	Volume of Diluent (mL)
4 mg	5 mL
3.5 mg	4.4 mL
3.3 mg	4.1 mL
3 mg	3.8 mL

Filters: Not required by manufacturer; however, use of a filter should not have an adverse effect.

Storage: Reclast: Store at CRT. Stable for 24 hours refrigerated at 2° to 8° C (36° to 46° F) after opening. **Zometa:** Store vials and ready-to-use container in carton at CRT. Use immediately after dilution or manipulation of ready-to-use container is preferred. Diluted solution may be refrigerated but must be used and the infusion completed within 24 hours of mixing. Do not store undiluted solution in a syringe (to avoid inadvertent injection).

COMPATIBILITY

RECLAST AND ZOMETA

Novartis manufactures both Reclast and Zometa and states, “Must not be mixed with calcium or other divalent cation-containing infusion solutions (e.g., LR). Should be administered as a single IV solution in a line separate from all other drugs.”

RECLAST

A vented IV set is required.

RATE OF ADMINISTRATION

A single dose equally distributed over no less than 15 minutes. After infusion is finished, flush IV line with 10 mL NS. An increase in renal toxicity that can progress to renal failure can result from shorter infusion times.

ACTIONS

ZOLEDRONIC ACID

A bisphosphonate that inhibits osteoclast-mediated bone resorption. Used as a bone resorption inhibitor in Paget’s disease (Reclast) and as a hypocalcemic agent to reduce hypercalcemia in oncology patients (Zometa). After administration, it rapidly partitions to the bone and localizes preferentially at sites of high bone turnover. Inhibits osteoclastic (destructive to bone) activity and induces osteoclast apoptosis (fragmentation of a cell into particles for elimination). Blocks the osteoclastic resorption of mineralized bone and cartilage through its binding to bone and inhibits the increased osteoclastic activity and skeletal calcium release induced by various tumors. Decreases serum calcium and phosphorus and increases urinary calcium and phosphorus excretion. Plasma protein binding of zoledronic acid is low; the unbound fraction ranges from 60% to 77%. Not metabolized. Most bound to bone and slowly released back into the systemic circulation. Primarily excreted intact via the kidney. Half-life is triphasic with a terminal half-life of 146 hours.

RECLAST

In Paget’s disease, it localizes preferentially at sites of high bone turnover and promotes bone of normal quality with no evidence of impaired bone remodeling or mineralization effect. Returns patients to normal levels of bone turnover; see [Indications](#).

ZOMETA

In oncology patients with hypercalcemia, it reduces serum calcium concentrations by inhibiting bone resorption. Reduction in calcium levels is seen in 24 to 48 hours, but maximum response may take up to 7 days.

INDICATIONS AND USES

RECLAST

Treatment of Paget's disease of the bone in men and women. Treatment indicated to induce remission (normalization of serum alkaline phosphatase) in patients with elevations in serum alkaline phosphatase of two times or higher than the upper limit of the age-specific reference range and in patients who are symptomatic or are at risk for complications from their disease. Paget's disease of the bone is a chronic focal skeletal disorder characterized by greatly increased and disorderly bone remodeling. Excessive osteoclastic bone resorption is followed by irregular osteoblastic new bone formation, which leads to replacement of the normal bone architecture by disorganized, enlarged, and weakened bone structure. ■ Prevention and treatment of osteoporosis in post-menopausal women. In osteoporosis diagnosed by a bone mineral density test or prevalent vertebral fractures, Reclast reduces the incidence of hip, vertebral, and non-vertebral osteoporosis-related fractures. In patients at high risk for fracture (defined as a recent low-trauma hip fracture), Reclast reduces the incidence of new clinical fractures. ■ Treatment to increase bone mass in men with osteoporosis. ■ Treatment and prevention of glucocorticoid-induced osteoporosis in men and women who are initiating or continuing systemic glucocorticoids in a daily dose that is equivalent to 7.5 mg or more of prednisone and who are expected to remain on glucocorticoids for at least 12 months.

Limitation of use: Safety and effectiveness for treatment of osteoporosis is based on 3 years of clinical data. Optimal duration of therapy is unknown. Consider for discontinuation of therapy after 3 to 5 years in patients at low risk for fracture. Re-evaluate the need for continued therapy on a periodic basis.

ZOMETA

Treatment of hypercalcemia of malignancy (HCM), which is defined as an albumin-corrected calcium [cCa] greater than or equal to 12 mg/dL [3 mmol/L] using the following formula:

$$\text{cCa in mg/dL} = \text{Ca in mg/dL} + 0.8 [4 \text{ Gm/dL} - \text{Patient albumin (Gm/dL)}]$$

■ Treatment of patients with multiple myeloma and patients with documented bone metastases from solid tumors in conjunction with chemotherapy. Prostate cancer should have progressed after treatment with at least one hormonal therapy.

Limitation of use: Safety for use in the treatment of hypercalcemia associated with hyperparathyroidism or with other non-tumor-related conditions has not been established.

CONTRAINDICATIONS

RECLAST AND ZOMETA

Hypersensitivity to zoledronic acid or any of its components.

RECLAST

Hypocalcemia, pregnancy, lactation, in patients with a CrCl less than 35 mL/min, and in patients with evidence of acute renal impairment.

PRECAUTIONS

RECLAST AND ZOMETA

A patient being treated with Zometa should not be treated with Reclast or another bisphosphonate (e.g., ibandronate [Boniva], pamidronate [Aredia]). A patient being treated with Reclast should not be treated with Zometa or another bisphosphonate (e.g., ibandronate [Boniva], pamidronate [Aredia]). ■ Bisphosphonates have been associated with deterioration of renal function and potential renal failure. Multiple cycles of zoledronic acid, doses over 4 or 5 mg, and/or a rate of administration less than 15 minutes increase this risk. Patients who are dehydrated, are receiving diuretics or other nephrotoxic drugs, or have pre-existing renal impairment may also be at increased risk. ■ Use with caution in patients with aspirin-sensitive asthma; bronchoconstriction has been reported in these patients. ■ Osteonecrosis of the jaw (ONJ) has been reported in patients receiving bisphosphonates. The majority of cases have been in cancer patients undergoing dental procedures. Risk factors include cancer, concomitant therapy (e.g., chemo-

therapy, radiotherapy, corticosteroids), and co-morbid conditions (e.g., anemia, coagulopathies, infection, pre-existing oral disease). Post-marketing experience suggests a greater frequency of reports based on tumor type (advanced breast cancer or multiple myeloma). ■ A routine oral exam is recommended before beginning therapy with bisphosphonates. Patients, especially cancer patients, should consider appropriate preventive dentistry and avoid invasive dental procedures during bisphosphonate therapy. Dental surgery may exacerbate ONJ in patients who develop ONJ while undergoing bisphosphonate therapy. Corticosteroids and chemotherapy may be risk factors for ONJ. ■ Severe and occasionally incapacitating bone, joint, and/or muscle pain has been reported. Onset of symptoms may be days to months after initiation of therapy. Symptoms usually resolve when zoledronic acid is discontinued; however, in some patients symptoms resolved slowly or persisted. ■ Atypical subtrochanteric and diaphyseal femoral fractures have been reported in bisphosphonate-treated patients. May be bilateral. Many patients report prodromal pain in the affected area (usually presenting as dull, aching thigh pain) weeks to months before a complete fracture occurs. Patients presenting with thigh or groin pain in the absence of trauma should be evaluated to rule out an incomplete femur fracture. Patients presenting with an atypical fracture should also be assessed for S/S of fracture in the contralateral limb. ■ See [Monitor](#).

RECLAST

Hypocalcemia may occur. Pre-existing hypocalcemia must be treated by adequate intake of calcium and vitamin D before initiating therapy. Concurrent dosing with calcium and vitamin D during therapy is required and is especially important in the 2 weeks following Reclast administration. ■ Effectively treat disturbances of calcium and mineral metabolism (e.g., hypoparathyroidism, thyroid surgery, parathyroid surgery, malabsorption syndromes, excision of the small intestine) before initiating therapy with Reclast.

ZOMETA

Calcium is bound to serum protein; concentration fluctuates with changes in blood volume. Changes in serum calcium (especially during rehydration) may not reflect true plasma levels. Measurement with ionized calcium levels is preferred. If unavailable, all calcium measurement should be corrected for albumin to establish a basis for treatment and evaluation of treatment. ■ Mild or asymptomatic hypercalcemia will be treated with conservative measures (e.g., saline hydration, with or without diuretics [after correcting hypovolemia]). Consider patient's cardiovascular status. Corticosteroids may be indicated if the underlying cancer is sensitive (e.g., hematologic cancers). ■ Not recommended for patients with bone metastases with a SCr greater than 3 mg/dL (265 micromol/L) or for patients with hypercalcemia of malignancy with a SCr equal to or greater than 4.5 mg/dL (400 micromol/L). These patients were excluded from the studies. After considering other treatment options, use only if benefit outweighs risk of renal failure. ■ Retreatment may increase potential for renal failure; before retreatment, consider other available treatment options and risk versus benefit; evaluate serum creatinine before each dose. ■ May be used adjunctively with chemotherapy, radiation, or surgery.

Monitor: RECLAST AND ZOMETA: Serum phosphate levels will decrease (hypophosphatemia) and may require treatment. Short-term supplemental therapy may also be required for hypocalcemia or hypomagnesemia. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

RECLAST: S/S of Paget's disease range from no symptoms to severe morbidity due to bone pain, bone deformity, pathologic fractures, and neurologic and other complications. Serum alkaline phosphatase provides an objective measure of disease severity and response to therapy. Diagnosis can be confirmed by radiographic evidence. ■ Obtain baseline measurement of serum alkaline phosphatase, serum calcium, electrolytes, phosphate, magnesium, and SCr. Monitor as indicated. Obtain serum creatinine and calculate CrCl before each dose. ■ Supplemental calcium and vitamin D required; see [Usual Dose](#). Very important in the 2 weeks following Reclast administration. ■ Adequate hydration required; a minimum of two glasses of liquid is recommended before dosing on day of administration. Additional hydration is required in patients undergoing diuretic ther-

apy. ■ Monitor calcium and mineral levels closely in patients with disturbances of calcium and mineral metabolism (e.g., hypoparathyroidism, thyroid surgery, parathyroid surgery, malabsorption syndromes, excision of the small intestine).

ZOMETA: Obtain baseline measurements of serum calcium (corrected for serum albumin), electrolytes, phosphate, magnesium, SCr, and CBC with differential and hematocrit/hemoglobin. Monitor all closely as indicated by baseline results (may be daily). ■ Monitor SCr before each dose to identify renal deterioration. During clinical studies, deterioration was considered as an increase of 0.5 mg/dL if the patient had a normal baseline; if the patient had an abnormal baseline, deterioration was considered as an increase of 1 mg/dL. ■ Patients with cancer-related hypercalcemia are often dehydrated. Must be adequately hydrated orally and/or IV before treatment is initiated. Hydration with saline is preferred to facilitate the renal excretion of calcium and correct dehydration. A pretreatment urine output of 2 L/day is recommended. Maintain adequate hydration and urine output throughout treatment. ■ Correct hypovolemia before using diuretics. ■ Avoid overhydration in patients with compromised cardiovascular status. Observe frequently for signs of fluid overload.

Patient Education: RECLAST AND ZOMETA: Avoid pregnancy; use of nonhormonal birth control recommended. Report a suspected pregnancy; may cause fetal harm. ■ Regular visits and assessment of lab tests imperative. ■ Take only prescribed medications. ■ Adequate hydration required. Drink at least two glasses of fluid before infusion. ■ Report abdominal cramps, chills, confusion, fever, muscle spasms, sore throat, and/or any new medical problems promptly. ■ Flu-like symptoms may occur within the first 3 days of therapy. Usually resolve within 3 days of onset but may last for up to 7 to 14 days. ■ Good dental hygiene and routine dental care required. Obtain a dental exam before initiating therapy, and avoid invasive dental procedures during therapy. ■ Report development of bone, joint, or muscle pain promptly. Onset of pain is variable. ■ Report thigh or groin pain promptly.

RECLAST: Calcium and vitamin D supplementation required to maintain calcium levels. ■ Tell your physician if you have had surgery to remove some or all of the parathyroid glands in your neck, have had sections of your intestine removed, or are unable to take calcium supplements. ■ Promptly report muscle spasms and/or numbness or tingling sensations (especially around the mouth); may indicate hypocalcemia.

ZOMETA: Dietary restriction of calcium and vitamin D may be required in hypercalcemia of malignancy. ■ An oral calcium supplement of 500 mg and a multivitamin with 400 IU of vitamin D are recommended for patients with multiple myeloma and bone metastasis of solid tumors.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. ■ Discontinue breast-feeding. ■ Not indicated for use in pediatric patients. Because of long-term retention in bone, zoledronic acid should be used in pediatric patients only when potential benefit outweighs potential risk. Has been used in pediatric patients with severe osteogenesis imperfecta; see manufacturer's prescribing information.

Elderly: Response similar to that seen in younger patients. ■ Use with caution based on age-related impaired organ function and concomitant disease or other drug therapy; monitor renal function closely. ■ Monitor fluid and electrolyte status carefully to avoid overhydration. ■ Acute phase reactions occur less frequently in the elderly; see [Side Effects](#).

DRUG/LAB INTERACTIONS

RECLAST AND ZOMETA

Concurrent use with **loop diuretics** (e.g., furosemide [Lasix]) may increase risk of hypocalcemia or nephrotoxicity. ■ Concurrent use with **aminoglycosides** (e.g., gentamicin) may have an additive hypocalcemic effect that may persist for a prolonged period. ■ Use caution when administered with other potentially **nephrotoxic drugs** (e.g., aminoglycosides [gentamicin, tobramycin], cisplatin [Platinol], NSAIDs [ibuprofen (Advil)],

naproxen (Aleve)); the risk of renal deterioration is increased. Consider monitoring of SCr. ■ Concurrent administration with **renally eliminated drugs** (e.g., digoxin) may lead to increased exposure of these drugs. Use caution and consider monitoring of SCr. ■ In vitro studies indicate that it does not inhibit microsomal CYP₄₅₀ enzymes.

ZOMETA

Does not interfere with any known primary cancer therapy. ■ Concurrent use with **thallidomide** does not result in a significant change in the pharmacokinetics or creatinine clearance of zoledronic acid; no dose adjustment indicated. ■ Effects may be antagonized by **calcium-containing preparations or vitamin D**; avoid use.

SIDE EFFECTS

RECLAST AND ZOMETA

Abdominal pain, anorexia, atypical femur fracture, conjunctivitis, constipation, dehydration, diarrhea, dyspnea, episcleritis, flu-like syndrome (e.g., arthralgias and/or bone pain, chills, fever, flushing, and myalgias), headache, hypersensitivity reactions (including rare case of anaphylaxis, angioedema, and urticaria), hypocalcemia (abdominal cramps, confusion, muscle spasms), hypomagnesemia, hypophosphatemia, hypotension, injection site reactions, nausea, ocular inflammation (e.g., iritis, uveitis, scleritis, orbital inflammation and edema), osteonecrosis (primarily of the jaw), rash, renal impairment, and vomiting.

RECLAST

Hypocalcemia is the most serious side effect. Dizziness, fatigue, and nausea were commonly reported. In addition to the previously noted side effects, an acute-phase reaction (e.g., chills; fever; headache; muscle, bone, or joint pain) and nausea and vomiting were reported. Symptoms may be significant and lead to dehydration. May occur within the first 3 days; is usually mild to moderate and lasts only a few days. Abdominal distention, anemia, asthenia, atrial fibrillation, back pain, dyspepsia, lethargy, musculoskeletal stiffness, pain, paresthesia, and peripheral edema have also been reported.

ZOMETA

The most commonly reported side effects are anemia, constipation, dyspnea, fever, and nausea. In addition to the previously noted side effects, agitation, anxiety, bronchoconstriction, chest pain, confusion, cough, dehydration, dysphagia, edema, granulocytopenia, hypokalemia, increased serum creatinine, musculoskeletal pain (e.g., bone pain and/or arthralgia and myalgias, which may be severe), pancytopenia, pleural effusion, pruritus, somnolence, thrombocytopenia, urinary tract infection, and weakness have occurred in 10% or more of patients. Fluid overload, hypokalemia, hypomagnesemia, and hypophosphatemia may occur more often with the use of concurrent fluid and diuretics.

Post-Marketing: Acute renal failure; angioneurotic edema; asthma exacerbation; atypical subtrochanteric and diaphyseal femoral fractures; blurred vision; bradycardia; bronchospasm; dehydration secondary to diuretic therapy, fever, or GI losses; dry mouth; hematuria; hyperesthesia; hyperkalemia; hypernatremia; hypersensitivity reactions; hypertension; increased SCr; increased sweating; influenza-like illness (asthenia, fatigue or malaise, fever persisting for more than 30 days); interstitial lung disease (ILD) with positive re-challenge; proteinuria; and weight increase. An acute-phase reaction has been reported to occur within 3 days of administration of **Zometa** (bone pain and/or arthralgias, chills, fatigue, fever, influenza-like illness, myalgias). Usually resolves within 3 days but may take up to 7 to 14 days.

Overdose: Clinically significant hypocalcemia (e.g., abdominal cramps; confusion; irregular heartbeats; muscle cramps in the hands, arms, feet, legs, or face; numbness and tingling around the mouth, fingertips, or feet), hypophosphatemia (e.g., unusual tiredness or weakness), and hypomagnesemia (e.g., muscle trembling or twitching) may occur. Elevated SCr levels and renal tubular necrosis may occur with excessive dose or rate of administration.

ANTIDOTE**RECLAST AND ZOMETA**

Keep physician informed of side effects. According to the manufacturer, no specific treatment was required in most cases of flu-like syndrome, GI symptoms, and infusion site reactions, and the symptoms subsided in 24 to 48 hours. Some side effects may respond to symptomatic treatment. IV fluids may be required for dehydration. Magnesium and phosphorus may require replacement if depletion is too severe. If mild, all will probably return toward normal in 7 to 10 days. For asymptomatic or mild to moderate hypocalcemia (6.5 to 8 mg/100 mL [1 dL] corrected for serum albumin), short-term calcium therapy (e.g., calcium gluconate) may be indicated. Discontinue drug for any symptoms of hypersensitivity or overdose. Discontinue for severe bone, joint, or muscle pain. Treat anaphylaxis and resuscitate as indicated.

ZOMETA

Monitor serum calcium and use vigorous IV hydration, with or without diuretics, for 2 to 3 days. Monitor intake and output to ensure adequacy and balance. Use short-term IV calcium therapy if indicated. Potassium phosphate and/or magnesium sulfate may be required to treat hypophosphatemia and hypomagnesemia. High fever may respond to steroids. RBC transfusions may be required in anemia.

APPENDIX A

Recommendations for the Safe Use and Handling of Cytotoxic Drugs

Numerous references are available on the topic of guidelines, recommendations, and regulations for handling antineoplastic agents.

The Department of Health and Human Services in the Centers for Disease Control and Prevention has publications and other references that cover all aspects of the topic at www.cdc.gov/niosh. Click on Hazards & Exposures, then click on Antineoplastic Agents. In 2004, The National Institute for Occupational Safety and Health (NIOSH) published *Preventing Occupational Exposure to Antineoplastic and Other Hazardous Drugs in Health Care Settings*, which can be found at www.cdc.gov/niosh/docs/2004-165.

Other frequently cited guidelines are available from the American Society of Hospital-System Pharmacists, the Oncology Nursing Society, and the International Society of Oncology Pharmacy Practitioners. The OSHA Technical Manual, *Controlling Occupational Exposure to Hazardous Drugs*, revised in 1995, is also available; however, it is very extensive and covers many more hazardous issues than just antineoplastic drugs. Any of these references can be searched on the Internet. To give you a sample of the requirements for the safe use and handling of cytotoxic drugs, the following recommendations are offered. Copies of this text and pictures illustrating each of the prescribed actions may be found at www.mtpinnacle.com/pdfs/CytotoxicDrugs.pdf.

INTRODUCTION

Cytotoxic drugs are toxic compounds and are known to have carcinogenic, mutagenic, and/or teratogenic potential. With direct contact they may cause irritation to the skin, eyes, and mucous membranes, and ulceration and necrosis of tissue. The toxicity of cytotoxic drugs dictates that the exposure of health care personnel to these drugs should be minimized. At the same time, the requirement for maintenance of aseptic conditions must be satisfied.*

POTENTIAL ROUTES OF EXPOSURE

This brochure reviews the routes through which exposure may occur and presents recommendations for the safe handling of parenteral cytotoxic drugs by pharmacists, nurses, physicians, and other personnel who participate in the preparation and administration of these drugs to patients. These guidelines apply in any setting where cytotoxic drugs are prepared—including pharmacies, nursing units, clinics, physicians' offices, and the home health care environment. The primary routes of exposure during the preparation and administration phases are through the inhalation of aerosolized drug or by direct skin contact.

During drug preparation, a variety of manipulations are used which may result in aerosol generation, spraying, and splattering. Examples of these manipulations include: the withdrawal of needles from drug vials; the use of syringes and needles or filter straws for drug transfer; the opening of ampules; and the expulsion of air from the syringe when measuring the precise volume of a drug. Pharmaceutical practice calls for the use of aseptic techniques and a sterile environment. Many pharmacies provide this sterile environment by using a horizontal laminar flow work bench. However, while this type of unit provides product protection, it may expose the operator and other room occupants to aerosols generated during drug preparation procedures. Therefore, a Class II laminar flow (vertical) biological safety cabinet that provides both product and operator protection is needed for the preparation of cytotoxic drugs. This is accomplished by filtering incoming and exhaust air through a high-efficiency particulate air (HEPA) filter. It should be noted that these filters are not effective for volatile materials because they do not capture vapors and gases. Personnel should be familiar with the capabilities, limitations, and proper utilization of the biological safety cabinet selected.

*Although it is no longer included in these guidelines, some authorities recommend avoiding exposure to cytotoxic agents during pregnancy and using caution or avoiding exposure during breast-feeding or if trying to conceive.

During administration, clearing air from a syringe or infusion line and leakage at tubing, syringe, or stopcock connections should be avoided to prevent opportunities for accidental skin contact and aerosol generation. Dispose of syringes and unclipped needles into a leak-proof and puncture-resistant container.

The disposal of cytotoxic drugs and trace contaminated materials (e.g., gloves, gowns, needles, syringes, vials) presents a possible source of exposure to pharmacists, nurses, and physicians as well as to ancillary personnel, especially the housekeeping staff. Excreta from patients receiving cytotoxic drug therapy may contain high concentrations of the drug. All personnel should be aware of this source of potential exposure and should take appropriate precautions to avoid accidental contact.

The potential risks to pharmacists, nurses, and physicians from repeated contact with parenteral cytotoxic drugs can be effectively controlled by using a combination of specific containment equipment and certain work techniques which are described in the recommendations sections. For the most part, the techniques are merely an extension of good work practices by health care and ancillary personnel, and similar in principle and practice to *Universal Precautions*.¹ These may be supplemented as deemed appropriate for the work being performed. By using these precautions, personnel are better able to minimize possible exposure to cytotoxic drugs.

RECOMMENDED PRACTICES FOR PERSONNEL PREPARING CYTOTOXIC DRUGS

Professionally accepted standards concerning the aseptic preparation of parenteral products should be followed. Only properly trained personnel should handle cytotoxic drugs. Training sessions should be offered to new professionals as well as to technical and housekeeping personnel who may come in contact with these drugs. Safe handling should be the focus of such training. To speed loading time, the information regarding safe preparation has been divided into 3 sections:

- Steps A, B, C
- Steps D, E, F, G
- Steps H, I, J, K, L

SAFE PREPARATION OF CYTOTOXIC DRUGS

A. Part 1—All procedures involved in the preparation of cytotoxic drugs should be performed in a Class II, Type A or Type B laminar flow biological safety cabinet. The cabinet exhaust should be discharged to the outdoors in order to eliminate the exposure of personnel to drugs that may volatilize after retention on filters of the cabinet. The cabinet of choice is a Class II, Type B which discharges exhaust to the outdoors and can be obtained with a bag-in/bag-out filter to protect the personnel servicing the cabinet and to facilitate disposal.

Part 2—Alternatively, a Class II, Type A cabinet can be equipped with a canopy or thimble unit which exhausts to the outdoors. For detailed information about the design, capabilities, and limitations of various types of biological safety cabinets, refer to the National Sanitation Foundation Standard 49.²

- B. The work surface of the safety cabinet should be covered with plastic-backed absorbent paper. This will reduce the potential for dispersion of droplets and spills and facilitate cleanup. This paper should be changed after any overt spill and at the end of each work shift.
- C. Personnel preparing the drugs should wear unpowdered latex surgical gloves and a disposal gown with elastic or knit cuffs. Gloves should be changed regularly and immediately if torn or punctured. Protective clothing should not be worn outside of the drug

¹ Centers for Disease Control. 1988. Update: Universal precautions for prevention of transmission of human immunodeficiency virus, hepatitis B virus, and other blood-borne pathogens in health-care settings. *Morbidity and Mortality Weekly Report*, 37(24): 377-382, 387-388.

² National Science Foundation. Standard 49 for Class II (Laminar Flow) Biohazard Cabinetry.

preparation area. Overtly contaminated gowns require immediate removal and replacement. In case of skin contact with any cytotoxic drug, thoroughly wash the affected area with soap and water. However, do not abrade the skin by using a scrub brush. Flush the affected eye(s), while holding back the eyelid(s), with copious amounts of water for at least 15 minutes. Then seek medical evaluation by a physician.

- D. Vials containing drugs requiring reconstitution should be vented to reduce the internal pressure with a venting device using a 0.22-micron hydrophobic filter or other appropriate means such as a chemotherapy dispensing pin. This reduces the probability of spraying and spillage.
- E. If a chemotherapy dispensing pin is not used, a sterile alcohol pad should be carefully placed around the needle and vial top during withdrawal from the septum.
- F. The external surfaces contaminated with a drug should be wiped clean with an alcohol pad before transfer or transport.
- G. When opening the glass ampule, wrap it and then snap it at the break point using an alcohol pad to reduce the possibility of injury and to contain the aerosol produced. Use a 5-micron filter needle or straw when removing the drug solution.
- H. Syringes and IV bottles containing cytotoxic drugs should be labeled and dated. Before these items leave the preparation area, an additional label reading, "*Caution—Chemotherapy, Dispose of Properly*" is recommended.
 - I. After completing the drug preparation process, wipe down the interior of the safety cabinet with water (for injection or irrigation) followed by 70% alcohol using disposable towels. All wastes are considered contaminated and should be disposed of properly.
 - J. Contaminated needles and syringes, IV tubing, butterfly clips, etc., should be disposed of intact to prevent aerosol generation and injury. **Do not recap needles.** Place these items in a puncture-resistant container along with any contaminated bottles, vials, gloves, absorbent paper, disposable gowns, gauze, and other waste. The container should then be placed in a box labeled, "**Cytotoxic waste only**," sealed and disposed of according to Federal, state, and local requirements. Linen contaminated with drugs, patient excreta, or body fluids should be handled separately.
- K. Hands should be washed between glove changes and after glove removal.
- L. Cytotoxic drugs are categorized as regulated wastes and therefore, should be disposed of according to Federal, state, and local requirements.

RECOMMENDED PRACTICES FOR PERSONNEL ADMINISTERING PARENTERAL CYTOTOXIC DRUGS

- A. A protective outer garment such as a closed-front surgical-type gown with elastic or knit cuffs should be worn. Gowns may be of the disposable or washable variety.
- B. Disposable latex surgical gloves should be worn during those procedures where exposure to the drugs may result and when handling patient body fluids or excreta. When bubbles are removed from syringes or IV tubing, an alcohol pad should be placed carefully over the tip of such items in order to collect any of the cytotoxic drugs which may be inadvertently discharged. Discard gloves after each use and wash hands.
- C. Contaminated needles and syringes and IV apparatus should be disposed of intact into a labeled, puncture-resistant container in order to minimize aerosol generation and risk of injury. **Do not recap needles.** The container, as well as other contaminated materials should be placed in a box labeled, "**Cytotoxic waste only**." Linen overtly contaminated with any cytotoxic agent or excreta from a patient within 48 hours following drug administration, may be safely handled by using the procedures prescribed for isolation cases. For example, place the contaminated articles in a "yellow" cloth bag lined with a water-soluble plastic bag and then place into the washing machine. Linen without overt contamination can be handled by routine laundering procedures.
- D. In case of skin contact with any cytotoxic drug, thoroughly wash the affected area with soap and water. However, do not abrade the skin by using a scrub brush. Flush affected eye(s), while holding back the eyelid(s), with copious amounts of water for at least 15 minutes. Then seek evaluation by a physician. Always wash hands after removing gloves.

APPENDIX B

FDA Pregnancy Categories

No drug should be used during pregnancy unless clearly needed and the risks to the fetus are outweighed by the benefits to the mother.

- Category A Adequate studies have not demonstrated a risk to the fetus in any trimester.
- Category B May have caused adverse effects in animals, but no adverse effects have been demonstrated in humans in any trimester or no demonstrated risk in animals but there are no adequate studies in pregnant women.
- Category C Animal studies have shown an adverse effect but there are no adequate studies in pregnant women or no animal studies and no studies in pregnant women.
- Category D Definite fetal risks. May be given in spite of risks if needed in life-threatening conditions.
- Category X Will cause fetal abnormalities. Risk of use outweighs benefits. Not recommended for use at any time during pregnancy. Consider alternatives before treating a pregnant woman.

Consider all men and women capable of conception when any drug in Category D or Category X is to be administered. Discuss birth control options to avoid pregnancy if a specific drug in these categories must be administered. Some drugs require birth control for months after all dosing is complete. Research complete information and keep patient informed.

APPENDIX C

U.S. Department of Health and Human Services, National Institutes of Health, National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE)

In Appendix C we have in the past incorporated the Common Toxicity Criteria (CTC) provided by the U.S. Department of Health and Human Services, the National Institutes of Health, and the National Cancer Institute. It was referred to throughout the text as the National Cancer Institute Common Toxicity Grading Criteria (NCI CTGC). This listing has been expanded and updated by these organizations and is too expansive to be included in an appendix. Web access to this material is available at www.cancer.gov. Search for CTCAE (Common Terminology Criteria for Adverse Events Version 4.0). Printed copies are available free of charge; call 1-800-4-CANCER (1-800-422-6237).

APPENDIX D

Information for Patients Receiving Immunosuppressive Agents

- Report allergic or sensitivity reactions you may have had to drugs or food.
- Report other medical problems you may have (e.g., exposure to chickenpox, herpes zoster, infections, bone marrow, heart, kidney, or liver problems).
- Provide a complete list of all medications you take, prescription and over the counter.
- In most situations birth control is essential and may be required for both patient and partner. Nonhormonal birth control reduces the possibility of drug interactions, but compliance is imperative. If there is any possibility you or your partner may be pregnant, inform your physician promptly.
- Discontinue breast-feeding.
- Take only prescribed medication(s) in the exact amounts prescribed and at the times prescribed. This will help to maintain correct blood levels and avoid drug interactions.
- Confirm procedure if you should miss a dose. If any questions, notify physician.
- Confirm procedure for correct storage of your medication(s).
- Close monitoring by your physician is very important; keep all appointments and have all required lab work done on schedule. Your medications may interfere with some test results. Discuss with your physician.
- Do not take any immunizations without your physician's approval. Polio vaccine is especially virulent in your condition; request family members to defer immunization and either avoid friends who have been immunized or wear a protective mask covering your nose and mouth while visiting.
- Dental procedures may need to be completed before starting therapy or deferred until therapy is completed. Use caution with your toothbrush, toothpicks, or dental floss. Alternate methods of dental hygiene may be necessary should your gums become tender, inflamed, or bleed.
- Review all side effects with your physician. Confirm those that may be a special problem for you and discuss solutions and expectations.
- Avoid anyone with an infection or fever. Report symptoms such as: chills, fever, cough, hoarseness, lower back or side pain, painful or difficult urination.
- Wash hands before touching your eyes or the inside of your nose.
- Report unusual bleeding, bruising, black tarry stools, blood in urine, or pinpoint red spots on your skin (petechiae).
- Report redness, swelling, or soreness in the mouth (symptoms of stomatitis).
- Report mild hair loss, nausea and vomiting, rash, tiredness, weakness.
- Avoid accidental cuts whenever possible (e.g., razors, fingernail and toenail clippers).
- Avoid contact sports where you might be bruised or injured.
- Drink adequate amounts of fluids to prevent increases in serum uric acid concentrations. Allopurinol (Zyloprim) and/or alkalinization of urine may be required.
- Anesthesia during dental, surgical, or emergency treatment may be a problem. It is best to consult with your physician, but inform all health care professionals about the medications you are taking before they treat you in any way.

APPENDIX E

Recently Approved Drugs

PROTHROMBIN COMPLEX CONCENTRATE (HUMAN) **BBW**

Antihemorrhagic

(PRO-throm-bin KOM-plex KAN-sen-trayt [HUE-man])

Kcentra

USUAL DOSE

(International Units [IU])

Dosing should be individualized based on the patient's baseline International Normalized Ratio (INR) value and body weight.

Vitamin K: Administer vitamin K (phytonadione) concurrently to maintain vitamin K-dependent factor levels once the effects of the prothrombin complex concentrate (human) have diminished.

Prothrombin complex concentrate (human): Coagulation factor levels may be unstable in patients with acute major bleeding who are receiving vitamin K. Obtain baseline INR (close to time of dosing). Using this INR and the patient's weight, individualize dose as shown in the following table.

Prothrombin Complex Concentrate (Human) Dosing Guidelines			
	Pretreatment INR		
	2 to Less Than 4	4 to 6	Greater Than 6
Dose of prothrombin complex concentrate [human]* (units [†] of factor IX/kg body weight)	25 IU/kg	35 IU/kg	50 IU/kg
Maximum dose (units of factor IX) [‡]	Not to exceed 2500 IU	Not to exceed 3500 IU	Not to exceed 5000 IU

*Dose is based on body weight. Dose is also based on actual potency as stated on the carton, which will vary from 20 to 31 factor IX units/mL.

[†]Units refer to International Units.

[‡]Dose is based on body weight up to but not exceeding 100 kg. For patients weighing more than 100 kg, maximum dose should not be exceeded.

Example dosing calculation for an 80-kg patient with a baseline INR of 5:

$$35 \text{ units of Factor IX/kg} \times 80 \text{ kg} = 2,800 \text{ units of Factor IX required}$$

For a vial with an actual potency of 30 units/mL factor IX, 93 mL would be given:

$$2800 \text{ units} \div 30 \text{ units/mL} = 93 \text{ mL}$$

Repeat dosing with prothrombin complex concentrate is not supported by clinical data and is not recommended.

DILUTION

Available in a kit that contains 500 units of prothrombin complex concentrate in a single-use vial, a 20-mL vial of SWFI, a Mix2Vial filter transfer set, and an alcohol swab. The actual potency per vial of factors II, VII, IX, and X and of proteins C and S is stated on the carton (potency in IU is defined by factor IX content). When reconstituted, the final

concentration of drug product in factor IX units will range from 20 to 31 units/mL (400 to 620 units/vial) depending on actual potency, which is listed on the carton. Nominal potency is 500 units per vial, which is approximately 25 units/mL after reconstitution. Record the lot number of the product in the patient's medical record when prothrombin complex concentrate is administered.

Begin the reconstitution process by bringing prothrombin complex concentrate and diluent vial to room temperature. Use of aseptic technique required. Remove vial tops and wipe stoppers with the alcohol swab. Open the Mix2Vial transfer set package, leaving transfer set in the clear package. Place **diluent vial** on a flat surface and hold vial tightly. Grip the Mix2Vial transfer set together with the clear package and push the plastic spike at the **blue end of the transfer set** firmly through the center of the diluent vial stopper. Carefully remove the clear package from the Mix2Vial transfer set. With the **prothrombin complex concentrate vial** firmly on a flat surface, invert the diluent vial with the transfer set attached and push the plastic spike of the **transparent adapter** firmly through the center of the stopper of the prothrombin complex concentrate vial. The diluent will automatically transfer into the prothrombin complex concentrate vial. With both vials still attached to the transfer set, gently swirl the prothrombin complex concentrate vial to ensure complete dissolution. **Do not shake.** Solution should be colorless, clear to slightly opalescent, and free from visible particles. With one hand, grasp the prothrombin complex concentrate side of the Mix2Vial transfer set, and with the other hand grasp the blue diluent side of the Mix2Vial transfer set, and unscrew the set into two pieces. Draw air into an empty, sterile syringe. While the prothrombin complex concentrate vial is upright, screw the syringe to the Mix2Vial transfer set. Inject air into the vial. While keeping the syringe plunger pressed, invert the system upside down and draw the concentrate into the syringe by pulling the plunger back slowly. Unscrew the syringe from the transfer set and attach to a suitable intravenous administration set. If the same patient is to receive more than one vial, contents of multiple vials may be pooled. Use a separate, unused Mix2Vial transfer set for each product vial.

Storage: Store lyophilized powder in carton at 2° to 25° C (36° to 77° F); protect from light and freezing. Stable for 36 months from date of manufacture. Do not use beyond the expiration date on the carton and vial labels. Product must be used within 4 hours following reconstitution. Reconstituted product can be stored at 2° to 25° C. If cooled, the solution should be warmed to 20° to 25° C (68° to 77° F, approximate room temperature) before administration. Do not freeze reconstituted product. Discard partially used vials.

COMPATIBILITY

Manufacturer states, "Do not mix with other medicinal products; administer through a separate infusion line. No blood should enter the syringe, as there is a possibility of fibrin clot formation."

RATE OF ADMINISTRATION

Administer at room temperature at a rate of 0.12 mL/kg/min (approximately 3 units/kg/min), up to a maximum of 8.4 mL/min (approximately 210 units/min).

ACTIONS

A purified, heat-treated, nanofiltered, and lyophilized nonactivated four-factor prothrombin complex concentrate prepared from human U.S. Source Plasma. Contains the vitamin K–dependent coagulation factors II, VII, IX, and X (together known as the prothrombin complex) and the antithrombotic proteins C and S. Factor IX is the lead factor for the potency of the preparation. (Human antithrombin III, heparin and human albumin, sodium chloride, and sodium citrate are listed as excipients.) A dose-dependent acquired deficiency of the vitamin K–dependent coagulation factors occurs during vitamin K antagonist (VKA) treatment. Vitamin K antagonists exert anticoagulant effects by lowering both factor synthesis and function. Administration of prothrombin complex concentrate rapidly increases plasma levels of the vitamin K–dependent coagulation factors II, VII, IX, and X as well as the antithrombotic proteins C and S. In clinical trials, prothrombin complex concentrate restored the decreased vitamin K–dependent clotting factors sig-

nificantly faster than plasma in patients on warfarin. A single dose of prothrombin complex concentrate produced a rapid and sustained increase in plasma levels of factors II, VII, IX, and X within 30 minutes post-treatment with 87% less volume than with plasma. In addition, infusion time with prothrombin complex concentrate was seven times faster than with plasma. In most subjects, prothrombin complex concentrate decreased INR to less than or equal to 1.3 within 30 minutes. The relationship between this or other INR values and clinical hemostasis in patients has not been established.

INDICATIONS AND USES

Indicated for the urgent reversal of acquired coagulation factor deficiency induced by vitamin K antagonists (e.g., warfarin) therapy in adult patients with acute major bleeding. Not indicated for urgent reversal of vitamin K antagonist anticoagulation in patients without acute major bleeding.

CONTRAINDICATIONS

Patients with known anaphylactic or severe systemic reactions to prothrombin complex concentrate or any of its components, including heparin; factors II, VII, IX, and X; proteins C and S; antithrombin III; and human albumin. ■ Patients with disseminated intravascular coagulation (DIC). ■ Patients with known heparin-induced thrombocytopenia (HIT). Prothrombin complex concentrate contains heparin.

PRECAUTIONS

For IV use only. ■ Hypersensitivity reactions have been reported. ■ Both fatal and nonfatal arterial and venous thromboembolic complications have been reported. Patients being treated with VKA therapy have underlying disease states that predispose them to thromboembolic events. The potential benefits of reversing VKA should be weighed against the potential risks of thromboembolic events, especially in patients with a history of a thromboembolic event. Resumption of anticoagulation should be carefully considered as soon as the risk of thromboembolic events outweighs the risk of acute bleeding. ■ Prothrombin complex concentrate has not been studied in subjects who have had a thromboembolic event, myocardial infarction, disseminated intravascular coagulation, cerebrovascular accident, transient ischemic attack, unstable angina pectoris, or severe peripheral vascular disease within the previous 3 months. Prothrombin complex concentrate may not be suitable in patients who have had a thromboembolic event in the previous 3 months. ■ Made from human blood and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, hepatitis C). Numerous steps in the manufacturing process are used to make the potential for transmission of infectious agents extremely remote. ■ Prothrombin complex concentrate has not been studied in patients with congenital factor deficiencies.

Monitor: Monitor INR and clinical response during and after treatment. ■ Standard clinical assessments (e.g., VS, hemoglobin measurements, CT assessments relevant to the type of bleeding [e.g., GI, cerebral]) may be used to evaluate effective hemostasis. ■ Monitor for S/S of hypersensitivity reactions (e.g., angioedema, anxiety, bronchospasm, dyspnea, flushing, hypotension, nausea, pulmonary edema, tachycardia, urticaria, wheezing, vomiting). ■ Monitor for signs and symptoms of thromboembolic events (e.g., deep venous thrombosis, pulmonary embolism, stroke) during and after administration of prothrombin complex concentrate.

Patient Education: Report any S/S of hypersensitivity promptly (e.g., hives, rash, tightness of chest, wheezing). ■ Report S/S of thrombosis (e.g., limb or abdominal swelling and/or pain, chest pain or pressure, shortness of breath, loss of sensation or motor power, altered consciousness, vision, or speech). ■ Prothrombin complex concentrate is made from human blood and may carry a remote risk of transmitting infectious agents. See Precautions.

Maternal/Child: Category C: safety for use during pregnancy, labor and delivery, and during breast-feeding not established; use only if clearly indicated. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response similar to other age-groups.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

The most common side effects observed were arthralgia, headache, hypotension, nausea, and vomiting. The most serious side effects were thromboembolic events, including deep vein thrombosis, pulmonary embolism, and stroke. Other side effects included abnormal breath sounds, chest pain, constipation, dyspnea, fluid overload, hypertension, hypokalemia, hypoxia, insomnia, intracranial hemorrhage, mental status changes, myocardial infarction, myocardial ischemia, pulmonary edema, respiratory distress, and tachycardia.

Post-Marketing: Hypersensitivity or allergic reactions (e.g., angioedema, anxiety, bronchospasm, dyspnea, flushing, hypotension, nausea, pulmonary edema, tachycardia, urticaria, vomiting, wheezing) and thromboembolic complications (arterial thromboembolic events [arterial thrombosis, acute MI], venous thromboembolic events [pulmonary embolism and venous thrombosis], and DIC).

ANTIDOTE

Notify physician of any side effect. If a severe hypersensitivity or anaphylactic-type reaction occurs, immediately discontinue administration and institute appropriate treatment (e.g., oxygen, hydrocortisone, epinephrine (Adrenalin), diphenhydramine (Benadryl), an H₂ antagonist [e.g., famotidine (Pepcid), ranitidine (Zantac)]).
