General Dilution Chart (Gm to mg)							
Amount of Drug Required in Grams	Amount of Diluent						
	1,000 mL	500 mL	250 mL	125 mL	100 mL	50 mL	25 mL
	mg/mL	mg/mL	mg/mL	mg/mL	mg/mL	mg/mL	mg/mL
20 Gm	20	40	80	160	200	400	800
19 Gm	19	38	76	152	190	380	760
18 Gm	18	36	72	144	180	360	720
17 Gm	17	34	68	136	170	340	680
16 Gm	16	32	64	128	160	320	640
15 Gm	15	30	60	120	150	300	600
14 Gm	14	28	56	112	140	280	560
13 Gm	13	26	52	104	130	260	520
12 Gm	12	24	48	96	120	240	480
11 Gm	11	22	44	88	110	220	440
10 Gm	10	20	40	80	100	200	400
9 Gm	9	18	36	72	90	180	360
8 Gm	8	16	32	64	80	160	320
7 Gm	7	14	28	56	70	140	280
6 Gm	6	12	24	48	60	120	240
5 Gm	5	10	20	40	50	100	200
4.5 Gm	4.5	9	18	36	45	90	180
4 Gm	4	8	16	32	40	80	160
3.5 Gm	3.5	7	14	28	35	70	140
3 Gm	3	6	12	24	30	60	120
2.5 Gm	2.5	5	10	20	25	50	100
2 Gm	2	4	8	16	20	40	80
1.5 Gm	1.5	3	6	12	15	30	60
1 Gm	1	2	4	8	10	20	40
0.5 Gm	0.5	1	2	4	5	10	20
0.25 Gm	0.25	0.5	1	2	2.5	5	10

To use chart:

1. Find mg/mL desired, track to amount of diluent desired and amount of drug in Grams required.
2. Find amount of drug in Grams required, track to diluent desired and/or mg/mL desired.
3. Find amount of diluent required, track to amount of drug in Grams and/or mg/mL desired.

Formula: Substitute any number for X

X Grams diluted in 1,000 mL = X mg/mL (1 Gram in 1,000 mL = 1 mg/mL)
X Grams diluted in 500 mL = 2 X mg/mL (1 Gram in 500 mL = 2 mg/mL)
X Grams diluted in 250 mL = 4 X mg/mL (1 Gram in 250 mL = 4 mg/mL)
X Grams diluted in 125 mL = 8 X mg/mL (1 Gram in 125 ml = 8 mg/mL)
X Grams diluted in 100 mL = 10 X mg/mL (1 Gram in 100 mL = 10 mg/mL)
X Grams diluted in 50 mL = 20 X mg/mL (1 Gram in 50 mL = 20 mg/mL)
X Grams diluted in 25 mL = 40 X mg/mL (1 Gram in 25 mL = 40 mg/mL)

Some variation occurs from manufacturer's overfill or if the drug is in liquid form. If absolute accuracy is required, these variations can be avoided by withdrawing an amount in mL from the diluent equal to manufacturer's overfill and/or an amount equal to the amount in mL of the drug. Consult the pharmacist for specific information on manufacturer's overfill of infusion fluids used in your facility.

General Dilution Chart (mg to mcg)							
Amount of Drug Required in Grams	Amount of Diluent						
	1,000 mL	500 mL	250 mL	125 mL	100 mL	50 mL	25 mL
	mcg/mL	mcg/mL	mcg/mL	mcg/mL	mcg/mL	mcg/mL	mcg/mL
20 mg	20	40	80	160	200	400	800
19 mg	19	38	76	152	190	380	760
18 mg	18	36	72	144	180	360	720
17 mg	17	34	68	136	170	340	680
16 mg	16	32	64	128	160	320	640
15 mg	15	30	60	120	150	300	600
14 mg	14	28	56	112	140	280	560
13 mg	13	26	52	104	130	260	520
12 mg	12	24	48	96	120	240	480
11 mg	11	22	44	88	110	220	440
10 mg	10	20	40	80	100	200	400
9 mg	9	18	36	72	90	180	360
8 mg	8	16	32	64	80	160	320
7 mg	7	14	28	56	70	140	280
6 mg	6	12	24	48	60	120	240
5 mg	5	10	20	40	50	100	200
4.5 mg	4.5	9	18	36	45	90	180
4 mg	4	8	16	32	40	80	160
3.5 mg	3.5	7	14	28	35	70	140
3 mg	3	6	12	24	30	60	120
2.5 mg	2.5	5	10	20	25	50	100
2 mg	2	4	8	16	20	40	80
1.5 mg	1.5	3	6	12	15	30	60
1 mg	1	2	4	8	10	20	40
0.5 mg	0.5	1	2	4	5	10	20
0.25 mg	0.25	0.5	1	2	2.5	5	10

To use chart:

1. Find mcg/mL desired, track to amount of diluent desired and amount of drug in mg required.
2. Find amount of drug in mg required, track to diluent desired and/or mcg/mL desired.
3. Find amount of diluent required, track to amount of drug in mg and/or mcg/mL desired.

Formula: Substitute any number for X

X mg diluted in 1,000 mL = X mcg/mL (1 mg in 1,000 mL = 1 mcg/mL)
X mg diluted in 500 mL = 2 X mcg/mL (1 mg in 500 mL = 2 mcg/mL)
X mg diluted in 250 mL = 4 X mcg/mL (1 mg in 250 mL = 4 mcg/mL)
X mg diluted in 125 mL = 8 X mcg/mL (1 mg in 125 mL = 8 mcg/mL)
X mg diluted in 100 mL = 10 X mcg/mL (1 mg in 100 mL = 10 mcg/mL)
X mg diluted in 50 mL = 20 X mcg/mL (1 mg in 50 mL = 20 mcg/mL)
X mg diluted in 25 mL = 40 X mcg/mL (1 mg in 25 mL = 40 mcg/mL)

Some variation occurs from manufacturer's overfill or if the drug is in liquid form. If absolute accuracy is required, these variations can be avoided by withdrawing an amount in mL from the diluent equal to manufacturer's overfill and/or an amount equal to the amount in mL of the drug. Consult the pharmacist for specific information on manufacturer's overfill of infusion fluids used in your facility.

HOW TO USE THIS BOOK

STEP 1

Refer to the index at the back of the book. You can find any drug by any name in less than 5 seconds. All drugs are cross-indexed by generic and all known trade names. The index is easily distinguished by a printed blue bar at the edge of the pages. Drugs are also indexed by pharmacologic action. With one turn of the page, all drugs included in the text with similar pharmacologic actions and their page numbers are available to you. Everything is strictly alphabetized; you will never be required to refer to additional pages to locate a drug.

STEP 2

Turn to the single page number given after the name of the drug. All information about the drug is included as continuous reading. You will rarely be required to turn to another section of the book to be completely informed. Specific breakdowns of each drug (Usual Dose, Pediatric Dose, Dose Adjustments, Dilution, Compatibility, Rate of Administration, Actions, Indications and Uses, Precautions, Contraindications, Drug/Lab Interactions, Side Effects, and Antidote) are consistent in format and printed in boldface type. Subheadings under these categories are in boldface. Scan quickly for a Usual Dose check, Dose Adjustment, Drug/Lab Interaction, Side Effect, or Antidote or carefully read all included information. The choice is yours. A quick scan will take 5 to 10 seconds. Even the most complicated drugs will take less than 2 minutes to read completely. Read each monograph carefully and completely before administering a drug to a specific patient for the first time and review it any time a new drug is added to the patient's drug profile.

That's it! A fast, complete, and accurate reference for anyone administering intravenous medications. The spiral binding is specifically designed to lie flat, leaving your hands free to secure needed supplies, prepare your medication, or even ventilate a patient while you read the needed information.

Develop the "look it up" habit. Clear, concise language and simplicity of form contribute to quick, easy use of this handbook. Before your first use, read the preface; it contains lots of helpful information.

Check out the *Intravenous Medications* website for monographs no longer included in this text and for other useful IV medication information:

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of the practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

PREFACE

This Year 2014 edition marks the forty-first year of publication of *Intravenous Medications*.

In this thirtieth edition, a total of 8 new drugs approved by the FDA for intravenous use have been incorporated. These new drugs are presented in individual monographs and include ado-trastuzumab emtansine (Kadcyla) for the treatment of patients with HER2-positive breast cancer; carfilzomib (Kyprolis) for the treatment of multiple myeloma; 6% hydroxyethyl starch 130/0.4 in sodium chloride (Voluven), a plasma volume substitute; pertuzumab (Perjeta) for the treatment of late-stage breast cancer; pooled plasma, human (Octaplas) for the replacement of multiple coagulation factors; raxibacumab (ABthrax) for the treatment of anthrax; and ziv-aflibercept (Zaltrap) for the treatment of metastatic colon cancer. Prothrombin complex concentrate, human (Kcentra) for the urgent reversal of acquired coagulation factor deficiency induced by vitamin K antagonists has recently been approved by the FDA and can be found in Appendix E.

Many new uses have been approved for established drugs, and numerous safety issues have been identified by the FDA. All of these changes are incorporated so our readers have the most current information available. All **Compatibilities** in this edition have been updated.

We continually strive to make information in this handbook informative and easier to access. **We continue to identify drugs with a Black Box Warning (BBW) in the main heading of the monograph.** In addition, **Black Box Warning statements are shaded in light gray and a different typeface is used** for instant identification wherever they appear in the text. **Blue-screened text** emphasizes a special circumstance not covered by a Black Box Warning. The FDA is now identifying **Limitations of Use** of drugs under Indications. Previously this information has been placed in Precautions.

In the past, we have incorporated the Common Toxicity Criteria (CTC) provided by the U.S. Department of Health and Human Services, the National Institutes of Health, and the National Cancer Institute. This listing has been expanded and updated by these organizations and is too expansive to be included in an appendix. Web access to this material is available at www.cancer.gov. Search for CTCAE (Common Terminology Criteria for Adverse Events Version 4.0). Printed copies are available free of charge; call 1-800-4-CANCER (1-800-422-6237).

We are all aware that **The Joint Commission** and the **Institute for Safe Medication Practices (ISMP)** have strongly emphasized various ways to reduce errors in drug ordering and administration. One of their suggestions is to refer to a drug by both its generic and its trade name. ***Intravenous Medications*** is the only reference that has consistently used both names since its first publication. They also recommend that symbols (e.g., <, >, ≤, ≥,) be spelled out. **Although we have always spelled out most of them, they are now all spelled out. The only exception is in charts, where there isn't room for the spelled out version.** The symbols are included in the Key to Abbreviations (p. xxi) if you need a refresher. **Some of the other ways we assist in safe administration** is to spell out the word *units*; we use Gm instead of gm so it is not confused with mg, use mcg instead of μg, and drop all trailing 0s (as in 1.0) to prevent overdoses. **The Joint Commission, ISMP, the American Pharmaceutical Association, and several other organizations have identified “High-Alert Medications” (a list of medications with the highest risk of injury when misused).** The websites of these organizations contain considerable information and identify common risk factors and suggested strategies. From the authors' viewpoint, **all drugs given by the IV route should be considered high-alert medications.** They have an immediate effect, are irretrievable, and can cause life-threatening side effects with incorrect usage.

We join The Joint Commission in urging you to pay special attention to **how tubes and catheters are connected to patients.** The Joint Commission challenges the manufacturers of these devices to redesign them in ways that will make dangerous misconnection much

less possible. Look up The Joint Commission suggestions. A preventive measure not mentioned by The Joint Commission is the **simple practice of labeling every line at the point of entry into the patient**. This should be done whenever more than a single piece of tubing (IV or other) is connected to a patient. Multiple-lumen catheters, 3-way stopcocks, chest tubes, nasogastric tubes, and any other tubing entering the patient should be labeled with its contents or use at the connection closest to the patient. In today's health care settings, patients frequently have multiple tubes inserted into their bodies. Correct labeling takes only a few seconds at the time of insertion and saves many moments of precious time every time the line needs to be accessed. Misconnection errors may be fatal; establish all of these suggestions as a standard of practice, and misconnection errors will be avoided.

Elsevier has an electronic version of *Intravenous Medications* for personal digital assistants (PDAs). This "handheld" electronic version is a convenient and portable supplement to the book. In addition, all drugs presently on the Evolve IV Meds website (<http://evolve.elsevier.com/IVMeds>) for *Intravenous Medications* (because of space limitations for the print version) are incorporated in this electronic version. Although the handheld version is easy to carry, keep in mind that only a few lines of text are available at any one time. It is the user's responsibility to be familiar with the complete monograph and **all** aspects of each drug before administration.

Health care today is an intense **environment**. The speed of change is overwhelming, but the authors and publisher of *Intravenous Medications* have a commitment to provide all health care professionals who have the responsibility to administer IV medications with annual editions that incorporate complete, accurate, and current information in a clear, concise, accessible, and reliable tool. FDA websites are monitored throughout the year and provide many important updates, such as dose changes, new pediatric doses, additional disease-specific doses, refinements in dosing applications, new indications, new drug interactions, additional precautions, updates on post-marketing side effects, and new information on antidotes. Most drugs currently approved for intravenous use are included. Exceptions are opaque dyes used in radiology, some general anesthetics used only in the OR, and a few rarely used drugs. To stay within the confines of the spiral binding, selected diagnostic agents, muscle relaxants intended for use only in the OR, and several other rarely used drugs have been moved to the Evolve IV Meds website: <http://evolve.elsevier.com/IVMeds>. (See p. ii for a listing.) Helpful charts for dilution and/or rate of administration are incorporated in selected monographs. A General Dilution Chart to simplify calculations is found on the inside front cover. Front matter material provides a Key to Abbreviations and Important IV Therapy Facts.

Intravenous Medications is designed for use in critical care areas, at the nursing station, in the office, in public health and home care settings, and by students and the armed services. Pertinent information can be found in a few seconds. Take advantage of its availability and quickly review every intravenous medication before administration.

The nurse is frequently placed in a variety of difficult situations. While the physician verbally requests or writes an order, the nurse must evaluate it for appropriateness, prepare it, administer it, and observe the effects. Intravenous drugs are instantly absorbed into the bloodstream, leading, it is hoped, to a prompt therapeutic action, but the risk of an inappropriate reaction is a constant threat that can easily become a frightening reality. It will be the nurse who must initiate emergency measures should adverse effects occur. This is an awesome responsibility.

If, after reviewing the information in *Intravenous Medications*, you have any questions about any order you are given, clarify it with the physician, consult the pharmacist, or consult your supervisor. The circumstances will determine whom you will approach first. If the physician thinks it is imperative to carry out an order even though you have unanswered questions, never hesitate to request that the physician administer the drug, drug combination, or dose himself or herself. In this era of constant change, the physician should be very willing to supply you, your supervisor, and/or the pharmacist with current studies documenting the validity and appropriateness of orders.

All information presented in this handbook is pertinent only to the intravenous use of the drug and not necessarily to intramuscular, subcutaneous, oral, or other means of administration.

Our sincere appreciation is extended to Meghan McElwain, Gregory Nazareno, Kim Huber, and Merrilee Newton for their ongoing participation in our efforts to bring you current, accurate, and relevant information; and to Lee Henderson, Rae Robertson, Deborah L. Vogel, Jodi M. Willard, and Jessica Williams at Elsevier and Joe Rekart at Graphic World, who are the editors, production staff, and design staff that make the publishing of *Intravenous Medications* happen each year. A special thank you to Betty's granddaughter Meghan McElwain Ortega, RN, BSN. She has provided much-appreciated help with the research needed to complete this edition and continues to be introduced to the process of preparing updated editions.

We also wish to thank you, the users of this reference. By seeking out this information, you serve your patients' needs and contribute to the safe administration of IV meds. We will continue to strive to earn your trust and confidence as we look forward together to an exciting future for health care.

FORMAT AND CONTENT OF INTRAVENOUS MEDICATIONS

Designed to facilitate quick reference, each entry begins with the generic name of the drug in boldface type. **Drugs with a Black Box Warning are identified with a symbol  in the main heading.** Phonetic pronunciations appear just below the generic name. Drug categories follow. The primary category may be followed by additional ones representing the multiple uses of a drug. Associated trade names are under the generic name. Boldface type and alphabetical order enable the reader to verify correct drug names easily. The use of a Canadian maple leaf symbol () after a trade name indicates availability in Canada only. The pH is listed in the lower right-hand corner of the title section. While this information is not consistently available, it is provided whenever possible. It represents the pH of the undiluted drug, the drug after reconstitution, or the drug after dilution for administration.

Headings within drug monographs are as follows:

Usual Dose: Doses recommended are the usual range for adults unless specifically stated otherwise. This information is presented first to enable the nurse to verify that the physician order is within acceptable parameters while checking the order and before preparation. If there are any questions, much time can be saved in clarifying them. If premedication is indicated, it will be noted here.

Pediatric Dose: Pediatric doses are specifically stated if they vary from mg/kg of body weight or M² dose recommended for adults. Not all drugs are recommended for use in children. See Maternal/Child for information on safety and effectiveness for use in pediatric patients.

Infant and/or Neonatal Dose: Included if available and distinct from Pediatric Dose. See Maternal/Child for information on safety and effectiveness for use in pediatric patients, including infants and neonates.

Dose Adjustments: Any situation that requires increasing or decreasing a dose is mentioned here. The range covers adjustments needed for elderly, debilitated, or hepatic or renal impairment patients; adjustments required by race or gender; or adjustments required in the presence of other medications or as physical conditions are monitored.

Dilution: Specific directions for dilution are given for all drugs if dilution is necessary or permissible. Drugs, diluents, and solutions must be appropriate for IV use. Certain medications may be available in more than one form (e.g., Advantage, Duplex); follow manufacturer's directions for reconstitution and stability. The manufacturing and approval of generics seems to be accelerating. They are usually similar to the trade version but may differ slightly, so be sure to double check the dose and dilution requirements. Sadly, extreme cost-consciousness has overtaken the health care system. Nurses are being requested not to dilute drugs unless specifically required by the manufacturer, in order to save the cost of a needle, a syringe, or a small vial of diluent. Always use your best judgment and keep the safety of the patient as your priority. Appropriate diluents are listed. The Solution Compatibility Chart on the inside back cover has been expanded and updated. Diluents that are not identified in Dilution will be listed in this chart. This is the only reference that provides calculation examples to simplify dilution and accurate dose measurement. Charts are available in selected monographs. If recommendations for pediatric dilutions are available, they are listed. In some situations mcg or mg/mL dilutions partially account for this variation. If there are any doubts, consult with the pharmacist and/or pediatric specialist. Generic dilution charts for grams to milligrams and milligrams to micrograms are featured on the inside front cover and facing page.

Filters: A subheading. Content here includes information included in prescribing information and information we have requested from manufacturers. Many drugs are filtered during the manufacturing process. There are numerous variations in recommendations for filtration after the manufacturing process. Filters are single-use one-way streets and are most effective when used at the last stage of mixing or dilution or in-line as administered to the patient. Most manufacturers expect that a drug distrib-

uted in an ampule will be filtered to eliminate the possibility of glass being drawn into a syringe on withdrawal of the drug. This is always a two-needle process. One process uses a standard needle to withdraw from the ampule; that needle is then replaced with a needle filter to inject the drug into the diluent. If it will not be added to a diluent, use the needle filter to withdraw from the ampule and replace it with a new standard needle to administer. When questioned, many manufacturers suggest following a specific hospital's standard, which may recommend that a drug distributed as a powder be filtered either with a needle filter on withdrawal from the vial, after reconstitution as added to the diluent, or with an in-line filter on delivery to the patient. Some acknowledge that in selected situations (e.g., open heart surgery) everything is filtered at some point before delivery to the patient. Although these responses are helpful, none of them clarify specific information about a drug. For questions, the manufacturer's pharmacist is available.

Storage: A subheading. Content here includes such items as stability, refrigeration versus room temperature, predilution versus postdilution. Newly approved generics may have slight differences; check the manufacturer's recommendations.

COMPATIBILITIES

The focus of this section is **compatibility**. **Any drug not listed as compatible should be considered incompatible. Incompatibilities are listed only when specifically identified by the manufacturer. No third-party incompatibilities are listed.**

Some monographs include only general information because that is all that is available. It may include the manufacturer's recommendation to administer separately from other drugs or the potential for reaction with some plastic infusion bags or tubing. Other monographs include manufacturers' statements regarding the potential inactivation or inhibition of one drug on another.

Compatibilities listed by the manufacturer are listed first, followed by **compatibilities** listed by another source, which may be divided into **additive and Y-site**. **Any drug not listed as compatible should be considered incompatible.** Drugs are alphabetized by generic name for ease in locating the drugs with which you are working. To make identification easier, common trade names accompany generic names, or examples are presented for drug categories. No other reference consistently provides this helpful information.

Because compatibilities may be influenced by many factors (e.g., temperature, pH, concentration, time together in solution, a specific order of mixing), **it is imperative that you verify compatibilities with your pharmacist.** Knowledge is growing daily in this field, and your pharmacist should have current information on the pharmacy computer or access to extensive references. Many compatibility studies have been done by other parties for both additive and Y-site compatibilities. Almost all are based on specific concentrations, which may or may not relate to usual doses or recommended concentrations.

Occasionally sources disagree on compatibility. If there is conflicting information about a compatibility, you will be told that this is not recommended by the manufacturer, or **the individual drugs that may have a conflict will be underlined.**

What steps should you consider before administering any drug?

- If the drug you wish to administer is not listed in the **Compatibility** section, **consider it to be incompatible.** To administer, you must turn off the infusing IV (at the stopcock or with a clamp close to the Y-site), flush the line with a solution compatible to both drugs (and/or solutions), administer the required drug, and flush the line again before turning the previously infusing IV back on. If you are unable to discontinue the infusion IV, you must have another IV access (e.g., a multi-lumen catheter, a second, IV line, or a heparin lock). Some drugs actually require separate tubing.
- If compatibilities are included in the package insert from the manufacturer, it will be so stated. If the manufacturer lists drugs as compatible by additive or Y-site and doesn't list concentrations, this is a good assurance of compatibility. If concentrations are listed, review the concentrations of both drugs to make sure they are within the defined parameters.

- If the drug you wish to administer is listed in the **Compatibility** section of the access you wish to use (e.g., **additive or Y-site**), **you must consult with the pharmacist to confirm any specific conditions that may apply**. After your consultation, write the results of your consultation regarding the specific directions for co-administering drugs on the patient's medication record or nursing care plan so others will not need to retrace your research steps when the medication is to be given again.
- When combining drugs in a solution (additives), always consider the required rate adjustments of each drug. Can each drug produce the desired effect at the suggested rate, or is continuous adjustment necessary for one drug, making the combination impractical?
- Y-site means that the specific drug in a specific monograph is compatible at its Y-site with an injection or an infusion containing one of the drugs listed under Y-site. The reverse Y-site compatibility may not be true.
- Although some drugs may be listed as compatible at the Y-site, some drugs can be administered at the Y-site only if they are further diluted in compatible solutions and given as an infusion (e.g., potassium concentrates [e.g., acetates, chlorides, phosphates], saline solution in concentrations greater than 0.9% or NS, amino acids, and dextrose solutions greater than 10% [unless in small amounts such as 50 mL dextrose 50% in insulin-induced hypoglycemia]).
- Because today's hospital units are very specialized (e.g., cancer care, emergency room, intensive coronary care, various intensive care units, transplant units, and orthopedic units to name just a few), nursing staff in each of these areas most likely administer similar combinations of drugs to their patients. **Take the initiative and research the drug combinations that are most frequently used on your unit. Then consult with the pharmacist and make your own compatibility chart for additives and Y-site (if applicable)**. By creating a chart specific to your unit, you will limit the number of consults required with the pharmacist to combinations that fall outside of the parameters you have researched. This approach will save time for every nurse on your unit and will give each of you the necessary compatibility information to administer the IV drug combinations specific to your unit.
- The Solution Compatibility Chart on the inside back cover has been expanded and updated. Diluents that are not identified in Dilution will be listed in this chart.

Rate of Administration: Accepted rates of administration are clearly stated. As a general rule, a slow rate is preferred. 25-gauge needles aid in giving a small amount of medication over time. Problems with rapid or slow injection rates are indicated here. Adjusted rates for infants, children, or the elderly are listed when available. Charts are available in selected monographs.

Actions: Clear, concise statements outline the origin of each drug, how it affects body systems, its length of action, and methods of excretion. If a drug crosses the placental barrier or is secreted in breast milk, it will be mentioned here if that information is available.

Indications and Uses: Uses recommended by the manufacturer are listed. **Limitations of Use** are now being identified by the manufacturer or FDA for some drugs. Unlabeled uses are stated as such.

Contraindications: Contraindications are those specifically listed by the manufacturer. Consult with the physician if an ordered drug is contraindicated for the patient. The physician may have additional historical information that alters the situation or may decide that use of the drug is indicated in a critical situation.

Precautions: The section on precautions covers many areas of information needed before injecting any drug, including black-box warnings from the prescribing information. Most Black Box Warnings appear in this Precautions section; however, **all actual Black Box Warning statements are shaded in light gray and a different typeface is used** for instant identification wherever they appear in the text. The range of information in this category covers all facets not covered under specific headings. Each listing is as important as the

next. To make it easier for spot checks (after reading the entire monograph), additional subdivisions are included.

Monitor: A subheading that includes information such as required prerequisites for drug administration, parameters for evaluation, and patient assessments.

Patient Education: A subheading that addresses only specific, important issues required for short-term IV use. It is expected that the health professional will always review the major points in the drug profile with any conscious patient, side effects to expect, how to cope with them, when to report them, special requirements such as the intake of extra fluids, and an overall review of what the drug does, why it is needed, and how long the patient can anticipate receiving it. Patient Medication Guides approved by the FDA are available for most drugs, and it is recommended that the patient review the Medication Guide whenever possible before beginning treatment and repeat the review as indicated.

Maternal/Child: A subheading that addresses FDA pregnancy categories (see Appendix B for a complete explanation), any known specifics affecting patients capable of conception, safety for use during lactation, safety for use in pediatric patients, and any special impact on infants and neonates.

Elderly: A subheading that is included whenever specific information impacting this patient group is available. Always consider age-related organ impairment (e.g., cardiac, hepatic, renal, insufficient bone marrow reserve), history of previous or concomitant disease or drug therapy, and route of excretion when determining dose and evaluating side effects.

Drug/Lab Interactions: Drug/drug or drug/lab interactions are listed here. To help identify these interactions more easily, **single drugs, drug categories when there are multiple drugs, and specific tests are in boldface type**. If a conflict with the patient's drug profile is noted, consult a pharmacist immediately. Increasing or decreasing the effectiveness of a drug can be a potentially life-threatening situation. Check with the lab first on drug/lab interactions; acceptable alternatives are usually available. After this consultation, notify the physician if appropriate. To facilitate recognition, common trade names accompany generic names or examples are presented for drug categories. No other reference consistently provides this helpful information.

Side Effects: In some monographs, the most common side effects may be listed first, followed by the most serious side effects. In all monographs, alphabetical order simplifies confirmation that a patient's symptom could be associated with specific drug use. Specific symptoms of overdose are listed where available or distinct from usual doses.

Post-Marketing: Post-marketing side effects reported that have not been previously recorded in the prescribing information are listed.

Antidote: Specific antidotes are listed in this section if available. In addition, specific nursing actions to reverse undesirable side effects are clearly stated—an instant refresher course for critical situations.

Within a heading there may be references to other sections within an individual monograph (e.g., see Precautions, see Monitor, see Dose Adjustments, see Maternal/Child). These references indicate additional requirements and should be consulted before administering the drug.

KEY TO ABBREVIATIONS

<	less than	D10W	10% dextrose in water
>	more than	D5/1/4NS	5% dextrose in one-quarter normal saline (0.2%)
1/4NS	one-fourth normal saline (0.2%)	D5/1/3NS	5% dextrose in one-third normal saline (0.33%)
1/3NS	one-third normal saline (0.33%)	D5/1/2NS	5% dextrose in one-half normal saline (0.45%)
1/2NS	one-half normal saline (0.45%)	D5LR	5% dextrose in lactated Ringer's solution
ABGs	arterial blood gases	D5NS	5% dextrose in normal saline
ACE	angiotensin converting enzyme	D5R	5% dextrose in Ringer's solution
ACT	activated coagulation time	D5W	5% dextrose in water

aPTT	activated partial thromboplastin time	EEG	electroencephalogram
ARDS	adult respiratory distress syndrome/ acute respiratory distress syndrome	ESRD	end-stage renal disease
AST	(SGOT) aspartate aminotransferase	F	Fahrenheit
AUC	area under the curve	GI	gastrointestinal
AV	atrioventricular	GFR	glomerular filtration rate
BMD	bone mass density	Gm	gram(s)
BP	blood pressure	gr	grain(s)
BSA	body surface area	gtt	drop(s)
BUN	blood urea nitrogen	GU	genitourinary
BWFI	bacteriostatic water for injection	Hb	hemoglobin
C	Celsius	Hct	hematocrit
Ca	calcium	Hg	mercury
CABG	coronary artery bypass graft	HIV	human immunodeficiency virus
CAD	coronary artery disease	hr	hour
CAPD	continuous ambulatory peritoneal dialysis	HR	heart rate
CBC	complete blood cell count	HSCT	hematopoietic stem cell transplant
CDAD	<i>Clostridium difficile</i> -associated diarrhea	ICU	intensive care unit
CHF	congestive heart failure	IgA	immune globulin A
Cl	chloride	IGIV	immune globulin intravenous
CNS	central nervous system	lL	microliters, μL , mm^3
CO₂	carbon dioxide	IM	intramuscular
CPK	creatinine-kinase	INR	International Normalized Ratio
CrCl	creatinine clearance	IP	intrapleural
CRF	chronic renal failure	IU	international unit(s)
CRT	controlled room temperature (20° to 25° C [68° to 77° F])	IV	intravenously
CSF	cerebrospinal fluid	IVIG	intravenous immune globulin
C/S	culture and sensitivity	K	potassium
CTCAE	Common Terminology Criteria for Adverse Events	KCl	potassium chloride
CVP	central venous pressure	kg	kilogram(s)
D10NS	10% dextrose in normal saline	L	liter(s)

lb	pound(s)	PSVT	paroxysmal supraventricular tachycardia
LDH	lactic dehydrogenase	PT	prothrombin time
LR	lactated Ringer's injection or solution	PTT	partial thromboplastin time
M	molar	PVC	polyvinyl chloride; premature ventricular contraction
M²	meter squared	R	Ringer's injection or solution
MAO	monoamine oxidase	RBC	red blood cell
MAP	mean arterial pressure	refrigerate	temperature at 2° to 8° C (36° to 46° F)
mcg	microgram(s)	RNA	ribonucleic acid
mCi	millicurie(s)	RT	room temperature
mEq	milliequivalent	RTS	room-temperature stable
Mg	magnesium	SA	sinoatrial
mg	milligram(s)	SC	subcutaneous
MI	myocardial infarction	SOB	shortness of breath
min	minute	SCr	serum creatinine
mL	milliliter	S/S	signs and symptoms
mmol	millimole(s)	SW or SWI	sterile water for injection
mm³	cubic millimeters, μL , fL	TEN	toxic epidermal necrolysis
MDRSP	multidrug-resistant strains	TIA	transient ischemic attacks
MRI	magnetic resonance imaging	TLS	tumor lysis syndrome
Na	sodium	TNA	3-in-1 combination of amino acids, glucose, and fat emulsion
NaCl	sodium chloride	TPN	2-in-1 combination of amino acids and glucose; total parenteral nutrition
NCI	National Cancer Institute; see CTCAE	TRALI	transfusion-related acute lung injury
ng	nanogram (millimicrogram)	TT	thrombin time
NS	normal saline (0.9%)	μL	microliters, mm^3 , fL
NSAID	nonsteroidal anti-inflammatory drug	ULN	upper limits of normal
NSCLC	non-small-cell lung cancer	URI	upper respiratory infection
NSR	normal sinus rhythm	UTI	urinary tract infection
N/V	nausea and vomiting	VF	ventricular fibrillation
OTC	over-the-counter	VS	vital signs
PAC	premature atrial contraction	VT	ventricular tachycardia
Pao₂	arterial oxygen pressure	v/v	volume-to-volume ratio
PCA	patient controlled analgesia	WBC	white blood cell
PCP	<i>Pneumocystis jiroveci</i> pneumonia	WBCT	whole blood clotting time
pg	picogram	w/v	weight-to-volume ratio
pH	hydrogen ion concentration	w/w	weight-to-weight ratio
PML	progressive multifocal leukoencephalopathy		
PO	by mouth/orally		
PRES	posterior reversible encephalopathy syndrome		

IMPORTANT IV THERAPY FACTS

- Read the Preface and Format and Contents sections at least once. They'll answer many of your questions and save time.

USUAL DOSE

- Doses calculated on body weight are usually based on pretreatment weight and not on edematous weight.
- Normal renal or hepatic function is usually required for drugs metabolized by these routes.
- Formula to calculate creatinine clearance (CrCl) from serum creatinine value (Cockcroft-Gault equation):

$$\text{Males: } \frac{\text{Weight in kg} \times (140 - \text{Age in years})}{72 \times \text{Serum creatinine (mg/dL)}} = \text{CrCl}$$

Females: $0.85 \times$ Male CrCl value calculated from above formula.

- Children: $K \times \frac{\text{Linear length or height (cm)}}{\text{SCr (mg/100 mL)}}$
K for children >1 year of age = 0.55
K for infants = 0.45
- Lean Body Weight (LBW)
Males = 50 kg + 2.3 kg for each inch over 5 foot.
Females = 45.5 kg + 2.3 kg for each inch over 5 foot.
Children weighing 15 kg or less—Use actual body weight in kg.
- Formula to calculate body surface area (BSA):

$$\text{BSA (M}^2\text{)} = \sqrt{\frac{\text{Height (cm)} \times \text{Weight (kg)}}{3600}}$$

DILUTION

- Check all labels (drugs, diluents, and solutions) to confirm appropriateness for IV use.
- Sterile technique is imperative in all phases of preparation.
- Use a filter needle when withdrawing IV meds from ampules to eliminate possible pieces of glass.
- Pearls: 1 Gm in 1 Liter yields 1 mg/mL
1 mg in 1 Liter yields 1 mcg/mL
% of a solution equals the number of grams/100 mL
(5% = 5 Gm/100 mL)
- Pediatric dilution: If you dilute 6.0 mg/kg in 100 mL, 1 mL/hr equals 1.0 mcg/kg/min
If you dilute 0.6 mg/kg in 100 mL, 1 mL/hr equals 0.1 mcg/kg/min
- See charts on inside front cover.
- Do not use bacteriostatic diluents containing benzyl alcohol for neonates. May cause a fatal toxic syndrome. S/S include CNS depression, hypotension, intracranial hemorrhage, metabolic acidosis, renal failure, respiratory problems, seizures.
- Ensure adequate mixing of all drugs added to a solution.
- When combining drugs in a solution (additives), always consider the required rate adjustment of each drug.
- Examine solutions for clarity and any possible leakage.
- Frozen infusion solutions should be thawed at room temperature (25° C [77° F]) or under refrigeration. Do not force by immersion in water baths or in the microwave. All ice crystals must be melted before administration. Do not refreeze.

- Syringe prepackaging for use in specific pumps is now available for many drugs. Concentrations are often the strongest permissible, but length of delivery is accurate.
- Controlled room temperature (CRT) is considered to be 25° C (77° F). Most medications tolerate variations in temperature from 15° to 30° C (59° to 86° F).

INCOMPATIBILITIES

- Some manufacturers routinely suggest discontinuing the primary IV for intermittent infusion; usually done to avoid any possibility of incompatibility. Flushing the line before and after administration may be indicated and/or appropriate for some drugs.
- The brand of intravenous fluids or additives, concentrations, containers, rate and order of mixing, pH, and temperature all affect solubility and compatibility. Consult your pharmacist with any question, and document appropriate instructions on care plan.

TECHNIQUES

- Never hang plastic containers in a series connection; may cause air embolism.
- Confirm patency of peripheral and/or central sites. Avoid extravasation.
- Avoid accidental arterial injection; can cause gangrene.

RATE OF ADMINISTRATION

- Life-threatening reactions (time-related overdose or allergy) are frequently precipitated by a too-rapid rate of injection.

PATIENT EDUCATION

- A well-informed patient is a great asset; review all appropriate drug information with every conscious patient.

SIDE EFFECTS

- Reactions may be caused by a side effect of the drug itself, allergic response, overdose, or the underlying disease process.

RESOURCES

PUBLICATIONS

The following publications have been used as a resource to assemble the information found in *Intravenous Medications*. Additional and more detailed information on drugs may be found in these publications:

ABATACEPT

(a-BAY-ta-sept)

Anti-rheumatic agent

Orencia

pH 7.2 to 7.8

USUAL DOSE

Dose is based on body weight in kilograms as shown in the following chart. After the initial dose, repeat administration at 2 and 4 weeks. Administer every 4 weeks thereafter. May be used as monotherapy or concomitantly with disease-modifying anti-rheumatic drugs (DMARDs) other than TNF antagonists; see [Contraindications](#) and [Drug Interactions](#). May be given by SC injection in adults; formulation and dose are different; see [Indications](#) and prescribing information.

Abatacept Adult Dosing Guidelines		
Body Weight (kg)	Dose (mg)	Number of Vials
<60 kg	500 mg	2 vials
60 to 100 kg	750 mg	3 vials
>100 kg	1,000 mg	4 vials

PEDIATRIC DOSE

Pediatric patients 6 to 17 years of age who weigh less than 75 kg: 10 mg/kg/dose based on patient's body weight at each administration. After the initial dose, repeat administration at 2 and 4 weeks. Administer every 4 weeks thereafter.

Pediatric patients 6 to 17 years of age who weigh more than 75 kg: See [Usual Dose](#) and the [Abatacept Adult Dosing Guidelines](#) chart. Do not exceed a maximum dose of 1,000 mg.

DOSE ADJUSTMENTS

There is a trend toward a higher clearance with increasing body weight; see [Usual Dose](#). No specific dose adjustments are required based on age or gender when corrected for body weight. ■ Withhold therapy in patients with severe infections. ■ The effects of renal or hepatic impairment have not been studied.

DILUTION

Using **ONLY the silicone-free disposable syringe provided** with each vial and an 18- to 21-gauge needle, reconstitute each 250-mg vial with 10 mL SWFI; final concentration is 25 mg/mL. (If reconstituted with a siliconized syringe, the solution must be discarded.) Direct stream of SWFI toward side of vial. Do not use vial if vacuum is not present. Rotate or swirl vial gently until contents have dissolved. Do not shake. After dissolution, vent vial with a needle to dissipate any foam that may be present. Solution should be clear and colorless to pale yellow. Reconstituted solution must be further diluted to 100 mL as follows: From a 100-mL infusion bag or bottle, withdraw a volume of NS equal to the volume of reconstituted abatacept solution required for the patient's dose (for 2 vials, remove 20 mL; for 3 vials, remove 30 mL; for 4 vials, remove 40 mL). Using the **same silicone-free disposable syringe provided**, slowly add the reconstituted abatacept into the infusion bag or bottle. Mix gently.

Filter: Administration through a 0.2- to 1.2-micron, non-pyrogenic, low-protein binding filter is required.

Storage: Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Do not use beyond expiration date. Protect from light. Before administration, the diluted solution may be stored at RT or refrigerated; however, infusion of the diluted solution should be completed within 24 hours of reconstitution. Discard diluted solution if not administered within 24 hours.

COMPATIBILITY

Manufacturer states, “Should not be infused concomitantly in the same intravenous line with other agents.” **Compatibility** studies have not been performed.

RATE OF ADMINISTRATION

Administration through a 0.2- to 1.2-micron, non-pyrogenic, low-protein binding filter is required.

A single dose equally distributed over 30 minutes.

ACTIONS

A soluble fusion protein that consists of the extracellular domain of human cytotoxic, T-lymphocyte-associated antigen 4 linked to the modified Fc portion of human immunoglobulin G1 (IgG1). Produced by recombinant DNA technology. Acts as a selective biologic response modulator by inhibiting T-lymphocyte activation, which is implicated in the pathogenesis of rheumatoid arthritis. Reduces pain and joint inflammation and slows the progression of structural damage to bone and cartilage. Mean half-life is 13.1 days (range 8 to 25 days).

INDICATIONS AND USES

Reduce the S/S, induce a major clinical response, inhibit the progression of structural damage, and improve the physical function in adult patients with moderately to severely active rheumatoid arthritis. May be used as monotherapy or concomitantly with DMARDs other than TNF antagonists. SC injection may be used in adult patients unable to receive an infusion, and/or adult infusion patients may transition to SC injection; see prescribing information. ■ Reduce the S/S in pediatric patients 6 years of age and older with moderately to severely active polyarticular juvenile idiopathic arthritis. May be used as monotherapy or concomitantly with methotrexate.

CONTRAINDICATIONS

Known hypersensitivity to abatacept or any of its components (maltose, monobasic sodium phosphate). Concomitant use with TNF antagonists or other biological rheumatoid arthritis agents such as anakinra (Kineret) is not recommended; see [Drug/Lab Interactions](#).

PRECAUTIONS

Concurrent use with a TNF antagonist (e.g., adalimumab [Humira], etanercept [Enbrel]) is associated with an increased risk of serious infections with no associated increased efficacy when compared with use of the TNF antagonist alone. Concurrent use is not recommended; see [Contraindications](#) and [Drug/Lab Interactions](#). ■ Hypersensitivity reactions, including anaphylaxis, have been reported. Emergency medical equipment and medications for treating these reactions must be readily available. ■ Serious infections, including sepsis and pneumonia, have been reported; some have been fatal. Patients receiving concomitant immunosuppressive therapy may be at increased risk. ■ Use caution in patients with a history of recurrent infections, underlying conditions that may predispose them to infections, or chronic, latent, or localized infections; see [Monitor](#). ■ Anti-rheumatic therapies have been associated with hepatitis B reactivation. Screening for viral hepatitis should be done before starting therapy with abatacept. Patients who screened positive for hepatitis were excluded from clinical studies. ■ Use with caution in patients with COPD. May be at increased risk for developing respiratory adverse events (e.g., COPD exacerbation, cough, dyspnea, rhonchi). ■ A small number of patients have developed binding antibodies to abatacept. No correlation of antibody development to clinical response or adverse events has been observed. ■ T-cells mediate cellular immune responses. Therefore drugs that inhibit T-cell activation, including abatacept, may affect patient defenses against infection and malignancies. The impact of abatacept on the development and course of malignancies is not fully understood. ■ See [Maternal/Child](#).

Monitor: Evaluate patients for latent tuberculosis (TB) with a TB skin test. Patients testing positive in TB screening should be treated with a standard TB regimen before initiating therapy with abatacept. ■ Screening for viral hepatitis is recommended before initiating therapy with abatacept; virus may reactivate with abatacept treatment. ■ Monitor for S/S of infection, especially if transitioning patient from TNF antagonist therapy to therapy

with abatacept. Discontinue therapy if a serious infection develops. ■ Monitor COPD patients for worsening of respiratory status. ■ Monitor for S/S of hypersensitivity or infusion-related reactions; see [Side Effects](#). ■ Do not administer live virus vaccines during or within 3 months of use. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Read manufacturer's patient information sheet prior to each infusion. ■ Review medication list and vaccination status with physician; see [Precautions](#). ■ Report S/S of allergic reaction (e.g., rash, itching wheezing), infusion reaction (e.g., dizziness, headache), or infection promptly. Discuss previous infections, current infections, or exposure to TB.

Maternal/Child: Category C: safety for use in pregnancy has not been established. Has been shown to cross the placenta in animal studies. Use caution. ■ Discontinue breast-feeding. ■ A pregnancy registry has been established; contact manufacturer. ■ Safety and effectiveness for use in pediatric patients under 6 years of age not established. ■ Safety and effectiveness for uses other than juvenile idiopathic arthritis in pediatric patients have not been established. ■ Patients with juvenile idiopathic arthritis should be brought up-to-date with all immunizations before initiating therapy with abatacept.

Elderly: Specific differences in safety and efficacy not noted. Incidence of infection and malignancy is higher in the elderly. Use caution; see [Precautions](#).

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Has been used with methotrexate, NSAIDs (e.g., naproxen [Naprosyn, Aleve], ibuprofen [Motrin, Advil]), corticosteroids (e.g., prednisone), azathioprine (Imuran), chloroquine (Aralen), gold (Myochrysin), hydroxychloroquine (Plaquenil), leflunomide (Arava), and sulfasalazine (Azulfidine). ■ Methotrexate, NSAIDs, corticosteroids, and TNF antagonists do not appear to influence abatacept clearance. ■ Concurrent use with a **TNF antagonist** (e.g., adalimumab [Humira], etanercept [Enbrel], infliximab [Remicade]) is associated with an increased risk of serious infections and no significant additional efficacy over use of the TNF antagonist alone. Concurrent use is not recommended. ■ With the IV formulation, falsely elevated blood glucose readings may occur on the day of the infusion with **specific blood glucose monitoring systems** that react to drug products containing maltose. IV formulation contains maltose; SC formulation does not contain maltose; see prescribing information. ■ Safety and efficacy of concurrent use with **anakinra** (Kineret) has not been established. Concurrent use is not recommended. ■ **Live virus vaccines** should not be given concurrently with or within 3 months of abatacept. ■ May blunt the effectiveness of some **vaccinations**.

SIDE EFFECTS

In adult and pediatric patients, side effects are similar in type and frequency. The most commonly reported side effects are headache, nasopharyngitis, nausea, and upper respiratory tract infections. The most serious adverse effects are infections and malignancies. Infections are the most likely adverse event to cause interruption or discontinuation of therapy. Acute infusion-related reactions (cough, dyspnea, dizziness, flushing, headache, hypertension, hypotension, nausea, pruritus, rash, urticaria, wheezing) have been reported and usually occur within 1 hour of the infusion. Hypersensitivity reactions (anaphylaxis [rare], dyspnea, hypotension, urticaria) have been reported, usually within 24 hours of infusion. Other reactions include back or extremity pain, COPD exacerbation, dyspepsia, immunogenicity (antibody formation), and rhonchi.

Post-Marketing: Vasculitis (including cutaneous vasculitis and leukocytoclastic vasculitis).

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. During clinical studies, most infusion-related reactions were mild to moderate, and therapy was discontinued in very few patients. Discontinue abatacept for any serious reaction or infection. Therapy may need to be interrupted in patients who develop infections. Treat infusion and hypersensitivity reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Resuscitate as necessary.

ABCIXIMAB

(ab-SIX-ih-mab)

Platelet aggregation inhibitor
 Antithrombotic
 Monoclonal antibody

ReoPro

pH 7.2

USUAL DOSE

Premedication: In all situations, premedication with histamine H₂ antagonists (e.g., famotidine [Pepcid], ranitidine [Zantac]) may be appropriate; prophylaxis should be considered when certain conditions are present (e.g., patients with HACA antibodies, readministration of abciximab).

Percutaneous coronary intervention: 0.25 mg/kg administered 10 to 60 minutes before percutaneous coronary intervention (PCI). Follow with a continuous infusion of 0.125 mcg/kg/min (weight adjusted) to a maximum of 10 mcg/min (non-weight adjusted) for 12 hours. Used concurrently with **heparin** and **aspirin**. Establish a separate IV site for heparin. Various heparin regimens were used in clinical studies; examples used in early studies include the following text and charts. See prescribing information for additional regimens. The initial bolus of **heparin** was based on the results of the baseline ACT according to low-dose weight-adjusted guidelines in the following chart, but not exceeding a total bolus dose of 7,000 units.

Guidelines for Heparin Dosing					
Low-Dose Weight-Adjusted Heparin (Target ACT ≥200 seconds)			Standard-Dose Weight-Adjusted Heparin (Target ACT ≥300 seconds)		
Initial Bolus	ACT (sec)	Heparin	Initial Bolus	ACT (sec)	Heparin
Not to exceed 7,000 units in patients >100 kg	<150	70 units/kg	Not to exceed 10,000 units in patients >100 kg	<150	100 units/kg
	150 to 199	50 units/kg		150 to 225	75 units/kg
	≥200	No heparin		226 to 299	50 units/kg
≥300				No heparin	
Additional bolus every 30 min or a 7-unit/kg/hr continuous infusion	<200	20 units/kg	Additional bolus every 30 min or a 10-unit/kg/hr continuous infusion	<275	50 units/kg
	≥200	No heparin		275 to 299	25 units/kg
				≥300	No heparin

Check ACT (Hemochron instrument used to measure) a minimum of 2 minutes after the initial and each additional heparin bolus. Give additional bolus doses of 20 units/kg until the target ACT of 200 seconds is achieved before PCI (a target ACT of up to 300 seconds using standard weight-adjusted doses of heparin has been used [see preceding chart] but may increase the risk of severe bleeding). During the procedure administer additional bolus doses every 30 minutes to maintain the target ACT. Alternately, after the target ACT is reached, a 7-unit/kg/hr continuous infusion *may be administered with no further measurement of ACT for the duration of the procedure. Unless contraindicated, administer aspirin, 325 mg, 2 hours before PCI and once daily thereafter.* At the completion of the procedure it is recommended that the heparin be discontinued and that removal of the sheath be accomplished within 6 hours; see **Monitor** for specific criteria. If prolonged therapy or later sheath removal is clinically indicated, do not discontinue heparin, but continue the 7-unit/kg/hr heparin infusion. Check the aPTT in 6 hours and adjust rate of heparin based on a target aPTT of 60 to 85 seconds. See **Precautions/Monitor**.

Unstable angina not responding to conventional medical therapy with planned PCI within 24 hours: *Heparin* is started before the abciximab; use a separate IV line. Maintain the aPTT between 60 and 85 seconds during the abciximab and heparin infusion period. Recent recommendations suggest that the low-dose weight-adjusted doses of heparin and anticoagulation guidelines described above are also appropriate for the planned PCI in unstable angina. The recommended dose of abciximab is 0.25 mg/kg as an IV bolus followed by a continuous infusion of 10 mcg/min for a minimum of 18 hours up to a maximum of 26 hours (PCI usually accomplished between 18 and 24 hours). Discontinue abciximab 1 hour after the PCI (i.e., removal of guidewire). Unless contraindicated, administer at least 250 mg of *aspirin* at the time heparin is begun and aspirin 50 to 500 mg daily through day 30. Oral or IV nitroglycerin may also be indicated throughout the course of treatment. The process after the completion of the procedure is the same as in percutaneous coronary intervention.

DILUTION

Available in 5-mL vials (2 mg/mL). Solution must be clear. Must be filtered with a non-pyrogenic, low-protein binding 0.2- to 0.5-micron filter before administering the bolus and the infusion. Filtering of the infusion may be done during preparation or at administration, using the appropriate in-line filter. Do not shake.

IV injection: Bolus injection may be given undiluted.

Infusion: Withdraw desired dose and further dilute with NS or D5W (5 mL [10 mg] diluted with 250 mL NS or D5W equals 40 mcg/mL).

Filters: Must be filtered with a nonpyrogenic, low-protein binding 0.2- to 0.22-micron filter before administering the bolus and the infusion. Filtering of the infusion may be done during preparation or at administration, using the appropriate in-line filter; see [Dilution](#).

Storage: Refrigerate before use. Do not freeze. Check expiration date on vial. Contains no preservative; discard any unused portion.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

According to the manufacturer, no **incompatibilities** have been shown with IV fluids or commonly used cardiovascular drugs; however, administration through a separate IV line and not mixing with other medications is recommended. No **incompatibilities** observed with glass bottles or polyvinyl chloride bags and administration sets.

One source suggests the following **compatibilities**:

Y-site: Adenosine (Adenocard, Adenoscan), argatroban, atropine, bivalirudin (Angio-max), diphenhydramine (Benadryl), fentanyl (Sublimaze), metoprolol (Lopressor), midazolam (Versed).

RATE OF ADMINISTRATION

IV injection: An initial dose as a bolus injection; filter at this point if not done when withdrawing from vial.

Infusion: See [Usual Dose](#). Must be administered through an in-line, nonpyrogenic, low-protein binding filter (0.2 or 0.22 microns), if not done during preparation, and controlled by a continuous infusion pump. A 40-mcg/mL solution (10 mg in 250 mL) at a rate of 10.5 mL/hr will deliver 7 mcg/min, and 15 mL/hr will deliver 10 mcg/min. Discard unused portion at the end of the infusion.

ACTIONS

The Fab fragment of the chimeric human-murine monoclonal antibody, abciximab binds to the glycoprotein GPIIb/IIIa receptor of human platelets and produces rapid dose-dependent inhibition of platelet function. It inhibits platelet aggregation by preventing the binding of fibrinogen, von Willebrand factor, and other adhesive molecules to GPIIb/IIIa receptor sites on activated platelets. Inhibition of platelet function is temporary following a bolus dose, but can be sustained at greater than 80% by continuous IV infusion. Has prevented acute thrombosis and resulted in lower rates of thrombosis as compared to aspirin and/or heparin. Initial half-life is 10 minutes. Second phase half-life is

30 minutes. After the infusion is ended, platelet function generally recovers gradually over 48 hours. In most patients, bleeding time returns to less than 12 minutes within 12 to 24 hours. Some abciximab remains in the circulation for 15 days or more.

INDICATIONS AND USES

An adjunct to PCI for the prevention of cardiac ischemic complications in patients undergoing PCI and in patients with unstable angina not responding to conventional medical therapy when PCI is planned within 24 hours. Abciximab use in patients not undergoing PCI has not been studied. Used concurrently with aspirin and heparin.

Unlabeled uses: Combined with low-dose alteplase or low-dose reteplase in the early treatment of acute MI. ■ Treatment of acute ischemic stroke.

CONTRAINDICATIONS

Active internal bleeding, administration of oral anticoagulants (e.g., warfarin [Coumadin]) within 7 days unless PT is at or less than 1.2 times control, aneurysm, arteriovenous malformation, bleeding diathesis, clinically significant GI or GU bleeding within 6 weeks, history of CVA within 2 years, history of CVA with significant residual neurologic deficit, history of vasculitis (presumed or documented), hypertension (severe and uncontrolled), intracranial neoplasm, known hypersensitivity to any component of abciximab or to murine proteins, major surgery or trauma within 6 weeks, thrombocytopenia (less than 100,000/mm³), or the use of IV dextran before PCI or intent to use it during PCI.

PRECAUTIONS

Administered only in the hospital under the direction of a physician knowledgeable in its use and with appropriate diagnostic, laboratory, and surgical facilities available. ■ Frequently causes major bleeding complications (e.g., retroperitoneal bleeding, spontaneous GI and GU bleeding, bleeding at the arterial access site). ■ Incidence of major bleeding was reduced in clinical trials that used weight-adjusted dosing of abciximab and low-dose weight-adjusted doses of heparin, with adherence to stricter anticoagulation guidelines and early sheath removal. This was true in patients weighing less than 75 kg (165 lb) that had increased incidences of bleeding with standard weight-adjusted heparin doses. ■ Incidence of major bleeding is increased in patients with a history of prior GI disease and in those receiving heparin, other anticoagulants, or thrombolytics (e.g., alteplase [tPA], reteplase [r-PA], streptokinase). Consider if benefits will outweigh risks, and proceed with extreme caution if use is considered necessary. ■ Incidence of major bleeding is also increased if PCI occurs within 12 hours of the onset of symptoms of an acute MI, if the PCI procedure is prolonged (lasting more than 70 minutes), or if PCI procedure fails. ■ Extreme care must be taken in accessing the femoral artery for femoral sheath placement. Only the anterior wall of the femoral artery should be punctured (use of a single-walled needle versus double-walled [Seldinger through and through technique] is important). If both walls are punctured, massive bleeding could occur. ■ Avoid concurrent sheath placement in the femoral vein if possible (sometimes used to access right coronary artery or administer large amounts of medication). ■ Use of heparin concurrently also increases the risk of bleeding. ■ Anaphylaxis can occur at any time (a protein solution). Emergency drugs and equipment must always be available. In addition, use may result in the formation of human anti-chimeric antibody (HACA). Can cause hypersensitivity reactions including anaphylaxis, thrombocytopenia, or diminished benefit if abciximab is readministered at another time or other monoclonal antibodies are administered. Consider premedication as outlined under Usual Dose. ■ See [Drug/Lab Interactions](#).

Monitor: Before initiating, obtain results of baseline CBC, platelet count, PT, ACT, and aPTT. Type and cross-match would also be appropriate. ■ Monitor heparin anticoagulation (ACT or aPTT) and PT closely. ■ While a femoral sheath is in place, the patient must be on strict bed rest, head of the bed should be less than 30 degrees, and the appropriate limb(s) restrained in a straight position. Monitor sheath insertion site(s) and distal pulses of affected leg(s) frequently while sheath is in place and for 6 hours after removal. Measure any hematoma and monitor for enlargement. ■ Monitor platelet count

2 to 4 hours following the bolus dose and at 24 hours or before discharge, whichever is first. More frequent monitoring may be indicated. ■ Monitor patient carefully and frequently for signs of bleeding; take vital signs (avoiding automatic BP cuffs), observe any invaded sites at least every 15 minutes (e.g., sheaths, IV sites, cutdowns, punctures, Foleys, NGs); watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, muscle weakness; and do neuro checks every hour. Continue until clotting functions move toward normal. ■ Use care in handling patient; avoid arterial puncture, venipuncture, and IM injection. Use extreme precautionary methods and only compressible sites if these procedures are absolutely necessary. Apply pressure for 30 minutes to any invaded site and then apply pressure dressings. Saline or heparin locks are suggested to facilitate blood draws. ■ Discontinue heparin at least 2 to 4 hours before femoral sheath(s) are to be removed. Sheath removal should not occur until aPTT is at or less than 50 seconds or ACT is at or less than 175 seconds (approaching normal limits). Discontinue heparin after PCI, and remove sheath no sooner than 2 hours and no later than 6 hours after heparin is discontinued and while the abciximab is still infusing (aPTT must be at or less than 50 seconds or ACT at or less than 175 seconds). After removal, apply pressure to the femoral artery for at least 30 minutes. When hemostasis is confirmed, apply a pressure dressing. Maintain strict bed rest for at least 6 to 8 hours after sheath removal and/or abciximab is discontinued or 4 hours after heparin is discontinued, whichever is later. ■ Throughout process medicate as needed for back or groin pain and nausea or vomiting. ■ Remove pressure dressing before ambulation. ■ If complications arise that indicate the need for surgery within 48 to 72 hours of treatment with abciximab, an Ivy bleeding time should be obtained. Platelet function may be partly restored with platelet transfusions. ■ See **Precautions, Drug/Lab Interactions, and Antidote**.

Patient Education: Compliance with all measures to minimize bleeding (e.g., strict bed rest, positioning) is imperative. ■ Avoid use of razors, toothbrushes, and other sharp items. ■ Use caution while moving to avoid excessive bumping. ■ Report all episodes of bleeding and apply local pressure if indicated. ■ Expect oozing from IV sites.

Maternal/Child: Category C: use only if clearly needed and with extreme caution. ■ Safety for use during breast-feeding not established. Not known if it is secreted in breast milk; use extreme caution; probably best to postpone breast-feeding until bleeding time approaches normal. ■ Safety and effectiveness for use in pediatric patients not established. Incidence of side effects may be increased with a weight under 75 kg.

Elderly: Increased risk of major bleeding complications if weight less than 75 kg or age over 65 years; see **Precautions**. ■ Consider age-related organ impairment, concomitant disease, or drug therapy; may also increase risk of bleeding.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Use with extreme caution with other drugs that affect hemostasis (e.g., **thrombolytics** [e.g., alteplase (tPA), streptokinase], **anticoagulants** [e.g., heparin, warfarin (Coumadin)], **NSAIDs** [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], **platelet aggregation inhibitors** [e.g., clopidogrel (Plavix), dipyridamole (Persantine), ticlopidine (Ticlid)] and **other glycoprotein GPIIb/IIIa receptor antagonists** [e.g., eptifibatid (Integrilin), tirofiban (Aggrastat)], and **selected antibiotics** [e.g., cefotetan]). ■ **Dextran solutions** increased the risk of major bleeding events when used concurrently with abciximab; see **Contraindications**. ■ **HACA titer** may precipitate an acute hypersensitivity reaction with other **diagnostic or therapeutic monoclonal antibodies** (e.g., muromonab-CD3).

SIDE EFFECTS

May cause major bleeding incidents (e.g., femoral artery or other access site, intracranial hemorrhage, spontaneous gross hematuria and other GU bleeds, spontaneous hematemesis and other GI bleeds, pulmonary hemorrhage, retroperitoneal bleeding). Decreases in hemoglobin greater than 5 Gm/dL or intracranial hemorrhage were defined as major during trials. Thrombocytopenia is common and may require platelet transfusion. Abdominal pain, back pain, bradycardia, chest pain, headache, hypotension, nausea, peripheral edema, positive HACA response, puncture site pain, and vomiting may occur. Other side

effects that may occur are anemia, arrhythmias (e.g., atrial fibrillation/flutter, bradycardia, complete AV block, supraventricular tachycardia, ventricular PVCs, tachycardia, or fibrillation), confusion, hyperesthesia, intermittent claudication, leukocytosis, limb embolism, pericardial effusion, pleural effusion or pleurisy, pneumonia, pulmonary embolism, pulmonary edema, and visual disturbances. Anaphylaxis has not been reported but may occur.

ANTIDOTE

Stop the infusions of abciximab and heparin if any serious bleeding not controllable with pressure occurs. Stop infusion in patients with failed PCIs. Stop infusion if a hypersensitivity reaction occurs. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Keep physician informed. If an acute platelet decrease occurs (less than 100,000/mm³ or a decrease of at least 25% from pretreatment value), obtain additional platelet counts in separate tubes containing ethylenediaminetetraacetic acid (EDTA), citrate, or heparin. This is to exclude pseudothrombocytopenia due to anticoagulant interaction. If true thrombocytopenia is verified, discontinue abciximab immediately. Platelet transfusions may be required. Heparin and aspirin should also be avoided if the platelet count drops below 60,000/mm³.

ACETAMINOPHEN

(ah-SEAT-ah-MIN-oh-fen)

Ofirmev

Antipyretic
Analgesic

pH 5.5

USUAL DOSE

May be given as a single or repeated dose. Minimum dosing interval is 4 hours. No dose adjustment is necessary when converting from oral to IV dosing. The maximum daily dose of acetaminophen is based on all routes of administration (i.e., IV, oral, and rectal) and on all products containing acetaminophen.

Summary of Acetaminophen Dosing in Adults and Adolescents

Age-Group	Dose Given q 4 hr	Dose Given q 6 hr	Maximum Single Dose	Maximum Total Daily Dose of Acetaminophen (By Any Routes)
Adults and adolescents (13 years and older) weighing ≥ 50 kg	650 mg	1,000 mg	1,000 mg	4,000 mg in 24 hr
Adults and adolescents (13 years and older) weighing < 50 kg	12.5 mg/kg	15 mg/kg	15 mg/kg	75 mg/kg in 24 hr (up to 3,750 mg)

PEDIATRIC DOSE

Pediatric patients 2 to 12 years of age: 15 mg/kg every 6 hours or 12.5 mg/kg every 4 hours. Do not exceed a maximum single dose of 15 mg/kg or a maximum daily dose of 75 mg/kg/day. See comments under [Usual Dose](#).

DOSE ADJUSTMENTS

A reduced total daily dose of acetaminophen may be appropriate in patients with hepatic impairment or active liver disease. ■ A reduced total daily dose and longer dosing intervals may be appropriate in patients with a CrCl less than or equal to 30 mL/min.

DILUTION

Available in a single-use vial containing 1,000 mg/100 mL (10 mg/mL) of acetaminophen. For adults and adolescent patients weighing 50 kg or more requiring a 1,000-mg dose, administer the dose by inserting a vented intravenous set through the septum of the 100-mL vial. Doses less than 1,000 mg should be withdrawn from the vial and placed into a separate empty container before administration to avoid inadvertent administration of an overdose. Withdraw appropriate dose (650 mg or weight-based) from 100-mL vial and place in an empty container (e.g., syringe, glass bottle, plastic intravenous container) for intravenous infusion.

Filter: Information not available.

Storage: Store unopened vial at CRT. Do not refrigerate or freeze. Discard 6 hours after entry into vial or transfer into an empty container. Single-use vial. Discard any unused solution.

COMPATIBILITY

Manufacturer states, “Do not add other medications to solution. **Incompatible** with diazepam and chlorpromazine. Do not administer simultaneously.”

RATE OF ADMINISTRATION

Administer as an infusion, equally distributed over 15 minutes. Pediatric doses up to 600 mg may be drawn up into a syringe and delivered via a syringe pump.

ACTIONS

A non-salicylate antipyretic and a non-opioid analgesic agent. Exact mechanism of action is unknown but is thought to act through central actions. Widely distributed into most tissues except fat. Low protein binding (10% to 25%). Half-life is approximately 2 to 3 hours. Metabolized in the liver via three different pathways. Metabolites excreted in the urine.

INDICATIONS AND USES

Management of mild to moderate pain. ■ Management of moderate to severe pain with adjunctive opioid analgesics. ■ Reduction of fever.

CONTRAINDICATIONS

Known hypersensitivity to acetaminophen or to any components of the IV formulation. ■ Patients with severe hepatic impairment or severe active liver disease.

PRECAUTIONS

Administration of doses higher than recommended may result in hepatic injury, including risk of severe hepatotoxicity and death. Do not exceed maximum recommended daily dose. ■ Use with caution in patients with hepatic impairment or active hepatic disease, alcoholism, chronic malnutrition, severe hypovolemia (e.g., due to dehydration or blood loss), or severe renal impairment (CrCl less than or equal to 30 mL/min). ■ Hypersensitivity and anaphylactic reactions have been reported. ■ Antipyretic effects may mask fever in patients treated for postsurgical pain.

Monitor: Monitor for S/S of hypersensitivity reaction (e.g., respiratory distress; pruritus; rash; swelling of the face, mouth, and throat; urticaria). ■ Baseline SCr and liver function tests may be indicated.

Maternal/Child: Category C: epidemiologic data on oral acetaminophen use in pregnant women show no increased risk of major congenital malformations. Safety of IV formulation for use in pregnancy not established. Use only if clearly needed. ■ Assess benefit versus risk before use during labor and delivery. ■ Safety for use in breast-feeding not established. Acetaminophen is secreted in human milk in small quantities after oral administration. Use caution. ■ Safety and effectiveness for treatment of acute pain or fever has not been studied in pediatric patients less than 2 years of age.

Elderly: No overall differences in safety and efficacy were observed between older and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

Substances that induce or regulate hepatic cytochrome enzyme CYP2E1 (e.g., ethanol, isoniazid) may alter the metabolism of acetaminophen and increase its hepatotoxic potential. Effects have not been studied. ■ Ethanol may induce hepatic cytochromes and may act as a competitive inhibitor of the metabolism of acetaminophen. ■ Chronic acetaminophen doses of 4,000 mg/day may cause an increase in INR in patients stabilized on **warfarin**. Effect of short-term use on INR has not been studied. Monitoring of INR recommended. ■ **Many available analgesics contain acetaminophen in combination with another analgesic** (e.g., hydrocodone/acetaminophen [Vicodin, Norco], oxycodone/acetaminophen [Percocet]). Monitor total daily dose of acetaminophen coming from all possible sources.

SIDE EFFECTS

Adult patients: The most common adverse reactions were headache, insomnia, nausea, and vomiting. Less frequently reported side effects included anxiety, dyspnea, fatigue, hypersensitivity reaction, hypertension, hypokalemia, hypotension, increased aspartate aminotransferase, infusion site pain, muscle spasms, peripheral edema, and trismus.

Pediatric patients: The most common adverse reactions were agitation, atelectasis, constipation, nausea, pruritus, and vomiting. Less commonly reported side effects included abdominal pain, anemia, diarrhea, fever, headache, hypersensitivity reaction, hypertension, hypervolemia, hypoalbuminemia, hypokalemia, hypomagnesemia, hypophosphatemia, hypotension, hypoxia, increased hepatic enzymes, injection site pain, insomnia, muscle spasm, oliguria, pain in extremities, periorbital edema, peripheral edema, pleural effusion, pulmonary edema, rash, stridor, tachycardia, and wheezing.

Overdose: Hepatic necrosis, renal tubular necrosis, hypoglycemic coma, and thrombocytopenia.

Post-Marketing: Hypersensitivity and anaphylaxis (e.g., respiratory distress; pruritus; rash; swelling of the face, mouth, and throat; urticaria).

ANTIDOTE

Notify the physician of significant side effects. Discontinue immediately if symptoms associated with hypersensitivity occur. Treat as indicated (e.g., diphenhydramine, epinephrine, albuterol). Resuscitate as necessary. If an acetaminophen overdose is suspected, obtain a serum acetaminophen level and baseline liver function studies. *N*-acetylcysteine antidote may be indicated. See monograph. Contact poison control center for additional information.

ACETAZOLAMIDE SODIUM

(ah-set-ah-ZOE-la-myd SO-dee-um)

Antiglaucoma
Anticonvulsant
Diuretic
Urinary alkalizer

Diamox

pH 9.2

USUAL DOSE

Antiglaucoma agent: 250 mg to 1 Gm/24 hr. May be given as 250-mg doses at 4- to 6-hour intervals. In the treatment of secondary glaucoma and in the preoperative treatment of some cases of acute congestive (closed-angle) glaucoma, the preferred dose is 250 mg every 4 hours. In acute cases, to rapidly lower intraocular pressure, an initial single dose of 500 mg followed by 125 to 250 mg at 4-hour intervals may be given.

Edema of congestive heart failure or drug therapy: 250 to 375 mg or 5 mg/kg of body weight as a single dose daily; when loss of edematous fluid stops, reduce to every other day or give for 2 days followed by a day of rest.

Anticonvulsant: Adults and pediatric patients: Dose in epilepsy may range from 8 to 30 mg/kg/24 hr in divided doses every 6 to 12 hours (2 to 7.5 mg/kg every 6 hours or 4 to 15 mg/kg every 12 hours). Reduce initial daily dose when given with other anticonvulsants.

Urinary alkalization: Adults and pediatric patients: 5 mg/kg/dose every 8 to 12 hours.

PEDIATRIC DOSE

See *Maternal/Child*.

Acute antiglaucoma agent: 5 to 10 mg/kg every 6 hours. Do not exceed 1,000 mg/24 hr.

Edema of congestive heart failure or drug therapy: 5 mg/kg as a single dose daily or every other day; see comment under *Usual Dose*. Do not exceed 1,000 mg/24 hr.

Slowly progressive hydrocephalus in infants 2 weeks to 10 months (unlabeled): 20 mg/kg/24 hr in equally divided doses every 8 hours (8.3 mg/kg every 8 hours). Up to 100 mg/kg/24 hr or a maximum dose of 2 Gm/24 hr has been used.

DOSE ADJUSTMENTS

Reduced dose required when introducing acetazolamide into a treatment regimen with other anticonvulsants. ■ Administer every 12 hours in patients with a CrCl from 10 to 50 mL/min. Avoid use in patients with a CrCl less than 10 mL/min (ineffective).

DILUTION

Each 500 mg should be diluted in 5 mL SWFI. May then be given by IV injection or added to standard IV fluids. IM administration not recommended.

Storage: Reconstituted solution stable for 12 hours at RT or 3 days refrigerated.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following compatibilities:

Additive: Ranitidine (Zantac).

Y-site: Diltiazem (Cardizem).

RATE OF ADMINISTRATION

500 mg or fraction thereof over at least 1 minute or added to IV fluids to be given over 4 to 8 hours.

ACTIONS

A potent carbonic anhydrase inhibitor and nonbacteriostatic sulfonamide, acetazolamide depresses the tubular reabsorption of sodium, potassium, and bicarbonate. Excreted unchanged in the urine, producing diuresis, alkalization of the urine, and a mild degree of metabolic acidosis.

INDICATIONS AND USES

Adjunctive treatment of edema due to congestive heart failure, drug-induced edema, centrencephalic epilepsies (petit mal, unlocalized seizures), chronic simple (open-angle) glaucoma, and secondary glaucoma, and preoperatively in acute angle-closure glaucoma when delay of surgery is desired to lower intraocular pressure. ■ Used orally for acute mountain sickness.

Unlabeled uses: Metabolic alkalosis, urine alkalization, respiratory stimulant in COPD.

CONTRAINDICATIONS

Depressed sodium and potassium levels, hyperchloremic acidosis, marked kidney or liver disease, adrenocortical insufficiency, hypersensitivity to acetazolamide or any of its components. Long-term use contraindicated in some glaucomas.

PRECAUTIONS

Chemically related to sulfonamides; may cause serious reactions in sensitive patients. ■ May be alternated with other diuretics to achieve maximum effect. ■ Greater diuretic action is achieved by skipping a day of treatment rather than increasing dose; failure in therapy may be due to overdose or too-frequent dosage. ■ IM administration not recommended. Administration by IV injection is preferred. ■ Use with caution in impaired respiratory function (e.g., pulmonary disease, edema, infection, obstruction); may cause severe respiratory acidosis. ■ Potassium excretion is proportional to diuresis.

Hypokalemia may result from diuresis or with severe cirrhosis. ■ Introduce or withdraw gradually when used as an anticonvulsant.

Monitor: Obtain baseline CBC and platelet count before use and monitor during therapy. ■ Periodic monitoring of electrolytes is recommended.

Patient Education: Consider birth control options.

Maternal/Child: Category D: avoid pregnancy; may cause premature delivery and congenital anomalies. ■ Discontinue breast-feeding or discontinue acetazolamide. ■ Safety for use in pediatric patients not established, but no problems are documented.

Elderly: Use caution; no documented problems, but age-related renal impairment may be a factor.

DRUG/LAB INTERACTIONS

May cause hypokalemia with concurrent use of **steroids**. ■ Hypokalemia may cause toxicity and fatal cardiac arrhythmias with **digoxin** or interfere with **insulin or oral antidiabetic agent** response, thus causing hyperglycemia. ■ Alkalinization of urine potentiates **amphetamines, ephedrine, flecainide** (Tambacor), **methenamine, procainamide, pseudoephedrine** (Sudafed), **quinidine, and tricyclic antidepressants** (e.g., amitriptyline [Elavil]) by decreasing rate of excretion. ■ May decrease response to **lithium, methotrexate, some antidepressants, phenobarbital, salicylates, and urinary antiinfectives** by increasing rate of excretion. ■ Metabolic acidosis induced by acetazolamide may potentiate **salicylate** toxicity (anorexia, tachypnea, lethargy, coma, and death can occur with high-dose aspirin). ■ Alkalinity may cause **false-positive urinary protein** and possibly **urinary steroid tests**. ■ May depress **iodine uptake** by the thyroid.

SIDE EFFECTS

Minimal with short-term therapy. Respond to symptomatic treatment or withdrawal of drug: acidosis, anorexia, bone marrow suppression, confusion, crystalluria, drowsiness, fever, hemolytic anemia, hypokalemia (ECG changes, fatigue, muscle weakness, vomiting), paresthesias, photosensitivity, polyuria, rash, renal calculus, thrombocytopenic purpura.

ANTIDOTE

Notify physician of any adverse effects and discontinue drug if necessary. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Moderately dialyzable (20% to 40%).

ACETYLCYSTEINE INJECTION **BBW***

(ah-see-till-**SIS**-tay-een in-**JEK**-shun)

Antidote

Acetadote

pH 6 to 7.5

*This drug is on the Black Box Warning list; however, a BBW is not provided in the parenteral prescribing information.

USUAL DOSE

Assess the potential risk of hepatotoxicity by determining plasma or serum acetaminophen concentrations as early as possible but no sooner than 4 hours following an acute overdose; see **Precautions** and **Monitor**. Total dose equals 300 mg/kg administered over 21 hours. Distribute dose as indicated in the following guidelines.

Loading dose (first): 150 mg/kg as an infusion over 60 minutes.

Maintenance dose (second): 50 mg/kg as an infusion over 4 hours. Follow with another **maintenance dose (third)** of 100 mg/kg as an infusion over 16 hours.

Acetylcysteine Dose Guidelines and Dilution by Weight, Patients More Than 40 kg				
Body Weight		LOADING DOSE 150 mg/kg in 200 mL diluent over 60 minutes	SECOND DOSE 50 mg/kg in 500 mL diluent over 4 hours	THIRD DOSE 100 mg/kg in 1,000 mL diluent over 16 hours
(kg)	(lb)	Acetylcysteine	Acetylcysteine	Acetylcysteine
40 kg	88 lb	30 mL	10 mL	20 mL
50 kg	110 lb	37.5 mL	12.5 mL	25 mL
60 kg	132 lb	45 mL	15 mL	30 mL
70 kg	154 lb	52.5 mL	17.5 mL	35 mL
80 kg	176 lb	60 mL	20 mL	40 mL
90 kg	198 lb	67.5 mL	22.5 mL	45 mL
100 kg	220 lb	75 mL	25 mL	50 mL

Adjust total volume administered for patients less than 40 kg and for those requiring fluid restriction according to the following chart.

Acetylcysteine Dose Guidelines and Dilution by Weight for Patients* Less Than 40 kg and/or Fluid-Restricted Patients							
Body Weight		LOADING DOSE 150 mg/kg over 60 minutes		SECOND DOSE 50 mg/kg over 4 hours		THIRD DOSE 100 mg/kg over 16 hours	
(kg)	(lb)	Acetyl- cysteine	Diluent	Acetyl- cysteine	Diluent	Acetyl- cysteine	Diluent
10 kg	22 lb	7.5 mL	30 mL	2.5 mL	70 mL	5 mL	140 mL
15 kg	33 lb	11.25 mL	45 mL	3.75 mL	105 mL	7.5 mL	210 mL
20 kg	44 lb	15 mL	60 mL	5 mL	140 mL	10 mL	280 mL
25 kg	55 lb	18.75 mL	100 mL	6.25 mL	250 mL	12.5 mL	500 mL
30 kg	66 lb	22.5 mL	100 mL	7.5 mL	250 mL	15 mL	500 mL

*For pediatric patients; see [Precautions](#) and [Maternal/Child](#).

Alternately, for pediatric patients weighing equal to or less than 20 kg but not exactly 10, 15, or 20 kg, the following formula is recommended:

Loading dose: 150 mg/kg. Dilute in an amount of diluent equal to 3 mL/kg of body weight (example: with a 7-kg weight, dilute 150 mg/kg [1,050 mg (5.25 mL)] of acetylcysteine in 3×7 mL, or 21 mL of diluent).

Maintenance dose (second): 50 mg/kg. Dilute in an amount of diluent equal to 7 mL/kg of body weight (example: with a 7-kg weight, dilute 50 mg/kg [350 mg (1.75 mL)] of acetylcysteine in 7×7 mL, or 49 mL of diluent).

Maintenance dose (third): 100 mg/kg. Dilute in an amount of diluent equal to 14 mL/kg of body weight (example: with a 7-kg weight, dilute 100 mg/kg [700 mg (3.5 mL)] of acetylcysteine in 14×7 mL, or 98 mL of diluent).

DOSE ADJUSTMENTS

Not required. Specific information and/or recommendations are not available for patients with impaired hepatic or renal function.

DILUTION

A hyperosmolar solution. Color of acetylcysteine may change from colorless to a slight pink or purple once the stopper is punctured; quality is not affected. May be diluted in D5W, $\frac{1}{2}$ NS, or SWFI.

Patients weighing 40 kg or more:

Loading dose (first): 150 mg/kg should be diluted in 200 mL of **compatible** diluent.

Maintenance dose (second): 50 mg/kg should be diluted in 500 mL of **compatible** diluent.

Maintenance dose (third): 100 mg/kg should be diluted in 1,000 mL of **compatible** diluent.

Patients weighing less than 40 kg or fluid-restricted patients: Total volume administered should be adjusted for patients less than 40 kg and for those requiring fluid restriction; see chart and alternate example under **Usual Dose**. Hyponatremia and seizures may result from large volumes in small children.

Filters: Data not available and use is not required by manufacturer. Studies on the use of filters are planned.

Storage: Store unopened vials at CRT. Diluted solution is stable for 24 hours at CRT. Do not use previously opened vials for IV administration. Discard unused portions.

COMPATIBILITY

Manufacturer states, “**Compatible** with D5W, ½NS, and SWFI.”

RATE OF ADMINISTRATION

Usual total infusion time of all 3 doses is 21 hours. Rate reduction may be required to manage S/S of infusion reactions; see **Monitor** and **Antidote**.

Patients weighing 40 kg or more, patients weighing less than 40 kg, and fluid-restricted patients:

Loading dose (first): An infusion evenly distributed over 60 minutes.

Maintenance dose (second): An infusion evenly distributed over 4 hours.

Maintenance dose (third): An infusion evenly distributed over 16 hours.

ACTIONS

Protects the liver by maintaining or restoring the glutathione levels (metabolites formed after an overdose of acetaminophen may deplete the hepatic stores of glutathione and cause binding of the metabolite to protein molecules within the hepatocyte, resulting in cellular necrosis). It may also act by forming an alternate compound and detoxifying the reactive metabolite. Half-life is approximately 5.6 hours. Metabolizes to various compounds. Crosses the placental barrier. Some excretion in urine.

INDICATIONS AND USES

To prevent or lessen hepatic injury after ingestion of a potentially hepatotoxic quantity of acetaminophen.

CONTRAINDICATIONS

Known hypersensitivity to acetylcysteine or any of its components.

PRECAUTIONS

Should be administered in a facility equipped to monitor the patient and respond to any medical emergency. ■ Most effective against severe hepatic injury when administered within 8 hours of ingestion. Administration before 4 hours does not allow enough time to determine an actual need for treatment with acetylcysteine; serum levels drawn before 4 hours have passed may be misleading. Effectiveness diminishes gradually after 8 hours. Should be administered if 24 hours or less has passed since ingestion, because the reported time of ingestion may not be correct and it does not appear to worsen the patient’s condition. ■ Total volume administered should be adjusted for patients less than 40 kg and for patients requiring fluid restriction. If volume is not adjusted, fluid overload can occur, potentially resulting in hyponatremia, seizure, and death; see **Usual Dose**. ■ Use caution in patients with asthma or a history of bronchospasm. Death occurred in a patient with asthma. ■ Infusion reactions and hypersensitivity reactions have occurred. Infusion reactions usually occur within 30 to 60 minutes of beginning the infusion. ■ Clearance decreased and half-life prolonged in patients with various stages of liver damage (Child-Pugh scores of 5 to 13). ■ Rumack-Matthew nomogram does not apply to patients with repeated supratherapeutic ingestion (RSI), which is defined as ingestion of acetaminophen at doses higher than those recommended for extended periods of time. For treatment information, see prescribing information for a professional assistance line for acetaminophen overdose, or contact a regional poison control center. ■ Vial stopper does not contain natural rubber latex. ■ See **Monitor** and **Antidote**.

Monitor: Acute ingestion of 150 mg/kg or more of acetaminophen may result in hepatic toxicity. Obtain baseline hepatic function studies and monitor throughout detoxification process.

Preferred method of treatment: Estimate time of acetaminophen ingestion. If less than 24 hours since overdose, draw serum for an acetaminophen level at 4 hours post-ingestion or as soon as possible thereafter to clarify the need for intervention with acetylcysteine. The serum acetaminophen level should be evaluated on the Rumack-Matthew nomogram to determine the probability of toxicity (see package insert for copy of nomogram). ■ If serum acetaminophen level is below the treatment line on the nomogram, discontinue the acetylcysteine if initiated as a precaution. If the plasma level is above the treatment line on the nomogram, initiate or continue treatment.

Secondary options for treatment: If serum acetaminophen levels are not available within 8 hours, initiate treatment. Do not delay treatment more than 8 hours post-ingestion. ■ If time of ingestion is unknown or if the patient is unreliable, consider empiric initiation of acetylcysteine treatment. ■ If a serum acetaminophen level is not available or cannot be interpreted and less than 24 hours has elapsed since ingestion, administer acetylcysteine regardless of the quantity reported to have been ingested.

All treatment options: Obtain serum acetaminophen level and baseline ALT, AST, bilirubin, blood glucose, BUN, electrolytes, PT, and SCr. Monitor as indicated by results. ■ Monitor BP and HR before, during, and after the infusion. ■ Evaluate serum acetaminophen level on the Rumack-Matthew nomogram. ■ Infusion reactions may begin with acute flushing and erythema of the skin and may occur within 30 to 60 minutes of beginning the infusion. May resolve spontaneously despite continued infusion of acetylcysteine or may progress to an acute hypersensitivity reaction and/or anaphylaxis. Observe continuously for initial S/S of a hypersensitivity reaction (e.g., hypotension, rash, shortness of breath, wheezing). ■ In suspected toxicity resulting from the extended-release acetaminophen preparation, an acetaminophen level drawn fewer than 8 hours post-ingestion may be misleading. Draw a second level at 4 to 6 hours after the initial level. If either acetaminophen level falls above the toxicity line, acetylcysteine treatment should be initiated. ■ See [Precautions](#) and [Antidote](#).

Patient Education: Report S/S of hypersensitivity promptly (e.g., flushing, itching, shortness of breath, feeling of faintness).

Maternal/Child: Category B: use during pregnancy only if clearly needed. ■ Use caution; safety for use during breast-feeding not established; effects unknown. After 30 hours, acetylcysteine should be cleared from maternal blood, and breast-feeding can be resumed. ■ No adequate or well-controlled studies in pediatric patients, but it has been used. Efficacy appears to be similar to that seen in adults; see [Side Effects](#). ■ Administered to a small number of preterm infants during clinical studies (a mean rate of 4.2 mg/kg/hr for 24 hours); half-life prolonged to approximately 11 hours in these newborns. ■ Acetylcysteine was measurable in the circulation and cord blood of three newborns whose mothers were treated for acetaminophen overdose. No adverse side effects were noted, and none of the infants had evidence of acetaminophen poisoning.

Elderly: Response compared to younger adults not yet known; insufficient numbers participated in clinical studies.

DRUG/LAB INTERACTIONS

Drug-drug interaction studies have not been done.

SIDE EFFECTS

Adult and pediatric patients: Pruritus, rash, and urticaria have been reported most frequently and most commonly occur during the initial loading dose. Other reported side effects include anaphylactoid reactions, angioedema, dyspepsia, dysphoria (abnormal thinking or confusion), dyspnea, edema, erythema of the skin, eye pain, facial flushing, gait disturbances, hypotension, nausea and vomiting, palmar erythema, respiratory symptoms (e.g., bronchospasm, chest tightness, cough, respiratory distress, shortness of breath, stridor, wheezing), sweating, syncope, tachycardia, vasodilation.

Overdose: S/S of acute toxicity in animals included ataxia, convulsions, cyanosis, hypoactivity, labored respiration, and loss of righting reflex.

ANTIDOTE

Keep physician informed of all side effects. Flushing and erythema of the skin are expected. If other symptoms of a hypersensitivity reaction occur (e.g., bronchospasm, dyspnea, hypotension, wheezing), discontinue acetylcysteine and treat with diphenhydramine (Benadryl) or epinephrine as indicated. After symptoms subside, the infusion may be carefully resumed. If S/S of hypersensitivity recur, discontinue infusion permanently and consider alternate treatments. Contact Poison Control Center for possible treatment alternatives.

ACYCLOVIR (ay-SYE-kloh-veer)	Antiviral
Zovirax	pH 10.5 to 11.6

USUAL DOSE

In all situations for adults, adolescents, children, and neonates, do not exceed a maximum dose of 20 mg/kg every 8 hours.

Adults and adolescents (12 years of age and older):

Herpes simplex infections; Mucosal and cutaneous HSV infections in immunocompromised patients: 5 mg/kg of body weight every 8 hours for 7 days.

Severe initial clinical episodes of herpes genitalis: 5 mg/kg every 8 hours for 5 days.

Herpes simplex encephalitis: 10 mg/kg every 8 hours for 10 days.

Herpes zoster infections (shingles) in immunocompromised patients: 10 mg/kg every 8 hours for 7 days.

PEDIATRIC DOSE

Pediatric patients under 12 years of age:

Herpes simplex infections; mucosal and cutaneous HSV infections in immunocompromised patients: 10 mg/kg every 8 hours for 7 days.

Herpes simplex encephalitis: Pediatric patients over 3 months of age: 20 mg/kg every 8 hours for 10 days.

Herpes zoster infections (shingles) in immunocompromised patients: 20 mg/kg every 8 hours for 7 days.

NEONATAL DOSE

Neonatal herpes simplex virus infections: Birth to 3 months: 10 mg/kg every 8 hours for 10 days. Doses of 15 mg/kg to 20 mg/kg every 8 hours have been used for up to 14 to 21 days; safety and efficacy have not been established.

DOSE ADJUSTMENTS

Calculate dose by ideal body weight in obese individuals. ■ Reduced dose may be indicated in the elderly based on the potential for decreased renal function and concomitant disease or drug therapy. ■ In adults and pediatric patients with impaired renal function, reduce dose and/or adjust dosing interval based on CrCl as indicated in the following chart.

Acyclovir Dosage Adjustments for Adults and Pediatric Patients with Renal Impairment		
Creatinine Clearance (mL/min per 1.73 M ²)	Percent of Recommended Dose	Dosing Interval (hours)
>50 mL/min	100%	Every 8 hr
25-50 mL/min	100%	Every 12 hr
10-25 mL/min	100%	Every 24 hr
0-10 mL/min	50%	Every 24 hr

Plasma concentrations decrease with hemodialysis; adjustment of the dosing schedule is recommended so that an additional dose is administered after each dialysis. No supplemental dose is indicated in peritoneal dialysis after adjustment of the dosing interval.

DILUTION

Initially dissolve each 500 mg with 10 mL SWFI (1,000 mg with 20 mL). Concentration equals 50 mg/mL. Do not use bacteriostatic water for injection (BWFI); will cause precipitation. Shake well to dissolve completely. Also available in liquid vials. Withdraw the desired dose and further dilute in an amount of solution to provide a concentration less than 7 mg/mL (70-kg adult at 5 mg/kg equals 350 mg dissolved in a total of 100 mL of solution equals 3.5 mg/mL). **Compatible** with most standard electrolyte and glucose infusion solutions.

Filters: No data available from manufacturer.

Storage: Store unopened vials at CRT. Use reconstituted solution within 12 hours; high pH may result in etching of glass vial surface after 12 hours. Use solution fully diluted for administration within 24 hours. Manufacturer will supply data showing stability for longer periods under specific conditions.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists bacteriostatic water for injection (BWFI) as **incompatible**. Dilution in biologic or colloidal fluids (e.g., blood products, protein solutions) is not recommended.

One source suggests the following **compatibilities**:

Additive: Fluconazole (Diflucan), meropenem (Merrem IV).

Y-site: Allopurinol (Aloprim), amikacin (Amikin), amphotericin B cholesteryl (Amphotec), ampicillin, anidulafungin (Eraxis), caspofungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chloramphenicol (Chloromycetin), cisatracurium (Nimbex), clindamycin (Cleocin), dexamethasone (Decadron), diltiazem (Cardizem), dimenhydrinate, diphenhydramine (Benadryl), docetaxel (Taxotere), doripenem (Doribax), doxorubicin liposomal (Doxil), doxycycline, droperidol (Inapsine), erythromycin (Erythrocin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fentanyl (Sublimaze), filgrastim (Neupogen), fluconazole (Diflucan), gallium nitrate (Ganite), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), imipenem-cilastatin (Primaxin), linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), milrinone (Primacor), morphine, multivitamins (M.V.I.), nafcillin (Nallpen), nalbupine, oxacillin (Bactocill), paclitaxel (Taxol), pemetrexed (Alimta), penicillin G potassium, pentobarbital (Nembutal), potassium chloride (KCl), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sodium bicarbonate, sulfamethoxazole/trimethoprim, teniposide (Vumon), theophylline, thiotepa, tobramycin, vancomycin, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose must be administered at a constant rate over 1 hour as an infusion. Renal tubular damage will occur with too-rapid rate of injection. Acyclovir crystals will occlude renal tubules. Use of an infusion pump or microdrip (60 gtt/mL) recommended.

ACTIONS

An antiviral agent with activity against herpes simplex virus types 1 (HSV-1) and 2 (HSV-2) and varicella-zoster virus (VZV). Inhibits replication of viral DNA. Widely distributed in tissues and body fluids. Metabolized to a small extent in the liver. Half-life is approximately 2.5 hours. Excreted mainly as unchanged drug in the urine. Crosses the placental and blood-brain barriers. Secreted in breast milk.

INDICATIONS AND USES

Treatment of initial and recurrent mucosal and cutaneous herpes simplex (HSV-1 and HSV-2) infections in immunosuppressed patients. ■ Severe initial clinical episodes of herpes genitalis in immunocompetent patients. ■ Herpes simplex encephalitis. ■ Neonatal herpes simplex virus infections. ■ Herpes zoster infections (shingles) in immunocompromised patients. ■ Oral acyclovir is used to treat varicella zoster (chickenpox).

Unlabeled uses: Prevention of HSV reactivation in HSCT, treatment of disseminated HSV or VZV, or empiric treatment of suspected encephalitis in immunocompromised patients with cancer.

CONTRAINDICATIONS

Hypersensitivity to acyclovir or valacyclovir (Valtrex). The ganciclovir monograph indicates a contraindication for ganciclovir with acyclovir.

PRECAUTIONS

Confirm diagnosis of herpes simplex virus (HSV-1 or HSV-2) through laboratory culture. Initiate therapy as quickly as possible after symptoms identified. ■ For IV use only; avoid IM or SC injection. ■ Use caution in patients with underlying neurologic abnormalities, those with serious renal, hepatic, or electrolyte abnormalities, or significant hypoxia. ■ Use caution in patients receiving interferon or intrathecal methotrexate, or with patients who have had previous neurologic reactions to cytotoxic drugs. ■ Incidence of CNS adverse events may be more common in the elderly or in patients with decreased renal function. ■ Isolates of herpes simplex viruses (HSV-1, HSV-2) and varicella-zoster virus (VZV) with reduced susceptibility to acyclovir have been identified. Consider the possibility of viral resistance to acyclovir in patients who show poor clinical response. ■ Thrombotic thrombocytopenic purpura/hemolytic uremic syndrome (TTP/HUS) has been reported in immunocompromised patients receiving acyclovir. Deaths have occurred. ■ See [Contraindications](#).

Monitor: Maintain adequate hydration and urine flow before and during infusion. Encourage fluid intake of 2 to 3 L/day. ■ Monitor CBC, liver function tests, and renal function; abnormal renal function (decreased CrCl can occur), concomitant use of other nephrotoxic drugs, pre-existing renal disease, and dehydration make further renal impairment with acyclovir more likely. ■ Confirm patency of vein; will cause thrombophlebitis. Rotate site of infusion.

Patient Education: Maintain adequate hydration. Virus remains dormant and can still spread to others. ■ Avoid sexual intercourse when visible herpes lesions are present. Use condoms routinely.

Maternal/Child: Category B: use during pregnancy only if benefits outweigh risk to fetus. ■ Breast milk concentrations can be higher than maternal serum concentrations. Discontinue breast-feeding or evaluate very carefully. ■ 10 mg/kg and 20 mg/kg doses in pediatric patients from 3 months to 16 years achieved concentrations similar to those in adults receiving 5 mg/kg to 10 mg/kg. ■ Use with caution in neonates; they have an age-related decrease in clearance and an increase in half-life (3.8 hours).

Elderly: Effectiveness is similar to younger adults. ■ Plasma concentrations are higher in the elderly compared to younger adults; may be due to age-related changes in renal function. ■ Duration of pain after healing was longer in patients 65 years or older. ■ Incidence of side effects (e.g., CNS adverse events [coma, confusion, hallucinations, somno-

lence], dizziness, nausea, renal adverse events, vomiting) was increased. ■ See [Dose Adjustments and Precautions](#).

DRUG/LAB INTERACTIONS

See [Precautions](#). May cause neurotoxicity (e.g., severe drowsiness and lethargy) with **zidovudine**. ■ Concurrent use with other **nephrotoxic agents** (e.g., aminoglycosides [gentamicin, tobramycin], cisplatin [Platinol]) may increase risk of nephrotoxicity, especially in patients with pre-existing renal impairment. ■ Potentiated by **probenecid**. ■ Synergistic effects with **ketoconazole and interferon** have been noted. Clinical importance not established. ■ In one case report, a patient stabilized on **phenytoin and valproic acid** experienced seizures and a reduction in antiepileptic drug serum concentrations when acyclovir was added to the regimen.

SIDE EFFECTS

Acute renal failure, aggressive behavior, agitation, angioedema, ataxia, coma, confusion, delirium, diaphoresis, disseminated intravascular coagulation (DIC), dizziness, dysarthria (difficulty articulating words), elevated transaminase levels, encephalopathy, hallucinations, headache, hematuria, hemolysis, hives, hyperbilirubinemia, hypersensitivity reactions (e.g., anaphylaxis), hypotension, inflammation at injection site, lethargy, nausea, obtundation, phlebitis, rash, seizures, transient increased BUN or SCr levels, tremors, vomiting. Some patients (fewer than 1%) may have abdominal pain, anemia, anorexia, anuria, chest pain, diarrhea, edema, fatigue, fever, hemoglobinemia, hepatitis, hypokalemia, ischemia of digits, jaundice, leukocytosis, light-headedness, myalgia, neutropenia, neutrophilia, paresthesia, psychosis, pulmonary edema with cardiac tamponade, rigors, skin reactions (e.g., erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis), thirst, thrombocytosis, thrombocytopenia, visual abnormalities.

ANTIDOTE

Notify physician of all side effects. Discontinue drug with onset of CNS side effects. Treatment will be symptomatic and supportive. Adequate hydration is indicated to prevent precipitation of acyclovir in the renal tubules. A 6-hour session of hemodialysis will reduce plasma acyclovir concentration by approximately 60%. Hemodialysis may be indicated in patients with acute renal failure and anuria. Treat anaphylaxis and resuscitate as necessary.

ADENOSINE

(ah-DEN-oh-seen)

Antiarrhythmic
Diagnostic agent

Adenocard, Adenoscan

pH 4.5 to 7.5

USUAL DOSE

Adenocard: Conversion of acute paroxysmal supraventricular tachycardia (PSVT): 6 mg initially. If supraventricular tachycardia not eliminated in 1 to 2 minutes, give 12 mg. May repeat 12-mg dose in 1 to 2 minutes if needed. Do not exceed 12 mg in any single dose.

Do not administer a repeat dose to patients who develop a high-level block on one dose of adenosine.

Adenosine is not blocked by atropine. Digitalis, quinidine, beta-adrenergic blocking agents (e.g., atenolol, esmolol), calcium channel blocking agents (e.g., verapamil), angiotensin-converting enzyme inhibitors (e.g., enalapril [Vasotec]), and other cardiac drugs can be administered without delay if indicated because of the short half-life of adenosine. Repeat episodes may be treated with adenosine or calcium channel blockers (e.g., diltiazem, verapamil).

Adenoscan: Noninvasive diagnosis of coronary artery disease with thallium tomography: 140 mcg/kg/min (0.14 mg/kg/min) as a 6-minute continuous peripheral infusion. Inject thallium at 3 minutes. May be injected directly into adenosine infusion set. Dose should be based on total body weight. ■ See [Drug/Lab Interactions](#).

PEDIATRIC DOSE

See [Maternal/Child](#).

Adenocard: Conversion of acute paroxysmal supraventricular tachycardia (PSVT) in pediatric patients weighing less than 50 kg: 0.05 to 0.1 mg/kg. May increase dose by 0.05 to 0.1 mg/kg increments every 2 minutes until PSVT terminated or maximum dose reached (0.3 mg/kg or 12 mg). AHA guidelines recommend 0.1 mg/kg rapid IV push. Follow each dose with a 5- to 10-mL NS flush. Double to 0.2 mg/kg if a second dose is required. Maximum first dose 6 mg. Maximum second dose and maximum single dose is 12 mg. ■ See comments in [Usual Dose](#).

Pediatric patients weighing more than 50 kg: Same as Usual Dose.

DOSE ADJUSTMENTS

Metabolism of adenosine is independent of hepatic or renal function. No dose adjustment indicated. ■ See [Drug/Lab Interactions](#); alternative therapy (e.g., calcium channel blockers) may be indicated.

DILUTION

Solution must be clear; do not use if discolored or particulate matter present.

Adenocard: Conversion of acute PSVT: Give undiluted directly into a vein. If given into an IV line, use the closest port to the insertion site and follow with a rapid NS flush (+/- 50 mL) to be certain the solution reaches the systemic circulation. Discard unused portion.

Adenoscan: Pharmacologic stress testing: Dilute a single dose in sufficient NS to distribute over 6 minutes.

Storage: Store at CRT 15° to 30° C (59° to 86° F); refrigeration will cause crystallization. If crystals do form, dissolve by warming to room temperature.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Abciximab (ReoPro).

RATE OF ADMINISTRATION

Adenocard: Conversion of acute PSVT: Must be given as a rapid bolus IV injection over 1 to 2 seconds. Follow each dose with NS flush; see [Dilution](#).

Adenoscan: Pharmacologic stress testing: See [Usual Dose](#).

ACTIONS

A naturally occurring nucleoside present in all cells of the body. Has many functions. When given as a rapid IV bolus, adenosine has antiarrhythmic properties, slowing cardiac conduction (particularly at the AV node), interrupting reentry pathways through the AV node, and restoring sinus rhythm in patients with PSVT. When used as a diagnostic aid and given as a continuous infusion, adenosine acts as a vasodilator. Dilates normal coronary vessels, increasing blood flow. Has little effect on stenotic arteries. When administered with thallium-201, helps differentiate between areas of heart supplied by normal blood flow and areas supplied by stenotic coronary arteries. When larger doses are given by infusion, adenosine decreases BP and produces a reflexive increase in HR. Adenocard and Adenoscan have the same molecular structure, same solvent, diluent, and concentration. The difference in their actions is in the rate of administration; however, the FDA has approved Adenocard for converting PSVT and Adenoscan for pharmacologic stress testing. When used for treatment of PSVT, it is effective within 1 minute. When used for diagnostic purposes, maximum effect is reached within 2 to 3 minutes of starting the infusion. Coronary blood flow velocity returns to basal levels within 1 to 2 minutes after the infusion is discontinued. Half-life is estimated to be less than 10 seconds. Adenosine is salvaged immediately by erythrocytes and blood vessel endothelial cells and metabolized for natural uses throughout the body (regulation of coronary and systemic vascular tone, platelet function, lipolysis in fat cells, intracardiac conduction).

INDICATIONS AND USES

Adenocard: To convert acute paroxysmal supraventricular tachycardia (PSVT) to normal sinus rhythm; a first-line agent according to AHA. Includes PSVT associated with accessory bypass tracts (Wolff-Parkinson-White syndrome). Does not convert atrial flutter, atrial fibrillation, or ventricular tachycardia to normal sinus rhythm (NSR).

Adenoscan: Adjunct to thallium-201 myocardial perfusion scintigraphy in patients unable to exercise adequately. (Results are similar to IV dipyridamole or exercise stress testing.)

CONTRAINDICATIONS

Known hypersensitivity to adenosine. ■ Symptomatic bradycardia, sick sinus syndrome, and second- or third-degree AV block unless a functioning artificial pacemaker is in place.

PRECAUTIONS

Both preparations: Absolutely confirm labeling for IV use. Do not use adenosine phosphate, which is for IM use in the symptomatic relief of varicose vein complications. ■ Emergency resuscitation drugs and equipment must always be available. ■ May produce short-lasting first-, second-, or third-degree heart block. Usually self-limiting due to short half-life. Patients who develop high-level block should not be given additional doses of adenosine. ■ May cause bronchoconstriction. Use with caution in patients with obstructive lung disease not associated with bronchoconstriction (e.g., emphysema, bronchitis). Avoid use in patients with bronchoconstrictive or bronchospastic disease (e.g., asthma).

Adenocard: Valsalva maneuver may be used before use of adenosine in PSVTs if clinically appropriate. ■ Transient or prolonged episodes of asystole and ventricular fibrillation have been reported. Deaths have occurred. In most instances, these cases were associated with the concomitant use of digoxin (Lanoxin) and, less frequently, with digoxin and verapamil. ■ Some slowing of ventricular response may occur if atrial flutter or fibrillation is also present.

Adenoscan: Fatal cardiac arrest, sustained ventricular tachycardia (requiring resuscitation), and nonfatal MI have been reported. Patients with unstable angina may be at greater risk. ■ Can cause significant hypotension. Use with caution in patients with autonomic dysfunction, stenotic valvular heart disease, pericarditis or pericardial effusion, stenotic carotid artery disease with cerebrovascular insufficiency, or uncorrected hypovo-

lemia; may be at increased risk for hypotensive complications. ■ Hypertension has been reported; usually resolves spontaneously. ■ Atrial fibrillation has been reported. In reported cases, it began 1.5 to 3 minutes into the infusion, lasted for 15 seconds to 6 hours, and spontaneously converted to NSR.

Monitor: Adenocard: Conversion of acute PSVT: Must reach systemic circulation; see [Dilution](#). ■ ECG monitoring during administration recommended. Monitor BP. At the time of conversion to normal sinus rhythm, PVCs, PACs, atrial fibrillation, sinus bradycardia, sinus tachycardia, skipped beats, and varying degrees of AV nodal block are seen on the ECG in many patients. Usually last only a few seconds and resolve without intervention. ■ Less likely to precipitate hypotension if arrhythmia does not terminate.

Adenoscan: Pharmacologic stress testing: ECG monitoring during administration recommended. Monitor HR and BP at regular intervals during infusion. ■ Obtain images when infusion complete and redistribution images 3 to 4 hours later.

Maternal/Child: Category C: use in pregnancy only if clearly needed. Some references recommend avoiding early pregnancy. ■ Safety for use in pediatric patients not established, but has been used for conversion of PSVT in neonates, infants, children, and adolescents. Safety for use in pharmacologic stress testing in patients under 18 years not established.

Elderly: Response similar to that seen in younger patients; however, greater sensitivity of some older patients cannot be ruled out. May have diminished cardiac function, nodal dysfunction, concomitant disease, or drug therapy that may alter hemodynamic function and produce severe bradycardia or AV block.

DRUG/LAB INTERACTIONS

Both preparations: Effects antagonized by **methylxanthines** (e.g., caffeine, theophylline); larger doses may be required or adenosine may not be effective. ■ Potentiated by **dipyridamole** (Persantine); smaller doses of adenosine may be indicated. ■ Cardiovascular effects increased by **nicotine**; rapid injection may induce anginal pain. ■ May produce a higher degree of heart block with **carbamazepine** (Tegretol). ■ Concomitant use with **digoxin alone or digoxin in combination with verapamil** associated with rare cases of ventricular fibrillation; see [Precautions](#). ■ See [Usual Dose](#). ■ **Adenoscan:** Before using Adenoscan for pharmacologic stress testing, avoid (or withhold for at least 5 half-lives) **adenosine antagonists** (e.g., methylxanthines) **and/or potentiators** (e.g., dipyridamole, papaverine).

SIDE EFFECTS

Both preparations: Generally predictable, short lived, and easily tolerated. Most will appear immediately and last less than 1 minute. Atrial fibrillation, bronchospasm, chest pressure, dizziness, dyspnea and/or shortness of breath, facial flushing, headache, hypertension, light-headedness, nausea, numbness, PACs, PVCs, sinus bradycardia, sinus tachycardia, skipped beats, varying degrees of AV nodal block. Less than 1% of patients complain of apprehension, blurred vision, burning, chest pain, head pressure, heavy arms, hyperventilation, hypotension, metallic taste, neck and back pain, palpitations, pressure in groin, seizures, sweating, tight throat, and tingling in arms.

Both preparations: Major: Arrhythmias (persistent), including VT, VF, atrial fibrillation, and torsades de pointes; bronchospasm (severe); myocardial infarction; pulmonary edema; third-degree AV block. Asystole with fatal outcome has been reported.

Post-Marketing: Both preparations: Seizure activity, including tonic-clonic (grand mal) seizures, and loss of consciousness. **Adenoscan:** Injection site reactions, respiratory arrest, throat tightness, vomiting. **Adenosine:** Atrial fibrillation, bradycardia, prolonged asystole, torsades de pointes, transient increase in blood pressure, VF, VT.

ANTIDOTE

Notify physician of any side effect that lasts more than 1 minute. If a side effect persists, decrease rate of infusion (Adenoscan [pharmacologic stress testing]). With either use, for progression to a major side effect discontinue adenosine. Treat symptomatically if indicated. Bradycardia may be refractory to atropine. Short half-life generally precludes overdose problems, but aminophylline 50 to 125 mg as a slow infusion is a competitive antagonist. Resuscitate as necessary.

ADO-TRASTUZUMAB EMTANSINE **BBW**Monoclonal antibody
Antineoplastic**Kadcyla****USUAL DOSE**

3.6 mg/kg as an infusion every 3 weeks (21-day cycle) until disease progression or unacceptable toxicity. **Do not administer doses greater than 3.6 mg/kg. Do not substitute ado-trastuzumab (Kadcyla) for or with trastuzumab.**

DOSE ADJUSTMENTS

No dose adjustment is indicated in patients with mild or moderate renal impairment. In patients with severe renal impairment (CrCl less than 30 mL/min), no dose adjustments can be recommended because of the limited data available. ■ If a planned dose is delayed or missed, **do not wait until the next planned cycle**; administer as soon as possible, and adjust the schedule to maintain a 3-week interval between doses.

Recommended Ado-Trastuzumab Dose Reduction Schedule for Adverse Events*	
Dose Reduction Schedule	Dose Level to Administer
Starting dose	3.6 mg/kg
First dose reduction	3 mg/kg
Second dose reduction	2.4 mg/kg
Requirement for further dose reduction	Discontinue treatment

*Ado-trastuzumab dose should not be re-escalated after a dose reduction is made.

Ado-Trastuzumab Dose Modification Guidelines for Increased Serum Transaminases (AST/ALT)		
Grade 2 (>2.5 to ≤5 × ULN)	Grade 3 (>5 to ≤20 × ULN)	Grade 4 (>20 × ULN)
Treat at same dose level.	Do not administer until AST/ALT recovers to Grade ≤2, and then reduce one dose level.	Permanently discontinue ado-trastuzumab.

ALT, Alanine transaminase; AST, aspartate transaminase; ULN, upper limit of normal.

Ado-Trastuzumab Dose Modification Guidelines for Hyperbilirubinemia		
Grade 2 (>1.5 to ≤3 × ULN)	Grade 3 (>3 to ≤10 × ULN)	Grade 4 (>10 × ULN)
Do not administer until total bilirubin recovers to Grade ≤1, and then treat at same dose level.	Do not administer until total bilirubin recovers to Grade ≤1, and then reduce one dose level.	Permanently discontinue ado-trastuzumab.

Ado-Trastuzumab Dose Modification Guidelines for Left Ventricular Dysfunction				
Symptomatic CHF	LVEF <40%	LVEF 40% to ≤45% and Decrease Is ≥10% Points from Baseline	LVEF 40% to ≤45% and Decrease Is <10% Points from Baseline	LVEF >45%
Discontinue ado-trastuzumab.	Do not administer ado-trastuzumab. Repeat LVEF assessment within 3 weeks. If LVEF <40% is confirmed, discontinue ado-trastuzumab.	Do not administer ado-trastuzumab. Repeat LVEF assessment within 3 weeks. If LVEF has not recovered to within 10% points from baseline, discontinue ado-trastuzumab.	Continue treatment with ado-trastuzumab. Repeat LVEF assessment within 3 weeks	Continue treatment with ado-trastuzumab.

CHF, Congestive heart failure; LVEF, left ventricular ejection fraction.

Ado-Trastuzumab Dose Modification Guidelines for Thrombocytopenia	
Grade 3	Grade 4
Platelets 25,000/mm ³ to <50,000/mm ³	Platelets <25,000/mm ³
Do not administer ado-trastuzumab until platelet count recovers to ≤Grade 1 (≥75,000/mm ³), and then treat at same dose level.	Do not administer ado-trastuzumab until platelet count recovers to ≤Grade 1 (≥75,000/mm ³), and then reduce one dose level.

Ado-Trastuzumab Dose Modification Guidelines for Other Adverse Events	
Adverse Event	Action
Serum transaminases >3 × ULN and concomitant total bilirubin >2 × ULN	Permanently discontinue ado-trastuzumab.
Diagnosed with nodular regenerative hyperplasia (NRH)	Permanently discontinue ado-trastuzumab.
Diagnosed with interstitial lung disease (ILD) or pneumonitis	Permanently discontinue ado-trastuzumab.
Grade 3 or 4 peripheral neuropathy	Temporarily discontinue ado-trastuzumab until resolution to ≤Grade 2.

DILUTION

Specific techniques required; see Precautions. Check vial label to avoid medication errors; should read Kadcylla (ado-trastuzumab emtansine), **NOT** trastuzumab. Trade name (Kadcylla) should be clearly recorded (or stated) in the patient file to improve traceability of biological medicinal products.

Available in single-dose vials of 100 mg/vial and 160 mg/vial. Reconstitute the 100-mg vial with 5 mL of SWFI. Reconstitute the 160-mg vial with 8 mL of SWFI. Both yield 20 mg/mL. Swirl vial gently; **do not shake**. Solution should be clear to slightly opalescent and colorless to light brown. Withdraw the calculated dose and transfer to an infusion bag of 250 mL of NS. *Do not use D5W*. Avoid foaming by gently inverting bag to mix. **Do not shake**. Immediate use preferred.

Filters: Use of a 0.22-micron, in-line, non-protein adsorptive polyethersulfone (PES) filter required for administration.

Storage: Store vials until time of reconstitution in refrigerator at 2° to 8° C (36° to 46° F). *Do not freeze or shake original vials or reconstituted or diluted solutions.* Reconstituted

vials and diluted solutions can be refrigerated for up to 4 hours. Discard unused reconstituted or diluted drug and discard any prepared ado-trastuzumab after 4 hours.

COMPATIBILITY

Manufacturer states, “Do not mix Kadcyla (ado-trastuzumab emtansine), or administer as an infusion, with other medicinal products.” **Incompatible** with D5W.

RATE OF ADMINISTRATION

For IV infusion only. Do not administer as an IV push or bolus. Use of a 0.22-micron, in-line, non-protein adsorptive polyethersulfone (PES) filter required. Slow or interrupt the infusion if patient develops an infusion-related reaction; see [Dose Adjustments](#), [Precautions](#), and [Antidote](#).

First infusion: Administer over 90 minutes.

Subsequent infusions: If initial and/or prior infusions are well tolerated, subsequent infusions may be administered over 30 minutes.

Delayed of missed infusions: Administer at the dose and rate tolerated in the most recent infusion.

ACTIONS

A HER2-targeted antibody-drug conjugate (ADC) that contains the humanized anti-HER2 IgG1, trastuzumab, covalently linked to the microtubule inhibitory drug DM1 (a maytansine derivative). Specific processes result in the intracellular release of DM1-containing cytotoxic catabolites. Binding of DM1 to tubulin disrupts microtubule networks in the cell, which results in cell-cycle arrest and apoptotic cell death. Ado-trastuzumab emtansine inhibits HER2 receptor signaling, mediates antibody-dependent cell-mediated cytotoxicity, and inhibits shedding of the HER2 extracellular domain in human breast cancer cells that overexpress HER2. Maximum concentrations have been observed close to the end of an infusion. DM1 is metabolized in the liver by CYP3A4/5. Elimination half-life is approximately 4 days.

INDICATIONS AND USES

Used as a single agent in the treatment of patients with HER2-positive, metastatic breast cancer who previously received trastuzumab and a taxane separately or in combination. Patients should have either received prior therapy for metastatic disease or developed a recurrence of disease during or within 6 months of completing other chemotherapy.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ **Do not administer doses greater than 3.6 mg/kg.** ■ **Do not substitute ado-trastuzumab (Kadcyla) for or with trastuzumab.** ■ Serious hypersensitivity and/or infusion reactions have occurred. Ado-trastuzumab has not been studied in patients who had trastuzumab permanently discontinued because of infusion-related reactions and/or hypersensitivity; treatment with ado-trastuzumab is not recommended for these patients. ■ Administer under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Exposure to ado-trastuzumab can result in embryo-fetal death or birth defects; see [Patient Education](#) and [Maternal/Child](#). ■ Hepatotoxicity, predominantly increases in serum transaminases, has been observed. Serious hepatotoxicity has been reported, including liver failure and death. ■ Nodular regenerative hyperplasia (NRH) of the liver has been identified from liver biopsies. NRH may lead to non-cirrhotic portal hypertension. ■ Cardiac toxicity has been reported. Treatment with ado-trastuzumab may lead to reductions in left ventricular ejection function (LVEF). ■ Interstitial lung disease (ILD), including pneumonitis, has been reported. Some have resulted in acute respiratory distress syndrome or fatal outcome. ■ Peripheral neuropathy (predominantly sensory) has been reported. ■ Effects on patients with severe renal impairment and/or hepatic impairment have not been studied. ■ A protein substance; has potential for immunogenicity. ■ See [Dose Adjustments](#), [Monitor](#), and [Antidote](#).

Monitor: Verify non-pregnancy status before beginning ado-trastuzumab therapy. ■ Assess HER2 status before beginning ado-trastuzumab therapy. Testing should be done by a laboratory with demonstrated proficiency in the testing process. ■ Obtain baseline CBC and differential with platelets before treatment and before each scheduled dose. ■ Obtain baseline AST, ALT, and bilirubin before treatment and before each scheduled dose (every 3 weeks). ■ Obtain baseline LVEF before treatment and at regular intervals (e.g., every 3 months) to confirm it remains within the prescribed parameters. ■ Avoid extravasation; monitor infusion site closely. ■ Monitor for S/S of a hypersensitivity or infusion reaction (e.g., asthenia, bronchospasm, chills, dizziness, dyspnea, fatigue, fever, flushing, hypotension, nausea, pruritus, rash, urticaria, vomiting, wheezing). Observe closely during and for 90 minutes after the first infusion and during and for at least 30 minutes after subsequent infusions. ■ Consider a possible diagnosis of NRH in patients with clinical symptoms of portal hypertension but with normal transaminases and no manifestations of cirrhosis. Diagnosis can be confirmed only by histopathology. ■ Monitor for S/S of ILD (e.g., cough, dyspnea, fatigue, and pulmonary infiltrates). May or may not occur as sequelae of infusion reactions. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for S/S of peripheral neuropathy (e.g., paresthesias, tingling, weakness).

Patient Education: Avoid pregnancy; potential serious risk to fetus. Effective contraception required while receiving therapy and for 6 months following the last dose. ■ If a pregnancy occurs during therapy or if ado-trastuzumab is administered during a pregnancy, report exposure immediately to the Genentech Adverse Event Line. ■ During infusion, promptly report S/S of an infusion or hypersensitivity reaction (e.g., asthenia, bronchospasm, chills, dizziness, dyspnea, fatigue, fever, flushing, hypotension, nausea, pruritus, rash, urticaria, vomiting, wheezing). ■ Promptly report S/S of acute hepatitis (e.g., abdominal pain, anorexia, dark urine, generalized pruritus, jaundice, nausea, vomiting). ■ Report new-onset or worsening SOB, cough, swelling of ankles/legs, weight gain. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. Exposure can result in embryo-fetal death and birth defects. Oligohydramnios, fatal pulmonary hypoplasia, skeletal abnormalities, and embryo-fetal death have been reported in post-marketing reports for trastuzumab; see [Patient Education](#). ■ Encourage patients who are exposed during pregnancy to enroll in the MoTHER Pregnancy Registry. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: No differences in safety and effectiveness noted compared with younger adults.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been done. DM1, a component of ado-trastuzumab, is metabolized mainly by CYP3A4 and to a lesser extent by CYP3A5. **Avoid concomitant use of strong CYP3A4 inhibitors** (e.g., atazanavir [Reyataz], clarithromycin [Biaxin], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase], telithromycin [Ketek], voriconazole [VFEND]). Consideration of an alternate medication with no or minimal potential to inhibit CYP3A4 is recommended, or delay ado-trastuzumab treatment until the strong CYP3A4 inhibitors have cleared from the circulation (approximately 3 elimination half-lives of the inhibitors). If coadministration cannot be delayed, closely monitor patients for adverse reactions.

SIDE EFFECTS

Constipation, fatigue, headache, increased transaminases, musculoskeletal pain, nausea, and thrombocytopenia were most common. Serious side effects include embryo-fetal toxicity, hepatotoxicity, hypersensitivity and/or infusion-related reactions, left ventricular dysfunction, neurotoxicity, nodular regenerative hyperplasia, portal hypertension,

pulmonary toxicity, and thrombocytopenia. Abdominal pain, anemia, arthralgia, asthenia, blurred vision, chills, conjunctivitis, cough, diarrhea, dizziness, dry eyes, dry mouth, dysgeusia, dyspepsia, dyspnea, epistaxis, fever, hypertension, hypokalemia, increased blood alkaline phosphatase, increased lacrimation, insomnia, myalgia, neutropenia, peripheral edema, pneumonitis, pruritus, rash, stomatitis, urinary tract infections, and vomiting have also been reported.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. If signs of an infusion reaction occur, slow or interrupt the infusion and treat appropriately. Monitor patients carefully until symptoms resolve. Discontinue immediately for a serious hypersensitivity reaction. Treat hypersensitivity reactions with epinephrine, antihistamines, corticosteroids, bronchodilators, and oxygen. See [Dose Adjustments](#) for recommendations to delay or permanently discontinue ado-trastuzumab with serious side effects (e.g., hyperbilirubinemia, increased serum transaminases, LVEF, nodular regenerative hyperplasia [NRH], peripheral neuropathy, pulmonary toxicity [ILD or pneumonitis], thrombocytopenia). Resuscitate as indicated.

ALBUMIN (HUMAN)

(al-BYOO-min HU-man)

Plasma volume expander
(plasma protein fraction)

Albumin (Human Preservative Free) 5%, 20%, & 25%, Albuminar 5% & 25%, AlbuRx 5% & 25%, Albutein 5% & 25%, Buminate 5% & 25%, Flexbumin 25%, Human Albumin Grifols 25%, Normal Serum Albumin, Plasbumin 5%, 20%, & 25%

pH 6.4 to 7.4

USUAL DOSE

Variable, depending on patient condition (e.g., presence of hemorrhage, hypovolemia, or shock, pulse, BP, hemoglobin and hematocrit, and amount of pulmonary or venous congestion present). Fluid and protein requirements and underlying condition determine the concentration of albumin used. 5% is usually indicated in hypovolemic or intravascularly depleted patients, and 20% or 25% is appropriate when fluid and sodium intake should be minimized (e.g., cerebral edema, hypoproteinemia, pediatric patients). The initial dose is usually 12.5 to 25 Gm. Amount of 5% given may be increased to 0.5 Gm/lb of body weight (10 mL/lb) with careful monitoring of the patient. Available as 5% solution (5 Gm/100 mL), 20% solution (20 Gm/100 mL), or 25% solution (25 Gm/100 mL). The maximum dose is 6 Gm/kg/24 hr or 250 Gm in 48 hours (250 Gm is equal to 5 liters of 5% or 1 liter of 25%). In the absence of active hemorrhage, the total dose usually does not exceed the normal circulating mass of albumin (e.g., 2 Gm/kg of body weight).

Hypoproteinemia (hypoalbuminemia): 50 to 75 Gm as a 5% or 25% solution. Repeat doses may be required in patients who continue to lose albumin.

Hypovolemia: 12 to 25 Gm as a 5%, 20%, or 25% solution. May be repeated in 15 to 30 minutes if response inadequate. If 25% solution is used, additional fluids may be needed.

Burns: Electrolyte replacement and crystalloids (e.g., IV fluids) to maintain plasma volume are required in the first 24 hours. Then begin with 25 Gm and adjust as necessary to maintain albumin level from 2 to 3 Gm/dL.

Acute nephrosis or acute nephrotic syndrome: 20 to 25 Gm of a 25% solution with a loop diuretic (e.g., furosemide [Lasix], torsemide [Demadex]) daily for 7 to 10 days.

Hemodialysis: 100 mL of a 20% or 25% solution.

Red blood cell resuspension: 20 to 25 Gm of a 20% or 25% solution/liter of RBCs.

Cardiopulmonary bypass: Achieve a plasma albumin of 2.5 Gm/dL and hematocrit concentration of 20% with either a 5% or 25% solution. Use crystalloids (IV fluids) as a pump prime.

PEDIATRIC DOSE

0.5 to 1 Gm/kg/dose. 25% solution is usually used in infants and other pediatric patients; **do not use in preterm infants**. Monitor hemodynamic response closely. Maximum dose 6 Gm/kg/24 hr or 250 Gm/48 hr.

Hypoproteinemia (hypoalbuminemia): 0.5 to 1 Gm/kg/dose. Repeat every 1 to 2 days as needed.

Hypovolemia: 0.5 to 1 Gm/kg/dose. May be repeated in 15 to 30 minutes if response inadequate.

Hemolytic disease of the newborn: 1 Gm/kg (4 mL/kg) of 25% albumin. One source recommends giving 1 hour before exchange transfusion. Another recommends 1 to 2 hours before blood transfusion or with transfusion (exchange 50 mL of albumin 25% for 50 mL plasma). **Do not use in preterm infants**.

Burns: See [Usual Dose](#).

DILUTION

May be given undiluted or further diluted with NS or D5W for infusion. NS is the preferred diluent. When sodium restriction is required, D5W may be substituted. The use of SWFI as a diluent is not recommended. Life-threatening hemolysis and acute renal failure can result if a sufficient volume of SWFI is used as a diluent. The 5% product is isotonic and osmotically approximates human plasma. One volume of 25% to four volumes of diluent is isotonic. Use only clear solutions.

Storage: Store at CRT. Use within 4 hours after opening. Discard unused portions.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Do not use SWFI as a diluent; see **Dilution**. Manufacturers state, "Do not mix with protein hydrolysates, amino acid mixtures, or solutions containing alcohol." Manufacturers also state, "May be administered in conjunction with or combined with other parenterals such as whole blood, plasma, glucose, saline, or sodium lactate."

One source suggests the following **compatibilities**:

Y-site: Diltiazem (Cardizem), lorazepam (Ativan).

RATE OF ADMINISTRATION

Variable, depending on indication, present blood volume, patient response, and concentration of solution. A too-rapid rate, especially in the presence of normal blood volume, may cause circulatory overload and pulmonary edema. Averages are:

Normal blood volume: 1 to 2 mL/min.

Deficient blood volume (hypovolemia): A single dose as rapidly as tolerated. Repeat dose as rapidly as tolerated if indicated. As volume approaches normal, slow 5% to 1 to 2 mL/min and 25% to 1 mL/min to prevent circulatory overload and pulmonary edema.

Hypoproteinemia: 2 to 3 mL/min in adults; a single dose over 30 to 120 minutes in pediatric patients.

Infants and other pediatric patients: For uses other than hypovolemia and hypoproteinemia, the rate of administration should be about one fourth to one half the adult rate.

ACTIONS

A sterile natural plasma protein substance prepared by a specific process, which makes it free from the danger of serum hepatitis. A blood volume expander that accounts for 70% to 80% of the colloid oncotic pressure of plasma. Expands blood volume proportionately to amount of circulating blood, improves cardiac output, prevents marked hemoconcentration, aids in reduction of edema, and raises serum protein levels. Low sodium content helps to maintain electrolyte balance and should promote diuresis in presence of edema (contains 130 to 160 mEq sodium/L). Also acts as a transport protein that binds both endogenous and exogenous substances, including bilirubin and certain drugs.

INDICATIONS AND USES

Hypovolemia (with or without shock [actual or impending], with or without hemorrhage); 5% if hypovolemic, 25% if adequate hydration or edema is present. ■ Hypoalbuminemia from inadequate production (e.g., burns, congenital analbuminemia, endocrine disorders, infection, liver disease, major injury, malignancy, malnutrition). ■ Hypoalbuminemia from excessive catabolism (e.g., burns, major injury, nephrosis, pancreatitis, pemphigus [chronic relapsing skin disease], peritonitis, thyrotoxicosis). ■ Hypoalbuminemia from loss from the body (e.g., hemorrhage, burn exudates, excessive renal excretion, exfoliative dermatoses, exudative enteropathy [e.g., inflammatory bowel disease]). ■ Hypoalbuminemia from redistribution within the body (e.g., cirrhosis with ascites, inflammatory conditions, major surgery). ■ Hypoalbuminemia secondary to pulmonary edema in adult respiratory distress syndrome (ARDS). ■ Raising plasma oncotic pressure to treat edema of nephrosis. ■ Cardiopulmonary bypass surgery. ■ Hemolytic disease of the newborn (bilirubin binding activity) as adjunct to exchange transfusion. ■ Provide adequate volume and prevent hypoproteinemia as an adjunct to RBC resuspension.

Unlabeled uses: Large-volume paracentesis, spontaneous bacterial peritonitis in patients with cirrhosis.

CONTRAINDICATIONS

Anemia (severe) or cardiac failure in the presence of normal or increased intravascular volume, hypersensitivity to albumin, pulmonary edema. ■ Buminate 25% should not be used in patients with chronic renal impairment; contains aluminum.

PRECAUTIONS

Whole blood or packed cells probably indicated if more than 1,000 mL 5% albumin required in hemorrhage; are adjunctive to use of large amounts of serum albumin to prevent anemia. Is not a substitute for whole blood in situations where both the oxygen-carrying capacity and plasma volume expansion provided by whole blood are required. ■ May be given regardless of patient blood group. ■ Use caution in hypertension, low cardiac reserve, hepatic or renal failure, or lack of albumin deficiency. ■ Use caution in patients with normal or increased intravascular volume; however, patients with hypoproteinemia may have normal blood volume. ■ Use caution in patients with burns, hypoproteinemia, or hypovolemia; an FDA-issued Dear Doctor letter identified concerns of an excess mortality rate when albumin administration was compared to NS administration in these critically ill patients. Trauma patients with concomitant traumatic brain injuries may also be at risk for increased mortality. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, hepatitis C). Numerous steps in the manufacturing process are used to make the potential for infection extremely remote. ■ 25 Gm of albumin is the osmotic equivalent of 2 units of fresh-frozen plasma. 25 Gm of albumin provides as much plasma protein as 500 mL of plasma or 2 units of whole blood. ■ Albumin is not a source of nutrition.

Monitor: Monitor BP. ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Hemoglobin, hematocrit, electrolyte, and serum protein evaluations are mandatory during therapy. Alkaline phosphatase may be elevated. ■ Hyponatremia may result from administration of large volumes of albumin diluted in D5W; additional monitoring of electrolytes may be required. ■ Observe patient carefully for increased bleeding resulting from more normal BP, circulatory embarrassment, pulmonary edema, or lack of diuresis. Central venous and/or pulmonary wedge pressure readings are most helpful. ■ Maintain hydration with additional fluids, especially in dehydrated patients. ■ Normal plasma albumin is 3.5 to 6 Gm/dL.

Maternal/Child: Category C: safety for use during pregnancy not established. ■ Do not use 25% solution in preterm infants.

Elderly: Monitor fluid intake carefully; more susceptible to circulatory overload and pulmonary edema. ■ Plasma albumin levels may be more volatile.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Chills, fever, headache, hypotension, nausea, salivation, skin rash or hives, tachycardia, vomiting.

Major: Congestive heart failure, decreased myocardial contractility, hypersensitivity reactions including anaphylaxis (rare), precipitous hypotension, pulmonary edema, salt and water retention.

ANTIDOTE

Notify the physician of all side effects. Minor side effects are generally tolerated and treated symptomatically. For major side effects, discontinue albumin and treat symptomatically. Resuscitate as necessary.

ALDESLEUKIN **BBW**(al-des-**LOO**-kin)

Antineoplastic
Immunomodulator
Biologic response modifier
Recombinant interleukin-2

Interleukin-2 Recombinant, Proleukin

pH 7.2 to 7.8

USUAL DOSE

(International units [IU])

Patient selection restricted. Prescreening and baseline studies required; see **Precautions/Monitor**.

Standard high-dose regimen: Intermittent IV: 600,000 International units (IU)/kg (0.037 mg/kg) every 8 hours for 14 doses. After 9 days of rest, repeat for up to 14 more doses; this constitutes one course (two 5-day [14 or fewer doses] treatment cycles separated by a rest period of 9 days). Treat with 28 doses or until dose-limiting toxicity requiring ICU-level support occurs. Dose is based on actual patient weight.

Retreatment: Evaluate for response 4 weeks after course completion and again before scheduling start of the next course. Additional courses are considered if there is some tumor shrinkage following the previous course and retreatment is not contraindicated. At least 7 weeks from hospital discharge should elapse before a subsequent course is administered.

Sometimes given in combination with other agents.

DOSE ADJUSTMENTS

Information on dosing in obese and underweight patients is not available; base dose on actual patient weight. ■ Doses are frequently withheld for toxicity. Doses are actually withheld, not reduced in amount. Median number of doses actually administered in a first course is 20 for metastatic renal cell carcinoma patients and 18 for metastatic melanoma patients. Continuous infusions can be interrupted as indicated by patient symptoms. ■ Hold doses and restart based on the following chart:

Guidelines for Holding Doses of Aldesleukin	
Hold Dose for	May Give Next Dose if
CARDIOVASCULAR	
Atrial fibrillation, supraventricular tachycardia, bradycardia that requires treatment or is recurrent or persistent.	Patient is asymptomatic with full recovery to normal sinus rhythm.
Systolic BP <90 mm Hg with increasing requirements for pressors.	Systolic BP ≥90 mm Hg and stable or improving requirements for pressors.
Any ECG change consistent with MI or ischemia with or without chest pain; suspicion of cardiac ischemia or myocarditis.	Patient is asymptomatic, MI and myocarditis have been ruled out, clinical suspicion of angina is low, there is no incidence of ventricular hypokinesia.

Guidelines for Holding Doses of Aldesleukin—cont'd	
Hold Dose for	May Give Next Dose if
PULMONARY	
O ₂ saturation <90%.	O ₂ saturation >90%.
CENTRAL NERVOUS SYSTEM	
Mental status changes (e.g., agitation, confusion, lethargy, somnolence). May result in coma.	Mental status changes completely resolved.
BODY AS A WHOLE	
Sepsis syndrome; patient is clinically unstable.	Sepsis syndrome has resolved, patient is clinically stable, infection is under treatment.
UROGENITAL	
SCr >4.5 mg/dL or a SCr of \geq 4 mg/dL in presence of severe volume overload, acidosis, or hyperkalemia.	SCr <4 mg/dL, and fluid and electrolyte status is stable.
Persistent oliguria, urine output of <10 mL/hr for 16 to 24 hr with rising SCr.	Urine output >10 mL/hr with a decrease of SCr >1.5 mg/dL or normalization of SCr.
DIGESTIVE	
Signs of hepatic failure including encephalopathy, increasing ascites, liver pain, hypoglycemia.	Discontinue for remainder of current course. May consider a new course of treatment in 7 weeks if all signs of hepatic failure have resolved.
Stool guaiac repeatedly >3 to 4 ⁺ .	Stool guaiac negative.
SKIN	
Bullous dermatitis or marked worsening of pre-existing skin condition (avoid topical steroid therapy).	Resolution of all signs of bullous dermatitis.

- After withholding a dose, no dose should be given until patient is globally assessed and specific criteria for restarting aldesleukin are met.

DILUTION

(International units [IU])

Each 22,000,000 IU vial (1.3 mg) must be reconstituted with 1.2 mL of preservative-free SWFI (18,000,000 IU/mL [1.1 mg (1,100 mcg)/mL]). Sterile technique imperative. Direct diluent to side of vial and gently swirl to avoid excess foaming. Do not shake. Further dilute the calculated dose in 50 mL D5W. Desired final infusion concentration is 30 to 70 mcg/mL. If the total dose is 1.5 mg or less (patient weighs less than 40 kg), the dose of aldesleukin should be diluted in a smaller volume of D5W so the final concentration remains in the acceptable range. Plastic infusion containers are preferred over glass. Do not use any filters for dilution or administration. Do not use any other diluent or infusion solution; may cause increased aggregation. Bring to room temperature before administration.

Filters: Do not use any filters for dilution or administration.

Storage: Store in refrigerator before and after reconstitution and dilution. Do not freeze. Protect from light. No stability problems will occur at CRT for 48 hours after dilution but has no preservatives. Do not use beyond expiration date on vial.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends not mixing with other drugs in the same container. Bacteriostatic water for injection (BWFI) or NS will increase aggregation.

One source suggests the following **compatibilities**:

Y-site: Amphotericin B (conventional), calcium gluconate, diphenhydramine (Benadryl), dopamine, fluconazole (Diflucan), foscarnet (Foscavir), heparin, magnesium sulfate, metoclopramide (Reglan), ondansetron (Zofran), potassium chloride (KCl), ranitidine (Zantac), sulfamethoxazole/trimethoprim, vancomycin.

RATE OF ADMINISTRATION

Intermittent IV: A single dose as an intermittent infusion over 15 minutes. Flush main line IV with D5W before and after each use. Manufacturer recommends that any keep-open IV in place for intermittent administration be D5W.

ACTIONS

A genetically engineered recombinant protein that possesses the biologic activity of naturally occurring interleukin-2. Exact mechanism of action is unknown. Immunoregulatory properties include enhancement of lymphocyte mitogenesis and stimulation of long-term growth of human interleukin-2 dependent cell lines, enhancement of lymphocyte cytotoxicity, induction of killer cell (lymphokine-activated [LAK] and natural [NK]) activity, and induction of interferon-gamma production. Immunologic effects occur in a dose-dependent manner and include activation of cellular immunity with profound lymphocytosis, eosinophilia, and thrombocytopenia, as well as the production of cytokines, including tumor necrosis factor, IL-1, and gamma interferon. In vivo experiments in murine tumor models have shown inhibition of tumor growth. Following a short infusion, aldesleukin distributes rapidly into the kidneys, liver, lungs, and spleen. Half-life is approximately 85 minutes. Eliminated by metabolism in the kidney with little or no bioactive protein excreted in urine.

INDICATIONS AND USES

Prescreening mandatory. Eligibility requirements for treatment are specific; see **Precautions** and **Contraindications**. ■ Treatment of metastatic renal cell carcinoma in adults. Patient selection should include assessment of performance status. See prescribing information for details. ■ Treatment of adults with metastatic melanoma.

Unlabeled uses: Acute myelogenous leukemia after autologous BMT.

CONTRAINDICATIONS

Abnormal thallium stress test or pulmonary function tests. ■ Known hypersensitivity to interleukin-2 or any component of aldesleukin. ■ Patients with organ allografts. ■ Exclude from treatment any patient with significant cardiac, pulmonary, renal, hepatic, or CNS impairment; any patient requiring treatment with steroidal agents; and any patient at higher risk for cardiovascular adverse events during periods of hypotension and fluid shifts.

Retreatment is permanently contraindicated in patients who experienced specific toxicities in a previous course of therapy (see the following chart).

Contraindications for Retreatment with Aldesleukin	
Organ System	Symptom
Cardiovascular	Sustained ventricular tachycardia ≥ 5 beats. Cardiac rhythm disturbances not controlled or unresponsive to management. Chest pain with ECG changes consistent with angina or myocardial infarction. Cardiac tamponade.
Pulmonary	Intubation required more than 72 hours.
Renal	Renal failure requiring dialysis for more than 72 hours.
Central nervous system	Coma or toxic psychosis lasting more than 48 hours. Repetitive or difficult-to-control seizures.
Gastrointestinal	Bowel ischemia or perforation. Bleeding requiring surgery.

PRECAUTIONS

Administered in the hospital under the supervision of a qualified physician (usually a medical oncologist and/or immunologist). Intensive care facilities and specialists in cardiopulmonary and/or intensive care medicine must be available. ■ Capillary leak syndrome (CLS [extravasation of plasma proteins and fluid into the extravascular space and loss of vascular tone]) can begin immediately after aldesleukin treatment starts and results in hypotension and reduced organ perfusion that can be severe enough to result in death. CLS may be associated with angina, arrhythmias (supraventricular and ventricular), edema, GI bleed or infarction, mental status changes, myocardial infarction, renal insufficiency, and respiratory insufficiency requiring intubation. Extravasation of protein and fluid into the extravascular space will lead to edema and the creation of new effusions. ■ Therapy should be restricted to patients with normal cardiac and pulmonary functions as defined by appropriate tests. ■ Use extreme caution in patients with normal thallium stress tests and pulmonary function tests who have a history of prior cardiac or pulmonary disease. ■ Patients who have had a nephrectomy are eligible for treatment if SCr is less than 1.5 mg/dL (85% of patients in one study). ■ Mental status changes (e.g., irritability, confusion, depression) may be indicators of bacteremia or early bacterial sepsis, hypoperfusion, occult CNS malignancy, or direct aldesleukin-induced CNS toxicity. Mental status changes due solely to aldesleukin may progress for several days before recovery begins. Permanent neurologic deficits have been reported. ■ Withhold administration in patients who develop moderate to severe lethargy or somnolence; continued administration may result in coma. ■ May exacerbate disease symptoms in clinically unrecognized or untreated CNS metastases. Thoroughly evaluate and treat CNS metastases before aldesleukin therapy. Should be neurologically stable and have a negative CT scan. New neurologic signs, symptoms, and anatomic lesions following aldesleukin therapy have been reported in patients without evidence of CNS metastases. Clinical manifestations include agitation, ataxia, change in mental status, hallucinations, obtundation, speech difficulties, and coma. Cortical lesions and demyelination have been seen using MRI studies. Neurologic S/S usually resolve following discontinuation of therapy; however, there have been reports of permanent damage. ■ Use extreme caution in patients with a history of seizures (may cause seizures), patients with fixed requirements for large volumes of fluid (e.g., hypercalcemia), those with autoimmune disorders (e.g., Crohn's disease, ulcerative colitis, psoriasis), previous cytotoxic drug therapy or radiation therapy, and patients sensitive to *Escherichia coli*-derived proteins. ■ May cause autoimmune disease and inflammatory disorders or exacerbate pre-existing conditions (e.g., Crohn's disease, diabetes mellitus, scleroderma, inflammatory arthritis, oculobulbar myasthenia gravis, glomerulonephritis, cholecystitis, cerebral vasculitis, thyroiditis, Stevens-Johnson syndrome, bullous pemphigoid). ■ Serious manifestations of eosinophilia involving eosinophilic infiltration of cardiac and pulmonary tissues can occur following aldesleukin administration. ■ Associated with impaired neutrophil function and an increased risk of disseminated infection, including sepsis and bacterial endocarditis. Pre-existing bacterial infections should be adequately treated before beginning therapy. Patients with indwelling central lines are at increased risk for infection with gram-positive organisms. Antibiotic prophylaxis with ciprofloxacin, nafcillin, oxacillin, or vancomycin has been associated with a reduced incidence of staphylococcal infections. ■ Induces significant hypotension; discontinue antihypertensives during treatment. ■ Kidney and liver function are impaired during aldesleukin therapy. ■ May impair thyroid function; changes may suggest autoimmunity; thyroid replacement therapy has been required in a few patients. ■ May cause hyperglycemia and/or diabetes mellitus. ■ Anti-aldesleukin antibodies have been detected in some patients. Impact of antibody formation on efficacy and safety of aldesleukin is unknown. ■ See [Drug/Lab Interactions](#).

Monitor: A central venous catheter (double or triple lumen) is frequently ordered on admission (required for continuous infusion). A minimum of two IV lines is usually required (one for the aldesleukin and its keep-open IV and one for other needed fluids and medications). One line could suffice if absolutely necessary since aldesleukin would be discontinued when colloids are administered. Flushing of line with D5W before and after aldesleukin is imperative. Ability to record CVP and draw blood samples should be avail-

able. ■ Admission chest x-ray, ECG, CBC with differential and platelet count, blood chemistries including electrolytes and renal and liver function tests, T₃, T₄, PT, PTT, urinalysis, and body weight should be obtained. Adequate pulmonary function, normal arterial blood gases, and normal ejection fraction and unimpaired wall motion (confirmed by thallium stress test and/or a stress echocardiogram) should be documented. ■ During drug administration obtain daily CBC with differential and platelet count, blood chemistries including electrolytes, renal and hepatic function tests, and chest x-rays. ■ Continuous cardiac monitoring is indicated (required with BP below 90 mm Hg or any cardiac irregularity). ■ Monitoring and flexibility in management of fluid balance and organ perfusion status is imperative. Requires constant management and balancing of effects of fluid shifts to prevent the consequences of hypovolemia (e.g., impaired organ perfusion) or fluid accumulation (e.g., edema, pulmonary edema, ascites, pulmonary effusion), which may exceed the patient's tolerance. ■ Assess hypovolemia by central venous catheterization and frequent central venous pressure monitoring. Administer colloids (albumin, plasmanate) or crystalloids (IV fluids) as indicated for a BP drop of 20 mm Hg or greater or a systolic BP less than 90. ■ Frequent neuro checks required (note agitation, blurred vision, confusion, depression, irritability, and persistent somnolence). ■ Vital signs and strict I&O are required every 2 to 4 hours (much more frequently as side effects develop). ■ Weigh daily. ■ Assess thyroid function periodically. ■ An ECG and cardiac enzymes are indicated for any S/S of chest pain, murmurs, gallops, irregular rhythm, or palpitations. A repeat thallium study is indicated for evidence of cardiac ischemia or CHF; may indicate ventricular hypokinesia due to MI or myocarditis. ■ Obtain a urinalysis as indicated. ■ Assess pulmonary function through examination, vital signs, and pulse oximetry. Arterial blood gases are indicated for any dyspnea or respiratory impairment. ■ Some routine medications are indicated prophylactically to reduce the incidence of side effects and to promote patient comfort. The morning of the first treatment, begin standard antipyretic therapy (e.g., acetaminophen 650 mg PO q 4 hr) and NSAIDs (e.g., naprosyn 500 mg q 12 hr PO) for fever and arthralgia. Use an H₂ antagonist (e.g., ranitidine 150 mg PO q 12 hr) to prevent GI bleeding. Continue administration of these drugs until 12 hours after last dose of aldesleukin. Low-dose dopamine 1 to 5 mcg/kg/min can help maintain organ perfusion and urine output if given at initial onset of CLS before hypotension occurs. Antiemetics, antidiarrheals, antichill/rigors (meperidine), antihistamines, and moisturizing skin lotions will also be used throughout treatment; see [Antidote](#) for specifics. ■ If fever occurs several days into treatment or recurs after subsiding, assume infection first, then drug. Confusion, depression, or irritability may also suggest infection. Draw cultures; administer appropriate antibiotics. ■ Patients who have had nephrectomies may be more at risk for increases in serum BUN or creatinine, electrolyte shifts, and reduced urine output. Evaluate fluid, electrolyte, and acid-base status promptly if any of the above occur. Gradual increases without other complications (marked fluid overload, hyperkalemia, acidosis) are frequently tolerated (SCr must not exceed 4.5 mg/dL). ■ Maintain pulmonary status as needed with O₂ and diuretics (furosemide). Assess pulmonary status with chest x-rays. ■ Monitor central and peripheral IV sites to reduce potential for infection. ■ No restrictions on activity; use caution ambulating (orthostatic hypotension). ■ No restrictions on diet. Encouragement may be required (anorexia and/or mouth sores). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Specific preparation required for discharge; refer to literature. ■ Manufacturer supplies excellent brochures for nurses and physicians with detailed guidelines in chart form on all aspects of monitoring, toxicity, and treatment. ■ Complete review and adequate preparation of all aspects of this therapy with the patient and family are imperative. Can reduce psychologic stress of toxicity. ■ Tumor regression has continued for up to 12 months after one or more courses of therapy. ■ See [Dose Adjustments](#), [Contraindications](#), and [Antidote](#).

Patient Education: Many side effects will occur; report any changes you perceive so they can be evaluated and treated if needed (e.g., changes in breathing, chest or other pain, temperature, mood, light-headedness, fatigue). ■ Request assistance for ambulation and always sit on the side of the bed first. ■ Take only prescribed medications. ■ Avoid alcohol. ■ Use of effective contraceptive measures recommended for fertile men and women. ■ Use 15 SPF sunscreen in sunlight to protect against photosensitivity. ■ See Appendix D, p. 1255, for additional information. ■ Manufacturer supplies a patient education booklet; review thoroughly and discuss with your physician and nurse.

Maternal/Child: Category C: benefits must outweigh risks. Contraceptive measures required before initial administration and throughout treatment. ■ Discontinue breastfeeding. ■ Safety for use in pediatric patients under 18 years of age not established; studies show responsiveness and toxicity similar.

Elderly: Response rates and toxicity similar to that seen in younger adults; however, some increased incidence of severe urogenital toxicities and dyspnea was noted in the elderly. ■ Use caution, consider age-related organ impairment.

DRUG/LAB INTERACTIONS

May cause interactions with **psychotropic drugs** (e.g., analgesics, antiemetics, narcotics, sedatives, tranquilizers) because aldesleukin also affects central nervous function. ■ Concomitant use with **cardiotoxic agents** (e.g., doxorubicin [Adriamycin]), **hepatotoxic agents** (e.g., methotrexate, asparaginase), **myelotoxic agents** (e.g., cytotoxic chemotherapy, radiation therapy), and **nephrotoxic agents** (e.g., aminoglycosides, indomethacin) may increase toxicity in these organ systems and/or delay excretion of these agents, increasing their toxicity. ■ Acute, atypical adverse reactions have been reported in patients treated with aldesleukin and subsequently administered **radiographic iodinated contrast media**. Reactions have included chills, diarrhea, edema, fever, hypotension, nausea, oliguria, pruritus, rash, and vomiting. Most reactions were reported when contrast media was given within 4 weeks after the last dose of aldesleukin. ■ **Glucocorticoids** (e.g., dexamethasone [Decadron]) reduce aldesleukin-induced side effects but also reduce its anti-tumor effectiveness. ■ Aldesleukin-induced hypotension may be potentiated by **beta-blockers** (e.g., metoprolol, atenolol) and **other antihypertensive agents** (e.g., ACE inhibitors [e.g., enalapril (Vasotec), lisinopril (Zestril)], calcium channel blockers [e.g., diltiazem (Cardizem), verapamil]). ■ Concurrent use with **interferon-alfa** may increase incidence of MI, myocarditis, ventricular hypokinesia, and severe rhabdomyolysis. ■ May cause hypersensitivity reactions in patients receiving combination regimens (**high-dose aldesleukin and antineoplastics** [e.g., dacarbazine, cisplatin, tamoxifen, interferon-alfa]). ■ Aldesleukin may decrease clearance and increase plasma levels of **indinavir** (Crixivan). ■ Capable of altering numerous lab values; see literature.

SIDE EFFECTS

Frequent, predictable, often severe; are usually clinically manageable and frequently require intensive care management. Begin to occur shortly after therapy begins (chills, fatigue, fever, hypotension, nausea, vomiting). Frequency and severity are dose-related and schedule-dependent. Most are reversible within 2 or 3 days of discontinuation of therapy. Even with intensive management, side effects can progress to death.

Initially anorexia, arthralgia, chills, fatigue, fever, nausea, and vomiting occur. Initial symptoms of capillary leak syndrome are edema, electrolyte abnormalities, hypotension, oliguria, respiratory distress, significant weight gain, tachycardia. Effects of CLS **successfully** result in **hypovolemia**, which in turn leads to hypotension → hypoperfusion → sinus tachycardia → angina → myocardial ischemia and infarction → arrhythmias (supraventricular and ventricular) → decreased renal perfusion → prerenal azotemia → oliguria → anuria; **fluid retention/weight gain**, which in turn leads to rales → dyspnea → cough → tachypnea → hypoxia → pleural effusion → respiratory insufficiency requiring intubation → diarrhea → edema of the bowel → refractory acidosis → edema → ascites; and **breakdown of blood-brain barrier** (neuropsychiatric toxicity [e.g., agitation, combativeness, confusion, hallucinations, lethargy, psychosis, somnolence]). Abdominal pain and GI bleeding may be related to diarrhea, vomiting, stomatitis, duodenal ulcer formation,

bowel ischemia, infarction, or perforation. Cerebral edema and concomitant medications may impact many side effects. Lethargy and/or somnolence may lead to coma. Anemia and thrombocytopenia may occur; coagulation abnormalities (PT, PTT) reflect liver dysfunction. Hemodynamic effects similar to septic shock may be caused by tumor necrosis factor. Erythematous rash and pruritus (can progress to dry desquamation) can occur in almost all patients and are extremely uncomfortable. See [Precautions](#) and [Drug/Lab Interactions](#).

Post-Marketing: Anaphylaxis, angioedema, cardiac tamponade, cardiomyopathy, cellulitis, cerebral hemorrhage, cerebral lesions, cholecystitis, colitis, demyelinating neuropathy, encephalopathy, eosinophilia, extrapyramidal syndrome, fatal endocarditis, fatal subdural and subarachnoid hemorrhage, febrile neutropenia, gastritis, hepatitis, hepatosplenomegaly, hypertension, hyperthyroidism, injection site necrosis, insomnia, intestinal obstruction, lymphocytopenia, myopathy, myositis, neuralgia, neuritis, neutropenia, pneumonia (bacterial, fungal, viral), retroperitoneal hemorrhage, rhabdomyolysis, urticaria.

ANTIDOTE

Temporarily discontinue aldesleukin and notify physician immediately of arrhythmias or rhythm changes, chest pain, marked changes in HR, positive neuropsychiatric check (agitation, blurred vision, persistent extreme somnolence), systolic BP below 90 mm Hg, apical HR over 120, temperature over 38° C (100.4° F), respirations over 25/min, complaints of dyspnea, decreased breath sounds, increased sputum production, severe diarrhea associated with refractory acidosis, vomiting refractory to treatment, acute changes in GI status. May be restarted based on patient response. Hold any subsequent dose for failure to maintain organ perfusion; see [Dose Adjustments](#). Fever is routinely treated with acetaminophen and indomethacin or naprosyn; increased doses may be needed. Suggested treatments include slow IV meperidine (Demerol) 25 to 50 mg for chills and rigidity; diphenoxylate (Lomotil), or loperamide (Imodium) PO for diarrhea (these meds may not help and diarrhea may be dose-limiting); diphenhydramine (Benadryl) 25 mg PO q 6 hr, a soothing skin cream (Eucerin), and oatmeal baths for urticaria and pruritus; temazepam (Restoril) for insomnia; ondansetron (Zofran) or prochlorperazine (Compazine) for nausea. Treat edema with furosemide (Lasix) once BP has normalized. IV fluids, albumin or plasmanate, and Trendelenburg positioning are used to maintain fluid balance and BP. If organ perfusion and BP are not sustained by dopamine 1 to 5 mcg/kg/min as a continuous infusion, increase to 6 to 10 mcg/kg/min or add phenylephrine (1 to 5 mcg/kg/min). Prolonged use of pressors at relatively high doses may cause cardiac arrhythmias. Treat arrhythmias as indicated (usually sinus or supraventricular tachycardia [adenosine, verapamil]). Use O₂ for decreased PaO₂. Use packed RBCs for anemia and to ensure maximum oxygen-carrying capacity. Platelet transfusions are indicated for thrombocytopenia or to reduce risk of GI bleeding. Use of blood modifiers to treat bone marrow toxicity may be indicated (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]). Special precautions may be required (e.g., avoid IM injections; test urine, emesis, stool, secretions for occult blood). All treatment is supportive; recovery should begin within a few hours of cessation of aldesleukin. With normalized BP, diuretics (furosemide [Lasix]) can hasten recovery. Low-dose haloperidol (Haldol) may help severe mental status changes.

More rapid onset of dose-limiting toxicities will occur with overdose. **Dexamethasone (Decadron)** is indicated to counteract life-threatening toxicities. May result in loss of therapeutic effect.

ALEMTUZUMAB **BBW**(ah-lem-**TOOZ**-uh-mab)Monoclonal Antibody
Antineoplastic

Campath

pH 6.8 to 7.4

USUAL DOSE

Premedication, dose escalation to the recommended maintenance dose, and anti-infective prophylaxis are required.

Premedication: Oral diphenhydramine (Benadryl) 50 mg and acetaminophen (Tylenol) 500 to 1,000 mg should be administered 30 minutes before the first dose, at dose escalations, and as clinically indicated. For cases in which severe infusion-related reactions have occurred, corticosteroids may be administered to help prevent or minimize subsequent reactions.

Dose escalation: Initiate at a dose of 3 mg daily. When this dose is tolerated (infusion-related toxicities are Grade 2 or less), the daily dose should be increased to 10 mg. When the 10-mg dose is tolerated, the maintenance dose of 30 mg may be initiated. In most cases, dose escalation to the maintenance dose of 30 mg can be achieved in 3 to 7 days.

Maintenance dose: 30 mg/day administered three times a week on alternate days (i.e., Monday, Wednesday, Friday). Administered for up to 12 weeks. Single doses greater than 30 mg or cumulative weekly doses greater than 90 mg have been associated with an increased incidence of pancytopenia and should **not** be administered.

Anti-infective prophylaxis: To minimize the risk of selected opportunistic infections, administer sulfamethoxazole/trimethoprim DS twice daily three times a week and famciclovir (Famvir) 250 mg or equivalent twice daily at the start of alemtuzumab therapy. Continue prophylaxis for 2 months after completion of therapy or until the CD4+ count is equal to or greater than 200 cells/mm³, whichever occurs later.

DOSE ADJUSTMENTS

There are no dose modifications recommended for lymphopenia. ■ Withhold alemtuzumab during serious infections or other serious adverse reactions until resolution. ■ Discontinue alemtuzumab for autoimmune anemia or autoimmune thrombocytopenia. ■ Recommendations for dose modification for severe neutropenia or thrombocytopenia are listed in the following chart.

Continued

Alemtuzumab Dose Modification for Neutropenia or Thrombocytopenia	
Hematologic Values	Dose Modification*
ANC less than 250/mm³ and/or platelet count equal to or less than 25,000/mm³	
First occurrence	Withhold alemtuzumab therapy. Resume alemtuzumab at 30 mg when ANC is equal to or greater than 500/mm ³ and platelet count is equal to or greater than 50,000/mm ³ .
Second occurrence	Withhold alemtuzumab therapy. Resume alemtuzumab at 10 mg when ANC is equal to or greater than 500/mm ³ and platelet count is equal to or greater than 50,000/mm ³ .
Third occurrence	Discontinue alemtuzumab therapy.
Equal to or greater than 50% decrease from baseline in patients initiating therapy with a baseline ANC equal to or less than 250/mm³ and/or a baseline platelet count equal to or less than 25,000/mm³	
First occurrence	Withhold alemtuzumab therapy. Resume alemtuzumab at 30 mg upon return to baseline value(s).
Second occurrence	Withhold alemtuzumab therapy. Resume alemtuzumab at 10 mg upon return to baseline value(s).
Third occurrence	Discontinue alemtuzumab therapy.

*If the delay between dosing is equal to or more than 7 days, resume alemtuzumab therapy at 3 mg and escalate to 10 mg and then to 30 mg as tolerated; see *Dose and Administration*.

DILUTION

Do not shake vial before use. Withdraw the necessary amount of alemtuzumab from the ampule into a syringe. Inject into 100 mL of NS or D5W. Gently invert the bag to mix solution. Discard any unused drug.

Filters: Filtering no longer recommended by the manufacturer.

Storage: Store ampules at 2° to 8° C (36° to 46° F). Do not freeze. If accidentally frozen, thaw at 2° to 8° C before administration. Protect from direct sunlight. Prepared solution may be stored at CRT or refrigerated. Protect from light and use within 8 hours of dilution.

COMPATIBILITY

Manufacturer states, "Other drug substances should not be added or simultaneously infused through the same intravenous line." No **incompatibilities** observed with PVC bags, PVC or polyethylene-lined PVC administration sets, or low-protein binding filters.

RATE OF ADMINISTRATION

A single dose as an infusion over 2 hours. **Do not administer** as an IV push or bolus. Subcutaneous administration is unlabeled but has been used.

ACTIONS

A recombinant, DNA-derived, humanized monoclonal antibody (Campath-1H) that binds to the 21-28 kD cell surface glycoprotein, CD52. CD52 is expressed on the surface of both normal and malignant B and T lymphocytes, NK cells, most monocytes, macrophages, a subpopulation of granulocytes. Alemtuzumab binding has been observed in lymphoid tissues, the mononuclear phagocyte system, and the male reproductive tract. A proportion of bone marrow cells, including some CD34+ cells, also express variable levels of CD52. The mechanism of action is thought to be an antibody-dependent lysis of leukemic cells following cell surface binding. Exhibits nonlinear kinetics. AUC and half-life increase with repeated dosing. Mean half-life was 11 hours (range 2 to 32 hours) after the first 30-mg dose and was 6 days (range 1 to 14 days) after the last 30-mg dose. The rise in serum alemtuzumab concentration corresponds with the reduction in malignant lymphocytosis.

INDICATIONS AND USES

Treatment of B-cell chronic lymphocytic leukemia (B-CLL).

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Administered under the supervision of a physician experienced in the use of antineoplastic therapy in a facility equipped to monitor patient and respond to any medical emergency. ■ Serious and, in rare instances, fatal pancytopenia/marrow hypoplasia, autoimmune idiopathic thrombocytopenia, and autoimmune hemolytic anemia have been reported. Have occurred at recommended dose. Do not exceed maximum daily or weekly recommended dose. See [Usual Dose](#), [Dose Adjustments](#), and [Antidote](#). ■ Serious and sometimes fatal bacterial, viral, fungal, and protozoan infections have been reported. Prophylaxis directed against *Pneumocystis jiroveci* pneumonia and herpes virus infections has been shown to decrease but not eliminate the occurrence of these infections. See [Usual Dose](#), [Dose Adjustments](#), and [Antidote](#). ■ Serious and sometimes fatal infusion reactions can occur; see [Monitor](#). ■ Use caution in patients who have had previous cytotoxic agents or radiation therapy or who have received agents that may cause blood dyscrasias; see [Drug/Lab Interactions](#). ■ Because of the potential for transfusion-associated graft-versus-host disease in severely lymphopenic patients, irradiation of any blood products is recommended. ■ A small percentage of patients have developed antibodies to alemtuzumab.

Monitor: Obtain a baseline CBC, including differential and platelet count. Monitor weekly or more frequently if worsening anemia, neutropenia, or thrombocytopenia develops. ■ Infusion reactions, including ARDS, bronchospasm, cardiac arrhythmias and/or arrest, chills, fever, hypotension, MI, N/V, pulmonary infiltrates, rash, respiratory arrest, rigors, shortness of breath, syncope, and/or urticaria may occur. Reactions may be severe. Acute infusion-related reactions were most common during the first week of therapy in clinical studies. Premedicate patient and monitor carefully during infusion. Gradual escalation to the recommended maintenance dose is required at the initiation of therapy and after interruption of therapy for 7 or more days. See [Usual Dose](#). ■ Monitor for CMV infection during and for 2 months after completion of therapy. Treat confirmed infection or viremia as indicated with ganciclovir (Cytovene) or equivalent. ■ Monitor blood pressure and hypotensive symptoms carefully in patients with ischemic heart disease and in patients taking antihypertensive medications; see [Drug/Lab Interactions](#). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ CD4+ counts should be followed after therapy until recovery to equal to or greater than 200 cells/mm³. See [Usual Dose](#).

Patient Education: Women of childbearing potential and men of reproductive potential should use effective contraceptive methods during treatment and for a minimum of 6 months following therapy. ■ Promptly report any unusual side effects or signs of bleeding or bruising, infection (e.g., fever), or infusion reaction (e.g., difficulty breathing, rash). ■ Irradiation of blood products is required until adequate lymphocyte recovery. ■ See Appendix D, p. 1255.

Maternal/Child: Category C: avoid pregnancy. May cause fetal harm. ■ Discontinue breast-feeding during treatment and for at least 3 months following completion of therapy. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Differences in safety and efficacy related to age have not been observed to date, but study numbers have been small.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been performed. ■ May cause additive effects with **bone marrow-suppressing agents, radiation therapy, or agents that cause blood dyscrasias** (e.g., amphotericin B, antithyroid agents [Methimazole (Tapazole)], azathioprine [Imuran], chloramphenicol, ganciclovir [Cytovene], interferon, plicamycin [Mithracin], zidovudine [AZT, Retrovir]). ■ May intensify effects of **antihypertensive medications**; see [Monitor](#). ■ Do not administer **chloroquine or live virus vaccines** to patients receiving anti-neoplastic agents.

SIDE EFFECTS

The most common serious side effects are cytopenias (anemia, lymphopenia, neutropenia, thrombocytopenia), immunosuppression/infections (CMV viremia, CMV infection, other infections), and infusion reactions (chills, dyspnea, fever, hypotension, nausea, rash, tachycardia, urticaria). GI symptoms (abdominal pain, N/V) and neurologic symptoms (insomnia, anxiety) are also reported commonly. Hypersensitivity reactions (including anaphylaxis), anorexia, arrhythmias, asthenia, autoimmune hemolytic anemia or autoimmune idiopathic thrombocytopenia, constipation, cough, depression, dizziness, dyspepsia, edema, epistaxis, febrile neutropenia, Goodpasture's syndrome, Graves disease, Guillain-Barré syndrome, headache, hypertension, infections (e.g., pneumonia, Epstein-Barr virus (EBV), progressive multifocal leukoencephalopathy (PML), and several other opportunistic infections), malaise, mucositis, myalgias, optic neuropathy, pain, purpura, rhinitis, serum sickness, somnolence, tremor, tumor lysis syndrome, and many others have been reported.

Post-Marketing: CHF, chronic inflammatory demyelinating polyradiculoneuropathy, fatal infusion reactions, fatal transfusion-associated graft-versus-host disease.

ANTIDOTE

Notify physician of all side effects. Treatment of most reactions will be supportive. Therapy should be temporarily discontinued during serious infection, serious hematologic toxicity (except lymphopenia), or other serious toxicity until the infection or adverse event resolves. Discontinue medication permanently for severe reactions, including autoimmune anemia or thrombocytopenia. Infusion reactions may be treated with acetaminophen, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone), and meperidine as indicated. Administration of irradiated blood products and/or blood modifiers (e.g., darbepoetin [Aransep], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Median durations of neutropenia were 28 to 37 days, and median durations of thrombocytopenia were 9 to 21 days. Median time to recovery of CD4+ counts to equal to or greater than 200/mm³ is 2 to 6 months; however, full recovery of CD4+ and CD8+ counts may take more than 12 months. Discontinue alemtuzumab and provide supportive therapy in overdose. Treat hypersensitivity reactions with epinephrine, antihistamines, and corticosteroids as needed. Resuscitate as indicated.

ALFENTANIL HYDROCHLORIDE

(al-FEN-tah-nil hy-droh-KLOR-eyed)

General anesthetic
Opioid analgesic agonist
Anesthesia adjunct

Alfenta

pH 4 to 6

USUAL DOSE

Adults and pediatric patients 12 years of age and older: Dose must be individualized and titrated to the desired effect in each patient according to body weight, physical status, underlying pathologic condition, use of other drugs, and type and duration of surgical procedure and anesthesia. Usually used in conjunction with short-acting barbiturates (e.g., thiopental [Pentothal]), neuromuscular blocking agents (e.g., pancuronium, succinylcholine), and an inhalation anesthetic (e.g., nitrous oxide) to maintain balanced anesthesia. Use reduced doses of a neuromuscular blocking agent prophylactically to prevent muscle rigidity or to induce muscle relaxation after rigidity occurs. Full paralyzing doses may be used after loss of consciousness. Use of a benzodiazepine (e.g., diazepam [Valium], midazolam [Versed]) may reduce induction dose requirements, decrease time to loss of consciousness, and diminish patient recall; see [Drug/Lab Interactions](#). See [Dose Adjustments](#).

Alfentanil Dosing Guidelines for Use During General Anesthesia	
SPONTANEOUSLY BREATHING/ASSISTED VENTILATION	
	Induction of analgesia: 8-20 mcg/kg Maintenance of analgesia: 3-5 mcg/kg q 5-20 min or 0.5-1 mcg/kg/min Total dose: 8-40 mcg/kg
ASSISTED OR CONTROLLED VENTILATION	
Incremental injection (To attenuate response to laryngoscopy and intubation)	Induction of analgesia: 20-50 mcg/kg Maintenance of analgesia: 5-15 mcg/kg q 5-20 min Total dose: Up to 75 mcg/kg
CONTINUOUS INFUSION	
(To provide attenuation of response to intubation and incision)	Infusion rates are variable and should be titrated to the desired clinical effect. SEE INFUSION DOSAGE GUIDELINES (BELOW) Induction of analgesia: 50-75 mcg/kg Maintenance of analgesia: 0.5-3 mcg/kg/min (average rate 1-1.5 mcg/kg/min) Total dose: Dependent on duration of procedure
ANESTHETIC INDUCTION	
	Induction of anesthesia: 130-245 mcg/kg Maintenance of analgesia: 0.5-1.5 mcg/kg/min or general anesthetic Total dose: Dependent on duration of procedure At these doses, truncal rigidity should be expected and a muscle relaxant should be utilized Administer slowly (over 3 minutes) Concentration of inhalation agents reduced by 30%-50% for initial hour
MONITORED ANESTHESIA CARE (MAC)	
For sedated and responsive, spontaneously breathing patients	Induction of MAC: 3-8 mcg/kg Maintenance of MAC: 3-5 mcg/kg q 5-20 min or 0.25-1 mcg/kg/min Total dose: 3-40 mcg/kg
INFUSION DOSAGE	
<p>Continuous infusion: 0.5-3 mcg/kg/min administered with nitrous oxide/oxygen in patients undergoing general surgery. Following an anesthetic induction dose of alfentanil, infusion rate requirements are reduced by 30%-50% for the first hour of maintenance.</p> <p>Changes in vital signs that indicate a response to surgical stress or lightening of anesthesia may be controlled by increasing the alfentanil to a maximum of 4 mcg/kg/min and/or administration of bolus doses of 7 mcg/kg. If changes are not controlled after three bolus doses given over a 5-minute period, a barbiturate, vasodilator, and/or inhalation agent should be used. Infusion rates should always be adjusted downward in the absence of these signs until there is some response to surgical stimulation. Rather than an increase in infusion rate, 7 mcg/kg bolus doses of alfentanil or a potent inhalation agent should be administered in response to signs of lightening of anesthesia within the last 15 minutes of surgery. Alfentanil infusion should be discontinued at least 10 to 15 minutes before the end of surgery. Discontinue 10 to 15 minutes before end of procedures in general anesthesia.</p> <p>Continue infusion to end of procedure during MAC, then discontinue.</p>	

PEDIATRIC DOSE

Safety for use in pediatric patients under 12 years of age not established; not recommended. Half-life and duration of action is decreased in pediatric patients; more frequent supplemental doses may be required; see *Maternal/Child*.

DOSE ADJUSTMENTS

Reduce dose of one or both agents when given in combination with other CNS depressants (e.g., barbiturates, inhalation anesthetics, narcotic analgesics, tranquilizers). ■ Calculate dose based on lean body weight in obese patients (more than 20% above ideal body weight). ■ Reduced initial dose required in elderly or debilitated patients (a 40% reduction was required in one study); reduced supplemental doses, a slower infusion rate,

Continued

or longer intervals between doses may be required based on effects of initial dose. ■ Doses appropriate for general population may cause serious respiratory depression in vulnerable patients. ■ Reduced dose may be required in hypothyroidism and in impaired hepatic function. ■ See [Drug/Lab Interactions](#).

DILUTION

IV injection: Small volumes may be given undiluted (usually by the anesthesiologist). Use of tuberculin syringe recommended (1 mL equals 500 mcg). Further dilution with 5 mL of SWFI or NS to facilitate titration is appropriate.

Infusion: Dilute 20 mL alfentanil with 230 mL NS, D5NS, D5W, or LR to achieve a concentration of 40 mcg/mL. Desired concentration range is 25 to 80 mcg/mL.

Storage: Store ampules at CRT; protect from light and freezing.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Bivalirudin (Angiomax), cisatracurium (Nimbex), dexmedetomidine (Precedex), etomidate (Amidate), fenoldopam (Corlopam), hetastarch in electrolytes (Hexend), linezolid (Zyvox), propofol (Diprivan), remifentanil (Ultiva).

RATE OF ADMINISTRATION

IV injection: Administer over a minimum of 3 minutes. Rapid administration of lower doses or administration of full anesthetic doses will result in muscle rigidity, apnea, respiratory paralysis, loss of vascular tone, and hypotension. Titrate rate to desired patient response.

Infusion: See [Usual Dose](#).

ACTIONS

An opioid derivative, narcotic analgesic, and descending CNS depressant. Less potent than fentanyl milligram for milligram, but achieves higher plasma concentrations. Produces hypnosis and respiratory depressant actions that outlast its analgesic effect. Onset of action is immediate. Produces analgesic effects in 1 minute. Peak effect (respiratory depression and analgesia) occurs within 1½ to 2 minutes. With induction doses, loss of consciousness occurs within 1 to 2 minutes. Provides dose-related protection against hemodynamic responses to surgical stress. Histamine release rarely occurs. May cause rigidity of chest, pharynx, and abdominal muscles, inhibiting ventilation; see [Precautions/Monitor](#), [Side Effects](#), [Antidote](#). Duration of action is 5 to 10 minutes. Has a terminal half-life of 90 to 111 minutes. Cumulative effects are somewhat less than with fentanyl or sufentanil, but with repeat doses recovery may be prolonged. Recovery should occur within 10 to 15 minutes of end of procedure or 25 to 30 minutes after last incremental dose or discontinuing the infusion. Metabolized in the liver. Excreted as metabolites in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Analgesic adjunct given in incremental doses in the maintenance of anesthesia with barbiturate/nitrous oxide/oxygen. ■ Analgesic administered by continuous infusion with nitrous oxide/oxygen in the maintenance of general anesthesia. ■ Primary anesthetic agent for the induction of anesthesia in patients undergoing general surgery requiring endotracheal intubation and mechanical ventilation. ■ Analgesic component for monitored anesthesia care (MAC) during surgical or diagnostic procedures.

CONTRAINDICATIONS

Known hypersensitivity to alfentanil or known intolerance to other opioid agonists (e.g., fentanyl, sufentanil). Use during labor and delivery not recommended.

PRECAUTIONS

For IV use only. ■ Administered by or under the direct observations of the anesthesiologist. Must have responsibility only for anesthesia and continuous observation of the patient during surgery and/or procedure. ■ Oxygen, controlled ventilation equipment, opioid antagonists (e.g., naloxone [Narcan]), neuromuscular blocking agents (e.g., pancuronium, succinylcholine [Anectine]), and all emergency drugs and equipment must be

immediately available. ■ Staff must be skilled in medical management of critically ill patients, cardiovascular resuscitation, and airway management. ■ Use caution; plasma clearance reduced and recovery time prolonged in the elderly and in patients with impaired liver function (half-life prolonged [up to 5.8 hours]); reduced dose may be indicated. ■ Use caution in patients with pulmonary disease, decreased respiratory reserve, or potentially compromised respiration. May cause rigidity of chest and abdominal muscles, decrease respiratory drive, and increase airway resistance; may require assisted or controlled ventilation. ■ Use caution in patients with head injury or increased intracranial pressure; risk of respiratory depression is increased. ■ Respiratory depression may cause an increased PCO_2 , cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. ■ Use caution in patients with bradyarrhythmias. ■ In general, narcotic analgesics are contraindicated in acute or severe bronchial asthma and when an upper airway obstruction or significant respiratory depression is present. ■ Use caution in patients with hypothyroidism; risk of respiratory depression and prolonged CNS depression is increased. Reduced doses may be indicated. ■ See [Drug/Lab Interactions](#).

Monitor: Can cause rigidity of respiratory muscles; concurrent use of a neuromuscular blocking agent can prevent or reverse muscle rigidity to permit controlled ventilation. ■ Adequate preoperative hydration is recommended to reduce incidence of hypotension. ■ Observe for hypotension, apnea, upper airway obstruction, and/or oxygen desaturation. Monitor vital signs and oxygen saturation continuously. If not unconscious, patient will appear to be asleep and forget to breathe unless commanded to do so. ■ Additional doses of alfentanil can be used to control tachycardia and hypertension during surgery. ■ Prolonged postoperative monitoring may be indicated; respiratory depression, respiratory arrest, bradycardia, asystole, arrhythmias, and hypotension may occur after initial recovery. ■ Keep patient supine; orthostatic hypotension and fainting may occur. ■ Has a short duration of action; pain medication may be required soon after initial recovery. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Avoid alcohol or other CNS depressants (e.g., antihistamines, benzodiazepines [e.g., diazepam (Valium)]). ■ Blurred vision, dizziness, drowsiness, or light-headedness may occur; request assistance with ambulation. ■ Review all medications for interactions.

Maternal/Child: Category C: safety for use in pregnancy not established; has embryocidal effects in rats and rabbits. ■ Not recommended for use during labor and delivery. ■ Postpone breast-feeding for at least 24 hours after use of alfentanil. ■ Muscle rigidity is more common in neonates than in older children or adults.

Elderly: See [Dose Adjustments](#) and [Precautions](#). ■ May markedly decrease pulmonary ventilation. ■ Decreased protein binding, decreased clearance, and possible increased brain sensitivity may make the elderly more sensitive to effects (e.g., respiratory depression, extended recovery time, urinary retention, constipation). ■ Lower doses may provide effective analgesia. ■ Consider age-related organ impairment; elimination half-life is extended, postoperative recovery may be delayed.

DRUG/LAB INTERACTIONS

Use of **benzodiazepines** (e.g., diazepam [Valium], midazolam [Versed]) may decrease dose of alfentanil required and decrease patient recall, but when given immediately before or in conjunction with high doses of alfentanil, benzodiazepines may produce vasodilation, severe hypotension, and result in delayed recovery. ■ After an anesthetic induction dose of alfentanil, requirements for **volatile inhalation anesthetics** (e.g., nitrous oxide) and/or **alfentanil infusion** are reduced by 30% to 50% for the first hour of maintenance. ■ **Beta-adrenergic blocking agents** (e.g., metoprolol, timolol) may be used preoperatively to decrease hypertensive episodes during surgical procedures, but chronic use (including ophthalmic preparations) may also increase the risk of initial bradycardia. ■ Respiratory depression, CNS depression, hypotensive effects, and duration of action increased with concomitant administration of other **CNS depressants** (e.g., antidepressants, antihistamines, barbiturates, benzodiazepines, haloperidol, inhalation anes-

thetics, narcotic analgesics, phenothiazines). Reduced doses of one or both agents usually required. ■ Clearance decreased by **cimetidine** (Tagamet) and **erythromycin**; risk of prolonged or delayed respiratory depression may be increased. ■ Respiratory depressant effects are additive with **neuromuscular blocking agents** (e.g., pancuronium, succinylcholine). ■ Other opioids have caused severe hypertension with **MAO inhibitors** (e.g., selegiline [Eldepryl]). Use extreme caution; beta-blockers (e.g., propranolol) and vasodilators (e.g., nitroglycerin) should be available. ■ Duration of action may be prolonged with other **agents that inhibit hepatic enzymes** (e.g., azole antifungals [e.g., itraconazole (Sporanox)], beta-blockers [e.g., metoprolol (Lopressor), propranolol, timolol (Novo-Timol)], calcium channel blockers [e.g., diltiazem (Cardizem), verapamil], fluoroquinolones [e.g., ciprofloxacin (Cipro), levofloxacin (Levaquin)], MAO inhibitors). ■ Monitor closely for S/S of respiratory depression and CNS depression with concurrent use of **protease inhibitors** (e.g., saquinavir [Invirase], ritonavir [Norvir]). ■ Use of **naltrexone** (ReVia) would require increased doses of alfentanil; may cause prolonged respiratory depression and/or circulatory collapse. Discontinue naltrexone several days before elective surgery if use of an opioid is necessary. ■ Analgesic effects may be antagonized by **opioid agonist/antagonist analgesics**; may also cause additive CNS and respiratory depressant effects. ■ May delay **gastric emptying** and invalidate diagnostic tests. ■ May interfere with some **hepatobiliary imaging**. ■ Delay **plasma amylase and lipase measurements** for at least 24 hours.

SIDE EFFECTS

Average dose: Bradycardia and hypotension may occur shortly after administration. Respiratory depression caused by alfentanil and/or muscle rigidity may progress to apnea. Agitation, arrhythmias (e.g., bradycardia, tachycardia), blurred vision, bradypnea, chest wall rigidity, dizziness, euphoria, headache, hypercapnia (increased CO₂), hypersensitivity reactions (e.g., anaphylaxis, bronchospasm, itching, laryngospasm, urticaria), hypertension, hypotension, muscle rigidity (skeletal muscles including abdomen, chest, pharynx, neck, and extremities), myoclonic movements, nausea, postoperative confusion, respiratory sedation, shivering, skeletal muscle movements, sleepiness, vomiting.

Overdose: Bradycardia; circulatory depression; cold, clammy skin; dizziness (severe); drowsiness (severe); hypotension; nervousness or restlessness (severe); pinpoint pupils of eyes; respiratory depression; weakness (severe).

ANTIDOTE

Many side effects are medical emergencies. Manage respiratory depression during surgery via endotracheal intubation and assisted or controlled ventilation; prolonged mechanical ventilation may be required. Treat postoperative respiratory depression with naloxone (Narcan); titrate dose carefully to improve respirations without reversing analgesic effects or causing other adverse effects (hypertension and tachycardia may result in left ventricular failure and pulmonary edema, especially in cardiac patients). Treat bradycardia with atropine, or alfentanil-induced bradycardia can be antagonized with the use of a neuromuscular blocking agent with vagolytic activity (e.g., pancuronium). Treat hypotension by placing the patient in a Trendelenburg position, if possible; administer IV fluids and a vasopressor (e.g., norepinephrine [Levophed], dopamine) if indicated. Naloxone may reverse hypotension postoperatively. Muscle rigidity during anesthesia induction or surgery must be controlled with neuromuscular blocking agents and controlled ventilation with oxygen. Use a neuromuscular blocking agent prophylactically to prevent muscle rigidity or to induce muscle relaxation after rigidity occurs. Neuromuscular blocking agents with vagolytic activity (e.g., pancuronium) may decrease risk of alfentanil-induced bradycardia and hypotension, but may increase the risk of hypertension or tachycardia in some patients. In patients with compromised cardiac function and/or those receiving a beta-adrenergic blocking agent preoperatively, a nonvagolytic neuromuscular blocking agent (e.g., succinylcholine) may increase the incidence and severity of bradycardia and hypotension. Respiratory depressant effects of neuromuscular blocking agents are additive with alfentanil. Postoperatively, naloxone may be used in small incremental doses to reverse skeletal muscle rigidity. Resuscitate as necessary.

ALLOPURINOL SODIUM

(al-oh-**PYOUR**-ih-nohl **SO**-dee-um)

Antigout
Antihyperuricemic
Antineoplastic adjunct

Aloprim

pH 11.1 to 11.8

USUAL DOSE

IV and oral doses are therapeutically equivalent. Oral dose can replace an IV dose at any time. See **Monitor**.

200 to 400 mg/M²/day as a single infusion or in equally divided doses at 6-, 8-, or 12-hour intervals (50 to 100 mg/M² every 6 hours, 67 to 133 mg/M² every 8 hours, or 100 to 200 mg/M² every 12 hours). Total dose should not exceed 600 mg/day.

PEDIATRIC DOSE

Recommended starting dose is 200 mg/M²/day. Usually given in equally divided doses at 6- to 8-hour intervals (50 mg/M² every 6 hours or 67 mg/M² every 8 hours). Another source says the daily dose may be given at 6-, 8-, or 12-hour intervals or as a single daily infusion. Studies found no significant difference in dose response in pediatric patients. See comments in **Usual Dose**.

DOSE ADJUSTMENTS

In patients with impaired renal function not on dialysis, reduce dose based on CrCl according to the following chart.

Allopurinol Dosing in Impaired Renal Function	
CrCl (mL/min)	Dose
10-20 mL/min	200 mg daily
3-10 mL/min	100 mg daily
<3 mL/min	100 mg daily at extended intervals (more than 24 hr if necessary)

Treat with the lowest effective dose to minimize side effects. ■ Dose with normal renal function may be increased or decreased based on electrolytes and serum uric acid levels. ■ Lower doses and/or extended intervals may be required in the elderly; consider potential for decreased organ function, concomitant disease, or other drug therapy. ■ See **Drug/Lab Interactions**.

DILUTION

Available as a single-dose vial containing 500 mg of allopurinol. Reconstitute with 25 mL of SWFI (yields 20 mg/mL). Swirl until completely dissolved. Must be further diluted with NS or D5W. Maximum concentration for administration is 6 mg/mL. 19 mL of additional diluent per 20 mg (1 mL) yields 1 mg/mL, 9 mL of additional diluent yields 2 mg/mL, and 2.3 mL of additional diluent yields 6 mg/mL.

Storage: Store unopened vials at CRT. Do not refrigerate the reconstituted and/or diluted product; begin infusion within 10 hours of reconstitution.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends administering sequentially and flushing before and after administration. Manufacturer lists the following drugs as **incompatible**: amikacin (Amikin), amphotericin B (conventional), carmustine (BiCNU), cefotaxime (Claforan), chlorpromazine (Thorazine), clindamycin (Cleocin), cytarabine (ARA-C), dacarbazine (DTIC), daunorubicin (Cerubidine), diphenhydramine (Benadryl), doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), floxuridine (FUDR), gentamicin, idarubicin

(Idamycin), imipenem-cilastatin (Primaxin), mechlorethamine (nitrogen mustard) (Mustargen), meperidine (Demerol), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), minocycline (Minocin), nalbuphine, ondansetron (Zofran), prochlorperazine (Compazine), promethazine (Phenergan), sodium bicarbonate, streptozocin (Zanosar), tobramycin, vinorelbine (Navelbine). **Do not use solutions containing sodium bicarbonate.**

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), aminophylline, aztreonam (Azactam), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), cefazolin (Ancef), cefotetan, ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), cisplatin (Platinol), cyclophosphamide (Cytosan), dactinomycin (Cosmegen), dexamethasone (Decadron), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), etoposide (VePesid), famotidine (Pepcid IV), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gallium nitrate (Ganite), ganciclovir (Cytovene), granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), lorazepam (Ativan), mannitol, mesna (Mesnex), methotrexate, metronidazole (Flagyl IV), mitoxantrone (Novantrone), morphine, potassium chloride (KCl), ranitidine (Zantac), sulfamethoxazole/trimethoprim, teniposide (Vumon), thiotepa, ticarcillin/clavulanate (Timentin), vancomycin, vinblastine, vincristine, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Manufacturer's recommendation not available. A maximum dose should take at least 1/2 to 1 hour or more based on volume with diluent and patient comfort and/or requirements. Include in hydration fluids. See [Compatibility](#).

ACTIONS

A xanthine oxidase inhibitor. Metabolized to oxypurinol. Acts on purine catabolism without disrupting the biosynthesis of purines. Reduces the production of uric acid by inhibiting the biochemical reactions immediately preceding its formation. Decreases uric acid concentrations in both serum and urine. Prevents or decreases urate deposition, decreasing the occurrence or progression of gout or urate nephropathy. Reduction of serum uric acid concentration occurs in 2 to 3 days. Peak concentrations are related to dose. Pharmacokinetic and plasma profiles of allopurinol and oxypurinol, as well as half-lives and systemic clearance, are similar with IV or oral administration. Systemic exposure to oxypurinol is also similar by both routes at each dose level. Cleared by glomerular filtration; some oxypurinol is reabsorbed in the kidney tubules. Secreted in breast milk.

INDICATIONS AND USES

Management of patients with leukemia, lymphoma, and solid tumor malignancies who are receiving cancer therapy that causes elevations of serum and urinary uric acid levels and who cannot tolerate oral therapy. Consider prophylactic use before initiation of and during chemotherapy in patients who are NPO, are nauseated and vomiting, or have malabsorption problems, dysphagia, or GI tract dysfunctions. Used prophylactically before the initiation of and during chemotherapy to prevent hyperuricemia caused by tumor lysis syndrome (TLS) and its sequela, acute uric acid nephropathy (AUAN).

Unlabeled uses: Preservation of cadaveric kidneys for transplantation.

CONTRAINDICATIONS

Any patient who has had a severe reaction to allopurinol (usually a hypersensitivity reaction).

PRECAUTIONS

For IV infusion only. ■ A skin rash or other beginning signs of hypersensitivity may be followed by exfoliative, urticarial, and purpuric lesions; Stevens-Johnson syndrome; generalized vasculitis; irreversible hepatotoxicity; and/or rarely death. ■ Incidence of hypersensitivity reactions may be increased in patients with decreased renal function who are receiving concurrent thiazides (e.g., chlorothiazide [Diuril]); use with caution. ■ See [Drug/Lab Interactions](#).

Monitor: Whenever possible, begin allopurinol therapy 24 to 48 hours before the start of chemotherapy known to cause tumor cell lysis (including adrenocorticosteroids). ■ Monitor serum uric acid levels and electrolytes before and during therapy. Monitor serum uric acid levels to determine dose and frequency required to maintain uric acid levels within the normal range. ■ Hydration with 3,000 mL/M²/day (twice the level of maintenance fluid replacement) is recommended to promote a high volume of urine output (more than 2 L/day in adults) with low urate concentration. ■ Maintain urine at neutral or slightly alkaline pH. To increase solubility of uric acid, alkalinity of urine may be increased with sodium bicarbonate. ■ Monitor renal and hepatic systems before and during therapy. ■ Monitoring of liver function suggested in patients with pre-existing liver disease, in patients with increases in liver function tests, and in patients who develop anorexia, pruritus, or weight loss. ■ Observe for symptoms of TLS (e.g., hyperuricemia, hyperkalemia, hyperphosphatemia, and hypocalcemia). If untreated, may develop AUAN leading to renal failure requiring hemodialysis. ■ Bone marrow suppression has been reported; monitor CBC periodically.

Patient Education: Maintain adequate hydration, avoid alcoholic drinks, and report nausea and vomiting and decreased urine production. ■ Report promptly blood in the urine, painful urination, irritation of the eyes, skin rash, or swelling of the lips or mouth. ■ Major acute toxicities may be allergic or renal. ■ May cause drowsiness; use caution in activities that require alertness. Request assistance for ambulation.

Maternal/Child: Category C: potential benefits must justify potential risks to fetus. ■ Use caution if required during breast-feeding.

Elderly: Lower-end initial doses or extended intervals may be appropriate in the elderly; see **Dose Adjustments**.

DRUG/LAB INTERACTIONS

May increase toxicity of **didanosine** (Videx); concurrent use not recommended. ■ Inhibits metabolism and increases effects and toxicity of **thiopurines** (e.g., azathioprine [Imuran], mercaptopurine [Purinethol]). Reduce dose of thiopurine to one third to one fourth. ■ **Uricosuric agents** (e.g., sulfinpyrazone [Anturane], probenecid [Benemid], colchicine) may increase elimination of active metabolites of allopurinol; may increase urinary excretions of uric acid. ■ Prolongs half-life of **dicumarol**; monitor PT or PTT and adjust anticoagulant dose as indicated. ■ Frequency of skin rash increased with **ampicillin/amoxicillin**. ■ Bone marrow suppression may be increased when given concurrently with **cytotoxic agents** (e.g., cyclophosphamide [Cytosan]); risk of bleeding or infection may be increased. ■ May prolong half-life of **chlorpropamide** (Diabinese). ■ Hypersensitivity reactions may be increased with **ACE inhibitors** (e.g., enalapril) or **thiazide diuretics** (e.g., chlorothiazide [Diuril]). ■ Concurrent use with **cyclosporine** (Sandimmune) may increase cyclosporine serum levels. A reduced dose of cyclosporine may be indicated; monitoring of cyclosporine serum levels suggested. ■ May decrease clearance and increase toxicity of **theophyllines** (e.g., Aminophylline).

SIDE EFFECTS

Fewer than 1% of patients have had side effects directly attributable to allopurinol. Most were hypersensitivity reactions (e.g., nausea and vomiting, rash, and renal failure/insufficiency) and of mild to moderate severity. Xanthine crystalluria has been rarely reported in long-term therapy with oral allopurinol.

ANTIDOTE

Discontinue allopurinol at the first sign of skin rash or any other allergic reaction. Do not restart. Keep physician informed of all side effects. Symptoms of TLS require immediate intervention and correction of electrolyte abnormalities to avoid kidney damage. Treat hypersensitivity reactions as indicated; may require epinephrine (Adrenalin), diphenhydramine (Benadryl), corticosteroids (hydrocortisone), and/or oxygen. Allopurinol is dialyzable, but effectiveness of hemodialysis or peritoneal dialysis in an overdose is not known.

ALPHA₁-PROTEINASE INHIBITOR (HUMAN)

(AL-fah PRO-teen-ayse in-HIB-ih-ter [HU-man])

Alpha₁-antitrypsin
replenisher

Alpha₁-antitrypsin, Alpha₁-PI, Aralast NP, Glassia,
Prolastin-C, Zemaira

pH 7.2 to 7.8 (Aralast NP) ■
pH 6.6 to 7.4 (Prolastin-C)

USUAL DOSE

60 mg/kg once a week as an infusion.

Manufacturers of Prolastin-C recommend immunizing every patient against hepatitis B before administration. If immediate treatment is required, give a single dose of hepatitis B immune globulin (human) 0.06 mL/kg IM at the same time as the initial dose of hepatitis B vaccine.

DILUTION

All preparations: Bring components to room temperature (diluent [SWFI], lyophilized preparation of alpha₁-PI, or ready-to-use solution). Must be used within 3 hours of reconstitution or entry into vial. Must be filtered before or during administration.

Aralast NP and Prolastin-C: Insert one end of the double-ended transfer needle (shortest end for Prolastin-C) into the diluent. Invert the bottle of diluent and insert the other end of the transfer needle at a 45-degree angle into the alpha₁-PI; diluent will be drawn into the alpha₁-PI by a vacuum. Remove the diluent bottle and transfer device.

Aralast NP—allow the reconstituted solution to stand until contents appear to be in solution, then swirl gently to completely dissolve. May take 5 to 10 minutes. **Do not shake or invert vial until ready to withdraw contents.**

Prolastin-C—swirl vigorously for 10 to 15 seconds immediately after adding diluent to thoroughly break up cake, then swirl continuously until the powder is completely dissolved. Some foaming will occur. If particles are visible, remove by passing through a sterile filter (e.g., 15-micron filter [not supplied]) used for administering blood products.

Glassia: Available as a single-use vial containing 1 Gm of functional alpha₁-PI in 50 mL of ready-to-use solution. Solution should be clear and colorless to yellow-green. Do not use if product is cloudy. Infusion can be made directly from the vial, or vials may be pooled in an empty, sterile IV container. When infusing directly from the vial, use a vented spike adapter and a 5-micron in-line filter (neither is supplied). When infusing from a sterile IV container, use a vent filter (not supplied) to withdraw Glassia from the vial, and then use the supplied 5-micron filter needle to transfer Glassia into the infusion container. Attach an IV administration set and administer through a 5-micron in-line filter (not supplied).

Zemaira: Insert the white end of the double-ended transfer needle into the center of the upright diluent vial. Invert the diluent vial and insert the green end of the double-ended transfer needle into the center of the product vial. Use minimum force. Diluent will be drawn into the alpha₁-PI by a vacuum. Wet the lyophilized cake completely by gently tilting the product vial. Do not allow the air inlet filter to face downward, and use care not to lose the vacuum. Remove the diluent bottle and transfer device. Gently swirl until the powder is completely dissolved. May take 5 to 10 minutes. **Do not shake or invert vial until ready to withdraw contents.**

Aralast NP will yield a 0.5 Gm/25 mL vial or a 1 Gm/50 mL vial (20 mg/mL).

Glassia will yield a 1 Gm/50 mL vial (20 mg/mL).

Prolastin-C will yield a 1 Gm/20 mL vial (50 mg/mL).

Zemaira will yield a 1 Gm/20 mL vial (50 mg/mL).

Filters: All products must be filtered before or during administration. Manufacturers supply either a filter needle to withdraw alpha₁-PI from the vial or an in-line filter (to be used in the IV line or for pooling). Several vials may be pooled into an empty sterile IV solution container. **Glassia** supplies only a filter needle for transfer; see [Dilution](#) for other filter requirements.

Storage: Refrigerate *Glassia* in carton until use. Contains no preservatives and no latex. *Aralast NP* and *Prolastin-C* should be stored at temperatures not to exceed 25° C (77° F). *Zemaira* may be refrigerated before reconstitution or stored at temperatures up to 25° C (77° F). **All Preparations:** Avoid freezing. Do not use after expiration date on vials. Must be used within 3 hours of reconstitution or entry into vial.

COMPATIBILITY

Manufacturers state, "Should be given alone, without mixing with other agents or diluting solutions."

RATE OF ADMINISTRATION

Aralast NP: Do not exceed 0.08 mL/kg/min.

Prolastin-C, Zemaira: 0.08 mL/kg/min is recommended.

Glassia: Do not exceed 0.04 mL/kg/min.

If an infusion reaction or other adverse effects occur, a reduced rate or interruption of the infusion may be indicated until symptoms subside; see [Side Effects](#) and [Antidote](#).

ACTIONS

Aralast NP, Prolastin-C, Zemaira are sterile, stable, lyophilized preparations. **Glassia** is a ready-to-use solution. All are obtained from human plasma. Increases and maintains functional levels of alpha₁-PI in the epithelial lining of the lower respiratory tract. Provides adequate antineutrophil elastase activity in the lungs of individuals with alpha₁-antitrypsin deficiency. Weekly infusions of alpha₁-PI usually maintain serum levels above a target threshold of 11 micromoles. Numerous processes employed during manufacture to eliminate potential for viral transmission from human plasma; see [Precautions](#).

INDICATIONS AND USES

Treatment of congenital alpha₁-antitrypsin deficiency, a potentially fatal deficiency; used for chronic replacement (augmentation and maintenance therapy) only in individuals with alpha₁-antitrypsin deficiency and selected types of clinically demonstrated emphysema.

CONTRAINDICATIONS

Individuals with selective IgA deficiencies (IgA level less than 15 mg/dL for **Aralast NP**) who have known antibodies against IgA (anti-IgA antibodies). IgA may be present and severe reactions, including anaphylaxis, can occur. ■ Known hypersensitivity to any alpha₁-PI product or any product components.

PRECAUTIONS

For IV use only. Confirm diagnosis of congenital alpha₁-antitrypsin deficiency with selected clinically demonstrated emphysema. ■ May contain trace amounts of IgA. Patients with selective or severe IgA deficiency and with known antibodies to IgA have a greater risk for developing severe hypersensitivity and anaphylactic reactions; see [Contraindications](#). ■ Each unit of plasma tested and found nonreactive to HIV antibody, Creutzfeldt-Jakob disease, hepatitis B surface antigen, and hepatitis C. Transmission of these viruses is still possible. ■ Will increase plasma volume; use caution in patients at risk for circulatory overload. ■ Long-term effects from continued use are not known. ■ Individuals severely deficient in endogenous alpha₁-PI are unable to maintain an adequate antiprotease defense and are subject to more rapid proteolysis of the alveolar walls leading to chronic lung disease. Pulmonary infections, including pneumonia and acute bronchitis, are common in these individuals.

Monitor: Monitor V/S and observe patient continuously throughout infusion. ■ Blood levels of alpha₁-PI have been maintained above the functional level of 80 mg/dL with this replacement therapy. Serum levels determined by commercial immunologic assays may not reflect actual functional alpha₁-PI levels. ■ Assess lung sounds and rate and quality of respirations before each infusion. ■ Monitor for S/S of a hypersensitivity reaction (e.g., dyspnea, flushing, hypotension, rash, tachycardia); emergency equipment, medications, and supplies must be available.

Patient Education: Inform of risks and of safety precautions taken during manufacturing process. ■ Note changes in breathing pattern or sputum production; avoid smoking. ■

Report S/S of a hypersensitivity reaction promptly (e.g., dyspnea, faintness, hypotension, hives, tightness of the chest). ■ Report S/S of parvovirus B19 (e.g., chills, drowsiness, fever, and runny nose, followed 2 weeks later by a rash and joint pain). Parvovirus B19 may be more serious in pregnant women and immune-compromised individuals.

Maternal/Child: Category C: use in pregnancy only when clearly needed. May present risk to fetus; benefits must justify risks. ■ Safety for use during breast-feeding not established, effects unknown. ■ Safety for use in pediatric patients not established.

Elderly: Differences in response compared to younger adults not known. As for all patients, dosing for elderly patients should be appropriate to their overall situation.

DRUG/LAB INTERACTIONS

No specific information available; see [Compatibility](#).

SIDE EFFECTS

All formulations: Consider risk potential for contracting AIDS, Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C. Hypersensitivity reactions, including anaphylaxis, chills, dyspnea, hypotension, rash, and tachycardia, have been reported; see [Contraindications](#).

Aralast NP: Cough, headache, musculoskeletal discomfort, and pharyngitis are most common. Asthma, back pain, bloating, bronchitis, dizziness, pain, peripheral edema, rash, rhinitis, sinusitis, somnolence, and viral infection may occur.

Glassia: Dizziness and headache are most common. Chest discomfort, cough, increased hepatic enzymes, sinusitis, and URI have been reported. Cholangitis, exacerbation of COPD, and severe headache may occur.

Prolastin-C: Chills, headache, hot flush, pruritus, and rash were most common. A severe abdominal and extremity rash occurred in one patient and recurred in two patients on rechallenge.

Zemaira: Asthenia, bronchitis, chest pain, cough, dizziness, fever, headache, injection site pain and/or hemorrhage, paresthesia, pruritus, rhinitis, sinusitis, sore throat, and upper respiratory infections may occur.

ANTIDOTE

All side effects except potential transmission of viral diseases usually subside spontaneously. Keep the physician informed. If side effects occur, interrupt or discontinue infusion until symptoms subside, then resume at a tolerated rate. Discontinue alpha₁-PI and treat anaphylaxis (antihistamines, epinephrine, corticosteroids) as indicated. Resuscitate as necessary.

ALPROSTADIL **BBW**(al-**PROSS**-tah-dill)Prostaglandin
(ductus arteriosus
patency adjunct)**Prostaglandin E₁, Prostin VR Pediatric****USUAL DOSE**

Pediatric patients: Begin with 0.05 to 0.1 mcg/kg of body weight/min. When therapeutic response is achieved, reduce infusion rate in increments to the lowest dose that maintains the response (e.g., reduce from 0.1 to 0.05 or from 0.025 to 0.01 mcg/kg/min). If necessary, dose may be increased gradually to a maximum of 0.4 mcg/kg/min. Generally these higher rates do not produce greater effects. May be given through infusion in a large vein or, if necessary, through an umbilical artery catheter placed at the ductal opening.

DILUTION

Each 500 mcg must be further diluted with NS or D5W. Various volumes may be used depending on infusion pump capabilities and desired infusion rate.

Guidelines for Dilution and Rate of Infusion for Desired Dose of Alprostadil			
Diluent (mL)	Concentration (mcg/mL)	Desired Dose (mcg/kg/min)	Rate of Infusion (mL/min/kg)
250 mL	2 mcg/mL	0.1 mcg/kg/min	0.05 mL/min/kg
25 mL	20 mcg/mL	0.1 mcg/kg/min	0.005 mL/min/kg

Storage: Refrigerate until dilution. Prepare fresh solution for administration every 24 hours.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Y-site: Ampicillin, cefazolin (Ancef), cefotaxime (Claforan), chlorothiazide (Diuril), dobutamine, dopamine, fentanyl (Sublimaze), gentamicin, methylprednisolone (Solu-Medrol), nitroprusside sodium, tobramycin, vancomycin, vecuronium.

RATE OF ADMINISTRATION

See **Usual Dose**. Infusion pump capable of delivering 0.005, 0.01, 0.02, or 0.05 mL/min/kg required. Use for the shortest time possible at the lowest rate therapeutically effective. Decrease rate of infusion *stat* if a significant fall in arterial pressure occurs.

ACTIONS

A naturally occurring acidic lipid. Smooth muscle of the ductus arteriosus is susceptible to its relaxing effect, which reduces BP and peripheral resistance and increases cardiac output and rate. In newborns it relaxes and may open the ductus. Metabolized by oxidation almost instantly (80% in one pass through the lungs). Remainder excreted as metabolites in the urine.

INDICATIONS AND USES

Temporarily maintain the patency of the ductus arteriosus until corrective or palliative surgery can be performed on infants with pulmonary atresia, pulmonary stenosis, tricuspid atresia, tetralogy of Fallot, interruption of the aortic arch, coarctation of the aorta, or transposition of the great vessels. ■ Used by intercavernosal injection to treat impotence.

CONTRAINDICATIONS

None known. Not indicated for infant respiratory distress syndrome (hyaline membrane disease).

PRECAUTIONS

Usually administered by trained personnel in pediatric intensive care facilities. ■ Establish a diagnosis of cyanotic heart disease (restricted pulmonary blood flow). ■ Response is poor in infants with PO_2 values of 40 torr or more or those more than 4 days old. More effective with lower PO_2 . ■ Apnea has been experienced in 10% to 20% of treated neonates. ■ Use caution in neonates with bleeding tendencies; inhibits platelet aggregation. **Monitor:** Monitor respiratory status continuously. Ventilatory assistance must be immediately available. May cause apnea, especially in infants under 2 kg. Apnea usually appears during the first hour of infusion. ■ Monitor arterial pressure intermittently by umbilical artery catheter, auscultation, or Doppler transducer. Decrease rate of infusion *stat* if a significant fall in arterial pressure occurs. ■ Decrease or stop infusion if infant develops increased respiratory distress; bleeding, bruising, or hematoma formation; or sudden changes in cardiac status (e.g., decreased BP, bradycardia, cardiac arrest, cyanosis). ■ Measure effectiveness with increase of PO_2 in infants with restricted pulmonary blood flow and increase of BP and blood pH in infants with restricted systemic blood flow.

DRUG/LAB INTERACTIONS

Inhibits **platelet aggregation**.

SIDE EFFECTS

Apnea, bradycardia, cardiac arrest, cerebral bleeding, cortical proliferation of long bones, diarrhea, DIC, fever, flushing, hyperextension of the neck, hyperirritability, hypotension, hypothermia, seizures, sepsis, tachycardia. Many other side effects have occurred in 1% or less of infants receiving alprostadil.

Overdose: Apnea, bradycardia, flushing, hypotension, pyrexia.

ANTIDOTE

Notify physician of all side effects. Discontinue immediately if apnea or bradycardia occurs. Institute emergency measures. If infusion is restarted use extreme caution. Decrease or stop infusion if infant develops increased respiratory distress; bleeding, bruising, or hematoma formation; or sudden changes in cardiac status (e.g., decreased BP, bradycardia, cardiac arrest, cyanosis). Decrease rate if pyrexia, hypotension, or fall in arterial pressure occurs. Flushing is usually caused by incorrect intra-arterial catheter placement. Reposition.

ALTEPLASE, RECOMBINANT

(AL-teh-playz)

Thrombolytic agent
(recombinant)

Activase, rt-PA[®], Tissue Plasminogen Activator,
tPA ■ Cathflo Activase

pH 7.3

USUAL DOSE

Selected indications (e.g., acute ischemic stroke, weight under 65 or 67 kg in acute MI) require exact weight-adjusted dosing. To deliver an accurate dose without possibility of overdose, calculate desired dose and withdraw any amount **NOT** needed from a 50- or 100-mg vial and discard. In all situations follow total dose with at least 30 mL of NS or D5W through the IV tubing to ensure administration of total dose.

ACUTE MYOCARDIAL INFARCTION

Total dose is based on patient weight and should not exceed 100 mg. Original studies used concurrent administration of heparin, aspirin, and/or dipyridamole (Persantine) in MI patients receiving alteplase therapy; see **Precautions** and **Monitor**. The earlier intervention occurs, the better the results. Most effective if administered within 4 to 6 hours of onset of symptoms of acute myocardial infarction.

Accelerated infusion; weight greater than 67 kg: A total dose of 100 mg titrated over 90 minutes as an IV infusion. Initially give a bolus of 15 mg over 2 minutes. Follow with 50 mg evenly distributed over 30 minutes. Infuse the remaining 35-mg dose evenly distributed over 60 minutes. See comments under [Usual Dose](#).

Accelerated infusion; weight equal to or less than 67 kg: See comments in first paragraph of [Usual Dose](#). Initially give a bolus of 15 mg over 2 minutes. Follow with 0.75 mg/kg (not to exceed a 50-mg dose) evenly distributed over 30 minutes. Then infuse 0.5 mg/kg (not to exceed a 35-mg dose) evenly distributed over 60 minutes. Total dose not to exceed 100 mg. See comments under [Usual Dose](#).

3-hour infusion; weight 65 kg or greater: A total dose of 100 mg titrated over 3 hours as an IV infusion. Initially, give a bolus of 6 to 10 mg over 2 minutes. Follow with 50 to 54 mg (total 60-mg dose) evenly distributed over the first hour. Follow with 20 mg/hr for 2 hours. See comments under [Usual Dose](#).

3-hour infusion; weight less than 65 kg: Calculate total dose using 1.25 mg/kg of body weight. See comments in first paragraph of [Usual Dose](#). Give three fifths (60%) of this total calculated dose in the first hour (10% of which should be given as an initial bolus dose). Give the remaining 40% of this total calculated dose equally distributed over 2 hours. See comments under [Usual Dose](#).

ACUTE ISCHEMIC STROKE

0.9 mg/kg. Do not exceed the maximum dose of 90 mg. See comments in [Usual Dose](#). Give a bolus of 10% of the calculated dose over 1 minute followed by balance of calculated dose (90%) as an infusion evenly distributed over 60 minutes. Treatment must start within 3 hours of onset of symptoms, but after bleeding in the brain has been ruled out (usually by a non-contrast CT scan of the brain). Do not give aspirin, heparin, or warfarin for 24 hours; see [Precautions](#).

PULMONARY EMBOLISM

100 mg titrated over 2 hours as an IV infusion. Diagnosis should be confirmed by objective means (e.g., lung scan, pulmonary angiography). Begin heparin at end of infusion or immediately after it is complete. Thrombin time (TT) or PTT should be twice normal or less.

CENTRAL VENOUS ACCESS DEVICE (CVAD) OCCLUSIONS, CATHFLO ACTIVASE

See [Rate of Administration](#), [Precautions](#), [Monitor](#), and [Maternal/Child](#).

Patient weight 30 kg or greater: Instill 2 mg in 2 mL into the occluded catheter.

Patient weight less than 30 kg: Instill 110% of the internal lumen volume of the occluded catheter into the occluded catheter. Do not exceed 2 mg in 2 mL.

Attempt to aspirate blood from the catheter after 30 minutes of dwell time. If catheter function has been restored, aspirate 4 to 5 mL of blood in patients equal to or greater than 10 kg or 3 mL of blood in patients less than 10 kg to remove Cathflo Activase and residual clot, then gently irrigate the catheter with NS.

If catheter function has not been restored (unable to aspirate blood), allow the first dose to remain in the catheter for 90 additional minutes of dwell time and then attempt to aspirate again (total elapsed time is 120 minutes). If catheter function has been restored, aspirate and irrigate as above. If function has not been restored, a second dose may be instilled and the dwell time and aspiration process repeated.

DILUTION

Myocardial infarction, stroke, and pulmonary embolism: Must be reconstituted with SWFI (without preservatives (provided by manufacturer)). Available in 50- and 100-mg vials (1 mg/mL). Consider patient's hemodynamic status. Use of filters or filter needles not recommended. Protein adsorption may occur with resulting drug loss.

50-mg vials: Use a large-bore (18-gauge) needle and direct the stream of diluent into the lyophilized cake. A vacuum must be present when the diluent is added to the powder for injection. Do not use if vacuum not present. Slight foaming is expected; let stand for several minutes to dissipate large bubbles. If necessary, may be further diluted to 0.5 mg/mL immediately before administration with an equal volume of NS or D5W. Do not shake. Mix by swirling or slow inversion; avoid agitation during dilution.

Bolus dose can be given when indicated by IV injection through a med port or by IV pump. Administer balance of dose using either a polyvinyl chloride bag or glass vial and infusion set. Adjust pump rate of delivery as required. Complete by flushing tubing with IV solution.

100-mg vial: Diluent and transfer device provided (does not contain a vacuum). Insert one end of transfer device into upright vial of diluent (do not invert diluent vial yet). Hold alteplase vial upside down and push center of vial down onto piercing pin. Now invert vials and allow diluent to flow into alteplase. Small amount (0.5 mL) of diluent will not transfer. Swirl gently to dissolve. Do not shake. Process takes several minutes. An infusion set may be inserted into puncture site created by piercing pin. Hang by plastic capping on bottom of vial. Prime tubing with alteplase and administer. Adjust pump rate of delivery as required. Complete by flushing tubing with IV solution.

Cathflo Activase for CVAD occlusion: Supplied as a sterile lyophilized powder in 2-mg vials. Must be reconstituted with 2.2 mL of SWFI without preservatives. Direct diluent stream into the powder. Allow to stand undisturbed until large bubbles dissipate; may foam slightly. Mix by swirling gently; do not shake. Should be completely dissolved within 3 minutes. Final concentration is 1 mg/mL. If the 2-mg vials are not available, some pharmacies dilute 50 mg of alteplase with 50 mL of SWFI without preservatives (1 mg/mL). Withdraw 2.2 mL (2.2 mg) to 2- or 5-mL sterile disposable syringes. In studies these were transferred to sterile glass vials and frozen. Defrost and use as needed (22 prepared doses).

Filters: Use of filters or filter needles not recommended. Protein adsorption may occur with resulting drug loss.

Storage: Systemic alteplase: Protect from light in cartons. May be stored at CRT or refrigerated before and/or after reconstitution. Manufacturer recommends reconstitution immediately before use. Must be used within 8 hours of reconstitution. Discard unused solution. Stable as a 0.5 mg/mL solution in NS or D5W for 8 hours at CRT.

Cathflo Activase: Refrigerate unopened vials; protect from light during extended storage. Reconstitution immediately before use is recommended, but solution may be used up to 8 hours after reconstitution if refrigerated at 2° to 30° C. Do not use beyond expiration date on vial. Discard unused solution.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “No other medication should be added to infusion solutions containing alteplase. Do not use other infusion solutions (e.g., SWFI, bacteriostatic water for injection [BWFI] or other preservative-containing solutions) for further dilution”; see **Dilution**. One source suggests D5W used for reconstitution or further dilution may cause a precipitate.

One source suggests the following **compatibilities**:

Y-site: Lidocaine, metoprolol (Lopressor), and propranolol through **Y-site** of free-flowing alteplase infusion.

RATE OF ADMINISTRATION

Systemic alteplase: See specific rates for each diagnosis under **Usual Dose**. In all situations use an infusion pump (preferred) or a metriset with microdrip (60 gtt/mL) and IV tubing without a filter to facilitate accurate administration. Do not use any filters. Distribute final flush over 30 minutes. NS preferred for flushing of IV line.

Cathflo Activase: Avoid excessive pressure or force while attempting to clear catheters; see **Usual Dose**, **Precautions**, and **Monitor**.

ACTIONS

A tissue plasminogen activator and enzyme produced by recombinant DNA. It binds to fibrin in a thrombus and converts plasminogen to plasmin. Plasmin digests fibrin and dissolves the clot. With therapeutic doses, a decrease in circulating fibrinogen makes the patient susceptible to bleeding. Onset of action is prompt, effecting patency of the vessel within 1 to 2 hours in most patients. Prompt opening of arteries increases probability of

improved function. Cleared from the plasma by the liver within 5 (50%) to 10 (80%) minutes after the infusion is discontinued. Some effects may linger for 45 minutes to several hours.

INDICATIONS AND USES

Systemic alteplase: Management of acute myocardial infarction in adults for the lysis of thrombi obstructing coronary arteries, the reduction of infarct size, the improvement of ventricular function, the reduction of the incidence of congestive heart failure, and the reduction of mortality associated with acute MI. Recent studies suggest alteplase or reteplase are the drugs of choice. ■ Management of acute ischemic stroke in adults to improve neurologic recovery and reduce incidence of disability. ■ Management of acute massive pulmonary embolism in adults for the lysis of acute pulmonary emboli either obstructing blood flow to a lobe or multiple segments of the lung or accompanied by unstable hemodynamics (e.g., failure to maintain BP).

Cathflo Activase: Restoration of function to CVADs as assessed by the ability to withdraw blood.

Unlabeled uses: Systemic alteplase: Treatment of unstable angina pectoris and deep vein thrombosis. Has been shown to restore blood flow to frostbitten limbs. Has been used in the occlusion of small blood vessels by microthrombi and in the management of peripheral thromboembolism (0.5 to 1 mg/hr intra-arterially).

CONTRAINDICATIONS

All systemic indications: Known hypersensitivity to alteplase or its components.

Acute myocardial infarction/pulmonary embolism: Active internal bleeding, arteriovenous malformation or aneurysm, bleeding diathesis, history of cerebrovascular accident, intracranial or intraspinal surgery or trauma within 2 months, intracranial neoplasm, severe uncontrolled hypertension.

Acute ischemic stroke: Active internal bleeding. Evidence of intracranial hemorrhage on pretreatment evaluation. Clinical presentation suggestive of subarachnoid hemorrhage (even with normal CT). History of intracranial hemorrhage, intracranial neoplasm, arteriovenous malformation, or aneurysm. History of intracranial surgery, serious head-trauma, or previous stroke within 3 months. Known bleeding diathesis (e.g., current use of oral anticoagulants [e.g., warfarin], an INR greater than 1.7 or a PT greater than 15 seconds, administration of heparin within 48 hours before onset of stroke with an elevated aPTT as presentation [greater than upper limit of normal for laboratory], platelet count less than 100,000/mm³). Seizure observed at the same time as the onset of stroke. Uncontrolled hypertension at time of treatment (e.g., systolic above 185 or diastolic above 110) and patient requires aggressive treatment to reduce BP to within these limits.

Cathflo Activase: Known hypersensitivity to alteplase or its components.

PRECAUTIONS

All systemic indications: Administered under the direction of a physician knowledgeable in its use and with appropriate emergency drugs and diagnostic and laboratory facilities available. ■ Bleeding is the most common complication. May be internal bleeding (involving intracranial or retroperitoneal sites or the GI, GU, or respiratory tracts) or superficial bleeding (involving invaded or disturbed sites [e.g., catheter sites, surgery sites]). ■ A greater alteration of hemostatic status than with heparin. Strict bed rest indicated to reduce risk of bleeding. Use extreme care with the patient; avoid any excessive or rough handling or pressure (including too-frequent BPs); avoid invasive procedures (e.g., arterial puncture, venipuncture, IM injection). If these procedures are absolutely necessary, use extreme precautionary methods (use radial artery instead of femoral; use small-gauge catheters and needles, and sites that are easily observed and compressible where bleeding can be controlled; avoid handling catheter sites; and use extended pressure application of up to 30 minutes). Minor bleeding occurs often at catheter insertion sites. Avoid use of razors and toothbrushes. ■ Use extreme caution in the following situations: major surgery or serious trauma (excluding head trauma; see [Contraindications](#)), GI or GU bleeding, or puncture of noncompressible vessels (e.g., arterial puncture, spinal puncture, thoracentesis) within the previous 10 days; cerebrovascular disease; hyperten-

sion (systolic equal to or greater than 175 mm Hg or diastolic above 110 mm Hg); mitral stenosis with atrial fibrillation (likelihood of left heart thrombus); acute pericarditis; subacute bacterial endocarditis; coagulation disorders, including those secondary to severe hepatic or renal disease; severe liver dysfunction; pregnancy and first 10 days postpartum; hemorrhagic ophthalmic conditions (e.g., diabetic hemorrhagic retinopathy); septic thrombophlebitis; patients on anticoagulants; patients over 75 years of age; any situation in which bleeding might be hazardous or difficult to manage because of location. Cholesterol embolism has been reported rarely; see [Side Effects](#). ■ There is no experience with re-administration of alteplase. If anaphylaxis occurs, discontinue infusion immediately and initiate appropriate treatment. Use caution if re-administration is attempted; detectable levels of antibody (a single-point measurement) were reported in one patient. ■ Orolingual angioedema has been reported in patients with acute MI and acute ischemic stroke. Onset may occur during or up to 2 hours after infusion. May be associated with concomitant use of angiotensin-converting enzyme inhibitors. Most resolved with prompt treatment; see [Drug/Lab Interactions](#).

Myocardial infarction: A 150-mg dose has caused increased intracranial bleeding; do not use. ■ Standard management of MI should be implemented concomitantly with alteplase treatment and continued simultaneously with alteplase therapy except if temporarily contraindicated (e.g., arterial blood gases, unless absolutely necessary). ■ Reperfusion arrhythmias occur frequently (e.g., sinus bradycardia, accelerated idioventricular rhythm, PVCs, ventricular tachycardia); have antiarrhythmic meds available at bedside.

Acute ischemic stroke: Treatment facility must be able to provide evaluation and management of intracranial hemorrhage. ■ Risks of alteplase therapy in the treatment of acute ischemic stroke may be increased in patients with severe neurologic deficit at presentation (increased risk of intracranial hemorrhage), patients with major early infarct signs on CT scan (e.g., substantial edema, mass effect, or midline shift). ■ Treatment may begin before coagulation study results are known in patients without recent use of oral anticoagulants or heparin. Discontinue infusion if pretreatment INR is greater than 1.7, PT is greater than 15 seconds, or an elevated aPTT is identified. ■ Benefits of therapy have not been studied in patients treated with alteplase more than 3 hours after the onset of symptoms; use is not recommended. Risk of intracranial hemorrhage increased; may cause cerebral edema with fatal brain herniation. ■ Use caution in patients with blood glucose values less than 50 or greater than 400 mg/dL. Risk of misdiagnosis of acute ischemic stroke increased. ■ Safety and efficacy in patients with minor neurologic deficit or rapidly improving symptoms before treatment is begun has not been studied; use is not recommended.

Pulmonary emboli: Treatment with alteplase does not constitute adequate treatment of underlying deep venous thrombosis. ■ Risk of re-embolization due to lysis of underlying DVT should be considered. Standard management of PE should be implemented concomitantly with alteplase treatment. Begin heparin at end of infusion or immediately after it is complete. Thrombin time (TT) or PTT should be twice normal or less.

Cathflo Activase: Consider causes of catheter dysfunction other than thrombus formation (e.g., catheter malposition, mechanical failure, constriction by a suture, lipid deposits or drug precipitates within the catheter lumen). ■ Do not apply vigorous suction during attempts to determine catheter occlusion; may risk damage to the vascular wall or collapse of soft-walled catheters. Avoid excessive pressure during instillation of Cathflo Activase into the catheter; may cause rupture of the catheter or expulsion of the clot into the circulation. ■ Use caution with patients who have active internal bleeding, thrombocytopenia, other hemostatic defects (including those secondary to hepatic or renal disease). ■ Use caution in patients who have conditions for which bleeding constitutes a significant hazard, who would be difficult to manage because of location, who are at high risk for embolic complication (e.g., venous thrombosis in the region of the catheter), or who have had any of the following within 48 hours: surgery, obstetrical delivery, percutaneous biopsy of viscera or deep tissues, or puncture of noncompressible vessels. ■ Use caution in the presence of known or suspected infection in the catheter; may release a

localized infection into the systemic circulation. ■ See **Monitor**. ■ Safety and effectiveness of doses greater than 2 mg has not been established.

Monitor: All systemic indications: Establish a separate IV line for alteplase. ■ Obtain appropriate clotting studies (e.g., PT, TT, PTT, aPTT, CBC, fibrinogen levels, platelets). ■ Diagnosis-specific baseline studies (e.g., ECG, CPK in myocardial infarction, non-contrast CT brain scan, and neurologic assessment in acute ischemic stroke, and lung scan or pulmonary angiography in pulmonary embolism) are indicated. ■ Baseline assessment (patient condition, pain, hematomas, petechiae, or recent wounds) should be completed before administration. ■ Type and cross-match may also be ordered. ■ Start IV if indicated (not previously established, other medications being administered through current IV, to have a line available for additional treatment). ■ Maintain strict bed rest; monitor the patient carefully and frequently for pain and signs of bleeding; observe catheter sites at least every 15 minutes and apply pressure dressings to any recently invaded site; watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, muscle weakness; and do neuro checks every hour (or more frequently if indicated). Continue until normal clotting function returns. ■ Monitor BP and maintain within appropriate limits with antihypertensives or vasopressors as indicated. ■ Monitor for signs of orolingual angioedema during and for at least 2 hours after infusion. ■ Watch for extravasation; may cause ecchymosis and/or inflammation. Restart IV at another site. Moist compresses may be helpful. ■ See **Precautions** and **Drug/Lab Interactions**.

Myocardial infarction: Monitor ECG continuously, and record strips with greatest ST segment elevation initially and every 15 minutes for at least 4 hours. A 12-lead ECG is indicated when therapy is complete.

Acute ischemic stroke: Printed protocol guidelines are available from manufacturer and include the following recommendations. ■ Before the initiation of therapy, determine actual time of onset of stroke. ■ Obtain baseline hematocrit, platelet count, and blood glucose. INR, PT, or aPTT is recommended in patients with recent use of oral anticoagulants or heparin. Obtain baseline BP, neurologic exam, and non-contrast CT brain scan. ■ Monitor BP every 15 minutes before beginning therapy; should be below 175/110 mm Hg. If over 175/110 mm Hg, BP may be treated with nitroglycerin paste (can be wiped off if BP drops quickly) and/or one or two 10- or 20-mg doses of labetalol given by IV injection within 1 hour. If these measures do not reduce BP below 175/110 mm Hg and keep it down, the patient should not be treated with alteplase. ■ During and after treatment, monitor BP every 15 minutes for 2 hours, every 30 minutes for 6 hours, then every 1 hour for 18 hours. Avoid hypotension; may decrease perfusion of alteplase; a diastolic BP around 100 mm Hg helps to maintain sufficient mean arterial pressure to reperfuse stroke area. **See Antidote for protocol to treat hypertension occurring after treatment has been started.** ■ Hemorrhage in the brain occurs frequently during treatment with alteplase during the first 36 hours; monitor carefully. Acute neurologic deterioration, new headache, acute hypertension, or nausea and vomiting may indicate the occurrence of intracranial hemorrhage. If intracranial hemorrhage is suspected, discontinue alteplase and obtain a non-contrast CT scan. ■ Monitor for S/S of atrial fibrillation and/or acute MI. ■ Studies did not show an increase in mortality and did confirm that more patients had minimal or no disability at 3 months.

Cathflo Activase: Aseptic technique imperative. ■ Avoid force while attempting to clear catheters; may rupture catheter or dislodge clot into the circulation. ■ To prevent air from entering the open catheter and the circulatory system, instruct the patient to exhale and hold his/her breath any time the catheter is not connected to the IV tubing or a syringe. ■ See **Precautions**.

Patient Education: Compliance with all measures to minimize bleeding (e.g., strict bed rest) is very important. ■ Avoid use of razors, toothbrushes, and other sharp items. Use caution while moving to avoid excessive bumping. ■ Report all episodes of bleeding and apply local pressure if indicated. Expect oozing from IV sites.

Maternal/Child: Systemic alteplase: Category C: safety for use in pregnancy, breast-feeding, and pediatric patients not established.

Cathflo Activase: Category C: use during pregnancy only if benefits justify potential risk to the fetus. ■ Use caution during breast-feeding. ■ Has been used in patients 2 weeks to 17 years of age. Rates of serious adverse events as well as restoration of catheter function similar to adults.

Elderly: Systemic alteplase: See **Indications** and **Precautions**. ■ May have poorer prognosis following acute MI and pre-existing conditions that may increase risk of intracranial bleeding. Select patients carefully to maximize benefits.

Cathflo Activase: No incidents of intracranial hemorrhage, embolic events, or major bleeding events were observed during studies. ■ Use caution in the elderly with conditions known to increase the risk of bleeding; see **Precautions**.

DRUG/LAB INTERACTIONS

Risk of bleeding may be increased by any medicine that affects blood clotting, including **anticoagulants** (e.g., heparin, warfarin [Coumadin]); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel [Plavix], dipyridamole [Persantine], glycoprotein GPIIb/IIIa receptor antagonists [e.g., abciximab (ReoPro), eptifibatid (Integrilin), tirofiban (Aggrastat)], plicamycin [Mithracin], sulfipyrazone [Anturane], ticlopidine [Ticlid], valproic acid [Depacon]). Concurrent use not recommended with the exception of heparin and aspirin (in AMI) to reduce the risk of rethrombosis. If concurrent or subsequent use indicated (e.g., management of acute coronary syndrome, percutaneous coronary intervention), monitor PT and aPTT closely. ■ Concurrent use with **nitroglycerin** decreases plasma concentrations of alteplase, impairing the thrombolytic effect. ■ Orolingual angioedema has been reported. Many patients, including patients with acute ischemic stroke, were receiving **angiotensin-converting enzyme inhibitors** (e.g., enalapril [Vasotec], enalaprilat [Vasotec IV], lisinopril [Zestril]). ■ **Coagulation tests** will be unreliable; specific procedures can be used; notify the lab of alteplase use.

SIDE EFFECTS

Systemic alteplase: Bleeding is most common: internal (GI tract, GU tract, retroperitoneal, or intracranial sites), epistaxis, gingival, and superficial or surface bleeding (venous cut-downs, arterial punctures, sites of recent surgical intervention). Mild to serious hypersensitivity reactions (including anaphylaxis) have occurred. Fever, hypotension, nausea and vomiting, reperfusion arrhythmias, and stroke have occurred. Cholesterol embolization syndrome (e.g., acute renal failure, bowel infarction, cerebral infarction, gangrenous digits, hypertension, livedo reticularis, myocardial infarction, pancreatitis, purple toe, retinal artery occlusion, rhabdomyolysis, spinal cord infarction) can occur with thrombolytics but has been reported rarely.

Post-Marketing: Orolingual angioedema; rare fatalities from upper airway hemorrhage from intubation trauma.

Cathflo Activase: Gastrointestinal bleeding, sepsis, and venous thrombosis have occurred. There were no reports of intracranial hemorrhage or pulmonary emboli during clinical trials.

ANTIDOTE

Systemic alteplase: Notify physician of all side effects. Note even the most minute bleeding tendency. Oozing at IV sites is expected. Control minor bleeding by local pressure. For severe bleeding in a critical location or suspected intracranial bleeding, discontinue alteplase and any heparin therapy immediately. Obtain PT, aPTT, platelet count, and fibrinogen. Draw blood for type and cross-match. Platelets and cryoprecipitate are most commonly used but whole blood, packed RBCs, fresh-frozen plasma, desmopressin, tranexamic acid (Cyklokapron), and aminocaproic acid (Amicar) may be indicated. Topical preparations of aminocaproic acid may stop minor bleeding. Consider protamine if heparin has been used. Treat bradycardia with atropine, reperfusion arrhythmias with appropriate antiarrhythmic; VT or VF may require cardioversion. If hypotension occurs, reduce rate promptly. If not resolved, vasopressors (e.g., dopamine), Trendelenburg posi-

tion, and suitable plasma expanders (e.g., albumin, plasma protein fraction [plasmanate], or hetastarch) may be indicated. Do not use dextran. If anaphylaxis occurs, discontinue infusion immediately and initiate appropriate treatment. ■ **Protocol for treatment of hypertension occurring during treatment for acute ischemic stroke:** Monitor BP every 15 minutes; observe for hypertension/hypotension. If diastolic BP is greater than 140 mm Hg, start an IV infusion of nitroprusside sodium (0.5 to 10 mcg/kg/min). If systolic BP greater than 230 mm Hg and/or diastolic BP is 121 to 140 mm Hg, give labetalol 20 mg IV over 1 to 2 minutes. This dose may be repeated and/or doubled every 10 minutes, up to 150 mg. Alternatively, following the first bolus of labetalol, an IV infusion of labetalol 2 to 8 mg/min may be initiated and continued until the desired BP is reached. If satisfactory response is not obtained, use nitroprusside sodium. If systolic BP is 180 to 230 mm Hg and/or diastolic BP is 105 to 120 mm Hg on two readings 5 to 10 minutes apart, give labetalol 10 mg IV over 1 to 2 minutes. The dose may be repeated or doubled every 10 to 20 minutes, up to 150 mg. Alternatively, following the first bolus of labetalol, an IV infusion of labetalol 2 to 8 mg/min may be initiated and continued until the desired BP is reached. Treat minor hypersensitivity reactions symptomatically. If angioedema occurs, treat promptly with antihistamines (e.g., diphenhydramine [Benadryl]), IV corticosteroids, or epinephrine and consider discontinuing the alteplase infusion. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary.

Cathflo Activase: Discontinue Cathflo Activase and withdraw it from the catheter if serious bleeding in a critical location (e.g., intracranial, gastrointestinal, retroperitoneal, pericardial) occurs. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary. In the event of accidental administration of a 2-mg dose directly into the systemic circulation, the concentration of circulating levels of alteplase would be expected to return to exogenous levels of 5 to 10 ng/mL within 30 minutes.

AMIFOSTINE

(am-ih-FOS-teen)

Ethylol

Antidote
Antineoplastic adjunct
Cytoprotective agent

USUAL DOSE

PROPHYLACTIC REDUCTION OF CISPLATIN-INDUCED NEPHROTOXICITY, PROPHYLACTIC REDUCTION OF CISPLATIN INDUCED-NEUROTOXICITY (UNLABELED), AND PROPHYLACTIC REDUCTION OF ANTINEOPLASTIC AGENT BONE MARROW TOXICITY (UNLABELED)

Must be administered in conjunction with cisplatin. Adequate hydration and premedication required before administration; see [Premedication](#) below, [Monitor](#), and cisplatin monograph.

Premedication: Premedication to prevent severe nausea and vomiting is recommended before each dose. Usual regimen includes dexamethasone 20 mg IV and a serotonin 5HT₃ receptor antagonist (e.g., ondansetron [Zofran], granisetron [Kytril]) given before and in conjunction with amifostine infusion. Additional antiemetics (e.g., aprepitant [EMEND]) may be required based on the chemotherapy drugs administered.

Amifostine: 910 mg/M². Cisplatin dose must be given within 30 minutes of starting the amifostine infusion, but only after the full dose of amifostine is administered.

REDUCTION OF MODERATE TO SEVERE XEROSTOMIA FROM RADIATION OF THE HEAD AND NECK

Premedication: Premedication to prevent nausea and vomiting is recommended before each dose. Oral 5HT₃ receptor antagonists alone or in combination with other antiemetics are recommended. Adequate hydration required; see [Monitor](#).

Amifostine: 200 mg/M² once daily as a 3-minute infusion, starting 15 to 30 minutes before standard fraction radiation therapy.

DOSE ADJUSTMENTS

Dosing should be cautious in the elderly. Consider potential for decreased organ function and concomitant disease or drug therapy.

Reduction of cumulative renal toxicity with chemotherapy: Temporarily discontinue the infusion if the systolic BP decreases significantly from the baseline value. See the following chart.

Guideline for Interrupting Amifostine Infusion Due to Decrease in Systolic Blood Pressure					
	Baseline Systolic Blood Pressure (mm Hg)				
	<100	100-119	120-139	140-179	≥180
Decrease in systolic blood pressure during infusion of amifostine (mm Hg)	20	25	30	40	50

Infusion may be restarted to deliver the full dose if the BP returns to normal within 5 minutes and the patient is asymptomatic. If the BP does not return to baseline within 5 minutes and/or the patient is symptomatic (e.g., bradycardia, fainting, unconscious), the full dose cannot be delivered and subsequent doses should be reduced to 740 mg/M².

DILUTION

Each 500-mg vial should be reconstituted with 9.7 mL of NS (50 mg/mL). May be further diluted with NS to concentrations from 5 to 40 mg/mL. An additional 2.5 mL of NS will yield 40 mg/mL; 90 mL NS will yield 5 mg/mL.

Filters: Not required by manufacturer. Additional data not available.

Storage: Store at CRT before reconstitution. Reconstituted or diluted solution prepared in PVC infusion bags is stable for 5 hours at room temperature or 24 hours if refrigerated.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Use of any additive, diluent, or solution other than NS is not recommended by manufacturer.

One source suggests the following **compatibilities**:

Y-site: Amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), cefazolin (Ancef), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), ciprofloxacin (Cipro IV), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), daunorubicin (Cerubidine), dexamethasone (Decadron), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), etoposide (VePesid), famotidine (Pepcid IV), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gallium nitrate (Ganite), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), leucovorin calcium, lorazepam (Ativan), magnesium sulfate, mannitol (Osmitol), mechlorethamine (nitrogen mustard), meperidine (Demerol), mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), mitomycin (Mutamycin), mitoxantrone (Novantrone), morphine, nalbuphine, ondansetron (Zofran), pemetrexed (Alimta), potassium chloride (KCl), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, streptozocin (Zanosar), sulfamethoxazole/trimethoprim, teniposide (Vumon), thiotepa, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vinblastine, vincristine, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Reduction of cumulative renal toxicity with chemotherapy: A single dose evenly distributed over 15 minutes. Complete amifostine dose but begin cisplatin within 30 minutes after beginning amifostine. Amifostine must be given over 15 minutes; longer infusion times increase the risk of side effects, especially hypotension. Shorter infusion times have not been studied.

Reduction of moderate to severe xerostomia from radiation of the head and neck: A single dose evenly distributed over 3 minutes. Begin infusion 15 to 30 minutes before standard fraction radiation therapy.

ACTIONS

A cytoprotective agent. Rapidly metabolized by alkaline phosphatase in tissues to an active metabolite that can reduce the nephrotoxic effects of cisplatin and the toxic effects of radiation on normal oral tissues. This protective metabolite is generated in greater amounts in normal tissues versus tumor tissues and is available to bind to and detoxify reactive metabolites of cisplatin and/or radiation. It reduces the incidence of cisplatin toxicity including nephrotoxicity but does not cause other toxic reactions. Its protective metabolite can also scavenge reactive oxygen species generated by exposure to either cisplatin or radiation. May adversely affect anti-tumor effects of cisplatin. Rapidly cleared from plasma with an elimination half-life of 8 minutes. Pretreatment with antiemetics does not alter its actions. Measurable levels of the metabolite have been found in bone marrow; minimal excretion in urine.

INDICATIONS AND USES

Reduce the cumulative renal toxicity associated with repeated administration of cisplatin in patients with advanced ovarian cancer. May allow higher cumulative doses of cisplatin and cyclophosphamide. ■ Reduce the incidence of moderate to severe xerostomia (dryness of the mouth from salivary gland dysfunction) in patients undergoing postoperative

radiation treatment for head and neck cancer, where the “radiation port” includes a substantial portion of the parotid glands.

Unlabeled uses: Reduce acute and cumulative hematologic toxicity associated with various chemotherapy regimens (e.g., cisplatin, cyclophosphamide, carboplatin; see literature). ■ Decrease frequency or severity of cisplatin-induced neurotoxicity. ■ Prevention of radiation proctitis in rectal cancer.

CONTRAINDICATIONS

Known sensitivity to aminothiols or mannitol. ■ Not recommended for patients receiving chemotherapy for malignancies if chemotherapy can produce significant survival benefit or cure; may interfere with effectiveness of chemotherapy regimen and reduce incidence of cure. ■ Not recommended for patients who are hypotensive, dehydrated, or for those receiving antihypertensive therapy that cannot be stopped for 24 hours before amifostine is administered. ■ Not recommended for patients receiving definitive radiotherapy. Tumor-protective effect in this setting has not been ruled out.

PRECAUTIONS

Use caution in the elderly and in patients with pre-existing cardiovascular or cerebrovascular conditions (e.g., arrhythmias, congestive heart failure, history of stroke, history of ischemic heart disease). ■ Hypotension and nausea and vomiting can be severe; use caution in any situation in which these side effects may have serious consequences. ■ Discontinue antihypertensive therapy 24 hours before administering amifostine. ■ Hypersensitivity reactions, including anaphylaxis and severe cutaneous reactions, have been reported; see **Monitor** and **Side Effects**. Deaths have occurred. ■ Facilities for monitoring the patient and responding to any medical emergency must be available.

Monitor: All indications: Adequate hydration required before administration of amifostine. ■ Monitor fluid balance carefully, especially in conjunction with highly emetogenic chemotherapy (e.g., cisplatin). ■ See **Usual Dose** for premedication requirements. Additional antiemetics may be required to offset nausea and vomiting of chemotherapy drugs. ■ Keep patient in supine position during and immediately after the infusion. ■ Hypersensitivity and/or severe cutaneous reactions may occur during or after infusion; monitor closely before, during, and after administration. Serious cutaneous reactions may develop weeks after initiation of therapy. ■ Monitor serum calcium. Risk of hypocalcemia increased in some patients (e.g., nephrotic syndrome or patients receiving multiple doses). Calcium supplements may be required. ■ See **Dose Adjustments**, **Rate of Administration**, and **Antidote**.

Reduction of cumulative renal toxicity with chemotherapy: Discontinue antihypertensive therapy if indicated; see **Contraindications**, **Precautions**, **Drug/Lab Interactions**. ■ Obtain baseline BP and monitor at least every 5 minutes during and immediately after the infusion. Continue monitoring BP as indicated. ■ Hypertension may be exacerbated by several causes (e.g., interruption of antihypertensive therapy, IV hydration). Monitor BP closely. ■ Hypotension can occur at any time but is more frequent toward the end of the infusion, and recovery usually begins within 5 to 6 minutes after infusion is discontinued.

Reduction of xerostomia from radiation: Monitor BP before and immediately after the infusion and as indicated by results.

Patient Education: Void before administration. ■ May produce significant hypotension. Effects may be additive with medications currently being taken. Review all medications (prescription and nonprescription) with nurse and/or physician. ■ Must remain in supine position until BP stabilized, then request assistance for ambulation. ■ Report feelings of faintness or nausea promptly. ■ Promptly report development of any rash or skin condition.

Maternal/Child: Category C: use only if potential benefits justify risk to fetus; embryotoxic in rabbits at doses lower than required for humans. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established; experience is limited.

Elderly: Response similar to younger adults; however, dosing should be cautious; see **Dose Adjustments**. ■ Monitor fluid balance closely; avoid dehydration. ■ Hypotension may be sudden and severe; monitor closely. ■ See **Contraindications** and **Precautions**.

DRUG/LAB INTERACTIONS

Antihypertensive therapy (e.g., **ACE inhibitors** [e.g., enalapril], **calcium channel blocking agents** [e.g., nifedipine, verapamil], **diuretics** [e.g., furosemide, torsemide], **nitroglycerin**, **nitroprusside sodium**) should be discontinued 24 hours before amifostine administration; see **Contraindications**. ■ Use extreme caution in any patient receiving medications with **hypotensive effects** (**antidepressants**, **benzodiazepines**, **beta-adrenergic blocking agents** [e.g., atenolol, esmolol, metoprolol, propranolol], **lidocaine**, **magnesium**, **narcotics**, **nitrates**, **paclitaxel**, **procainamide**); will cause additive hypotension.

SIDE EFFECTS

Hypotension and severe nausea and vomiting occur frequently. Hypotension may be associated with apnea, arrhythmias (e.g., atrial fibrillation/flutter, bradycardia, extrasystoles, tachycardia), chest pain, dyspnea, hypoxia, myocardial ischemia, and rarely renal failure, respiratory and cardiac arrest, seizures, and unconsciousness. Dehydration, dizziness, feelings of cold or warmth, flushing, hiccups, hypocalcemia, loss of consciousness, somnolence, and/or transient hypertension or exacerbation of pre-existing hypertension may occur. Hypersensitivity reactions (e.g., anaphylaxis [rare], arrhythmias, chest tightness, chills, cutaneous eruptions, dyspnea, fever, hypoxia, laryngeal edema, pruritus, sneezing, urticaria) have occurred. Most cutaneous eruptions, pruritus, and urticaria were mild; however, serious skin reactions such as erythema multiforme, exfoliative dermatitis, rash, Stevens-Johnson syndrome (rare), toxic epidermal necrolysis, and urticaria have been reported. Serious skin reactions have been reported more frequently when amifostine is used as a radioprotectant.

Overdose: Hypotension is the most likely symptom. Anxiety and reversible urinary retention have occurred at higher doses. Up to 3 doses have been given within 24 hours without unexpected side effects.

ANTIDOTE

Keep physician informed of side effects. Treatment of nausea and vomiting is imperative to encourage patients to continue treatment with full doses of chemotherapeutic agents. Hypotension may be dose-limiting. If the systolic BP decreases significantly (see **Dose Adjustments** chart), temporarily discontinue the amifostine still infusing, place the patient in Trendelenburg position, and administer an infusion of NS at a separate site. Vasopressors (e.g., dopamine, norepinephrine [Levophed]) may be required. If indicated, restart infusion if BP returns to baseline within 5 minutes and patient is asymptomatic. Discontinue amifostine immediately and permanently if an acute hypersensitivity or cutaneous reaction occurs. Dermatologic consult may be required. Treat anaphylaxis and resuscitate as necessary.

AMIKACIN SULFATE **BBW**

(am-ih-KAY-sin SUL-fayt)

Antibacterial
(aminoglycoside)**Amikin****pH 3.5 to 5.5****USUAL DOSE**

Up to 15 mg/kg of body weight/24 hr equally divided into 2 or 3 doses at equally divided intervals (5 mg/kg every 8 hours or 7.5 mg/kg every 12 hours). Dosage based on ideal weight of lean body mass. Do not exceed a total adult dose of 15 mg/kg/24 hr in an average weight patient or 1.5 Gm in heavier patients by all routes in 24 hours.

Studies suggest that a single daily dose of 15 to 20 mg/kg (instead of divided into 2 or 3 doses) may provide higher peak levels and enhance drug effectiveness while actually reducing or having no adverse effects on risk of toxicity. Various procedures for monitoring blood levels are in use. Some health facilities are monitoring with trough levels; others may draw levels at predetermined times and plot the concentration on nomograms. Depending on the protocol in place, doses or intervals may be adjusted. See [Precautions](#).

PEDIATRIC DOSE

15 to 22.5 mg/kg/24 hr equally divided into 2 or 3 doses and given every 8 to 12 hours (5 to 7.5 mg/kg every 8 hours or 7.5 to 11.25 mg/kg every 12 hours). Do not exceed 1.5 Gm/24 hr. A single daily dose is also being used in pediatric patients. See comments under [Usual Dose](#).

NEWBORN DOSE

See [Maternal/Child](#).

10 mg/kg of body weight as a loading dose, then 7.5 mg/kg/dose. Intervals of 7.5 mg/kg dose adjusted based on age as follows:

Under 28 weeks' gestation and less than 7 days of age: Give every 24 hours.

Under 28 weeks' gestation and over 7 days or 28 to 34 weeks' gestation and under 7 days of age: Give every 18 hours.

28 to 34 weeks' gestation and over 7 days of age or over 34 weeks' gestation and under 7 days of age: Give every 12 hours.

Over 34 weeks' gestation and over 7 days of age: Give every 8 hours.

DOSE ADJUSTMENTS

Reduce daily dose commensurate with amount of renal impairment and/or increase intervals between injections. ■ Reduced dose or extended intervals may be required in the elderly. ■ See [Drug/Lab Interactions](#).

DILUTION

Each 500 mg or fraction thereof is diluted with 100 to 200 mL D5W, D5NS, or NS. Amount of diluent may be decreased proportionately with dosage for infants and other pediatric patients. Available for pediatric injection as 50 mg/mL.

Storage: Stable for 24 hours at RT at concentrations of 0.25 and 0.5 mg/mL when diluted in specific solutions; see prescribing information.

COMPATIBILITY**(Underline Indicates Conflicting Compatibility Information)**

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Do not physically premix with other drugs; administer separately as recommended by manufacturer. Inactivated in solution with beta-lactam antibiotics (e.g., cephalosporins, penicillins) and vancomycin. Do not mix in the same solution. Appropriate spacing required because of physical **incompatibilities**. See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

Solution: Manufacturer lists D5W, D5¹/₄NS, D5¹/₂NS, NS, LR, D5 in Normosol M (Plasma-Lyte 56 in D5W), D5 in Normosol R (Plasma-Lyte 148 in D5W). Other sources list additional solutions.

Y-site: Acyclovir (Zovirax), amifostine (Ethyol), amiodarone (Nexterone), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), caspofungin (Cancidas), cefepime (Maxipime), ceftazidime (Fortaz), cisatracurium (Nimbex), cyclophosphamide (Cytoxan), dexamethasone (Decadron), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doripenem (Doribax), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), furosemide (Lasix), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), idarubicin (Idamycin), labetalol, levofloxacin (Levaquin), linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), midazolam (Versed), milrinone (Primacor), morphine, nicardipine (Cardene IV), ondansetron (Zofran), paclitaxel (Taxol), pemetrexed (Alimta), remifentanyl (Ultiva), sargramostim (Leukine), teniposide (Vumon), thiotepa, tigecycline (Tygacil), vinorelbine (Navelbine), warfarin (Coumadin), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose over at least 30 to 60 minutes. Infants should receive a 1- to 2-hour infusion.

ACTIONS

An aminoglycoside antibiotic with neuromuscular blocking action. Bactericidal against many gram-negative organisms resistant to other antibiotics including other aminoglycosides such as gentamicin, kanamycin, and tobramycin. Well distributed through all body fluids. Usual half-life is 2 to 3 hours. Crosses the placental barrier. Excreted in the kidneys. Cross-allergenicity does occur between aminoglycosides.

INDICATIONS AND USES

Short-term treatment of serious infections caused by susceptible organisms (e.g., gram-negative bacteria) generally resistant to alternate drugs that have less potential toxicity. ■ Effective in infections of the respiratory and urinary tracts, CNS (including meningitis), skin and soft tissue, intra-abdominal (including peritonitis), bacterial septicemia (including neonatal sepsis), burns, and postoperative infections. ■ Considered initial therapy in suspected gram-negative infections after culture and sensitivity is drawn. ■ In certain severe infections (e.g., neonatal sepsis), empiric concomitant treatment with an antibiotic effective against gram-positive organisms (e.g., penicillin) may be required until the results of C/S are obtained.

Unlabeled uses: Treatment of *Mycobacterium avium* complex, a common infection in AIDS (part of a multiple [3 to 5] drug regimen), tuberculosis.

CONTRAINDICATIONS

Known amikacin or aminoglycoside sensitivity. Sulfite sensitivity may be a contraindication.

PRECAUTIONS

Sensitivity studies indicated to determine susceptibility of causative organism to amikacin. ■ Response should occur in 24 to 48 hours. Safety for use longer than 14 days not established. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ May contain sulfites; use caution in patients with asthma. ■ Single daily dosing has been used effectively in abdominal, pelvic inflammatory, and GU infections in patients with normal renal function. Not recommended in bacteremia caused by *Pseudomonas aeruginosa*, endocarditis, meningitis, during pregnancy or in patients less than 6 weeks postpartum. Limited data available for use in all other situations (e.g., burns, cystic fibrosis, elderly, pediatrics, renal impairment). ■ Potentially nephrotoxic, ototoxic, and neurotoxic. Risk of nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity) increased in patients with pre-existing renal damage or in normal renal function with prolonged use. Partial or total irreversible deafness may continue to develop after amikacin is discontinued. ■ Use with caution in patients with muscular disorders (e.g., myasthenia gravis, parkinsonism) because these drugs may aggravate muscle weakness. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present

with diarrhea during or after treatment with amikacin. ■ See [Monitor](#) and [Drug/Lab Interactions](#).

Monitor: Maintain good hydration. ■ Narrow range between toxic and therapeutic levels. Periodically monitor peak and trough concentrations. Manufacturer recommends avoiding peak serum concentrations greater than 35 mcg/mL and trough serum concentrations above 10 mcg/mL. ■ Monitor urine protein, presence of cells and casts, and decreased specific gravity. Watch for decreased urine output, rising BUN and SCr, and declining CrCl levels. Dose adjustment may be necessary. ■ Closely monitor patients with impaired renal function for nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity); nephrotoxicity may be reversible. ■ In extended treatment, monitor serum levels, electrolytes, and renal, auditory, and vestibular functions frequently. ■ See [Drug/Lab Interactions](#).

Patient Education: Report promptly any changes in balance, hearing loss, weakness, or dizziness. ■ Consider birth control options. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category D: avoid pregnancy. Potential hazard to fetus. ■ Safety for use during breast-feeding not established; use extreme caution. ■ Peak concentrations are generally lower in infants and young children. ■ Use extreme caution in premature infants and neonates; immature kidney function will result in prolonged half-life.

Elderly: Consider less toxic alternatives. ■ Longer intervals between doses may be more important than smaller doses. ■ Monitor renal function and drug levels carefully. Measurement of CrCl more useful than BUN or SCr to assess renal function. ■ Half-life prolonged.

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **beta-lactam antibiotics** (e.g., cephalosporins, penicillins) and **vancomycin**. Synergism may be inconsistent; see [Compatibility](#). ■ Concurrent use topically or systemically with any other **ototoxic or nephrotoxic agents** should be avoided. May have dangerous additive effects with **anesthetics** (e.g., enflurane), **other neuromuscular blocking antibiotics** (e.g., kanamycin), **diuretics** (e.g., furosemide [Lasix]), **beta-lactam antibiotics** (e.g., cephalosporins), **vancomycin, and many others**. ■ **Neuromuscular blocking muscle relaxants** (e.g., atracurium [Tracrium], succinylcholine) are potentiated by aminoglycosides. *Apnea can occur*. ■ Aminoglycosides are potentiated by **anticholinesterases** (e.g., edrophonium), **antineoplastics** (e.g., nitrogen mustard, cisplatin).

SIDE EFFECTS

Occur more frequently with impaired renal function, higher doses, prolonged administration, in dehydrated or elderly patients, and in patients receiving other ototoxic or nephrotoxic drugs. Fever, headache, hypotension, nausea, paresthesias, seizures, skin rash, tremor, vomiting.

Major: Albuminuria, anemia, arthralgia, azotemia, CDAD, eosinophilia, loss of balance, neuromuscular blockade, oliguria, ototoxicity, RBCs and WBCs or casts in urine, respiratory depression or arrest, rising SCr.

ANTIDOTE

Notify physician of all side effects. If minor side effects persist or any major symptom appears, discontinue drug and notify physician. Treatment is symptomatic, or a reduction in dose may be required. In overdose hemodialysis may be indicated. Monitor fluid balance, CrCl, and plasma levels carefully. Complexation with ticarcillin may be as effective as hemodialysis. Consider exchange transfusion in the newborn. Calcium salts or neostigmine may reverse neuromuscular blockade. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Resuscitate as necessary.

AMINOCAPROIC ACID

(a-mee-noh-ka-**PROH**-ick **AS**-id)

Antifibrinolytic
Antihemorrhagic

Amicar

pH 6 to 7.6

USUAL DOSE

4 to 5 Gm initially over 1 hour. Follow with 1 Gm/hr for 8 hours or until bleeding is controlled. In acute bleeding syndromes, the 4- to 5-Gm dose may be given as a continuous infusion over the first hour, followed by a continuous infusion of 1 Gm/hr for 8 hours or until bleeding is controlled. Maximum dose is 30 Gm/24 hr.

Prevent recurrence of subarachnoid hemorrhage (unlabeled): 36 Gm/24 hr. One source suggests administering 18 Gm in 400 mL D5W every 12 hours for 10 days. Follow with oral therapy.

Prevention of perioperative bleeding during cardiac surgery (unlabeled): 10 Gm as an infusion over 20 to 30 minutes before skin incision. Follow with 1 to 2.5 Gm/hr (usually 2 Gm/hr) until the end of the operation. Infusion may be continued for 4 hours after protamine reversal of heparin. In addition, 10 Gm may be added to the cardiopulmonary bypass circuit priming solution. An alternate regimen is 10 Gm over 20 to 30 minutes before skin incision, followed by 10 Gm after heparin administration, then 10 Gm when cardiopulmonary bypass is discontinued and before protamine reversal of heparin. Another source suggests a loading dose of 80 mg/kg over 20 minutes followed by 30 mg/kg/hr, or a loading dose of 60 mg/kg over 20 minutes followed by 30 mg/kg/hr plus a 10-mg/kg dose in the priming solution of the cardiopulmonary bypass pump.

PEDIATRIC DOSE

Acute bleeding syndromes (unlabeled): See [Maternal/Child](#). **Loading dose:** 100 to 200 mg/kg. Follow with a maintenance dose of 100 mg/kg/dose every 4 to 6 hours. Maximum dose is 30 Gm/24 hr.

DOSE ADJUSTMENTS

May accumulate in patients with renal impairment, and reduced doses are suggested; however, specific recommendations are not available from the manufacturer. Another source suggests decreasing dose to 15% to 25% of the normal dose in patients with renal impairment.

DILUTION

1 Gm equals 4 mL of prepared solution. Further dilute with **compatible** infusion solutions (NS, D5W, SWFI, or Ringer's solution). Up to 50 mL of diluent may be used for each 1 Gm.

Storage: Before use store at CRT. Do not freeze.

COMPATIBILITY

Compatible in D5W, Ringer's solution, and NS. One source suggests **compatibility** at the **Y-site** with fenoldopam (Corlopan).

RATE OF ADMINISTRATION

5 Gm or fraction thereof over first hour in 250 mL of solution; then administer each succeeding 1 Gm over 1 hour in 50 to 100 mL of solution. Use of an infusion pump for accurate dose recommended. Rapid administration or insufficient dilution may cause hypotension, bradycardia, and/or arrhythmia.

ACTIONS

A nonaminocarboxylic acid that acts as an inhibitor of fibrinolysis. Inhibits plasminogen activator substances; to a lesser degree inhibits plasmin activity. Increases fibrinogen activity in clot formation by inhibiting the enzyme required for destruction of formed fibrin. Onset of action is prompt, but will last less than 3 hours. Partially metabolized. Half-life is 2 hours. Excreted in urine. Easily penetrates RBCs and tissue cells after prolonged administration.

INDICATIONS AND USES

Useful in enhancing hemostasis when fibrinolysis contributes to bleeding. ■ Treatment of fibrinolytic bleeding, which may be associated with surgical complications following heart surgery (with or without cardiac bypass procedures) and portacaval shunt, hematologic disorders such as aplastic anemia, acute and life-threatening abruptio placentae, hepatic cirrhosis, and neoplastic disease such as carcinoma of the prostate, lung, stomach, and cervix. ■ Urinary fibrinolysis (normal physiologic phenomenon), which may result from severe trauma, anoxia, shock, surgical hematuria complications following prostatectomy and nephrectomy, or nonsurgical hematuria resulting from polycystic or neoplastic disease of the GU system.

Unlabeled uses: Prevent recurrence of subarachnoid hemorrhage. ■ Control of bleeding in thrombocytopenia. ■ Prevention of perioperative bleeding during cardiac surgery. ■ Prophylaxis and treatment during dental surgical procedures (hemophilia and/or hemorrhage).

CONTRAINDICATIONS

Evidence of an active intravascular clotting process. ■ Uncertainty as to whether the cause of bleeding is primary fibrinolysis (PF) or disseminated intravascular coagulation (DIC). This distinction must be made before administration; see [Precautions](#). ■ Do not use aminocaproic acid in the presence of DIC without concomitant heparin.

PRECAUTIONS

Should not be administered without a definite diagnosis and/or lab findings indicative of hyperfibrinolysis. ■ The following tests are used to differentiate primary fibrinolysis (PF) from disseminated intravascular coagulation (DIC). Platelet count should be normal in PF but is usually decreased in DIC; protamine paracoagulation test is negative in PF and positive in DIC (a precipitate forms when protamine sulfate is dropped into citrated plasma); euglobulin clot lysis test is abnormal in PF but normal in DIC. ■ In life-threatening situations, transfusion and other appropriate emergency measures may be required. ■ Avoid use in patients with hematuria of upper urinary tract origin. Has caused glomerular capillary thrombosis in the renal pelvis and ureters, leading to intrarenal obstruction. ■ Use with caution in patients with cardiac disease. May cause hypotension and bradycardia. Endocardial hemorrhage and fatty degeneration of the myocardium have been reported in animals. ■ Use with caution in patients with hepatic disease. Etiology of bleeding may be multifactorial and difficult to diagnose. ■ Use with caution in patients with renal impairment; see [Dose Adjustments](#). Kidney stones have been reported in animal studies. ■ Skeletal muscle weakness with necrosis of muscle fibers has been reported after prolonged use; see [Monitor](#). ■ An increased incidence of certain neurologic deficits (e.g., cerebral ischemia, cerebral vasospasm, hydrocephalus) associated with the use of antifibrinolytic agents in the treatment of subarachnoid hemorrhage has been reported. Relationship to drug therapy versus natural disease process or diagnostic procedures (e.g., angiography) is unclear.

Monitor: See [Precautions](#) and [Contraindications](#). ■ Use only in conjunction with general and specific tests to determine the amount of fibrinolysis present (e.g., fibrinogen, PT, aPTT). ■ Monitor lab evaluations as appropriate for diagnosis (e.g., platelet count, clotting factors, CPK, AST). ■ Vital signs, intake and output, any signs of bleeding, and neurologic assessment should be monitored based on patient condition. ■ Observe for thromboembolic complications (e.g., chest pain, dyspnea, edema, hemoptysis, leg pain, or positive Homans' sign). ■ Monitor for S/S of skeletal muscle damage. May range from mild myalgias with weakness to severe proximal myopathy with rhabdomyolysis, myoglobinuria, and acute renal failure. ■ Monitor lab evaluations as appropriate for diagnosis (e.g., platelet count, clotting factors, CPK, AST).

Patient Education: Move slowly with help to avoid orthostatic hypotension.

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding not established. ■ Safety for use in pediatric patients not established but is used. ■ Contains

benzyl alcohol, which has been associated with “gaspings syndrome” in neonates (sudden onset of gasping respirations, hypotension, bradycardia, and cardiovascular collapse).

Elderly: Consider age-related impaired organ function; reduced dose may be indicated.

DRUG/LAB INTERACTIONS

Potential for thrombus formation increased with concurrent use of **estrogens**. ■ Frequently used with **clotting factor complexes** (e.g., factor IX complex, anti-inhibitor coagulant complex), but risk of thrombus formation may be increased. Delay administration for 8 or more hours after clotting factor complexes. ■ Prolongation of template **bleeding time** has been reported during continuous infusions exceeding 24 Gm/day.

SIDE EFFECTS

Generally well tolerated. Abdominal pain, agranulocytosis, bradycardia, coagulation disorder, confusion, cramps, decreased vision, diarrhea, dizziness, dyspnea, edema, grand mal seizure, hallucinations, headache, hypersensitivity reactions (including anaphylaxis), hypotension, increased BUN and CPK, injection site reactions, intracranial hypertension, leukopenia, malaise, muscle weakness, myalgia, myopathy, myositis, nausea, peripheral ischemia, pruritus, pulmonary embolism, renal failure, rhabdomyolysis, rash, stuffy nose, stroke, syncope, tearing, thrombocytopenia, thrombophlebitis, thrombosis, tinnitus, vomiting.

Overdose: Acute renal failure, convulsions, death.

ANTIDOTE

Treat side effects symptomatically. Discontinue use of drug with any suspicion of thrombophlebitis, thromboembolic complications, or if CPK is elevated (myopathy). In life-threatening situations, fresh whole blood transfusions, fibrinogen infusions, and other emergency measures may be required. May be removed by hemodialysis or peritoneal dialysis.

AMINOPHYLLINE

(am-ih-**NOFF**-ih-lin)

Bronchodilator
Respiratory stimulant

(79% Theophylline), Theophylline Ethylenediamine

pH 8.6 to 9

USUAL DOSE

To obtain maximum benefit with minimal risk of adverse effects, dosing must be individualized based on serum theophylline concentration and patient response. Monitor frequently to avoid toxicity. Only aminophylline premixed in solution or aminophylline containing 20 mg of theophylline for each 25 mg of aminophylline is intended for IV use (approximately 79% theophylline). **All doses are based on lean body weight**; theophylline does not distribute into fatty tissue. **All doses listed are milligrams of aminophylline to be administered.**

BRONCHODILATION IN ACUTE ASTHMA OR BRONCHOSPASM

With an average mean volume of distribution of 0.5 L/kg (range is 0.3 to 0.7 L/kg), each mg/kg of theophylline given over 30 minutes should result in an average 2 mcg/mL increase in serum theophylline concentration.

Adults, children, infants and neonates who have not received a theophylline preparation in the previous 24 hours: An **initial loading dose** of 5 to 6 mg/kg of lean body weight (5.7 mg of aminophylline is equal to 4.6 mg/kg of theophylline) should produce a serum concentration of 10 mcg/mL (range 6 to 16 mcg/mL). Measure serum theophylline concentration in 30 minutes to determine if additional loading doses are indicated. Once a serum concentration of 10 to 15 mcg/mL is obtained with loading dose(s), it should be maintained with a continuous infusion. Rate of infusion is based on the pharmacokinetic parameters (e.g., volume of distribution, clearance, concomitant disease states) of the specific patient population and should achieve a target serum concentration of 10 mcg/mL. See [Dose Adjustments](#) and [Monitor](#) for recommendations of serum theophylline testing after an infusion is started.

Adults, children, infants and neonates who have received a theophylline preparation in the previous 24 hours: A **serum theophylline concentration must be obtained before considering any loading dose.** Calculate the appropriate loading dose with the following formula.

$$D = (\text{Desired } C - \text{Measured } C) \times (V)$$

D is the loading dose, C is the serum theophylline concentration, and V is the volume of distribution (0.5 L/kg). Desired serum concentration in this situation should be conservative (e.g., 10 mcg/mL) to allow for variability in the volume of distribution; carefully evaluating the patient condition and risk versus benefit. It is not recommended by the manufacturer, but another source suggests that a smaller loading dose may be considered if it is not immediately possible to obtain a theophylline serum concentration. Carefully evaluate the patient's condition and risk versus benefit. The potential for theophylline toxicity must be ruled out. For example, if significant respiratory distress is present, a smaller loading dose of 2.5 mg/kg should increase the theophylline level by approximately 5 mcg/mL. In the absence of toxicity, this increase is unlikely to cause significant side effects and may improve the clinical picture. In all situations, measure serum theophylline concentration in 30 minutes to determine if additional loading doses are indicated. Once a serum concentration of 10 to 15 mcg/mL is obtained with or without loading dose(s), it should be maintained with a continuous infusion. Rate of infusion is based on the pharmacokinetic parameters (e.g., volume of distribution, clearance, concomitant disease states) of the specific patient population and should achieve a target serum concentration of 10 mcg/mL. See [Dose Adjustments](#) and [Monitor](#) for recommendations of serum theophylline testing after an infusion is started.

Maintenance infusion: Desired theophylline serum concentration is 10 mcg/mL. Most maintenance doses can be reduced within the first 12 hours based on serum theophylline levels and depending on patient condition and response; see [Dose Adjustments](#). Because of a large interpatient variability in theophylline clearance, each patient may differ from the mean value used to calculate these infusion rates. Another serum concentration is recommended one expected half-life after starting the continuous infusion; see [Dose Adjustments](#).

Aminophylline Infusion Rates Following an Appropriate Loading Dose	
Patient Population	Aminophylline Infusion Rate in mg/kg/hr^a (Actual theophylline administered in mg/kg/hr is in parentheses)
Neonates up to 24 days of age	1.27 mg/kg <i>every 12 hours</i> (1 mg/kg <i>every 12 hours</i>) ^b
Neonates over 24 days of age	1.9 mg/kg <i>every 12 hours</i> (1.5 mg/kg <i>every 12 hours</i>) ^b
Infants 6 to 52 weeks of age	mg/kg/hr = 0.01 × age in weeks + 0.21 ^c ÷ 79 (0.008 × Age in weeks + 0.21)
Children 1 to 9 years	1 mg/kg/hr (0.8 mg/kg/hr)
Children 9 to 12 years	0.875 mg/kg/hr (0.7 mg/kg/hr)
Adolescent smokers 12 to 16 years	0.875 mg/kg/hr (0.7 mg/kg/hr)
Adolescent nonsmokers 12 to 16 years	0.625 mg/kg/hr (0.5 mg/kg/hr) ^d
Adults (healthy nonsmokers 16 to 60 years)	0.5 mg/kg/hr (0.4 mg/kg/hr) ^d
Elderly over 60 years	0.375 mg/kg/hr (0.3 mg/kg/hr) ^e
Cardiac decompensation, cor pulmonale, liver dysfunction, sepsis with multi-organ failure, or shock	0.25 mg/kg/hr (0.2 mg/kg/hr) ^e

^aLower initial dose may be required for patients receiving other drugs that decrease theophylline clearance (e.g., cimetidine [Tagamet]).

^bTo achieve a target concentration of 7.5 mcg/mL for neonatal apnea.

^cThe 0.21 factor was not adjusted from the theophylline formula because it may not have the same proportional value. See package insert or contact Abbott if additional information desired.

^dNot to exceed 900 mg/day unless serum levels indicate need for a larger dose.

^eNot to exceed 400 mg/day or 21 mg/hr (17 mg/hr as theophylline) unless serum levels indicate need for a larger dose.

REVERSE ADENOSINE-MEDIATED EFFECTS OF DIPYRIDAMOLE IN ADULTS (UNLABELED)

50 to 100 mg over 30 to 60 seconds. Do not exceed a rate of 50 mg/30 sec. Maximum dose is 250 mg.

NEONATAL DOSE

Apnea and bradycardia of prematurity (unlabeled): **Loading dose:** 5 to 6 mg/kg given over 20 to 30 minutes. See all criteria under [Usual Dose](#).

Maintenance dose: See Maintenance Infusion under [Usual Dose](#). Manufacturer recommends keeping serum theophylline level at 7.5 mcg/mL. Another source recommends 1 to 2 mg/kg/dose every 6 to 8 hours.

DOSE ADJUSTMENTS

To determine if the concentration is accumulating or declining from the post-loading dose level, a serum concentration is recommended one expected half-life after starting the continuous infusion; see the following chart or see literature for a complete summary. If the level is declining (higher than average clearance) consider an additional loading dose or increasing the infusion rate. If the level is increasing, assume accumulation and decrease the infusion rate before the level exceeds 20 mcg/mL.

Continued

Theophylline Half-Life (Approximate)	
Age	Half-Life Mean (Range) in Hours
Premature neonates, see Maternal/Child	
3 to 15 days	30 (17 to 43) hours
25 to 57 days	20 (9.4 to 30.6) hours
Term infants, see Maternal/Child	
1 to 2 days	25.7 (25 to 26.5) hours
3 to 30 weeks	11 (6 to 29) hours
Children	
1 to 4 years	3.4 (1.2 to 5.6) hours
4 to 12 years	Not reported in studies
13 to 15 years	Not reported in studies
16 to 17 years	3.7 (1.5 to 5.9) hours
Adults (16 to 60 years) and healthy nonsmoking asthmatics	
Elderly (over 60 years); nonsmokers with normal cardiac, liver, and renal function	
	8.7 (6.1 to 12.8) hours
	9.8 (1.6 to 18) hours

There are huge variances in patients with concurrent illness or altered physiologic states (e.g., acute pulmonary edema, COPD, cystic fibrosis, fever with acute viral respiratory illness in pediatric patients [9 to 15 years], liver disease, pregnancy, sepsis with multi-organ failure, thyroid disease); see package insert. ■ In patients with cor pulmonale, cardiac decompensation, liver dysfunction, or in those taking drugs that markedly reduce theophylline clearance (e.g., cimetidine [Tagamet]), the initial aminophylline infusion rate should not exceed 21 mg/hr (17 mg/hr as theophylline) unless serum concentrations can be monitored every 24 hours. Up to 5 days may be required before steady state is reached in these patients; see **Drug Interactions**. ■ To decrease the risk of side effects associated with unexpected large increases in serum theophylline concentration, dose adjustment recommendations should be considered as the upper limit.

Final Dose Adjustment Guided by Serum Theophylline Concentration*	
Peak Serum Concentration	Dose Adjustment
Less than 9.9 mcg/mL	If symptoms are not controlled and current dose is tolerated, increase infusion rate about 25%. Recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults for further dose adjustment.
10 to 14.9 mcg/mL	If symptoms are controlled and current dose is tolerated, maintain infusion rate and recheck serum concentration at 24-hour intervals. If symptoms are not controlled and current dose is tolerated, consider adding additional medication(s) to treatment regimen.
15 to 19.9 mcg/mL	Consider 10% decrease in infusion rate to provide greater margin of safety, even if current dose is tolerated.†
20 to 24.9 mcg/mL	Decrease infusion rate by 25%, even if no side effects are present. Recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults to guide further dose adjustment.

Final Dose Adjustment Guided by Serum Theophylline Concentration*—cont'd	
Peak Serum Concentration	Dose Adjustment
25 to 30 mcg/mL	Stop infusion for 12 hours in pediatric patients and 24 hours in adults and decrease subsequent infusion rate at least 25% even if no side effects are present. Recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults to guide further dose adjustment. If symptomatic, stop infusion and consider need for overdose treatment; see <i>Antidote</i> .
Over 30 mcg/mL	Stop the infusion and treat overdose as indicated; see <i>Antidote</i> . If aminophylline is subsequently resumed, decrease infusion rate by at least 50% and recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults to guide further dose adjustment.

*Dose increases should not be made in patients with an acute exacerbation of symptoms unless the steady-state serum theophylline concentration is less than 10 mcg/mL.

†Dose reduction and/or serum theophylline concentration measurement is indicated whenever side effects are present, physiologic abnormalities that can reduce theophylline clearance occur (e.g., sustained fever), or a drug that interacts with theophylline is added or discontinued; see *Precautions and Drug/Lab Interactions*.

DILUTION

Check vial carefully; must state, "For IV use." Warm to room temperature. Only the 25 mg/mL solution may be given by IV injection undiluted, but further dilution for infusion in at least 100 to 200 mL of D5W is preferred. NS or dextrose in saline solutions may be used. Available prediluted. Crystals will form if solution pH falls below 8.

Storage: Usually stored between 15° and 30° C (59° and 86° F). Protect from light and freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be mixed in a syringe with other drugs but should be added separately to the IV solution," and recommends discontinuing other solutions infusing at the same site if there is a potential problem with admixture **incompatibility**. Manufacturer recommends avoiding admixtures with alkali labile drugs (e.g., epinephrine, norepinephrine [Levophed], isoproterenol [Isuprel], penicillin G potassium). Precipitation in acidic media may occur with the undiluted solution but not to dilute solutions in IV infusions.

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), ascorbic acid, calcium gluconate, chloramphenicol (Chloromycetin), dexamethasone (Decadron), dimenhydrinate, diphenhydramine (Benadryl), dopamine, erythromycin (Erythrocin), esmolol (Brevibloc), flumazenil (Romazicon), furosemide (Lasix), heparin, hydrocortisone sodium succinate (Solu-Cortef), lidocaine, meropenem (Merrem IV), methyl dopate, methylprednisolone (Solu-Medrol), midazolam (Versed), nafcillin (Nallpen), nitroglycerin IV, pentobarbital (Nembutal), phenobarbital (Luminal), potassium chloride (KCl), ranitidine (Zantac), sodium bicarbonate, vancomycin.

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), ceftazoline (Teflaro), ceftazidime (Fortaz), cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doripenem (Doribax), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), famotidine (Pepcid IV), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), labetalol, levofloxacin (Levaquin), linezolid (Zyvox), melphalan (Alkeran), meropenem (Merrem IV), miconazole (Mycamine), morphine, nifedipine (Cardene IV), paclitaxel (Taxol), pancuronium, pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), raniti-

dine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), teniposide (Vumon), thiotepa, vecuronium.

RATE OF ADMINISTRATION

A single dose over a minimum of 20 to 30 minutes. Most references suggest a minimum of 30 minutes. Do not exceed an average rate of 1 mL or 25 mg/min when giving by IV injection or as an infusion. Rapid administration may cause cardiac arrhythmias. Discontinue primary infusion if theophylline administered by piggyback or additive tubing and a possible **incompatibility** problem exists.

Reverse adenosine-mediated effects of dipyridamole: See **Usual Dose**.

ACTIONS

An alkaloid xanthine derivative. It relaxes smooth muscle in the airways (bronchodilation) and suppresses the response of the airways to stimuli (non-bronchodilator prophylactic effects). Cardiac output, urinary output, and sodium excretion are increased. Skeletal and cardiac muscles are stimulated, as is the CNS to a lesser degree. There is peripheral vasodilation. It decreases pulmonary artery pressure and lowers the threshold of the respiratory center to CO₂. Well distributed throughout the body. In adults and pediatric patients over 1 year of age, 90% of a dose is metabolized in the liver. Because of a large interpatient variability in theophylline clearance, half-life varies extensively based on age, concurrent illness, or altered physiological state; see **Dose Adjustments**, **Precautions**, **Maternal/Child**, and **Elderly**. Excreted in a changed form in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Adjunct to inhaled beta-2 selective agonists (e.g., albuterol) and systemic corticosteroids for the treatment of acute exacerbations of the symptoms and reversible airflow obstruction associated with asthma and other chronic lung diseases (e.g., emphysema, chronic bronchitis).

Unlabeled uses: Apnea and bradycardia of prematurity. ■ Reduce bronchospasm in cystic fibrosis and acute descending respiratory infections. ■ Relieve periodic apnea and increase arterial blood pH in patients with Cheyne-Stokes respirations. ■ Reverse adenosine-mediated effects of dipyridamole- (Persantine), adenosine- (Adenocard, Adenoscan), or regadenoson- (Lexiscan) induced adverse reactions (e.g., angina pectoris, bronchospasm, severe hypotension, ventricular arrhythmias).

CONTRAINDICATIONS

Known hypersensitivity to theophylline or ethylenediamine.

PRECAUTIONS

There is an increase in the volume of distribution of theophylline (primarily due to reduction in plasma protein binding) in premature neonates, patients with hepatic cirrhosis, uncorrected acidemia, the elderly, and women during the third trimester of pregnancy. Toxicity may occur in the therapeutic range. ■ Theophylline clearance may be reduced in neonates (term and premature); children less than 1 year; elderly (over 60 years); infants less than 3 months of age with reduced renal function; patients with acute pulmonary edema, congestive heart failure, cor pulmonale, hypothyroidism, liver disease (e.g., cirrhosis, acute hepatitis), sepsis with multi-organ failure, shock; or in patients with a fever of 102° F or more for 24 hours or more, or lesser temperature elevations for longer periods. Risk of severe toxicity increased in these patient populations; dose reduction and more frequent monitoring may be required. ■ Use with extreme caution in patients with active peptic ulcer disease, cardiac arrhythmias (not including bradyarrhythmias), or seizures; may exacerbate these conditions. ■ Initiate oral therapy as soon as symptoms are adequately improved. ■ See **Maternal/Child** and **Drug/Lab Interactions**.

Monitor: Monitor serum levels as directed in **Usual Dose** and **Dose Adjustments** to achieve maximum benefit with minimum risk. Each 0.5 mg/kg will increase serum theophylline by 1 mcg/mL. 10 mcg/mL to less than 20 mcg/mL is considered therapeutic. Peak serum level is best measured 20 to 30 minutes after initial loading dose, a half life after the initial infusion, or 12 to 14 hours into continuous infusion. ■ Monitor vital signs, including lung sounds. ■ Monitor for all signs of toxicity; see **Side Effects**. Serious toxicity may not be preceded by less severe side effects. ■ Serum theophylline measurements are

indicated before making a dose increase; whenever signs or symptoms of toxicity are present; whenever a new illness presents, an existing illness worsens, or a change in treatment regimen is initiated that may alter theophylline clearance (e.g., sustained fever, hepatitis [see [Precautions](#)], or drugs that may interact [see [Drug/Lab Interactions](#)]); and every 24 hours throughout the infusion. ■ Stop the IV infusion and obtain a serum theophylline concentration immediately in any patient on aminophylline who develops nausea or vomiting (particularly repetitive vomiting) or if any other signs of toxicity occur, even if another cause is suspected. ■ Dose increases should not be made in patients with an acute exacerbation of symptoms unless the steady-state serum theophylline concentration is less than 10 mcg/mL. ■ Patients with a very high initial clearance rate (low steady-state serum theophylline concentrations at above-average doses) are likely to experience large changes in serum concentration in response to dose changes. ■ Maintain hydration. ■ See [Precautions](#), [Maternal/Child](#), [Elderly](#), and [Drug/Lab Interactions](#).

Patient Education: Do not take or discontinue any prescription or over-the-counter medication, including herbal products, without physician's approval. ■ Promptly report S/S of toxicity (e.g., nausea and vomiting).

Maternal/Child: Category C: use in pregnancy only if clearly indicated. ■ Neonates may have therapeutic blood levels and may develop apnea from theophylline withdrawal. ■ Elimination of drug is prolonged in premature infants, neonates, and children up to 1 year. Use with extreme caution in pediatric patients. Has caused fatal reactions. Elimination reaches maximum values by 1 year of age, remains fairly constant to 9 years of age, and slowly decreases by approximately 50% to adult values at 16 years of age. ■ Pediatric patients under the age of 1 year, as well as neonates with decreased renal function, require careful attention to dosing and frequent monitoring of serum theophylline concentrations. ■ Secreted in breast milk; some sources recommend discontinuing breastfeeding. If the decision is made to breast-feed, monitor infant for evidence of side effects.

Elderly: Compared to healthy young adults, clearance of theophylline is decreased an average of 30% in healthy elderly. Monitor dosing carefully; frequent serum theophylline concentrations are recommended. See [Dose Adjustments](#), [Precautions](#), and [Monitor](#).

DRUG/LAB INTERACTIONS

Review of patient drug profile by pharmacist is imperative at time of initiation of aminophylline and with any change in medication regimen. ■ Do not use one xanthine derivative concurrently with another xanthine derivative, ephedrine, or other sympathomimetic drugs. ■ Xanthines antagonize or potentiate or are themselves antagonized or potentiated by many drug groups. Monitor serum levels as indicated. **Theophylline clearance increased and serum levels decreased by aminoglutenide, barbiturates, carbamazepine (Tegretol), ethmozine (Moricizine), isoproterenol (Isuprel), hydantoins (e.g., phenytoin [Dilantin]), rifampin (Rifadin), smoking, sulfipyrazone (Anturane). Theophylline clearance decreased and serum levels increased by alcohol, allopurinol, beta-adrenergic blockers (e.g., propranolol), cimetidine (Tagamet), ciprofloxacin (Cipro IV), clarithromycin, disulfiram (Antabuse), enoxacin (Penetrex), erythromycin, estrogen-containing oral contraceptives, fluvoxamine (Luvox), interferon alfa-A, methotrexate, mexiletine, pentoxifylline (Trental), propafenone (Rythmol), tacrine (Cognex), thiabendazole (Mintezol), ticlopidine (Ticlid), troleandomycin (TAO), verapamil.** ■ Inhibits **pancuronium**; increased doses of pancuronium may be required to achieve neuromuscular blockade. ■ **Carbamazepine (Tegretol) and loop diuretics (e.g., furosemide [Lasix])** may increase or decrease serum levels. ■ Reduces sedative effect of **benzodiazepines (e.g., diazepam [Valium], midazolam [Versed]) and of propofol (Diprivan)**; increased doses of sedatives may be required. To avoid respiratory depression, reduce sedative dose if aminophylline is discontinued or if dose is significantly reduced. ■ May decrease **lithium** levels. Dose adjustment and monitoring of lithium levels may be indicated. ■ Concurrent use with **halothane** may induce cardiac arrhythmias. ■ Concurrent use with **ketamine** may lower aminophylline seizure level. ■ Concurrent use with **ephedrine** may increase nausea, nervousness, and insomnia. ■ May increase **lab values** for free fatty acids, glucose, HDL, LDL, total cholesterol, uric acid, and urinary free cortisol excretion. ■ Caffeine and xanthine metabolites in neonates or pa-

tients with renal dysfunction may cause readings from some **immunoassay techniques** to be higher than the actual serum theophylline concentration. ■ Interferes with **dipyridamole-assisted MI perfusion studies**.

SIDE EFFECTS

Headache, insomnia, nausea, vomiting most common when peak serum concentrations are less than 20 mcg/mL. Rarely a severe hypersensitivity reaction of the skin (e.g., exfoliative dermatitis) may occur. Toxicity resulting in death may occur suddenly at levels less than 20 mcg/mL, especially in certain populations (see **Precautions**); may occur more frequently with serum levels above 20 mcg/mL. Anxiety, cardiac arrest, arrhythmias (e.g., atrial fibrillation, ventricular fibrillation), convulsions, delirium, dizziness, flushing, hyperpyrexia, intractable seizures, nausea, peripheral vascular collapse, persistent vomiting, restlessness, temporary hypotension.

Overdose: Acute: Acid/base disturbances, arrhythmias (e.g., sinus tachycardia), hyperglycemia, hypokalemia, seizures (usually with serum concentrations over 100 mcg/mL), vomiting, and death have occurred.

Chronic: All of the above plus various arrhythmias, seizures (with serum concentration greater than 30 mcg/mL), and death.

ANTIDOTE

With onset of any side effect, discontinue drug and notify physician. ■ Stop the IV infusion and obtain a serum theophylline concentration immediately in any patient on aminophylline who develops nausea or vomiting (particularly repetitive vomiting) or if any other signs of toxicity occur, even if another cause is suspected. ■ For mild symptoms the physician may choose to continue the drug at a decreased dose and rate of administration. All side effects will be treated symptomatically. Maintain adequate ventilation and adequate hydration. Grand mal seizures may not respond to anticonvulsants. Diazepam (Valium) may be most effective. Treat atrial arrhythmias with verapamil, ventricular arrhythmias with lidocaine or procainamide. Use dopamine for hypotension. Do not use stimulants. Resuscitate as necessary.

MANUFACTURER'S SPECIFIC RECOMMENDATIONS FOR ACUTE AND CHRONIC OVERDOSE

Acute overdose (e.g., excessive loading dose or excessive infusion rate for less than 24 hours) or chronic overdose (e.g., excessive infusion rate for more than 24 hours): Serum concentration 20 to 30 mcg/mL:

Stop the infusion, monitor the patient, and obtain a serum theophylline concentration in 2 to 4 hours to ensure that the concentration is decreasing.

Acute overdose with a serum concentration of 30 to 100 mcg/mL or chronic overdose with serum concentrations greater than 30 mcg/mL in patients less than 60 years of age:

Stop the infusion. Administer multiple-dose, oral-activated charcoal and measures to control emesis. Monitor the patient and obtain serial theophylline concentrations every 2 to 4 hours to determine the effectiveness of therapy and to determine further treatment decisions. Institute extracorporeal removal if emesis, seizures, or cardiac arrhythmias cannot be adequately controlled.

Acute overdose with a serum concentration greater than 100 mcg/mL or chronic overdose with serum concentrations greater than 30 mcg/mL in patients 60 years or older:

Stop the infusion. Consider prophylactic anticonvulsant therapy. Administer multiple-dose oral-activated charcoal and measures to control emesis. Consider extracorporeal removal, even if the patient has not experienced a seizure. Monitor the patient and obtain serial theophylline concentrations every 2 to 4 hours to determine the effectiveness of therapy and to determine further treatment decisions.

Extracorporeal removal:

Weigh risk versus benefits. Charcoal hemoperfusion is the most effective and increases theophylline clearance up to six-fold, but hypotension, hypocalcemia, and platelet consumption and bleeding diatheses may occur. Hemodialysis is about as efficient as multiple-dose oral-activated charcoal and has a lower risk of serious complications. Consider hemodialysis when charcoal hemoperfusion is not feasible and multiple-dose oral-activated charcoal is ineffective because of intractable emesis. Serum theophylline concentrations may rebound 5 to 10 mcg/mL after either treatment is discontinued due to redistribution of theophylline from the tissue compartment. Peritoneal dialysis is ineffective, and exchange transfusions in neonates have been minimally effective.

AMIODARONE HYDROCHLORIDE

Antiarrhythmic

(am-ee-OH-dah-rohn hy-droh-KLOR-eyed)

Nexterone

pH 4.08

USUAL DOSE**TREATMENT AND PROPHYLAXIS OF VENTRICULAR TACHYCARDIA (VT) AND VENTRICULAR FIBRILLATION (VF)**

1,000 mg over the first 24 hours in 3 distinct segments; two loading infusions and a maintenance infusion. Use of a dedicated central venous catheter preferred.

Rapid loading infusion: 150 mg specifically diluted solution (1.5 mg/mL) over 10 minutes (15 mg/min). Follow immediately with the slow loading infusion.

Slow loading infusion: 360 mg specifically diluted solution (1.8 mg/mL) at 1 mg/min over the next 6 hours.

Maintenance infusion: 540 mg of 1.8 mg/mL solution at 0.5 mg/min over 18 hours. Maintenance infusion is usually continued at 0.5 mg/min for 48 to 96 hours or until ventricular arrhythmias are stabilized. May be continued with caution for up to 2 to 3 weeks. Transfer to oral therapy as soon as feasible (guidelines are in package insert).

TREATMENT OF BREAKTHROUGH VENTRICULAR FIBRILLATION (VF) OR HEMODYNAMICALLY UNSTABLE VENTRICULAR TACHYCARDIA (VT)

At any time that breakthrough VF or hemodynamically unstable VT occurs during administration, a supplemental rapid loading infusion (150 mg over 10 minutes) may be repeated. May be specifically diluted 1.5 mg/mL solution or rate of the maintenance infusion (1.8 mg/mL) may be temporarily increased to equal 150 mg (83.33 mL) over 10 minutes. During trials total doses above 1,800 to 2,100 mg (including added doses for breakthrough VF/VT) increased the risk of hypotension. In life-threatening arrhythmias, AHA guidelines state that this rapid loading infusion (150 mg over 10 minutes) may be repeated every 10 minutes as needed and recommend a maximum cumulative dose of 2.2 Gm/24 hr.

CARDIAC ARREST (UNLABELED)

300 mg (6 mL) or 5 mg/kg as a bolus injection. Flush with 10 mL D5W or NS. Should be given through a separate IV line immediately after the first dose of epinephrine (1 mg) and before the fourth electrical countershock. Supplemental doses of 150 mg (3 mL) may be given for recurrent bouts of VT/VF. AHA guidelines recommend a first dose of 300 mg IV push and a second dose, if needed, of 150 mg IV push. After return of spontaneous circulation (ROSC), initiate the slow loading infusion and maintenance infusion as above. If effective, discontinue amiodarone and reassess arrhythmia management within 6 to 24 hours.

SUPRAVENTRICULAR ARRHYTHMIAS (UNLABELED)

150 mg over 10 minutes as a loading dose (15 mg/min). Follow with an infusion of 360 mg over 6 hours (1 mg/min) followed by a maintenance infusion of 0.5 mg/min for 18 hours. Other regimens used during studies to convert atrial fibrillation and atrial flutter to sinus rhythm include 5 mg/kg over 3 to 5 minutes; 5 to 7 mg/kg as a 30- to 60-minute infusion followed by a continuous infusion of 1.2 to 1.8 Gm/24 hr followed with oral dosing until a 10-Gm total dose is reached; or an infusion of 2 mg/kg/hr continued for up to 2 hours after conversion to a stable sinus rhythm or a maximum dose of 2,400 mg/24 hr.

INTRAVENOUS TO ORAL TRANSITION

Guidelines for IV to oral transition are located in manufacturer's literature. See Prescribing Information or consult pharmacist.

Continued

PEDIATRIC DOSE

Safety for use in pediatric patients (particularly infants and neonates) not established and not recommended; see [Contraindications](#) and [Maternal/Child](#).

Treatment of refractory pulseless VT, VF (unlabeled): AHA guidelines recommend 5 mg/kg by IV bolus (maximum single dose is 300 mg). May repeat to a maximum of 15 mg/kg/24 hr. Total dose in adolescents is 2.2 Gm/24 hr.

Treatment of perfusing supraventricular and ventricular arrhythmias (unlabeled): AHA guidelines recommend 5 mg/kg as an infusion over 20 to 60 minutes (maximum single dose 300 mg). May repeat to a maximum of 15 mg/kg/24 hr. Total dose in adolescents is 2.2 Gm/24 hr.

DOSE ADJUSTMENTS

Rate of maintenance infusion may be increased to achieve effective arrhythmia suppression. ■ Not required in renal or hepatic disease. Another source suggests a reduced dose in hepatic failure. ■ Dose selection should be cautious in the elderly. Reduced initial doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Available as a premixed solution in 1.5 mg/mL and 1.8 mg/mL concentrations or as a vial that must be further diluted. To further dilute vials, do not use evacuated glass intravenous bottles. Use only commercially available D5W (D5W or NS may be used for Nexterone) solutions in polyolefin or glass containers in any prepared solution that will be given over more than 2 hours. PVC containers are suitable only for dilution of the rapid loading dose; see [Compatibility](#) and [Precautions](#).

Rapid-loading infusion: Dilute 150 mg (3 mL) in 100 mL D5W; concentration is 1.5 mg/mL (D5W or NS may be used for Nexterone).

Slow-loading infusion and maintenance infusion: Dilute 900 mg (18 mL) in 500 mL D5W; concentration is 1.8 mg/mL (D5W or NS may be used for Nexterone). Dilutions from 1 to 6 mg/mL have been used for maintenance solutions after the first 24 hours. Use of a central venous catheter is recommended; however, concentrations over 2 mg/mL for longer than 1 hour must be administered through a central venous catheter. Higher concentrations (3 to 6 mg/mL) have caused peripheral vein phlebitis and hepatocellular necrosis; see [Precautions](#).

Cardiac arrest (unlabeled): Loading dose (300 mg or 5 mg/kg) or supplemental boluses (150 mg) may be given undiluted. Has also been diluted in up to 20 mL D5W (D5W or NS may be used for Nexterone).

Filters: Use of a 0.2-micron in-line filter recommended by manufacturer. States “filtering does not affect potency.” Another source suggests no significant loss of drug potency with the use of a 0.22-micron cellulose ester membrane filter.

Storage: Store ampules and premixed solutions in their carton at CRT. Use solutions diluted in PVC containers within 2 hours; use those diluted in glass or polyolefin containers within 24 hours. Protect from light and freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommendations include: Do not use evacuated glass intravenous bottles. Administer through a dedicated IV line (central venous catheter preferred). Absorbs to PVC tubing but loss accounted for in specified dose; follow infusion regimen closely. Leaches out plasticizers, including DEHP, from IV tubing. The degree of leaching increases when the solution is infused at a higher concentration or a slower infusion rate than recommended. Manufacturer lists aminophylline, cefazolin (Ancef), heparin, mezlocillin (Mezlin), and sodium bicarbonate as **incompatible** at the **Y-site**.

One source suggests the following **compatibilities**:

Additive: Dobutamine, furosemide (Lasix), lidocaine, potassium chloride (KCl), procainamide (Pronestyl), quinidine, verapamil.

Y-site: Amikacin (Amikin), amphotericin B (conventional), atracurium (Tracium), atropine, calcium chloride, calcium gluconate, caspofungin (Cancidas), cefazolin (Ancef), ceftaroline (Teflaro), ceftriaxone (Rocephin), cefuroxime (Zinacef), ciprofloxacin (Cipro IV), clindamycin (Cleocin), dexmedetomidine (Precedex), dobutamine, dopamine, doripenem (Doribax), doxycycline, epinephrine (Adrenalin), eptifibatid (Integrilin), erythromycin (Erythrocin), esmolol (Brevibloc), famotidine (Pepcid IV), fenoldopam (Corlopan), fentanyl (Sublimaze), fluconazole (Diflucan), furosemide (Lasix), gentamicin, hetastarch in electrolytes (Hextend), insulin (regular), isoproterenol (Isuprel), labetalol, lidocaine, lorazepam (Ativan), magnesium sulfate, methylprednisolone (Solu-Medrol), metoprolol (Lopressor), midazolam (Versed), milrinone (Primacor), morphine, nesiritide (Natrecor), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), penicillin G potassium, phentolamine (Regitine), phenylephrine (Neo-Synephrine), potassium chloride (KCl), procainamide (Pronestyl), tirofiban (Aggrastat), tobramycin, vancomycin, vasopressin, vecuronium.

RATE OF ADMINISTRATION

Volumetric pump required for administration. Surface properties of diluted solution reduce drop size; use of a drop counter infusion set causes underdosing. Use of a 0.2-micron in-line filter is also recommended. A central venous catheter is recommended for all concentrations and is required for concentrations greater than 2 mg/mL. Adhere to prescribed rates; risk of hypotension is increased in the first hours of treatment and with increased rates; may cause secondary renal or hepatic failure; see **Precautions**. Avoid IV bolus doses in patients with marked cardiomegaly, a continuous infusion is preferred. Do not use plastic containers in a series; could result in air embolism.

Rapid loading infusion or breakthrough treatment of VF/VT: 150 mg over 10 minutes (15 mg/min). Do not exceed a rate of 30 mg/min.

Slow loading infusion: 1 mg/min or 33.3 mL/hr (0.556 mL/min) of 1.8 mg/mL solution for 6 hours.

Maintenance infusion: 0.5 mg/min or 16.6 mL/hr (0.278 mL/min) of 1.8 mg/mL solution for 18 hours. A continuing maintenance solution should deliver 720 mg/24 hr at 0.5 mg/min whether the concentration is 1.8 mg/mL or 6 mg/mL. May be continued at this rate for up to 2 to 3 weeks as described in Usual Dose.

Cardiac arrest (unlabeled): Loading or supplemental doses by IV bolus injection. Follow with 10 mL flush of D5W or NS through Y-tube or three-way stopcock. May be given through a free-flowing infusion of D5W (D5W or NS may be used for Nexterone). After return of spontaneous circulation (ROSC), initiate the slow loading and maintenance infusions as above.

ACTIONS

An antiarrhythmic agent. Generally considered a class III antiarrhythmic drug, but possesses characteristics of all four antiarrhythmic classes. Decreases number of VT/VF events. It prolongs the duration of action potentials in cardiac fibers, depresses conduction velocity, slows conduction and prolongs refractoriness at the AV node, and exhibits some alpha and beta blockade activity. Raises the threshold for VF and may prevent its recurrence. Also has vasodilatory effects that decrease cardiac workload and myocardial oxygen consumption. Uptake by the myocardium is rapid; antiarrhythmic effect is prompt (clinically relevant within hours); however, full effect may take days. Has an exceptionally long half-life. Metabolized in the liver by cytochrome P₄₅₀ enzymes (specifically CYP3A4 and CYP2C8). Primarily excreted in bile. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of acute life-threatening VT/VF and prophylaxis of frequently recurring VF and hemodynamically unstable VT in patients refractory to other therapy (e.g., lidocaine, procainamide). Used until ventricular arrhythmias are stabilized; usually 48 to 96 hours, but may be given for longer periods (i.e., up to 3 weeks). ■ Treatment of patients taking oral amiodarone who are unable to take oral medication.

Unlabeled uses: Conversion of atrial fibrillation to a normal sinus rhythm and maintenance of a normal sinus rhythm. ■ Cardiac arrest with persistent VT or VF if defibrillation, CPR, and vasopressor administration have failed. ■ Control of hemodynamically stable monomorphic VT, polymorphic VT with a normal baseline QT interval, or wide-complex tachycardia of uncertain origin. ■ Control of rapid ventricular rate due to accessory pathway conduction in pre-excited atrial arrhythmias. ■ Heart rate control in patients with atrial fibrillation and heart failure with no accessory pathway. ■ Pharmacologic adjunct to ICD (implantable cardioverter defibrillator) therapy to suppress symptomatic ventricular tachyarrhythmias in otherwise optimally treated patients with heart failure.

CONTRAINDICATIONS

Cardiogenic shock, corneal refractive laser surgery, known hypersensitivity to amiodarone or any of its components, including iodine; marked sinus bradycardia; second- or third-degree AV block unless a functioning pacemaker is available; sinus node dysfunction. See [Drug/Lab Interactions](#). ■ Not recommended for use in neonates or infants. ■ Contraindicated with nelfinavir (Viracept) and ritonavir (Norvir).

PRECAUTIONS

Usually administered by or under the direction of the physician specialist with facilities for monitoring the patient and responding to any medical emergency. ■ Correct hypokalemia and hypomagnesemia before use; may exaggerate a prolonged QTc and cause arrhythmias (e.g., torsades de pointes). ■ May cause transient increases in liver enzymes but abnormal baseline hepatic enzymes is not a contraindication to use. ■ Use of higher than recommended loading dose concentrations and increased rates of administration have been associated with hepatocellular necrosis, hepatic coma, acute renal failure, and death. ■ May worsen existing arrhythmias or precipitate new ones, primarily torsades de pointes or new-onset VF. ■ Combination of amiodarone with other antiarrhythmics that can prolong the QTc interval should be reserved for patients with life-threatening ventricular arrhythmias who do not respond to single agent therapy; see [Drug/Lab Interactions](#). ■ Risk of QTc prolongation is increased (with or without torsades de pointes) with other medications that can prolong the QTc (e.g., fluoroquinolones [e.g., levofloxacin (Levaquin)], macrolide antibiotics [e.g., erythromycin (Erythrocin)], azoles [e.g., fluconazole (Diflucan)]); see [Drug/Lab Interactions](#). ■ Hypotension is the most common side effect. Usually occurs within the first several hours of therapy and appears to be rate-related. Do not exceed initial rates recommended by manufacturer. In some cases, hypotension has been refractory to treatment. Deaths have occurred. See [Monitor](#) and [Antidote](#). ■ May cause visual impairment (e.g., optic neuropathy or optic neuritis); has progressed to permanent blindness. ■ May cause pulmonary toxicity (e.g., ARDS, bronchospasm, cough, dyspnea, hemoptysis, hypoxemia, wheezing). Usually seen with long-term use, but acute pulmonary hypersensitivity has been reported after short-term IV use and with or without IV use. Has progressed to respiratory failure and death. The elderly and patients with pre-existing lung disease may be at increased risk and have a poorer prognosis if pulmonary toxicity develops; see [Side Effects](#). ■ Adult respiratory distress syndrome (ARDS) has been reported in patients receiving oral amiodarone following surgery. ■ Monitor patients undergoing general anesthesia closely; may increase sensitivity to myocardial depressant and conduction defects of halogenated inhalation anesthetics (hypotension and atropine-resistant bradycardia). ■ Use caution in patients with cardiomyopathy, hepatic failure, left ventricular dysfunction, or thyroid dysfunction. ■ May cause hypothyroidism or hyperthyroidism. Amiodarone-induced hyperthyroidism may result in thyrotoxicosis and/or the possibility of arrhythmia breakthrough or aggravation. Deaths have occurred. ■ Thyroid nodules and/or thyroid cancer have been reported in patients treated with amiodarone. ■ See [Compatibility](#) and [Drug/Lab Interactions](#).

Monitor: Continuous ECG and HR monitoring is mandatory to observe for arrhythmias. Watch for QTc prolongation; may cause proarrhythmia (torsades de pointes). ■ Monitor for bradycardia and AV block. A temporary pacemaker should be available. Consider the possibility of hyperthyroidism if new signs of arrhythmia appear. ■ Monitor BP closely

to minimize hypotension (occurs frequently with initial rates); see [Rate of Administration](#), [Precautions](#), and [Antidote](#). ■ Confirm patency of vein. Reduce rate or concentration for pain or redness at injection site. Incidence of phlebitis markedly increased with concentrations above 2.5 mg/mL. For infusions longer than 1 hour, do not exceed a concentration of 2 mg/mL unless a central venous line is used. ■ Monitor serum electrolytes and acid-base balance, especially in patients with prolonged diarrhea and those receiving diuretics. ■ Monitor liver enzymes (AST, ALT, GGT) for elevations indicating progressive injury. ■ Monitor pulmonary status (e.g., FiO_2 , SaO_2 , PaO_2 , chest x-ray); baseline pulmonary function tests recommended; repeat as indicated. ■ Monitor thyroid function tests before treatment and periodically thereafter. Patients with a history of thyroid nodules, goiter, or other thyroid dysfunction and the elderly should be monitored closely. Amiodarone is eliminated slowly, and abnormal function tests may persist for weeks or months after it is discontinued. ■ Regular ophthalmic exams, including funduscopy and slit lamp exams, are recommended. Prompt ophthalmic exams recommended at first sign of visual impairment. May require discontinuation of amiodarone therapy. ■ Serum amiodarone levels greater than 2.5 mcg/mL have been associated with a higher incidence of side effects. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Most manufacturers of corneal refractive laser surgery devices contraindicate this procedure in patients receiving amiodarone. ■ Report promptly any feelings of faintness, difficulty breathing, or pain or stinging along injection site. Review side effect profile, including S/S of hypothyroidism or hyperthyroidism. ■ Nonhormonal birth control recommended. ■ Numerous drug interactions. Review all medications, including OTC medications, with physician or pharmacist. ■ Avoid grapefruit juice if transitioned to oral amiodarone.

Maternal/Child: Category D: avoid pregnancy or use only if benefit to mother justifies risk to fetus. Has caused infrequent neonatal congenital goiter/hypothyroidism and hyperthyroidism in addition to other adverse effects. ■ Discontinue breast-feeding. ■ Safety for use during labor and delivery not established. ■ Safety and effectiveness for use in pediatric patients not established. ■ A manufacturer's warning letter has been issued citing potentially fatal or developmental side effects in infants and neonates; see [Contraindications](#). Another source suggests amiodarone may adversely affect male reproductive tract development in infants, neonates, and toddlers. ■ Vials contain benzyl alcohol, which has been associated with "gaspings syndrome" in neonates (sudden onset of gasping respirations, hypotension, bradycardia, and cardiovascular collapse).

Elderly: Differences in response between the elderly and younger patients have not been identified; however, clearance is slower and half-life may be doubled (up to 47 days). See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Amiodarone has a long half-life; drug interactions may persist long after it is discontinued.

Contraindicated with nelfinavir (Viracept) and ritonavir (Norvir). Should not be given concurrently with **ibutilide (Corvert)**. ■ Concurrent use with other **antiarrhythmic agents** (e.g., disopyramide [Norpace], mexiletine, procainamide [Pronesty], quinidine) increases their serum concentrations and may result in additive increases in QT prolongation and serious arrhythmias. One source recommends reducing the dose of previously given antiarrhythmic agents by 30% to 50% several days after starting amiodarone and then gradually withdrawing them altogether. Another suggests reducing the dose of any antiarrhythmic therapy required in addition to amiodarone to one-half the recommended dose. Monitor serum levels if possible. ■ QT prolongation has been reported with concomitant administration of amiodarone and **fluoroquinolones** (e.g., levofloxacin [Levaquin]), **macrolide antibiotics** (e.g., erythromycin [Erythrocin]), **azoles** (e.g., fluconazole [Diflucan]), **loratadine (Claritin)**, **trazodone (Desyrel)**, and **grapefruit juice (oral therapy)**; see [Precautions](#). ■ May decrease metabolism and increase serum levels of **digoxin**. One source recommends reducing digoxin dose by 50% or withdrawing completely when amiodarone therapy is initiated. ■ Use with **potassium-depleting diuretics** (e.g., chloro-

thiazide [Diuril], furosemide [Lasix], indapamide [Lozol]) may lead to increased risk of arrhythmias due to hypokalemia. ■ Inhibits metabolism and increases anticoagulant effect (e.g., increased PT and INR) of **warfarin** (Coumadin). Dose reduction of the anticoagulant and careful monitoring of PT or INR recommended. Effects may persist long after amiodarone discontinued. ■ May decrease metabolism and increase serum levels of **cyclosporine** (Sandimmune), **flecainide** (Tambocor), **hydantoins** (e.g., phenytoin [Dilantin]), **lidocaine**, **methotrexate**, **procainamide** (Pronestyl), **quinidine**, and **theophyllines** (Aminophylline). May cause toxicity; monitor serum levels. Reduced doses indicated. ■ Concomitant use with **HMG-CoA reductase inhibitors** that are CYP3A4 substrates (e.g., lovastatin [Mevacor], simvastatin [Zocor]) has been associated with myopathy/rhabdomyolysis. In patients taking amiodarone, limit the dose of lovastatin to 40 mg daily and limit the dose of simvastatin to 20 mg daily. Lower starting and maintenance doses of other CYP3A4 substrates (e.g., atorvastatin [Lipitor]) may also be required. ■ May cause bradycardia, decreased cardiac output, and hypotension with **fentanyl** (Sublimaze). ■ Therapeutic plasma concentrations of **flecainide** (Tambocor) can be maintained with reduced doses because amiodarone interferes with flecainide metabolism. ■ Amiodarone clearance increased and plasma levels decreased with **cholestyramine** (Questran), **phenytoin** (Dilantin), **rifampin** (Rifadin), and **St. John's wort**. ■ **Cimetidine** (Tagamet) and **protease inhibitors** (e.g., indinavir [Crixivan]) may decrease clearance and increase plasma levels of amiodarone. ■ May increase risk of atrioventricular block, bradycardia, and hypotension with **beta-blockers** (e.g., propranolol) and **calcium channel blockers** (e.g., diltiazem [Cardizem], verapamil). ■ May inhibit conversion of **clopidogrel** (Plavix) to its active metabolite, resulting in ineffective inhibition of platelet aggregation. ■ Monitor patients undergoing **general anesthesia** closely. May increase sensitivity to myocardial depressant and conduction defects of **halogenated inhalation anesthetics** (hypotension and atropine-resistant bradycardia). ■ PO use for longer than 2 weeks may decrease metabolism and increase serum levels of **dextromethorphan** (Robitussin DM), **methotrexate**, and **phenytoin**. ■ See **Precautions**.

SIDE EFFECTS

Hypotension or pain at the IV site are the most common side effects. Agranulocytosis, anaphylaxis, anemia (aplastic and/or hemolytic), angioedema, anorexia, arrhythmias (e.g., AV block, bradycardia, new onset VT/VF, sinus arrest, torsades de pointes), adult respiratory distress syndrome (ARDS), ataxia, cardiac arrest, cardiogenic shock, confu-

sion, congestive heart failure, delirium, disorientation, dizziness, dry eyes, hallucinations, hepatotoxicity (liver function test abnormalities), impotence, muscle weakness, myopathy, nausea, nephrotoxicity, neutropenia, pancreatitis, pancytopenia, paresthesias, peripheral neuropathy, photosensitivity, pleuritis, pruritus, pseudotumor cerebri (swelling that resembles a tumor), pulmonary toxicity (including bronchiolitis obliterans organizing pneumonia [may be fatal]), renal impairment, respiratory disorders (including cough, dyspnea, hemoptysis, hypoxia, pulmonary infiltrates and/or mass on chest x-ray, respiratory failure), rhabdomyolysis, skin disorders (e.g., epididymitis, erythema multiforme, exfoliative dermatitis, Stevens-Johnson syndrome, toxic epidermal necrolysis [may be fatal]), syndrome of inappropriate antidiuretic hormone secretion (SIADH), thrombocytopenia, thyroid dysfunction, and visual impairment/loss of vision may occur. In addition to these side effects, overdose or extended use may cause hepatic and/or renal failure secondary to hypotension.

Overdose: AV block, bradycardia, cardiogenic shock, death, hepatotoxicity, hypotension.

ANTIDOTE

Keep physician informed of all side effects and treat promptly as appropriate; many are life threatening. Reduce rate and/or concentration for pain at IV site. Monitor hepatic enzymes closely. Reduce rate or discontinue for progressive hepatic injury. Treat hypotension and cardiogenic shock by slowing the infusion rate. Vasopressors (e.g., dopamine, norepinephrine [Levophed]), inotropic agents (e.g., digoxin), and volume expansion may be indicated. Slow infusion rate or discontinue if bradycardia and/or AV block occur; may require a temporary pacemaker. If torsades de pointes occurs, stop all cardioactive drugs (e.g., antiarrhythmics, digoxin, antidepressants, phenothiazines) and normalize electrolytes (e.g., potassium, magnesium). Atrial overdrive pacing may be required to stabilize cardiac rhythm. Dose reduction or discontinuation of amiodarone may be required if thyroid abnormalities develop. Thyroid hormone supplementation may be required in hypothyroidism. Initiation of antithyroid drugs (e.g., propylthiouracil [PTU]), beta-blockers (e.g., propranolol), and/or temporary corticosteroid therapy may be necessary for treatment of hyperthyroidism. In severe thyrotoxicosis where amiodarone cannot be discontinued, thyroidectomy may be used as treatment. Experience with surgical intervention is limited; could induce thyroid storm. Amiodarone is not dialyzable. Resuscitate as necessary.

AMPHOTERICIN B **BBW*** ■ AMPHOTERICIN B LIPID-BASED PRODUCTS

(am-foe-**TER**-ih-sin)

Antifungal
Antiprotozoal (AmBisome)

Abelcet, AmBisome, Amphotec

pH 5.7 to 8 ■ 5 to 6

*The Black Box Warning applies only to the generic formulation.

USUAL DOSE

Each product has different biochemical, pharmacokinetic, and pharmacodynamic properties. They are not interchangeable from dose to dose, in a given patient, between each other or conventional amphotericin.

ABELCET (AMPHOTERICIN B LIPID COMPLEX INJECTION)

Adults and pediatric patients: 5 mg/kg/24 hr as an infusion. Repeat daily until clinical response or mycologic cure.

AMPHOTEC (AMPHOTERICIN B CHOLESTERYL SULFATE COMPLEX FOR INJECTION)

Adults and pediatric patients: 3 to 4 mg/kg/24 hr as an infusion. Pretreatment with antipyretics, antihistamines, or corticosteroids may be indicated; see [Precautions](#) and [Antidote](#). On the first day of treatment, begin with a test dose of 10 mL of the final diluted preparation and infuse over 15 to 30 minutes. Observe the patient for the next 30 minutes. If there is no adverse reaction, continue with the calculated dose. May be increased to 6 mg/kg/24 hr if there is no improvement or if the fungal infection progresses. See [Indications](#).

AMBISOME (AMPHOTERICIN B LIPOSOME FOR INJECTION)

Adults, children, and infants over 1 month of age: All doses are by infusion.

Empirical therapy in febrile, neutropenic patients: 3 mg/kg/24 hr.

Systemic fungal infections (e.g., *Aspergillus*, *Candida*, *Cryptococcus*): 3 to 5 mg/kg/24 hr.

Treatment of cryptococcal meningitis in HIV-infected patients: 6 mg/kg/24 hr.

Visceral leishmaniasis in immunocompetent patients: 3 mg/kg/24 hr on Days 1 through 5. Repeat 3 mg/kg on Day 14 and on Day 21. A repeat course of therapy may be useful if parasitic clearance is not achieved.

Visceral leishmaniasis in immunocompromised patients: 4 mg/kg/24 hr on Days 1 through 5. Repeat 4 mg/kg on Days 10, 17, 24, 31, and 38. During clinical studies parasitic clearance was not achieved or relapse within 6 months occurred in 88.2% of patients. Usefulness of repeat courses not determined.

GENERIC (CONVENTIONAL AMPHOTERICIN B)

Adults and pediatric patients: Begin with a test dose of 0.1 mg/kg up to 1 mg maximum dose in 20 mL D5W. Infuse over 20 to 30 minutes. Determine size of therapeutic dose by intensity of reaction over a 2- to 4-hour period. Usual starting dose is 0.25 mg/kg of body weight/24 hr. Gradually increase dose by 5 to 10 mg/day (0.125 to 0.25 mg/kg in pediatric patients) to a final dose of 0.5 to 0.7 mg/kg. Total daily dose may range up to 1 mg/kg/day, or up to 1.5 mg/kg/24 hr may be given on alternate-day therapy. Several months of therapy are usually required and recommended for cure. Dosage must be adjusted to each specific patient. In some instances, higher doses can be used. Do not exceed a total daily dose of 1.5 mg/kg under any circumstances.

DOSE ADJUSTMENTS

ABELCET: Full dose usually required; base on SCr and overall patient condition.

AMPHOTEC/AMBISOME: No dose adjustments suggested.

GENERIC (CONVENTIONAL): In all situations, gradual dose increases are essential. Whenever medicine is not given for 7 days or longer, restart treatment at lowest dosage level.

Patients with impaired cardio-renal function or a severe reaction to the test dose: Initiate with smaller daily doses (i.e., 5 to 10 mg).

Patients who experience amphotericin-induced nephrotoxicity: One source recommends reducing the total daily dose by 50% or administering the dose every other day.

Severe and rapidly progressive fungal infection: Initiate treatment with a daily dose of 0.3 mg/kg.

DILUTION

ABELCET: Available in 100-mg (20-mL) vials. Shake vial until all yellow sediment is dissolved. Maintain aseptic technique. Withdraw an exact total daily dose from one or more vials using one or more syringes and 18-gauge needles. Replace needle(s) on syringe(s) with the 5-micron filter(s) supplied with each vial. A new filter must be used for each 400 mg (80 mL) of Abelcet. Empty syringe contents through filter into an infusion of D5W. 4 mL of diluent (D5W) is required for each 1 mL (5 mg) of Abelcet to achieve a final concentration of 1 mg/mL. For **pediatric** and/or fluid-restricted patients (e.g., patients with cardiovascular disease) reduce diluent by half (approximate concentration of 2 mg/mL).

AMPHOTEC: Available in 50-mg or 100-mg vials. Reconstitute by rapidly adding 10 mL of SWFI for each 50 mg of Amphotec (5 mg/mL). Use of a 20-gauge needle is recommended. Shake gently, rotating the vial until all solids have dissolved. May be opalescent or clear. Must be further diluted for infusion with D5W (see the following chart). Final desired concentration is approximately 0.6 mg/mL (range with recommended amounts of diluent is 0.16 mg/mL to 0.83 mg/mL). Do not filter or use an in-line filter. See **Compatibility** and **Rate of Administration**.

Guidelines for Dilution of Amphotec		
Dose of Amphotec (mg)	Volume of Reconstituted Amphotec (mL)	Infusion Bag Size for D5W for Injection (mL)
10-35 mg	2-7 mL	50 mL
35-70 mg	7-14 mL	100 mL
70-175 mg	14-35 mL	250 mL
175-350 mg	35-70 mL	500 mL
350-1,000 mg	70-200 mL	1,000 mL

AMBISOME: Reconstitute each 50-mg vial with 12 mL SWFI (without a bacteriostatic agent) to yield 4 mg/mL. Shake vial vigorously for 30 seconds; forms a yellow translucent suspension. Withdraw an exact total daily dose from one or more vials using one or more 20-mL syringes and needles. Replace needle(s) with the 5-micron filter(s) supplied with each vial. A new filter must be used for each 50-mg vial. Empty syringe contents through filter into an infusion of D5W. Use sufficient diluent to achieve a final concentration of 1 to 2 mg/mL, pH 5 to 6. For **pediatric patients:** may be further diluted to concentrations of 0.2 to 0.5 mg/mL for infants and small children to provide adequate volume for infusion.

GENERIC (CONVENTIONAL): A 50-mg vial is initially diluted with 10 mL of SWFI (without a bacteriostatic agent); 5 mg equals 1 mL. Shake well until solution is clear. Further dilute each 1 mg in at least 10 mL of D5W. Dextrose must have a pH above 4.2. Concentration of solution must not be greater than 0.1 mg/mL. Do not use any other diluent. Use a sterile 20-gauge or larger needle at each step of the dilution. Maintain aseptic technique. Larger pore 1-micron filters may be used. Use only fresh solutions without evidence of precipitate or foreign matter. Light sensitive; protect from light during administration.

Filters: Abelcet: 5-micron filter(s) supplied with each vial. A new filter must be used for each 400 mg (80 mL) of Abelcet. Empty syringe contents through filter into an infusion solution. Do not use an in-line filter.

Amphotec: Do not filter or use an in-line filter.

AmBisome: 5-micron filter(s) supplied with each vial. A new filter must be used for each 50-mg vial. Empty syringe contents through filter into an infusion solution. Do not use an in-line filter smaller than 1 micron.

Generic (Conventional): Larger pore 1-micron filters may be used; see [Dilution](#).

Storage: Abelcet: Before reconstitution, refrigerate in carton until time of use and protect from light. Do not freeze. Diluted solution is stable 48 hours if refrigerated and an additional 6 hours at room temperature. Discard unused drug.

Amphotec: Store unopened vials in carton at CRT. Refrigerate reconstituted or diluted solutions; must be used within 24 hours. Do not freeze. Discard unused drug.

AmBisome: Unopened vials may be stored at temperatures up to 25° C (77° F). Vials reconstituted with SWFI may be refrigerated for up to 24 hours. Do not freeze. Infusion of fully diluted solution must begin within 6 hours. Discard unused drug.

Generic (Conventional): Before reconstitution, refrigerate vials and protect from light. Do not freeze. Preserve concentrate in refrigerator up to 7 days or 24 hours at room temperature. Use diluted solution promptly.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

ALL FORMULATIONS

In all situations, use a separate infusion line or flush an existing line with D5W before and after administration.

ABELCET

Do not mix with any other diluent, drug, or solution. Use only D5W. Manufacturer states that **compatibility** with any other diluent has not been established. Another source lists **compatibility** at the **Y-site** with anidulafungin (Eraxis), doripenem (Doribax).

AMBISOME/AMPHOTEC/GENERIC

Do not mix with any other diluent, drug, or solution. Use only SWFI for reconstitution and D5W for dilution for infusion. Use of any other solution or the presence of a bacteriostatic agent (e.g., benzyl alcohol) may cause precipitation. Another source lists AmBisome as **compatible** at the **Y-site** with anidulafungin (Eraxis), doripenem (Doribax).

AMPHOTEC

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), aminophylline, cefoxitin (Mefoxin), clindamycin (Cleocin), cytarabine (ARA-C), dexamethasone (Decadron), doripenem (Doribax), fentanyl (Sublimaze), furosemide (Lasix), ganciclovir (Cytovene), granisetron (Kytril), hydrocortisone sodium succinate (Solu-Cortef), ifosfamide (Ifex), lorazepam (Ativan), mannitol, methotrexate, methylprednisolone (Solu-Medrol), nitroglycerin IV, sulfamethoxazole/trime-thoprim, sufentanil (Sufenta), vinblastine, vincristine, zidovudine (AZT, Retrovir).

GENERIC (CONVENTIONAL)

One source suggests the following **compatibilities**:

Additive: Not recommended by manufacturer. Fluconazole (Diflucan), heparin, hydrocortisone sodium succinate (Solu-Cortef), sodium bicarbonate.

Y-site: Aldesleukin (Proleukin, Interleukin-2), amiodarone (Nexterone), cisatracurium (Nimbex), diltiazem (Cardizem), doripenem (Doribax), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), teniposide (Vumon), thiotepa, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

ALL AMPHOTERICINS: Rapid infusion may cause hypotension, hypokalemia, arrhythmia, and shock. Infusion reactions can occur with all amphotericin B formulations. See [Precautions](#), [Side Effects](#), and [Antidote](#). With all formulations, flush existing line with D5W before and after administration or use a separate IV line.

ABELCET: Total daily dose as an infusion at 2.5 mg/kg/hr. Contents of diluted solution must be mixed by shaking at least every 2 hours. Do not use an in-line filter.

AMPHOTEC: See rate for test dose in [Usual Dose](#). Give total daily dose as an infusion at 1 mg/kg/hr. Infusion time may be shortened to a minimum of 2 hours for patients who

show no evidence of intolerance or infusion-related reactions. May be extended for acute reactions or if infusion volume is not tolerated. Do not use filters.

AMBISOME: Total daily dose as an infusion over 2 hours. Use of a controlled infusion device is recommended. Infusion time may be shortened to a minimum of 1 hour for patients who show no evidence of intolerance or infusion-related reactions. Infusion time may be extended for patient discomfort or acute reactions or if infusion volume is not tolerated. Do not use any in-line filter less than 1 micron.

GENERIC (CONVENTIONAL): Daily dose over 2 to 6 hours by slow IV infusion. Expected reactions usually less severe with slower rate. A minimum 1-micron filter may be used.

ACTIONS

Antifungal antibiotic agents that bind to the sterol component of fungal cell membranes resulting in leakage of cellular contents. May be fungistatic or fungicidal according to body fluid concentration and susceptibility of the fungus. Abelcet is amphotericin B complexed with two phospholipids in a 1:1 drug-to-lipid ratio. Amphotec is amphotericin B complexed with cholesteryl sulfate in a colloidal dispersion in a 1:1 drug-to-lipid ratio. AmBisome is amphotericin B intercalated into a liposomal membrane with several components. Assay tests cannot distinguish lipid-based amphotericin from conventional amphotericin B. Modification of amphotericin to the various lipid-based products alters the drug's functional properties. It allows for increased levels of drug at the site of action (usually areas where the fungi are). Overall effect is increased effectiveness with less toxicity. Not effective against bacteria, rickettsiae, or viruses. Long terminal half-life probably reflects a slow redistribution from tissues. Actual distribution to organs is somewhat selective and may help to decide which product is best to use in a given situation. Route of metabolism not known. Excreted very slowly in the urine.

INDICATIONS AND USES

ABELCET: Treatment of invasive fungal infections in patients who are refractory to or intolerant of conventional amphotericin B therapy.

AMPHOTEC: Treatment of invasive aspergillosis in patients refractory to or intolerant of conventional amphotericin B or in patients in whom conventional amphotericin treatment has failed.

AMBISOME: Empirical therapy for presumed fungal infection in febrile, neutropenic patients. ■ Treatment of patients with aspergillosis, candida, and/or cryptococcus infections refractory to conventional amphotericin B or in patients in whom renal impairment or unacceptable toxicity precludes the use of conventional amphotericin B. ■ Treatment of visceral leishmaniasis. ■ Treatment of cryptococcal meningitis in HIV-infected patients.

GENERIC (CONVENTIONAL): Treatment of fungal infections that are progressive and potentially fatal, such as aspergillosis, cryptococcosis, blastomycosis, and disseminated forms of candidiasis, coccidioidomycosis, and histoplasmosis, mucormycosis, and sporotrichosis. These infections must be caused by specific organisms. Not recommended for treatment of noninvasive forms of fungal disease in patients with normal neutrophil counts.

Unlabeled uses: AmBisome has been used to prevent fungal infections in bone marrow transplant patients.

CONTRAINDICATIONS

All amphotericin formulations: Known sensitivity to amphotericin B or any components of its formulations unless a life-threatening situation is present.

PRECAUTIONS

ALL AMPHOTERICIN FORMULATIONS: Diagnosis should be positively established by culture or histologic study. ■ Close clinical observation is imperative. Anaphylaxis has occurred; emergency equipment and supplies must be available. ■ Infusion reactions are common and usually occur 1 to 3 hours after the start of the infusion. Frequency and severity of reactions generally diminish with subsequent doses. Pretreatment with antipyretics, antihistamines (e.g., diphenhydramine [Benadryl]), and/or selective use of corticosteroids may be indicated. ■ Use caution in patients receiving leukocyte transfusions; may cause acute pulmonary toxicity. Separate times of administration as much as possible. ■ Neph-

rotoxicity is the usual dose-limiting factor for use of conventional amphotericin B. Impairment may improve with dose reduction or alternate-day therapy, but some residual dysfunction is possible. Lipid-based formulations are associated with less nephrotoxicity. Most studies show equivalent or superior effectiveness compared with conventional amphotericin. Introduction of lipid-based products to patients with increased CrCl and BUN from conventional amphotericin has decreased the CrCl and BUN.

ABELCET: Renal toxicity is dose dependent but has been consistently less nephrotoxic than conventional amphotericin B.

AMPHOTEC/AMBISOME: Incidence of renal toxicity significantly lower than with conventional amphotericin B.

GENERIC (CONVENTIONAL): Should be used primarily for treatment of patients with progressive and potentially life-threatening fungal infections. It should not be used to treat non-invasive forms of fungal disease such as oral thrush, vaginal candidiasis, and esophageal candidiasis in patients with normal neutrophil counts. ■ To prevent overdose, verify product name and dose, especially if dose exceeds 1.5 mg/kg. ■ Therapy is often initiated in infusion centers. ■ A small amount of heparin added to the infusion may reduce the incidence of thrombophlebitis. ■ Meperidine (Demerol), nonsteroidal anti-inflammatory agents (e.g., ibuprofen), or hydrocortisone before administration may prevent febrile reactions, including chills; corticosteroids not recommended for concomitant use in other situations because they exaggerate hypokalemia. ■ Prophylactic antiemetics and antihistamines are also appropriate.

Monitor: All amphotericin formulations: Obtain baseline CBC, PT, serum electrolytes, renal (e.g., creatine kinase, BUN, SCr) and liver function (e.g., ALT, AST) tests. Repeat frequently during therapy; recommended weekly. Monitor PT as indicated during therapy. ■ Discontinue or reduce dose until renal function improves if increase in BUN or SCr is clinically significant. Side effects (e.g., hypokalemia, hypomagnesemia, impaired renal function) may be life threatening. ■ Monitor vital signs and I&O. Record every 30 minutes for up to 4 hours after infusion is complete. ■ Monitor for S/S of hypersensitivity or infusion reactions (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Encourage fluids to maintain hydration.

Patient Education: All amphotericin formulations: Review all medical conditions and medications before beginning treatment. ■ Discomfort associated with infusion. ■ Promptly report S/S of an acute reaction (e.g., anorexia, chills, fever, headache, hypotension, nausea or vomiting, shortness of breath). ■ Long-term therapy required to effect a cure. ■ Report diarrhea, fever, increased or decreased urination, loss of appetite, stomach pain, sore throat, and any unusual bleeding or bruising, tiredness, or weakness. ■ Maintain adequate hydration.

Maternal/Child: All amphotericin formulations: Category B: has been used successfully during pregnancy but adequate studies not available. Use only if clearly needed. ■ Safety for use in breast-feeding and pediatric patients not established. Discontinue nursing. ■ Conventional amphotericin B has been used in pediatric patients. Lipid-based preparations have been used in pediatric patients without any unexpected side effects. Safety of use of AmBisome in infants under 1 month of age not established.

Elderly: Consider age-related impaired body functions. Lipid-based preparations have been used without unexpected side effects.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been done for lipid-based preparations, but interactions similar to conventional amphotericin B are expected. ■ **Corticosteroids** will increase hypokalemia and may cause arrhythmias. Use with caution only if indicated to control drug reactions or, if necessary, monitor serum electrolytes and cardiac function closely. ■ Hypokalemic effect may be increased with **thiazides**, may potentiate **digoxin** toxicity, and/or may enhance the curariform effect of **neuromuscular blocking agents** (e.g., rocuronium [Zemuron], succinylcholine); monitor serum potassium levels. ■ Avoid use

or use extreme caution with other **nephrotoxic drugs** (e.g., **aminoglycosides** [e.g., gentamicin, tobramycin], **selected antibiotics** [e.g., vancomycin], **anesthetics** [e.g., methoxyflurane]), **antituberculars** [e.g., capreomycin (Capestat)], **diuretics** [e.g., furosemide (Lasix), torsemide (Demadex)], **pentamidine**). Nephrotoxic effects are additive. Frequent monitoring of renal function indicated if any other nephrotoxic drug must be used. ■ Nephrotoxicity and myelotoxicity are both increased when given concurrently with **zidovudine** (AZT, Retrovir). ■ Potentiates nephrotoxicity of **cyclosporine**; alternate immunosuppressive therapy recommended. ■ Concurrent use with **antineoplastic agents** (e.g., cisplatin, methotrexate) **or radiation therapy** may increase renal toxicity and incidence of bronchospasm and hypotension. ■ Enhances antifungal effects of **flucytosine** (Ancobon) **and other anti-infectives**. May increase toxicity. ■ Antagonism between amphotericin B and **imidazole antifungals** (e.g., ketoconazole, miconazole, fluconazole) has been reported. ■ Acute pulmonary toxicity occurred in patients receiving **leukocyte transfusion**; separate administration times as much as possible. ■ **False elevations of serum phosphate** may occur if patient samples are analyzed using the PHOSm assay.

SIDE EFFECTS

LIPID-BASED PREPARATIONS: Most side effects similar to conventional amphotericin B but occur with less frequency and intensity. Acute reactions, including fever and chills, may occur within 1 to 3 hours of starting the infusion. Infusion-related cardiorespiratory reactions may include dyspnea, hypertension, hyperventilation, hypotension, hypoxia, tachycardia, and vasodilation. Arrhythmia, bronchospasm, and shock can occur. Anaphylaxis and cardiac arrest from overdose have been reported.

GENERIC (CONVENTIONAL): Common even at doses below therapeutic; may begin to occur within 15 to 20 minutes: anorexia, chills, convulsions, diarrhea, fever, headache, phlebitis, vomiting. Anaphylactoid reactions, anemia, cardiac disturbances (including fibrillation and arrest), coagulation defects, hypertension, hypokalemia, hypotension, and numerous other side effects occur fairly frequently. Renal function impaired in 80% of patients. May reverse after treatment ends, but some permanent damage likely.

Post-Marketing: AmBisome: Agranulocytosis, angioedema, bronchospasm, cyanosis/hypoventilation, edema, erythema, hemorrhagic cystitis, pulmonary edema, rhabdomyolysis.

ANTIDOTE

ALL AMPHOTERICIN FORMULATIONS: Notify the physician of all side effects. Many are reversible if the drug is discontinued. Some will respond to symptomatic treatment. Acute reactions (e.g., fever, chills, hypotension, nausea, and vomiting) usually lessen with subsequent doses. These acute infusion-related reactions can be managed by pretreatment with antipyretics, antihistamines, and/or corticosteroids or reduction of the rate of infusion and prompt treatment with antihistamines and/or corticosteroids and meperidine (Demerol) for chills. If anaphylaxis or serious respiratory distress occurs, discontinue amphotericin and treat as necessary. Give no further infusions. Hemodialysis not effective in overdose. Discontinue if BUN and alkaline phosphatase are abnormal. Dantrolene has been used to prevent (50 mg PO) or treat (50 mg IV) severe, shaking chills.

GENERIC (CONVENTIONAL): Administration of conventional amphotericin B on alternate days may decrease the incidence of some side effects. Urinary alkalizers may minimize renal tubular acidosis.

ABELCET/AMPHOTEC: Overdose has caused cardiac arrest. Discontinue drug and treat symptomatically.

AMPICILLIN SODIUM

(am-pih-SILL-in SO-dee-um)

Antibacterial
(penicillin)

pH 8 to 10

USUAL DOSE

Range is from 1 to 12 Gm/24 hr for adults and pediatric patients weighing 20 kg or more. Larger doses may be indicated based on the seriousness of the infection. Some clinicians suggest a weight of 40 kg to receive adult dose range.

Respiratory tract or skin and skin structure infections: 250 to 500 mg every 6 hours.

GI or GU infections: 500 mg every 6 hours.

Septicemia or bacterial meningitis: 8 to 14 Gm or 150 to 200 mg/kg/24 hr in equally divided doses every 3 to 4 hours (18.75 to 25 mg/kg every 3 hours or 25 to 33.3 mg/kg every 4 hours). Administer IV a minimum of 3 days; then may be given IV or IM.

Treatment of gonorrhea: 500 mg. Repeat in 8 to 12 hours. May repeat 2-dose regimen IV or IM if indicated. Ceftriaxone (Rocephin) IV or IM is most commonly used.

Listeriosis: 50 mg/kg every 6 hours.

Prevention of bacterial endocarditis in dental or respiratory tract surgery or instrumentation: 2 Gm of ampicillin 30 minutes before procedure.

Prevention of bacterial endocarditis in GI, GU, or biliary tract surgery or instrumentation: *Low to moderate risk:* A single dose of 2 Gm of ampicillin 30 minutes before procedure. *Moderate to high risk:* 2 Gm of ampicillin in conjunction with gentamicin 1.5 mg/kg (up to 80 mg) 30 minutes before procedure. Repeat 1 Gm of ampicillin or give oral amoxicillin 1 Gm in 6 hours.

Prophylaxis in high-risk cesarean section patients: 1 to 2 Gm immediately after clamping cord.

Prophylaxis of neonatal group B *Streptococcal* disease: 2 Gm to the mother during labor. Should be given at least 4 hours before delivery to ensure amniotic fluid concentrations and placental transfer of ampicillin. May repeat 1 to 2 Gm every 4 to 6 hours until delivery. Continue treatment postpartum if active signs of maternal infection develop. Routine use of prophylaxis in neonates born to these mothers is not recommended; risk must be assessed on an individual basis for each infant.

Leptospirosis (unlabeled): 500 mg to 1 Gm every 6 hours.

Typhoid fever (unlabeled): 25 mg/kg every 6 hours.

PEDIATRIC DOSE

Range is from 25 to 400 mg/kg of body weight/24 hr for pediatric patients weighing less than 20 kg. Some clinicians suggest a weight up to 40 kg is appropriate for pediatric use. Do not exceed adult dose or 12 Gm.

Respiratory tract or skin and skin structure infections: 25 to 50 mg/kg/24 hr in equally divided doses every 4 to 6 hours (4.16 to 8.3 mg/kg every 4 hours or 6.25 to 12.5 mg/kg every 6 hours).

GI or GU infections: 50 to 100 mg/kg/24 hr in equally divided doses every 6 hours (12.5 to 25 mg/kg every 6 hours).

Septicemia or bacterial meningitis: 100 to 200 mg/kg/24 hr in equally divided doses every 3 to 4 hours (12.5 to 25 mg/kg every 3 hours or 16.6 to 33.3 mg/kg every 4 hours).

Empiric treatment of bacterial meningitis in infants and children 2 months to 12 years of age: Some clinicians recommend 200 to 400 mg/kg/24 hr in equally divided doses every 4 to 6 hours (33.3 to 66.6 mg/kg every 4 hours to 50 to 100 mg/kg every 6 hours). Given in conjunction with chloramphenicol. Satisfactory response should occur within 48 hours or initiate alternate therapy. Administer any regimen IV a minimum of 3 days, then may be given IV or IM.

Prevention of bacterial endocarditis in dental or respiratory tract surgery or instrumentation: 50 mg/kg of ampicillin 30 minutes before procedure.

Prevention of bacterial endocarditis in GI, GU, or biliary tract surgery or instrumentation: *Low to moderate risk:* A single dose of 50 mg/kg 30 minutes before procedure. *Moderate to high risk:* 50 mg/kg of ampicillin in conjunction with gentamicin 1.5 mg/kg (up to 80 mg) 30 minutes before procedure. Repeat 25 mg/kg of ampicillin or oral amoxicillin in 6 hours.

NEONATAL DOSE

Age up to 7 days: *Weight less than 2,000 Gm:* 25 mg/kg every 12 hours. *2,000 Gm or more:* 25 mg/kg every 8 hours.

Over 7 days of age: *Weight less than 1,200 Gm:* 25 mg/kg every 12 hours. *1,200 to 2,000 Gm:* 25 mg/kg every 8 hours. *More than 2,000 Gm:* 25 mg/kg every 6 hours.

Empiric treatment of bacterial meningitis in neonates and infants less than 2 months of age: 100 to 300 mg/kg/24 hr in equally divided doses (e.g., 33.3 to 100 mg/kg every 8 hours) in conjunction with IM gentamicin. Administer any regimen IV a minimum of 3 days, then may be given IV or IM.

Bacterial meningitis in neonates and infants less than 2 months of age:

Age up to 7 days: *Weight less than 2,000 Gm:* 50 to 75 mg/kg every 12 hours.

2,000 Gm or more: 50 to 75 mg/kg every 8 hours.

Over 7 days of age: *Weight less than 2,000 Gm:* 50 mg/kg every 8 hours.

2,000 Gm or more: 50 mg/kg every 6 hours.

DOSE ADJUSTMENTS

Patients with a CrCl of 10 to 50 mL/min may require the usual dose every 6 to 12 hours. Reduce dose by increasing interval to 12 to 24 hours in severe renal impairment (CrCl less than 10 mL/min). Another source suggests no dose adjustment with a CrCl of 30 mL/min or greater and dosing every 8 hours for a CrCl of 10 mL/min or less. Administer 250 mg every 12 hours to peritoneal dialysis patients. Hemodialysis patients should receive 1 to 2 Gm after dialysis on dialysis days.

DILUTION

Each 500 mg or fraction thereof must be reconstituted with at least 5 mL of SWFI. Use within 1 hour of reconstitution. May be further diluted in 50 mL or more of selected IV solutions. Stable for 8 hours at concentrations up to 30 mg/mL in NS, LR, sodium lactate, or SWFI. Stable in D5 $\frac{1}{2}$ NS or 10% invert sugar in water for 4 hours at concentrations up to 2 mg/mL. Stable in D5W for 4 hours at concentrations up to 2 mg/mL but only for 2 hours at concentrations up to 20 mg/mL. Must be administered before stability expires.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Inactivated in solution with aminoglycosides (e.g., amikacin [Amikin], gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

Additive: Aztreonam (Azactam), cefepime (Maxipime), clindamycin (Cleocin), erythromycin (Erythrocin), furosemide (Lasix), heparin, hydrocortisone sodium succinate (Solu-Cortef), lincomycin (Lincocin), metronidazole (Flagyl IV), ranitidine (Zantac), verapamil.

Y-site: Acyclovir (Zovirax), alprostadiol, amifostine (Ethyol), amidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), calcium gluconate, cisatracurium (Nimbex), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doxapram (Dopram), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), famotidine (Pepcid IV), filgrastim (Neupogen), fludarabine (Fludara), foscarnet (Foscavir), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hetastarch in NS (Hespan), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), insulin (regular), labetalol, levofloxacin (Levaquin), linezolid (Zyvox), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), milrinone (Primacor), morphine, multivitamins (M.V.I.), pantoprazole (Protonix IV), pemetrexed (Alimta), phytonadione (vitamin K₁), potassium chloride (KCl), propo-

fol (Diprivan), remifentanil (Ultiva), tacrolimus (Prograf), teniposide (Vumon), theophylline, thiotepa, vancomycin.

RATE OF ADMINISTRATION

A single dose over 10 to 15 minutes when given by IV injection. In 100 mL or more of solution, administer at prescribed infusion rate but never exceed IV injection rate. Too-rapid injection may cause seizures.

ACTIONS

A semisynthetic penicillin. Bactericidal against many gram-positive and some gram-negative organisms. Appears in all body fluids. Appears in cerebrospinal fluid only if inflammation is present. Crosses the placental barrier. Excreted in urine. Secreted in breast milk.

INDICATIONS AND USES

Highly effective against severe infections caused by gram-positive and some gram-negative organisms (e.g., respiratory tract, skin and skin structure, GI and GU, bacterial meningitis, endocarditis, listeriosis, septicemia). Not effective with penicillinase-producing staphylococci. ■ Prevention of bacterial endocarditis in dental and respiratory tract surgery or instrumentation. ■ Prevention of bacterial endocarditis in GI, GU, or biliary surgery or instrumentation. Used concurrently with gentamicin. ■ Drug of choice during labor for prevention of neonatal group B streptococcal infections.

Unlabeled uses: Prophylaxis in high-risk cesarean section patients. Treatment of leptospirosis. Treatment of typhoid fever.

CONTRAINDICATIONS

Known penicillin or cephalosporin sensitivity (not absolute); see [Precautions](#). Infectious mononucleosis because of increased incidence of rash.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients undergoing penicillin therapy; most likely to occur in patients with a history of penicillin allergy or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to ampicillin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ampicillin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Avoid prolonged use of this drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ampicillin. ■ Side effects increased in some patients; see [Side Effects](#).

Monitor: Watch for early symptoms of hypersensitivity reactions, especially in individuals with a history of allergic problems. ■ AST may be increased. Renal, hepatic, and hematopoietic function should be checked during prolonged therapy. ■ May cause thrombophlebitis; observe carefully and rotate infusion sites.

Patient Education: May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: use only if clearly needed. ■ May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Elimination rate markedly reduced in neonates.

Elderly: Consider degree of age-related impaired renal function.

DRUG/LAB INTERACTIONS

Streptomycin potentiates bactericidal activity against enterococci. ■ May be used concurrently with **aminoglycosides** (e.g., gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer at separate

sites. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, and tetracyclines); may interfere with bactericidal action. ■ Concomitant use with **beta-adrenergic blockers** (e.g., propranolol) may increase risk of anaphylaxis and inhibit treatment. ■ Potentiated by **probenecid** (Benemid); toxicity may result. ■ Increased risk of bleeding with **heparin**. ■ May decrease clearance and increase toxicity of **methotrexate**. ■ Decreases effectiveness of **oral contraceptives**; breakthrough bleeding or pregnancy could result. ■ Ampicillin-induced skin rash potentiated by **allopurinol** (Alloprim). ■ False-positive glucose reaction with **Clinitest and Benedict's or Fehling's solution**. ■ May cause **false values** in other lab tests; see literature.

SIDE EFFECTS

Primarily hypersensitivity reactions such as anaphylaxis, exfoliative dermatitis, rashes, and urticaria. May cause CDAD. Hypersensitivity myocarditis can occur (fever, eosinophilia, rash, sinus tachycardia, ST-T changes, and cardiomegaly). Anemia, leukopenia, and thrombocytopenia have been reported. Thrombophlebitis will occur with long-term use. Higher than normal doses may cause neurologic adverse reactions including convulsions, especially with impaired renal function. Incidence of side effects increased in patients with viral infections or those taking allopurinol (Alloprim).

ANTIDOTE

Notify the physician of any side effect. For severe symptoms, discontinue the drug, treat hypersensitivity reactions (antihistamines, epinephrine, corticosteroids), and resuscitate as necessary. Hemodialysis is effective in overdose. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated.

AMPICILLIN SODIUM AND SULBACTAM SODIUM

(am-pih-SILL-in SO-dee-um and sull-BACK-tam SO-dee-um)

Antibacterial
(penicillin and beta-lactamase inhibitor)

Unasyn

pH 8 to 10

USUAL DOSE

Adults and pediatric patients weighing 40 kg or more: 1.5 to 3 Gm every 6 hours (1 Gm ampicillin with 0.5 Gm sulbactam to 2 Gm ampicillin with 1 Gm sulbactam). All commercial preparations in the U.S. have a 2:1 ratio of ampicillin to sulbactam (e.g., 1.5 Gm = 1 Gm ampicillin plus 0.5 Gm sulbactam). Do not exceed 4 Gm **sulbactam**/24 hr. **All doses in this monograph include ampicillin and sulbactam within the recommended dose.**

PEDIATRIC DOSE

IV use for more than 14 days is not recommended. See comments under [Adult Dose](#).

Skin and skin structure infections in pediatric patients over 1 year of age and less than 40 kg: 300 mg/kg/day (200 mg/kg ampicillin and 100 mg/kg sulbactam) in equally divided doses as an infusion every 6 hours (75 mg/kg every 6 hours).

The American Academy of Pediatrics suggests use in pediatric patients over 1 month of age in the following doses.

Mild to moderate infections: 150 to 225 mg/kg/day (100 to 150 mg/kg of ampicillin and 50 to 75 mg/kg sulbactam) in equally divided doses as an infusion every 6 hours (37.5 to 56.5 mg/kg every 6 hours).

Severe infections: 300 to 450 mg/kg/day (200 to 300 mg/kg of ampicillin and 100 to 150 mg/kg of sulbactam) in equally divided doses as an infusion every 6 hours (75 mg/kg to 112.5 mg/kg every 6 hours).

DOSE ADJUSTMENTS

May be indicated in the elderly. ■ Reduce total daily dose in impaired renal function according to the following chart.

Ampicillin/Sulbactam Dose Guidelines in Impaired Renal Function	
Creatinine Clearance (mL/min per 1.73 M ²)	Dose/Frequency
30 mL/min or more	Usual recommended dose q 6 to 8 hr
15 to 29 mL/min	Usual recommended dose q 12 hr
5 to 14 mL/min	Usual recommended dose q 24 hr
Hemodialysis patients*	Usual recommended dose q 24 hr On day of dialysis, give immediately after dialysis

*One source recommends 1.5 to 3 Gm every 12 to 24 hours for hemodialysis patients, given after dialysis on dialysis days. A dose of 3 Gm/24 hr has been recommended for peritoneal dialysis patients.

DILUTION

Each 1.5 Gm or fraction thereof must be initially reconstituted with 4 mL of SWFI (375 mg/mL). Allow to stand to dissipate foaming. Solution should be clear. Must be further diluted to a final concentration of 3 to 45 mg/mL in one of the following solutions and given by slow IV injection or as an intermittent IV infusion: D5W, D5¹/₂NS, 10% invert sugar in water, LR, 1/6 M sodium lactate solution, or NS. 3 Gm/L equals 3 mg/mL, 3 Gm/125 mL equals 24 mg/mL. Also available in piggyback vials and ADD-Vantage vials for use with ADD-Vantage infusion containers.

Storage: Store at CRT before dilution. Stable in all specifically listed solutions in any dilution for at least 2 hours. Stability in each solution varies (see literature).

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

May be inactivated in solution with aminoglycosides (e.g., amikacin [Amikin], gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. See [Drug/Lab Interactions](#).

One source suggests the following **compatibilities**:

Additive: Aztreonam (Azactam).

Y-site: Amifostine (Ethyol), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), cisatracurium (Nimbex), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), enalaprilat (Vasotec IV), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), insulin (regular), linezolid (Zyvox), meperidine (Demerol), morphine, paclitaxel (Taxol), palonosetron (Al-oxi), pemetrexed (Alimta), remifentanyl (Ultiva), tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepa, vancomycin.

RATE OF ADMINISTRATION

IV injection: A single dose over a minimum of 10 to 15 minutes.

Intermittent IV: A single dose over 15 to 30 minutes or longer, depending on amount of solution. Too-rapid injection may cause seizures.

ACTIONS

A semisynthetic penicillin. The addition of sulbactam improves ampicillin's bactericidal activity against beta-lactamase-producing strains resistant to penicillins and cephalosporins. A broad-spectrum antibiotic and beta-lactamase inhibitor effective against selected gram-positive, gram-negative, and anaerobic organisms (see literature). Peak serum levels achieved by end of infusion. Appears in all body fluids. Half-life is 1 hour. Crosses the placental barrier. Excreted in the urine. Secreted in breast milk.

INDICATIONS AND USES

Treatment of skin and skin structure and intra-abdominal and gynecologic infections due to susceptible strains of specific organisms.

CONTRAINDICATIONS

Known penicillin, cephalosporin (not absolute [see [Precautions](#)]), or beta-lactamase inhibitor sensitivity (not absolute [see [Precautions](#)]); infectious mononucleosis because of increased incidence of rash.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients undergoing penicillin therapy; most likely to occur in patients with a history of penicillin allergy or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Studies indicated to determine the causative organism and susceptibility to ampicillin/sulbactam. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ampicillin and sulbactam should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Avoid prolonged use of this drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ampicillin and sulbactam.

Monitor: Watch for early symptoms of hypersensitivity reactions, especially in individuals with a history of allergic problems. ■ AST may be increased. Renal, hepatic, and hematopoietic function should be checked during prolonged therapy. ■ May cause thrombophlebitis. Observe carefully and rotate infusion sites.

Patient Education: Report promptly; fever, rash, sore throat, unusual bleeding or bruising, severe stomach cramps, and/or diarrhea, seizures. ■ May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: studies in rabbits have not shown adverse effects on fertility or in the fetus. Use only if clearly needed. ■ May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Safety for IV use in pediatric patients over 1 year of age has been established for skin and skin structure infections but not for other uses; however, it is in use. Elimination rate markedly reduced in neonates. ■ Safety and effectiveness of IM use in pediatric patients not established.

Elderly: Consider degree of age-related impaired renal function. ■ See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Concurrent use with probenecid may increase ampicillin and sulbactam blood levels. ■ Frequently used concomitantly with **aminoglycosides** (e.g., gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer at separate sites. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ May decrease clearance and increase toxicity of **methotrexate**. ■ Ampicillin-induced skin rash potentiated by **allopurinol** (Aloprim). ■ False-positive glucose reaction with **Clinitest and Benedict's or Fehling's solution**. ■ May cause **false values** in other lab tests; see literature.

SIDE EFFECTS

Full scope of hypersensitivity reactions, including anaphylaxis, are possible. Burning, discomfort, and pain at injection site; diarrhea, rash, and thrombophlebitis occur most frequently. Abdominal distention; candidiasis; chest pain; chills; decreased hemoglobin, hematocrit, RBC, WBC, lymphocytes, neutrophils, and platelets; decreased serum albumin and total protein; dysuria; edema; epistaxis; erythema; facial swelling; fatigue; flatulence; glossitis; headache; increased alkaline phosphatase, BUN, creatinine, LDH, AST, ALT; increased basophils, eosinophils, lymphocytes, monocytes, and platelets; itching, malaise, mucosal bleeding, nausea and vomiting, RBCs and hyaline casts in urine, substernal pain, tightness in throat, and urine retention can occur. May cause CDAD. Higher than normal doses may cause neurologic adverse reactions, including convulsions; especially with impaired renal function.

ANTIDOTE

Notify the physician of any side effect. For severe symptoms, discontinue the drug, treat hypersensitivity reactions as indicated (e.g., antihistamines, epinephrine, corticosteroids) and resuscitate as necessary. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis may be effective in overdose.

ANIDULAFUNGIN

(a-nid-yoo-luh-FUN-jin)

Antifungal
(Echinocandin)

Eraxis

USUAL DOSE

Candidemia and other Candida infections (intra-abdominal abscess and peritonitis): Begin with a **loading dose** of 200 mg as an infusion on Day 1. Follow with a daily dose of 100 mg as an infusion beginning on Day 2. Base duration of treatment on patient's clinical response. In general, antifungal therapy should continue for at least 14 days after the last positive culture.

Esophageal candidiasis: Begin with a **loading dose** of 100 mg as an infusion on Day 1. Follow with a daily dose of 50 mg as an infusion beginning on Day 2. Treat for a minimum of 14 days and for at least 7 days following resolution of symptoms. Relapse of esophageal candidiasis has occurred in patients with HIV infections; suppressive antifungal therapy may be considered after a course of treatment.

DOSE ADJUSTMENTS

No dose adjustment is indicated based on age, gender, or race; in patients with any degree of renal or hepatic insufficiency; or in patients using concomitant medications that are known metabolic substrates, inhibitors, or inducers of cytochrome P₄₅₀ (CYP450) isoenzymes; see [Drug/Lab Interactions](#). ■ No dose adjustment is required in patients with HIV who are receiving concomitant antiretroviral therapy (e.g., HIV protease inhibitors [e.g., amprenavir (Agenerase), indinavir (Crixivan), nelfinavir (Viracept), ritonavir (Norvir), saquinavir (Invirase)]).

DILUTION

Each 50-mg vial must be reconstituted with 15 mL of SWFI, and each 100-mg vial must be reconstituted with 30 mL of SWFI. The resulting concentration is 3.33 mg/mL. Aseptically transfer the reconstituted dose (50, 100, or 200 mg) into the appropriately sized IV container of D5W or NS for infusion as shown in the following chart. The final concentration of infusion solution is 0.77 mg/mL.

Dilution Requirements for Administration of Anidulafungin				
Dose (mg)	Number of Unit Packs Required	Total Reconstituted Volume (mL)	Volume of NS or D5W for Infusion	Total Infusion Volume (mL)
50 mg	1-50 mg	15 mL	50 mL	65 mL
100 mg	2-50 mg or 1-100 mg	30 mL	100 mL	130 mL
200 mg	4-50 mg or 2-100 mg	60 mL	200 mL	260 mL

Filters: No data available from manufacturer.

Storage: Store unopened vials at 2° to 8° C (36° to 46° F). Do not freeze. Excursions for 96 hours up to 25° C (77° F) are permitted, and the vial can be returned to storage at 2° to 8° C. Reconstituted solution can be stored at up to 25° C (77° F) for up to 24 hours. Infusion solution can be stored at temperatures up to 25° C for up to 48 hours or stored frozen for at least 72 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not mix or co-infuse with other medications or electrolytes. **Compatibility** of anidulafungin with intravenous substances, additives, or medications other than D5W or NS has not been established."

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), amikacin (Amikin), aminophylline, amphotericin B lipid complex (Abelcet), amphotericin liposomal (AmBisome), ampicillin, ampicillin/sulbactam (Unasyn), carboplatin (Paraplatin), cefazolin (Ancef), cefepime (Maxipime), cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), ciprofloxacin (Cipro IV), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytosan), cyclosporine (Sandimmune), cytarabine (ARA-C), daunorubicin (Cerubidine), dexamethasone (Decadron), digoxin (Lanoxin), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin (Adriamycin), epinephrine (Adrenalin), erythromycin (Erythrocin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fentanyl (Sublimaze), fluconazole (Diflucan), fluorouracil (5-FU), furosemide (Lasix), ganciclovir (Cytovene), gemcitabine (Gemzar), gentamicin, heparin, hydrocortisone sodium succinate (Solu-Cortef), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), levocovorin calcium, levofloxacin (Levaquin), linezolid (Zyvox), meperidine (Demerol), meropenem (Merrem IV), methylprednisolone (Solu-Medrol), metronidazole (Flagyl IV), midazolam (Versed), morphine, mycophenolate (CellCept IV), norepinephrine (Levophed), paclitaxel (Taxol), pantoprazole (Protonix IV), phenylephrine (Neo-Synephrine), piperacillin/tazobactam (Zosyn), potassium chloride, quinupristin/dalfopristin (Synercid), ranitidine (Zantac), sulfamethoxazole/trimethoprim, tacrolimus (Prograf), ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vincristine, voriconazole (VFEND IV), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Flush IV line with D5W or NS before and after infusion.

Do not exceed an infusion rate of 1.1 mg/min (equivalent to 1.4 mL/min or 84 mL/hr when diluted as directed). Infusion at a rate greater than 1.1 mg/min may cause histamine-mediated reactions (e.g., bronchospasm, dyspnea, flushing, hypotension, pruritus, rash, urticaria).

ACTIONS

A semi-synthetic lipopeptide, anidulafungin is an echinocandin, the newest class of antifungal agents. Acts by inhibiting the synthesis of 1,3-beta-D-glucan, an integral component of the fungal cell wall not present in mammalian cells. Extensively protein bound. Steady state is achieved after a loading dose. Not metabolized, it undergoes slow chemical degradation. Hepatic metabolism has not been observed. Anidulafungin is not a clinically relevant substrate, inducer, or inhibitor of cytochrome P₄₅₀ (CYP450) isoenzymes. Terminal half-life ranges from 40 to 50 hours. Some excretion in feces, with minimal excretion in urine.

INDICATIONS AND USES

Treatment of the following fungal infections: candidemia and other forms of *Candida* infections (intra-abdominal abscess and peritonitis) and esophageal candidiasis.

Limitation of use: Has not been studied in *Candida* infections associated with endocarditis, osteomyelitis, and meningitis. ■ Has not been studied in sufficient numbers of neutropenic patients to determine effectiveness.

CONTRAINDICATIONS

Hypersensitivity to anidulafungin or any of its components (e.g., fructose, mannitol, polysorbate 80, tartaric acid, sodium hydroxide, and/or hydrochloric acid); or other echinocandins (e.g., micafungin [Mycamine]).

PRECAUTIONS

Do not give as an IV bolus; for IV infusion only. ■ Abnormal liver function tests have been reported. Isolated cases of significant hepatic dysfunction, hepatitis, or worsening hepatic failure have occurred. Incidence may be increased in patients with serious underlying conditions who are receiving additional concomitant medications. Evaluate risk versus benefit of continued anidulafungin therapy. ■ During studies, endoscopically documented relapse rates were higher in patients treated for esophageal candidiasis with anidulafungin than in patients treated with fluconazole (Diflucan). ■ *Candida* isolates with reduced susceptibility to anidulafungin have been reported, which suggests a poten-

tial for development of drug resistance. Clinical significance unknown. Cross-resistance with other echinocandins (e.g., micafungin [Mycamine]) have not been studied. ■ Has been shown to be active against *Candida albicans* resistant to fluconazole (Diflucan). ■ See **Monitor** and **Antidote**.

Monitor: Specimens for fungal culture, serologic testing, and histopathologic testing should be obtained before therapy to isolate and identify causative organisms. Therapy may begin as soon as all specimens are obtained and before results are known. Reassess after test results are known. ■ Baseline CBC with differential and platelet count, BUN, and liver function tests (e.g., ALT, AST) may be indicated. ■ Monitor for evidence of impaired hepatic function (e.g., increased ALT, AST, serum alkaline phosphatase). ■ Monitor for S/S of infusion-related, possibly histamine-related, adverse reactions (e.g., bronchospasm, dyspnea, flushing, hypotension, pruritus, rash, urticaria). ■ Anaphylaxis, including shock, has been reported. Monitor for S/S of a hypersensitivity reaction (e.g., bronchospasm, dyspnea, hives, hypotension, pruritus, rash, swelling of eyelids, lips, or face); discontinue infusion if a hypersensitivity reaction occurs.

Patient Education: Promptly report any hypersensitivity or infusion-related reactions (e.g., bronchospasm, dyspnea, dizziness, flushing, itching, rash, urticaria). Report S/S of liver dysfunction (anorexia, fatigue, jaundice, nausea and vomiting, dark urine, or pale stools).

Maternal/Child: Category B: use during pregnancy only if benefits justify risk to fetus. Some abnormalities, including skeletal changes, occurred in animal studies. ■ Use caution if required during breast-feeding. Secreted in milk of drug-treated rats; not known if anidulafungin is secreted in human milk. ■ Safety and effectiveness for use in pediatric patients 16 years of age or younger has not been established; however, some immunocompromised pediatric (2 through 11 years) and adolescent (12 through 17 years) patients with neutropenia were included in studies; see prescribing information.

Elderly: Differences in response compared to younger adults not identified.

DRUG/LAB INTERACTIONS

Anidulafungin is not a clinically relevant substrate, inducer, or inhibitor of cytochrome P₄₅₀ (CYP450) isoenzymes. It is considered unlikely that it will have a clinically relevant effect on the metabolism of drugs metabolized by CYP450 isoenzymes and/or other drugs likely to be coadministered with it. ■ No dose adjustment of either drug is indicated when coadministered with **cyclosporine** (Sandimmune), **tacrolimus** (Prograf), or **voriconazole** (VFEND IV). ■ No dose adjustment of anidulafungin is indicated when it is coadministered with **liposomal amphotericin B** (AmBisome) or **rifampin** (Rifadin).

SIDE EFFECTS

Patients treated for candidemia and other *Candida* infections: Deep vein thrombosis; diarrhea; elevated ALT, AST, alkaline phosphatase, and hepatic enzymes; and hypokalemia, fever, insomnia, nausea, vomiting.

Patients treated for esophageal candidiasis: Anemia; diarrhea; dyspepsia (aggravated); elevated ALT, AST, and gamma-glutamyl transferase; fever; headache; leukopenia; nausea; neutropenia; phlebitis; rash; and vomiting.

Histamine-mediated reactions (e.g., bronchospasm, dyspnea, flushing, hypotension, pruritus, rash, urticaria) or hypersensitivity reactions (including anaphylaxis) may occur. Significant hepatic dysfunction (e.g., hepatitis, hepatocellular damage, hyperbilirubinemia, or hepatic failure) has occurred. Many other side effects have been reported in small numbers of patients.

Post-Marketing: Anaphylactic reaction, anaphylactic shock, bronchospasm.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Reduce rate of infusion if a histamine-mediated reaction occurs. If a hypersensitivity reaction occurs, discontinue anidulafungin and treat as indicated. Appropriate treatment may include oxygen, epinephrine, antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, IV fluids, and ventilation equipment. S/S indicative of hepatic side effects may require evaluation of benefits versus risk of continuing anidulafungin therapy. Not removed by hemodialysis. Resuscitate as indicated.

ANTHEMOPHILIC FACTOR (HUMAN OR RECOMBINANT)

Antihemorrhagic

(an-tie-hee-moe-FIL-ik FAK-tor)

Advate, AHF, Factor VIII, Helixate FS, Hemofil M, Koate DVI, Kogenate FS, Monarc-M, Monoclate-P, Recombinate, ReFacto, Xyntha

Available factor VIII products and their origins include the following:

Advate, Helixate FS, Kogenate FS, ReFacto, Xyntha: Recombinant, stabilized without human albumin. Advate is formulated with trehalose; Helixate FS, Kogenate FS, ReFacto, and Xyntha are formulated with sucrose (amount of sucrose should not affect blood glucose concentrations).

Recombine: Recombinant, stabilized in human albumin.

Alphanate and Humate P (see AHF and von Willebrand Factor Complex), Koate DVI: From human plasma, intermediate and high purity.

Hemofil M, Monarc-M, Monoclate-P: From human plasma, immunoaffinity purified (ultra-high purity).

USUAL DOSE

(International units [IU])

Adults and pediatric patients: Completely individualized. Based on degree of deficiency, desired antihemophilic factor level, body weight, severity of bleeding, and presence of factor VIII inhibitors. Identify factor VIII deficiency and level assays before administration. One International unit (IU) is approximately equal to the level of factor VIII activity in 1 mL of fresh pooled human plasma. Recombinant products may be substituted for plasma-derived products without disrupting treatment regimen. A plasma antihemophilic factor level of about 30% of normal is needed for effective hemostasis when hemorrhage is present; greater percentages are required for surgical procedures, and only 5% to 10% of normal may be needed to control hemarthrosis. Each preparation suggests a different formula; end results are similar. An example is:

$$\begin{aligned} \text{AHF/IU required} &= \\ \text{Body weight (kg)} \times \text{Desired factor VIII increase (\% of normal)} \times 0.5 &= \\ \text{Expected factor VIII increase (\% of normal)} &= \\ \text{AHF/IU/kg dose administered} \times 2 &= \end{aligned}$$

Examples of doses are as follows:

Prophylactic management: (e.g., severe factor VIII deficiency with frequent hemorrhages). Raise factor VIII level to 15% of normal. Repeat every 1 to 2 days. Usually requires 250 units daily in patients weighing less than 50 kg, 500 units daily in patients weighing more than 50 kg. Increase dose until bleeding episodes are adequately controlled.

Early hemarthrosis (blood into a joint or its synovial cavity), muscle bleed, or oral bleed: Raise factor VIII level to 20% to 40%. Usually requires 5 to 10 units/kg initially. Repeat infusion every 12 to 24 hours for 1 to 3 days until the bleeding episode as indicated by pain is resolved or healing is achieved. If early hemarthrosis is treated promptly, lowest doses may be adequate.

More extensive hemarthrosis, muscle bleed, or hematoma: Raise factor VIII level to 30% to 60%. Usually requires 10 to 25 units/kg initially. Adjust dose based on circulating AHF levels and repeat infusion every 8 or 12 to 24 hours for 3 days or more until pain and disability are resolved.

Life-threatening bleeds (e.g., head injury, throat bleed, severe abdominal pain): Raise factor VIII level to 60% to 100%. Usually requires 40 to 50 units/kg initially. Adjust dose based on circulating AHF levels and repeat infusion every 8 to 24 hours until threat is resolved.

Minor surgery, including tooth extraction: Raise factor VIII level to 60% to 80% (**Advate** 60% to 100%, **Xyntha** 30% to 60%). Usually requires 25 to 40 units/kg. A single infusion plus oral antifibrinolytic therapy within 1 hour is sufficient in 70% of patients. Additional dosing every 12 to 24 hours may be needed to control bleeding.

Major surgery: Raise factor VIII level to 80% to 100% (**Advate** 80% to 120%, **Xyntha** 60% to 100%). Usually requires 45 to 50 units/kg initially. Repeat infusion every 8 to 24 hours depending on state of healing. Reduce dose as indicated by state of healing. Increase dose if level falls below 30%.

Maintenance doses: Vary slightly with specific products; see literature.

DOSE ADJUSTMENTS

If AHF does not significantly improve the PTT, factor VIII antibodies are probable; may respond to an increased dose, especially if titer is less than 10 Bethesda units/mL. Frequent determinations of circulating AHF levels indicated.

DILUTION

Consult individual product instructions in the package insert; each product has a specific process for dilution. Information may be updated frequently. All preparations provide diluent and usually provide administration equipment, including needles (single- or double-ended), filters or filter needles, syringes, and/or administration sets for each vial. Actual number of AHF units shown on each vial. Use only the diluent provided, and maintain strict aseptic technique. Use a plastic syringe to prevent binding to glass surfaces. Warm to room temperature (25° C) before dilution and maintain throughout administration to avoid precipitation of active ingredients.

Filters: Supplied by manufacturer. If more than one bottle is required for a dose, multiple bottles may be drawn into the same syringe; however, a new filter needle must be used to withdraw contents of each bottle of antihemophilic factor.

Storage: Before reconstitution, store all formulations at 2° to 8° C (35° to 46° F). Do not freeze. Most formulations can be stored at CRT not to exceed 25° C (77° F) for 2 months or more before reconstitution; check individual product. Protect Xyntha from light during storage. Do not use beyond expiration dates on bottles.

COMPATIBILITY

Administration through a separate line without mixing with other IV fluids or medications is recommended. If antihemophilic factor is given as a continuous IV, one source says heparin 1 to 5 units/mL of concentrate may be added to avoid thrombophlebitis.

RATE OF ADMINISTRATION

Reduce rate of infusion or temporarily discontinue if there is a significant increase in pulse rate or S/S of hypersensitivity occur. Rate is based on patient comfort.

Most preparations suggest beginning with a rate of 2 mL/min and increasing gradually up to 10 mL/min if appropriate. Administration of a single dose in 5 to 10 minutes is generally well tolerated. Consult product information. Other sources list the following information:

Advate: A single dose over 5 minutes or less. Do not exceed a rate of 10 mL/min.

Hemofil M, Monarc-M, and Recombinate: May be given at a rate not to exceed 10 mL/min.

Helixate FS, Kogenate FS, ReFacto: A single dose over 5 to 10 minutes is usually well tolerated. Do not exceed a rate of 10 mL/min.

Monoclate-P: Begin with a rate of 2 mL/min. Do not exceed 4 mL/min.

Xyntha: A single dose over several minutes, based on patient comfort.

ACTIONS

AHF is one of nine major factors in the blood that must act in sequence to produce coagulation, or clotting. It is the specific clotting factor deficient in patients with hemophilia A (classic hemophilia) and can temporarily correct the coagulation defect in these patients. Has a half-life of 10 to 18 hours. One IU of AHF increases the plasma concentration of factor VIII by 2%. **Plasma-based AHF:** A lyophilized concentrate of coagulation factor VIII (antihemophilic factor) prepared by various processes (e.g., heat treatment, chemical inactivation, solvent detergent treatment, immunoaffinity chromatography). Obtained from fresh (less than 3 hours old) human plasma cryoprecipitate. Tested and

determined free from hepatitis and HIV viruses and containing acceptable ALT concentrations. **Recombinant AHF:** Produced through genetic engineering technology. Purified using monoclonal antibody purification techniques, ion exchange chromatography, and immunoaffinity chromatography. Risk of viral transmission eliminated because it is not derived from human blood.

INDICATIONS AND USES

Control or prevent bleeding episodes and for perioperative management in patients with hemophilia A. (Congenital factor VIII deficiency of classic hemophilia.) Advate is considered to be of therapeutic value in patients with factor VIII inhibitors not exceeding 10 Bethesda units. ReFacto is recommended for short-term routine prophylaxis.

Unlabeled uses: Adjunct in the treatment of disseminated intravascular coagulation (DIC).

CONTRAINDICATIONS

Hypersensitivity to a specific component of a product (e.g., mouse, hamster, or bovine protein [monoclonal-antibody–derived factor VIII], various stabilizers) or a previous life-threatening hypersensitivity reaction, including anaphylaxis, to a specific product. Not effective for bleeding in patients with von Willebrand's disease.

PRECAUTIONS

Should be administered under the direction of the physician specialist. ■ Treatment of choice when volume or RBC replacement is not needed; avoids hypervolemia and hyperproteinemia. ■ Desmopressin is preferred treatment in mild to moderate hemophilia A. ■ Hepatitis B vaccination indicated in all patients with hemophilia; usually done at birth or time of diagnosis. ■ Risk of transmitting hepatitis or HIV is markedly reduced with newer plasma-based products. There are no reported instances of new seroconversions to HIV with currently marketed products. ■ No risk of any viral transmission (hepatitis or HIV) with recombinant products. ■ Intravascular hemolysis can occur when large volumes are given to individuals with blood groups A, B, or AB. Monitor for progressive anemia. ■ Type-specific cryoprecipitate has been used to maintain adequate factor VIII levels and is appropriate in selected cases; carries risk of possible delayed seroconversion after viral infection (HIV, hepatitis A, B, or C). ■ Inhibitor titers above 10 Bethesda units/mL may make hemostatic control with AHF impossible or impractical because of the large dose required. Inhibitor titer may rise after AHF infusion due to an anamnestic (immunologic memory) response to the AHF antigen. Use of an alternate product may be indicated (e.g., factor IX complex concentrates, anti-inhibitor coagulant complex). ■ Not useful to treat other coagulation factor deficiencies. ■ Components of some products may contain latex; use caution to avoid a hypersensitivity reaction.

Monitor: Identification of factor VIII deficiency with determination of circulating AHF levels should be obtained before administration and during treatment. Adjust dose as indicated. ■ Monitor pulse before and during treatment. ■ Monitor for the development of factor VIII inhibitors. Should be suspected if factor VIII plasma levels are not obtained or if bleeding is not controlled with an appropriate dose. ■ Monitor patients with a known or suspected inhibitor to factor VIII more frequently. ■ Monitor for S/S of a hypersensitivity reaction. ■ See [Precautions](#).

Patient Education: Prophylactic hepatitis B vaccine recommended. ■ Instruction for self-administration and proper preparation may be appropriate. ■ Discontinue antihemophilic factor and immediately report S/S of a hypersensitivity reaction (e.g., hives, itching, hypotension, rash, tightness of the chest, wheezing). ■ HIV screening every 2 to 3 months; not required with recombinant products. ■ Review prescription and non-prescription medications with a health care provider.

Maternal/Child: Category C: use only if clearly needed. ■ Use caution during breastfeeding. ■ Safe for use in pediatric patients of all ages, including newborns. (*Advate* and *Xyntha* did not include newborns in clinical trials.)

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Usually respond to reduced rate of administration. Massive doses may cause acute hemolytic anemia, hyperfibrinogenemia, increased bleeding tendency, or jaundice (rare).

Plasma-based AHF: Clouding or loss of consciousness, flushing, headache, hypersensitivity reactions (anaphylaxis, backache, chills, erythema, fever, hives, hypotension, nausea, stinging at infusion site, tightness of chest, urticaria, wheezing), lethargy, paresthesias, somnolence, tachycardia, or vomiting may occur. Consider risk potential of contracting AIDS or hepatitis; risk of withholding treatment outweighs any risk associated with use.

Recombinant products: Arthralgia; asthenia; burning, erythema, and pruritus at injection site; chest discomfort; chills; cold feet; cough; diarrhea; dizziness; edema of lower extremities; fever; flushing; headache; hypotension (slight); increased sweating; lethargy; nausea; rash; sore throat; or an unusual taste in the mouth may occur. Hypersensitivity reactions, including anaphylaxis, may occur.

ANTIDOTE

Most side effects usually subside spontaneously in 15 to 20 minutes and are generally related to the rate of infusion. Keep the physician informed. Slow or discontinue infusion temporarily if pulse rate increases or beginning S/S of hypersensitivity reactions occur. Discontinue immediately and treat hypersensitivity reactions (antihistamines, epinephrine, corticosteroids). Resuscitate as necessary.

ANTIHEMOPHILIC FACTOR ■ VON WILLEBRAND FACTOR COMPLEX (HUMAN)

Antihemorrhagic

(an-tie-hee-moe-FIL-ik FAK-tor)

Alphanate, Humate-P**USUAL DOSE**

(International units [IU])

Completely individualized. Based on degree of deficiency, desired antihemophilic factor level, body weight, severity of bleeding, and presence of factor VIII inhibitors. One International unit (IU) of factor VIII or 1 IU of von Willebrand factor:Ristocetin Cofactor (vWF:RCof) is approximately equal to the level of factor VIII activity or vWF:RCof found in 1 mL of fresh pooled human plasma.

ALPHANATE

Treatment of hemophilia A (adults): Dose requirements and frequency are calculated on the basis of an expected initial response of 2% of normal FVIII:C IU/kg of body weight administered. Assess adequacy of treatment by clinical effects and monitoring of factor VIII activity. See **Precautions**. The following general dosages are recommended for adult patients:

Continued

Alphanate Dose Guidelines for the Treatment of Adults with Hemophilia A	
Hemorrhagic Event	Dosage (AHF FVIII:C IU/kg body weight)
Minor hemorrhage: Bruises, cuts, or scrapes or uncomplicated joint hemorrhage	FVIII:C levels should be brought to 30% of normal (15 FVIII IU/kg twice daily) until hemorrhage stops and healing has been achieved (1 to 2 days).
Moderate hemorrhage: Nose, mouth, and gum bleeds; dental extractions; hematuria	FVIII:C levels should be brought to 50% (25 FVIII IU/kg twice daily). Continue until healing has been achieved (2 to 7 days on average).
Major hemorrhage: Joint or muscle hemorrhage, major trauma, hematuria, intracranial and/or intraperitoneal bleeding	FVIII:C levels should be brought to 80% to 100% of normal for at least 3 to 5 days (40 to 50 FVIII IU/kg twice daily). Then maintain at 50% (25 FVIII IU/kg twice daily) until healing has been achieved. May require treatment for up to 10 days.
Surgery	Prior to surgery, FVIII:C levels should be brought to 80% to 100% of normal (40 to 50 FVIII IU/kg twice daily). For the next 7 to 10 days or until healing has been achieved, patient should be maintained at 60% to 100% FVIII levels (25 to 50 FVIII IU/kg twice daily).

IU, International unit.

Alphanate Dose Guidelines for Prophylaxis During Surgery and Invasive Procedures of Adult and Pediatric Patients with von Willebrand Disease (Except Type 3 Patients Undergoing Surgery)	
Bleeding Prophylaxis for Surgical or Invasive Procedures	Dosage (AHF vWF:RCof IU/kg body weight)
Adult	Preoperative dose: 60 vWF:RCof IU/kg body weight. Subsequent infusions: 40 to 60 vWF:RCof IU/kg body weight at 8- to 12-hour intervals as clinically needed. Dosing may be reduced after the third postoperative day. Continue treatment until healing is complete.
Adult	Minor procedure: vWF activity of 40% to 50% for at least 1 to 3 days postoperatively.
Adult	Major procedure: vWF activity of 40% to 50% for at least 3 to 7 days postoperatively.
Pediatric	Initial dose: 75 vWF:RCof IU/kg body weight. Subsequent infusions: 50 to 75 vWF:RCof IU/kg body weight at 8- to 12-hour intervals as clinically needed. Dosing may be reduced after the third postoperative day. Continue treatment until healing is complete.

IU, International unit.

HUMATE-P

Treatment of hemophilia A (adults): As a general rule, 1 IU of factor VIII activity per kg body weight will increase the circulating factor VIII level by approximately 2 IU/dL. Assess adequacy of treatment by clinical effects and monitoring of factor VIII activity. See *Precautions*. The following general dosages are recommended for adult patients:

Humate-P Dose Recommendations for the Treatment of Hemophilia A*	
Hemorrhage Event	Dosage (IU† FVIII:C/kg body weight)
<p>Minor</p> <ul style="list-style-type: none"> • Early joint or muscle bleed • Severe epistaxis 	<p>Loading dose 15 IU FVIII:C/kg to achieve FVIII:C plasma level of approximately 30% of normal; one infusion may be sufficient If needed, half of the loading dose may be given once or twice daily for 1-2 days</p>
<p>Moderate</p> <ul style="list-style-type: none"> • Advanced joint or muscle bleed • Neck, tongue, or pharyngeal hematoma without airway compromise • Tooth extraction • Severe abdominal pain 	<p>Loading dose 25 IU FVIII:C/kg to achieve FVIII: C plasma level of approximately 50% of normal Followed by 15 IU FVIII:C/kg every 8-12 hours for first 1-2 days to maintain FVIII:C plasma level at 30% of normal Then same dose once or twice a day for up to 7 days or until adequate wound healing</p>
<p>Life-threatening</p> <ul style="list-style-type: none"> • Major operations • Gastrointestinal bleeding • Neck, tongue, or pharyngeal hematoma with potential for airway compromise • Intracranial, intra-abdominal, or intrathoracic bleeding • Fractures 	<p>Initially 40-50 IU FVIII:C/kg Followed by 20-25 IU FVIII:C/kg every 8 hours to maintain FVIII:C plasma level at 80%-100% of normal for 7 days Then continue the same dose once or twice a day for another 7 days in order to maintain the FVIII:C level at 30%-50% of normal</p>

*In all cases, the dose should be adjusted individually by clinical judgment of the potential for compromise of a vital structure, and by frequent monitoring of factor VIII activity in the patient’s plasma.

†IU, International unit.

Treatment of von Willebrand Disease (vWD) (adults and pediatric patients): As a rule, 40-80 IU vWF:RCof (corresponding to 16 to 32 IU factor VIII in Humate-P) per kg body weight given every 8 to 12 hours. Repeat doses are administered as needed based on monitoring of appropriate clinical and laboratory measures. Expected levels of vWF:RCof are based on an expected in vivo recovery of 1.5 IU/dL rise per IU/kg vWF:RCof administered. The administration of 1 IU of factor VIII per kg body weight can be expected to lead to a rise in circulating vWF:RCof of approximately 3.5 to 4 IU/dL. The following general dosages are recommended for adult and pediatric patients:

Continued

Humate-P Dose Recommendations for Treatment of von Willebrand Disease in Adult and Pediatric Patients		
Classification	Hemorrhage	Dosage (IU* vWF:RCof/kg body weight)
TYPE 1		
Mild (Where use of desmopressin is known or suspected to be inadequate) Baseline vWF:RCof activity typically >30% of normal (i.e., >30 IU/dL)	Major (examples) <ul style="list-style-type: none"> • Severe or refractory epistaxis • GI bleeding • CNS trauma • Traumatic hemorrhage 	Loading dose 40 to 60 IU/kg Then 40 to 50 IU/kg every 8 to 12 hours for 3 days to keep the nadir level of vWF:RCof >50% of normal (i.e., >50 IU/dL) Then 40 to 50 IU/kg daily for a total of up to 7 days of treatment
	Moderate or Severe Baseline vWF:RCof activity typically <30% of normal (i.e., <30 IU/dL)	Minor (examples) <ul style="list-style-type: none"> • Epistaxis • Oral bleeding • Menorrhagia
	Major (examples) <ul style="list-style-type: none"> • Severe or refractory epistaxis • GI bleeding • CNS trauma • Hemarthrosis • Traumatic hemorrhage 	Loading dose of 50 to 75 IU/kg Then 40 to 60 IU/kg every 8 to 12 hours for 3 days to keep the nadir level of vWF:RCof >50% of normal (i.e., >50 IU/dL) Then 40 to 60 IU/kg daily for a total of up to 7 days of treatment <i>Factor VIII:C levels should be monitored and maintained according to the guidelines for hemophilia A therapy†</i>
TYPE 2 (ALL VARIANTS) AND TYPE 3		
	Minor (clinical indications above)	40 to 50 IU/kg (1 or 2 doses)
	Major (clinical indications above)	Loading dose of 60 to 80 IU/kg Then 40 to 60 IU/kg every 8 to 12 hours for 3 days to keep the nadir level of vWF:RCof >50% of normal (i.e., >50 IU/dL) Then 40 to 60 IU/kg daily for a total of up to 7 days of treatment <i>Factor VIII:C levels should be monitored and maintained according to the guidelines for hemophilia A therapy†</i>

*IU, International unit.

†In instances where both FVIII and vWF levels must be monitored.

Prevention of excessive bleeding during and after surgery in vWD: In the case of emergency surgery, administer a loading dose of 50 to 60 IU/kg Humate-P and closely monitor the patient's trough coagulation factor levels. Measurement of incremental in vivo recovery (IVR) and assessment of baseline plasma vWF:RCof and FVIII:C levels is recommended in all patients prior to surgery. Calculation of the loading dose requires four values: the target peak plasma vWF:RCof level, the baseline vWF:RCof level, body weight (BW) in kilograms, and IVR. If individual recovery values are not available, a standardized loading dose can be used based on an assumed vWF:RCof IVR of 2 IU/dL per IU/kg of vWF:RCof product administered.

vWF:RCof and FVIII:C Humate-P Loading Dose Recommendations for the Prevention of Excessive Bleeding During and After Surgery			
Type of Surgery	vWF:RCof Target Peak Plasma Level	FVIII:C Target Peak Plasma Level	Calculation of Loading Dose (to be administered 1 to 2 hours before surgery)
Major	100 IU/dL	80 to 100 IU/dL	$\Delta^* \text{ vWF:RCof} \times \text{BW (kg)/IVR}^\dagger = \text{IU vWF:RCof required}$ If incremental IVR is not available, assume an IVR of 2 IU/dL per IU/kg and calculate the loading dose as follows: $(100 - \text{Baseline plasma vWF:RCof}) \times \text{BW (kg)}/2$ In the case of emergency surgery, administer a dose of 50 to 60 IU/kg.
Minor/oral ‡	50 to 60 IU/dL	40 to 50 IU/dL	$\Delta^* \text{ vWF:RCof} \times \text{BW (kg)/IVR}^\dagger = \text{IU vWF:RCof required}$

* Δ = Target peak plasma vWF:RCof – Baseline plasma vWF:RCof.

†IVR = Incremental recovery as measured in the patient.

‡Oral surgery is defined as removal of fewer than three teeth, if the teeth are non-molars and have no bony involvement.

Removal of more than one impacted wisdom tooth is considered major surgery due to the expected difficulty of the surgery and the expected blood loss, particularly in subjects with type 2A or type 3 vWD. Removal of more than two teeth is considered major surgery in all patients.

vWF:RCof and FVIII:C Target Trough Plasma Level and Minimum Duration of Treatment Recommendations for Subsequent Maintenance Doses of Humate-P for the Prevention of Excessive Bleeding During and After Surgery					
Type of Surgery	vWF:RCof Target Trough Plasma Levels*		FVIII:C Target Trough Plasma Levels*		Minimum Duration of Treatment
	Up to 3 Days Following Surgery	After Day 3	Up to 3 Days Following Surgery	After Day 3	
Major	>50 IU/dL	>30 IU/dL	>50 IU/dL	>30 IU/dL	72 hours
Minor	≥30 IU/dL	—	—	>30 IU/dL	48 hours
Oral†	≥30 IU/dL	—	—	>30 IU/dL	8 to 12 hours‡

*Trough levels for either coagulation factor should not exceed 100 IU/dL.

†See note on oral surgery in previous chart.

‡At least one maintenance dose following surgery based on individual pharmacokinetic values.

PEDIATRIC DOSE

Treatment of hemophilia A (unlabeled): For immediate control of bleeding, follow the general recommendations for dosing and administration for adults. See Usual Dose and Maternal/Child.

DOSE ADJUSTMENTS

Adjust subsequent doses based on FVIII:C plasma level achieved or as outlined in specific charts.

DILUTION

Consult individual product instructions in the package insert; each product has a specific process for dilution. Information may be updated frequently. **Alphanate** provides diluent, a double-ended transfer needle, and a microaggregate filter for use in administration. **Humate-P** provides diluent and a filter transfer set.

Alphanate and Humate-P: Actual number of AHF units are shown on each vial. Use only the diluent provided and maintain strict aseptic technique. Use a plastic syringe to prevent binding to glass surfaces. Warm to room temperature (25° C) before dilution and maintain throughout administration to avoid precipitation of active ingredients.

Filters: Filters supplied by manufacturer; see Dilution.

Storage: **Alphanate:** Refrigerate before use. Avoid freezing. May be stored at CRT for up to 2 months. Label vial with date removed from refrigeration. **Humate-P:** Store up to 25° C (up to 77° F). Avoid freezing. **Alphanate and Humate-P:** Do not refrigerate after reconstitution. Confirm expiration date on vial. Administer within 3 hours of reconstitution to ensure sterility. Discard any unused solution.

COMPATIBILITY

Specific information not available. Administration through a separate line without mixing with other IV fluids or medications is generally recommended for these products.

RATE OF ADMINISTRATION

Inject solution slowly. Rapid administration may result in vasomotor reactions.

Humate-P recommends a maximum rate of 4 mL/min.

Alphanate recommends a maximum rate not to exceed 10 mL/min.

ACTIONS

A purified, sterile, lyophilized concentrate of antihemophilic factor (factor VIII) and von Willebrand Factor (vWF). Factor VIII is an essential cofactor in the activation of factor X, leading ultimately to the formation of thrombin and fibrin. It is the specific clotting factor deficient in patients with hemophilia A (classic hemophilia). vWF is important for correcting the coagulation defect in patients with von Willebrand disease (vWD). It promotes platelet aggregation and platelet adhesion on damaged vascular endothelium and acts as a stabilizing carrier protein for the procoagulant protein factor VIII. vWF activity is measured with an assay that uses an agglutinating cofactor called Ristocetin (RCof). The vWF:RCof assay provides a quantitative measurement of vWF function by determining how well vWF helps platelets adhere to one another. Reduced vWF:RCof activity indicates a deficiency of vWF. Following administration of FVIII/vWF, there is a rapid increase of plasma factor VIII activity, followed by a rapid decrease in activity and then a slower rate of decrease in activity. The mean initial half-life in hemophilic patients is 8.3 to 27.5 hours with Alphanate and 12.2 hours (range: 8.4 to 17.4 hours) with Humate-P. In patients with vWD, bleeding time decreases. Antihemophilic factor/von Willebrand Factor Complex is obtained from pooled human fresh-frozen plasma. Multiple methods of purification are used to inactivate infectious agents, including viruses.

INDICATIONS AND USES

ALPHANATE

Prevention and control of bleeding in patients with factor VIII deficiency due to hemophilia A or acquired factor VIII deficiency. ■ Prophylaxis for surgical and/or invasive procedures in adult and pediatric patients with von Willebrand disease (vWD) (type 1 or 2) in which the use of desmopressin is either ineffective or contraindicated. ■ Not indicated for patients with severe vWD (type 3).

HUMATE-P

Treatment and prevention of bleeding in adult patients with hemophilia A. ■ Treatment of spontaneous and trauma-induced bleeding episodes and prevention of excessive bleeding during and after surgery in adult and pediatric patients with severe vWD or with mild or moderate vWD in which the use of desmopressin is known or suspected to be inadequate. ■ Safety and efficacy of prophylactic dosing to prevent spontaneous bleeding and to prevent excessive bleeding related to surgery have not been established in patients with vWD.

CONTRAINDICATIONS

ALPHANATE: None known when used as indicated.

HUMATE-P: History of anaphylactic or severe systemic response to AHF-vWF preparations or known hypersensitivity to any of its components.

PRECAUTIONS

ALPHANATE AND HUMATE-P: For IV use only. ■ Health care professionals should use caution during administration; may have risk of exposure to viral infection. ■ Important to establish that coagulation disorder is caused by factor VIII or vWF deficiency. Not useful in treatment of other deficiencies. ■ Manufactured from human plasma. Risk of transmitting infectious agents (e.g., HIV, hepatitis and, theoretically, Creutzfeldt-Jakob dis-

ease) has been greatly reduced by screening, testing, and manufacturing techniques. However, risk of transmission cannot be totally eliminated. ■ Hepatitis A and B vaccines are recommended for patients receiving plasma derivatives. ■ Thrombotic events have been reported. Use caution in patients with known risk factors for thrombosis. Incidence may be higher in females. ■ Inhibitors may develop with large or frequent doses; see **Monitor**.

Monitor: Complex contains blood group isoagglutinins (anti-A and anti-B). When very large or frequently repeated doses are needed, as when inhibitors are present or when presurgical and postsurgical care is involved, patients of blood groups A, B, and AB should be monitored for signs of intravascular hemolysis and decreasing hematocrit values; see **Antidote**. ■ Replacement therapy should be monitored by appropriate coagulation tests, especially in cases involving major surgery. Monitor factor VIII and vWF:RCof as indicated in dosing guidelines.

Patient Education: Prophylactic hepatitis A and hepatitis B vaccines recommended. ■ Report symptoms of possibly transmitted viral infections immediately. Symptoms may include anorexia, arthralgias, fatigue, jaundice, low grade fever, nausea, or vomiting. ■ Report rash or any other sign of hypersensitivity reaction promptly.

Maternal/Child: Category C: use only if clearly needed. ■ Adequate and well-controlled studies with long-term evaluation of joint damage have not been done in pediatric patients. Joint damage may result from suboptimal treatment of hemarthroses. ■ Safety and effectiveness for use in neonates with vWD has not been established. Has been used safely in infants, children, and adolescents with vWD.

Elderly: Numbers insufficient to determine differences in response compared with younger adults. Consider overall status in dosing.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

ALPHANATE AND HUMATE-P: Usually well tolerated. Rare cases of hypersensitivity reactions, including anaphylaxis, have been reported (symptoms may include chest tightness, edema, fever, pruritus, rash, throat tightness). Other reported side effects include chills, headache, lethargy, nausea and vomiting, paresthesia, phlebitis, somnolence, and vasodilation. Inhibitors of factor VIII may occur.

Post-Marketing: **Alphanate:** In addition to the above, cardiac arrest, femoral venous thrombosis, flushing, itching, joint pain, pulmonary embolus, seizure, shortness of breath, swelling of the parotid gland, urticaria. **Humate-P:** Hypersensitivity reactions (including anaphylaxis), development of inhibitors to factor VIII, hemolysis, hypervolemia, thromboembolic complications.

ANTIDOTE

Keep physician informed of all side effects. If mild reactions occur (mild allergic reaction, chills, nausea, or stinging at the infusion site) and additional treatment is indicated, a product from a different lot should be considered. Discontinue immediately at first sign of a moderate to severe hypersensitivity reaction. Treat as necessary (antihistamines, epinephrine, corticosteroids). Development of acute hemolytic anemia, increased bleeding tendency, or hyperfibrinogenemia may require transfusion with Type O red blood cells. Discontinue administration of Alphanate/Humate-P and consider alternative therapy. Resuscitate as necessary.

ANTI-INHIBITOR COAGULANT COMPLEX **BBW**

Antihemorrhagic

(an-TIE-in-HIH-bih-tor coe-AG-you-lant COM-plex)

Feiba NF**USUAL DOSE**

A unit of **Feiba NF (nanofiltered and vapor heated)** is expressed as factor VIII inhibitor bypassing activity. Identification of factor VIII inhibitor levels and PT mandatory before administration.

FEIBA NF

Range is 50 to 100 units/kg.

Specific suggested dosing regimens include:

Joint hemorrhage: 50 units/kg; repeat at 12-hour intervals if indicated. May be increased to 100 units/kg if indicated. Continue treatment until clinical improvement (e.g., mobilization of the joint, reduction of swelling, relief of pain). **Do not exceed 200 units/kg/24 hr.**

Mucous membrane bleeding: 50 units/kg; repeat at 6-hour intervals if indicated. Monitor visible bleeding sites and hematocrit closely. May be increased to 100 units/kg every 6 hours for up to 2 doses if bleeding does not stop. **Do not exceed 200 units/kg/24 hr.**

Serious soft tissue hemorrhage: 100 units/kg; repeat at 12-hour intervals if indicated.

Other severe hemorrhage (e.g., CNS bleeding): 100 units/kg; repeat at 12-hour intervals if indicated. Feiba NF may be indicated at 6-hour intervals until clear clinical improvement occurs.

DILUTION

Actual number of units shown on each vial. Use only the diluent provided and maintain strict aseptic technique. Bring to room temperature before reconstitution. Follow manufacturer's guidelines for reconstitution using the BAXJECT device. May stick to sides of glass syringes; use of plastic syringes recommended. Gently swirl. Do not shake. May be given through Y-tube or three-way stopcock of infusion set. To avoid hypotension from prekallikrein activator (PKA), give **Feiba NF** within 3 hours of reconstitution.

Filters: The manufacturer of **Feiba NF** uses a needleless transfer device and has no recommendation for use of an in-line filter.

Storage: Refrigerate before reconstitution; do not refrigerate after reconstitution. Avoid freezing. Within the indicated shelf life, may be stored at RT (not to exceed 25° C [77° F]) for up to 6 months. Do not leave at RT beyond its shelf life and do not return to refrigeration. Record date of removal from refrigeration on package before moving to RT.

COMPATIBILITY

Specific information not available. Administration through a separate line without mixing with other IV fluids or medications is generally recommended. If anti-inhibitor coagulant is given as a continuous IV, one source says heparin 5 to 10 units/mL of concentrate may be added to avoid thrombophlebitis.

RATE OF ADMINISTRATION

If symptoms of too-rapid infusion (headache, flushing, changes in BP or pulse rate) occur, discontinue until symptoms subside. Restart at a lower rate.

Feiba NF: Do not exceed 2 units/kg/min.

ACTIONS

An activated prothrombin complex prepared from pooled human plasma. Controls bleeding in patients with factor VIII inhibitors. Mechanism of action is not well understood. Onset of response is usually within 12 hours. Peak response is usually seen within 36 to 72 hours.

Feiba NF: 1 unit of activity is the amount of anti-inhibitor coagulant complex (AICC) that will shorten the aPTT of a high-titer factor VIII inhibitor reference plasma to 50% of the blank value.

INDICATIONS AND USES

Prophylaxis and treatment of hemorrhagic complications in hemophiliacs (hemophilia A or B) with factor VIII inhibitors who are bleeding or will undergo elective or emergency surgery. Anti-inhibitor coagulant complex (AICC) is most frequently indicated if presenting factor VIII inhibitor levels are above 5 to 10 Bethesda units (BU) or rise to that level following treatment with antihemophilic factor (AHF). Patients whose factor VIII inhibitor levels are between 5 and 10 BU and whose inhibitor levels remain at those levels may be treated with either AHF or AICC. Patients whose inhibitor levels are less than or equal to 5 BU and whose inhibitor levels remain at those levels may be treated with AHF.

Unlabeled uses: Feiba NF has been used in the prophylaxis and treatment of hemorrhagic complications in non-hemophiliacs with acquired inhibitors to factors VIII, XI, and XII.

CONTRAINDICATIONS

Patients with a normal coagulation mechanism; patients with significant signs of DIC; treatment of bleeding due to coagulation factor deficiencies in the absence of inhibitors to coagulation factors VIII or IX.

PRECAUTIONS

Anamnestic responses (development of antibodies, reducing effectiveness of the drug) with a rise in factor VIII inhibitor titers have been seen in up to 20% of cases. ■ Thrombotic and thromboembolic events have been reported (e.g., DIC, venous thrombosis, pulmonary embolism, MI, and stroke). Risk of complications may be increased in surgical patients, in patients with thrombotic risk factors, and in patients receiving higher doses. Patients receiving more than 100 units/kg/dose or 200 mg/kg/day are at increased risk for DIC or acute coronary ischemia. Use high doses only as long as necessary to stop bleeding. ■ Patients with DIC, advanced atherosclerotic disease, crush injury, septicemia, or concomitant treatment with recombinant factor VIIa (e.g., NovoSeven, NovoSeven RT) have an increased risk of developing thrombotic events due to circulating tissue factor (TF) or predisposing coagulopathy. ■ Use with caution and only if there are no therapeutic alternatives in patients at risk for DIC or arterial or venous thrombosis or in patients with existing thrombotic conditions (e.g., MI or venous thrombosis). ■ Use with caution in patients with a history of coronary heart disease, liver disease, or postoperative immobilization, in the elderly, and in neonates; weigh benefits versus risk. ■ Do not use Feiba NF for the treatment of bleeding episodes resulting from coagulation factor deficiencies. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C). Numerous steps in the manufacturing process are used to reduce the potential for infection. ■ See [Drug/Lab Interactions](#).

Monitor: Monitor PT before and after treatment. Only accurate means of treatment evaluation; see [Drug/Lab Interactions](#). ■ Monitor vital signs before, during, and after the infusion. ■ Monitor for S/S of acute coronary ischemia, DIC, and other thrombotic or thromboembolic events (e.g., changes in BP and HR, chest pain, cough, respiratory distress); see [Antidote](#). ■ Laboratory indications of DIC may include decreased fibrinogen, decreased platelet count, and/or the presence of fibrin-fibrinogen degradation products (FDP) or significantly prolonged TT, PT, or PTT. ■ Monitor for S/S of a hypersensitivity reaction (e.g., rash, shortness of breath).

Patient Education: Manufactured from pooled human plasma. Possibility of viral transmission exists. Promptly report S/S of viral infections (e.g., chills, drowsiness, fever, runny nose followed by joint pain, rash, and/or S/S of hepatitis A [e.g., days to weeks of poor appetite, low-grade fever, and tiredness followed by abdominal pain, dark urine, jaundice, nausea, vomiting]).

Maternal/Child: Category C: use only if clearly needed. ■ Data not available for use in newborns. ■ Safety for use in breast-feeding not established.

Elderly: May have increased risk for thromboembolic complications.

DRUG/LAB INTERACTIONS

Not recommended for use with **antifibrinolytic products** (aminocaproic acid, tranexamic acid). Feiba NF has been used with **antifibrinolytics**; however, they should be used with caution and not administered until at least 12 hours after Feiba NF. ■ aPTT, WBCT, and other **clotting factor tests** do not correlate with clinical improvement. Attempts to normalize these values may lead to overdose and DIC.

SIDE EFFECTS

Anaphylaxis, bradycardia, chest pain, chills, cough, decreased fibrinogen concentration, decreased platelet count, DIC, fever, flushing, headache, hypertension, hypotension, myocardial infarction, prolonged PT, prolonged PTT, prolonged thrombin time, respiratory distress, tachycardia, thrombosis or thromboembolism, urticaria. Consider risk potential of contracting AIDS or hepatitis.

Overdose: Increased risk for DIC, MI, or thromboembolism.

Post-Marketing: Anaphylactic reaction, DIC, hypersensitivity, hypoaesthesia, facial hypoaesthesia, hypotension, injection site pain, thromboembolism, thrombosis.

ANTIDOTE

If side effects occur, discontinue the infusion and notify the physician. May be resumed at a slower rate or discontinued, or an alternate product may be used. Symptoms of DIC (BP and pulse rate changes, respiratory discomfort, chest pain, cough, prolonged clotting tests, cyanosis of hands and feet, persistent bleeding from puncture sites or mucous membranes) require discontinuation of the infusion and immediate treatment. Treat anaphylaxis or other hypersensitivity reactions (changes in BP or HR [may indicate prekalikrein activity]) with antihistamines, epinephrine, corticosteroids and resuscitate as necessary.

ANTITHROMBIN III (HUMAN)

(an-tie-**THROM**-bin)

Anticoagulant
Antithrombotic

AT-III, Thrombate III

pH 6.5 to 7.5

USUAL DOSE

(International units [IU])

Loading dose, maintenance dose, and dosing intervals are completely individualized based on confirmed diagnosis (see **Precautions**), patient weight, clinical condition, degree of deficiency, type of surgery or procedure involved, physician judgment, desired level of antithrombin III (AT-III), and actual plasma levels achieved as verified by appropriate lab tests. One unit/kg should raise the level of AT-III by 1.4%. The desired AT-III level after the first dose should be about 120% of normal (normal is 0.1 to 0.2 Gm/L). AT-III levels must be maintained at normal or at least above 80% of normal for 2 to 8 days depending on individual patient factors. Usually achieved by administration of a maintenance dose once daily. Concomitant administration of heparin usually indicated; see **Drug/Lab Interactions**.

Calculate the initial loading dose using the following formula (assumes a plasma volume of 40 mL/kg):

$$\text{Dosage units} = \frac{(\text{Desired AT-III level [\%]} - \text{Baseline AT-III [\%]}) \times \text{Body weight (kg)}}{\div 1.4\%}$$

For a 70-kg patient with a baseline AT-III level of 57% the initial dose of Thrombate III would be $(120\% - 57\%) \times 70 \div 1.4 = 3,150$ International units (IU). Measurement of

plasma levels is suggested preinfusion, 20 minutes postinfusion (peak), 12 hours postinfusion, and preceding next infusion (trough). If recovery differs from the anticipated rise of 1.4% for each IU/kg, modify the formula accordingly. If the above patient has a 20-minute AT-III level of 147%, the increase in AT-III measured for each 1 IU/kg administered is $(147\% - 57\%) \times 70 \text{ kg} \div 3,150 \text{ IU} = 2\%$ rise for each IU/kg administered. This in vivo recovery would be used to calculate future doses. A maintenance dose of approximately 60% of the loading dose every 24 hours is the average required to maintain plasma levels between 80% and 120%. Dose and interval based on plasma levels.

DOSE ADJUSTMENTS

See [Drug/Lab Interactions](#).

DILUTION

Diluent, double-ended needles for dilution, and filter needle for aspiration into a syringe are provided. Warm unopened diluent and concentrate to room temperature. Enter diluent bottle with double-ended transfer needle first. Enter vacuum concentrate bottle with double-ended transfer needle at a 45-degree angle. Direct diluent from above to sides of vial to gently moisten all contents. Remove diluent bottle and transfer needle; swirl continuously until completely dissolved. Draw into a syringe through the filter needle. Remove filter needle; replace with an administration set (not provided). For larger doses, several bottles may be drawn into one syringe. Use a separate filter needle for each bottle.

Filters: Filter needle supplied by manufacturer; see [Dilution](#). For larger doses, several bottles may be drawn into one syringe. Use a separate filter needle for each bottle.

Storage: Store in refrigerator before dilution; avoid freezing. Do not refrigerate after reconstitution. Use within 3 hours of reconstitution.

COMPATIBILITY

Administration through a separate line without mixing with other IV fluids or medications is recommended.

RATE OF ADMINISTRATION

Too-rapid injection may cause dyspnea.

A single dose over 10 to 20 minutes.

ACTIONS

Manufactured from human plasma, purified and heat treated through specific processes, AT-III is a plasma-based protein produced by the body to inactivate specific clotting proteins and control clot formation. Identical to heparin cofactor I, a factor in plasma necessary for heparin to exert its anticoagulant effect. It inactivates thrombin and the activated forms of factors IX, X, XI, and XII (all coagulation enzymes except factors VIIa and XIIIa). Increases AT-III levels within 30 minutes and has a half-life of up to 3 days.

INDICATIONS AND USES

Treatment of patients with hereditary AT-III deficiency to prevent thrombosis during surgical or obstetric procedures (replacement therapy) or during acute thrombotic episodes.

CONTRAINDICATIONS

None when used as indicated.

PRECAUTIONS

For IV use only. ■ Confirm diagnosis of hereditary AT-III deficiency based on a clear family history of venous thrombosis as well as decreased plasma AT-III levels and the exclusion of acquired deficiency. Present laboratory tests may not be able to identify all cases of congenital AT-III deficiency. ■ Every unit of plasma used to manufacture AT-III is tested and found nonreactive for HBsAg and negative for antibody to HIV by FDA-approved tests, then heat-treated by a special process. Even with these precautions, individuals who receive multiple infusions may develop viral infection, particularly non-A, non-B hepatitis. HIV infection remains a remote possibility. ■ May reverse heparin resistance.

Monitor: See varying methods for measuring AT-III levels under **Usual Dose**. Should be measured at least twice daily until the patient is stabilized and peak and trough levels established, then measured daily. All blood work should be drawn immediately before the next infusion of AT-III.

Patient Education: Inform of risks of thrombosis in connection with pregnancy and surgery and the fact that AT-III deficiency is hereditary.

Maternal/Child: Neonatal AT-III levels should be measured immediately after birth if parents are known to have AT-III deficiency (fatal neonatal thromboembolism [e.g., aortic thrombi] has occurred). Treatment of the neonate should be under the direction of a physician knowledgeable about coagulation disorders. Normal full-term and premature infants have lower than adult averages of AT-III plasma levels. ■ Category B: use only if clearly indicated. Fetal abnormalities not noted when administered in the third trimester. ■ Safety for use in pediatric patients not established.

DRUG/LAB INTERACTIONS

Half-life of AT-III decreases with concurrent **heparin** treatment. The anticoagulant effect of heparin is enhanced, and a reduced dose of heparin and low-molecular-weight heparins (LMWHs) is indicated to avoid bleeding.

SIDE EFFECTS

Bowel fullness, chest pain, chest tightness, chills, cramps, dizziness, fever, film over eye, foul taste in mouth, hives, light-headedness, oozing and hematoma formation, and shortness of breath have occurred with Thrombate III. Some patients with acquired AT-III deficiency diagnosed with disseminated intravascular coagulation (DIC) have had diuretic and vasodilatory effects. Rapid infusion may cause dyspnea.

ANTIDOTE

Levels of 150% to 210% found in a few patients have not caused any apparent complications. Observe for bleeding. Reduce rate of infusion immediately for dyspnea. Decrease rate or interrupt infusion as indicated until side effects subside. Keep physician informed of patient's lab values and condition.

ANTITHROMBIN RECOMBINANT

(an-tie-**THROM**-bin re-**KOM**-be-nant)

Atryn

**Anticoagulant
Antithrombotic**

pH 7

USUAL DOSE

(**International Units [IU]**)

Dose must be individualized for each patient and is based on the pretreatment level of functional antithrombin (AT) (expressed in percent of normal) and on body weight in kilograms according to the following chart. Treatment goal is to restore and maintain functional AT activity levels between 80% and 120% (0.8 to 1.2 IU/mL) of normal. Treatment should be initiated before delivery or approximately 24 hours before surgery to ensure AT level is in the target range. Different dosing formulas are used for the treatment of surgical and pregnant patients. Pregnant women being treated with antithrombin recombinant for any peripartum or perioperative event, including a cesarean section, should be treated according to the dosing formula for pregnant women.

Antithrombin Recombinant Dosing Formula for Surgical Patients and Pregnant Women	
Loading Dose (IU)	Maintenance Dose (IU/hr)
Surgical Patients	
$\frac{(100 - \text{Baseline AT activity level})}{2.3} \times \text{Body weight (kg)}$	$\frac{(100 - \text{Baseline AT activity level})}{10.2} \times \text{Body weight (kg)}$
Pregnant Women	
$\frac{(100 - \text{Baseline AT activity level})}{1.3} \times \text{Body weight (kg)}$	$\frac{(100 - \text{Baseline AT activity level})}{5.4} \times \text{Body weight (kg)}$

Check AT level just after surgery or delivery; AT activity may be rapidly decreased by surgery or delivery. If AT activity level is below 80%, administer an additional bolus dose to rapidly restore decreased AT activity level. Then restart the maintenance dose at the same rate of infusion as before the bolus. Monitor AT activity at least once or twice daily and adjust doses according to the table in [Dose Adjustments](#). Continue treatment until adequate follow-up anticoagulation is established.

DOSE ADJUSTMENTS

Antithrombin Recombinant AT Activity Monitoring and Dose Adjustment			
Initial Monitor Time	AT Level	Dose Adjustment	Recheck AT Level
2 hr after initiation of treatment	<80%	Increase by 30%	2 hr after each dose adjustment
	80% to 100%	None	6 hr after initiation of treatment or dose adjustment
	>120%	Decrease by 30%	2 hr after each dose adjustment

DILUTION

Bring vials to RT no more than 3 hours before reconstitution. Each vial contains approximately 1,750 IU; exact potency is stated on the carton and label. Immediately before use, each vial **must** be reconstituted with 10 mL SWFI. **Do not shake**. Draw the reconstituted solution from one or more vials into a sterile syringe. May administer reconstituted solution directly or may further dilute in an infusion bag containing NS (e.g., dilute to obtain a final concentration of 100 IU/mL). Administer using an infusion set with a 0.22-micron in-line filter.

Filters: Use of a 0.22-micron in-line filter required during infusion.

Storage: Before use, refrigerate vials between 2° and 8° C (36° and 46° F). Use reconstituted or diluted solution within 8 to 12 hours of preparation. Do not use beyond expiration date on vial. Discard unused product.

COMPATIBILITY

Specific information not available. Because of specific use and unique formulation, consider administering through a separate line without mixing with other IV fluids or medications.

RATE OF ADMINISTRATION

Loading dose: Administer as an infusion over 15 minutes. Follow immediately with the **maintenance dose** as a continuous infusion at the calculated IU/hr rate.

ACTIONS

A recombinant human antithrombin produced by DNA technology. A DNA coding sequence for human antithrombin and a mammary gland-specific DNA sequence are introduced into genetically engineered goats. The goats' milk contains the antithrombin. The amino acid sequence of antithrombin recombinant is identical to that of human plasma-derived antithrombin. Purified through numerous processes to eliminate potential vi-

ruses. AT is the principal inhibitor of thrombin and factor Xa. AT neutralizes the activity of thrombin and factor Xa by forming a complex that is rapidly removed from the circulation. When AT is bound to heparin, the ability of antithrombin to inhibit thrombin and factor Xa can be enhanced by greater than 300- to 1,000-fold. Half-life range based on IU/kg is 11.6 to 17.7 hours. This recombinant formulation has a shorter half-life and more rapid clearance compared with plasma-derived antithrombin (e.g., Thrombate III). Secreted in breast milk.

INDICATIONS AND USES

Prevention of perioperative and peripartum thromboembolic events in patients with hereditary antithrombin deficiency. ■ **Not indicated for treatment** of thromboembolic events in patients with hereditary antithrombin deficiency.

CONTRAINDICATIONS

Known hypersensitivity to goat and goat milk proteins.

PRECAUTIONS

For IV use only. ■ Confirm diagnosis of hereditary antithrombin deficiency. ■ Hypersensitivity reactions may occur at any time during the infusion, thus requiring discontinuation of the infusion. ■ The anticoagulant effect of drugs that use antithrombin to exert their anticoagulation (e.g., heparin, low-molecular-weight heparins such as enoxaparin [Lovenox]) may be altered when antithrombin recombinant is added or withdrawn. Avoid excessive or insufficient anticoagulation by monitoring coagulation tests suitable for the anticoagulant used (e.g., aPTT and anti-factor Xa activity). To avoid bleeding or thrombosis, perform these tests regularly and at close intervals, especially during the first hours after the start or withdrawal of antithrombin recombinant. ■ See [Drug/Lab Interactions](#).

Monitor: Specific coagulation tests are required before administration and throughout the infusion process; see [Usual Dose](#) and [Precautions](#). ■ Monitor throughout the infusion for S/S of a hypersensitivity reaction (e.g., hives, hypotension, generalized urticaria, tightness of the chest, wheezing, and/or anaphylaxis). ■ Monitor for S/S of bleeding or thrombosis.

Patient Education: Inform physician of a past or present allergy to goats or goat milk. ■ Promptly report S/S of a hypersensitivity reaction (e.g., rash, shortness of breath, wheezing). ■ Risk of bleeding increased when used with other anticoagulants. Report bleeding from any source.

Maternal/Child: Category C: use during pregnancy only if clearly needed. Studies have not shown that antithrombin recombinant increases the risk of fetal abnormalities if administered during the third trimester of pregnancy. Adverse reactions have not been reported in neonates born to women treated with antithrombin recombinant during clinical trials. ■ Indicated for prevention of thromboembolic events in women with hereditary antithrombin deficiency during labor and delivery. ■ Levels that appear in breast milk are estimated to be the same as in normal lactating women; however, use only if clearly needed and with caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Numbers in clinical studies insufficient to determine if elderly patients respond differently than younger subjects. Dosing should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

The anticoagulant effect of **heparin and low-molecular-weight heparin** is enhanced by antithrombin. Concurrent use with these anticoagulants may alter the half-life of antithrombin. Concurrent use with **heparin, low-molecular-weight heparins** such as enoxaparin (Lovenox), **or other anticoagulants** that use antithrombin to exert their anticoagulant effect must be monitored clinically and biologically. To avoid excessive anticoagulation, perform regular coagulation tests (aPTT and, where appropriate, anti-factor Xa activity) at close intervals and adjust the dose of anticoagulant as indicated.

SIDE EFFECTS

Hemorrhage and infusion site reactions were most commonly reported. Hemorrhage may be serious (intra-abdominal, hemothorax, and postprocedural). Less common side effects include feeling hot, hematoma, hematuria, hepatic enzyme abnormalities, hypersensitivity reactions (including anaphylaxis), and non-cardiac chest pain.

ANTIDOTE

Keep physician informed of patient's lab values and condition. Discontinue the infusion if a hypersensitivity reaction occurs. ■ Treat anaphylaxis immediately with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol (Ventolin), IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

ANTI-THYMOCYTE GLOBULIN (RABBIT) **BBW**

Immunosuppressant

(an-tie-THI-mo-cite GLOB-you-lin)

Thymoglobulin, Atgam (equine)*

pH 7 to 7.4

USUAL DOSE

Premedication: To reduce the incidence and intensity of side effects during the infusion of anti-thymocyte globulin; premedication 1 hour before the infusion with corticosteroids (e.g., dexamethasone [Decadron]), acetaminophen (e.g., Tylenol), and/or an antihistamine (e.g., diphenhydramine [Benadryl]) is recommended.

Anti-thymocyte globulin: 1.5 mg/kg of body weight daily for 7 to 14 days. Given as an infusion into a high flow vein. Used in conjunction with maintenance immunosuppression (e.g., tacrolimus [Prograf], mycophenolate [Cell-Sept]); see [Drug/Lab Interactions](#).

DOSE ADJUSTMENTS

Reduce dose by one-half if WBC count is between 2,000 and 3,000 cells/mm³ or if platelet count is between 50,000 and 75,000 cells/mm³. ■ Consider withholding dose or stopping anti-thymocyte therapy if WBC count falls below 2,000 cells/mm³ or platelets fall below 50,000 cells/mm³.

DILUTION

Calculate the number of vials required (25 mg/vial), 5 mL of SWFI as diluent per vial is supplied. Drug and diluent must be warmed to room temperature before dilution. Absolute sterile technique required throughout dilution process. For each vial required use a new syringe and needle. Withdraw 5 mL of diluent and inject into lyophilized powder. Rotate vial gently until powder is completely dissolved. Do not shake. Each reconstituted vial contains 25 mg (5 mg/mL). Must be further diluted by transferring into 50 mL of infusion solution (saline or dextrose) for each 25 mg of anti-thymocyte globulin. Total volume is usually between 50 to 500 mL. Invert the infusion bag gently once or twice to mix the solution.

Filters: Use of a 0.22-micron in-line filter recommended.

Storage: Refrigerate and protect from light until removed to prepare for reconstitution. Do not freeze. Do not use after expiration date on vial. Use reconstituted vials within 4 hours. Use infusion solutions immediately. Discard unused drug.

*See Index for monograph of Lymphocyte Immune Globulin, the equine product of Anti-Thymocyte Globulin.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Administration through a separate line without mixing with other IV fluids or medications is suggested because of specific use and potential for anaphylaxis.

One source suggests the following **compatibilities**:

Y-site: Heparin, hydrocortisone sodium succinate (Solu-Cortef).

RATE OF ADMINISTRATION

Use of a high-flow vein and a 0.22-micron filter recommended. Well-tolerated and less likely to produce side effects (e.g., chills and fever) when administered at the recommended rate and the patient is premedicated.

Initial dose: A total daily dose equally distributed over a minimum of 6 hours.

Subsequent doses: A total daily dose equally distributed over a minimum of 4 hours.

ACTIONS

A purified, pasteurized, gamma immune globulin, obtained by immunization of rabbits with human thymocytes. Mechanism of action not fully understood. May induce immunosuppression by T-cell depletion and immune modulation. Made up of a variety of antibodies that recognize key receptors on T-cells (those cells responsible for attacking and rejecting a foreign substance within the body). Anti-thymocyte globulin antibodies can inactivate and kill these T-cells, thus reversing the rejection process. May prevent organ loss and reduce the need for retransplantation. T-cell depletion is usually observed within a day of initiating thymoglobulin therapy. Half-life averages 2 to 3 days but the drug remains active, targeting the offending immune cells for days to weeks after treatment.

INDICATIONS AND USES

Treatment of kidney transplant acute rejection in conjunction with concomitant immunosuppression.

Unlabeled uses: Compassionate use in the treatment of acute rejection in bone marrow, heart, and liver transplants. Treatment of myelodysplastic syndrome (MDS).

CONTRAINDICATIONS

Patients with a known allergy to rabbit proteins, an acute viral illness, or a history of anaphylaxis during rabbit immunoglobulin administration.

PRECAUTIONS

Administered only under the direction of a physician experienced in immunosuppressive therapy and management of renal transplant patients in a facility with adequate laboratory and supportive medical resources. ■ Not considered effective for treating antibody-mediated (humoral) rejections. ■ Prolonged use or overdose in combination with other immunosuppressive agents may cause over-immunosuppression resulting in severe infections and may increase the incidence of lymphoma or post-transplant lymphoproliferative disease (PTLD) or other malignancies. Use of appropriate antiviral, antibacterial, antiprotozoal, and/or antifungal prophylaxis is recommended. In clinical trials, viral prophylaxis with ganciclovir infusion was used. ■ In clinical trials, anti-rabbit antibodies developed in 68% of patients. Controlled studies on repeat use of anti-thymocyte globulin in patients with anti-rabbit antibodies have not been conducted. Use caution if repeat courses are indicated, monitoring of lymphocyte count is recommended to ensure that T-cell depletion is achieved. ■ If anaphylaxis occurs during or after therapy, further administration of anti-thymocyte globulin is contraindicated.

Monitor: Close clinical observation is imperative. Monitor for side effects during and after infusion. Anaphylaxis has occurred; emergency equipment, medications, and supplies must be available. ■ Obtain baseline and monitor WBC and platelet counts during therapy. Thrombocytopenia or neutropenia may occur and are reversible following dose adjustment; see [Dose Adjustments](#). ■ Monitoring of the lymphocyte count (i.e., total lymphocyte count and T-cell counts [absolute and/or subset]) may help assess the degree of T-cell depletion. ■ Monitor carefully for signs of infection. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Imperative that all medications (especially immunosuppressants) be reviewed with physician. ■ Report any previous hypersensitivity/anaphylactic reaction. ■ Report acute viral infections immediately. ■ Promptly report chest pain, irregular or rapid heartbeat, shortness of breath, swelling of the face or throat, or wheezing during infusion of medication. ■ See Appendix D, p. 1255. ■ May be associated with an increased risk of malignancy.

Maternal/Child: Category C: safety for use during pregnancy and breast-feeding not established. Safety and effectiveness for use in pediatric patients not established. Use only if clearly needed. ■ Has been used in pediatric patients in limited European studies and in the United States for compassionate use. Response similar to adults.

Elderly: Specific information not available.

DRUG/LAB INTERACTIONS

Concurrent use with **immunosuppressants** (e.g., azathioprine [Imuran], cyclosporine [Sandimmune], mycophenolate [Cell-Sept], tacrolimus [Prograf]) may potentiate the immunosuppressive action of these agents; many transplant centers decrease maintenance immunosuppression therapy during the period of antibody therapy. ■ May **stimulate the production of antibodies**, which cross-react with rabbit immune globulins. ■ May interfere with **rabbit antibody-base immunoassays** and with **cross-match or panel-reactive antibody cytotoxicity assays**.

SIDE EFFECTS

Are dose-limiting. Abdominal pain, asthenia, diarrhea, dizziness, dyspnea, fever, headache, hyperkalemia, hypertension, infection, infusion reaction (e.g., chills and fever), leukopenia, malaise, nausea, pain, peripheral edema, tachycardia, and thrombocytopenia were reported frequently. Anaphylaxis has been reported.

Overdose: Leukopenia or thrombocytopenia.

ANTIDOTE

Notify physician of all side effects. Most can be managed symptomatically. Manage leukopenia or thrombocytopenia during therapy or in overdose with dose reduction. Infusion reactions are managed with premedication and reduction in the rate of infusion. Treat infections aggressively; see **Precautions**. May require discontinuation of therapy. Discontinue infusion and/or therapy immediately if anaphylaxis occurs. Treat anaphylaxis immediately with epinephrine (Adrenalin), diphenhydramine (Benadryl), oxygen, vasopressors (e.g., dopamine), corticosteroids, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

ANTIVENIN CROTALIDAE POLYVALENT IMMUNE FAB (OVINE)

Antivenin

(an-tee-**VEN**-in kro-**TAL**-ih-day pol-ih-**VAY**-lent im-**MYOUN** fab)

CroFab

USUAL DOSE

Contact Poison Control Center for individual treatment advice.

Premedication: Premedication may be indicated for patients with allergies. Obtain blood work before administration; see [Contraindications](#), [Precautions](#), and [Monitor](#). Initiate as soon as possible after crotalid snakebite in patients who develop signs of progressive envenomation (e.g., worsening local injury, coagulation abnormality, or systemic signs of envenomation); see [Monitor](#). Has been effective when given within 6 hours of snakebite.

Initial dose: Skin testing for sensitivity to serum is not required. 4 to 6 vials is the recommended initial dose based on clinical experience. Adjust based on severity of envenomation when patient is initially assessed. Observe for up to 1 hour after initial dose administered. Desired outcome is complete control of the envenomation (i.e., complete arrest of local manifestations, and return of coagulation tests and systemic signs to normal).

Repeat doses: If control of symptoms is not accomplished by the initial dose, give an additional dose of 4 to 6 vials. This dose may be repeated until initial control of the envenomation syndrome has been achieved. After initial control has been established, give additional 2-vial doses every 6 hours for up to 18 hours (3 doses). Optimal dosing following the 18-hour scheduled dose has not been determined. Additional 2-vial doses may be given as directed by the treating physician, based on the patient's clinical response. Up to 18 vials have been given without any observed direct toxic effect. Scheduled dosing/rather than PRN dosing may provide better control of envenomation symptoms caused by the continued leaking of venom from depot sites.

PEDIATRIC DOSE

Absolute venom dose following snakebite is expected to be the same in pediatric patients and adults, no dose adjustment for age is required. See [Maternal/Child](#).

DOSE ADJUSTMENTS

No dose adjustments recommended.

DILUTION

Reconstitute each vial with 10 mL SWFI. Mix by continuous gentle swirling. Further dilute the contents of the reconstituted vial(s) in 250 mL NS and mix by gently swirling.

Storage: Refrigerate unopened vials, do not freeze. Reconstituted vials and diluted solution must be used within 4 hours.

COMPATIBILITY

Specific information not available. Administration through a separate line without mixing with other IV fluids or medications is suggested because of specific use and potential for anaphylaxis.

RATE OF ADMINISTRATION

Infuse at a rate of 25 to 50 mL/hr over the first 10 minutes. Carefully observe for hypersensitivity reactions. If no adverse reaction occurs, increase rate to administer 250 mL equally distributed over 1 hour. Reduce rate of administration if infusion-related reactions occur (e.g., fever, low back pain, nausea, wheezing), and monitor closely.

ACTIONS

A venom-specific Fab fragment of immunoglobulin G (IgG) obtained from the blood of healthy sheep flocks immunized with one of four snake venoms; see [Indications](#) for specific venoms. To obtain the final product, the four different monospecific antivenins are

mixed. Works by binding and neutralizing venom toxins, facilitating their redistribution away from target tissues and their elimination from the body. Half-life is estimated to be 12 to 23 hours.

INDICATIONS AND USES

Management of patients with minimal or moderate North American rattlesnake envenomation (*Crotalus atrox* [Western Diamondback rattlesnake], *Crotalus adamanteus* [Eastern Diamondback rattlesnake], *Crotalus scutulatus* [Mohave rattlesnake], and *Agkistrodon piscivorus* [Cottonmouth or Water Moccasin]). Early use (within 6 hours) is advised to prevent clinical deterioration and the occurrence of systemic coagulation abnormalities. ■ No clinical data is available supporting effectiveness in patients presenting with severe envenomation.

Unlabeled uses: May possess antigenic cross-reactivity against the venoms of some Middle Eastern and North African snakes, no clinical data available.

CONTRAINDICATIONS

Known history of hypersensitivity to sheep, papaya, or papain unless benefits outweigh risks and appropriate management for anaphylactic reactions is readily available.

PRECAUTIONS

Usually administered in the hospital by or under the direction of the physician specialist with adequate diagnostic and treatment facilities readily available. ■ Patients with allergies to dust mites, latex, papain, chymopapain, other papaya extracts, the pineapple enzyme bromelain, or sheep protein may be at risk for a hypersensitivity reaction to this antivenin; see [Contraindications](#), use caution. ■ Contains 0.11 mg of mercury per vial (ethyl mercury from thimerosal). Exposure from 18-vial dose is 1.9 mg of mercury. Definitive data not available, literature suggests that information related to methyl mercury toxicities may be applicable. ■ Recurrent coagulation abnormalities (e.g., decreased fibrinogen, decreased platelets, and elevated PT) defined as the return of a coagulation abnormality after it has been successfully treated with antivenin, were observed in patients who experienced coagulation abnormalities during their initial hospitalization and occurred in approximately one-half of patients studied. Crotalidae immune fab has a shorter persistence in the blood than crotalid venoms that can leak from depot sites over a prolonged period of time; repeat dosing to prevent or treat such recurrence may be necessary. Optimal dosing to prevent recurrent coagulopathy has not been determined. ■ Use caution if a repeat course of treatment is required for a subsequent envenomation episode, crotalidae immune fab is a foreign protein and antibodies may develop producing sensitivity.

Monitor: Before antivenin is administered, draw adequate blood for baseline studies (e.g., type and cross-match, CBC, hematocrit, platelet count, PT, clot retraction, bleeding and coagulation times, BUN, electrolytes, and bilirubin). ■ Severity of envenomation is based on six body categories: cardiovascular, gastrointestinal, hematologic, local wound (e.g., pain, swelling, and ecchymosis), nervous system, and pulmonary effects. Specific parameters of minimal, moderate, and severe envenomation are outlined in the following chart.

Definition of Minimal, Moderate, and Severe Envenomation Used in Clinical Studies of Crotalidae Polyvalent Immune Fab	
Envenomation Category	Definition
Minimal	<i>Swelling, pain, and ecchymosis</i> limited to the immediate bite site. <i>Systemic signs and symptoms</i> absent. <i>Coagulation parameters</i> normal with no clinical evidence of bleeding.
Moderate	<i>Swelling, pain, and ecchymosis</i> involving less than a full extremity or, if bite was sustained on the trunk, head or neck, extending less than 50 cm. <i>Systemic signs and symptoms</i> may be present but not life-threatening, including but not limited to nausea, vomiting, oral paresthesia or unusual tastes, mild hypotension (systolic BP less than 90 mm Hg), mild tachycardia (HR less than 150), and tachypnea. <i>Coagulation parameters</i> may be abnormal, but no clinical evidence of bleeding present. Minor hematuria, gum bleeding, and nosebleeds are allowed if they are not considered severe in the investigator's judgment.
Severe	<i>Swelling, pain, and ecchymosis</i> involving more than an entire extremity or threatening the airway. <i>Systemic signs and symptoms</i> are markedly abnormal, including severe alteration of mental status, severe hypotension, severe tachycardia, tachypnea, or respiratory insufficiency. <i>Coagulation parameters</i> are abnormal, with serious bleeding or severe threat of bleeding.

■ Anaphylactic and anaphylactoid reactions, delayed hypersensitivity reactions (late serum reaction or serum sickness), and a possible febrile response to immune complexes formed by animal antibodies and neutralized venom components may occur. Observe all patients continuously for signs and symptoms of an acute hypersensitivity reaction (e.g., angioedema, bronchospasm with wheezing or cough, erythema, hypotension, pruritus, stridor, tachycardia, urticaria). ■ Monitor all vital signs at frequent intervals. Observe for signs of shock; treat with IV fluids, blood products, plasma expanders, vasopressors (e.g., dopamine) as indicated. ■ Keep emergency equipment available at all times, including oxygen, epinephrine, antihistamines (e.g., IV diphenhydramine [Benadryl]), corticosteroids, albuterol, vasopressors (e.g., dopamine), and ventilation equipment. ■ Initiate two IV lines as soon as possible; one to be used for supportive therapy, the other for antivenin and electrolytes. ■ A decrease in platelets not responsive to whole blood transfusion can occur with rattlesnake bites, platelet count should approach normal limits within 1 hour of administering crotalidae immune fab. ■ Follow-up monitoring is required for S/S of delayed hypersensitivity reactions or serum sickness (e.g., arthralgia, fever, myalgia, rash). ■ Test urine specimens for microscopic erythrocytes. ■ If coagulation abnormalities occur, consider other disease processes associated with coagulation disorders (e.g., cancer, collagen disease, CHF, diarrhea, elevated temperature, hepatic disorder, hyperthyroidism, poor nutritional state, steatorrhea, vitamin K deficiency). ■ Monitor patients who experience coagulopathy due to snakebite during hospitalization for initial treatment for several weeks after discharge. Recurrent coagulopathy may persist for 2 weeks or more. Assess the need for retreatment and/or use of anticoagulant or antiplatelet agents. ■ Supportive measures to treat other manifestations of the snakebite (e.g., hypotension, pain, swelling, wound infection) should be implemented.

Patient Education: Immediately report any S/S of delayed hypersensitivity reactions or serum sickness (e.g., pruritus, rash, or urticaria occurring after discharge). ■ Promptly report unusual bruising or bleeding (e.g., nosebleeds, excessive bleeding after toothbrushing or superficial injuries, blood in stools or urine, excessive menstrual bleeding, petechiae). May occur for up to 1 week or longer and indicate need for additional treatment.

Maternal/Child: Category C: use during pregnancy only if clearly needed. ■ Use caution, safety for use during breast-feeding not established. ■ Exposure to mercury has been associated with neurological and renal toxicities. Developing fetuses and very young children are most susceptible and are at greater risk.

Elderly: No specific studies on elderly patients.

DRUG/LAB INTERACTIONS

Studies have not been conducted.

SIDE EFFECTS

Pruritus, rash, and urticaria are frequent side effects. Anorexia, back pain, cellulitis, chest pain, chills, circumoral paresthesia, cough, delayed hypersensitivity reactions (late serum reaction or serum sickness), ecchymosis, febrile response to immune complexes formed by animal antibodies and neutralized venom components, general paresthesia, hypersensitivity reactions including anaphylaxis, hypotension, increased sputum, myalgia, nausea, nervousness, recurrent coagulopathy, and wound infection have occurred.

ANTIDOTE

Keep physician informed of all side effects and extent or progression of envenomation. Reduce the rate of administration if infusion-related reactions occur (e.g., fever, low back pain, nausea, wheezing). Monitor closely and discontinue antivenin if symptoms worsen or a hypersensitivity reaction occurs. Treat hypersensitivity reactions and/or anaphylaxis immediately with oxygen, epinephrine, antihistamines (e.g., IV diphenhydramine [Benadryl]), corticosteroids, albuterol, vasopressors (e.g., dopamine), and ventilation equipment as indicated. Recurrent coagulopathy may require re-hospitalization and additional antivenin administration. Resuscitate as necessary.

ANTIVENIN (*LATRODECTUS MACTANS*)

Antivenin

(an-tee-**VEN**-in **lat**-roh-**DEK**-tus **MACK**-tans)

Black Widow Spider Species Antivenin

USUAL DOSE

Testing for sensitivity to horse serum required before use. See [Precautions](#) for additional pretreatment requirements.

Entire contents of 1 vial of antivenin (2.5 mL) is recommended for adults and pediatric patients. One vial is usually enough, but a second dose may be necessary in rare instances. Best results obtained if administered within 4 hours of envenomation.

PEDIATRIC DOSE

Same as adult dose. See [Maternal/Child](#).

DILUTION

Each single dose (6,000 antivenin units) must be initially diluted with 2.5 mL SWFI (supplied). Keep needle in rubber stopper of antivenin and shake vial to dissolve contents completely. Must be further diluted in 10 to 50 mL NS for IV injection.

Storage: Refrigerate unopened vials; do not freeze. Refrigerate reconstituted and/or diluted solution; discard in 6 hours.

COMPATIBILITY

Specific information not available. Administration through a separate line without mixing with other IV fluids or medications is suggested because of specific use and potential for anaphylaxis.

RATE OF ADMINISTRATION

A single dose over a minimum of 15 minutes.

ACTIONS

Prepared from the blood serum of horses immunized against the venom of the black widow spider. One unit will neutralize one average mouse-lethal dose of black widow spider venom when both are injected simultaneously under lab conditions.

INDICATIONS AND USES

Treatment of patients with symptoms resulting from bites of black widow spiders (*Latrodectus mactans*) and similar spiders.

CONTRAINDICATIONS

Hypersensitivity to horse serum unless only treatment available for a life-threatening situation. Several techniques including preload of antihistamine and/or desensitization may be considered (see literature).

PRECAUTIONS

Read drug literature supplied with antivenin completely before use. Essential to evaluate symptoms and individual status of each patient. ■ Determine patient response to any previous injections of serum of any type and history of any hypersensitivity reactions. ■ Hospitalize patient if possible. ■ Muscle relaxants may be the initial treatment of choice in healthy individuals between 16 and 60. Antivenin use may be deferred while patient is observed. ■ Test every patient without exception for sensitivity to horse serum (1-mL vial of 1:10 dilution horse serum supplied). Conjunctival test and skin test recommended for maximum safety. Usually begin with the conjunctival test.

Conjunctival test: Instill 1 drop 1:10 horse serum into conjunctival sac for adults (1 drop 1:100 dilution for pediatric patients). Itching, redness, burning, and/or lacrimation within 10 minutes is a positive reaction. A drop of NS in the opposite eye is used as a control and should be asymptomatic. Reverse adverse effects of positive reaction with 1 drop epinephrine ophthalmic solution.

Skin test: Inject no more than 0.02 mL of 1:10 horse serum intradermally. In patients with a history of allergies, use a 1:100 solution. A similar injection of NS can be used as a control. Compare in 10 minutes. An urticarial wheal surrounded by a zone of erythema is a positive reaction.

- A systemic reaction may occur even when both sensitivity tests are negative. ■ May be given IM. IV preferred in severe cases, if patient is in shock, or in pediatric patients under 12 years of age.

Monitor: Supportive therapy is indicated. 10 mL of 10% calcium gluconate IV may control muscle pain. Morphine may be needed. Barbiturates or diazepam may be used for restlessness. Prolonged warm baths are helpful; corticosteroids have been used. ■ Observe patient constantly for respiratory paralysis. Can occur from toxin alone, and narcotics and sedatives may precipitate respiratory depression. ■ Observe for serum sickness for 8 to 12 days.

Patient Education: Contact physician immediately for any S/S of a delayed hypersensitivity reaction (e.g., rash, pruritus, urticaria) after hospital discharge.

Maternal/Child: Category C: use only if clearly needed. ■ Safety for use in breast-feeding not established. ■ Safety for use in pediatric patients not established, but there have been no adverse effects when used.

DRUG/LAB INTERACTIONS

Concomitant use of **antihistamines** may interfere with sensitivity tests. **Narcotics** and **sedatives** may precipitate respiratory depression.

SIDE EFFECTS

Acute anaphylaxis with urticaria, respiratory distress, and vascular collapse. Serum sickness may occur. Usually appears in 7 to 12 days. Local pain, local erythema, and urticaria without systemic reaction can occur.

ANTIDOTE

Discontinue the drug and notify the physician of all side effects. Treat anaphylaxis immediately. Epinephrine (Adrenalin), diphenhydramine (Benadryl), oxygen, vasopressors (dopamine), corticosteroids, H₂ antagonists (e.g., ranitidine [Zantac]), and ventilation equipment must always be available. Resuscitate as necessary.

ARGATROBAN

(ahr-GAT-troe-ban)

Anticoagulant
pH 3.2 to 7.5

USUAL DOSE

Discontinue all parenteral anticoagulants (e.g., heparin) and obtain baseline blood tests including an aPTT (prophylaxis or treatment) and ACT (PCI) before administration of argatroban; see [Monitor](#).

Prophylaxis or treatment of thrombosis in patients with or at risk for heparin-induced thrombocytopenia (HIT/HITTS): Begin *argatroban* with an initial dose of 2 mcg/kg/min as a continuous infusion. Steady-state levels usually obtained within 1 to 3 hours. Check the aPTT in 2 hours. Adjust the mcg/kg/min dose (not to exceed 10 mcg/kg/min) as clinically indicated until the steady-state aPTT is 1.5 to 3 times the initial baseline value (not to exceed 100 seconds).

Anticoagulant in patients with or at risk for HIT/HITTS undergoing percutaneous coronary interventions (PCI): *Aspirin* 325 mg 2 to 24 hours before planned PCI was administered in studies. After venous or arterial sheaths are in place, begin *argatroban* with an initial infusion of 25 mcg/kg/min via a large-bore IV line. Next, administer a bolus of 350 mcg/kg over 3 to 5 minutes. 5 to 10 minutes after completion of bolus dose, check the ACT. The PCI may proceed if the ACT is greater than 300 seconds but less than 450 seconds. If ACT is less than 300 seconds, give an additional IV bolus of 150 mcg/kg, increase the infusion rate to 30 mcg/kg/min, and check the ACT in 5 to 10 minutes. If ACT is greater than 450 seconds, decrease the infusion rate to 15 mcg/kg/min and recheck the ACT in 5 to 10 minutes. When a therapeutic ACT has been achieved (between 300 and 450 seconds), the infusion dose in effect at the time the therapeutic ACT is achieved should be continued for the duration of the procedure. For situations outside these parameters, see [Dose Adjustment](#). If anticoagulation is required after PCI, continue argatroban, but lower infusion rate to between 2.5 and 5 mcg/kg/min. Draw an aPTT in 2 hours and adjust the infusion rate as clinically indicated (not to exceed 10 mcg/kg/min) to reach an aPTT between 1.5 and 3 times baseline value (not to exceed 100 seconds); see All Situations in [Monitor](#) if transfer to oral anticoagulation is indicated.

DOSE ADJUSTMENTS

All situations: No dose adjustment indicated in patients with impaired renal function, or based on age or gender.

Prophylaxis or treatment of thrombosis in patients with or at risk for heparin-induced thrombocytopenia (HIT/HITTS): Reduce initial dose to 0.5 mcg/kg/min in patients with moderate hepatic impairment. There is a four-fold decrease in argatroban clearance in these patients, titrate dose carefully and monitor aPTT closely.

Anticoagulant in patients with or at risk for HIT/HITTS undergoing percutaneous coronary interventions (PCI): In case of dissection, impending abrupt closure, thrombus formation during the procedure, or inability to achieve or maintain an ACT over 300 seconds, additional bolus doses of 150 mcg/kg may be given and the infusion rate increased to 40 mcg/kg/min. Check the ACT after each additional bolus or change in rate of infusion. ■ See [Precautions](#) for patients with clinically significant liver disease.

DILUTION

Each 250-mg vial must be diluted in 250 mL of NS, D5W, or LR to a concentration of 1 mg/mL. Mix by repeated inversion of the diluent bag for a minimum of 1 minute. Solution may initially be briefly hazy. Do not expose prepared solutions to direct sunlight.

Storage: Store vials in carton at CRT, protected from light and freezing. Diluted solution stable in ambient indoor light for 24 hours at 25° C (77° F), with excursions to 15° to 30° C (59° to 86° F) permitted. Light-resistant measures such as foil protection for IV lines are not necessary. Stable for up to 96 hours protected from light and stored at CRT or refrigerated.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Should not be mixed with other drugs prior to dilution in a suitable IV fluid.” Consider specific use and dose adjustment requirements.

One source suggests the following **compatibilities**:

Y-site: Abciximab (ReoPro), atropine, diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, dopamine, eptifibatid (Integrilin), fenoldopam (Corlopam), fentanyl (Sublimaze), furosemide (Lasix), hydrocortisone sodium succinate (Solu-Cortef), lidocaine, metoprolol (Lopressor), midazolam (Versed), milrinone (Primacor), morphine, nesiritide (Natrekor), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), phenylephrine (Neo-Synephrine), tirofiban (Aggrastat), vasopressin, verapamil.

RATE OF ADMINISTRATION

Prophylaxis or treatment of thrombosis in patients with or at risk for heparin-induced thrombocytopenia (HIT/HITTS):

Argatroban Infusion Rates for 2 mcg/kg/min Dose (1 mg/mL Final Concentration)	
Body Weight (kg)	Infusion Rate (mL/hr)
50 kg	6 mL/hr
60 kg	7 mL/hr
70 kg	8 mL/hr
80 kg	10 mL/hr
90 kg	11 mL/hr
100 kg	12 mL/hr
110 kg	13 mL/hr
120 kg	14 mL/hr
130 kg	16 mL/hr
140 kg	17 mL/hr

Anticoagulant in patients with or at risk for HIT/HITTS undergoing percutaneous coronary interventions (PCI): See [Usual Dose](#) and/or [Dose Adjustments](#) for specific rates and criteria.

ACTIONS

An anticoagulant that is a highly selective synthetic direct thrombin inhibitor. It reversibly binds to the thrombin active site and exerts its anticoagulant effects by inhibiting thrombin-catalyzed or induced reactions, including fibrin formation; activation of coagulation factors V, VIII, and XIII and protein C; and platelet aggregation. Highly selective for thrombin with little or no effect on related serine proteases (trypsin, factor Xa, plasmin, and kallikrein). Inhibits both free and clot-bound thrombin. Does not require the co-factor antithrombin III for antithrombic activity, and does not interact with heparin-induced antibodies. Produces a dose-dependent increase in aPTT, ACT, INR, PT, and TT. Anticoagulant effects are immediate. Steady-state levels of both drug and anticoagulant effect are usually attained within 1 to 3 hours and are maintained until the infusion is discontinued or the dose adjusted. Distribution is primarily in the extracellular fluid. Metabolized in the liver. Half-life range is 39 to 51 minutes. Excreted primarily in feces with some excretion in urine.

INDICATIONS AND USES

An anticoagulant for prophylaxis or treatment of thrombosis in patients with heparin-induced thrombocytopenia (HIT). ■ An anticoagulant in patients with or at risk for heparin-induced thrombocytopenia undergoing percutaneous coronary intervention (PCI). May be used in combination with aspirin.

Unlabeled uses: An alternative to heparin during hemodialysis.

CONTRAINDICATIONS

Hypersensitivity to argatroban or any of its components and patients with overt major bleeding.

PRECAUTIONS

All situations: Use with extreme caution in disease states and other circumstances in which there is an increased danger of hemorrhage, including severe hypertension; immediately following lumbar puncture; spinal anesthesia; major surgery, especially involving the brain, spinal cord, or eye; hematologic conditions associated with increased bleeding tendencies such as congenital or acquired bleeding disorders and gastrointestinal lesions such as ulcerations. ■ Concomitant therapy with thrombolytic agents (e.g., alteplase [tPA], reteplase [Retavase], streptokinase) may increase the risk of bleeding, including life-threatening intracranial bleeding; see [Drug/Lab Interactions](#). ■ Safety and effectiveness of argatroban for cardiac indications other than PCI in patients with HIT not established.

Prophylaxis or treatment of thrombosis: Use caution in patients with hepatic disease, argatroban clearance is decreased four-fold and elimination half-life is increased. Full reversal of anticoagulant effect may require longer than 4 hours. See [Dose Adjustments](#).

PCI: Avoid use of high dose of argatroban in PCI patients with clinically significant hepatic disease or AST/ALT levels greater than 3 times the upper limit of normal. These patients were not included in clinical trials.

Monitor: All situations: Obtain baseline and monitor platelet count, hemoglobin, hematocrit, and occult blood in stool in addition to required aPTT or ACT; see [Usual Dose](#) and specific parameters as follows. ■ Other coagulation tests (e.g., PT, INR, and TT) are affected by argatroban but therapeutic ranges for these tests have not been identified. ■ Observe carefully for symptoms of a hemorrhagic event (e.g., unexplained fall in hematocrit, fall in BP, or any other unexplained symptom). ■ Recovery of platelet count usually occurs by day 3. ■ HIT is a serious, immune-mediated complication of heparin therapy that may result in subsequent venous and arterial thrombosis. Initial treatment of HIT is to discontinue all heparin, but patients still require anticoagulation for prevention and treatment of thromboembolic events. ■ Initiate oral anticoagulation with warfarin (Coumadin) when appropriate. Do not use a loading dose of warfarin, use the expected daily dose. Monitor INR daily. Concurrent use with warfarin results in prolongation of the PT and INR beyond that produced by warfarin alone. With doses of argatroban up to 2 mcg/kg/min, argatroban can be discontinued when the INR is greater than 4 on combined therapy. After argatroban is discontinued, repeat the INR in 4 to 6 hours. If the INR is below the desired therapeutic range, resume the infusion of argatroban and repeat the procedure daily until the desired therapeutic range on warfarin alone is reached. See [Drug/Lab Interactions](#). With doses of argatroban more than 2 mcg/kg/min the INR relationship is less predictable. Reduction of dose to 2 mcg/kg/min is recommended.

Prophylaxis or treatment of thrombosis: Obtain a baseline aPTT before treatment begins. Repeat aPTT in 2 hours, after any dose adjustment, and as indicated to achieve desired target aPTT of 1.5 to 3 times baseline. ■ No enhancement of aPTT response was observed in subjects receiving repeated administration of argatroban. Repeated administration has been tolerated with no loss of anticoagulant activity and no evidence of neutralizing antibodies. No change in dose is required.

PCI: Obtain baseline ACT before dosing; repeat ACT 5 to 10 minutes after bolus dosing, after a change in infusion rate, and at the end of the PCI procedure. Draw additional ACTs every 20 to 30 minutes during a prolonged procedure. ■ Follow standard procedures for maintenance and care of venous or arterial sheaths. Remove sheaths no sooner than 2 hours after discontinuing argatroban and when ACT has decreased to less than 160 seconds. ■ See [Dose Adjustments](#) if anticoagulation is required after PCI.

Patient Education: Report all episodes of bleeding. ■ Report tarry stools. ■ Compliance with all measures to minimize bleeding is very important (e.g., avoid use of razors, toothbrushes, other sharp items). ■ Use caution while moving to avoid excess bumping.

Maternal/Child: Category B: use during pregnancy only if clearly needed. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 18 years of

age not established. ■ Has been used in a small number of pediatric patients with HIT or HITTS who require an alternative to heparin therapy. See package insert for dosing recommendations and monitoring parameters. Clearance is decreased in seriously ill pediatric patients.

Elderly: Response similar to that in younger patients. See [Dose Adjustments](#) for the elderly with impaired liver function.

DRUG/LAB INTERACTIONS

If argatroban is to be initiated after cessation of **heparin** therapy, allow sufficient time for heparin's effect on the aPTT to decrease. ■ Drug interactions have not been demonstrated between argatroban and concomitantly administered **aspirin or acetaminophen**. ■ Risk of bleeding may be increased by any medicine that affects blood clotting, including **anticoagulants** (e.g., heparin, warfarin [Coumadin]); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel [Plavix], dipyridamole [Persantine], glycoprotein GPIIb/IIIa receptor antagonists [e.g., abciximab (ReoPro), eptifibatid (Integrilin), tirofiban (Aggrastat)], plicamycin [Mithracin], sulfipyrazone [Anturane], ticlopidine [Ticlid], valproic acid [Depacon]). If concurrent or subsequent use is indicated, monitor aPTT and PT closely. ■ In clinical testing, was not found to interact with **digoxin or erythromycin** (a potent inhibitor of CYP3A4/5). ■ Concurrent use with **warfarin** results in prolongation of the PT and INR beyond that produced by warfarin alone; see [Monitor](#). The combination causes no further reduction in vitamin K dependent factor Xa than that seen with warfarin alone. Relationship between INR obtained on combined therapy and INR obtained on warfarin alone is dependent on both the dose of argatroban and the thromboplastin reagent used.

SIDE EFFECTS

All situations: Bleeding is the most frequent adverse event. Hypersensitivity reactions (e.g., coughing, dyspnea, hypotension, rash) have been reported, most frequently in patients who also received streptokinase or contrast media.

Prophylaxis or treatment of thrombosis: During clinical trials, intracranial bleeding occurred only in patients with AMI receiving argatroban concurrently with thrombolytic therapy (streptokinase or TPA) and in patients who had an onset of acute stroke within 12 hours of study entry. Other bleeding included a decreased hemoglobin and hematocrit, GI bleeding, GU bleeding, hematuria, hemoptysis, limb and below-knee amputation stump, multisystem hemorrhage and DIC, venous access. Abdominal pain, abnormal renal function, arrhythmias (e.g., atrial fibrillation, ventricular tachycardia), cardiac arrest, cerebrovascular disorder, coughing, diarrhea, fever, hypotension, nausea, pain, pneumonia, sepsis, URI, and vomiting have occurred.

PCI: Retroperitoneal and GI bleeding occurred in a few patients. Other minor bleeding included coronary arteries, a decreased hemoglobin and hematocrit; GI bleeding; GU bleeding; hematuria; groin, hemoptysis, and access site (venous or arterial). Abdominal pain, back pain, bradycardia, chest pain, fever, headache, hypotension. MI and other serious coronary events, nausea, and vomiting have occurred.

Overdose: Symptoms of acute toxicity in animals included clonic convulsions, coma, loss of righting reflex, paralysis of hind limbs, and tremors.

ANTIDOTE

No specific antidote is available. Obtain aPTT, ACT, and/or other coagulation tests. Overdose with or without bleeding may be controlled by discontinuing argatroban or by decreasing the infusion dose; aPTT should return to baseline within 2 to 4 hours after discontinuation. Reversal may take longer in patients with hepatic impairment. If life-threatening bleeding develops and excessive plasma levels of argatroban are suspected, immediately stop argatroban infusion. Determine aPTT and hemoglobin and prepare for blood transfusion as appropriate. Follow current guidelines for treatment of shock as indicated (fluid, vasopressors [e.g., dopamine], Trendelenburg position, plasma expanders [e.g., albumin, hetastarch]). Approximately 20% of argatroban may be cleared through dialysis.

ARSENIC TRIOXIDE **BBW**

Antineoplastic

(AR-sen-ik try-OKS-ide)

Trisenox

pH 7.5 to 8.5

USUAL DOSE

12-lead ECG, serum electrolytes (calcium, magnesium, and potassium), and serum creatinine required before beginning therapy; see **Monitor**.

Induction schedule: 0.15 mg/kg of body weight daily as an infusion until bone marrow remission. Total induction dose should not exceed 60 doses.

Consolidation schedule: Begin 3 to 6 weeks after completion of induction therapy. 0.15 mg/kg daily for 25 doses over a period of up to 5 weeks.

PEDIATRIC DOSE

Pediatric patients from 5 to 16 years of age: See **Usual Dose**. See **Maternal/Child**.

DOSE ADJUSTMENTS

Patients with severe renal impairment (CrCl less than 30 mL/min) or severe hepatic impairment (Child-Pugh Class C) should be closely monitored for toxicity. Dose reduction may be indicated. ■ Use in dialysis has not been studied.

DILUTION

Specific techniques required; see **Precautions.** Ampule contains 10 mg/10 mL (1 mg/mL). Dilute each daily dose with 100 to 250 mL D5W or NS immediately after withdrawal from the ampule and give as an infusion.

Storage: Store ampules at CRT. Do not freeze. Do not use beyond expiration date. Discard unused portions of each ampule, contains no preservatives. Diluted solutions are stable for 24 hours at RT and 48 hours if refrigerated.

COMPATIBILITY

Manufacturer states, "Do not mix arsenic trioxide with other medications."

RATE OF ADMINISTRATION

A single daily dose as an infusion over 1 to 2 hours. May be extended up to 4 hours if acute vasomotor reactions are observed (e.g., flushing, hypertension, hypotension, pallor). May be given through a peripheral vein, a central venous catheter is not required.

ACTIONS

An antineoplastic agent. Mechanism of action not understood. May cause morphologic changes and DNA fragmentation in selected promyelocytic leukemia cells and damage or degrade selected fusion proteins. In clinical trials, median time to bone marrow remission was 44 days and to onset of complete remission (absence of visible leukemic cells in bone marrow and peripheral recovery of platelets and WBC with a confirmatory bone marrow about 30 days later) was 53 days. Responses were seen in all age-groups ranging from 6 to 72 years. Arsenious acid is the pharmacologically active species of arsenic trioxide. Metabolized in the liver (not by the cytochrome P₄₅₀ family of isoenzymes). Elimination half-life is 10 to 14 hours. Arsenic is stored mainly in liver, kidney, heart, lung, hair, and nails. Excreted in urine. Crosses the placental barrier. Secreted in breast-milk.

INDICATIONS AND USES

Induction of remission and consolidation in patients with acute promyelocytic leukemia (APL) who are refractory to, or have relapsed from, retinoid and anthracycline chemotherapy, and whose APL is characterized by the presence of the t(15;17) translocation or PML/RAR-alpha gene expression.

Unlabeled uses: Orphan drug status for treatment of chronic myeloid leukemia (CML), acute promyelocytic leukemia (APL), multiple myeloma (MM), malignant glioma, myelodysplastic syndrome, liver cancer, and chronic lymphocytic leukemia (CLL).

CONTRAINDICATIONS

Known hypersensitivity to arsenic.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of a physician experienced in the management of patients with acute leukemia, with facilities for monitoring the patient and responding to any medical emergency. ■ Symptoms similar to those associated with retinoic-acid–acute promyelocytic leukemia (RA-APL) or APL differentiation syndrome (dyspnea, fever, pleural or pericardial effusions, pulmonary infiltrates, and weight gain with or without leukocytosis) have been reported in some patients treated with arsenic trioxide and can be fatal. See **Monitor** and **Antidote**. ■ May cause QT interval prolongation and complete atrioventricular block. QT prolongation can lead to torsades de pointes, which can be fatal. Risk of torsades de pointes is increased by extent of QT prolongation, concomitant administration of QT prolonging drugs, a history of torsades de pointes, pre-existing QT interval prolongation, congestive heart failure, administration of potassium-wasting diuretics, or other conditions that result in hypokalemia or hypomagnesemia; see **Drug/Lab Interactions**. QT prolongation was observed between 1 and 5 weeks after infusion and returned toward baseline by the end of 8 weeks after infusions were complete. ■ Has been associated with the development of hyperleukocytosis. WBC counts during induction were higher than during consolidation. Treatment with additional chemotherapy was not required. ■ Use caution in patients with impaired renal function; exposure may be increased. Monitor patients with severe renal impairment (CrCl less than 30 mL/min) closely for toxicity; dose reduction may be required. ■ Use with caution in patients with impaired hepatic function. Data are limited. Monitor patients with severe hepatic impairment (Child-Pugh Class C) closely for toxicity.

Monitor: Before initiating therapy: Obtain baseline 12-lead ECG, CBC with differential, platelet count, coagulation profile (e.g., PT), serum electrolytes (e.g., calcium, magnesium, and potassium), and serum creatinine. Correct pre-existing electrolyte abnormalities and, if possible, discontinue drugs that are known to prolong the QT interval; see **Drug/Lab Interactions**. If the QT interval is greater than 500 msec, corrective measures should be completed and the QT interval reassessed with serial ECGs before starting arsenic trioxide. **During therapy:** Monitor electrolytes, CBC (including differential), platelet count, and coagulation profile (e.g., PT) at least twice weekly during induction and weekly during consolidation. May be indicated more frequently. Keep potassium concentrations above 4 mEq/dL and magnesium concentrations above 1.8 mg/dL. ■ Monitor ECG weekly and more frequently in unstable patients. No data on the effect of arsenic trioxide on the QT interval during the infusion. If the QT interval is greater than 500 msec at any time during therapy, reassess the patient, correct concomitant risk factors, and consider risk/benefit of continuing versus suspending arsenic trioxide. If syncope or rapid or irregular heartbeat develops, the patient should be hospitalized for ECG monitoring and monitoring of serum electrolytes. Temporarily discontinue arsenic trioxide. Do not resume therapy until the QT interval is less than 460 msec, electrolyte abnormalities are corrected, and syncope and irregular heartbeat cease. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for signs of APL differentiation syndrome (e.g., abnormal chest auscultatory findings or radiographic abnormalities, dyspnea, weight gain, and unexplained fever). If symptoms occur, irrespective of the leukocyte count, begin immediate treatment with high-dose steroids (e.g., dexamethasone 10 mg IV twice daily); continue for at least 3 days or longer until S/S resolve. Termination of arsenic trioxide treatment is not usually required. ■ See **Precautions**.

Patient Education: Avoid pregnancy, may cause fetal harm. Nonhormonal birth control recommended. Notify physician immediately if a pregnancy is suspected. ■ Report dizziness, dyspnea, fainting, fever, rapid or irregular heartbeat, and weight gain immediately. ■ Review all prescription and nonprescription drugs with your physician. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. May cause fetal harm. Effective birth control required. ■ Discontinue breast-feeding. ■ Limited clinical data for pediatric use. In one study, five patients ranging in age from 5 to 16 years were included in clinical studies, and three achieved a complete response. In another study, the toxicity profile ob-

served in 13 pediatric patients was similar to that seen in adults. ■ Safety and effectiveness for pediatric patients under 4 years of age not established.

Elderly: Response similar to that in younger patients. ■ Monitor renal function closely.

DRUG/LAB INTERACTIONS

Concurrent use with **other drugs that prolong the QT interval, including antiarrhythmics** (e.g., amiodarone [Nexterone], disopyramide [Norpace], ibutilide [Corvert], mexiletine, procainamide [Pronestyl], quinidine), **antihistamines, azole antifungals** (e.g., itraconazole [Sporanox]), **fluoroquinolones** (e.g., levofloxacin [Levaquin]), **phenothiazines** (e.g., thioridazine [Mellaril]), **and tricyclic antidepressants** (e.g., amitriptyline [Elavil], imipramine [Tofranil]); may cause torsades de pointes and could be fatal. ■ Concurrent use with drugs that may cause hypokalemia or other electrolyte abnormalities (e.g., **amphotericin B, diuretics** [e.g., furosemide (Lasix)]) may increase the risk of hypokalemia and cardiac arrhythmias.

SIDE EFFECTS

Abdominal pain, anemia, chest pain, cough, diarrhea, dizziness, dyspnea, edema, fatigue, headache, hyperglycemia, hyperkalemia, hypertension, hypokalemia, hypomagnesemia, hypotension, hypoxia, itching, leukocytosis, nausea, neutropenia (may be febrile), palpitations, pleural effusion, rash, thrombocytopenia, URI, and vomiting. Numerous other side effects have been reported (see literature).

Major: Adverse events rated Grade 3 or 4 on the Common Terminology Criteria for Adverse Events (CTCAE) were common. APL differentiation syndrome, atrial arrhythmias, hyperglycemia, hyperleukocytosis, QT interval 500 msec or more (with or without torsades de pointes) also occurred.

Overdose: Acute arsenic toxicity (e.g., confusion, convulsions, and muscle weakness).

Post-Marketing: Pancytopenia, peripheral neuropathy, ventricular extrasystoles, and tachycardia associated with QT prolongation.

ANTIDOTE

Keep physician informed of all side effects. Those classified as average will usually be treated symptomatically. Major side effects may be fatal and require aggressive treatment as well as temporarily withholding or discontinuing arsenic trioxide. In all situations, monitor electrolytes; maintain potassium and magnesium within prescribed limits. Treat APL differentiation syndrome immediately with high-dose steroids (dexamethasone [Decadron] 10 mg IV twice daily) for at least 3 days or until signs and symptoms resolve (interruption of arsenic trioxide therapy not consistently required). Temporarily discontinue arsenic trioxide for QT prolongation 500 msec or more; see **Monitor** for recommendations and treat any serious or symptomatic arrhythmia (e.g., conduction abnormalities, VT, torsades de pointes) promptly. Discontinue therapy and treat acute arsenic intoxication with dimercaprol (BAL) 3 mg/kg IM every 4 hours until immediate life-threatening toxicity subsides. Then treat with penicillamine 250 mg PO up to four times a day (approximately 1 Gm/day). Hyperleukocytosis was not treated with additional chemotherapy during clinical trials.

ASCORBIC ACID

(a-SKOR-bik AS-id)

Nutritional supplement
(vitamin)**Sodium Ascorbate, Vitamin C**

pH 5.5 to 7

USUAL DOSE

Up to 6 Gm/24 hr has been given without toxicity.

Nutritional protection: 70 to 150 mg daily. 100 to 200 mg daily may be required during chronic dialysis.**Prevention or treatment of scurvy:** 300 to 1,000 mg daily. Another source suggests 100 to 250 mg 1 to 3 times daily. Give for a minimum of several days; up to 2 to 3 weeks may be indicated.**Enhance wound healing:** 300 to 500 mg daily for 7 to 10 days.**Burns:** 1 to 2 Gm daily.**PEDIATRIC DOSE****Nutritional protection:** 30 mg daily. Another source suggests 35 to 100 mg/day. **Premature infants** may require 75 to 100 mg daily.**Prevention or treatment of scurvy:** 100 to 300 mg/24 hr. May be given once daily or divided into two doses (BID). Give for a minimum of several days; up to 2 to 3 weeks may be indicated.**DILUTION**

Pressure may develop within a vial during storage. Use care when withdrawing and/or relieve pressure by first inserting a sterile, empty syringe into vial to release pressure. Dilution in a large volume of NS or Dextrose solution is recommended. Soluble in the more commonly used solutions, such as D5W, D5NS, NS, LR, Ringer's injection, or sodium lactate injection. Slight coloration does not affect the medication.

Storage: Protect from freezing and from light. Storage requirements are product specific and range from 2° to 8° C (36° to 46° F) to below 25° C (77° F).**COMPATIBILITY**(Underline Indicates Conflicting Compatibility Information)**Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.**One source suggests the following **compatibilities:****Additive:** Amikacin (Amikin), aminophylline, calcium chloride, calcium gluconate, chloramphenicol (Chloromycetin), chlorpromazine (Thorazine), colistimethate (Coly-Mycin M), diphenhydramine (Benadryl), erythromycin (Erythrocin), heparin, methyl dopate, penicillin G potassium, prochlorperazine (Compazine), promethazine (Phenergan), verapamil.**Y-site:** Warfarin (Coumadin).**RATE OF ADMINISTRATION****Infusion:** Administer at ordered rate for standard infusion (e.g., over 4 to 8 hours). Avoid too-rapid injection.**ACTIONS**

This water-soluble vitamin is necessary for the formation of collagen in all fibrous tissue, carbohydrate metabolism, connective tissue repair, maintenance of intracellular stability of blood vessels, and many other body functions. Not stored in the body. Daily requirements must be met. Completely utilized; excess is excreted unchanged in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Prevention and treatment of vitamin C deficiency, which may lead to scurvy. ■ Give pre-op and post-op to enhance wound healing. ■ Prolonged IV therapy. ■ Increased vitamin requirements or replacement therapy in severe burns, extensive injuries, and severe infections. ■ Prematurity. ■ Deficient intestinal absorption of water-soluble vita-

mins. ■ Prolonged or wasting diseases. ■ Hemovascular disorders and delayed fracture and wound healing require increased intake.

CONTRAINDICATIONS

There are no absolute contraindications.

PRECAUTIONS

Vitamin C is better absorbed and utilized by IM injection. ■ Use caution in cardiac patients. ■ Use caution in diabetics and patients prone to recurrent renal calculi or undergoing stool occult blood tests. May contain sulfites; use caution in allergic individuals. ■ Some products may contain aluminum; use with caution in neonates and in patients with renal insufficiency.

Monitor: Increased urinary excretion is diagnostic for vitamin C saturation. ■ Continue curative doses until clinical symptoms subside or urinary saturation occurs.

Maternal/Child: Category C: use caution in pregnancy and breast-feeding; high dose may adversely affect fetus.

DRUG/LAB INTERACTIONS

Potentiates **oral contraceptives and ferrous iron absorption**. ■ May antagonize **anticoagulants**. ■ 2 Gm/day will lower urine pH and will cause reabsorption of **acidic drugs and crystallization with sulfonamides**. ■ May cause false-negative **occult blood** in stool. ■ May cause false-positive or false-negative results in **urine glucose tests**. ■ **Can alter numerous test results**; must be individually evaluated.

SIDE EFFECTS

Occur only with too-rapid injection: temporary dizziness or faintness. Diarrhea or renal calculi may occur with large doses.

ANTIDOTE

Discontinue administration temporarily. Resume administration at a decreased rate. If side effects persist, discontinue drug and notify the physician.

ASPARAGINASE(ah-**SPAIR**-ah-jin-ays)**Elspar, Kidrolase** Antineoplastic
(enzyme)

pH 7.4

USUAL DOSE

(International units [IU])

ADULTS AND PEDIATRIC PATIENTS

Therapeutic dose may be given IV or IM.

Skin test: Often recommended before initial dose and after several days elapse between doses. See **Dilution** for preparation. Give 2 International units (IU) intradermally and observe for 1 hour for the appearance of a wheal or erythema.**Intermittent IV:** 6,000 IU/M² three times a week. Very specific amount to be given on a specific day or days in a specific regimen with other chemotherapeutic agents. When used as a single agent (rare unless combination therapy is not appropriate), the usual dose for adults and pediatric patients is 200 IU/kg/day for 28 days.**Desensitization process for administration:** Extensive process. See drug literature.**DILUTION**

(International units [IU])

Specific techniques required; see Precautions. Initially reconstitute each 10-mL vial (10,000 IU) with 4 mL of SWFI for Kidrolase and 5 mL of SWFI or NS for Elspar. Both result in 2,000 IU/mL.**Skin test:** Withdraw 0.1 mL from the above solution and further dilute with 9.9 mL NS (20 IU/mL). 0.1 mL of this solution equals 2 IU.**Intermittent IV:** Draw up calculated dose into a syringe. Administer through Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS. Use only clear solutions.**Filters:** May contain fiberlike particles; use of 5-micron in-line filter recommended. Loss of potency has been observed with the use of a 0.2-micron filter.**Storage:** Refrigerate before and after dilution. Discard Elspar after 8 hours. Reconstituted Kidrolase may be refrigerated up to 14 days. Discard any solution that is cloudy.**COMPATIBILITY****Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.**One source suggests the following **compatibilities:****Y-site:** Methotrexate, sodium bicarbonate.**RATE OF ADMINISTRATION****Intermittent IV:** Each dose evenly distributed over at least 30 minutes.**ACTIONS**An enzyme derived from *Escherichia coli* that rapidly depletes asparagine from cells. Some leukemic cells have a metabolic defect that makes them dependent on exogenous asparagine for survival. They are unable to synthesize asparagine as normal cells do. Undergoes metabolic degradation. Range of plasma half-life is 8 to 30 hours. Trace amounts excreted in urine.**INDICATIONS AND USES**

A component of a multi-agent chemotherapeutic regimen for the treatment of acute lymphoblastic leukemia (ALL). ■ Not indicated for use as a single agent unless combination therapy is not appropriate.

Unlabeled uses: Treatment of lymphoblastic lymphoma, acute lymphocytic leukemia.**CONTRAINDICATIONS**Hypersensitivity to asparaginase or *Escherichia coli* proteins, or a history of pancreatitis, thrombosis, or serious hemorrhagic events with prior asparaginase or other *E. coli*-derived L-asparaginase therapy.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist in a hospital setting with facilities for monitoring the patient and responding to any medical emergency. ■ Hypersensitivity reactions are frequent. Risk is increased if patient has received asparaginase before. ■ Serious thrombotic events, including sagittal sinus thrombosis, have been reported. ■ Pancreatitis, including fulminant and fatal cases, has been reported. ■ Glucose intolerance has been reported and may be irreversible. ■ Coagulopathies (e.g., increased PTT, increased aPTT, and hypofibrinogenemia) can occur. CNS hemorrhages have been observed. ■ Rarely used as a single agent; not recommended for maintenance therapy.

Monitor: Observe patient carefully during and after infusion. Monitor BP and respiratory status every 15 minutes for at least 1 hour. ■ Appropriate treatment for anaphylaxis must always be available. ■ Obtain baseline serum glucose and coagulation parameters and repeat periodically during and after therapy. ■ Evaluate patients with abdominal pain for pancreatitis. ■ Allopurinol, increased fluid intake, and alkalization of the urine may be required to reduce uric acid levels. ■ Frequent blood cell counts, bone marrow evaluation, serum amylase, and evaluation of liver and kidney function are necessary. ■ Nausea and vomiting can be severe. Prophylactic administration of antiemetics recommended to increase patient comfort. ■ Predisposition to infection probable. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Report all symptoms promptly; verbalize all questions. ■ Assess birth control requirements. Nonhormonal contraception advised. ■ See Appendix D, p. 1255.

Maternal/Child: Category C: will have teratogenic effects on the fetus. Evaluate benefit versus risk for anyone who is pregnant or may become pregnant. ■ Discontinue breastfeeding.

Elderly: Not usually used in the geriatric population.

DRUG/LAB INTERACTIONS

Formal drug interactions studies have not been performed. ■ Do not administer any **live virus vaccine** to patients receiving antineoplastic drugs. ■ See **Precautions**.

SIDE EFFECTS

The most common side effects are hypersensitivity reactions (including anaphylaxis), CNS thrombosis, coagulopathy, elevated transaminases, hyperbilirubinemia, hyperglycemia, and pancreatitis. Other side effects include agitation, azotemia, bleeding, bone marrow suppression, coma, confusion, depression, fatigue, hallucinations, hepatitis, hyperthermia (fatal), hypofibrinogenemia and depression of other clotting factors, liver function abnormalities (increased ALT, AST, alkaline phosphatase, and bilirubin; decreased albumin), nausea and vomiting, and seizures.

ANTIDOTE

Notify physician of all side effects. Discontinue asparaginase in patients with serious hypersensitivity reactions, serious thrombotic events, and pancreatitis. If other side effects occur, asparaginase may need to be discontinued until recovery or permanently discontinued. Symptomatic and supportive treatment is indicated. Treat anaphylaxis with epinephrine, corticosteroids, oxygen, and antihistamines. Administration of fresh frozen plasma may be indicated to replace coagulation factors in patients with severe or symptomatic coagulopathy. There is no specific antidote.

ATRACURIUM BESYLATE **BBW**(ah-trah-KYOUR-ee-um **BES**-ih-layt)Neuromuscular blocking agent
(nondepolarizing)
Anesthesia adjunct**Atracurium Besylate PF, Tracrium**

pH 3.25 to 3.65

USUAL DOSE

Adjunct to general anesthesia for adults and pediatric patients over 2 years of age: Must be individualized, depending on previous drugs administered and degree and length of muscle relaxation required. 0.4 to 0.5 mg/kg of body weight initially as an IV bolus. Must be used with adequate anesthesia and/or sedation and after unconsciousness induced. To maintain muscle relaxation during prolonged surgical procedures, a maintenance dose of 0.08 to 0.1 mg/kg may be given as a bolus injection. The first maintenance dose is usually required 20 to 45 minutes after the initial bolus and may be repeated every 15 to 25 minutes. Higher maintenance doses (up to 0.2 mg/kg) permit maintenance dosing at longer intervals. Repeated doses have no cumulative effect if recovery is allowed to begin before administration. A peripheral nerve stimulator is used to determine the beginning symptoms of neuromuscular blockade reversal. May alternately be given as a continuous IV infusion. An initial infusion rate of 9 to 10 mcg/kg/min may be required to counteract the spontaneous recovery of neuromuscular function. Thereafter a rate of 5 to 9 mcg/kg/min may be adequate. Rates as low as 2 or as high as 15 mcg/kg/min may be required. Repeated doses have no cumulative effect if recovery is allowed to begin before administration.

Adjunct to general anesthesia for infants and children 1 month to 2 years of age: 0.3 to 0.4 mg/kg for infants and children under halothane anesthesia. See [Usual Dose](#) for maintenance dose; may be required more frequently.

Support of intubated, mechanically ventilated, adult ICU patients: An initial infusion rate of 11 to 13 mcg/kg/min (range 4.5 to 29.5) provides adequate neuromuscular blockade. Published reports describe a wide interpatient variability in dosing requirements, and requirements may increase or decrease with time. Re-administration of a bolus dose may be necessary to re-establish neuromuscular block following recovery and before reinstitution of the infusion.

DOSE ADJUSTMENTS

Reduce dose by one third (0.25 to 0.35 mg/kg) if isoflurane or enflurane are used as general anesthetics. ■ Reduce dose to 0.3 to 0.4 mg/kg in patients with a history of cardiovascular disease, a history suggesting greater risk of histamine release (allergies), or following succinylcholine administration. Succinylcholine must show signs of wearing off before atracurium is given. Use caution. ■ Reduce maintenance dose by one half when hypothermia is induced (e.g., during cardiac bypass). Consider reduced doses in patients with neuromuscular disease, severe electrolyte disorders, or carcinomatosis in which potentiation of neuromuscular block or difficulties with reversal have been demonstrated. ■ No dose adjustment required in patients with renal disease. ■ See [Drug/Lab Interactions](#).

DILUTION

Initial IV bolus may be given undiluted. Maintenance dose for anesthesia and mechanical ventilation support may be further diluted in NS, D5W, or D5NS and given as a continuous infusion titrated to symptoms of neuromuscular blockade reversal. 20 mg (2 mL) diluted in 98 mL yields 200 mcg/mL (0.2 mg/mL). 50 mg (5 mL) diluted in 95 mL yields 500 mcg/mL (0.5 mg/mL).

Storage: Refrigerate in carton at 2° to 8° C (36° to 46° F), protect from light, and do not freeze. If removed to RT, it must be used within 14 days even if re-refrigerated. Diluted solution stable for 24 hours refrigerated or at room temperature; discard after 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Ciprofloxacin (Cipro IV), dobutamine, dopamine, esmolol (Brevibloc), gentamicin, isoproterenol (Isuprel), lidocaine, morphine, potassium chloride (KCl), procainamide (Pronestyl), vancomycin.

Y-site: Amiodarone (Nexterone), cefazolin (Ancef), cefuroxime (Zinacef), dexmedetomidine (Precedex), dobutamine, dopamine, epinephrine (Adrenalin), esmolol (Brevibloc), etomidate (Amidate), fenoldopam (Corlopam), fentanyl (Sublimaze), gentamicin, heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), isoproterenol (Isuprel), lorazepam (Ativan), midazolam (Versed), milrinone (Primacor), morphine, nitroglycerin IV, nitroprusside sodium, propofol (Diprivan), ranitidine (Zantac), sulfamethoxazole/trimethoprim, vancomycin.

RATE OF ADMINISTRATION

In adults or pediatric patients, adjust infusion rate according to clinical assessment of the patient's response. Use of a peripheral nerve stimulator is recommended.

Adjunct to general anesthesia: Initial IV bolus over 30 to 60 seconds.

Maintenance dose: In the 200 mcg/mL dilution, 5 mcg/kg/min will be delivered by a rate of 0.025 mL/kg/min or 1.75 mL/min for a 70-kg patient (105 mL/hr). Adjust rate to specific dose desired. Drug literature has additional rate calculations.

Mechanical ventilation support in ICU: See **Usual Dose** for specific rates and criteria.

ACTIONS

A nondepolarizing skeletal muscle relaxant. A less potent histamine releaser than metocurine. Causes paralysis by interfering with neural transmission at the myoneural junction. Onset of action is dose dependent. Produces maximum neuromuscular blockade within 3 to 5 minutes and lasts about 25 minutes. When infusion is discontinued, some recovery occurs within 30 minutes. Recovery to 75% averages 60 minutes (range 32 to 108 minutes). It may be several hours before complete recovery occurs. Excreted as metabolites in bile and urine. Crosses the placental barrier.

INDICATIONS AND USES

Adjunctive to general anesthesia to facilitate endotracheal intubation and to relax skeletal muscles during surgery or mechanical ventilation.

CONTRAINDICATIONS

Known hypersensitivity to atracurium.

PRECAUTIONS

For IV use only. ■ Administered by or under the observation of the anesthesiologist. Appropriate emergency drugs and equipment for monitoring the patient and responding to any medical emergency must be readily available. ■ Use extreme caution in patients with significant cardiovascular disease or a history of allergies or allergic reaction. ■ Severe anaphylactic reactions have been reported with neuromuscular blocking agents; some have been fatal. Use caution in patients who have had an anaphylactic reaction to another neuromuscular blocking agent (depolarizing or nondepolarizing); cross-reactivity has occurred. ■ Myasthenia gravis and other neuromuscular diseases increase sensitivity to drug. Can cause critical reactions. ■ Respiratory depression with propofol (Diprivan) or morphine may be preferred in some patients requiring mechanical ventilation. ■ Bradycardia is fairly common since atracurium will not counteract the bradycardia produced by many anesthetic agents or vagal stimulation. ■ Acid-base and/or electrolyte imbalance, debilitation, hypoxic episodes, and/or the use of other drugs (e.g., broad-spectrum antibiotics, narcotics, steroids) may prolong the effects of atracurium.

Monitor: This drug produces apnea. Controlled artificial ventilation with oxygen must be continuous and under direct observation at all times. Maintain a patent airway. ■ Use a peripheral nerve stimulator to monitor response to atracurium and avoid overdose. ■ Patient may be conscious and completely unable to communicate by any means. Has no analgesic or sedative properties. ■ Action potentiated by hypokalemia and some carci-

nomas. ■ Action is altered by dehydration, electrolyte imbalance, body temperature, and acid-base imbalance. **Mechanical ventilation support in ICU:** Physical therapy is recommended to prevent muscular weakness, atrophy, and joint contracture. Muscular weakness may be first noticed during attempts to wean patient from the ventilator.

Maternal/Child: Category C: use in pregnancy only if use justifies potential risk to fetus. Has been used during cesarean section; monitor infant carefully. ■ Use caution during breast-feeding. ■ Safety for use in infants under 1 month of age not established. ■ Contains benzyl alcohol; may cause “gassing syndrome” in premature infants.

Elderly: No adjustments identified.

DRUG/LAB INTERACTIONS

Potentiated by **general anesthetics** (e.g., enflurane, isoflurane, halothane), **many antibiotics** (e.g., lincosamides [clindamycin (Cleocin)], aminoglycosides [kanamycin, gentamicin], polypeptides [bacitracin, colistimethate]), **corticosteroids, diuretics, diazepam (Valium) and other muscle relaxants, magnesium sulfate, meperidine, morphine, procainamide (Pronestyl), quinidine, succinylcholine, verapamil, and others.** May need to reduce dose of atracurium; use with caution. ■ Duration of neuromuscular block may be shorter and dose requirements may be higher during maintenance infusion in patients stabilized on **carbamazepine (Tegretol) and phenytoin (Dilantin).** ■ Antagonized by **acetylcholine, anticholinesterases, azathioprine, and theophylline.** ■ **Succinylcholine** must show signs of wearing off before atracurium is given. Use caution.

SIDE EFFECTS

Prolonged action resulting in respiratory insufficiency or apnea. Airway closure caused by relaxation of epiglottis, pharynx, and tongue muscles. Hypersensitivity reactions including anaphylaxis are possible. Bradycardia, bronchospasm, dyspnea, flushing, histamine release, hypotension, laryngospasm, reaction at injection site, shock, and tachycardia may occur. Rare reports of seizures with use of atracurium in ICU could be caused by other conditions or medications. Malignant hyperthermia is rare but may occur.

ANTIDOTE

All side effects are medical emergencies. Treat symptomatically. Controlled artificial ventilation must be continuous. Pyridostigmine (Regonol) or neostigmine given with atropine will probably reverse the muscle relaxation. Not effective in all situations; may aggravate severe overdosage. Resuscitate as necessary.

ATROPINE SULFATE

(AH-troh-peen SUL-fayt)

Anticholinergic
Antiarrhythmic
Antidote

pH 3.5 to 6.5

USUAL DOSE

Bradycardias: AHA guidelines recommend 0.5 mg every 3 to 5 minutes as needed, the **total dose not to exceed 0.04 mg/kg (3 mg).** The use of shorter dosing intervals (3 minutes) and higher maximum dose range (0.04 mg/kg) is suggested in severe clinical conditions. Another source suggests 0.5- to 1-mg bolus repeated every 3 to 5 minutes up to a total dose of 2 mg to achieve a desired pulse rate above 60. Subsequent doses of 0.5 to 1 mg may be given at 4- to 6-hour intervals. Doses under 0.5 mg may cause paradoxical slowing of HR.

Smooth muscle relaxation and suppression of secretions: 0.4 to 0.6 mg every 4 to 6 hours.

During surgery: Above doses appropriate except during cyclopropane anesthesia. Start with 0.4 mg or less. Administer very slowly to avoid ventricular arrhythmias; see [Drug/Lab Interactions](#).

Cardiac asystole or pulseless electrical activity: AHA guidelines state, “Routine use during pulseless electrical activity or asystole is unlikely to have a therapeutic benefit.”

Antidote to reverse muscarinic effects of anticholinesterase agents: 0.6 to 1.2 mg for each 0.5 to 2.5 mg of neostigmine or 10 to 20 mg of pyridostigmine administered. Administer in a separate syringe, concurrently or a few minutes before the anticholinesterase agent. If bradycardia is present, bring pulse up to 80 by giving IV atropine first. See neostigmine, pyridostigmine, or physostigmine monographs.

Antidote for acute poisoning from exposure to anticholinesterase compounds (e.g., organophosphate pesticides, nerve gases, and mushroom poisoning): 1 to 2 mg may be given in a single dose and repeated every 5 to 60 minutes. In severe poisoning 2 to 6 mg may be given and repeated at 5- to 60-minute intervals until muscarinic signs and symptoms subside and repeated if they appear. Up to 50 mg may be required in the first 24 hours. Use oral atropine for maintenance; withdraw gradually to avoid recurrence of symptoms (e.g., pulmonary edema). A cholinase reactivator (e.g., pralidoxime) is administered concomitantly except in carbamate exposure.

PEDIATRIC DOSE

Fatal dose of atropine in pediatric patients may be as low as 10 mg. See [Maternal/Child](#).

Bradycardias: 0.01 to 0.03 mg/kg of body weight can be used to achieve a pulse rate above 80 in a distressed infant under 6 months or above 60 in a child. Minimum dose is 0.1 mg. Maximum single dose is 0.5 mg in a child, 1 mg for an adolescent. May be repeated in 5-minute intervals two times. AHA guidelines recommend 0.02 mg/kg. May repeat dose one time. Maximum total dose for a child is 1 mg, for an adolescent 3 mg. When used for bradycardia or asystole in infants and small children, vagolytic doses are required. Doses less than 0.1 mg may cause paradoxical bradycardia.

Smooth muscle relaxation and suppression of secretions: 0.01 mg/kg. Minimum dose is 0.1 mg in the newborn; up to 0.4 mg for a 12 year old. Usually given SC. May repeat every 4 to 6 hours.

Bronchospasm: 0.05 mg/kg in 2.5 mL NS every 6 to 8 hours. Minimum dose 0.25 mg; maximum dose is 1 mg.

Antidote to reverse muscarinic effects of anticholinesterase agents: 0.02 mg/kg of atropine concomitantly with 0.04 mg/kg of neostigmine. See [Usual Dose](#) for additional information.

Antidote for acute poisoning from exposure to anticholinesterase compounds (e.g., organophosphate compounds, nerve gases, mushroom poisoning): 0.05 mg/kg; repeat every 10 to 30 minutes until muscarinic signs and symptoms subside, and repeat if they reappear. See [Usual Dose](#) for additional information.

DOSE ADJUSTMENTS

Reduced dose may be indicated in the elderly. ■ See [Drug/Lab Interactions](#) and [Pediatric Dose](#).

DILUTION

May be given undiluted, but may prefer to dilute desired dose in at least 10 mL of SWFI. Do not add to IV solutions. Inject through Y-tube or three-way stopcock of infusion set. Also available in combination with edrophonium (Enlon-Plus) to reverse cholinesterase toxicity caused by reversal of nondepolarizing muscle relaxants.

COMPATIBILITY

[\(Underline Indicates Conflicting Compatibility Information\)](#)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following compatibilities:

Additive: Dobutamine, furosemide (Lasix), meropenem (Merrem IV), sodium bicarbonate, verapamil.

Y-site: Abciximab (ReoPro), amiodarone (Nexterone), argatroban, bivalirudin (Angio-max), dexmedetomidine (Precedex), doripenem (Doribax), etomidate (Amidate), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), meropenem

(Merrem IV), methadone (Dolophine), morphine, nafcillin (Nallpen), palonosetron (Aloxi), potassium chloride (KCl), propofol (Diprivan), tirofiban (Aggrastat).

RATE OF ADMINISTRATION

1 mg or fraction thereof over 1 minute.

ACTIONS

Atropine is an anticholinergic drug and a potent belladonna alkaloid. It produces local, central, and peripheral effects on the body. The main therapeutic uses of atropine are peripheral, affecting smooth muscle, cardiac muscle, and gland cells. Reverses cholinergic-mediated decreases in HR, systemic vascular resistance, and BP. This drug can interfere with vagal stimuli. It is widely distributed in all body fluids. Metabolized by the liver and excreted in urine and bile. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of symptomatic sinus bradycardia, syncope from Stokes-Adams syndrome, and high-degree atrioventricular block with profound bradycardia. ■ AHA guidelines recommend as the primary drug to treat symptomatic sinus bradycardia and as the second drug (after) epinephrine for asystole or pulseless electrical activity. ■ Suppression of salivary, gastric, pancreatic, and respiratory secretions. ■ To relieve pylorospasm, hypertonicity of the small intestine, and hypermotility of the colon. ■ To relieve biliary and ureteral colic. ■ Antidote to reverse cholinesterase toxicity (muscarinic effects) caused by reversal of nondepolarizing muscle relaxants by neostigmine, physostigmine, and pyridostigmine. ■ Antidote for specific poisons such as organophosphorus insecticides, nerve gases, and mushroom poisoning (*Amanita muscaria*). ■ Temporary, reversible muscarinic blockade when excessive (or sometimes normal) muscarinic effects are judged to be life threatening or are producing severe symptoms. ■ Used in combination with many other drugs to produce a desired effect (e.g., edrophonium [Enlon, Enlon-Plus]).

CONTRAINDICATIONS

Hypersensitivity to atropine, acute glaucoma, acute hemorrhage with unstable cardiovascular status, asthma, hepatic disease, intestinal atony of the elderly or debilitated, myasthenia gravis, myocardial ischemia, obstructive disease of the GI or GU tracts, paralytic ileus, pyloric stenosis, renal disease, severe ulcerative colitis, tachycardia, toxic megacolon.

PRECAUTIONS

Use caution in prostatic hypertrophy, chronic lung disease, infants and small children, the elderly and debilitated, in urinary retention, during cyclopropane anesthesia, and in myocardial ischemia or infarction. ■ Increases myocardial oxygen demand and can trigger tachyarrhythmias. ■ Doses less than 0.5 mg may further slow HR. ■ May be given endotracheally. ■ Considered possibly harmful in AV block at the His-Purkinje level or with newly appearing wide QRS complexes.

Monitor: Vital signs and/or ECG based on specific situation.

Patient Education: Use caution if task requires alertness; may cause blurred vision, dizziness, or drowsiness. ■ Report eye pain, flushing, or skin rash promptly. ■ Report dry mouth, difficulty urinating, constipation, or increased light sensitivity.

Maternal/Child: Category C: safety for use in pregnancy, breast-feeding, and pediatric patients not established. ■ Toxicity to nursing infants probable.

Elderly: May produce excitement, agitation, confusion, or drowsiness. ■ May precipitate undiagnosed glaucoma. ■ Potential for constipation and urinary retention increased. ■ Has potential to increase memory impairment. ■ See [Dose Adjustments and Precautions](#).

DRUG/LAB INTERACTIONS

Potentiated by **other drugs with anticholinergic activity** (e.g., amantadine [Symmetrel], glycopyrrolate [Robinul], phenothiazines [e.g., prochlorperazine (Compazine)], tricyclic antidepressants [e.g., amitriptyline (Elavil), imipramine (Tofranil)]). Reduce dose of atropine. ■ Antipsychotic effects of **phenothiazines** (e.g., prochlorperazine [Compazine])

may be decreased. ■ Concurrent use with **cyclopropane anesthesia** may cause ventricular arrhythmias; use of **glycopyrrolate** in increments of 0.1 mg or less is preferred. ■ Potentiates effects of many oral drugs by delaying gastric emptying and increasing rate of absorption (e.g., **atenolol, digoxin, nitrofurantoin, thiazide diuretics**). ■ Antagonistic to many drugs (e.g., **edrophonium** [Tensilon], **pyridostigmine** [Regonol]).

SIDE EFFECTS

Anhidrosis, anticholinergic psychosis, blurred vision, bradycardia (temporary), constipation, dilation of the pupils, dryness of the mouth, flushing, gastroesophageal reflux, heat prostration from decreased sweating, nausea, paralytic ileus, postural hypotension, tachyarrhythmias, urinary hesitancy and retention (especially in males), and vomiting may occur.

Overdose: Coma, death, delirium, elevated BP, fever, paralytic ileus, rash, respiratory failure, stupor, tachycardia.

ANTIDOTE

Discontinue if side effects increase or are severe. Notify physician. Use standard treatments to manage cardiac arrhythmias. Physostigmine salicylate (Antilirium) reverses most cardiovascular and CNS effects; however, it may cause profound bradycardia, seizures, or asystole. Neostigmine methylsulfate (Prostigmin) is an alternate antidote. Sustain physiologic functions at a normal level. Use diazepam (Valium), phenobarbital (Luminal), or chloral hydrate to relieve excitement. Administer pilocarpine, 10 mg (SC), until the mouth is moist.

AZACITIDINE

(ay-za-SYE-ti-deen)

Antineoplastic

Vidaza

USUAL DOSE

Premedication: Prophylactic administration of antiemetics (e.g., granisetron [Kytril], ondansetron [Zofran]) is indicated before each dose.

First treatment cycle: An initial dose of 75 mg/M² as an IV infusion or as a SC injection once daily for 7 days is recommended for all patients regardless of baseline hematology.

Subsequent treatment cycles: Cycles should be repeated every 4 weeks. Dose may be increased to 100 mg/M² if no beneficial effect is seen after 2 treatment cycles and if no toxicity other than nausea and vomiting has occurred. Treatment is recommended for a minimum of 4 to 6 cycles; however, a complete or partial response may require additional treatment cycles. Repeat cycles may be administered as long as the patient continues to benefit. See [Dose Adjustments](#) for dose delay or reduction recommendations for hematologic response, renal toxicities, and/or electrolyte disturbances.

DOSE ADJUSTMENTS

Dose Adjustments of Azacitidine Based on Baseline Hematologic Responses			
<p>In any given subsequent cycle for patients with a baseline (start of treatment) WBC equal to or greater than $3 \times 10^9/L$ (3,000 cells/mm³), ANC equal to or greater than $1.5 \times 10^9/L$ (1,500 cells/mm³), and platelets equal to or greater than $75 \times 10^9/L$ (75,000 cells/mm³): Adjust the dose based on nadir counts according to the following chart.</p>			
Nadir Counts		% Dose in the Next Cycle	
ANC (cells/mm ³)	Platelets (cells/mm ³)		
<500 cells/mm ³	<25,000 cells/mm ³	50%	
500 to 1,500 cells/mm ³	25,000 to 50,000 cells/mm ³	67%	
>1,500 cells/mm ³	>50,000 cells/mm ³	100%	
<p>In any given subsequent cycle for patients with a baseline (start of treatment) WBC less than $3 \times 10^9/L$ (3,000 cells/mm³), ANC less than $1.5 \times 10^9/L$ (1,500 cells/mm³), or platelets less than $75 \times 10^9/L$ (75,000 cells/mm³): Adjust the dose based on nadir counts and bone marrow biopsy cellularity at the time of the nadir according to the following chart. <i>The exception is the presence of clear improvement in differentiation (% of mature granulocytes is higher and ANC is higher than at the onset of that course) at the time of the next cycle. If this improvement occurs, the dose of the current treatment should be continued.</i></p>			
WBC or Platelet Nadir (% Decrease in Counts from Baseline)	Bone Marrow Biopsy Cellularity at Time of Nadir (%)		
	30% to 60%	15% to 30%	<15%
50% to 75%	% Dose in the Next Course		
	100%	50%	33%
	75%	50%	33%
>75%	75%	50%	33%

If a nadir as defined in this table has occurred, the next course of treatment should be given 28 days after the start of the preceding course, provided that both the WBC and the platelet count are greater than 25% above the nadir and are rising. If a greater than 25% increase above the nadir is not seen by day 28, counts should be reassessed every 7 days. If a 25% increase is not seen by day 42, the patient should be treated with 50% of the scheduled dose.

Dose adjustments of azacitidine based on renal function and serum electrolytes: If unexplained reductions in serum bicarbonate levels to less than 20 mEq/L occur, reduce the dose by 50% on the next course. ■ If unexplained elevations of BUN or SCr occur, delay the next cycle until values return to baseline and then reduce the dose by 50% on the next course. ■ Use care in dose selection for the elderly; reduced doses may be indicated based on overall renal function.

DILUTION

Specific techniques required; see *Precautions*. Available as a lyophilized powder in single-use vials containing 100 mg. More than one vial may be required for a single dose. Reconstitute each vial with 10 mL SWFI. Vigorously shake or roll each vial until all solids are dissolved. Solution equals 10 mg/mL. Withdraw the required amount of azacitidine to deliver the desired dose and inject into a 50- or 100-mL infusion bag of NS or LR. Administration must be complete within 1 hour of reconstitution. Discard unused portions appropriately.

Filters: Specific information not available.

Storage: Store in cartons at CRT. Reconstituted solutions may be held at 25° C (77° F), but administration must be complete within 1 hour of reconstitution.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists azacitidine as **incompatible** with D5W, hetastarch, or any solution that contains bicarbonate. These solutions have the potential to increase the rate of degradation of azacitidine.

RATE OF ADMINISTRATION

A single dose equally distributed over 10 to 40 minutes. Administration must be complete within 1 hour of reconstitution.

ACTIONS

A pyrimidine nucleoside analog of cytidine. A hypomethylating antineoplastic agent. Cytotoxic effects cause the death of rapidly dividing cells, including cancer cells that are no longer responsive to normal growth control mechanisms. Non-proliferating cells are relatively insensitive to azacitidine. This hypomethylation may restore normal function to genes that are critical for cellular differentiation and proliferation and also allow the formation of normal bone marrow cells. May be metabolized by the liver. Half-life is 4 hours. Primarily excreted in urine with minimal excretion in feces.

INDICATIONS AND USES

Treatment of patients with the following French-American-British (FAB) myelodysplastic syndrome (MDS) subtypes such as refractory anemia, refractory anemia with ringed sideroblasts (if accompanied by neutropenia or thrombocytopenia or requiring transfusions), refractory anemia with excess blasts, refractory anemia with excess blasts in transformation, and chronic myelomonocytic leukemia.

CONTRAINDICATIONS

Known hypersensitivity to azacitidine or mannitol, patients with advanced malignant hepatic tumors.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents; see Appendix A, p. 1251. ■ If azacitidine comes into contact with skin, immediately wash with soap and water. If it comes into contact with mucous membranes, flush thoroughly with water. ■ Administer by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Use caution in patients with liver disease; potentially hepatotoxic in patients with severe pre-existing hepatic impairment; see *Contraindications*. Cases of progressive hepatic coma and death have been reported in patients with extensive tumor burden due to metastatic disease, especially when baseline albumin is less than 3 Gm/dL. ■ Rare reports of renal abnormalities (e.g., elevated serum creatinine, renal failure, and death) have occurred in patients treated with azacitidine in combination with other chemotherapeutic agents for

non-MDS conditions. ■ Renal tubular acidosis (a fall in serum bicarbonate to less than 20 mEq/L in association with an alkaline urine and hypokalemia [serum potassium less than 3 mEq/L]) developed in 5 patients treated with azacitidine and etoposide. ■ The effects of race or renal or hepatic impairment on the pharmacokinetics of azacitidine have not been studied. ■ Anemia, leukopenia, neutropenia, and thrombocytopenia may be dose-limiting toxicities. ■ Patients with MDS produce poorly functioning and immature blood cells and experience anemia, bleeding, fatigue, infection, and weakness. High-risk MDS patients may experience bone marrow failure, which may lead to death from bleeding and infection. ■ MDS can progress to acute leukemia.

Monitor: Obtain a baseline CBC with platelets and monitor before each dosing cycle and as indicated to monitor response and toxicity between cycles. ■ Obtain baseline renal and hepatic function (BUN, SCr, bilirubin) studies and electrolytes; monitor during treatment as indicated. ■ Use prophylactic antiemetics to reduce nausea and vomiting and to increase patient comfort. ■ Monitor for S/S of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Avoid administration of live virus vaccine to immunocompromised patients. ■ Observe for S/S of a hypersensitivity reaction; specific information not available. ■ See [Precautions](#) and [Antidote](#).

Patient Education: Avoid pregnancy; nonhormonal birth control recommended for both males and females. Women should report a suspected pregnancy immediately. Males should not father a child during treatment with azacitidine. ■ Inform physician about any underlying liver or renal disease.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. Males should not father a child while receiving treatment with azacitidine. ■ Discontinue breast-feeding; has the potential for causing serious harm to nursing infants. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Safety and effectiveness similar to younger adults. ■ Consider age-related renal impairment; dosing should be cautious; see [Dose Adjustments](#). Monitor renal function.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been completed. ■ Effect on metabolism by known microsomal enzyme inhibitors or inducers has been studied. Does not appear to inhibit CYP2B6 or CYP2C8. Potential to inhibit other P₄₅₀ enzymes is not known. Does not appear to induce CYP1A2, CYP2C19, or CYP3A4/5. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents.

SIDE EFFECTS

Hypokalemia, petechiae, rigors, and weakness are the most common side effects. Other common side effects include anemia; constipation; diarrhea; ecchymosis; fatigue; fever; infection; injection site bruising, erythema, and pain; leukopenia; nausea; neutropenia; rales; thrombocytopenia; and vomiting. Febrile neutropenia, fever, leukopenia, neutropenia, pneumonia, and thrombocytopenia were the most frequent cause of dose reduction, delay, and discontinuation. Infusion site erythema or pain and catheter site reactions such as infection, erythema, or hemorrhage were reported with IV administration. Elevated SCr, hepatic coma, hypokalemia, renal failure, and renal tubular acidosis have also been reported. Numerous other side effects may be associated with azacitidine.

Post-Marketing: Injection site necrosis, interstitial lung disease, Sweet's syndrome (acute febrile neutrophilic dermatosis), tumor lysis syndrome.

ANTIDOTE

Notify physician of any side effects. Most will be treated symptomatically. Dose may be reduced or delayed for hematologic toxicity, renal toxicity, or electrolyte disturbances. See [Dose Adjustments](#) for specific criteria. Blood and blood products, antibiotics, and other adjunctive therapies must be available. No known antidote; monitor blood counts and provide supportive care in overdose. ■ Resuscitate as necessary.

AZATHIOPRINE SODIUM **BBW**(ay-zah-**THIGH**-oh-preen **SO**-dee-um)

Immunosuppressant

pH 9.6

USUAL DOSE

3 to 5 mg/kg of body weight/24 hr. Begin treatment within 24 hours of renal homotransplantation. In some cases, doses are given 1 to 3 days prior to transplantation. Maintenance dose is 1 to 3 mg/kg/24 hr. Individualized adjustment is imperative. Do not increase to toxic levels because of threatened rejection. Oral and IV doses are therapeutically equivalent; transfer to oral therapy as soon as practical.

DOSE ADJUSTMENTS

Dose reduction is recommended in patients with reduced thiopurine S-methyltransferase (TPMT) activity; see **Precautions**. ■ Reduce dose in impaired kidney function (especially immediately after transplant or with cadaveric kidneys) and in persistent negative nitrogen balance. ■ Dose reduction may be required if there is a rapid fall or a persistently low leukocyte count. ■ Decrease dose to one third to one fourth of the usual dose when given concomitantly with allopurinol. Consider further dose reduction or alternative therapy in patients with low or absent TPMT activity who are receiving both drugs. ■ To minimize risk of malignancy secondary to immunosuppression, immunosuppressive drug therapy should be maintained at the lowest effective levels. ■ See **Drug/Lab Interactions** and **Precautions/Monitor**.

DILUTION

Specific techniques suggested; see Precautions. Each 100 mg should be initially reconstituted with 10 mL of SWFI. Swirl the vial gently until completely in solution. May be further diluted in a minimum of 50 mL of NS, D5W, or D5NS and given as an infusion. See **Compatibility**.

Storage: Store unopened vials at 15° to 25° C (59° to 77° F). Protect from light. Use diluted solution within 24 hours.

COMPATIBILITY

Specific information not available. Listed as **incompatible** with preservatives (e.g., methylparaben, phenol, propylparaben). Administer separately. Converts to 6-mercaptopurine in alkaline solutions and sulfhydryl compounds. Flush IV line with a **compatible** IV fluid before and after administration.

RATE OF ADMINISTRATION

A single dose properly diluted and infused over 30 to 60 minutes. Actual range may be 5 minutes to 8 hours.

ACTIONS

An immunosuppressive antimetabolite that aids in inhibition of renal homograft rejection. It is chemically cleaved to the antineoplastic compound 6-mercaptopurine. Exact method of action is unknown. It suppresses hypersensitivities of the cell-mediated type and causes variable alterations in antibody production. Action depends on the temporal relationship to antigenic stimulus or engraftment. Has little effect on established graft rejections or secondary responses. Also suppresses disease manifestations and underlying pathology of autoimmune disease (e.g., rheumatoid arthritis [RA]). Exact mechanism of action is unknown. Metabolized readily with small amounts excreted in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Adjunct to prevent rejection in renal homotransplantation. ■ Used PO to treat rheumatoid arthritis; see package insert.

CONTRAINDICATIONS

Known hypersensitivity to azathioprine. ■ Patients with rheumatoid arthritis who have been treated with alkylating agents (e.g., chlorambucil [Leukeran], cyclophosphamide [Cytoxan], melphalan [Alkeran]) may have a prohibitive risk of malignancy if treated with azathioprine.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents; see Appendix A, p. 1251. ■ Usually administered in the hospital by or under the direction of a physician experienced in immunosuppressive therapy and management of organ transplant patients. ■ Adequate laboratory and supportive medical resources must be available. ■ Chronic immunosuppression increases the risk of malignancy. Reports of malignancy include post-transplant lymphoma, increased risk of developing lymphoma and other malignancies (particularly of the skin), and hepatosplenic T-cell lymphoma (HSTCL) in patients with inflammatory bowel disease. Has mutagenic potential to both men and women. Patients with Crohn's disease or inflammatory bowel disease, particularly adolescents and young adults, may have a higher risk of malignancies, including hepatosplenic T-cell lymphoma (HSTCL), with azathioprine alone or in combination therapy with TNF blockers (e.g., infliximab [Remicade]). Safety and efficacy of azathioprine for treatment of Crohn's disease and ulcerative colitis have not been established. ■ Use caution with other myelosuppressive drugs or radiation therapy. ■ Toxic hepatitis or biliary status may necessitate discontinuing drug. ■ Severe leukopenia, thrombocytopenia, macrocytic anemia, and/or pancytopenia may occur. ■ Serious infections (bacterial, fungal, protozoal, and viral) may occur and can be fatal. ■ Rapid bone marrow suppression progressing to severe, life-threatening myelotoxicity may occur in patients with inherited intermediate, low, or absent TPMT. Genotyping or phenotyping may help identify these patients. Accurate phenotyping results are not possible in patients who have received recent blood transfusions. TPMT testing cannot substitute for required CBC and platelet monitoring. ■ Hematologic toxicities are dose-related and may be more severe in renal transplant patients whose homograft is undergoing rejection. ■ A GI hypersensitivity reaction (e.g., severe nausea and vomiting) has been reported. May also cause diarrhea, elevations of liver function tests, fever, hypotension, malaise, myalgias, and rash. Usually develops within the first several weeks of therapy and resolves when azathioprine is discontinued.

Monitor: Monitor CBC with platelets weekly for the first month, twice monthly for the second and third months, then monthly or more frequently if dose adjustments or other therapy changes are necessary. Drug should be withdrawn or dose reduced at first sign of abnormally large fall in the leukocyte count or other evidence of persistent bone marrow suppression. ■ Observe constantly for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for S/S of malignancies such as HSTCL (e.g., abdominal pain, hepatomegaly, night sweats, persistent fever, weight loss).

Patient Education: Avoid pregnancy; nonhormonal birth control recommended. ■ Promptly report abdominal pain, fever, unusual bruising or bleeding, and/or S/S of infection. ■ Obtain all lab work as directed. ■ Wear protective clothing and use sunscreen to limit exposure to sunlight and ultraviolet light. ■ See Appendix D, p. 1255.

Maternal/Child: Category D; avoid pregnancy. Can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Dose selection should be cautious; consider age-related renal impairment; see **Dose Adjustments**. Monitor renal function.

DRUG/LAB INTERACTIONS

Allopurinol (Aloprim) inhibits the metabolism of azathioprine, increasing its activity and toxicity. Reduce dose of azathioprine to one third or one fourth of usual; see **Dose Adjustments**. ■ Inhibits anticoagulant effects of **warfarin** (Coumadin). ■ Concurrent use with **bone marrow suppressants, radiation therapy, other immunosuppressants** (e.g., cyclosporine [Sandimmune]) or **other drugs that may cause blood dyscrasias** (e.g., sulfamethoxazole/trimethoprim [Bactrim]) may increase toxicity. ■ Concurrent use with **ACE inhibitors**

(e.g., captopril [Capoten]) may induce anemia and severe leukopenia. ■ Plasma levels of the metabolite 6-MP may be increased by **methotrexate**. ■ **Aminosalicylates** (e.g., sulfasalazine [Azulfidine], mesalamine [Asacol, Pentasa], olsalazine [Dipentum]) may inhibit TPMT, increasing the risk of toxicity. Use caution if concomitant therapy is required. ■ **Ribavirin** (Rebetol, Vizoral) inhibits azathioprine metabolism. Concurrent use may induce severe pancytopenia. Dose adjustment and careful monitoring required if concurrent use necessary. ■ Antibody response to **vaccines** may be suppressed. Do not use **live virus vaccines** in patients receiving azathioprine.

SIDE EFFECTS

Principal and potentially serious side effects are hematologic and gastrointestinal. Risk of infection and malignancy are also significant. Frequency and severity of side effects depend on dose, duration of therapy, and on patient's underlying condition and concomitant therapy. Leukopenia and/or thrombocytopenia are dose-dependent and dose limiting. Other side effects include alopecia; anemia; anorexia; arthralgia; bleeding; diarrhea; fever; hepatic veno-occlusive disease; hepatosplenic T-cell lymphoma; hepatotoxicity characterized by elevation of serum alkaline phosphatase, bilirubin, and serum transaminases (e.g., ALT, AST); hypotension; infection; jaundice; malaise; myalgias; nausea; neoplasia; oral lesions; pancreatitis; skin rash; Sweet's syndrome (acute febrile neutrophilic dermatosis); vomiting. A GI hypersensitivity reaction (e.g., severe nausea and vomiting) has been reported; see **Precautions**.

ANTIDOTE

Notify the physician of all side effects. Most can be treated symptomatically and may reverse when the drug is discontinued. The GI hypersensitivity reactions can occur within hours of a rechallenge. Drug may be decreased or discontinued or other immunosuppressive agents utilized. Hematopoietic depression may require temporary or permanent discontinuation of treatment and may be indicated even if rejection of graft may occur. Dialysis may be useful in overdose (partially dialyzable).

AZITHROMYCIN

(az-zith-roh-MY-sin)

**Antibacterial
(azalide/macrolide)****Zithromax****pH 6.4 to 6.6****USUAL DOSE**

Community-acquired pneumonia: 500 mg as a single daily dose for a minimum of 2 days. Follow with 500 mg of oral azithromycin as a single daily dose. Total course of therapy (IV + oral) should be 7 to 10 days.

Pelvic inflammatory disease: 500 mg as a single daily dose for 1 to 2 days. Follow with 250 mg of oral azithromycin as a single daily dose. Total course of therapy (IV + oral) should be 7 days. If anaerobic microorganisms are also suspected, concurrent administration of an antibacterial agent with anaerobic activity is recommended (e.g., metronidazole [Flagyl]).

DOSE ADJUSTMENTS

Reduced dose may be required in impaired liver or renal function; see **Precautions**. ■ See **Drug/Lab Interactions**.

DILUTION

Each 500-mg vial must be reconstituted with 4.8 mL SWFI. Shake well to ensure dilution (100 mg/mL). Further dilute each 500 mg of reconstituted solution with 250 to 500 mL of one of the following solutions: D5W, NS, ½NS, D5/⅓NS, D5/½NS, D5/⅔NS with 20 mEq KCl, LR, D5LR, D5/Normosol M, D5/Normosol R. 500 mL diluent yields 1 mg/mL, 250 mL yields 2 mg/mL. Concentrations greater than 2 mg/mL have caused local IV site reactions and should be avoided.

Storage: Reconstituted or diluted solution stable at CRT for 24 hours. Diluted solution stable for up to 7 days if refrigerated.

COMPATIBILITY**(Underline Indicates Conflicting Compatibility Information)**

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Other IV substances, additives, or medications should not be added to azithromycin, or infused simultaneously through the same IV line." Flush IV line with a **compatible** IV fluid before and after administration.

One source suggests the following **compatibilities**:

Y-site: Bivalirudin (Angiomax), caspofungin (Cancidas), ceftaroline (Teflaro), dexmedetomidine (Precedex), diphenhydramine (Benadryl), dolasetron (Anzemet), doripenem (Doribax), droperidol (Inapsine), hetastarch in electrolytes (Hextend), ondansetron (Zofran), telavancin (Vibativ), tigecycline (Tygacil).

RATE OF ADMINISTRATION

Do not give by IV bolus; must be infused over at least 1 hour.

1 mg/mL dilution: A single dose equally distributed over a minimum of 1 hour; over 3 hours is preferred.

2 mg/mL dilution: A single dose equally distributed over at least 1 hour.

ACTIONS

A macrolide/azalide antibiotic. Active against selected organisms, including aerobic and facultative gram-positive and gram-negative organisms and other organisms, including *Chlamydia* and *Mycoplasma pneumoniae*. It is derived from erythromycin but is chemically different. Interferes with microbial protein synthesis by binding a ribosomal subunit of a susceptible microorganism. Concentration in phagocytes may contribute to distribution in inflamed tissues. Activity not affected by beta-lactamase production. Trough levels increase with successive doses. Terminal half-life of 68 hours allows for once-daily dosing. Prolonged half-life is thought to result from extensive uptake and subsequent release of drug from tissues. Eliminated by the liver. Primarily excreted as unchanged drug in bile. Up to 14% excreted in urine within 24 hours.

INDICATIONS AND USES

Treatment of community-acquired pneumonia and pelvic inflammatory disease caused by specific organisms (e.g., *Staphylococcus aureus*, *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Neisseria gonorrhoeae*, *Chlamydia trachomatis*). See product insert for complete list). Many other indications for oral use.

CONTRAINDICATIONS

Hypersensitivity to azithromycin, erythromycin, or any macrolide antibiotic or ketolide antibiotic (e.g., telithromycin [Ketek]). ■ Patients with a history of cholestatic jaundice/hepatic dysfunction associated with prior use of azithromycin.

PRECAUTIONS

For IV use only. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to azithromycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, azithromycin should be used only to treat or prevent infections proven or strongly suspected to be caused by bacteria. ■ Has demonstrated cross-resistance with erythromycin-resistant gram-positive organisms. Most strains of *Enterococcus faecalis* and methicillin-resistant staphylococci are resistant to azithromycin. ■ Serious hypersensitivity reactions, including angioedema, anaphylaxis, and dermatologic reactions (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis) have been reported. Use extreme caution; hypersensitivity reactions have recurred even after azithromycin was discontinued and hypersensitivity reactions treated. ■ Principally eliminated in the liver; use caution in patients with impaired hepatic function. Hepatotoxicity, including abnormal liver function, hepatitis, cholestatic jaundice, hepatic necrosis, and hepatic failure have been reported; deaths have occurred. ■ Use caution in patients with impaired renal function; no data available on effects of IV azithromycin. ■ Macrolide antibiotics (including azithromycin) have caused ventricular arrhythmias, including ventricular tachycardia and torsades de pointes, which can be fatal. Consider risk/benefit of azithromycin use in at-risk patients, such as patients with known prolonged QT intervals, a history of torsades de pointes, congenital long QT syndrome, bradyarrhythmias, or uncompensated heart failure; patients taking drugs known to prolong the QT interval; patients with ongoing pro-arrhythmic conditions (e.g., uncorrected hypokalemia or hypomagnesemia) or clinically significant bradycardia; and patients receiving Class IA (quinidine, procainamide) or Class III (amiodarone, dofetilide [Tikosyn], sotalol [Betapace AF]) antiarrhythmic agents. ■ Timing of transfer to oral therapy should be based on clinical response. ■ Avoid prolonged use; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with azithromycin. ■ May cause exacerbations of symptoms of myasthenia gravis or new onset of myasthenia syndrome.

Monitor: Monitor vital signs. ■ Observe closely for signs of a hypersensitivity reaction; see [Antidote](#). ■ Monitoring of liver function may be indicated; see [Precautions](#). ■ ECG monitoring for QT prolongation may be indicated; see [Precautions](#). ■ Monitor infusion site for inflammation and/or extravasation. ■ Contains 4.96 mEq of sodium/vial. Observe for electrolyte imbalance and cardiac irregularities. May aggravate CHF. ■ See [Drug/Lab Interactions](#) and [Antidote](#).

Patient Education: Discontinue azithromycin and report any signs of an allergic reaction immediately (difficulty breathing, itching, rash, swelling). ■ Discontinue azithromycin and report S/S of hepatitis (e.g., dark urine, jaundice, loss of appetite, malaise, nausea and vomiting). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Review all prescription and non-prescription medications with your health care provider.

Maternal/Child: Category B: safety for use during pregnancy and breast-feeding not established; use with caution and only if clearly needed. ■ Safety and effectiveness for use in pediatric patients under 16 years of age not established. ■ Has been administered to

pediatric patients age 6 months to 16 years by the oral route. The most common side effects in this age-group included abdominal pain, diarrhea, headache, nausea, rash, and vomiting.

Elderly: Response similar to that seen in younger adults. May be more susceptible to development of drug-associated effects on the QT interval than younger patients. ■ Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

May have a modest effect on the pharmacokinetics of **atorvastatin** (Lipitor), **carbamazepine** (Tegretol), **cetirizine** (Zyrtec), **didanosine** (Videx), **efavirenz** (Sustiva), **fluconazole** (Diflucan), **indinavir** (Crixivan), **midazolam** (Versed), **rifabutin** (Mycobutin), **sildenafil** (Viagra), **theophylline**, **sulfamethoxazole/trimethoprim** (Bactrim, Septra), or **zidovudine** (AZT, Retrovir). No dose adjustment required with coadministration of these drugs. ■ **Efavirenz and fluconazole** may have a modest effect on the pharmacokinetics of azithromycin. No dose adjustment is necessary with coadministration of these drugs. ■ May increase the anticoagulant effects of **warfarin** (Coumadin); monitoring of PT is indicated. ■ Coadministration with nelfinavir (Viracept) results in increased azithromycin levels. Dose adjustment is not recommended, but close monitoring for known side effects (e.g., liver enzyme abnormalities, hearing impairment) is suggested. ■ In healthy subjects, coadministration of azithromycin and chloroquine (known to prolong the QT interval) increased the QTc interval in a dose- and concentration-dependent manner; see **Precautions**. ■ **Other macrolide antibiotics cause interactions when given concomitantly with the following drugs; azithromycin has not been studied.** ■ May inhibit metabolism and increase serum levels and effects of **cyclosporine** (Sandimmune), **phenytoin** (Dilantin), and **terfenadine**; reduced doses of these drugs may be indicated. ■ May increase **digoxin levels**; monitoring of digoxin levels is indicated. ■ May cause acute ergot toxicity (severe peripheral vasospasm and dysesthesia) with **ergotamine** or **dihydroergotamine**.

SIDE EFFECTS

Usually mild to moderate in severity and reversible after azithromycin discontinued. Abdominal pain; anemia; anorexia; arrhythmias; cough; diarrhea; dizziness; dyspnea; facial edema; fatigue; fungal infections; hypotension; increase in AST, ALT, and/or alkaline phosphatase levels; injection site pain or local inflammation; leukopenia; malaise; nausea; oral candidiasis; pancreatitis; pharyngitis; pleural effusion; rashes; rhinitis; stomatitis; vaginitis; vomiting. Serious abnormal liver function, including hepatitis and cholestatic jaundice, cases of hepatic necrosis, and hepatic failure (some resulting in death) have occurred. Acute interstitial nephritis (fever, joint pain, skin rash) is rare but may cause acute renal failure. Allergic reactions (e.g., angioedema, anaphylaxis, and dermatologic reactions including Stevens-Johnson syndrome and toxic epidermal necrolysis) have been reported rarely and may be fatal; see **Precautions**. Rare reports of QT prolongation and torsades de pointes have been reported. CDAD has been reported.

ANTIDOTE

Notify physician of any side effects. Discontinue azithromycin for hypersensitivity reactions and S/S of hepatitis. Treat hypersensitivity reactions as indicated and resuscitate as necessary. Additional hypersensitivity reactions have recurred after azithromycin has been discontinued and initial treatment completed. Prolonged observation is required. Mild cases of CDAD may respond to discontinuation of azithromycin. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated.

AZTREONAM(az-**TREE**-oh-nam)**Antibacterial
(monobactam)****Azactam****pH 4.5 to 7.5****USUAL DOSE**

Dose determined by susceptibility of the causative organism(s), severity and site of infection, and condition of the patient.

Urinary tract infection: 500 mg to 1 Gm every 8 or 12 hours.

Moderately severe systemic infections: 1 or 2 Gm every 8 to 12 hours.

Severe systemic, or life-threatening infections: 2 Gm every 6 or 8 hours. Use the full suggested dose. Do not exceed 8 Gm/24 hr.

Normal renal function required. Duration of therapy depends on the severity of the infection. Continue for at least 2 days after all symptoms of infection subside. Can produce therapeutic serum levels given intraperitoneally in dialysis fluid.

PEDIATRIC DOSE

See **Maternal/Child**.

Mild to moderate infections: 30 mg/kg every 8 hours.

Moderate to severe infections: 30 mg/kg every 6 or 8 hours. Maximum recommended dose is 120 mg/kg/24 hr.

Cystic fibrosis: 50 mg/kg every 6 to 8 hours. Maximum dose is 8 Gm/24 hr.

NEONATAL DOSE

Neonatal doses are **unlabeled**; see **Maternal/Child**.

30 mg/kg/dose. Interval between doses based on age and weight as follows:

Less than 1,200 Gm and 0 to 4 weeks of age: Give every 12 hours.

Less than 2,000 Gm and 0 to 7 days of age: Give every 12 hours.

1,200 to 2,000 Gm and over 7 days of age: Give every 8 hours.

More than 2,000 Gm and 0 to 7 days of age: Give every 8 hours.

More than 2,000 Gm and over 7 days of age: Give every 6 hours.

DOSE ADJUSTMENTS

Dosing in the elderly should be cautious and reduced based on CrCl; consider potential for decreased organ function and concomitant disease or drug therapy. ■ Prolonged serum levels may occur in patients with renal insufficiency. After an initial loading dose of 1 or 2 Gm, reduce succeeding doses by 50% in patients with CrCl between 10 and 30 mL/min/1.73 M². ■ After an initial loading dose of 500 mg, 1 Gm, or 2 Gm, reduce succeeding doses by 75% in patients with CrCl less than 10 mL/min/1.73 M² or in patients supported by dialysis. In addition 12.5% of the maintenance dose may be given after a dialysis session in serious or life-threatening situations.

DILUTION

Usually light yellow, may become slightly pink on standing; does not affect potency.

IV injection: Reconstitute a single dose with 6 to 10 mL of SWFI. Shake immediately and vigorously. Use immediately and discard any unused solution.

Intermittent IV: Initially reconstitute each single dose with a minimum of 3 mL of SWFI. Shake immediately and vigorously. Must be further diluted in at least 50 mL of D5W, NS, or other **compatible** infusion solutions for each 1 Gm of aztreonam (see chart on inside back cover or literature). Concentration should not exceed 20 mg/mL or 2% w/v. Available in vials and premixed Galaxy infusion bags.

Storage: Concentrations exceeding 2% should be used promptly unless prepared with SWFI or NS. Other reconstituted or diluted solutions are stable for 48 hours at room temperature or up to 7 days if refrigerated. Vials are for single use only; discard unused amounts. When specific diluents are used, may be frozen for up to 3 months. Thaw at room temperature (see literature); do not refreeze.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with metronidazole (Flagyl IV), nafcillin (Nallpen).

One source suggests the following **compatibilities**:

Solution: See chart on inside back cover. Others listed by manufacturer include D5/Ionosol B, Isolyte E, D5/Isolyte E, D5/Isolyte M, Normosol-R, D5/Normosol-R, D5/Normosol-M, Mannitol 5% and 10%, D5/Plasma-Lyte, Travert injection 10%, Travert injection 10% and Electrolytes (multiple).

Additive: Manufacturer lists ampicillin, cefazolin (Ancef), clindamycin (Cleocin), gentamicin, tobramycin, and vancomycin diluted in specific concentrations and in specific solutions and states, "Other admixtures are not recommended."

Other sources list ampicillin/sulbactam (Unasyn), cefexitin (Mefoxin), ciprofloxacin (Cipro IV), linezolid (Zyvox), mannitol (Osmitol), vancomycin.

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), bivalirudin (Angiomax), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), casprofungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytosan), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), daptomycin (Cubicin), dexamethasone (Decadron), dexmedetomidine (Precedex), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), etoposide (VePesid), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), foscarnet (Foscavir), furosemide (Lasix), gallium nitrate (Ganite), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), insulin (regular), leucovorin calcium, linezolid (Zyvox), magnesium sulfate, mannitol, mechlorethamine (nitrogen mustard), melphalan (Alkeran), meperidine (Demerol), mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), morphine, nalbuphine, nicardipine (Cardene IV), ondansetron (Zofran), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), promethazine (Phenergan), propofol (Diprivan), quinupristin/dalfopristin (Synercid 20 mg/mL), ranitidine (Zantac), remifentanyl (Ultiva), sargamostim (Leukine), sodium bicarbonate, sulfamethoxazole/trimethoprim, teniposide (Vumon), theophylline, thiotepea, ticarcillin/clavulanate (Timentin), tigecycline (Tygacil), tobramycin, vancomycin, vinblastine, vincristine, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

IV injection: A single dose equally distributed over 3 to 5 minutes.

Intermittent IV: A single dose over 20 to 60 minutes. May be given through Y-tube or three-way stopcock of infusion set. Do not infuse simultaneously with other drugs or solutions except in proven **compatibility**. Flush common IV tubing before and after administration.

ACTIONS

A synthetic monobactam antibiotic. Bactericidal through inhibition of bacterial cell wall synthesis to a wide spectrum of specific gram-negative aerobic organisms including *Pseudomonas aeruginosa*. Effective against many otherwise resistant organisms. Therapeutic levels widely distributed into many body fluids and tissues. Peak serum levels reached in 1 hour. Serum half-life averages 1.7 hours; range is 1.5 to 2 hours. Primarily excreted in the urine with some excretion through feces. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, urinary tract, skin and skin structure, gynecologic, and intra-abdominal infections and bacterial septicemia. Most effective against specific gram-negative organisms (see literature). ■ Adjunctive therapy to surgery for the management of infections.

CONTRAINDICATIONS

Known hypersensitivity to aztreonam or its components.

PRECAUTIONS

Specific studies are indicated to identify the causative organism and susceptibility to aztreonam. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, aztreonam should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Before C/S data are available, antimicrobial therapy with agents to cover gram-positive and/or anaerobic microorganisms may be indicated. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of non-susceptible organisms may result. ■ Cross-reactivity with other beta-lactam antibiotics (e.g., penicillins, cephalosporins, and/or carbapenems) is rare but can occur with or without prior exposure. Use with caution in patients with a history of hypersensitivity reactions to beta-lactam antibiotics. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with aztreonam. ■ Epidermal necrolysis has been reported rarely in patients receiving aztreonam who have undergone BMT and have other risk factors (e.g., graft-versus-host disease, radiation therapy, sepsis).

Monitor: Watch for early symptoms of a hypersensitivity reaction. Use caution in patients with known sensitivity to penicillins, cephalosporins, or carbapenems. ■ Monitor renal and hepatic function, especially in the elderly. ■ Monitor renal function with concurrent administration of higher doses or prolonged administration of aminoglycosides (e.g., gentamicin). ■ May cause thrombophlebitis. Use small needles and large veins and rotate infusion sites.

Patient Education: Report pain or burning at injection site or S/S of a hypersensitivity reaction (e.g., difficulty breathing, flushing, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: use in pregnancy and breast-feeding only if clearly needed. ■ Consider discontinuing breast-feeding. ■ Safety for use in infants under 9 months of age not established. ■ Limited data are available for treatment of infants and pediatric patients with septicemia or skin and skin-structure infections (caused by *H. influenzae* type b). ■ Higher doses of aztreonam may be indicated in pediatric patients with cystic fibrosis. ■ IV route is suggested for pediatric patients; data are limited for IM injection and impaired renal function.

Elderly: Reduced doses may be indicated. Monitor renal function; see [Dose Adjustments](#). ■ Response is similar to that seen in younger patients; however, clearance is decreased and half-life is prolonged.

DRUG/LAB INTERACTIONS

Adverse interaction may occur with **beta-lactamase-inducing antibiotics** (e.g., ceftiofur, imipenem); do not use concurrently. ■ May be used concomitantly with **aminoglycosides** in severe infections. Nephrotoxicity and ototoxicity can be markedly increased when both drugs are utilized. ■ **Probenecid and furosemide** do increase blood levels; not clinically significant. ■ Bactericidal activity of aztreonam may be antagonized by **chloramphenicol** (Chloromycetin). ■ See [Side Effects](#).

SIDE EFFECTS

Full scope of allergic reactions, including anaphylaxis, angioedema, bronchospasm. Burning, discomfort, and pain at injection site; diarrhea; nausea and vomiting; and rash occur most frequently. Abdominal cramps; altered taste; CDAD; confusion; diaphoresis; diplopia; dizziness; dyspnea; elevated alkaline phosphatase, AST, ALT, and Scr; eosinophilia; erythema multiforme; exfoliative dermatitis; fever; halitosis; headache; hemato-

logic changes (e.g., anemia, neutropenia); hepatitis; hypotension; insomnia; jaundice; mouth ulcer; nasal congestion; numb tongue; paresthesia; petechiae; phlebitis/thrombophlebitis; positive Coombs' test; prolonged PT and PTT; pruritus; purpura; seizures; sneezing; tinnitus; transient ECG changes (ventricular bigeminy and PVCs); urticaria; vaginitis; vertigo can occur.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis or peritoneal dialysis may be useful in overdose.

BASILIXIMAB **BBW**

(bah-zih-LIX-ih-mab)

Recombinant monoclonal antibody
Immunosuppressant

Simulect

USUAL DOSE

Basiliximab should only be administered once it has been determined that the patient will receive the graft and concomitant immunosuppression. Patients who have received a previous course of basiliximab should only be re-exposed to a subsequent course of therapy with extreme caution. Used concurrently with cyclosporine (Sandimmune) and corticosteroids.

Organ rejection prophylaxis in renal transplant: 2 doses of 20 mg each as an infusion. Administer the first dose within 2 hours before transplantation. Give the second dose 4 days after transplantation. Withhold the second dose if complications such as severe hypersensitivity reactions to basiliximab or graft loss occurs.

PEDIATRIC DOSE

Less than 35 kg: 2 doses of 10 mg each (discard remaining product after each dose).

35 kg or more: 2 doses of 20 mg each.

In all pediatric patients, administer the first dose within 2 hours before transplantation. Give the second dose 4 days after transplantation. See [Actions](#) and [Maternal/Child](#). Withhold second dose if complications occur (e.g., hypersensitivity reactions or graft loss).

DOSE ADJUSTMENTS

No dose adjustments indicated.

DILUTION

Reconstitute each single 20-mg vial with 5 mL of SWFI. Reconstitute each 10-mg vial with 2.5 mL SWFI. Shake gently to dissolve powder. After reconstitution, may be given as an IV injection or may be further diluted to 50 mL with NS or D5W. When mixing, gently invert to avoid foaming; do not shake.

Storage: Store unopened vials in the refrigerator (2° to 8° C [36° to 46° F]). Should be used within 4 hours of reconstitution. If necessary, may be refrigerated for up to 24 hours. Discard prepared solution after 24 hours.

COMPATIBILITY

Manufacturer states, "Other drug substances should not be added or infused simultaneously through the same IV line." No **incompatibilities** observed with polyvinyl chloride bags and administration sets.

RATE OF ADMINISTRATION

May be given through a peripheral or central vein.

IV injection: May be given as a bolus injection over 30 to 60 seconds. Incidence of N/V and local reaction including pain increased.

Infusion: A single dose properly diluted over 20 to 30 minutes.

ACTIONS

A chimeric (murine/human) monoclonal antibody produced by recombinant DNA technology. Functions as an immunosuppressant. Specifically binds to and blocks the interleukin-2 receptor alpha chain (IL-2R α , also known as CD25 antigen), thereby inhibiting IL-2 driven proliferation of activated T-cells, which play a key role in organ rejection. Reduces/minimizes acute rejection. IL-2R α is expressed selectively on activated, but not resting, T-cells. This selectivity prevents the profound generalized immunosuppression seen with other immunosuppressants used in organ transplantation and may decrease the risk of infection and development of lymphoproliferative disorders. Two 20-mg doses block the receptor for 4 to 6 weeks post-transplantation, the critical risk period for acute organ rejection. Has reduced the incidence of biopsy-confirmed acute rejections while minimizing side effects seen with other immunosuppressants. Clinical benefit demonstrated in a broad range of patients, regardless of age, gender, race, donor type, or history of diabetes mellitus as long as serum levels exceed 0.2 mg/mL (by ELISA). Mean half-life is 4 to 10.4 days. Half-life is increased (5.2 to 17.8 days) and distribution volume and clearance are decreased by about 50% in pediatric patients 2 to 11 years of age. Crosses the placental barrier. May be secreted in breast milk.

INDICATIONS AND USES

Prophylaxis of acute organ rejection in patients receiving renal transplants. Used as part of an immunosuppressive regimen that includes cyclosporine and corticosteroids. Dosing regimen may also include either azathioprine (Imuran) or mycophenolate (CellCept IV).

CONTRAINDICATIONS

Known hypersensitivity to basiliximab or any of its components (composite of human and murine antibodies).

PRECAUTIONS

Usually administered by or under the direction of a physician experienced in immunosuppressive therapy and management of organ transplant patients. Adequate laboratory and supportive medical resources must be available. ■ Severe acute (onset within 24 hours) hypersensitivity reactions including anaphylaxis have been reported both with initial exposure and/or following re-exposure after several months. Emergency equipment and drugs for the treatment of severe hypersensitivity reactions must be readily available. Withhold the second dose of basiliximab if a hypersensitivity reaction occurs. ■ Re-administration after an initial course of therapy has not been studied in humans, but other monoclonal antibodies have precipitated anaphylactoid reactions. ■ Potential for causing lymphoproliferative disorders, CMV, and other opportunistic infections is unknown. ■ Use with caution in patients with infections or malignancies. ■ It is not known whether basiliximab use will have a long-term effect on the ability of the immune system to respond to antigens first encountered during induced immunosuppression. ■ Low titers of anti-idiotypic antibodies and human antimurine antibodies (HAMA) to basiliximab have been detected in some patients during treatment; no adverse effects have been noted.

Monitor: Obtain baseline CBC with differential and platelets and baseline renal and liver tests if not already completed for other immunosuppressant agents. ■ Monitor vital signs. ■ Observe closely for signs of infection (fever, sore throat, tiredness) or unusual bleeding or bruising. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile immunosuppressed patient. ■ Symptoms of cytokine release syndrome (e.g., chills, fever, dyspnea, and malaise) have not been reported but may occur; observe carefully. ■ See [Drug/Lab Interactions](#).

Patient Education: Report difficulty in breathing or swallowing, rapid heartbeat, rash, or itching immediately. ■ Report swelling of lower extremities and weakness. ■ Avoid pregnancy; nonhormonal birth control preferred. Women with childbearing potential should use effective contraception before beginning basiliximab therapy, during therapy, and for 2 months after completion. ■ See Appendix D, p. 1255.

Maternal/Child: Category B: use during pregnancy only if benefits justify the potential risk to the fetus. Avoid pregnancy; effective contraception required; see [Patient Education](#). ■ Discontinue breast-feeding. ■ Has been used in pediatric patients from 2 to 15 years of age. No adequate or well-controlled studies completed. See differences in Actions. Most frequent side effects were fever and urinary infections.

Elderly: Age-related dosing not required. Adverse events similar to younger adults. Use caution when giving immunosuppressive drugs to the elderly.

DRUG/LAB INTERACTIONS

Has been administered concurrently with **antilymphocyte globulin (ALG)**, **antithymocyte globulin (ATG)**, **azathioprine (Imuran)**, **corticosteroids**, **cyclosporine (Sandimmune)**, **muromonab CD3 (Orthoclone)**, and **mycophenolate (CellCept)**; no additional adverse reactions noted. ■ **May increase or decrease numerous lab values**, including serum calcium and potassium and fasting blood glucose.

SIDE EFFECTS

Basiliximab did not appear to alter the pattern, frequency, or severity of known side effects associated with the use of immunosuppressive drugs. Abdominal pain, anemia, constipation, diarrhea, edema, fever, headache, hyperkalemia, hypersensitivity reactions (including anaphylaxis, bronchospasm, capillary leak syndrome, cardiac failure, cytokine release syndrome, dyspnea, hypotension, pruritus, pulmonary edema, rash, respiratory failure, sneezing, tachycardia, urticaria, wheezing), hypertension, hypokalemia, insomnia, nausea, pain, peripheral edema, upper respiratory infections, urinary tract infections. Incidence of N/V and local reaction including pain increased with bolus injection. Severe hypersensitivity reactions (including anaphylaxis), capillary leak syndrome, and cytokine release syndrome have been reported. Incidence of infections, lymphomas, or other malignancies similar to placebo groups in studies.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Basiliximab may be discontinued or alternate immunosuppressive agents substituted. Discontinue immediately if anaphylaxis occurs, and treat with oxygen, epinephrine, corticosteroids, and/or antihistamines (e.g., diphenhydramine [Benadryl]). Resuscitate as necessary.

BELATACEPT **BBW**

(bel-AT-a-sept)

Immunosuppressant

Nulojix

pH 7.2 to 7.8

USUAL DOSE

Administration of higher-than-recommended doses or more frequent dosing of belatacept is not recommended because of an increased risk of post-transplant lymphoproliferative disorder (PTLD), progressive multifocal leukoencephalopathy (PML), and serious CNS infections.

Premedication is not required. Base the total infusion dose on actual body weight at the time of transplantation.

Dosing of Belatacept for Kidney Transplant Recipients*	
Dosing for Initial Phase	Dose
Day 1 (day of transplantation, before implantation) and Day 5 (approximately 96 hours after Day 1 dose)	10 mg/kg
End of Week 2 and Week 4 after transplantation	10 mg/kg
End of Week 8 and Week 12 after transplantation	10 mg/kg
Dosing for Maintenance Phase	Dose
End of Week 16 after transplantation and every 4 weeks (plus or minus 3 days) thereafter	5 mg/kg

*The dose prescribed must be evenly divisible by 12.5 mg (evenly divisible increments are 0, 12.5, 25, 37.5, 50, 62.5, 75, 87.5, and 100). For example: At 10 mg/kg/dose, a patient weighing 64 kg would receive 640 mg. The closest doses evenly divisible by 12.5 below and above 640 mg are 637.5 mg and 650 mg. The nearest dose is 637.5 mg, and this would be the actual prescribed dose.

Regimen includes basiliximab (Simulect) induction, mycophenolate mofetil (MMF, CellCept), and corticosteroids.

Basiliximab: 20 mg IV on the day of transplantation and 4 days later.

Mycophenolate mofetil: 1 Gm as an initial dose twice on the first day. Adjust subsequent doses based on clinical signs of adverse events or efficacy failure.

Corticosteroid doses should be consistent with those used in clinical trials. In clinical trials, the median corticosteroid doses were tapered to approximately 15 mg (10 to 20 mg) per day by the first 6 weeks and remained at approximately 10 mg (5 to 10 mg) per day for the first 6 months post-transplant; see **Precautions**. Actual corticosteroid dosing in clinical trials is summarized in the following table.

Actual Corticosteroid ^a Dosing in Studies 1 and 2		
Day of Dosing	Median (Q1-Q3) Daily Dose ^{b,c}	
	Study 1	Study 2
Week 1	31.7 mg (26.7 to 50 mg)	30 mg (26.7 to 50 mg)
Week 2	25 mg (20 to 30 mg)	25 mg (20 to 30 mg)
Week 4	20 mg (15 to 20 mg)	20 mg (15 to 22.5 mg)
Week 6	15 mg (10 to 20 mg)	16.7 mg (12.5 to 20 mg)
Month 6	10 mg (5 to 10 mg)	10 mg (5 to 12.5 mg)

^aCorticosteroid = Prednisone or prednisolone.

^bProtocols allowed for flexibility in determining corticosteroid dose and rapidity of taper after Day 15. It is not possible to distinguish corticosteroid doses used to treat acute rejection versus doses used in a maintenance regimen.

^cQ1 and Q3 are the 25th and 75th percentiles of daily corticosteroid doses, respectively.

DOSE ADJUSTMENTS

Do not modify the dose during the course of therapy unless there is a change in body weight of greater than 10%. ■ Age, gender, race, renal function, hepatic function, diabetes, and concomitant dialysis do not affect the clearance of belatacept.

DILUTION

Belatacept is for IV infusion only. **Must be reconstituted/prepared using only the silicone-free disposable syringe provided with each vial. This syringe will be required for both reconstitution and the preparation of the final infusion. Maintain sterility. Any solution prepared with other than the provided silicone-free syringe must be discarded** (contact the manufacturer to obtain an additional supply of silicone-free disposable syringes).

Each vial contains 250 mg of belatacept lyophilized powder. Calculate the number of vials needed to provide the total infusion dose. Reconstitute the contents of each vial with 10.5 mL of SWFI, NS, or D5W using the silicone-free disposable syringe and an 18- to 21-gauge needle. Direct the stream of diluent to the glass wall of the vial. To avoid

foaming, rotate the vial and swirl gently until contents are completely dissolved. *Avoid prolonged or vigorous agitation. Do not shake.* Reconstituted solution yields 25 mg/mL and should be clear to slightly opalescent and colorless to pale yellow. Calculate the total volume of reconstituted solution required to provide the prescribed dose:

$$\text{Volume of 25 mg/mL belatacept solution (in mL)} = \text{Prescribed dose (in mg)} \div 25 \text{ mg/mL}$$

The reconstituted solution must be further diluted in infusion fluid. If reconstituted with SWFI, dilute with either NS or D5W. If reconstituted with NS, further dilute with NS. If reconstituted with D5W, further dilute with D5W. From the appropriate-size infusion container (typically an infusion volume of 100 mL is appropriate, but volumes from 50 to 250 mL may be used), withdraw a volume of infusion fluid equal to the total volume of reconstituted belatacept required to provide the prescribed dose. Using the same silicone-free disposable syringe used for reconstitution, withdraw the required amount of belatacept and inject it into the infusion container. Gently rotate to ensure mixing. Concentration should range from 2 mg/mL to 10 mg/mL.

Filters: Must be administered with a non-pyrogenic, low-protein binding, 0.2- to 1.2-micron filter.

Storage: Refrigerate vials of lyophilized powder at 2° to 8° C (36° to 46° F) in carton to protect from light. The reconstituted solution should be further diluted in infusion fluid immediately. The infusion must be completed within 24 hours. Infusion solution can be refrigerated protected from light for up to 24 hours. A maximum of 4 hours of those 24 hours can be at CRT and room light. Discard any unused solution remaining in vials.

COMPATIBILITY

Manufacturer states, “Must be reconstituted/prepared using only the silicone-free disposable syringe provided with each vial. Any solution prepared with other than the provided silicone-free syringe must be discarded” and “Infuse in a separate line; should not be infused concomitantly in the same IV line with other agents.”

RATE OF ADMINISTRATION

A single dose evenly distributed over 30 minutes.

ACTIONS

A selective T-cell co-stimulation blocker. Produced by recombinant DNA technology. Binds to CD80 and CD86 on antigen-presenting cells, thereby blocking CD28-mediated co-stimulation of T-lymphocytes. Belatacept binds to CD80 and CD86 more readily than abatacept (the parent molecule from which it is derived). Belatacept-mediated co-stimulation blockade results in the inhibition of cytokine production by T-cells required for antigen-specific antibody production by B-cells and inhibits T-lymphocyte proliferation. Activated T-lymphocytes are the predominant mediators of immunologic rejection. Half-life ranges from 6.1 to 15.6 days. In clinical trials, trough concentrations were consistently maintained from 6 months up to 3 years post-transplant. Increasing body weight may result in a trend toward higher clearance.

INDICATIONS AND USES

Prophylaxis of organ rejection in adult patients receiving a kidney transplant. Used in combination with basiliximab (Simulect) induction, mycophenolate mofetil (CellCept), and corticosteroids.

Limitation of use: Use only in patients who are Epstein-Barr virus (EBV) seropositive. ■ Use for prophylaxis of organ rejection in transplanted organs other than the kidney not established. Not recommended for use in liver transplant patients; risk of graft loss and death is increased.

CONTRAINDICATIONS

Transplant recipients who are Epstein-Barr virus (EBV) seronegative or who have unknown EBV serostatus because of risk of post-transplant lymphoproliferative disorder (PTLD) predominantly involving the CNS.

PRECAUTIONS

For IV use only. ■ Usually administered by or under the direction of a physician experienced in immunosuppressive therapy and management of organ transplant patients. Adequate laboratory and

supportive medical resources must be available. Increased risk for developing post-transplant lymphoproliferative disorder (PTLD), predominantly involving the CNS. Recipients without immunity to Epstein-Barr virus (EBV) are at a particularly increased risk; therefore use in EBV-seropositive patients only. Do not use belatacept in transplant recipients who are EBV-seronegative or who have unknown EBV serostatus. ■ Other known risk factors for PTLD include CMV infection and T-cell-depleting therapy. Use T-cell-depleting therapies to treat acute rejection with caution. Cytomegalovirus (CMV) prophylaxis is recommended for at least 3 months after transplantation. Patients who are EBV seropositive and CMV seronegative may be at increased risk for PTLD compared with patients who are EBV seropositive and CMV seropositive. ■ Minimization of the corticosteroid dose to 5 mg/day between Day 3 and Week 6 post-transplantation has been associated with an increased rate and grade of acute rejection, particularly Grade III rejection. Graft loss occurred in some patients. Corticosteroid use should be consistent with clinical trial experience; see [Usual Dose](#). ■ Increased susceptibility to infection and possible development of malignancies may result from immunosuppression. Increased risk of developing other malignancies, including malignancies of the skin, appears related to intensity and duration of use. Avoid prolonged exposure to UV light and sunlight. Risk of developing bacterial, viral (e.g., CMV and herpes), fungal, and protozoal infections, including opportunistic infections such as tuberculosis (TB) or polyoma virus-associated nephropathy (PVAN), is increased and may lead to serious (including fatal) outcomes. Prophylaxis for *Pneumocystis jiroveci* is recommended after transplantation. ■ PML (a rapidly progressive and fatal opportunistic infection of the CNS that is caused by the JC virus) has been reported. ■ Infusion-related reactions have occurred within 1 hour of infusion; however, no serious reactions or anaphylaxis have been reported. ■ Anti-belatacept antibody development was not associated with an altered clearance of belatacept. The clinical impact of anti-belatacept antibodies has not been determined.

Monitor: Monitor for new or worsening neurologic, cognitive, or behavioral signs and symptoms. May indicate PTLD or PML. ■ Evaluate patients for latent tuberculosis (TB). Patients testing positive in TB screening should be treated with a standard TB regimen before initiating belatacept therapy. ■ Monitor for S/S of infection; see [Antidote](#). ■ Monitor renal function closely and consider PVAN if renal function is deteriorating. ■ New-onset diabetes, dyslipidemia, and hypertension may occur; monitor blood sugar, lipid panel, and BP. ■ Do not administer live virus vaccines; see [Drug/Lab Interactions](#). ■ See [Precautions](#).

Patient Education: Read manufacturer's patient information sheet before each infusion. ■ Risk of other malignancies is increased. Limit exposure to sunlight and UV light. Wear protective clothing and use a sunscreen with a high protection factor. ■ Promptly report confusion, thinking problems, and loss of memory; decreased strength or weakness on one side of the body; and changes in mood or behavior, walking or talking, and vision. ■ Promptly report S/S of infection (e.g., fever, malaise). Adherence to prescribed antimicrobial prophylaxis is imperative. ■ May cause fetal harm. Pregnancy Registry available to monitor maternal-fetal outcomes.

Maternal/Child: Category C: May cause fetal harm. Use only if potential benefit to mother outweighs potential risk to fetus. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients less than 18 years of age not established.

Elderly: Safety or effectiveness similar to that seen in younger adults.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been conducted. ■ May potentially alter metabolism of **coadministered drugs known to be metabolized by the CYP₄₅₀ enzyme system**, such as atazanavir (Reyataz), atorvastatin (Lipitor), carbamazepine (Tegretol), clarithromycin (Biaxin), dexamethasone (Decadron), indinavir (Crixivan), itraconazole (Sporanox), ketoconazole (Nizoral), nefazodone, nelfinavir (Viracept), phenytoin (Dilantin), phenobarbital (Luminal), rifabutin (Mycobutin), rifapentine (Priftin), rifampin (Rifadin), ritonavir (Norvir), saquinavir (Invirase), St. John's wort, telithromycin (Ketek), voriconazole (VFEND). Monitor for effectiveness and potential side effects. ■ Plasma concentrations

of mycophenolic acid (MPA) may be increased relative to coadministration of **mycophenolate mofetil** (MMF) with cyclosporine. A change of MPA exposure may occur with a crossover from **cyclosporine** to belatacept or from belatacept to cyclosporine in patients concomitantly receiving MMF. ■ Avoid the use of **live vaccines** during treatment with belatacept, including but not limited to intranasal influenza, measles, mumps, rubella, oral polio, BCG, yellow fever, varicella, and Ty21a typhoid vaccines.

SIDE EFFECTS

Anemia, constipation, cough, diarrhea, fever, graft dysfunction, headache, hyperkalemia, hypertension, hypokalemia, leukopenia, nausea, peripheral edema, urinary tract infection, and vomiting are most common. Post-transplant lymphoproliferative disorder (PTLD), predominantly CNS PTLD; other malignancies; and serious infections, including JC virus–associated progressive multifocal leukoencephalopathy (PML) and polyoma virus-associated nephropathy (PVAN), are the most serious potential side effects and may be life threatening. Abdominal pain, acne, anxiety, arthralgia, back pain, bronchitis, cytomegalovirus (CMV) and herpes infections, dyslipidemia, dysuria, hematuria, hypercholesterolemia, hyperglycemia, hyperuricemia, hypocalcemia, hypomagnesemia, hypophosphatemia, hypotension, influenza, insomnia, nasopharyngitis, proteinuria, renal tubular necrosis, tremor, tuberculosis, and upper respiratory infections may occur.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. If PML is suspected, confirmation of the diagnosis by consultation with a neurologist, brain imaging, CSF testing for JC viral DNA, and/or brain biopsy is indicated. If PML is confirmed, consider reducing or discontinuing immunosuppression, taking into account the risk to the allograft. Therapy may need to be interrupted in patients who develop infections. Treat infusion reactions as indicated. Resuscitate as necessary.

BELIMUMAB

(be-LIM-ue-mab)

Monoclonal antibody

Benlysta

pH 6.5

USUAL DOSE

Premedication: Consider premedication (e.g., antihistamines [e.g., diphenhydramine (Benadryl)], H₂ antagonists [e.g., ranitidine (Zantac)], and/or corticosteroids [e.g., dexamethasone (Decadron)]) to help prevent or minimize hypersensitivity/infusion reactions.

Belimumab: 10 mg/kg as an infusion at 2-week intervals for the first 3 doses. Administer at 4-week intervals thereafter.

DILUTION

Available in two strengths (120 mg or 400 mg). Allow vial to reach RT before reconstitution (approximately 10 to 15 minutes). Reconstitute the 120-mg vial with 1.5 mL SWFI and the 400-mg vial with 4.8 mL SWFI. Concentration for both will equal 80 mg/mL. Direct the SWFI toward the side of the vial to minimize foaming. Gently swirl for 60 seconds. Allow to sit at RT and gently swirl for 60 seconds every 5 minutes until completely dissolved. **Do not shake.** Reconstitution may take up to 30 minutes. Protect from sunlight. Solution should be opalescent and colorless to pale yellow. Small air bubbles are expected and are acceptable. If reconstituted with a mechanical swirler, do not exceed 500 rpm and/or a duration of 30 minutes. Desired dose of the reconstituted solution must be further diluted to 250 mL with NS by withdrawing and discarding a volume equal to the desired dose from a 250-mL infusion bag or bottle of NS. Add the desired dose of belimumab to the infusion bag or bottle and invert to mix the solution; see **Storage**.

Filters: No data available from manufacturer.

Storage: Before use, refrigerate vials (2° to 8° C [36° to 46° F]) in original carton, protected from light. Do not freeze. Avoid exposure to heat. Do not use beyond expiration date. Reconstituted solution, if not used immediately, should be refrigerated protected from direct sunlight. Solution diluted in NS may be refrigerated or kept at RT. Total time from reconstitution to completion of the infusion should not exceed 8 hours. Discard any unused product.

COMPATIBILITY

Manufacturer states, “**Incompatible** with dextrose solutions,” “No **incompatibilities** with polyvinylchloride or polyolefin bags observed,” and “Should not be infused concomitantly in the same IV line with other agents.”

RATE OF ADMINISTRATION

A single dose, properly diluted, as an infusion equally distributed over 1 hour. Slow or interrupt infusion rate if an infusion reaction develops.

ACTIONS

A recombinant, DNA-derived, humanized monoclonal antibody. It is a B-lymphocyte stimulator (BLyS)-specific inhibitor that blocks the binding of soluble BLyS (a B-cell survival factor) to its receptors on B-cells. Does not bind with B-cells directly. However, by binding BLyS, it inhibits the survival of B-cells (including auto-reactive B-cells) and reduces the differentiation of B-cells into immunoglobulin-producing plasma cells. Significantly reduces circulating CD19+, CD20+, naïve, and activated B-cells, plasmacytoid cells, and the SLE B-cell subset. Reductions in IgG and anti-dsDNA and increases in complement (C3 and C4) were observed as early as Week 8 and sustained through Week 52. Terminal half-life is 19.4 days.

INDICATIONS AND USES

Treatment of adult patients with active, autoantibody-positive, systemic lupus erythematosus (SLE) who are receiving standard therapy. ■ Not recommended in patients with severe active lupus nephritis or severe active central nervous system lupus; has not been studied in these situations.

CONTRAINDICATIONS

Patients who have experienced an anaphylactic hypersensitivity reaction with belimumab.

PRECAUTIONS

For IV infusion only. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Serious hypersensitivity/infusion reactions, including anaphylaxis and death, have occurred. Patients with a history of multiple drug allergies or significant hypersensitivity may be at increased risk. ■ Serious and sometimes fatal infections have been reported. Use with caution in patients with chronic infections. Therapy should not be started if a patient is receiving any therapy for a chronic infection. ■ Depression and suicidality have been reported. Most patients had a history of depression or other serious psychiatric disorders and were receiving psychoactive medications. ■ More deaths were reported with belimumab than with placebo during the controlled period of clinical trials. Etiologies included cardiovascular disease, infection, and suicide. No single cause of death predominated. ■ The impact of treatment with belimumab on the development of malignancies is not known. ■ Anti-belimumab antibodies developed in a small percentage of patients. Clinical relevance is unknown. ■ Response rates were lower in Black/African-American patients; use with caution. ■ Use in patients with impaired renal or hepatic function has not been studied.

Monitor: Obtain a baseline CBC, including a differential and platelet count. Monitor as indicated. ■ Monitor for hypersensitivity reactions carefully during and for an appropriate period of time after administration; delayed onset of severe hypersensitivity reactions has been reported. S/S reported include anaphylaxis, angioedema, dyspnea, hypotension, pruritus, rash, and urticaria. ■ On the day of the infusion, monitor for S/S of an infusion reaction (e.g., bradycardia, headache, hypotension, myalgia, nausea, rash, urticaria). ■ Consider interrupting therapy if a new infection develops during treatment with belimumab.

Patient Education: Women of childbearing potential should use effective contraceptive methods during treatment and for a minimum of 4 months after the final treatment. ■ Manufacturer has established a pregnancy registry, and patients who are or who become pregnant are encouraged to register. ■ Tell your health care provider if you are allergic to any medications. ■ Promptly report difficulty breathing; dizziness or fainting; headache; itching; nausea; skin rash, redness, or swelling; swelling of the face, lips, mouth, tongue, or throat; may indicate a hypersensitivity/infusion reaction. ■ Promptly report bloody diarrhea, chest discomfort or pain, chills, cold sweats, coughing up mucus, dizziness, fever, nausea, new or worsening depression or suicidal thoughts, pain or burning with urination, unusual changes in behavior or mood.

Maternal/Child: Category C: use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Numbers in clinical studies are insufficient to determine if the elderly respond differently than younger subjects; use with caution.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. ■ Has not been studied in combination with other **biologics, including B-cell-targeted therapies or IV cyclophosphamide**; concurrent use is not recommended. ■ Do not administer **live virus vaccines** for 30 days before or concurrently with belimumab. ■ Has been administered concomitantly with corticosteroids, antimalarials, immunomodulatory and immunosuppressive agents (including azathioprine, methotrexate, and mycophenolate), angiotensin-pathway antihypertensives, HMG-CoA reductase inhibitors (statins), and NSAIDs without meaningful clinical effect on belimumab pharmacokinetics.

SIDE EFFECTS

Bronchitis, depression, diarrhea, fever, insomnia, nasopharyngitis, migraine, nausea, pain in extremities, and pharyngitis were most commonly reported. The most common serious infections included bronchitis, cellulitis, pneumonia, and urinary tract infections. Anxiety, cystitis, depression, hypersensitivity/infusion reactions, influenza, leukopenia, sinusitis, and viral gastroenteritis also were reported.

Post-Marketing: Fatal anaphylaxis.

ANTIDOTE

Notify physician of all side effects. Treatment of most side effects will be supportive. Consider interrupting therapy if a new infection develops during treatment with belimumab. Slow or interrupt infusion rate if an infusion reaction develops. Infusion reactions may be treated with acetaminophen, antiemetics (e.g., ondansetron [Zofran]), antihistamines (e.g., diphenhydramine [Benadryl]), H₂ antagonists (e.g., ranitidine [Zantac]), or corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]) as indicated. Discontinue if a serious hypersensitivity reaction occurs. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine).

BENDAMUSTINE HYDROCHLORIDE

(ben-deh-MUS-teen)

Antineoplastic
Alkylating agent

Treanda

pH 2.5 to 3.5

USUAL DOSE

Premedication with antihistamines (e.g., diphenhydramine [Benadryl]), antipyretics (e.g., acetaminophen [Tylenol]), and corticosteroids may be indicated; see [Monitor](#) and [Antidote](#).

Chronic lymphocytic leukemia (CLL): 100 mg/M² as an IV infusion on Days 1 and 2 of a 28-day cycle. May be repeated for up to 6 cycles.

Non-Hodgkin's lymphoma (NHL): 120 mg/M² as an IV infusion on Days 1 and 2 of a 21-day cycle. May be repeated for up to 8 cycles.

DOSE ADJUSTMENTS

Chronic lymphocytic leukemia (CLL) and non-Hodgkin's lymphoma (NHL): Delay treatment for Grade 4 hematologic toxicity or clinically significant nonhematologic toxicity equal to or greater than Grade 2. In addition, dose reduction may be indicated; see specific indication. Reinitiate treatment, if indicated, when nonhematologic toxicity has recovered to equal to or less than Grade 1 and/or the ANC has recovered to equal to or greater than 1,000 cells/mm³ and platelets have recovered to equal to or greater than 75,000 cells/mm³. ■ No dose adjustment indicated based on age or gender; see [Precautions](#).

Chronic lymphocytic leukemia (CLL): Reduce dose to 50 mg/M² on Days 1 and 2 of each cycle for Grade 3 or greater hematologic toxicity. If Grade 3 or greater toxicity recurs, reduce dose to 25 mg/M² on Days 1 and 2 of each cycle. ■ Reduce dose to 50 mg/M² on Days 1 and 2 of each cycle for clinically significant Grade 3 or greater nonhematologic toxicity. ■ Dose re-escalation in subsequent cycles may be considered by the treating physician.

Non-Hodgkin's lymphoma (NHL): Reduce dose to 90 mg/M² on Days 1 and 2 of each cycle for Grade 4 hematologic toxicity. If Grade 4 toxicity recurs, reduce the dose to 60 mg/M² on Days 1 and 2 of each cycle. ■ Reduce dose to 90 mg/M² on Days 1 and 2 of each cycle for Grade 3 or greater nonhematologic toxicity. If Grade 3 or greater toxicity recurs, reduce the dose to 60 mg/M² on Days 1 and 2 of each cycle.

DILUTION

Specific techniques required; see [Precautions](#): Reconstitute each 25-mg vial with 5 mL of SWFI and each 100-mg vial with 20 mL of SWFI; concentration is 5 mg/mL. Shake well. Should completely dissolve within 5 minutes. Do not use if particulate matter is observed. Within 30 minutes of reconstitution, withdraw the desired dose from the vial(s) and further dilute in 500 mL NS or D2.5/½NS. Final concentration of infusion solution should be 0.2 to 0.6 mg/mL. Mix thoroughly; solution should be clear and colorless to slightly yellow.

Filters: Specific information not available.

Storage: Protect unopened vials from light in original package and store at CRT. Solution diluted in NS or D2.5/½NS is stable for 3 hours at CRT and room light or for 24 hours refrigerated at 2° to 8° C (36° to 47° F). Administration must be completed within these times (e.g., 3 or 24 hours based on type of storage). Discard any unused solution.

COMPATIBILITY

Manufacturer states, “**Compatibility** with other diluents has not been determined.”

RATE OF ADMINISTRATION

Chronic lymphocytic leukemia (CLL): Total daily dose as an infusion equally distributed over 30 minutes.

Non-Hodgkin's lymphoma (NHL): Total daily dose as an infusion equally distributed over 60 minutes.

ACTIONS

A bifunctional mechlorethamine derivative. An alkylating agent. Active against both quiescent and dividing cells. Exact mode of action unknown. May lead to cell death by damaging the DNA in cancer cells as well as by disrupting normal cell division. Highly protein bound. Distributes freely in human red blood cells. Primarily metabolized via hydrolysis to metabolites with low cytotoxic activity and excreted in feces.

INDICATIONS AND USES

Treatment of patients with chronic lymphocytic leukemia (CLL). Has resulted in a delay in disease progression, and some patients had no signs of disease in their blood after treatment. Effectiveness compared with first-line therapies other than chlorambucil (Leukeran) has not been studied. ■ Treatment of patients with indolent B-cell non-Hodgkin's lymphoma that has progressed during or within 6 months of treatment with rituximab (Rituxan) or a rituximab-containing regimen.

CONTRAINDICATIONS

Known hypersensitivity to bendamustine or mannitol.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist in a facility equipped to monitor the patient and respond to any medical emergency. ■ Do not use in patients with a CrCl less than 40 mL/min. Use with caution in patients with mild or moderate renal impairment; no formal studies conducted. ■ Use with caution in patients with mild hepatic impairment. Do not use in patients with moderate hepatic impairment (AST or ALT 2.5 to 10 times the ULN and total bilirubin 1.5 to 3 times the ULN) or severe hepatic impairment (total bilirubin greater than 3 times the ULN). No formal studies conducted. ■ Myelosuppression may be severe and require a dose delay. Deaths from myelosuppression-related adverse reactions have occurred; see [Dose Adjustments](#). ■ Infections, including pneumonia and sepsis, have been reported. Has been associated with septic shock and death. ■ Infusion and/or hypersensitivity reactions are common and have resulted in anaphylaxis (rare). Usually occur in the second and/or subsequent cycles of therapy. ■ Tumor lysis syndrome (TLS) has been reported and may occur in the first treatment cycle. S/S are rapid reduction in tumor volume, renal insufficiency, hyperkalemia, hypocalcemia, hyperuricemia, or hyperphosphatemia. May lead to acute renal failure and death. ■ Skin reactions, including rash, toxic skin reactions, and bullous exanthema, have been reported; see [Drug/Lab Interactions](#) and [Antidote](#). ■ Premalignant and malignant diseases, including myelodysplastic syndrome, myeloproliferative disorders, acute myeloid leukemia, and bronchial carcinoma have been reported. Causal relationship has not been determined.

Monitor: Obtain baseline CBC with differential and platelet count. Monitor CBC with differential weekly, and monitor platelet count each cycle. Hematologic nadir usually occurs in the third week. If recovery to recommended values does not occur before Day 28, delay dose until recovery occurs. ■ Obtain baseline CrCl, AST, ALT, and total bilirubin; repeat as indicated. ■ Monitor closely for S/S of infusion or hypersensitivity reactions (e.g., chills, fever, pruritus, rash). Discontinue bendamustine if a severe reaction occurs. Inquire about possible symptoms that suggest a minor reaction after the first infusion. Consider premedication with antihistamines (e.g., diphenhydramine [Benadryl]), antipyretics (e.g., acetaminophen [Tylenol]), and corticosteroids in patients who have experienced a Grade 1 or 2 infusion reaction; see [Antidote](#). ■ Monitor for S/S of TLS. In patients at risk for TLS, prevention and treatment of hyperuricemia may be accomplished with adequate hydration. Allopurinol has been used during the beginning of bendamustine therapy; see [Drug/Lab Interactions](#). Monitor uric acid levels. Monitor electrolytes, particularly potassium, and treat as indicated. ■ Monitor patients with skin reactions closely. Withhold or discontinue bendamustine if skin reactions are severe or progressive. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Observe for S/S of infection (e.g., fever). Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for throm-

bocytopenia (platelet count less than 50,000 cells/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor IV site for signs of extravasation during and after administration (e.g., infection, pain, redness, swelling, necrosis); extravasation has resulted in hospitalization. **Patient Education:** Avoid pregnancy; nonhormonal birth control is recommended for both men and women throughout treatment and for 3 months after treatment is complete; report a suspected pregnancy immediately. May pose a risk to reproductive capacity in both males and females. ■ Promptly report signs of infection (e.g., chills, fever) or allergic reaction (e.g., dyspnea, itching, rash) and severe or worsening itching or rash. ■ Report IV site burning or stinging promptly. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; can cause fetal harm. May also cause impaired spermatogenesis, azoospermia, and total germinal aplasia in males. Males and females of childbearing age must use birth control. ■ If the drug is used during pregnancy or if the patient becomes pregnant during therapy, inform the patient of the potential hazard to the fetus. ■ Has the potential for serious side effects; discontinue breastfeeding. ■ Effectiveness for use in pediatric patients not established. Evaluation of one small Phase 1/2 trial suggests that the safety profile in pediatric patients is similar to that seen in adults; see prescribing information.

Elderly: Side effect profile similar for all age-groups studied.

Chronic lymphocytic leukemia (CLL): Response to bendamustine was improved in all age-groups over the response to chlorambucil; however, response in the elderly was less than in younger adults. The progression-free survival time was somewhat longer for younger adults compared with those 65 years of age or older.

Non-Hodgkin's lymphoma (NHL): Effectiveness and duration of response similar for all age-groups.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been conducted. ■ Active metabolites of bendamustine are formed via cytochrome P₄₅₀ CYP1A2. **Inhibitors of CYP1A2** (e.g., ciprofloxacin [Cipro], fluvoxamine [Luvox]) may increase plasma concentrations of bendamustine and decrease plasma concentrations of active metabolites. **Inducers of CYP1A2** (e.g., omeprazole [Prilosec], smoking) may decrease plasma concentrations of bendamustine and increase plasma concentrations of its active metabolites. Use caution or consider alternative treatments if concomitant treatment with CYP1A2 inhibitors or inducers is indicated. ■ Not likely to inhibit metabolism via other selected CYP isoenzymes or to induce the metabolism of substrates of cytochrome P₄₅₀ enzymes. ■ Cases of Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) have been reported with concomitant administration of **allopurinol and other medications known to cause these syndromes** (e.g., rituximab [Rituxan]). ■ *In vitro* data suggest that P-glycoprotein breast cancer resistance protein (BCRP) and/or other efflux transporters may have a role in bendamustine transport.

SIDE EFFECTS

Anorexia, constipation, cough, diarrhea, dyspnea, fatigue, fever, headache, myelosuppression (anemia, febrile neutropenia, leukopenia, lymphopenia, neutropenia, thrombocytopenia), nausea, rash, vomiting, and weight loss were most common. Other side effects reported include asthenia; chills; decreased CrCl; dry mouth; elevated AST, ALT, and bilirubin levels; herpes simplex; hypersensitivity and/or infusion reactions (e.g., anaphylaxis [rare], pruritus, rash); hypertension; hyperuricemia; infections; malaise; malignancies; mucosal inflammation; nasopharyngitis; pneumonia; sepsis; somnolence; stomatitis; TLS; and weakness. Hypersensitivity reactions and fever required study withdrawal in some patients.

Post-Marketing: Anaphylaxis, extravasation resulting in hospitalization, infusion site reactions (irritation, pain, phlebitis, pruritus, swelling), Stevens-Johnson syndrome, and toxic epidermal necrolysis.

Overdose: Ataxia, cardiac arrhythmias, convulsions, respiratory distress, sedation, tremor.

ANTIDOTE

Keep physician informed of all side effects and hematologic parameters. Side effects may decrease in severity with reduced dose. Bone marrow depression may require withholding bendamustine until recovery occurs. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) may be required. Selected blood modifiers (e.g., erythropoiesis-stimulating agents [ESAs (Aranesp, Epogen, Mircera)], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Discontinue the infusion immediately for any life-threatening side effect (e.g., clinically significant bronchospasm, cardiac arrhythmias, severe hypotension). Consider premedication with antihistamines (e.g., diphenhydramine [Benadryl]), antipyretics (e.g., acetaminophen [Tylenol]), and corticosteroids in subsequent cycles in patients who have experienced a Grade 1 or 2 hypersensitivity and/or infusion reaction. Grade 3 or 4 reactions have not typically been re-challenged, consider discontinuing bendamustine. Withhold or discontinue bendamustine if skin reactions are severe or progressive. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. ECG monitoring may be indicated to evaluate cardiac side effects.

BEVACIZUMAB **BBW**
(beh-vah-SIZZ-ih-mab)

Recombinant monoclonal antibody
Angiogenesis inhibitor
Antineoplastic

Avastin

pH 6.2

USUAL DOSE

Do not begin therapy until at least 28 days after major surgery. Surgical incisions should be fully healed. May be used in combination with other antineoplastic agents or as a single agent. See **Dose Adjustments**, **Monitor**, and **Precautions**. Continue treatment until disease progression or unacceptable toxicity occurs.

Metastatic carcinoma of the colon or rectum: Administered as an infusion. Recommended doses are either 5 mg/kg or 10 mg/kg every 2 weeks when used in combination with intravenous 5-FU–based chemotherapy. Administer 5 mg/kg when used in combination with bolus IFL (irinotecan [Camptosar], fluorouracil [5-FU], leucovorin calcium). Administer 10 mg/kg when used in combination with FOLFOX4 (fluorouracil [5-FU], leucovorin calcium, and oxaliplatin [Eloxatin]).

Administer 5 mg/kg every 2 weeks or 7.5 mg/kg every 3 weeks when used in combination with a fluoropyrimidine-irinotecan–based or a fluoropyrimidine-oxaliplatin–based chemotherapy regimen in patients who have progressed on a first-line bevacizumab-containing regimen.

Nonsquamous, non–small cell lung cancer: 15 mg/kg as an infusion every 3 weeks in combination with carboplatin (Paraplatin) and paclitaxel (Taxol).

Glioblastoma: 10 mg/kg every 2 weeks.

Metastatic renal cell carcinoma: 10 mg/kg every 2 weeks in combination with interferon alfa.

DOSE ADJUSTMENTS

No dose adjustments are recommended based on age, gender, or race. ■ No dose adjustments are recommended for patients with impaired hepatic or renal function; bevacizumab was not studied in these patients. ■ Permanently discontinue if GI perforation, fistula formation in the GI tract (e.g., enterocutaneous, esophageal, duodenal, rectal), intra-abdominal abscess, fistula formation involving an internal organ, wound dehiscence (parting of the sutured lips of a surgical wound) or wound healing complications requiring medical intervention, serious bleeding, a severe arterial thromboembolic event, ne-

phrotic syndrome, hypertensive crisis or hypertensive encephalopathy, or reversible posterior leukoencephalopathy syndrome (RPLS) develops; see **Monitor** and **Precautions**. ■ Temporarily discontinue if moderate to severe proteinuria (equal to or greater than 2 Gm), severe hypertension not controlled with medical management, and/or a severe infusion reaction occurs; see **Monitor** and **Precautions**. ■ Withhold bevacizumab for at least 4 weeks before elective surgery (half-life is approximately 20 days but has a wide range). Incision must be fully healed before therapy is resumed.

DILUTION

Available in single-use vials containing 100 mg in 4 mL or 400 mg in 16 mL (25 mg/mL). Calculate desired dose and choose the appropriate vial or combination of vials. Withdraw the required volume of bevacizumab and dilute in a total volume of 100 mL with NS.

Filters: Not required by manufacturer; however, studies using a 0.2-micron in-line filter were done, and drug potency appeared to be maintained.

Storage: Store in original carton in refrigerator at 2° to 8° C (36° to 46° F). Protect from light. **Do not shake or freeze.** Diluted solutions may be refrigerated for up to 8 hours. Contains no preservatives; unused portions must be discarded.

COMPATIBILITY

Manufacturer states, “Should not be administered with or mixed with dextrose solutions.” **Incompatibilities** with polyvinylchloride or polyolefin bags have not been observed.

RATE OF ADMINISTRATION

Do not administer as an IV push or bolus. Must be given as an infusion. Administer following concurrent chemotherapy. Infusion reactions are not common but may occur; see **Monitor**.

Initial infusion: A single dose equally distributed over 90 minutes.

Second infusion: If the initial infusion is well tolerated, the second infusion may be administered equally distributed over 60 minutes.

Subsequent infusions: If the 60-minute infusion is well tolerated, subsequent infusions may be administered equally distributed over 30 minutes.

ACTIONS

A humanized IgG₁ monoclonal antibody produced by recombinant DNA technology. Has anti-angiogenesis properties; it binds to and inhibits the biologic activity of human vascular endothelial growth factor (VEGF). The interaction of VEGF with its receptors leads to endothelial cell proliferation and new blood vessel formation. By binding VEGF, bevacizumab prevents the interaction of VEGF with its receptors on the surface of endothelial cells, thus inhibiting the development of new blood vessels around tumors (a tumor-starving mechanism) and resulting in a reduction of microvascular growth and an inhibition of metastatic disease progression. Predicted time to steady-state was 100 days. Half-life is approximately 20 days (range is 11 to 50 days). IgG antibodies may cross the placental barrier and be secreted in breast milk.

INDICATIONS AND USES

First-line or second-line treatment of metastatic carcinoma of the colon or rectum. Used in combination with intravenous 5-fluorouracil-based chemotherapy (e.g., IFL, FOLFOX4). Effectiveness as a single agent has not been established. ■ Second-line treatment of metastatic colorectal cancer in patients who have progressed on a first-line bevacizumab-containing regimen. Used in combination with fluoropyrimidine-irinotecan-based or fluoropyrimidine-oxaliplatin-based chemotherapy. ■ First-line treatment of patients with unresectable, locally advanced, recurrent, or metastatic nonsquamous, non-small cell lung cancer. Given in combination with carboplatin and paclitaxel. ■ Treatment of glioblastoma in adult patients as a single agent for patients with progressive disease following prior therapy. (Effectiveness is based on an improvement in objective response rate. There are no data showing an improvement in disease-related symptoms or increased survival with bevacizumab.) ■ Treatment of metastatic renal cell cancer. Given in combination with interferon alfa.

Limitation of use: Not indicated for adjuvant treatment of colon cancer.

CONTRAINDICATIONS

Manufacturer states, “No known contraindications.” However, bevacizumab must be discontinued if GI perforation, wound dehiscence requiring medical intervention, serious bleeding, nephrotic syndrome, or hypertensive crisis develops. ■ Use with caution in patients with known hypersensitivity to murine proteins, bevacizumab, or any of its components. ■ Not recommended for use in patients with recent hemoptysis (greater than or equal to ½ teaspoon of red blood).

PRECAUTIONS

Do not administer as an IV push or bolus. Must be given as an infusion. ■ Should be administered by or under the direction of a physician specialist in a facility equipped to monitor the patient and respond to any medical emergency. ■ Has been shown to impair wound healing; withhold bevacizumab for a minimum of 28 days after major surgery; surgical incision must be fully healed. Withhold at least 28 days before elective surgery (half-life is approximately 20 days but has a wide range). Appropriate intervals between surgery and the beginning of bevacizumab therapy and/or the end of bevacizumab therapy and subsequent elective surgery have not been determined. ■ GI perforation with or without fistula formation and/or intra-abdominal abscesses have occurred at various times during treatment; deaths have been reported. Consider GI perforation in any patient with complaints of abdominal pain associated with constipation, fever, nausea, and vomiting. ■ Non-gastrointestinal fistula formation has been reported, in some cases with a fatal outcome. Fistula formations involving tracheoesophageal, bronchopleural, biliary, vaginal, renal, and bladder areas have been reported. ■ Severe or fatal hemorrhage, including CNS hemorrhage, epistaxis, GI bleed, hemoptysis, and vaginal bleeding occurred up to five times more frequently in patients receiving bevacizumab. Do not administer bevacizumab to patients with serious bleeding or hemoptysis. ■ May cause severe hypertension that may be persistent. Treatment is required. Complications can include hypertensive encephalopathy and CNS hemorrhage; see [Monitor](#) and [Antidote](#). ■ Reversible posterior leukoencephalopathy syndrome (RPLS) has been reported. May present with blindness and other visual and neurologic disturbances, confusion, headache, lethargy, and seizures. Mild to severe hypertension may be present. MRI is required to confirm diagnosis. Symptoms usually resolve gradually with discontinuation of bevacizumab and treatment of hypertension. ■ Severe neutropenia, febrile neutropenia, and infection with neutropenia have been reported in patients treated with myelosuppressive chemotherapy plus bevacizumab. ■ Proteinuria occurred during studies and progressed to nephrotic syndrome in some patients. Findings consistent with thrombotic microangiopathy have been found on kidney biopsy in some patients. In other patients, proteinuria decreased within several months after therapy was discontinued. ■ CHF has been reported. Incidence is higher in patients receiving chemotherapy plus bevacizumab compared with patients receiving chemotherapy alone. ■ Infusion reactions are infrequent but have occurred. S/S may include chest pain, diaphoresis, Grade 3 hypersensitivity, headache, hypertension, hypertensive crisis associated with neurologic S/S, oxygen desaturation, rigors, and wheezing. ■ Serious and sometimes fatal arterial thromboembolic events (e.g., CVA [stroke], MI, TIA, angina) and venous thromboembolic events (e.g., deep vein thrombosis, intra-abdominal thrombosis) have been reported. Incidence is greater with bevacizumab given in combination with chemotherapy as compared to those receiving chemotherapy alone. Risk increased in patients with a history of arterial thromboembolism and in patients greater than 65 years of age. ■ Bevacizumab increases the risk of ovarian failure (defined as amenorrhea lasting 3 or more months, FSH level equal to or greater than 30 mIU/mL, and a negative serum β -HCG pregnancy test). Recovery of ovarian function occurred in some but not all women following discontinuation of therapy. Long-term effects of bevacizumab exposure on fertility are unknown. ■ A protein substance, it has the potential for producing an immune response. However, neutralizing antibodies against bevacizumab have been found using a specific immunosorbent assay; clinical significance is not known. ■ See [Drug/Lab Interactions](#) and [Antidote](#).

Monitor: Obtain baseline BP, CBC with differential and platelets, electrolytes, and urinalysis. ■ Monitor for S/S of an infusion reaction (e.g., chest pain, chills, diaphoresis,

headache, hypertension, hypertensive crisis associated with neurologic S/S, oxygen desaturation, wheezing). ■ Monitor V/S and BP at least every 2 weeks; monitor more frequently in patients with hypertension. ACE inhibitors, beta-blockers, calcium channel blockers, and diuretics may be used to manage hypertension. Continue to monitor BP at regular intervals after therapy is discontinued. ■ Repeat CBC with differential and platelets and electrolytes as indicated. ■ Use of prophylactic antibiotics may be indicated pending C/S in a febrile, neutropenic patient. ■ Obtain serial urinalyses in patients with 1+ proteinuria. Obtain 24-hour urine collections in patients with new-onset, worsening proteinuria or 2+ proteinuria. Monitor patients with moderate to severe proteinuria until improvement and/or resolution is observed. Repeat urinalyses and/or 24-hour urine collections as indicated. ■ Monitor for S/S of CHF (e.g., cyanosis, dyspnea on mild exertion, edema, fatigue on exertion, hypoxemia, intolerance to cold, jugular venous distention, orthopnea, pulmonary rales, tachycardia, third heart sound). ■ Check surgical wounds for wound dehiscence and monitor for S/S of bleeding or GI perforation (e.g., abdominal pain, constipation, fever, hypotension, nausea and vomiting). ■ See [Dose Adjustments, Rate of Administration, Precautions, and Antidote](#).

Patient Education: Avoid pregnancy during treatment and for an extended period after completion of therapy (some drug could remain in the system for up to 6 months or more). Nonhormonal birth control recommended; see [Maternal/Child](#). Women should report a suspected pregnancy immediately. ■ Increases risk of ovarian failure and may impair fertility. ■ Full disclosure of health history is imperative. ■ Report any unusual or unexpected symptoms or side effects promptly (e.g., abdominal pain, bleeding from any source, constipation, dyspnea, persistent cough, sudden onset of worsening neurologic function, vomiting, wound separation). ■ Routine monitoring of BP required. ■ See Appendix D, p. 1255.

Maternal/Child: Category C: use during pregnancy or in any woman not using adequate contraception only if potential benefit justifies potential risk to fetus. Adverse fetal outcomes have been observed in rabbits. Angiogenesis is critical to fetal development. Inhibition of angiogenesis by bevacizumab is likely to harm a fetus. ■ May cause ovarian failure in premenopausal women; long-term effects on fertility are unknown. ■ Discontinue breast-feeding during treatment with bevacizumab and for a prolonged period following treatment (half-life may be up to 50 days). ■ Safety and effectiveness for use in pediatric patients (including glioblastoma) not established. ■ Dose-related physal dysplasia (variations in the growth plate) occurred in tested juvenile monkeys; partially reversible after therapy is discontinued.

Elderly: Overall survival was similar compared to younger adults; however, the incidence of some side effects was increased (e.g., anemia, anorexia, arterial thromboembolic events [e.g., CVA (stroke), MI, TIA, angina], asthenia, CHF, constipation, deep thrombophlebitis, dehydration, diarrhea, dyspepsia, edema, epistaxis, fatigue, GI hemorrhage, hypertension, hypokalemia, hyponatremia, hypotension, ileus, increased cough, leukopenia, nausea and vomiting, proteinuria, sepsis, venous thromboembolic events [e.g., deep vein thrombosis, intra-abdominal thrombosis, pulmonary embolism], voice alteration).

DRUG/LAB INTERACTIONS

Drug interaction studies have not been completed. ■ Has been administered concurrently with a regimen of **irinotecan, 5-fluorouracil, and leucovorin**. Studies indicate no significant effect of bevacizumab on the pharmacokinetics of irinotecan or its active metabolite SN-38. ■ Has been administered with **carboplatin, paclitaxel, and interferon alfa**. ■ Several cases of microangiopathic hemolytic anemia (MAHA) have been reported in patients with solid tumors who are receiving concomitant therapy with bevacizumab and **sunitinib malate** (Sutent). This combination therapy is not approved and not recommended. ■ **ACE inhibitors, beta-blockers, calcium channel blockers, and diuretics** have been coadministered to control hypertension.

SIDE EFFECTS

The most common side effects include back pain, dry skin, epistaxis, exfoliative dermatitis, headache, hypertension, lacrimation (excess), proteinuria, rectal hemorrhage, rhini-

tis, and taste alteration. Major, dose-limiting, and potentially life-threatening side effects include arterial thromboembolic events (e.g., angina, cerebral infarction, MI, TIA), bleeding episodes (e.g., CNS hemorrhage, epistaxis [severe], GI hemorrhage, hemoptysis, vaginal bleeding), GI perforations, hypertensive crises, non-gastric intestinal fistula formation, proteinuria and/or nephrotic syndrome, reversible posterior leukoencephalopathy syndrome (RPLS), and surgery and wound healing complications. Other reported side effects included abdominal pain, abnormal gait, alopecia, anorexia, asthenia, bilirubinemia, CHF, colitis, confusion, constipation, cough, dehydration, diarrhea, dizziness, dry mouth, dyspepsia, dysphonia, dyspnea, edema, fatigue, flatulence, hematologic toxicity (e.g., anemia, leukopenia, neutropenia, thrombocytopenia), hypokalemia, hyponatremia, hypotension, ileus, infection, myalgia, nail disorder, nausea, pain, pneumonitis, renal thrombotic microangiopathy (manifested as severe proteinuria), sensory neuropathy, sepsis, skin discoloration, skin ulcer, stomatitis, syncope, urinary frequency and urgency, venous thromboembolic events (e.g., deep vein thrombosis, intra-abdominal thrombosis, pulmonary embolism), voice alteration, vomiting, weight loss.

Post-Marketing: Anastomotic ulceration, acute hypertensive episodes, gallbladder perforation, GI fistula formation (e.g., gastrointestinal, enterocutaneous, esophageal, duodenal, rectal), GI perforation, GI ulcer, hepatobiliary disorders, intestinal necrosis, intra-abdominal abscess, mesenteric venous occlusion, nasal septum perforation, osteonecrosis of the jaw, ovarian failure, pancytopenia, polyserositis, pulmonary hypertension.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Permanently discontinue if any of the following develop: GI perforation, fistula formation in the GI tract (e.g., enterocutaneous, esophageal, duodenal, rectal), intra-abdominal abscess, fistula formation involving an internal organ, wound dehiscence requiring medical intervention, serious bleeding requiring medical intervention, nephrotic syndrome, a severe arterial thromboembolic event, reversible posterior leukoencephalopathy syndrome, hypertensive crisis, or hypertensive encephalopathy. Treat these side effects aggressively; see [Precautions](#) and [Monitor](#). Discontinue bevacizumab for severe infusion reactions and treat as indicated (e.g., epinephrine, diphenhydramine [Benadryl], IV fluids, oxygen). Data on rechallenge not available. Temporarily discontinue if moderate to severe proteinuria (equal to or greater than 2 Gm) occurs. Resume therapy when proteinuria is less than 2 Gm/24hr; see [Monitor](#) and [Precautions](#). Temporarily discontinue if severe hypertension not controlled with medical management occurs; see [Monitor](#) and [Precautions](#). Thromboembolic events (e.g., deep vein thrombosis, intra-abdominal thrombosis, pulmonary embolism) were treated with full-dose warfarin (Coumadin) during clinical trials. Monitor INR closely. Bleeding occurred in patients with elevated INRs; relationship to bevacizumab not determined. Withhold bevacizumab for at least 28 days before elective surgery (half-life is approximately 20 days but has a wide range). Incision must be fully healed before therapy is resumed.

BIVALIRUDIN

(by-val-ih-ROO-din)

Anticoagulant

Angiomax

pH 5 to 6

USUAL DOSE

Obtain baseline blood tests before administration; see **Monitor** and **Drug/Lab Interactions**. Initiate just prior to percutaneous coronary intervention (PCI). Given in combination with aspirin.

Aspirin: 300 to 325 mg before PCI and daily thereafter.

Bivalirudin: Begin with an IV bolus dose of 0.75 mg/kg. Follow with an infusion at 1.75 mg/kg/hr for the duration of the PCI procedure. Perform an ACT 5 minutes after the bolus dose has been administered. An additional bolus dose of 0.3 mg/kg should be given if needed (e.g., ACT less than 225 seconds). The infusion may be continued for 4 hours post-procedure at the discretion of the treating physician. After 4 hours a reduced infusion rate of 0.2 mg/kg/hr may be administered for up to 20 hours if indicated. Administration with glycoprotein GPIIb/IIIa inhibitors (e.g., abciximab [ReoPro], eptifibatid [Integrilin], tirofiban [Aggrastat]) should be considered in any of the following circumstances:

- Decreased flow or reflow
- Dissection with decreased flow
- New or suspected thrombus
- Persistent residual stenosis
- Distal embolization
- Unplanned stent placement
- Suboptimal stenting
- Side branch closure
- Abrupt closure, clinical instability
- Prolonged ischemia

DOSE ADJUSTMENTS

Reduce infusion rate in impaired renal function as indicated in the following chart. No reduction in the bolus dose is needed.

Guidelines for Bivalirudin Dose Adjustments in Impaired Renal Function*	
Renal Function (GFR)	Infusion Rate (mg/kg/hr)
GFR >30 mL/min	1.75 mg/kg/hr
GFR 10 to 29 mL/min	1 mg/kg/hr
Patients on hemodialysis	0.25 mg/kg/hr

*The ACT should be monitored in renally impaired patients.

DILUTION

Bolus and initial infusion: Reconstitute each 250-mg vial with 5 mL SWFI. Gently swirl to dissolve. Each 250-mg vial must be further diluted in 50 mL of D5W or NS to yield a final concentration of 5 mg/mL (e.g., 1 vial in 50 mL, 2 vials in 100 mL, and 5 vials in 250 mL).

Low rate or subsequent infusion: After reconstitution as above, the 250-mg vial should be further diluted in 500 mL of D5W or NS to yield a final concentration of 0.5 mg/mL.

Storage: Store unopened vials at RT. Do not freeze reconstituted or diluted solution. Reconstituted solution stable for 24 hours refrigerated. Concentrations between 0.5 mg/mL and 5 mg/mL are stable at CRT for up to 24 hours. Discard unused portion of reconstituted solution.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug **NOT** listed as compatible to be **INCOMPATIBLE** until consulting a pharmacist; specific conditions may apply.

Manufacturer lists alteplase (Activase, tPA), amiodarone (Nexterone), amphotericin B (conventional), chlorpromazine (Thorazine), diazepam (Valium), dobutamine, prochlorperazine (Compazine), reteplase (Retavase, r-PA), streptokinase, and vancomycin as **incompatible** through the same IV line (**Y-site** or piggyback). No **incompatibilities** observed with glass bottles or polyvinyl chloride bags and administration sets.

One source suggests the following **compatibilities**:

Y-site: Abciximab (ReoPro), alfentanil (Alfenta), amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), atropine, azithromycin (Zithromax), aztreonam (Azactam), bumetanide, butorphanol (Stadol), calcium gluconate, cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefotetan, ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), ciprofloxacin (Cipro IV), clindamycin (Cleocin), dexamethasone (Decadron), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, dopamine, doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), ephedrine, epinephrine (Adrenalin), epoprostenol (Flolan), eptifibatid (Integrilin), erythromycin (Erythrocin), esmolol (Brevibloc), famotidine (Pepcid IV), fentanyl (Sublimaze), fluconazole (Diflucan), furosemide (Lasix), gentamicin, heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), isoproterenol (Isuprel), labetalol, levofloxacin (Levaquin), lidocaine, lorazepam (Ativan), magnesium, mannitol (Osmitol), meperidine (Demerol), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metoprolol (Lopressor), metronidazole (Flagyl IV), midazolam (Versed), milrinone (Primacor), morphine, nalbuphine, nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), phenylephrine (Neo-Synephrine), piperacillin/tazobactam (Zosyn), potassium chloride, procainamide (Pronestyl), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, sufentanil (Sufenta), sulfamethoxazole/trimethoprim, theophylline, ticarcillin/clavulanate (Timentin), tirofiban (Aggrastat), tobramycin, verapamil, warfarin (Coumadin).

RATE OF ADMINISTRATION

The following chart details by patient weight in kilograms, the amount of the bolus dose, the rate in mL/hr of the initial infusion, and the rate in mL/hr of the subsequent infusion.

Bivalirudin Dosing Guidelines			
Weight (kg)	Using 5 mg/mL Concentration		Using 0.5 mg/mL Concentration
	Bolus (0.75 mg/kg) (mL)	Infusion (1.75 mg/kg/hr) (mL/hr)	Subsequent Low-rate Infusion (0.2 mg/kg/hr) (mL/hr)
43-47	7 mL	16 mL/hr	18 mL/hr
48-52	7.5 mL	17.5 mL/hr	20 mL/hr
53-57	8 mL	19 mL/hr	22 mL/hr
58-62	9 mL	21 mL/hr	24 mL/hr
63-67	10 mL	23 mL/hr	26 mL/hr
68-72	10.5 mL	24.5 mL/hr	28 mL/hr
73-77	11 mL	26 mL/hr	30 mL/hr
78-82	12 mL	28 mL/hr	32 mL/hr
83-87	13 mL	30 mL/hr	34 mL/hr

143-147	22 mL	51 mL/hr	58 mL/hr
148-152	22.5 mL	52.5 mL/hr	60 mL/hr

ACTIONS

An anticoagulant that is a specific and reversible direct thrombin inhibitor. It directly inhibits thrombin by specifically binding both to the catalytic site and to the anion-binding exosite of circulating and clot-bound thrombin. Inhibits both free and clot-bound thrombin without requiring endogenous cofactors (i.e., mode of action is independent of antithrombin III and is not inhibited by components of the platelet release reaction [e.g., platelet factor 4]). Produces a dose-dependent increase in aPTT, PT, TT, and ACT. Anticoagulant effect is immediate. Cleared from plasma by a combination of renal mechanisms and proteolytic cleavage. The binding of bivalirudin to thrombin is reversible resulting in recovery of thrombin active site functions. Coagulation times return to baseline approximately 1 hour after completion of infusion. Half-life averages 25 minutes. 20% of unchanged drug excreted in urine.

INDICATIONS AND USES

An anticoagulant for use in patients with unstable angina undergoing percutaneous transluminal coronary angioplasty (PTCA). (Used in place of heparin.) Used concurrently with aspirin. ■ As an anticoagulant for use in patients undergoing PCI. Used in combination with aspirin and may be used in combination with glycoprotein GPIIb/IIIa antagonists (e.g., abciximab [ReoPro], eptifibatid [Integrilin]) as medically indicated. ■ Patients with, or at risk for, heparin-induced thrombocytopenia (HIT) or heparin-induced thrombocytopenia and thrombosis syndrome (HITTS) undergoing percutaneous coronary intervention (PCI).

Unlabeled uses: Has been used in place of heparin in cardiac catheterization, AMI, and unstable angina; safety and effectiveness not established.

CONTRAINDICATIONS

Hypersensitivity to bivalirudin or its components; active major bleeding.

PRECAUTIONS

For IV use only. ■ Most bleeding associated with the use of bivalirudin in PCI/PTCA occurs at the site of arterial puncture, however, hemorrhage can occur at any site. Consider a hemorrhagic event if there is an unexplained fall in BP or hematocrit or other unexplained symptom and discontinue bivalirudin. ■ Has been associated with an increased risk of thrombus formation when used in gamma brachytherapy (percutaneous intracoronary brachytherapy). Fatalities have occurred. Imperative to maintain meticulous catheter technique, with frequent aspiration and flushing to minimize conditions of stasis within the catheter and vessels. ■ Use with caution in disease states and other circumstances in which there is an increased danger of hemorrhage including severe

hypertension; immediately following lumbar puncture; spinal anesthesia; major surgery, especially involving the brain, spinal cord, or eye; hematologic conditions associated with increased bleeding tendencies such as congenital or acquired bleeding disorders and gastrointestinal lesions such as ulcerations. ■ Safety for use in combination with thrombolytic agents (e.g., alteplase [tPA], reteplase [Retavase], streptokinase) has not been established; see [Drug/Lab Interactions](#). ■ Safety for use in patients with unstable angina who are not undergoing PCI or in patients with other acute coronary syndromes has not been established. ■ Half-life extended in patients with impaired renal function; see [Dose Adjustments](#). ■ Limited data regarding reexposure to bivalirudin; positive antibodies developed in 2 patients and neither developed clinical evidence of a hypersensitivity reaction.

Monitor: Discontinue low-molecular-weight heparin at least 8 hours prior to the procedure and administration of bivalirudin. ■ Before therapy, obtain platelet count, hemoglobin and hematocrit, SCr, ACT, aPTT, TT, and PT. ■ Dose is not titrated to ACT; however the ACT was checked at 5 minutes and again in 45 minutes during original clinical studies. ■ Monitor anticoagulation status in patients with impaired renal function receiving reduced doses. ■ Observe carefully for symptoms of a hemorrhagic event (e.g., unexplained fall in hematocrit, fall in BP, or any other unexplained symptom).

Patient Education: Risk of bleeding may be increased; discuss medical history and list of all medications (prescription and over-the-counter) with your health care provider; see [Drug Interactions](#). ■ Report all episodes of bleeding. ■ Report tarry stools. ■ Compliance with all measures to minimize bleeding is very important (e.g., avoid use of razors, toothbrushes, other sharp items). ■ Use caution while moving to avoid excess bumping.

Maternal/Child: Category B: safety for use during pregnancy not established. May have adverse effects on the fetus and the potential for maternal bleeding is increased, particularly during the third trimester. Use only if clearly needed. ■ Not known if bivalirudin is secreted in human milk, use caution if required during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response similar to younger adults. ■ See [Dose Adjustments](#) for the elderly with impaired renal function. ■ Bleeding events are more common in the elderly. Puncture site hemorrhage and hematoma were observed more frequently in patients over 65 years of age.

DRUG/LAB INTERACTIONS

Discontinue **low-molecular-weight heparin** at least 8 hours prior to the procedure and administration of bivalirudin. ■ Risk of bleeding may be increased by any medicine that affects blood clotting, including **anticoagulants** (e.g., heparin, warfarin [Coumadin]); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel [Plavix], dipyridamole [Persantine], glycoprotein GPIIb/IIIa receptor antagonists [e.g., abciximab (ReoPro), eptifibatide (Integrilin), tirofiban (Aggrastat)], plicamycin [Mithracin], sulfapyrazone [Anturane], ticlopidine [Ticlid], valproic acid [Depacon]). If concurrent or subsequent use is indicated, monitor closely.

SIDE EFFECTS

Bleeding is the most frequent adverse event; incidence in clinical studies was less than with heparin. Abdominal pain, anxiety, back pain, bradycardia, dyspepsia, fever, headache, hypersensitivity reactions including anaphylaxis, hypertension, hypotension, injection site pain, insomnia, nausea, nervousness, pain, pelvic pain, thrombus formation (with fatalities), urinary retention, and vomiting have occurred.

ANTIDOTE

No specific antidote is available. Overdose with or without bleeding may be controlled by discontinuing bivalirudin. Discontinuation leads to a gradual reduction in anticoagulant effects due to metabolism of the drug depending on dose/overdose and concentration achieved. ACT or aPTT should return to normal within 1 to 4 hours after discontinuation. Reversal may take longer in patients with renal impairment. If life-threatening bleeding

develops and excessive plasma levels of bivalirudin are suspected, immediately stop infusion. Determine aPTT, ACT, and hemoglobin and prepare for blood transfusion as appropriate. Follow current guidelines for treatment of shock as indicated (fluid, vasopressors [e.g., dopamine], Trendelenburg position, plasma expanders [e.g., albumin, hetastarch]). Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Bivalirudin is removed by hemodialysis.

<p>BLEOMYCIN SULFATE BBW (blee-oh-MY-sin SUL-fayt)</p>	<p>Antineoplastic (antibiotic)</p>
<p>Blenoxane</p>	<p>pH 4.5 to 6</p>

USUAL DOSE

Squamous cell carcinoma, non-Hodgkin’s lymphoma, testicular carcinoma: 0.25 to 0.5 units/kg of body weight/dose (10 to 20 units/M²), once or twice weekly (1 unit equals 1 mg). The first two doses in lymphoma patients should not exceed 2 units in order to rule out hypersensitivity.

Hodgkin’s disease: Dosage as above. After a 50% response, a maintenance dose of 1 unit daily or 5 units weekly is recommended.

DOSE ADJUSTMENTS

Unit/kg dose based on average weight in presence of edema or ascites. ■ Dose selection in the elderly should be cautious; consider decreased renal function and concomitant disease or drug therapy. ■ Reduce dose in impaired renal function as indicated in the following table.

CrCl (mL/min)	Bleomycin Dose
50 mL/min and above	100%
40-50 mL/min	70%
30-40 mL/min	60%
20-30 mL/min	55%
10-20 mL/min	45%
5-10 mL/min	40%

DILUTION

Specific techniques required; see Precautions. Each 15 units or fraction thereof must be reconstituted with 5 mL or more of NS. For IV injection, further dilution is not necessary, but has been further diluted in 50 to 100 mL NS and given as an intermittent infusion. May be given through Y-tube or three-way stopcock of a free-flowing IV.

Filters: No data available from manufacturer. Another source indicates no significant drug loss with the use of a 0.22-micron filter.

Storage: Refrigerate powder. Diluted solution stable at room temperature for 24 hours.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Should not be reconstituted or diluted with D5W or other dextrose-containing diluents.”

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), dexamethasone (Decadron), diphenhydramine (Benadryl), fluorouracil (5-FU), gentamicin, heparin, streptomycin, tobramycin, vinblastine, vincristine.

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), aztreonam (Azactam), cisplatin (Platinol), cyclophosphamide (Cytosan), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), droperidol (Inapsine), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gemcitabine (Gemzar), granisetron (Kytril), heparin, leucovorin calcium, melphalan (Alkeran), methotrexate, metoclopramide (Reglan), mitomycin (Mutamycin), ondansetron (Zofran), paclitaxel (Taxol), piperacillin/tazobactam (Zosyn), sargramostim (Leukine), teniposide (Vumon), thiotepa, vinblastine, vincristine, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

IV injection: Each 15 to 30 unit dose over 10 minutes.

Intermittent infusion: A single dose over 15 to 30 minutes or 1 unit/minute.

ACTIONS

An antibiotic antineoplastic agent, cell cycle phase-specific, that seems to act by splitting and fragmentation of double-stranded DNA. Inhibits DNA synthesis and, to a lesser extent, RNA and protein synthesis. It localizes in tumors. Improvement usually noted within 2 to 3 weeks. Widely distributed throughout the body. Inactivated by an enzyme that is widely distributed in normal tissue with the exception of the skin and lungs. Half-life is approximately 2 hours. About 60% to 70% excreted in urine.

INDICATIONS AND USES

Testicular carcinoma; may induce complete remission with vinblastine and cisplatin. ■ Palliative treatment, adjunct to surgery or radiation, in patients not responsive to other chemotherapeutic agents or those with squamous cell carcinoma of the skin, head, esophagus, neck, or GU tract, including the cervix, vulva, scrotum, and penis; in Hodgkin's disease and other lymphomas. ■ Injected into pleural cavity to treat malignant pleural effusion.

CONTRAINDICATIONS

Patients who have demonstrated a hypersensitive or idiosyncratic reaction to it.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ May be given by the IM, IV, SC, or IP routes. ■ Administered by or under the direction of the physician specialist. ■ Administer in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ May be used with other antineoplastic drugs to achieve tumor remission. ■ Pulmonary toxicity may progress from nonspecific pneumonitis to pulmonary fibrosis and death. Pulmonary toxicity increases markedly with advancing age or with total doses greater than 400 units but has been seen in younger patients and in patients treated with lower doses. It may occur at lower doses when bleomycin is used in combination with other antineoplastic agents. Risk of developing pulmonary toxicity is greater when O₂ is administered in surgery. To prevent this side effect, it has been recommended that the FiO₂ be maintained at concentrations approximating that of room air during surgery and in the postoperative period. Additionally, fluid replacement should be closely monitored and focus more on colloid (e.g., albumin) administration rather than on crystalloid (e.g., NS, LR) administration. ■ A severe idiosyncratic reaction (similar to anaphylaxis) has been reported in approximately 1% of lymphoma patients. S/S include hypotension, mental confusion, fever, chills, and wheezing; may be immediate or delayed for several hours. More common after the first or second doses. ■ Use with extreme caution in patients with significant renal impairment or compromised pulmonary function.

Monitor: Obtain a baseline chest x-ray, and recheck every 1 to 2 weeks to detect pulmonary changes. ■ To identify subclinical pulmonary toxicity, monitor pulmonary diffusion capacity for carbon monoxide monthly. Should remain 30% to 35% above pretreatment value. Earliest signs of pulmonary toxicity are rales and dyspnea. ■ Monitor renal, hepatic, and central nervous systems and skin for symptoms of toxicity. ■ Determine

patency of vein; avoid extravasation. ■ Maintain adequate hydration. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Observe closely for all signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Acetaminophen, diphenhydramine (Benadryl), and steroids (e.g., hydrocortisone) may be used prophylactically to reduce incidence of fever and anaphylaxis. ■ See [Precautions](#).

Patient Education: Use nonhormonal contraception. ■ Report any possible side effects promptly. ■ Report stinging or burning at IV site promptly. ■ See Appendix D, p. 1255. ■ Pulmonary toxicity more likely in smokers.

Maternal/Child: Category D: avoid pregnancy. ■ Not recommended during breastfeeding. ■ Safety and effectiveness for use in pediatric patients not established. Volume of distribution and half-life is comparable to that in adults.

Elderly: Response similar to that seen in younger adults; however, pulmonary toxicity is more common in patients older than 70 years of age. ■ See [Dose Adjustments](#); monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

See [Precautions](#). ■ Vascular toxicities (e.g., myocardial infarction, CVA, thrombotic microangiopathy, cerebral arteritis) or Raynaud's phenomenon have occurred rarely when bleomycin is used in combination with **other antineoplastic agents**. ■ May decrease GI absorption of **digoxin and hydantoins** (e.g., phenytoin). ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Causes sensitization of lung tissue to O₂; increases risk of pulmonary toxicity with O₂ and **general anesthetics**. ■ **Cisplatin** may inhibit renal elimination and increase toxicity.

SIDE EFFECTS

Alopecia, anorexia, chills, dyspnea, fever, hypotension, malaise, nausea, phlebitis (infrequent), rales, scleroderma-like skin changes, stomatitis, tenderness of the skin, tumor site pain, vomiting, weight loss.

Major: Severe idiosyncratic reaction similar to anaphylaxis (up to 6 hours after test dose), chest pain (acute with sudden onset suggestive of pleuropericarditis), pneumonitis, pulmonary fibrosis, skin toxicity (including nodules on hands, desquamation of skin, hyperpigmentation, and gangrene).

ANTIDOTE

Notify the physician of all side effects. Minor side effects will be treated symptomatically. Discontinue the drug immediately and notify the physician of any symptom of major side effects. Provide immediate treatment (epinephrine [Adrenalin] and diphenhydramine [Benadryl] for anaphylaxis, antibiotics and steroids for pneumonitis) or supportive therapy as indicated.

BORTEZOMIB

(bore-TEH-zo-mib)

Antineoplastic

Velcade

pH 2 to 6.5

USUAL DOSE

See [Dose Adjustments](#) for recommended starting dose modifications for patients with moderate to severe hepatic impairment.

Previously untreated multiple myeloma: 1.3 mg/M²/dose as an IV bolus. Given in combination with oral melphalan (Akeran) and oral prednisone for nine 6-week cycles as outlined in the following chart. For Cycles 1 to 4, administer twice weekly (Days 1, 4, 8, 11, 22, 25, 29, 32). For Cycles 5 to 9, administer once weekly (Days 1, 8, 22, 29). At least 72 hours should elapse between consecutive doses of bortezomib.

Dosage Regimen for Patients with Previously Untreated Multiple Myeloma												
Twice-Weekly Bortezomib (Cycles 1-4 When Used in Combination with Melphalan and Prednisone)												
Week	1				2		3	4		5		6
Bortezomib (1.3 mg/M ²)	Day 1	—	—	Day 4	Day 8	Day 11	Rest period	Day 22	Day 25	Day 29	Day 32	Rest period
Melphalan (9 mg/M ²) Prednisone (60 mg/M ²)	Day 1	Day 2	Day 3	Day 4	—	—	Rest period	—	—	—	—	Rest period
Once-Weekly Bortezomib (Cycles 5-9 When Used in Combination with Melphalan and Prednisone)												
Week	1				2		3	4		5		6
Bortezomib (1.3 mg/M ²)	Day 1	—	—	—	Day 8	—	Rest period	Day 22	—	Day 29	—	Rest period
Melphalan (9 mg/M ²) Prednisone (60 mg/M ²)	Day 1	Day 2	Day 3	Day 4	—	—	Rest period	—	—	—	—	Rest period

Relapsed multiple myeloma and mantle cell lymphoma: 1.3 mg/M²/dose as an IV bolus 2 times a week for 2 weeks (Days 1, 4, 8, and 11). Follow with a 10-day rest period (Days 12 through 21). At least 72 hours should elapse between doses of bortezomib (e.g., Days 1, 4, 8, and 11). A treatment cycle is 21 days. See [Dose Adjustments](#). For extended therapy of more than 8 cycles, bortezomib may be administered on the above standard schedule or on a maintenance schedule of once weekly for 4 weeks (Days 1, 8, 15, and 22), followed by a 13-day rest period (Days 23 to 35).

Combination therapy in multiple myeloma (unlabeled in bortezomib prescribing information):

Bortezomib: Administer 1.3 mg/M² as an IV bolus on Days 1, 4, 8, and 11 every 3 weeks.

Doxil: Administer 30 mg/M² on Day 4 following bortezomib. Continue for up to 8 cycles until disease progression or the occurrence of unacceptable toxicity.

DOSE ADJUSTMENTS

Dose adjustments are based on clinical toxicities. ■ Dose adjustments are not required for patients with renal insufficiency, including those requiring dialysis. Bortezomib may be partially removed by dialysis. Administer after dialysis. ■ Dose adjustments based on age, gender, or race have not been evaluated; see [Precautions](#). ■ See the following charts for recommended starting dose modifications for patients with moderate to severe hepatic impairment, dose adjustments in combination therapy with melphalan and predni-

sone, and bortezomib-related neuropathic pain and/or peripheral sensory or motor neuropathy in relapsed multiple myeloma and mantle cell lymphoma.

Recommended Starting Dose Modification for Bortezomib in Patients with Hepatic Impairment			
	Bilirubin Level	SGOT (AST) Levels	Modification of Starting Dose
Mild	≤1 × ULN	>ULN	None
Mild	>1 to 1.5 × ULN	Any	None
Moderate	>1.5 to 3 × ULN	Any	Reduce bortezomib to 0.7 mg/M ² in the first cycle. Consider dose escalation to 1 mg/M ² or further dose reduction to 0.5 mg/M ² in subsequent cycles based on patient tolerance.
Severe	>3 × ULN	Any	

Combination therapy with melphalan and prednisone in previously untreated multiple myeloma: Before each treatment cycle, platelet count should be equal to or greater than 70 × 10⁹/L, and ANC should be equal to or greater than 1 × 10⁹/L. Nonhematologic toxicities should have resolved to Grade 1 or baseline. Dose modifications for subsequent cycles are outlined in the following chart.

Dose Modifications During Cycles of Combination Bortezomib, Melphalan, and Prednisone Therapy*	
Toxicity	Dose Modification or Delay
Hematologic toxicity during a cycle: If prolonged Grade 4 neutropenia or thrombocytopenia, or thrombocytopenia with bleeding, is observed in the previous cycle	Consider reducing the melphalan dose by 25% in the next cycle.
If platelet count is ≤30 × 10 ⁹ /L or ANC is ≤0.75 × 10 ⁹ /L on a bortezomib-dosing day (other than Day 1)	Withhold bortezomib dose.
If several bortezomib doses in consecutive cycles are withheld due to toxicity	Reduce bortezomib dose by 1 dose level (from 1.3 mg/M ² to 1 mg/M ² , or from 1 mg/M ² to 0.7 mg/M ²).
Grade ≥3 nonhematologic toxicities	Withhold bortezomib therapy until symptoms of the toxicity have resolved to Grade 1 or baseline. Bortezomib may then be reinitiated with 1 dose-level reduction (from 1.3 mg/M ² to 1 mg/M ² , or from 1 mg/M ² to 0.7 mg/M ²). For bortezomib-related neuropathic pain and/or peripheral neuropathy, hold or modify bortezomib as outlined in the chart for dose modification for bortezomib-related neuropathic pain and/or peripheral neuropathy.

*Graded according to Common Terminology Criteria for Adverse Events (CTCAE).

Relapsed multiple myeloma and mantle cell lymphoma: Withhold dose if a Grade 3 nonhematologic toxicity (e.g., 6 to 10 emeses/24 hr, severe infection) or a Grade 4 hematologic toxicity (e.g., thrombocytopenia less than 25,000/mm³) occurs. When symptoms have resolved, resume treatment with a dose reduced by 25% (1.3 mg/M²/dose reduced to 1 mg/M²/dose, 1 mg/M²/dose reduced to 0.7 mg/M²/dose). ■ See Doxil monograph for additional dose adjustments required in Doxil and bortezomib combination therapy for treatment of multiple myeloma. ■ Reduce dose in patients who develop bortezomib-related neuropathic pain and/or peripheral sensory or motor neuropathy according to the following chart.

Continued

Recommended Dose Modification for Bortezomib-Related Neuropathic Pain and/or Peripheral Sensory or Motor Neuropathy*	
Severity of Peripheral Neuropathy Signs and Symptoms	Modification of Dose and Regimen
Grade 1 (asymptomatic; loss or deep tendon reflexes or paresthesias) without pain or loss of function	No action.
Grade 1 with pain or Grade 2 (moderate symptoms; limiting instrumental Activities of Daily Living [ADL])†	Reduce dose to 1 mg/M ² .
Grade 2 with pain or Grade 3 (severe symptoms; limiting self-care ADL‡)	Withhold therapy until toxicity resolves. When toxicity resolves, reinitiate with a reduced dose of 0.7 mg/M ² and change treatment schedule to once per week.
Grade 4 (life-threatening consequences; urgent intervention indicated)	Discontinue bortezomib.

*Graded according to Common Terminology Criteria for Adverse Events (CTCAE).

†Instrumental ADL (e.g., preparing meals, shopping for groceries or clothes, using telephone, managing money).

‡Self-care ADL (e.g., bathing, dressing and undressing, feeding self, using the toilet, taking medications, and not bedridden).

DILUTION

Specific techniques required; see Precautions. Reconstitute each 3.5-mg vial with 3.5 mL NS. Concentration equals 1 mg/mL. *The SC route uses less diluent and results in a different concentration (2.5 mg/mL).* To prevent overdosage, use caution when diluting and calculating volume to administer. Manufacturer supplies a sticker that specifies indicated route of administration. Place sticker on syringe of prepared bortezomib.

Storage: Stable until expiration date when stored at CRT in original package and protected from light. Reconstituted solution stable at CRT for up to 8 hours in a syringe or in original vial when exposed to normal indoor lighting. Must be given within 8 hours.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

A single dose as an IV bolus injection over 3 to 5 seconds. May be given into a peripheral vein. To ensure the full dose is administered, flush with NS after injection.

May also be given through an IV port if the primary IV is temporarily discontinued. Flush with NS before and after administration.

ACTIONS

A reversible inhibitor of the 26S proteasome, which is a large protein complex that degrades ubiquitinated proteins. The blocking of this proteasome disrupts numerous biologic pathways related to the growth and survival of cancer cells and can lead to cell death. Distributes widely to peripheral tissues. Over 80% is bound to plasma proteins. Mean elimination half-life after multiple doses ranges from 76 to 108 hours after the 1.3 mg/M² dose. Metabolized in the liver via selected cytochrome P₄₅₀ enzymes. Pathways of elimination in humans have not been determined. Median time to response was 38 days (range 30 to 127 days).

INDICATIONS

Treatment of patients with multiple myeloma. ■ Treatment of multiple myeloma in combination with doxorubicin liposomal injection (Doxil) in patients who have received one prior therapy but have not previously received bortezomib. ■ Treatment of patients with mantle cell lymphoma who have been treated with at least one prior therapy.

CONTRAINDICATIONS

Hypersensitivity to bortezomib, boron, or mannitol (not including local reactions); intrathecal administration.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ For IV or SC use only. ■ Administered by or under the supervision of a physician experienced in the use of antineoplastic therapy in a facility equipped to monitor the patient and respond to any medical emergency. ■ Bortezomib therapy causes peripheral neuropathy. Both sensory and motor peripheral neuropathy have been reported. Use caution in patients with pre-existing peripheral neuropathy; symptoms may worsen. Many have been treated previously with neurotoxic agents. Incidence of peripheral neuropathy may be less with SC administration. Use of the SC route may be considered for patients who have pre-existing or are at high risk for peripheral neuropathy. ■ May cause orthostatic/postural hypotension. Use with caution in patients with a history of syncope, in patients receiving concomitant medications that may cause hypotension, and in patients who are dehydrated. ■ Hypersensitivity reactions (including anaphylactic reactions) have been reported. ■ Thrombocytopenia and neutropenia have been reported; see **Monitor**. ■ Gastrointestinal and intracerebral hemorrhages have been reported. ■ Acute development or exacerbation of CHF and/or new onset of decreased left ventricular ejection fraction has been reported. ■ Pulmonary disorders of unknown etiology such as pneumonitis, interstitial pneumonia, lung infiltration, and acute respiratory distress syndrome (ARDS) have occurred. ■ Pulmonary hypertension in the absence of left heart failure or significant pulmonary disease has been reported. ■ Posterior reversible encephalopathy syndrome (PRES), formerly termed reversible posterior leukoencephalopathy syndrome (RPLS), has occurred. Patients may present with blindness, confusion, headache, hypertension, lethargy, seizure, or other visual or neurologic disturbances. MRI may be used to confirm diagnosis. ■ Use caution in patients with moderate to severe liver impairment. Clearance decreased; see **Monitor** and **Dose Adjustments**. Use caution in patients who are receiving multiple concomitant medications and/or who have serious underlying medical conditions; asymptomatic increases in liver enzymes, hyperbilirubinemia, hepatitis, and rare cases of acute liver failure have been reported. May be reversible if bortezomib is discontinued. Information on rechallenging these patients is limited. ■ Tumor lysis syndrome has been reported; patients with a high tumor burden are at increased risk. ■ GI adverse events, including constipation, diarrhea, ileus, nausea and vomiting, have been reported and may require treatment. ■ Consider antiviral prophylaxis. Herpes simplex and herpes zoster reactivation have been reported.

Monitor: Obtain baseline CBC with differential and platelet count; monitor frequently during treatment. Monitor platelet count before each dose. ■ Obtain baseline electrolytes, including serum calcium and potassium and serum and urine M-protein. Monitor fluid and electrolyte balance and replace as indicated. Prevent dehydration. ■ Monitor BP closely. Dehydration and/or concomitant medications may cause hypotension. Assist with ambulation. ■ Monitor patients at risk for or with existing heart disease closely for S/S of CHF (e.g., exertional dyspnea, orthopnea, edema, tachycardia, pulmonary rales, a third heart sound, jugular venous distention) and/or for new onset of decreased left ventricular ejection fraction. ■ Confirm patency of vein; however, tissue damage did not occur with extravasation during clinical studies. ■ Monitor patients with impaired liver function closely for S/S of bortezomib toxicity. Baseline liver studies may be appropriate. Repeat as indicated. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Antidiarrheal medication (e.g., loperamide [Imodium]) may be indicated. ■ Monitor for S/S of peripheral neuropathy (e.g., hyperesthesia [sensitivity of skin], hypoesthesia [impairment of any sense, especially touch], neuropathic pain or weakness, paresthesia [abnormal sensation such as burning, prickling]). Incidence may be increased in patients treated previously with neurotoxic agents (e.g., cisplatin [Platinol], thalidomide [Thalomid], vinca alkaloids [e.g., vincristine]). See **Dose Adjustments**; may require change of dose or schedule. Improvement in or a resolution of peripheral neuropathy has been reported following dose adjustment or discontinuation of bortezomib. ■ Monitor for neutropenia and thrombocytopenia (platelet count less than 50,000/mm³). Occurs in a cyclical pattern with nadirs occurring after the last dose of

each cycle and typically recovering before initiation of the next cycle. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor uric acid levels before and during therapy. Allopurinol and/or alkalinization of the urine may be indicated for serious tumor lysis syndrome. ■ Hypoglycemia and hyperglycemia have been reported in patients taking oral diabetic agents. Monitor blood glucose levels and adjust antidiabetic medications as indicated; see **Drug/Lab Interactions**. ■ Monitor respiratory status closely. Any change in condition should be evaluated promptly and treated as indicated.

Patient Education: Avoid pregnancy; use effective contraceptive measures. Should pregnancy occur, notify physician immediately and discuss potential hazards. ■ May cause dizziness, fatigue, hypotension, or syncope; use caution when driving or operating machinery. ■ Review all medications with your physician and/or pharmacist; effects of medications for high blood pressure and other medications that may lower blood pressure may increase hypotension. Other agents may increase peripheral neuropathy. May interfere with medications for diabetes. ■ Review of monitoring requirements and adverse events before therapy is imperative. ■ Avoid dehydration; promptly report diarrhea, dizziness, fainting spells, light-headedness, and vomiting. ■ Promptly report any signs of infection (e.g., chills, fever, night sweats) or signs of bleeding (e.g., bruising, tarry stools, blood in urine, pinpoint red spots on skin). ■ Promptly report symptoms of peripheral neuropathy (e.g., burning sensation, skin sensitivity, impairment of any sense [especially touch]). If these symptoms pre-existed, report if they seem to be worse. ■ Promptly report shortness of breath or swelling of the ankles, feet, or legs. ■ Report any visual or neurologic disturbances. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. Use of effective contraception required. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Safety and effectiveness similar to other age-groups; however, greater sensitivity in the elderly cannot be ruled out. In clinical trials, patients over 65 years of age had a slightly increased incidence of Grade 3 or 4 toxicity.

DRUG/LAB INTERACTIONS

Drug interaction studies are limited. ■ Coadministration with **prednisone and melphalan** (Alkeran) increases bortezomib exposure. Increase is unlikely to be significant. ■ Has been administered with **omeprazole** (Prilosec) without effect. ■ Coadministration of **dexamethasone** has no effect on bortezomib levels. ■ Bortezomib is a substrate of CYP3A4, 2C19, and 1A2; concomitant administration of **inhibitors or inducers of selected cytochrome P₄₅₀ enzymes** may cause toxicity or reduce effectiveness of bortezomib. Consult pharmacist. **Inhibitors** may reduce metabolism and increase serum levels of bortezomib. ■ Coadministration with **ketoconazole** (Nizoral), an inhibitor, increases bortezomib exposure. Monitor for toxicity. Other examples of **inhibitors** may include cimetidine (Tagamet), erythromycins, grapefruit juice, antifungal agents (e.g., itraconazole [Sporanox]), nefazodone, ritonavir (Norvir), verapamil. Patients receiving bortezomib in conjunction with a strong CYP3A4 inhibitor should be closely monitored. **Inducers** may increase metabolism and decrease serum levels and effectiveness of bortezomib. Examples of **inducers** may include carbamazepine (Tegretol), phenobarbital (Luminal), phenytoin (Dilantin), rifampin (Rifadin). Concomitant use of **strong CYP3A4 inducers** (e.g., rifampin [Rifadin]) is not recommended. ■ **St. John's wort** may decrease levels of bortezomib unpredictably. Concurrent use should be avoided. ■ Hypotension may be increased by **agents that induce hypotension** (e.g., alcohol, antihypertensives [e.g., ACE inhibitors (e.g., lisinopril)], beta-blockers [e.g., atenolol (Tenormin)], opioid narcotics, sildenafil [Viagra], tricyclic antidepressants [e.g., amitriptyline (Elavil), imipramine (Tofranil)]). ■ Peripheral neuropathy may be increased by numerous agents. Some examples are **acyclovir** (Zovirax), **amiodarone** (Nexterone), **antineoplastics** (e.g., cisplatin [Platinol]), **vinca alkaloids** [e.g., vincristine]), **foscarnet** (Foscavir), **isoniazid** (INH), **nitrofurantoin** (Furadantin), **thalidomide** (Thalomid), **statins** (e.g., lovastatin [Mevacor], simva-

statin [Zocor]). ■ May increase or decrease the effects of **oral antidiabetic agents** (e.g., glyburide [DiaBeta], glipizide [Glucotrol]). Monitor blood glucose levels and adjust dose of antidiabetic medication as indicated.

SIDE EFFECTS

Diarrhea, fatigue, peripheral neuropathy, excessive vomiting, and thrombocytopenia may be dose limiting. Most common side effects reported include anemia, anorexia, constipation, diarrhea, fatigue, fever, leukopenia, lymphopenia, nausea and vomiting, neuralgia, neutropenia, peripheral neuropathy, rash, and thrombocytopenia. Abdominal pain, arthralgia, asthenia, bronchitis, chills, cough, dehydration, dizziness, dysesthesia, edema, headache, hypertension, malaise, nasopharyngitis, paresthesia, peripheral edema, pneumonia, psychotic disorders (e.g., anxiety, agitation, confusion, insomnia, mental status change, suicidal ideation), reactivation of herpesvirus infections (zoster and simplex), respiratory tract infections, upper abdominal pain, weakness, and weight loss have also been reported. Numerous other side effects have been reported that may or may not be related to bortezomib and may include hypersensitivity reactions (including anaphylaxis and immune complex-mediated hypersensitivity), ARDS and other pulmonary disorders, bleeding (e.g., GI, intracerebral), CVA, GI disorders (serious [e.g., acute pancreatitis, ischemic colitis, paralytic ileus]), hepatic disorders (e.g., cholestasis, liver failure, portal vein thrombosis), hyperbilirubinemia, hypernatremia, hyperuricemia, hypocalcemia, hypokalemia, hyponatremia, infections (e.g., aspergillosis, bacteremia, herpes, listeriosis, oral candidiasis, septic shock, toxoplasmosis, URI), MI, pleural effusion, PRES, pulmonary embolism, pulmonary hypertension, renal disorders (e.g., acute or chronic renal failure, calculus, hemorrhagic cystitis, hydronephrosis), respiratory distress, and tumor lysis syndrome.

Post-Marketing: Acute diffuse infiltrative pulmonary disease, acute febrile neutrophilic dermatosis (Sweet's syndrome), acute pancreatitis, blindness, cardiac arrhythmias (including complete AV block), cardiac tamponade, deafness (bilateral), DIC, dysautonomia, encephalopathy, hepatitis, herpes meningoencephalitis, ischemic colitis, ophthalmic herpes, optic neuropathy, progressive multifocal leukoencephalopathy (PML), and toxic epidermal necrolysis. 2% of patients died. Cause of death may have been related to bortezomib and included cardiac arrest, CHF, pneumonia, renal failure, respiratory failure, and sepsis.

Overdose: Profound progressive hypotension, tachycardia, and decreased cardiac contractility. Symptomatic hypotension and thrombocytopenia with fatal outcomes have been reported in patients who received more than twice the recommended dose.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. Temporarily discontinue bortezomib if Grade 4 thrombocytopenia occurs (less than 25,000/mm³); may be resumed at a reduced dose after thrombocytopenia is resolved. Severe thrombocytopenia may require platelet transfusions. Reduce dose, withhold dose, or discontinue based on S/S of peripheral neuropathy. Symptoms of peripheral neuropathy may improve or return to baseline if bortezomib is discontinued. Hypotension may respond to adjustment of antihypertensive medications, hydration, or administration of mineralocorticoids. Recovery from neutropenia may be spontaneous or may be treated with filgrastim (G-CSF, Neupogen) or pegfilgrastim (Neulasta). Treat anemia as indicated with whole blood products (e.g., packed RBCs) or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen]). For new or worsening cardiopulmonary symptoms, consider interrupting bortezomib until a prompt and comprehensive diagnostic evaluation is conducted. For symptoms of serious liver dysfunction, interrupt bortezomib to assess reversibility. Discontinue bortezomib in patients who develop PRES. In overdose, monitor V/S continuously and provide supportive care. Maintain BP with dopamine, epinephrine, or norepinephrine (Levophed) as needed. Maintain body temperature. There is no specific antidote; supportive therapy will help sustain the patient in toxicity. Resuscitate as indicated.

BOTULISM IMMUNE GLOBULIN (INTRAVENOUS HUMAN)

Immunizing agent
(passive)

(BOT-yoo-lism im-MYOUN GLOB-you-lin, in-tra-VEE-nus HU-man)

BabyBIG

Available from the California Department of Health Services.

PEDIATRIC DOSE

Infants under 1 year of age: 1 mL/kg (50 mg/kg) as a single-dose IV infusion. Administer as soon as the diagnosis of infant botulism is made. See [Maternal/Child](#).

DILUTION

Calculate the number of vials required for the desired dose. Each single-dose vial contains 100 mg. A 10-kg infant would require 500 mg ($50 \text{ mg/kg} \times 10 \text{ kg} = 500 \text{ mg}$, or 5 vials). Reconstitute the lyophilized powder with 2 mL of SWFI provided by the manufacturer to provide a 50 mg/mL solution. A transfer needle or large syringe may be used to add the SWFI. If a transfer needle is used, insert one end into the vial of SWFI first. Supplied in an evacuated vial; the SWFI should transfer by suction. Direct the stream of SWFI toward the side of the vial. To hasten the dissolution, release the residual vacuum after the water is transferred into the evacuated vial. Rotate the vial gently to wet all the powder. **Do not shake.** Allow approximately 30 minutes for dissolution. Solution should be clear, colorless, and free of particulate matter. Further dilution is not required.

Storage: Store lyophilized product between 2° and 8° C (35.6° and 46.4° F). Infusion should begin within 2 hours of reconstitution and should be completed within 4 hours of reconstitution.

Filter: Use of an in-line or syringe-tip, sterile, disposable filter (18 micron) is recommended.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends administration through a separate IV line without admixture with other drugs. May be “piggybacked” into a pre-existing line if the line contains either NS or one of the following dextrose solutions (with or without NaCl added): D2½W, D5W, D10W, or D20W. If a pre-existing line must be used, botulism immune globulin should not be diluted more than 1:2 with any of the previously named solutions.

RATE OF ADMINISTRATION

Administer intravenously using a low-volume tubing (e.g., 60 gtts/mL) and a constant infusion pump. An in-line or syringe-tip, sterile, disposable filter (18 micron) is recommended. Begin infusion at 0.5 mL/kg/hr (25 mg/kg/hr). If no untoward reactions after 15 minutes, the rate may be increased to 1 mL/kg/hr (50 mg/kg/hr) for the remainder of the infusion. **Do not exceed this rate.** Reduce rate at onset of patient discomfort, any minor side effects (e.g., flushing), or other adverse reactions. Discontinue for significant hypotension or S/S of hypersensitivity. At the recommended rate, the infusion should be completed after 67.5 minutes. See [Precautions](#).

ACTIONS

A specialty immunoglobulin (IgG) containing neutralizing antibodies to botulinum toxin types A and B. Should provide the relevant antibodies at levels sufficient to neutralize the expected levels of circulating neurotoxins in infants who may have been exposed to botulinum toxin types A or B. Pooled from adult human plasma selected for their high titers of neutralizing antibody against botulinum neurotoxins type A and B. Purified and standardized by several specific methods (e.g., solvent-detergent viral inactivation process decreases the possibility of transmission of blood-borne pathogens [e.g., HIV, hepatitis]). Half-life is approximately 28 days. Should provide a protective level of neutralizing antibodies for 6 months.

INDICATIONS AND USES

Treatment of infants less than 1 year of age with infant botulism caused by toxin type A or B. Has been shown to decrease the average length of hospital and ICU stay, the average length of time on a mechanical ventilator, and the average number of weeks tube feeding is required in patients with infant botulism.

CONTRAINDICATIONS

Patients with a prior history of severe reaction to other human immunoglobulin preparations or any component of the formulation. Patients with selective immunoglobulin A deficiency have the potential to develop antibodies to immunoglobulin A and could have anaphylactic reactions to subsequent administration of blood products that contain immunoglobulin A.

PRECAUTIONS

IGIV products have been associated with renal dysfunction, acute renal failure, osmotic nephrosis, and death. IGIV products that contain sucrose as a stabilizer have demonstrated an increased risk of renal dysfunction. Botulism immune globulin contains sucrose as a stabilizer. Use extreme caution in patients with any degree of renal insufficiency or in patients who may be predisposed to acute renal failure. Predisposed patients may include patients with diabetes mellitus, paraproteinemia, sepsis, or volume depletion and/or patients receiving known nephrotoxic drugs. Consider benefit versus risk before use. Use of the minimum concentration available and the minimum rate of infusion is recommended. ■ May cause aseptic meningitis syndrome (AMS). May begin from 2 hours to 2 days after treatment. Symptoms are drowsiness, fever, headache (severe), nausea and vomiting, nuchal rigidity, painful eye movements, and photophobia. CSF studies may be positive with pleocytosis and elevated protein levels. Other causes of meningitis must be ruled out. AMS usually resolves with discontinuation of therapy. ■ With the use of botulism immune globulin, as with all plasma products, there is a slight possibility for transmission of blood-borne viral agents and, theoretically, the Creutzfeldt-Jakob disease agent. Risk is reduced by screening donors and various manufacturing processes such as viral inactivation. Risk of transmission versus benefit of treatment must be assessed for each patient.

Monitor: Obtain a baseline SCr and BUN. ■ Assess infant's volume status prior to initiating treatment. Patients must not be volume depleted. ■ Monitor vital signs and observe patient continuously during infusion. ■ Acute systemic hypersensitivity reactions were not observed in clinical trials but are possible. Epinephrine and emergency equipment should be readily available. ■ Monitor renal function (e.g., BUN, SCr) and urine output as indicated in infants at increased risk for renal failure.

Patient Education: Inform parents of possible side effects. ■ Review possible alteration of immunization schedule.

Maternal/Child: Not indicated for adult patients. ■ Safety and effectiveness for use in pediatric patients over 1 year of age not established.

Elderly: Not indicated for adult patients.

DRUG/LAB INTERACTIONS

May interfere with immune response to **live virus vaccines** (e.g., polio, measles, mumps, rubella). Defer vaccination with live virus vaccines until approximately 5 months after administration of botulism immune globulin. If such vaccinations were given shortly before or after administration of botulism immune globulin, a revaccination may be necessary.

SIDE EFFECTS

Many of the adverse events observed in studies are part of the known pathophysiology of infant botulism. The most common side effect was a mild, transient, erythematous rash of the face or trunk. Other frequent side effects included back pain, chills, fever, muscle cramps, nausea, rash, vomiting, and wheezing. Other reported reactions included abdominal distention, agitation, anemia, atelectasis, body temperature decrease, convulsions, cough, dehydration, dysphagia, edema, hypertension, hyponatremia, hypotension, injection site reaction, irritability, metabolic acidosis, nasal congestion, neurogenic blad-

der, oral candidiasis, otitis media, pneumonia, rales, respiratory arrest, rhonchi, stridor, tachycardia, tachypnea, urinary tract infections. Possible reactions not yet reported with botulism immune globulin but reported with other IVIG products include anaphylaxis, angioneurotic edema, renal toxicity (e.g., increased SCr and BUN, acute renal failure, acute tubular necrosis, proximal tubular nephropathy, osmotic nephrosis), and volume overload.

ANTIDOTE

Reduce rate of infusion for patient discomfort or any sign of adverse reaction and in patients at risk for renal insufficiency. Discontinue the drug immediately for any signs of hypersensitivity reaction or renal insufficiency. Notify the physician. Treat anaphylaxis immediately. Epinephrine (Adrenalin), diphenhydramine (Benadryl), oxygen, vasopressors (e.g., dopamine), corticosteroids, and ventilation equipment must always be available. Resuscitate as necessary.

BRENTUXIMAB VEDOTIN **BBW**

(bren-TUX-i-mab ve-DOE-tin)

Antineoplastic
(monoclonal antibody)

Adcetris

pH 6.6

USUAL DOSE

1.8 mg/kg as an IV infusion over 30 minutes every 3 weeks. For patients weighing more than 100 kg, base calculated dose on a weight of 100 kg. Continue treatment for a maximum of 16 cycles or until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

Dose Modification of Brentuximab in Peripheral Neuropathy	
New or worsening Grade 2 or 3 neuropathy	Hold dosing until neuropathy improves to Grade 1 or baseline; then restart at 1.2 mg/kg.
Grade 4 peripheral neuropathy	Discontinue brentuximab.

Dose Modification of Brentuximab with Neutropenia	
Grade 3 or 4 neutropenia	Hold dosing until neutropenia resolves to baseline or Grade 2 or lower. Consider growth factor support (e.g., filgrastim [Neupogen]) for subsequent cycles in patients who experience Grade 3 or 4 neutropenia.
Recurrent Grade 4 neutropenia despite the use of growth factors	Discontinuation or dose reduction of brentuximab to 1.2 mg/kg may be considered.

DILUTION

Specific techniques required; see Precautions. Each vial contains 50 mg of brentuximab. Calculate the number of vials required.

- 1.8 mg/kg \times 70 kg = 126 mg
- 126 mg \div 50 mg/vial = 2.5+ vials; so 3 vials would be needed

Reconstitute each vial with 10.5 mL of SWFI to yield 5 mg/mL. Direct the stream of diluent toward the sides of the vial. Gently swirl to aid dissolution. *Do not shake.* Solution should be clear to slightly opalescent and colorless. Withdraw the calculated dose from the vials (126 mg [from the previous example] \div 5 mg/mL = 25.2 mL). This cal-

culated dose must be further diluted in a minimum of 100 mL of NS, D5W, or LR. Gently invert to mix the solution.

Filters: No specific recommendations stated.

Storage: Refrigerate vials in carton at 2° to 8° C (36° to 46° F) to protect from light. Immediate further dilution of reconstituted vials is preferred; however, they may be refrigerated for up to 24 hours. Do not freeze. Immediate use of fully diluted solutions is preferred; however, they may be refrigerated but must be used within 24 hours of reconstitution. Do not freeze.

COMPATIBILITY

Manufacturer states, “Do not mix with, or administer as an infusion with, other medicinal products.”

RATE OF ADMINISTRATION

A single dose as an IV infusion equally distributed over 30 minutes.

ACTIONS

A CD30-directed antibody-drug conjugate (ADC). Produced by recombinant DNA technology with three components: (1) the chimeric IgG1 antibody cAC10, specific for human CD30; (2) the microtubule-disrupting agent MMAE; and (3) a protease-cleavable linker that covalently attaches MMAE to cAC10. Anticancer activity is thought to result from the binding of the ADC to CD30-expressing cells, followed by internalization of the ADC-CD30 complex and the release of MMAE via proteolytic cleavage. Binding of MMAE to tubulin disrupts the microtubule network within the cell, inducing cell-cycle arrest and apoptotic death of the cells. Terminal half-life is approximately 4 to 6 days. Minimal to no accumulation noted with every-3-week dosing. Minimal metabolism of MMAE occurs via oxidation by CYP3A4/5. Moderate amounts excreted as mostly unchanged MMAE in feces and urine.

INDICATIONS AND USES

Treatment of patients with Hodgkin lymphoma (HL) after failure of autologous stem cell transplant (ASCT) or after failure of at least two prior multi-agent chemotherapy regimens in patients who are not ASCT candidates. ■ Treatment of patients with systemic anaplastic large cell lymphoma (sALCL) after failure of at least one prior multi-agent chemotherapy regimen. ■ Indications based on response rates. No data demonstrating improvement in patient outcomes or survival has been demonstrated.

CONTRAINDICATIONS

Pulmonary toxicity. Concomitant use with bleomycin is contraindicated due to pulmonary toxicity; see [Drug/Lab Interactions](#).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ For IV infusion only; do not administer as an IV push or bolus. ■ Usually administered in a setting with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ JC virus infection resulting in progressive multifocal leukoencephalopathy (PML) and death can occur. ■ Causes a peripheral neuropathy that is predominantly sensory and cumulative. Peripheral motor neuropathy has also been reported. ■ Infusion-related reactions, including anaphylaxis, have occurred; see [Monitor](#) and [Antidote](#). ■ Prolonged (1 week or longer) severe neutropenia can occur. ■ Risk of tumor lysis syndrome is increased in patients with rapidly proliferating tumor and high tumor burden. ■ Stevens-Johnson syndrome has been reported. ■ Patients who develop persistently positive antibodies demonstrated a higher incidence of infusion-related reactions. ■ Influence of renal or hepatic impairment on the pharmacokinetics of brentuximab is not known.

Monitor: Obtain baseline CBC and monitor before each dose. Consider more frequent monitoring for patients with Grade 3 or 4 neutropenia. Dose delay, reduction, or discontinuation of therapy may be required; see [Dose Adjustments](#). ■ Monitor for S/S of neuropathy (e.g., a burning sensation, discomfort, hyperesthesia, hypoesthesia, neuropathic pain, paresthesia, weakness). New or worsening neuropathy may require a delay of

therapy or change in dose; see [Dose Adjustments](#). ■ Monitor closely during infusion for S/S of hypersensitivity or infusion reactions (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). Patients who have experienced a prior infusion-related reaction should be premedicated for subsequent infusions; may include acetaminophen, an antihistamine, and a corticosteroid. Immediately and permanently discontinue brentuximab if anaphylaxis occurs. ■ Monitor for early signs of tumor lysis syndrome (e.g., flank pain and hematuria); monitoring of uric acid levels may be required; maintain hydration. Allopurinol and/or alkalinization of urine may be indicated. ■ Monitor for S/S of PML (e.g., changes in mood or unusual behavior; confusion; thinking problems; loss of memory; changes in vision, speech, or walking; and decreased strength or weakness on one side of the body); see [Antidote](#).

Patient Education: Avoid pregnancy. Use effective birth control. Report a suspected pregnancy immediately. ■ Promptly report S/S of infection (e.g., chills, cough, fever of 100.5° F or greater, pain with urination). ■ Promptly report S/S of peripheral neuropathy (e.g., muscle weakness, numbness or tingling of the hands or feet). ■ Promptly report S/S of an infusion reaction (e.g., breathing problems, chills, fever, or rash within 24 hours of an infusion). ■ Promptly report changes in mood or unusual behavior; confusion; thinking problems; loss of memory; changes in vision, speech, or walking; and decreased strength or weakness on one side of the body. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: Avoid pregnancy, can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Numbers in clinical studies insufficient to determine if elderly patients respond differently than younger subjects. Safety and effectiveness not established.

DRUG/LAB INTERACTIONS

Concomitant use with **bleomycin** is contraindicated; has resulted in an increased risk of pulmonary toxicity compared with other chemotherapy regimens. ■ Coadministration with **ketoconazole** (Nizoral), a potent CYP3A4 inhibitor, increases exposure to MMAE; monitor closely for adverse reactions. ■ Coadministration with **rifampin** (Rifadin), a potent CYP3A4 inducer, reduces exposure to MMAE, reducing its effectiveness. ■ MMAE does not inhibit other CYP enzymes at relevant clinical concentrations and is not expected to alter the exposure to drugs that are metabolized by CYP3A4 enzymes, including midazolam (Versed).

SIDE EFFECTS

Anemia, cough, diarrhea, fatigue, fever, nausea, neutropenia, peripheral sensory neuropathy, rash, upper respiratory tract infection, thrombocytopenia, and vomiting are most common. Neutropenia and peripheral neuropathy occur with some frequency; can be severe and dose-limiting. Other severe side effects include PML, Stevens-Johnson syndrome, and tumor lysis syndrome. Abdominal pain, alopecia, anorexia, anxiety, arthralgia, back pain, chills, constipation, dizziness, dry skin, dyspnea, headache, infusion-related reactions (including anaphylaxis), insomnia, lymphadenopathy, muscle spasms, myalgia, night sweats, oropharyngeal pain, peripheral edema, pain (including extremity pain), pruritus, and weight loss have also occurred.

Post-Marketing: PML.

ANTIDOTE

Notify physician of all side effects. Treatment of most reactions will be supportive. No known antidote for overdose; monitor closely, especially for neutropenia. If PML is suspected, hold brentuximab. Confirmation of the diagnosis by consultation with a neurologist, brain imaging, CSF testing for JC viral DNA, and/or brain biopsy is indicated. If PML is confirmed, discontinue brentuximab. Discontinue the infusion if Stevens-Johnson syndrome occurs and treat as indicated. Discontinue the infusion immediately and treat anaphylaxis with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol, and IV fluids as indicated. Resuscitate as necessary.

BUMETANIDE **BBW**

(byou-MET-ah-nyd)

Diuretic (loop)

pH 6.8 to 7.8

USUAL DOSE

0.5 to 1 mg. May be repeated at 2- to 3-hour intervals. Do not exceed 10 mg/24 hr. Can be used for patients allergic to furosemide. 1:40 mg ratio (bumetanide to furosemide) is used to determine dose. Individualize dose and schedule; see [Precautions/Monitor](#).

DOSE ADJUSTMENTS

Start at lower end of dosing range in the elderly. Consider decreased cardiac, hepatic, or renal function; concomitant disease; and other drug therapy.

DILUTION

May be given undiluted. Not usually added to IV solutions but **compatible** with D5W, NS, and LR. Usually given through Y-tube or three-way stopcock of infusion set. Use only freshly prepared solutions for infusion. Discard after 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Furosemide (Lasix).

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), aztreonam (Azactam), bivalirudin (Angiomax), caspofungin (Cancidas), ceftaroline (Teflaro), cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doripenem (Doribax), etoposide phosphate (Etopophos), filgrastim (Neupogen), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hextend), lorazepam (Ativan), melphalan (Alkeran), meperidine (Demerol), micafungin (Myca-mine), milrinone (Primacor), morphine, oxaliplatin (Eloxatin), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), propofol (Diprivan), remifentanyl (Ultiva), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

A single dose by IV injection over 1 to 2 minutes. Give infusion at prescribed rate.

ACTIONS

A sulfonamide diuretic, antihypertensive, and antihypercalcemic agent related to the thiazides. A loop diuretic agent. Extremely potent. Onset of action is within minutes and duration of action may last 4 to 6 hours. Apparently acts on the proximal and distal ends of the tubule and the ascending limb of the loop of Henle to excrete water, sodium, chloride, and potassium. Will produce diuresis in alkalosis or acidosis. Rapidly distributed, it is excreted primarily in the urine.

INDICATIONS AND USES

Edema associated with congestive heart failure, cirrhosis of the liver with ascites, renal diseases including nephrotic syndrome. ■ Acute pulmonary edema. ■ Edema unresponsive to other diuretic agents. ■ Diuresis in patients allergic to furosemide. ■ Adjuvant in combination with other antihypertensive agents in the treatment of hypertensive crisis.

Unlabeled uses: Treatment of hypercalcemia.

CONTRAINDICATIONS

Anuria, known hypersensitivity to bumetanide. Use caution in patients with hepatic coma or in states of severe electrolyte depletion. Do not use until condition is improved or corrected. See [Precautions](#).

PRECAUTIONS

May be used concurrently with aldosterone antagonists (e.g., spironolactone [Aldactone]) for more effective diuresis and to prevent excessive potassium loss. ■ May increase blood glucose; has precipitated diabetes mellitus. ■ May lower serum calcium

level, causing tetany. ■ In rare instances may precipitate an acute attack of gout. ■ Risk of ototoxicity increased with higher doses, rapid injection, decreased renal function, or concurrent use with other ototoxic drugs; see [Drug/Lab Interactions](#). ■ Patients allergic to sulfonamides may have an allergic reaction to bumetanide. ■ Excessive doses can lead to profound diuresis with water and electrolyte depletion.

Monitor: Monitor for excessive diuresis with water and electrolyte depletion. Routine checks on electrolyte panel, CO₂, serum glucose, uric acid, and BUN are necessary during therapy. Potassium chloride replacement may be required.

Patient Education: Hypotension may cause dizziness; move slowly, and request assistance to sit on edge of bed or ambulate. ■ May decrease potassium levels and require a supplement.

Maternal/Child: Category C: use in pregnancy only if clearly needed. ■ Consider discontinuing breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. ■ Has been used in infants age 4 days to 6 months at doses ranging from 0.005 mg/kg to 0.1 mg/kg. Maximal diuretic effect seen at doses of 0.035 to 0.04 mg/kg. Elimination half-life decreases during the first month of life from approximately 6 hours at birth to 2.4 hours at 1 month.

Elderly: Response similar to that seen in younger patients; however, dose selection should be cautious; see [Dose Adjustments](#). Consider increased sensitivity to hypotensive and electrolyte effects and increased risk of circulatory collapse or thromboembolic episodes. ■ Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

Causes excessive potassium depletion with **corticosteroids**, **thiazide diuretics** (e.g., hydrochlorothiazide [Hydrodiuril]), **amphotericin B** (all formulations). ■ Potentiates **antihypertensive drugs** (e.g., nitroglycerin, nitroprusside sodium); reduced dose of the antihypertensive agent or both drugs may be indicated. ■ May cause transient or permanent deafness with doses exceeding the usual or when given in conjunction with **other ototoxic drugs** (e.g., aminoglycosides [e.g., gentamicin], cisplatin). ■ **Amphotericin B** (all formulations) may increase potential for ototoxicity and nephrotoxicity; avoid concurrent use. ■ Nephrotoxicity increased by other **nephrotoxic agents** (e.g., acyclovir [Zovirax], aminoglycosides, ciprofloxacin [Cipro], cyclosporine [Sandimmune], vancomycin); avoid concurrent use. ■ May increase serum levels of **lithium** (may cause toxicity). ■ May cause cardiac arrhythmias with **amiodarone** (Nexterone) or **digoxin** (potassium depletion). ■ Risk of cardiotoxicity increased with **pimozide** (Orap) and **sparfloxacin** (Zagam); concurrent use not recommended. ■ May enhance or inhibit actions of **nondepolarizing muscle relaxants** (e.g., atracurium [Tracrium]) or **theophyllines**. ■ May cause hyperglycemia with **insulin** or **sulfonylureas** (e.g., tolbutamide) by decreasing glucose tolerance. ■ Effects may be inhibited by **ACE inhibitors** (e.g., captopril [Capoten]), **NSAIDs** (e.g., ibuprofen [Motrin]), **probenecid**, or in patients with cirrhosis and ascites who are taking **salicylates**. ■ May cause profound diuresis and serious electrolyte abnormalities with **thiazide diuretics** (e.g., chlorothiazide [Diuril]) because of synergistic effects. ■ Do not use concomitantly with **ethacrynic acid** (Edecrin); risk of ototoxicity markedly increased. ■ Smoking may increase secretion of ADH-decreasing diuretic effects and cardiac output. ■ See [Precautions](#).

SIDE EFFECTS

Usually occur in prolonged therapy, seriously ill patients, or following large doses.

Abdominal pain, arthritic pain, azotemia, dizziness, ECG changes, elevated SCr, encephalopathy, headache, hyperglycemia, hyperuricemia, hypocalcemia, hypochloremia, hypomagnesemia, hyponatremia, hypotension, impaired hearing, muscle cramps, nausea, pruritus, rash.

Major: Anaphylactic shock, blood volume reduction, circulatory collapse, dehydration, excessive diuresis, hypokalemia, metabolic acidosis, thrombocytopenia, vascular thrombosis, and embolism.

ANTIDOTE

If minor side effects are noted, discontinue the drug and notify the physician, who may treat the side effects symptomatically and continue the drug. If side effects are progressive or any major side effect occurs, discontinue the drug immediately and notify the physician. Treatment of major side effects is symptomatic and aggressive and includes fluid and electrolyte replacement. Resuscitate as necessary.

BUPRENORPHINE HYDROCHLORIDE

(byou-pren-OR-feen hy-droh-KLOR-eyed)

Narcotic analgesic
(agonist-antagonist)
Anesthesia adjunct

Buprenex

pH 3.5 to 5.5

USUAL DOSE

Pain control: 0.3 mg (1 mL). Repeat every 6 hours as necessary. May be repeated in 30 to 60 minutes, if indicated. These dose recommendations have been lowered because of excessive respiratory depression with doses up to 0.6 mg. 25 to 250 mcg/hr has been given as a continuous infusion to manage postoperative pain.

Reverse fentanyl-induced anesthesia (unlabeled): 0.3 to 0.8 mg 1 to 4 hours after induction of anesthesia and 30 minutes before end of surgery.

PEDIATRIC DOSE

2 to 12 years of age: Pain control: 2 to 6 mcg/kg of body weight every 4 to 8 hours. A repeat dose in 30 to 60 minutes is not recommended. Longer intervals (6 to 8 hours) are suggested and should provide sufficient pain relief. Determine appropriate interval through clinical assessment. See [Maternal/Child](#).

DOSE ADJUSTMENTS

Reduce dose by one half in high-risk patients (e.g., elderly or debilitated, respiratory disease), when other CNS depressants have been given, and in the immediate postoperative period; see [Drug/Lab Interactions](#). ■ Reduced dose may be required in impaired liver function.

DILUTION

IV injection: May be given undiluted.

Infusion: May be further diluted with NS, D5W, D5NS, or LR injection and given as an infusion. 1 mg in 250 mL = 4 mcg/mL, 3 mg in 250 mL = 12 mcg/mL.

Filters: Not required by manufacturer; however, 0.2-micron filters were used during manufacturing. No loss of drug potency expected.

Storage: Before use, store at CRT. Avoid freezing and/or prolonged exposure to light.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), aztreonam (Azactam), cisatracurium (Nimbex), cladribine (Leustatin), docetaxel (Taxotere), etoposide phosphate (Etoposfos), filgrastim (Neupogen), gemcitabine (Gemzar), granisetron (Kytril), linezolid (Zyvox), melphalan (Alkeran), oxaliplatin (Eloxatin), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), propofol (Diprivan), remifentanyl (Ultiva), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Titrate slowly according to symptom relief and respiratory rate.

IV injection: A single dose over 3 to 5 minutes.

Infusion: See **Usual Dose**. Use of a metriset (60 gtt/min) or a controlled infusion device recommended.

ACTIONS

A synthetic narcotic agonist-antagonist analgesic. Thirty times as potent as morphine in analgesic effect (0.3 mg equivalent to 10 mg morphine) and has the antagonist effect of naloxone in larger doses. Does produce respiratory depression. Pain relief is effected in 2 to 3 minutes and lasts up to 6 hours. Metabolized in the liver. Primarily excreted through feces. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Relief of moderate to severe pain.

Unlabeled use: Reverse fentanyl-induced anesthesia.

CONTRAINDICATIONS

Hypersensitivity to buprenorphine.

PRECAUTIONS

Usually given IM. ■ May precipitate withdrawal symptoms if stopped too quickly after prolonged use or if patient has been on opiates. ■ Use caution in asthma, respiratory depression or difficulty from any source, impaired renal or hepatic function, the elderly or debilitated, myxedema or hypothyroidism, adrenocortical insufficiency, CNS depression or coma, toxic psychoses, prostatic hypertrophy or urethral stricture, acute alcoholism, delirium tremens, or kyphoscoliosis. ■ May elevate cerebrospinal fluid pressure; use caution in head injury, intracranial lesions, and other situations with increased intracranial pressure.

Monitor: Naloxone (Narcan), oxygen, and controlled respiratory equipment must be available. Naloxone is only partially effective in reversing respiratory depression. ■ Observe patient frequently and monitor vital signs. ■ Keep patient supine to minimize side effects; orthostatic hypotension and fainting may occur. Observe closely during ambulation. ■ Pain control usually more effective with routinely administered doses. Determine appropriate interval through clinical assessment.

Patient Education: Avoid use of alcohol or other CNS depressants (e.g., antihistamines, diazepam [Valium]). ■ Use caution performing any task requiring alertness; may cause dizziness, euphoria, and sedation. ■ Request assistance for ambulation. ■ May be habit forming.

Maternal/Child: Category C: safety for use during pregnancy, labor and delivery, or breastfeeding not established. Use only when clearly needed. ■ Not recommended in pediatric patients under 2 years of age but has been used in pediatric patients as young as 9 months of age.

Elderly: See **Dose Adjustments**. ■ May be more sensitive to effects (e.g., respiratory depression, urinary retention, constipation, dizziness). ■ Analgesia should be effective with lower doses. ■ Consider possibility of decreased organ function.

DRUG/LAB INTERACTIONS

Respiratory and CNS effects may be additive with **barbiturate anesthetics** (e.g., thiopental [Pentothal]); reduced doses of both drugs may be indicated. ■ May cause respiratory depression and cardiovascular collapse with **diazepam** (Valium); reduced doses of both drugs may be indicated. ■ May decrease analgesic effects of **other narcotics**; avoid concurrent use. ■ Clearance decreased and serum levels increased by **cytochrome P₄₅₀ inhibitors** (e.g., azole antifungal agents [e.g., itraconazole (Sporanox)], macrolide antibiotics [e.g., erythromycin], protease inhibitors [e.g., ritonavir (Norvir)]). Monitor with concurrent use; dose adjustment may be indicated. ■ Clearance increased and serum levels decreased by **cytochrome P₄₅₀ inducers** (e.g., carbamazepine [Tegretol], phenytoin [Dilantin], rifampin [Rifadin]). Use caution; dose adjustments may be indicated. ■ Manufacturer suggests caution when used in combination with **MAO inhibitors** (e.g., selegiline [Eldepryl]).

SIDE EFFECTS

Excessive sedation is a major side effect. Has caused death from respiratory depression. Acute and chronic hypersensitivity reactions (e.g., anaphylaxis, angioneurotic edema, bronchospasm, hives, pruritus, rash), bradycardia, clammy skin, constipation, cyanosis, dizziness, dyspnea, headache, hypertension, hypotension, nausea, pruritus, tachycardia, vertigo, visual disturbances, vomiting.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. Naloxone hydrochloride (Narcan) will help to reverse respiratory depression, but is not as effective as it is with other narcotics. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Treat anaphylaxis and resuscitate as necessary.

BUSULFAN **BBW**

(byou-SUL-fan)

Antineoplastic
(alkylating agent)

Busulfex

pH 3.4 to 3.9

USUAL DOSE

Administered in combination with cyclophosphamide as a component of a conditioning regimen prior to bone marrow or peripheral blood progenitor cell replacement support.

Premedication: Premedicate patients with phenytoin (use of other anticonvulsants not recommended) and an antiemetic (e.g., 5HT₃ antiemetics such as ondansetron [Zofran], granisetron [Kytril]). Continue antiemetic administration on a fixed schedule throughout busulfan therapy. See [Monitor](#), [Drug Interactions](#), and [Side Effects](#).

Busulfan: 0.8 mg/kg of ideal body weight (IBW) or actual body weight, whichever is lower, administered through a central venous catheter every 6 hours for 4 days (16 doses). Six hours after the 16th busulfan dose (on BMT day minus 3 [3 days prior to BMT]), begin cyclophosphamide at a dose of 60 mg/kg/day for 2 days. Before and after each infusion, flush the catheter line with 5 mL NS or D5W.

PEDIATRIC DOSE

See [Maternal/Child](#).

Initial doses are based on a small trial and are unlabeled. Therapeutic drug monitoring and dose adjustment based on AUC determination following the first dose are recommended. See manufacturer's literature for details.

Actual body weight equal to or less than 12 kg: 1.1 mg/kg.

Actual body weight greater than 12 kg: 0.8 mg/kg.

DOSE ADJUSTMENTS

In obese or severely obese patients, dose should be based on an adjusted ideal body weight (AIBW). Calculate as follows:

$$\text{AIBW} = \text{IBW} + 0.25 \times (\text{Actual weight [kg]} - \text{IBW})$$

- Busulfan has not been studied in patients with renal or hepatic insufficiency. See [Precautions](#).

DILUTION

Specific techniques required; see [Precautions](#). Supplied in vials containing 60 mg/10 mL (6 mg/mL). Must be diluted prior to infusion with either NS or D5W. The diluent volume should be 10 times the busulfan volume to ensure a final concentration of approximately 0.5 mg/mL. Remove calculated dose of busulfan from vial. Inject the contents of the syringe into an intravenous bag or syringe that contains the calculated amount of diluent.

Always add the busulfan to the diluent rather than the diluent to the busulfan. Mix thoroughly by inverting several times. The dose for a 70-kg patient would be prepared using the following steps:

1. $70 \text{ kg} \times 0.8 \text{ mg/kg} = 56 \text{ mg}$.
2. $56 \text{ mg} \div 6 \text{ mg/mL} = 9.3 \text{ mL busulfan needed}$.
3. $9.3 \times 10 = 93 \text{ mL}$.
4. Add 9.3 mL of busulfan to 93 mL of NS or D5W.

Filters: 5-micron Nylon filter has been used; see [Compatibility](#).

Storage: Refrigerate. Busulfan diluted with NS or D5W is stable for 8 hours at room temperature, but infusion must be completed within that time. When diluted with NS and refrigerated, it is stable for 12 hours, but infusion must be completed within that time.

COMPATIBILITY

Do not use polycarbonate syringes or polycarbonate filter needles. Manufacturer states, "Do not infuse concomitantly with another intravenous solution of unknown **compatibility**. Flush central venous catheter line before and after administration with at least 5 mL of NS or D5W."

RATE OF ADMINISTRATION

Before and after each infusion, flush the catheter line with 5 mL NS or D5W.

Busulfan: Infuse over 2 hours using an infusion pump.

Cyclophosphamide: Infuse over 1 hour.

ACTIONS

A bifunctional alkylating agent. Cell cycle phase–nonspecific. Interferes with DNA replication, leading to cytotoxicity and cell death. Distributes equally into plasma and CSF. Metabolized in the liver. Excreted partially in the urine, primarily as metabolites.

INDICATIONS AND USES

For use in combination with cyclophosphamide as a conditioning regimen prior to allogeneic hematopoietic progenitor cell transplantation for chronic myelogenous leukemia.

Unlabeled uses: Component of pre-transplant conditioning regimens in patients undergoing bone marrow transplant for acute myeloid leukemia and nonmalignant diseases (e.g., sickle cell disease). ■ Patients 5 to 16 years of age undergoing allogeneic hematopoietic stem cell transplantation (HSCT).

CONTRAINDICATIONS

Previous hypersensitivity to busulfan or any of its components (polyethylene glycol and dimethylacetamide).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251.

■ Administered by or under the direction of a physician who is experienced in allogeneic hematopoietic stem cell transplantation, the use of cancer chemotherapeutic drugs, and the management of patients with severe pancytopenia. ■ Adequate diagnostic and treatment facilities must be readily available to manage therapy and any complications that arise. ■ Profound myelosuppression, including granulocytopenia, thrombocytopenia, anemia, or any combination of these will occur. ■ Seizures have been reported. Use caution when administering to patients with a history of seizures or head trauma or patients who are receiving other potentially epileptogenic drugs (e.g., imipenem-cilastatin [Primaxin], meperidine [Demerol]). ■ Anticonvulsant prophylactic therapy should be initiated with phenytoin before busulfan treatment. ■ High busulfan AUC values (greater than $1,500 \mu\text{M}\cdot\text{min}$) may be associated with an increased risk of developing hepatic veno-occlusive disease (HVD). Patients who have received prior radiation therapy, three or more cycles of chemotherapy, or a prior progenitor cell transplant may be at an increased risk of developing hepatic HVD with the recommended busulfan dose and regimen. ■ Cardiac tamponade has been reported in pediatric patients with thalassemia who received high doses of oral busulfan and cyclophosphamide. No patients treated in the busulfan injection trials experienced cardiac tamponade. ■ Bronchopulmonary dysplasia with pulmonary fibrosis is a rare but serious complication following chronic busulfan therapy. Average onset of symptoms is 4 years

after therapy (range: 4 months to 10 years). ■ May cause cellular dysplasia in many organs. Dysplasia may be severe enough to cause difficulty in interpretation of exfoliative cytologic examinations of the lungs, bladder, breast, and the uterine cervix. ■ Secondary malignancies, including acute nonlymphocytic leukemia, myeloproliferation syndrome, and carcinoma have been reported in patients treated with alkylating agents.

Monitor: Obtain a baseline and a daily CBC, including differential and platelet count, during treatment and until engraftment is demonstrated. Absolute neutrophil count (ANC) dropped below $0.5 \times 10^9/L$ at a median of 4 days post-transplant and recovered at a median of 13 days when prophylactic G-CSF was used. Thrombocytopenia (platelets less than $25,000/mm^3$ or platelet transfusion required) occurred at a median of 5-6 days. ■ Monitor for signs of local or systemic infection or bleeding. Antibiotic therapy and platelet and RBC support should be used when medically indicated. ■ Monitor for thrombocytopenia (platelet count less than $50,000/mm^3$). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Serum transaminases, alkaline phosphatase, and bilirubin should be obtained daily through transplant day 28 to monitor for signs of hepatotoxicity, and the onset of hepatic VOD. Jones' criteria may be used to diagnose VOD (hyperbilirubinemia, and two of the following three findings: painful hepatomegaly, weight gain more than 5%, or ascites). ■ Obtain baseline and periodic uric acid concentrations. ■ Use of anticonvulsants other than phenytoin may result in higher busulfan plasma AUCs and an increased risk of VOD or seizures. When other anticonvulsants are used, plasma busulfan AUC should be monitored; see [Drug/Lab Interactions](#).

Patient Education: Nonhormonal birth control recommended. ■ May be at increased risk of developing a secondary malignancy. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. Can cause fetal harm. Has mutagenic potential. ■ Discontinue breast-feeding. ■ Safety and efficacy for use in pediatric patients not established. Clearance has been shown to be higher in pediatric patients than in adults, necessitating the development of alternative dosing regimens for oral busulfan in pediatric patients. A recent small pharmacokinetic study suggests an unlabeled dosing regimen; see [Pediatric Dose](#) and manufacturer's literature.

Elderly: Has been used in a small number of patients over 55 years of age. All achieved myeloablation and engraftment.

DRUG/LAB INTERACTIONS

Itraconazole (Sporanox), **metronidazole** (Flagyl), and **cyclophosphamide** (Cytoxan) decrease busulfan clearance, increasing the AUC and risk of toxicity. ■ **Phenytoin** increases the clearance of busulfan. Because the pharmacokinetics of busulfan were studied in patients treated with phenytoin, the clearance of busulfan at the recommended dose may be lower and the AUC higher in patients not treated with phenytoin. ■ **Acetaminophen** (Tylenol) may decrease clearance of busulfan. Avoid administration of acetaminophen 72 hours prior to or with busulfan therapy. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Busulfan has been used with **fluconazole** (Diflucan), **ondansetron** (Zofran), and **granisetron** (Kytril). ■ May cause additive effects with **bone marrow-suppressing agents or agents that cause blood dyscrasias** (e.g., amphotericin B, antithyroid agents, azathioprine [Imuran], chloramphenicol, ganciclovir [Cytovene], interferon, plicamycin [Mithracin], zidovudine) and **radiation therapy**. Adjust busulfan dose based on blood cell counts. ■ Risk of uric acid nephropathy increased with **sulfipyrazone** (Anturan); allopurinol may be preferred to prevent or treat hyperuricemia. ■ See [Precautions](#).

SIDE EFFECTS

Profound myelosuppression, including granulocytopenia, thrombocytopenia, anemia, or a combination of these, will occur in 100% of patients. ■ Other nonhematologic adverse events occurring in more than 20% of patients include abdominal pain or enlargement, ALT elevation, anorexia, anxiety, asthenia, back pain, chest pain, chills, constipation, cough, creatinine elevation, depression, diarrhea, dizziness, dry mouth, dyspepsia, dys-

pnea, edema, epistaxis, fever, headache, hyperbilirubinemia, hyperglycemia, hypersensitivity reactions, hypertension, hypervolemia, hypocalcemia, hypokalemia, hypomagnesemia, infection, inflammation or pain at injection site, insomnia, lung disorders, nausea, pain, pruritus, rash, rectal disorder, rhinitis, seizures, stomatitis (mucositis), tachycardia, third-degree heart block, thrombosis, vasodilation (flushing or hot flashes), vomiting, weight gain secondary to edema. ■ Graft-versus-host disease, hepatic veno-occlusive disease and death have also been reported. ■ Dimethylacetamide (DMA), the solvent used in busulfan formulation, has been associated with adverse reactions such as confusion, hallucinations, hepatotoxicity, lethargy, and somnolence. The relative contribution of DMA to neurologic and hepatic toxicities observed with busulfan is difficult to determine. ■ Numerous other side effects have occurred.

Post-Marketing: Febrile neutropenia, thrombotic microangiopathy, tumor lysis syndrome, and severe bacterial, viral (e.g., CMV viremia), and fungal infections and sepsis.

ANTIDOTE

Treat minor side effects symptomatically. In the absence of hematopoietic progenitor cell transplantation, the normal dosage of busulfan injection constitutes an overdose. Monitor hematologic status closely, and institute supportive measures as indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Dialysis and administration of glutathione may be considered in an overdose (busulfan is metabolized by conjugation with glutathione).

BUTORPHANOL TARTRATE

(byou-TOR-fah-nohl TAHR-trayt)

Narcotic analgesic
(agonist-antagonist)
Anesthesia adjunct

Butorphanol Tartrate PF, Stadol, Stadol PF

pH 3 to 5.5

USUAL DOSE

Pain control: 1 mg. Repeat every 3 to 4 hours as necessary. Range is 0.5 to 2 mg.

Preoperative or preanesthetic: 2 mg 60 to 90 minutes before surgery. Individualize dose. Usually given IM.

Labor: 1 to 2 mg at full term in early labor; may be repeated after 4 hours. Use alternate analgesia if delivery is expected to occur within 4 hours.

Adjunct to balanced anesthesia: 2 mg just before induction or 0.5 to 1 mg in increments during anesthesia. Increments may be up to 0.06 mg/kg and should be based on previous sedative, analgesic, and hypnotic drugs. Patients seldom require less than 4 mg or more than 12.5 mg. Administered only under the direction of the anesthesiologist.

DOSE ADJUSTMENTS

Reduce dose to one half of the recommended dose and increase the interval between doses to at least 6 hours for impaired liver or renal function and in the elderly; adjust as indicated by patient response. ■ Another source suggests that patients with a glomerular filtration rate (GFR) of 10 to 50 mL/min receive 75% of the usual dose given at the normal dosage interval and that patients with a GFR less than 10 mL/min receive 50% of the usual dose given at the normal dosage interval. No dose adjustment is necessary for patients with a GFR greater than 50 mL/min. ■ Reduce dose when other CNS depressants have been given and in the immediate postoperative period. Use the smallest effective dose and extend intervals between doses. ■ See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted. Avoid aerosol spray while preparing a syringe for use. Rinse with cool water following skin contact. Available preservative free.

Storage: Store at CRT. Protect from light and freezing.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), aztreonam (Azactam), bivalirudin (Angiomax), cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), docetaxel (Taxotere), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), fenoldopam (Corlopam), filgrastim (Neupogen), fludarabine (Fludara), gemcitabine (Gemzar), granisetron (Kytril), heta-starch in electrolytes (Hextend), labetalol, linezolid (Zyvox), melphalan (Alkeran), nicardipine (Cardine IV), oxaliplatin (Eloxatin), paclitaxel (Taxol), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Each 2 mg or fraction thereof over 3 to 5 minutes. Frequently titrated according to symptom relief and respiratory rate.

ACTIONS

A potent narcotic analgesic with some narcotic agonist-antagonist effects. Exact mechanism of action is unknown. Analgesia similar to morphine is produced. Does produce respiratory depression, but this does not increase markedly with larger doses. Pain relief is effected almost immediately, peaks at 30 minutes, and lasts about 2 to 4 hours. Causes some hemodynamic changes that increase the workload of the heart. Metabolized in the liver. Excreted in urine and feces. Crosses the blood-brain barrier and placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Relief of moderate to severe pain. ■ Preoperative or preanesthetic medication, as a supplement to anesthesia. ■ Relief of pain during early labor.

CONTRAINDICATIONS

Hypersensitivity to butorphanol or its components (some products contain benzethonium chloride).

PRECAUTIONS

Not used for narcotic-dependent patients because of antagonist activity. ■ May increase cardiac workload; use in myocardial infarction, ventricular dysfunction, and coronary insufficiency only if benefits outweigh risks. ■ Use caution in respiratory depression or difficulty from any source, obstructive respiratory conditions, head injury, and impaired liver or kidney function. ■ May elevate cerebrospinal pressure. ■ Prolonged continuous use may result in physical dependence or tolerance. ■ In overdose situations, always consider the possibility of multiple drug ingestion.

Monitor: Naloxone (Narcan), oxygen, and controlled respiratory equipment must be available. Duration of action of butorphanol usually exceeds that of naloxone; repeated dosing may be necessary. ■ Observe patient frequently and monitor vital signs. ■ Keep patient supine to minimize side effects; orthostatic hypotension and fainting may occur. Observe closely during ambulation. ■ Pain control usually more effective with routinely administered doses. Determine appropriate interval through clinical assessment.

Patient Education: Avoid use of alcohol or other CNS depressants (e.g., antihistamines, diazepam [Valium]). ■ Use caution performing any task requiring alertness; may cause dizziness, euphoria, and sedation. ■ Request assistance for ambulation. ■ May be habit forming.

Maternal/Child: Category C: safety for use in pregnant women before 37 weeks' gestation not established; use only if benefit justifies potential risk to fetus. ■ Has been used safely during labor of term infants. Has been associated with transient (10 to 90 minutes) sinusoidal fetal heart rate patterns. Use caution if abnormal fetal heart rate is present; manufacturer states "was not associated with adverse outcomes." Alternative analgesia suggested if delivery is expected to occur within 4 hours. ■ Use caution in breast-feeding; an estimated 4 mcg/L has been found in breast milk; may be clinically insignificant. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly: Mean half-life may be extended by 25%, may be more sensitive to effects (e.g., respiratory depression, constipation, dizziness, urinary retention). ■ Analgesia should be effective with lower doses; see **Dose Adjustments**. ■ Consider decreased organ function, concomitant disease, or other drug therapy.

DRUG/LAB INTERACTIONS

Potentiated by **cimetidine** (Tagamet), **phenothiazines** (e.g., chlorpromazine [Thorazine]), **droperidol** (Inapsine), and **CNS depressants** such as narcotic analgesics, general anesthetics, alcohol, anticholinergics, antihistamines, barbiturates, benzodiazepines (e.g., diazepam [Valium]), hypnotics, MAO inhibitors, neuromuscular blocking agents (e.g., atracurium [Tracrium]), psychotropic agents, and sedatives. Reduced doses of both drugs may be indicated; use the smallest effective dose of butorphanol and/or extend intervals between doses. ■ Effects may be altered by other **medications that affect hepatic metabolism of drugs** (e.g., aminophylline, erythromycin). Reduced doses of butorphanol and/or longer intervals between doses may be indicated. ■ May decrease analgesic effects of **other narcotics**; avoid concurrent use. ■ Will cause an increase in conjunctival changes with **pancuronium**.

SIDE EFFECTS

Dizziness, nausea and/or vomiting, and somnolence occur most frequently. Abdominal pain, anorexia, anxiety, asthenia, bronchitis, clammy skin, confusion, constipation, cough, diplopia, dizziness, drug dependence, dry mouth, dyspnea, euphoria, floating feeling, flushing, hallucinations, headache, hypersensitivity reactions (e.g., pruritis), hypotension, insomnia, lethargy, nervousness, palpitations, paresthesia, respiratory depression, sweating, tremor, unusual dreams, vasodilation, vertigo, warmth. May cause increased pulmonary artery pressure, pulmonary wedge pressure, left ventricular end-diastolic pressure, systemic arterial pressure, pulmonary vascular resistance, and cardiac workload.

Overdose: Cardiovascular insufficiency, hypoventilation, coma, and death. May be associated with ingestion of multiple drugs.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. Most side effects will be treated symptomatically. Treat hypertension with antihypertensives (e.g., nitroglycerin, nitroprusside sodium). Naloxone hydrochloride (Narcan) will reverse respiratory depression. Duration of action of butorphanol usually exceeds that of naloxone; repeated dosing may be necessary. A patent airway, adequate ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Vasodilation may cause hypotension.

C1 ESTERASE INHIBITOR (HUMAN)

Protein C1 Inhibitor

(C 1 ES-ter-ase in-HIB-it-or)

Berinert

pH 4.5 to 8.5

USUAL DOSE

20 units/kg as an IV injection.

DILUTION

Available in a kit containing one 500-unit vial of C1 esterase inhibitor, one 10-mL vial of SWFI, one Mix2Vial filtered transfer set, and one alcohol swab. Bring components to room temperature. C1 esterase inhibitor is a lyophilized concentrate and requires reconstitution. The Mix2Vial transfer set provided requires a specific technique to accomplish reconstitution; see manufacturer's literature for instructions. Alternately, for each vial of C1 esterase inhibitor and provided diluent, place all components on a flat surface, remove the flip caps from the drug and diluent vials, swab the vials with alcohol, and allow them to dry. Insert one end of a double-ended transfer needle into the diluent. Invert the diluent bottle and insert the other end of the transfer needle into the drug vial. Diluent will be drawn into the drug vial by a vacuum. Remove the transfer device and diluent vial. Gently swirl the drug vial to fully dissolve. Solution should be colorless, clear, and free from visible particles. Concentration equals 50 units/mL. Do not use if cloudy, discolored, or contains particulates. Attach a vented filter spike to a 10-mL (or larger) syringe and withdraw the contents. Contents of multiple vials may be pooled in a single administration device (e.g., syringe). Use a double-ended transfer needle and a new vented filter spike for each vial requiring reconstitution.

Filters: A Mix2Vial filtered transfer set is provided for each single-use dose or, alternately, a double-ended needle and a vented filter spike are required.

Storage: Store in carton at 2° to 25° C (36° to 77° F) until ready for use. Do not freeze. Protect from light. Do not use beyond expiration date. Reconstituted solution must be used within 8 hours; do not refrigerate or freeze. Discard unused drug.

COMPATIBILITY

Manufacturer states, "Do not mix C1 esterase inhibitor with other medicinal products, and administer by a separate infusion line."

RATE OF ADMINISTRATION

A single dose at a rate of approximately 4 mL/min.

ACTIONS

C1 esterase inhibitor is a normal constituent of human blood and is a serine proteinase inhibitor. It has an important inhibiting potential on several of the major cascade systems, including the complement system, the intrinsic coagulation (contact) system, the fibrinolytic system, and the coagulation cascade. Hereditary angioedema (HAE) patients have low levels of endogenous or functional C1 esterase inhibitor. It is thought that increased vascular permeability and the clinical manifestation of HAE attacks (e.g., local tissue swelling of hands, feet, limbs, face, intestinal tract, and airway [larynx or trachea]) are primarily mediated through contact system activation. Suppression of contact system activation by C1 esterase inhibitor through the inactivation of plasma kallikrein and factor XIIa is thought to modulate vascular permeability by preventing the generation of bradykinin. Supplying additional C1 esterase inhibitor activity by IV injection facilitates the normal process. One unit of C1 inhibitor corresponds to the amount of C1 esterase inhibitor present in 1 mL of fresh citrated plasma. Plasma levels of C1 inhibitor increase within 1 hour or less of IV administration. The half-life range is 7.4 to 22.8 hours.

INDICATIONS AND USES

Treatment of acute abdominal or facial attacks of hereditary angioedema (HAE) in adult and adolescent patients. ■ Safety and effectiveness for use as prophylactic therapy not

established. An alternate C1 inhibitor product, Cinryze, is approved for routine prophylaxis.

CONTRAINDICATIONS

Known life-threatening hypersensitivity reactions, including anaphylaxis to C1 esterase inhibitor preparations.

PRECAUTIONS

Severe hypersensitivity reactions, including anaphylaxis, may occur. Administer in a facility capable of monitoring the patient and responding to any medical emergency. Epinephrine should be immediately available. ■ Thrombotic events (e.g., myocardial infarction, pulmonary embolism, arterial thrombosis, deep vein thrombosis) have occurred in patients receiving off-label high-dose C1 esterase inhibitor therapy. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C). Numerous steps in the manufacturing process are used to reduce the potential for infection.

Monitor: Observe for symptoms of a hypersensitivity reaction (e.g., anaphylaxis, generalized urticaria, hives, hypotension, tightness in the chest, wheezing). Reaction may occur during injection or after injection is complete. ■ Symptoms of an HAE attack may be similar to S/S of hypersensitivity reactions. Evaluate carefully to initiate the correct treatment. There is usually no itching or hives with an HAE attack. ■ Monitor patients with known risk factors for thrombotic events; see [Precautions](#).

Patient Education: Inform patients of the risks for infectious agent transmission and of safety precautions taken during manufacturing process. ■ Promptly report symptoms of a hypersensitivity reaction (e.g., difficulty breathing, feeling faint, hives, itching, tightness in the chest, wheezing). ■ Promptly report symptoms of a possible thrombosis (e.g., altered consciousness or speech; loss of sensation or motor power; new-onset swelling and pain in the abdomen, chest, or limbs; shortness of breath). ■ Discuss all medications used (e.g., prescription, nonprescription, over-the-counter, herbal, supplements) with the physician. ■ Consult a health care professional before travel.

Maternal/Child: Category C: safety and effectiveness for use during pregnancy, labor, and delivery has not been established; use only if clearly needed. ■ Not known if C1 esterase inhibitor is secreted in human milk; use only if clearly needed during breastfeeding. ■ Safety and effectiveness for use in pediatric patients less than 12 years of age not established.

Elderly: Numbers in clinical studies insufficient to determine if the elderly respond differently than do younger subjects.

DRUG/LAB INTERACTIONS

No drug interaction studies have been conducted.

SIDE EFFECTS

The most common side effects observed include abdominal pain, diarrhea, headache, muscle spasms, pain, subsequent HAE attack, and vomiting. An increase in the severity of pain associated with HAE was the most serious side effect during clinical trials. Other reported side effects include back pain, dysgeusia, facial pain, and hereditary angioedema.

Post-Marketing: Reported side effects from use outside the United States include hypersensitivity/anaphylactic reactions, viral transmission (e.g., acute hepatitis C), chills, fever, and injection site pain or redness.

ANTIDOTE

Keep the physician informed of side effects. Interrupt or discontinue injection if indicated (e.g., hypersensitivity reaction, HAE attack, thrombotic event). If appropriate and if symptoms subside, infusion may be resumed at a tolerated rate. ■ Discontinue C1 esterase inhibitor and treat anaphylaxis immediately with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol (Ventolin), IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

C1 INHIBITOR (HUMAN)

(C 1 in-HIB-a-tor)

Protein C1 inhibitor

Cinryze

pH 6.6 to 7.4

USUAL DOSE

1,000 units as an IV injection over 10 minutes (1 mL/min). May be repeated every 3 or 4 days as necessary for routine prophylaxis against angioedema attacks in patients with hereditary angioedema (HAE).

DILUTION

(International units [IU])

If refrigerated, bring components to RT (two 500-unit vials of C1 inhibitor and two 5-mL vials of SWFI [not supplied by manufacturer]). For each 500-unit vial, insert one end of a double-ended transfer needle into the SWFI diluent. Invert the bottle of diluent and rapidly insert the other end of the transfer needle into the slightly angled C1 inhibitor vial. Diluent will be drawn into the C1 inhibitor vial by a vacuum. Do not use if there is no vacuum. Remove the transfer device and diluent vial. Gently swirl the C1 inhibitor vial until the powder is completely dissolved. Do not use if turbid or discolored (should be colorless to slightly blue and clear). Attach a filter needle to a 10-mL syringe and withdraw 500 units (5 mL) from each vial (total dose 1,000 units in 10 mL [100 units/mL]).

Filters: Use of a filter needle is required to withdraw reconstituted solution into a syringe; may be used for both 500-IU vials (a single dose).

Storage: Store in carton between 2° and 25° C (36° and 77° F). Protect from light. Do not freeze. Reconstituted solution must be administered at RT within 3 hours of preparation. Do not use beyond expiration date on vial. Discard unused product.

COMPATIBILITY

Manufacturer states, "Do not mix with other materials."

RATE OF ADMINISTRATION

A single dose equally distributed over 10 minutes (1 mL/min).

ACTIONS

C1 inhibitor is a normal constituent of human blood; a serine proteinase inhibitor. It regulates activation of the complement and intrinsic coagulation (contact system) pathway and regulates the fibrinolytic system. Patients with HAE have low levels of endogenous or functional C1 inhibitor. It is thought that increased vascular permeability and the clinical manifestation of HAE attacks are mediated primarily through contact system activation. Suppression of contact system activation by C1 inhibitor through the inactivation of plasma kallikrein and factor XIIa is thought to modulate vascular permeability by preventing the generation of bradykinin. Supplying additional C1 inhibitor activity by IV injection facilitates the normal process. One unit of C1 inhibitor corresponds to the amount of C1 inhibitor present in 1 mL of normal fresh plasma. Plasma levels of C1 inhibitor increase within 1 hour or less of IV administration. Half-life is 56 hours (range 11 to 108 hours).

INDICATIONS AND USES

Routine prophylaxis against angioedema attacks in adolescent and adult patients with hereditary angioedema (HAE). HAE is caused by low levels or improper functioning of a protein called C1 inhibitor. Blood vessels are affected, and people with HAE can develop rapid swelling of the hands, feet, limbs, face, intestinal tract, or airway (larynx or trachea). Has caused death by suffocation.

CONTRAINDICATIONS

Known life-threatening hypersensitivity to C1 inhibitor or its components.

PRECAUTIONS

Severe hypersensitivity reactions, including anaphylaxis, may occur. Administer in a facility capable of monitoring the patient and responding to any medical emergency. Epinephrine should be immediately available. ■ Thrombotic events (e.g., myocardial in-

faction, pulmonary embolism, arterial thrombosis, deep vein thrombosis) have occurred in patients receiving off-label high-dose C1 inhibitor therapy. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C). Numerous steps in the manufacturing process are used to reduce the potential for infection.

Monitor: Observe for symptoms of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Symptoms of an HAE attack may be similar to S/S of hypersensitivity reactions. Evaluate carefully to initiate the correct treatment. There is usually no itching or hives with an HAE attack. ■ Monitor patients with known risk factors for thrombotic events; see [Precautions](#).

Patient Education: Inform patient of risks for infectious agent transmission and of safety precautions taken during the manufacturing process. ■ Promptly report symptoms of a hypersensitivity reaction (e.g., difficulty breathing, feeling faint, hives, itching, tightness in the chest, wheezing). ■ Promptly report symptoms of a possible thrombosis (e.g., altered consciousness or speech; loss of sensation or motor power; new-onset swelling and pain in the abdomen, chest, or limbs; shortness of breath).

Maternal/Child: Category C: safety and effectiveness for use during pregnancy, labor, and delivery not established; use only if clearly needed. ■ Not known if C1 inhibitor is secreted in human milk; use caution if required during breast-feeding. ■ Safety and effectiveness for use in neonates, infants, or other pediatric patients not established. Clinical studies included patients 9, 14, and 16 years of age.

Elderly: Numbers in clinical studies insufficient to determine if elderly patients respond differently than younger subjects.

DRUG/LAB INTERACTIONS

No drug interaction studies have been conducted.

SIDE EFFECTS

The most common side effects reported include headache, rash, sinusitis, and upper respiratory tract infections. Back pain, bronchitis, limb injury, pain in extremity, pruritus, and viral URIs also occurred. Hypersensitivity reactions, including anaphylaxis, hives, hypotension, tightness of the chest, urticaria, and wheezing, have occurred. Serious events not considered drug related have occurred and include death due to foreign body embolus, exacerbation of HAE attacks, pre-eclampsia resulting in an emergency cesarean section, and stroke.

ANTIDOTE

Keep the physician informed of any side effects. Interrupt or discontinue injection if indicated until symptoms subside, then resume at a tolerated rate. ■ Discontinue C1 inhibitor and treat anaphylaxis immediately with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol (Ventolin), IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

CABAZITAXEL **BBW**

(ka-BAZ-i-TAX-el)

Antineoplastic agent
(taxane)

Jevtana

USUAL DOSE

Premedication: Must be premedicated at least 30 minutes before each dose to prevent severe hypersensitivity reactions. Usual regimen includes IV administration of an antihistamine (diphenhydramine [Benadryl] 25 mg or equivalent), a corticosteroid (dexamethasone [Decadron] 8 mg or equivalent steroid), and an H₂ antagonist (ranitidine [Zantac] 50 mg or equivalent H₂ antagonist).

Antiemetic prophylaxis is recommended and may be given orally or IV as needed.

Cabazitaxel: 25 mg/M² as a 1-hour infusion every 3 weeks. Given in combination with oral prednisone 10 mg administered daily throughout cabazitaxel treatment.

DOSE ADJUSTMENTS

Recommendations for dose adjustment for adverse reactions are listed in the following chart.

Recommended Cabazitaxel Dose Modifications for Adverse Reactions	
Toxicity*	Dose Modification
Prolonged Grade ≥ 3 neutropenia (greater than 1 week) despite appropriate medication, including G-CSF	Delay treatment until neutrophil count is $>1,500$ cells/mm ³ , then reduce dose of cabazitaxel to 20 mg/M ² . Use G-CSF for secondary prophylaxis.
Febrile neutropenia	Delay treatment until improvement or resolution and until neutrophil count is $>1,500$ cells/mm ³ , then reduce dose of cabazitaxel to 20 mg/M ² . Use G-CSF for secondary prophylaxis.
Grade ≥ 3 diarrhea or persisting diarrhea despite appropriate medication and fluid and electrolytes replacement.	Delay treatment until improvement or resolution, then reduce dose of cabazitaxel to 20 mg/M ² .

*Toxicities graded in accordance with National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE), version 3.0.

Discontinue if any of these reactions continue at a cabazitaxel dose of 20 mg/M².

DILUTION

Specific techniques required; see Precautions. Must be diluted by a specific 2-step process and given as an infusion. Do not use PVC infusion containers and polyurethane infusion sets for preparation or administration. A clear yellow to brownish-yellow viscous solution.

Step 1: Initially withdraw the entire contents of the provided diluent and insert into the vial of cabazitaxel (60 mg/1.5 mL). When transferring the diluent, direct the needle onto the inside wall of the cabazitaxel vial to limit foaming. Gently mix by repeated inversions for at least 45 seconds to ensure full mixing of drug and diluent. Do not shake. Allow to stand for a few minutes to allow most of the foam to dissipate. Should not contain visible particulate matter. Concentration of the resultant dilution is 10 mg/mL. This initially diluted solution should be used immediately but must be used within 30 minutes of entry into the vial.

Step 2: Withdraw the recommended dose from the 10-mg/mL vial of cabazitaxel. Further dilute into a sterile 250-mL PVC-free container of either NS or D5W for infusion. If a dose greater than 65 mg is required, use a larger volume of NS or D5W infusion so a concentration of 0.26 mg/mL is not exceeded. Concentration of the final solution should be between 0.10 and 0.26 mg/mL. Thoroughly mix by gently inverting the bag or bottle.

Filters: Use of a 0.22-micron in-line filter is required for administration (not supplied).

Storage: Before use, store at 25° C (77° F), with excursions permitted between 15° to 30° C (59° to 86° F). Do not refrigerate. Initial diluted solution should be used immediately but must be used within 30 minutes; discard any unused portion. Final infusion solution should be used within 8 hours (including infusion time) at RT or within 24 hours (including infusion time) if refrigerated. Both solutions are supersaturated and may crystallize over time. Discard if crystallization occurs. Discard if either the initial diluted solution or final solution is not clear or appears to have precipitation.

COMPATIBILITY

Manufacturer states, “Do not use PVC infusion containers and polyurethane infusion sets for preparation or administration. Should not be mixed with any other drugs.”

RATE OF ADMINISTRATION

A single dose properly diluted as an infusion over 1 hour. Use of a 0.22-micron in-line filter required for administration. See [Dilution](#) and [Compatibility](#).

ACTIONS

An antineoplastic belonging to the taxane class. Prepared by semi-synthesis with a precursor extracted from yew needles. A microtubule inhibitor, it binds to tubulin and promotes its assembly into microtubules while simultaneously inhibiting disassembly. This leads to the stabilization of microtubules, which results in the inhibition of mitotic and interphase cellular functions. It is active in docetaxel-sensitive tumors and has demonstrated activity in tumor models insensitive to chemotherapy, including docetaxel. Highly protein bound (89% to 92%). Equally distributed between blood and plasma. Extensively metabolized in the liver, mainly by the CYP3A4/5 isoenzyme and to a lesser extent by CYP2C8. Terminal half-life is approximately 95 hours. Mainly excreted in feces as numerous metabolites with minimal excretion of unchanged drug in urine.

INDICATIONS AND USES

Treatment of patients with hormone-refractory metastatic prostate cancer previously treated with a docetaxel-containing treatment regimen. Used in combination with oral prednisone.

CONTRAINDICATIONS

Patients with neutrophil counts of equal to or less than 1,500/mm³. ■ Patients with a history of severe hypersensitivity reactions to cabazitaxel or other drugs formulated with polysorbate 80. ■ Not recommended for patients with impaired hepatic function (total bilirubin equal to or greater than the ULN, or AST and/or ALT equal to or greater than 1.5 times the ULN).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Usually administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ If initial or fully diluted solution should come in contact with the skin, immediately and thoroughly wash with soap and water. If contact with mucosa occurs, immediately and thoroughly wash with water. ■ Neutropenia resulting in fatal infections (sepsis or septic shock) has occurred. Primary prophylaxis with G-CSF should be considered in high-risk patients (e.g., extensive prior radiation ports, over 65 years of age, poor nutritional status, poor performance status, previous episodes of febrile neutropenia, or other serious co-morbidities that may result in increased complications from prolonged neutropenia). Therapeutic use of G-CSF and secondary prophylaxis should be considered in all patients considered to be at increased risk for neutropenia complications. ■ Severe hypersensitivity reactions have occurred; all patients are premedicated to lessen the intensity of a hypersensitivity reaction. Patients with a history of severe hypersensitivity reactions should not be rechallenged with cabazitaxel. ■ Nausea, vomiting, and severe diarrhea may occur. Deaths related to diarrhea and electrolyte imbalance have occurred. ■ Deaths due to renal failure have occurred, and most occurred in association with sepsis, dehydration, or obstructive uropathy. ■ Use with caution in patients with severe renal impairment (CrCl less than 30 mL/min) or in patients with ESRD. ■ Patients with impaired hepatic function (total bilirubin equal to or greater than the ULN, or AST and/or ALT equal to or

greater than 1.5 times the ULN) were excluded from clinical trials, and cabazitaxel should not be administered to these patients. Hepatic impairment increases the risk of severe and life-threatening complications in patients receiving other drugs belonging to the same class as cabazitaxel (metabolized in the liver); see [Drug/Lab Interactions](#).

Monitor: Obtain baseline CBC with differential and platelets. Monitor weekly during Cycle 1 and before each treatment cycle thereafter. ■ If febrile neutropenia or prolonged neutropenia (greater than 1 week) occur despite appropriate medications (e.g., G-CSF), dose reduction is indicated. May not be restarted until the neutrophil count recovers to a level greater than 1,500 cells/mm³; see [Contraindications](#) and [Dose Adjustments](#). ■ G-CSF may be administered to reduce the risks of neutropenia complications; see [Precautions](#). ■ Monitor closely for hypersensitivity reactions, especially during the first and second infusions. May occur within the first few minutes, and beginning symptoms may include bronchospasm, generalized rash/erythema, and hypotension. ■ Monitor for nausea, vomiting, and diarrhea. Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. Rehydrate and use antidiarrheal medications as indicated. ■ Monitor for S/S of impending renal failure (dehydration, reduced urine output). Monitoring of CrCl or SCr may be indicated. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Avoid pregnancy; nonhormonal birth control recommended. ■ Routine monitoring of blood counts imperative. ■ Oral prednisone must be taken as prescribed. ■ Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face). ■ May cause severe and/or fatal infections, dehydration, and renal failure. Take your temperature often and promptly report a fever. ■ Promptly report burning on urination, cough, decreased urine output, hematuria, muscle aches, and/or significant diarrhea or vomiting. ■ Drug interactions may occur, review prescription and non-prescription drugs with your physician. ■ Certain side effects may be more frequent or severe in the elderly. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. Can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Patients over 65 years of age are more likely to experience fatal outcomes not related to disease progression and certain serious adverse reactions, including neutropenia and febrile neutropenia. The incidence of asthenia, dehydration, dizziness, fatigue, fever, and urinary tract infections was also increased in the elderly.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Prednisone administered at 10 mg daily did not affect the pharmacokinetics of cabazitaxel. ■ Primarily metabolized through CYP3A. Concomitant administration with **strong CYP3A4 inhibitors** (e.g., atazanavir [Reyataz], clarithromycin [Biaxin], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase], telithromycin [Ketek], and voriconazole [VFEND]) should be avoided. Serum concentration of cabazitaxel is expected to increase. ■ Use caution when administered concomitantly with **moderate CYP3A inhibitors**. ■ Concomitant administration with **strong CYP3A4 inducers** (e.g., carbamazepine [Tegretol], phenytoin [Dilantin], phenobarbital [Luminal], rifabutin [Mycobutin], rifampin [Rifadin], and rifapentine [Priftin]) should be avoided. Serum concentration of cabazitaxel is expected to decrease. ■ Avoid use of **St. John's wort**; may also decrease concentration of cabazitaxel.

SIDE EFFECTS

Abdominal pain, alopecia, anorexia, arthralgia, asthenia, back pain, bone marrow suppression (e.g., anemia, leukopenia, neutropenia, thrombocytopenia), constipation, cough, diarrhea, dysgeusia, dyspnea, fatigue, fever, hematuria, nausea, peripheral neuropathy,

and vomiting are most common. Serious side effects include gastrointestinal symptoms, hypersensitivity reactions, neutropenia, febrile neutropenia, and renal failure. Cardiac arrhythmia, dehydration, dizziness, dyspepsia, dysuria, headache, hypotension, mucosal inflammation, muscle spasms, pain, peripheral edema, UTI, and weight loss have also occurred.

Overdose: Exacerbation of adverse reactions such as bone marrow suppression and GI disorders.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. Minor hypersensitivity reactions may subside with temporary discontinuation of cabazitaxel and additional antihistamines, corticosteroids, or H₂ antagonists. Reduction in rate of administration may allow continued treatment. Discontinue immediately if severe reactions occur; may require epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., dexamethasone [Decadron]), or bronchodilators (e.g., albuterol [Ventolin], theophylline [Aminophylline]). Neutropenia can be profound but may be treated with filgrastim (G-CSF, Neupogen). Severe thrombocytopenia may require platelet transfusions. Severe anemia (less than 8 Gm/dL) may require packed cell transfusions; moderate anemia (less than 11 Gm/dL) may be treated with darbepoetin alfa (Aranesp) or epoetin alfa (Epogen). Discontinue cabazitaxel if adverse reactions continue after the dose adjustment to 20 mg/M². There is no specific antidote for overdose. Administer G-CSF as soon as possible and closely monitor chemistry, vital signs, and other functions. Resuscitate if indicated.

CAFFEINE CITRATE

(KAF-feen SIT-rayt)

Cafcit

CNS stimulant

Respiratory stimulant adjunct

pH 4.7

PEDIATRIC DOSE

The dose expressed as caffeine base is one half the dose when expressed as caffeine citrate. The recommended loading dose and maintenance dose are listed in the following chart.

Guidelines for Loading and Maintenance Doses of Caffeine Citrate		
	Dose of Cafcit (volume)	Dose Expressed as Caffeine Citrate
Loading dose	1 mL/kg	20 mg/kg for 1 dose
Maintenance dose	0.25 mL/kg	5 mg/kg every 24 hours

Begin maintenance dose 24 hours after loading dose. Maintenance dose may be given IV or orally. Duration of treatment beyond 10 to 12 days has not been studied. See [Precautions](#).

DOSE ADJUSTMENTS

May adjust maintenance dose using serum concentrations of caffeine. ■ To avoid toxicity in neonates with impaired renal or hepatic function, use with caution and monitor serum concentrations.

DILUTION

Both the IV and the oral doses are supplied in vials containing 60 mg/3 mL of caffeine citrate (30 mg/3 mL of caffeine base). Confirm vial is for IV use. Withdraw calculated dose and dilute with sufficient D5W to administer at the recommended rate of administration.

Storage: Store at CRT. Single-use vial. Discard any unused solution. Stable for 24 hours at room temperature when mixed with any of the solutions listed by the manufacturer in Compatibility.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Solution: Manufacturer lists D5W; another source adds D5 $\frac{1}{4}$ NS, D5 $\frac{1}{4}$ NS with 20 mEq KCL/L.

Additive: Manufacturer lists amino acid solution 8.5% (Aminosyn 8.5%), calcium gluconate 10%, D5W, dextrose 50%, dopamine 40 mg/mL diluted to 0.6 mg/mL with D5W, fentanyl 50 mcg/mL diluted to 10 mcg/mL with D5W, heparin sodium 1,000 units/mL diluted to 1 unit/mL with D5W, IV fat emulsion 20% (Intralipid 20%).

One source suggests the following **compatibilities:**

Y-site: Doxapram (Dopram), fentanyl (Sublimaze), heparin, levofloxacin (Levaquin).

RATE OF ADMINISTRATION

Use of a syringe pump infuser is recommended.

Loading dose: Infuse over 30 minutes.

Maintenance dose: Infuse over 10 minutes.

ACTIONS

A bronchial smooth muscle relaxant, a CNS and cardiac stimulant, and a diuretic. Structurally related to other methylxanthines (e.g., theophylline and theobromine). Exact mechanism of action in apnea of prematurity is not known. Postulated mechanisms include stimulation of the respiratory center, increased minute ventilation, decreased threshold to hypercapnia, increased response to hypercapnia, increased skeletal muscle tone, decreased diaphragmatic fatigue, increased metabolic rate, increased oxygen consumption, blood vessel dilatation, central vessel vasoconstriction, and smooth muscle relaxation. Readily distributes into the brain. Caffeine levels in the CSF of preterm neonates approximate plasma levels. Metabolized in the liver by the cytochrome P₄₅₀ system. Metabolism and elimination in the preterm neonate are much slower than in adults due to immature hepatic and/or renal function. Mean half-life and fraction excreted unchanged in the urine is inversely related to gestational/postconceptual age. In neonates, the half-life is approximately 3 to 4 days and the fraction excreted unchanged in the urine is approximately 86% (within 6 days). By 9 months of age, the metabolism of caffeine approximates that seen in adults (half-life is 5 hours and amount excreted unchanged is 1%). Interconversion between caffeine and theophylline have been reported in preterm neonates. After theophylline administration, caffeine levels are approximately 25% of theophylline levels. After caffeine administration, 3% to 5% of caffeine administered converts to theophylline.

INDICATIONS AND USES

Short-term treatment of apnea of prematurity in infants more than 28 but less than 33 weeks' gestational age. In one study apnea of prematurity was defined as having at least 6 apnea episodes of more than 20 seconds duration in a 24-hour period with no other identifiable cause of apnea.

Unlabeled uses: Prevention of postoperative apnea in former preterm infants.

CONTRAINDICATIONS

Hypersensitivity to any of its components.

PRECAUTIONS

Reports in the literature suggest a possible association between the use of methylxanthines and the development of necrotizing enterocolitis. Necrotizing enterocolitis, resulting in death in some cases, has been reported in neonates receiving caffeine citrate. ■ Apnea of prematurity is a diagnosis of exclusion. Other causes of apnea (e.g., CNS disorders, primary lung disease, anemia, sepsis, metabolic disturbances, cardiovascular abnormalities, or obstructive apnea) should be ruled out or properly treated prior to initiating therapy with caffeine citrate. ■ Is a CNS stimulant. Use with caution in infants with seizure disorders. ■ May increase heart rate, left ventricular output, and stroke

volume. Use with caution in infants with cardiovascular disease. ■ Duration of treatment of apnea of prematurity in trials has been limited to 10 to 12 days. Safety and efficacy of therapy beyond this time have not been established. ■ Safety and efficacy for use in prophylactic treatment of sudden infant death syndrome (SIDS) or before extubation in mechanically ventilated infants have not been established. ■ Use with caution in infants with impaired renal or hepatic function; see [Dose Adjustments](#) and [Monitor](#). ■ Patients sensitive to other xanthines (e.g., aminophylline) may also be sensitive to caffeine.

Monitor: Obtain baseline serum caffeine levels in infants previously treated with theophylline, since preterm infants metabolize theophylline to caffeine; see [Actions](#). Levels should also be obtained in infants born to mothers who ingested caffeine before delivery, as caffeine readily crosses the placenta. Caffeine levels ranged from 8 to 40 mg/L in clinical trials. A therapeutic plasma concentration range has not been determined, but one source suggests 5 to 25 mcg/mL. Serious toxicity has been reported at levels exceeding 50 mg/L. Monitor levels periodically during treatment to avoid toxicity. Monitoring is especially important in infants with impaired renal or hepatic function; see [Dose Adjustments](#). ■ Monitor serum glucose periodically. Hypoglycemia and hyperglycemia have been reported. ■ Monitor for S/S of necrotizing enterocolitis (e.g., gastric distention, vomiting, bloody stools). Screening stools for occult blood may be helpful in identifying early-onset necrotizing enterocolitis.

Patient Education: Caregivers should be instructed to consult physician if infant continues to have apnea events and to not increase the dose of caffeine citrate without consulting a physician. ■ Contact physician at the first sign of lethargy or GI intolerance (e.g., abdominal distention, vomiting, or bloody stools). ■ Dose must be accurately measured, and any unused solution must be discarded.

Maternal/Child: Category C: no controlled studies; benefits should outweigh risks. ■ Half-life is increased in pregnant women. ■ Half-life may be in excess of 100 hours in infants under 6 months of age due to immature liver function.

DRUG/LAB INTERACTIONS

Metabolized by the cytochrome P₄₅₀ system. Lower caffeine doses may be required with coadministration of medications that **inhibit the P₄₅₀ system**, decreasing the elimination of caffeine (e.g., cimetidine [Tagamet] and ketoconazole [Nizoral]). Higher caffeine doses may be needed with coadministration of medications that **induce the P₄₅₀ system**, increasing the elimination of caffeine (e.g., phenobarbital and phenytoin). ■ Interconversion between caffeine and **theophylline** has been reported. Concurrent use of these drugs is not recommended; see [Actions](#).

SIDE EFFECTS

Cardiovascular effects (e.g., tachycardia, increased left ventricular output, and increased stroke volume), CNS stimulation (e.g., irritability, jitteriness, restlessness), GI effects (e.g., feeding intolerance, gastritis, increased gastric aspirate, and necrotizing enterocolitis), hyperglycemia, hypoglycemia, renal effects (e.g., increased urine output, increased CrCl, and increased sodium and calcium excretion).

Overdose: Signs and symptoms of caffeine overdose in the preterm infant may include: elevated BUN, elevated total leukocyte concentration, fever, fine tremor of extremities, hyperglycemia, hypertonia, insomnia, jitteriness, nonpurposeful jaw and lip movements, opisthotonos, seizures, tachypnea, tonic-clonic movements, or vomiting.

ANTIDOTE

Notify the physician of any side effects. Treatment of overdose is primarily symptomatic and supportive. Seizures may be treated with intravenous administration of diazepam (Valium) or a barbiturate such as pentobarbital (Nembutal). Caffeine levels have been shown to decrease after exchange transfusions. Resuscitate as necessary.

CALCITRIOL

(kal-si-TRYE-ole)

Vitamin D

Calcijex

pH 5.9 to 7

USUAL DOSE

Effectiveness of calcitriol therapy is dependent on adequate daily intake of calcium. The RDA of calcium in adults is 800 mg. Calcium supplementation or proper dietary measures must be initiated and maintained.

Hypocalcemia and/or secondary hyperparathyroidism: Recommended initial dose, depending on the severity of hypocalcemia and/or secondary hyperparathyroidism, is 1 mcg (0.02 mcg/kg) to 2 mcg administered at each hemodialysis treatment (three times weekly, approximately every other day). Initial doses have ranged from 0.5 to 4 mcg three times weekly.

Information supplied by the manufacturer suggests that the relative dosing of paricalcitol to calcitriol is 4:1. When converting a patient from calcitriol to paricalcitol, the initial dose of paricalcitol should be four times greater than the patient's dose of calcitriol.

PEDIATRIC DOSE

Hypocalcemia in end stage renal disease (ESRD) (unlabeled): 0.01 to 0.05 mcg/kg/dose given 3 times a week; see [Maternal/Child](#). See all comments under [Usual Dose](#).

DOSE ADJUSTMENTS

Adjust dosing based on patient response. Begin dosing at lower end of dose range in the elderly; see [Elderly](#). If a satisfactory response is not observed, dose may be increased by 0.5 to 1 mcg at 2- to 4-week intervals. Monitor serum calcium, phosphorus, and calcium \times phosphorus product ($\text{Ca} \times \text{P}$) frequently during any dose adjustment period; see [Monitor](#). ■ Discontinue therapy if elevated calcium level or a $\text{Ca} \times \text{P}$ product of greater than 70 is noted. Reinitiate therapy at a lower dose when parameters normalize. ■ Calcitriol dose may need to be reduced as the parathyroid hormone (PTH) levels decrease in response to therapy. The currently accepted target range for intact parathyroid hormone (iPTH) in chronic renal failure (CRF) patients is no more than 1.5 to 3 times the non-uremic upper limit of normal. Incremental dosing must be individualized and commensurate with PTH, serum calcium, and phosphorus levels. The following chart is a suggested approach to dose titration.

Calcitriol Suggested Dosing Guidelines	
PTH Levels	Calcitriol Dose
The same or increasing	Increase
Decreasing by <30%	Increase
Decreasing by >30% but <60%	Maintain
Decreasing by >60%	Decrease
One and one-half to three times the upper limit of normal	Maintain

DILUTION

May be given undiluted. Available in 1-mcg/mL ampules.

Storage: Store ampules at CRT. Protect from light. Calcitriol may be drawn up into a syringe up to 8 hours prior to administration but must be protected from direct sunlight.

COMPATIBILITY

Y-site: D5W, NS, SWFI.

RATE OF ADMINISTRATION

Administer as a bolus dose into the venous line at the end of hemodialysis.

ACTIONS

The active form of vitamin D₃ (cholecalciferol). Must be metabolically activated in liver and kidney before it is fully active on its target tissues. In bone, acts with PTH to stimulate resorption of calcium. In kidneys, increases tubular reabsorption of calcium. Stimulates intestinal calcium transport, and directly suppresses synthesis and release of PTH from the parathyroid gland. A vitamin D-resistant state may exist in uremic patients because of the failure of the kidney to adequately convert precursors to the active compound, calcitriol. Duration of action is 3 to 5 days.

INDICATIONS AND USES

Management of hypocalcemia in patients undergoing chronic renal dialysis. Has been shown to significantly reduce elevated PTH levels, which results in improvement in renal osteodystrophy.

CONTRAINDICATIONS

Patients with hypercalcemia or evidence of vitamin D toxicity.

PRECAUTIONS

Since calcitriol is the most potent form of vitamin D available, oral vitamin D supplements should be discontinued during treatment. ■ Dietary phosphorus should be restricted and a non-aluminum phosphate-binding compound (e.g., calcium acetate [PhosLo], sevelamer [Renagel]) should be administered to control serum phosphorus levels in patients undergoing dialysis.

Monitor: Obtain baseline serum calcium, phosphorus, aluminum, albumin, and PTH assays. ■ Serum calcium levels should be corrected for serum albumin using the following equation: $\text{Corrected Ca} = \text{observed Ca} + 0.8 \times (\text{normal albumin} - \text{observed albumin})$. For example: If serum calcium is 7 mg/dL and observed albumin is 2.5 Gm/dL, $\text{Corrected Ca} = 7 + 0.8 \times (4 - 2.5) = 8.2 \text{ mg/dL}$. All decisions regarding therapy should be based on corrected calcium values. ■ Monitor magnesium, alkaline phosphatase, and 24-hour urinary calcium and phosphorus periodically. ■ Criteria used to determine if calcitriol should be administered include: serum calcium less than 11.5 mg/dL, $\text{Ca} \times \text{P}$ less than 70, serum albumin less than 60 mcg/L (within normal limits), and PTH more than 3 times the upper limit of normal. ■ Serum calcium, phosphorus, and the $\text{Ca} \times \text{P}$ product should be monitored twice weekly during dose titration. Once stable, decrease monitoring to once monthly. See [Dose Adjustments](#). ■ PTH levels, once stable, should be monitored every 3 months. Adynamic bone lesions may develop if PTH levels are suppressed to abnormal levels. If PTH levels fall below the target range (1.5 to 3 times the upper limit of normal), the calcitriol dose should be reduced. Discontinuation may result in rebound effect. Therefore, gradual titration downward to a new maintenance dose is recommended; see [Dose Adjustments](#). ■ Overdosage of vitamin D is dangerous. May induce hypercalcemia and/or hypercalciuria. If clinically significant hypercalcemia develops, dose should be reduced or held. Chronic hypercalcemia can lead to generalized vascular calcification, nephrocalcinosis, and other soft-tissue calcification. The serum $\text{Ca} \times \text{P}$ product should not be allowed to exceed 70. Radiographic evaluation of suspect anatomical regions may be useful in early detection of this condition; see [Side Effects](#) and [Antidote](#). ■ Use with caution in patients receiving digoxin. Hypercalcemia may precipitate cardiac arrhythmias; see [Drug/Lab Interactions](#).

Patient Education: Report symptoms of hypercalcemia promptly. Dose adjustment or treatment may be required. Strict adherence to dietary supplementation of calcium and restriction of phosphorus is required to ensure optimal effectiveness of therapy. Phosphate-binding compounds (e.g., calcium acetate [PhosLo]) may be needed to control serum phosphorus levels in patients with CRF, but excessive use of aluminum-containing products (e.g., aluminum hydroxide gel [Alternagel]) should be avoided. ■ Avoid use of unapproved nonprescription medications, including magnesium-containing antacids.

Maternal/Child: Category C: safety for use in pregnancy not established. Benefits must outweigh risks. ■ Safety for use in breast-feeding not established. A decision should be made whether to discontinue nursing or to discontinue the drug. ■ Safety and effectiveness have been studied in a small number of pediatric patients, ages 13 to 18 years, with ESRD on hemodialysis. The mean weekly dose ranged from 1 to 1.4 mcg. Use in this study program appeared to be safe and effective. See package insert for study information. **Elderly:** Begin dosing at lower end of dose range. Consider age-related organ impairment, concomitant disease, and/or drug therapy; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Specific interaction studies have not been performed. ■ **Digoxin** toxicity is potentiated by hypercalcemia. Use caution when calcitriol is prescribed concomitantly with digoxin compounds. ■ **Phosphate or vitamin D-related compounds** should not be taken concomitantly with calcitriol. ■ **Magnesium-containing antacids** and calcitriol should not be used concomitantly. Hypermagnesemia may result.

SIDE EFFECTS

Overdose or chronic administration may lead to hypercalcemia, hypercalciuria, and hyperphosphatemia. High intake of calcium and phosphate concomitant with calcitriol therapy may lead to similar abnormalities. Signs and symptoms of vitamin D intoxication associated with hypercalcemia include **Early:** bone pain, constipation, dry mouth, headache, metallic taste, muscle pain, nausea, somnolence, vomiting, and weakness. **Late:** albuminuria, anorexia, cardiac arrhythmias, conjunctivitis (calcific), decreased libido, ectopic calcification, elevated BUN, elevated AST and ALT, hypercholesterolemia, hypertension, hyperthermia, nocturia, overt psychosis (rare), pain at injection site, pancreatitis, photophobia, polydipsia, polyuria, pruritus, rhinorrhea, and weight loss. Rare cases of hypersensitivity reactions, including anaphylaxis, have been reported.

ANTIDOTE

Notify physician of any side effects. Treatment of patients with clinically significant hypercalcemia (more than 1 mg/dL above the upper limit of normal range) consists of supportive measures, immediate dose reduction or interruption of therapy, initiation of a low-calcium diet, withdrawal of calcium supplements, patient mobilization, attention to fluid and electrolyte imbalances, assessment of electrocardiographic abnormalities (critical in patients receiving digoxin), and hemodialysis or peritoneal dialysis against a calcium-free dialysate, as warranted. Hypercalcemia usually resolves in 2 to 7 days. Monitor serum calcium levels frequently until calcium levels return to within normal limits. May reinstitute calcitriol therapy at a dose 0.5 mcg less than prior dose. See [Dose Adjustments](#).

CALCIUM CHLORIDE

(KAL-see-um K-LOR-eyed)

Electrolyte replenisher
Antihypocalcemic
Cardiotonic
Antihyperkalemic
Antihypermagnesemic

pH 5.5 to 7.5

USUAL DOSE

In a 10% solution, 10 mL (1 Gm) contains 13.6 mEq (272 mg) of calcium; 1 mL (100 mg), 1.36 mEq (27.2 mg). All doses based on a 10% solution.

Hypocalcemic disorders (prophylaxis, treatment, electrolyte replacement, maintenance): 5 to 10 mL (500 mg to 1 Gm) at intervals of 1 to 3 days. Repeat doses may be required and are based on patient response or serum calcium levels. May be given as part of a TPN program.

Magnesium intoxication: 5 mL (500 mg). Observe for signs of recovery before giving any additional calcium.

Hyperkalemia ECG disturbances of cardiac function: 1 to 10 mL (100 mg to 1 Gm); titrate dose by monitoring ECG changes. AHA guidelines recommend 5 to 10 mL of a 10% solution (500 mg to 1 Gm). Repeat as needed.

Cardiac resuscitation (see [Indications for specific uses](#)): 0.02 to 0.04 mL/kg (2 to 4 mg/kg); repeat at 10-minute intervals as indicated or as measured by serum deficits of calcium. Consider need for calcium (usually gluconate or gluceptate) for every 500 mL of whole blood if arrest occurs in a situation requiring copious blood replacement.

Overdose of calcium channel blockers or beta adrenergic blockers (unlabeled): AHA guidelines recommend 5 to 10 mL of a 10% solution (500 mg to 1 Gm). May repeat as needed.

PEDIATRIC DOSE

Do not administer into a scalp vein in pediatric patients; see [Precautions](#), [Monitor](#), and [Maternal/Child](#).

Hypocalcemic disorders: 0.027 to 0.05 mL/kg of body weight (2.7 to 5 mg/kg) of a 10% solution. Up to 10 mL (1 Gm)/day may be required. No data from clinical trials is available regarding repeat doses. Sources suggest repeat doses every 4 to 6 hours based on patient response or serum calcium levels.

Cardiac resuscitation (see [Indications for specific uses](#)): 0.2 mL/kg of a 10% solution (20 mg/kg). Repeat as indicated at 10-minute intervals. AHA guidelines recommend consideration of this dose for documented or suspected hypocalcemia or hyperkalemia as well as for hypomagnesemia and calcium channel blocker overdose.

DILUTION

May be given undiluted, but preferably diluted with an equal amount of SWFI or NS for injection to make a 5% solution. Solution should be warmed to body temperature. May be further diluted with most common infusion solutions and given as an intermittent or continuous infusion.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Calcium salts not generally mixed with carbonates, phosphates, sulfates, or tartrates. **Extreme caution and a specific multi-step process are required when calcium and phosphates are combined in parenteral nutrition solutions. Consult pharmacist.**

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), ascorbic acid, chloramphenicol (Chloromycetin), dobutamine, dopamine, hydrocortisone sodium succinate (Solu-Cortef), isoproterenol (Isuprel), lidocaine, magnesium sulfate, norepinephrine (Levophed), penicillin G potassium and

sodium, pentobarbital (Nembutal), phenobarbital (Luminal), sodium bicarbonate, verapamil.

Y-site: Amiodarone (Nexterone), dobutamine, doxapram (Dopram), epinephrine (Adrenalin), esmolol (Brevibloc), 6% hydroxyethyl starch (Voluven), micalfungin (Mycamine), milrinone (Primacor), morphine, nitroprusside sodium (Nitropress), paclitaxel (Taxol).

RATE OF ADMINISTRATION

0.5 to 1 mL of solution over 1 minute. Administration into a central or deep vein is preferred; see **Monitor**. Stop or slow infusion rate if patient complains of discomfort. Do not exceed the equivalent of 1 mL calcium chloride/minute by IV injection or infusion. Rapid administration may cause bradycardia; heat waves; local burning sensation; metallic, calcium, or chalky taste; moderate drop in BP; peripheral vasodilation; or a sense of oppression.

ACTIONS

Calcium is a basic element prevalent in the human body. It affects bones, nerves, muscles, glands, cardiac and vascular tone, and normal coagulation of the blood. It is excreted in the urine and feces.

INDICATIONS AND USES

Calcium preparations other than calcium chloride are often preferred except in cardiac resuscitation or calcium channel blocker toxicity. ■ Increase plasma calcium levels in hypocalcemic disorders (e.g., tetany [neonatal, parathyroid deficiency], vitamin D deficiency, alkalosis, conditions associated with intestinal malabsorption). ■ Treat ECG disturbances caused by hyperkalemia. ■ Adjunctive therapy in sensitivity reactions (especially with urticaria), insect bites or stings (relieve muscle cramping), acute symptoms of lead colic, rickets, or osteomalacia. ■ Cardiac resuscitation only to treat hypocalcemia, hyperkalemia, or calcium-channel blocker toxicity (verapamil, diltiazem), or after open heart surgery if epinephrine does not produce effective myocardial contractions. ■ Antidote for cardiac and respiratory depression of magnesium sulfate toxicity.

Unlabeled uses: Treatment of arrhythmias and/or hypotension caused by an overdose of calcium channel blockers (e.g., diltiazem [Cardizem], verapamil) or beta-adrenergic blockers (e.g., atenolol [Tenormin], metoprolol [Lopressor], propranolol). ■ Prevention of hypotension caused by calcium channel blockers.

CONTRAINDICATIONS

Digitalized patients, hypercalcemia, ventricular fibrillation. Not recommended in the treatment of asystole and electromechanical dissociation.

PRECAUTIONS

Three times more potent than calcium gluconate. ■ For IV use only. ■ See **Drug/Lab Interactions**.

Monitor: Confirm patency of vein; select a large vein and use a small needle to reduce vein irritation. Administration into a central or deep vein is preferred. Necrosis and sloughing will occur with IM or SC injection or extravasation. ■ Keep patient recumbent after injection to prevent postural hypotension. ■ Monitor vital signs carefully. ■ Monitor serum calcium levels as indicated. May cause hyperchloremic acidosis.

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding not established. Use only when clearly needed. ■ Rarely used IV in pediatric patients. Use of a less irritating salt preferred because of small vein size.

DRUG/LAB INTERACTIONS

Will increase **digoxin** toxicity and may cause arrhythmias. If necessary, give small amounts very slowly. ■ Potentiated by **thiazide diuretics** (e.g., chlorothiazide [Diuril]); may cause hypercalcemia or calcium toxicity. ■ May reduce plasma levels of **atenolol** (Tenormin). ■ Can reduce neuromuscular paralysis and respiratory depression produced by **antibiotics such as kanamycin**. ■ Antagonizes **verapamil**; can reverse clinical effects. ■ May cause metabolic alkalosis and inhibit binding of potassium with **sodium polystyrene sulfonate**.

SIDE EFFECTS

Usual doses will produce a local burning sensation, moderate drop in BP, and peripheral vasodilation. May cause bradycardia, cardiac arrest, heat waves; metallic, calcium, or chalky taste; prolonged state of cardiac contraction, sense of oppression, or tingling sensation, especially with a too-rapid rate of administration.

Overdose: Coma, intractable nausea and vomiting, lethargy, markedly elevated plasma calcium level, weakness, and sudden death.

ANTIDOTE

If side effects occur, further dilution and decrease in the rate of administration may be necessary. If side effects persist, discontinue the drug and notify the physician. IV infusion of sodium chloride (to maintain normovolemia) and furosemide (Lasix) 80 to 100 mg IV every 2 to 4 hours (with caution) is recommended in overdose. Sodium chloride competes with calcium for reabsorption in the renal tubules; furosemide enhances the activity. Together they will reduce hypercalcemia by causing a marked increase in calcium excretion. Monitoring of fluid, electrolytes, and cardiac and respiratory status is imperative. Disodium edetate may be used with extreme caution as a calcium chelating agent if overdose is critical. For extravasation inject affected area with 1% procaine hydrochloride and hyaluronidase to reduce venospasm and dilute calcium. Use a 27- or 25-gauge needle. Warm, moist compresses may be helpful. Resuscitate as necessary.

CALCIUM GLUCONATE

(KAL-see-um GLOO-koh-nayt)

Electrolyte replenisher
 Antihypocalcemic
 Cardiotonic
 Antihyperkalemic
 Antihypermagnesemic
 pH 6 to 8.2

USUAL DOSE

All doses based on a 10% solution, which yields 10 Gm/100 mL or 100 mg/mL.

Hypocalcemia disorders/maintenance: 2 to 15 Gm/24 hr in divided doses every 6 hours (0.5 to 3.75 Gm every 6 hours). Larger amounts may be given as an intermittent or continuous IV infusion. 10 mL (1 Gm in a 10% solution) contains 4.65 mEq (93 mg) of calcium.

Cardiac resuscitation (see [Indications for specific uses](#)): 500 to 800 mg/dose. Repeat at 10-minute intervals as indicated by clinical condition or serum calcium level.

Hypocalcemic tetany: 1 to 3 Gm IV over 10 to 30 minutes; repeat in 6 hours if indicated.

Magnesium intoxication: 500 to 800 mg/dose (maximum dose 3 Gm). Repeat as indicated by patient response; observe for signs of recovery before giving additional calcium.

Hypocalcemia secondary to citrated blood infusion: 500 mg to 1 Gm/500 mL of citrated blood (infuse into another vein).

PEDIATRIC DOSE

Do not administer into a scalp vein in pediatric patients; see [Precautions/Monitor](#). *All doses based on a 10% solution.*

Hypocalcemia disorders/maintenance: 200 to 500 mg/kg/24 hr in divided doses every 6 hours (50 to 125 mg/kg [0.5 to 1.25 mL/kg] every 6 hours).

Hypocalcemic tetany: 100 to 200 mg/kg/dose (1 to 2 mL/kg) IV over 5 to 10 minutes. Repeat dose 6 hours later if indicated. Maximum dose 500 mg/kg/24 hr.

Cardiac resuscitation (see [Indications for specific uses](#)): 100 mg/kg/dose (1 mL/kg/dose) IV every 10 minutes. AHA guidelines recommend 0.6 to 1 mL/kg of a 10% solution (60 to 100 mg/kg). Repeat if indicated. AHA guidelines recommend consideration of this dose

for documented or suspected hypocalcemia or hyperkalemia as well as for hypomagnesemia and calcium channel blocker overdose.

NEONATAL DOSE

Do not administer into a scalp vein in neonates; see [Precautions/Monitor](#).

Hypocalcemia disorders/maintenance: 200 to 800 mg/kg/24 hr in divided doses every 6 hours (50 to 200 mg/kg/dose [0.5 to 2 mL/kg/dose] every 6 hours).

Hypocalcemic tetany: 100 to 200 mg/kg/dose (1 to 2 mL/kg) IV over 5 to 10 minutes. Repeat dose 6 hours later if indicated; maximum dose 500 mg/kg/24 hr.

DILUTION

May be given undiluted or may be further diluted in up to 1,000 mL of NS for infusion. Solution should be warmed to body temperature. Solution must be clear and free of crystals. Crystals can be dissolved by heating to 80° C (146° F) in a dry heat oven for at least 1 hour. Shake vigorously; cool to room temperature. Discard if crystals persist.

Pediatric and neonatal dilution: Must be further diluted with NS.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Calcium salts not generally mixed with carbonates, phosphates, sulfates, or tartrates.

Extreme caution and a specific multi-step process are required when calcium and phosphates are combined in parenteral nutrition solutions. Consult pharmacist.

One source suggests the following **compatibilities:**

Additive: Amikacin (Amikin), aminophylline, ascorbic acid, chloramphenicol (Chloromycetin), furosemide (Lasix), heparin, hydrocortisone sodium succinate (Solu-Cortef), lidocaine, magnesium sulfate, norepinephrine (Levophed), penicillin G potassium and sodium, phenobarbital (Luminal), potassium chloride (KCl), prochlorperazine (Compazine), tobramycin, vancomycin, verapamil.

Y-site: Aldesleukin (Proleukin), allopurinol (Aloprim), amifostine (Ethyol), amiodarone (Nexterone), ampicillin, aztreonam (Azactam), bivalirudin (Angiomax), cefazolin (Ancef), ceftaroline (Teflaro), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), dobutamine, docetaxel (Taxotere), doripenem (Doribax), doxapram (Dopram), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), epinephrine (Adrenalin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), filgrastim (Neupogen), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), 6% hydroxyethyl starch (Voluven), labetalol, linezolid (Zyvox), melphalan (Alkeran), meropenem (Merrem IV), micafungin (Mycamine), midazolam (Versed), milrinone (Primacor), nicardipine (Cardene IV), oxaliplatin (Eloxatin), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), prochlorperazine (Compazine), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), thiotepe, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

In all situations stop or slow infusion rate if patient complains of discomfort. Rapid administration may cause vasodilation, decreased BP, cardiac arrhythmias, syncope, and cardiac arrest.

IV injection: Undiluted, each 0.5 mL or fraction thereof over 1 minute. Do not exceed 1 mL/min (100 mg). 100 mg over 10 to 20 seconds in cardiac arrest.

Intermittent IV: Do not exceed a rate of 100 mg/min (IV injection rate).

Infusion: Do not exceed 120 to 240 mg/kg/hr with a maximum concentration of 50 mg/mL.

Pediatric and neonatal rate of administration: Slow rate of administration considerably. Observe continuously.

ACTIONS

Calcium is a basic element prevalent in the human body. It affects bones, nerves, glands, cardiac and vascular tone, and normal coagulation of the blood. It crosses the placental barrier and is secreted in breast milk. It is excreted in the urine and feces.

INDICATIONS AND USES

Increase plasma calcium levels in hypocalcemic disorders (e.g., tetany [neonatal, parathyroid deficiency], vitamin D deficiency, alkalosis, conditions associated with intestinal malabsorption). ■ Adjunctive therapy in sensitivity reactions (especially with urticaria), insect bites or stings (relieve muscle cramping), acute symptoms of lead colic, rickets, or osteomalacia. ■ Cardiac resuscitation only to treat hypocalcemia, hyperkalemia, or calcium-channel blocker overdose (verapamil, diltiazem). ■ Antidote for cardiac and respiratory depression of magnesium sulfate toxicity. ■ Prevention of hypocalcemia during exchange transfusions. ■ Decrease capillary permeability in allergic conditions, nonthrombocytopenic purpura and exudative dermatoses (e.g., dermatitis herpetiformis). ■ Treat pruritus of eruptions caused by drugs. ■ Treat ECG disturbances caused by hyperkalemia or verapamil-induced hypotension.

Unlabeled uses: Treatment of verapamil overdose, acute hypotension from verapamil, and prevention of initial hypotension when it could be detrimental to a specific patient and verapamil is required.

CONTRAINDICATIONS

IM use in infants and small children. Digitalized patients, hypercalcemia, ventricular fibrillation.

PRECAUTIONS

Has only one third the potency of calcium chloride. ■ For IV use only; IM use permitted in adults only if IV administration cannot be accomplished; see **Monitor**.

Monitor: Confirm patency of vein; select a large vein and use a small needle to reduce vein irritation. Local necrosis and abscess formation can occur with IM or SC injection or extravasation. ■ Keep patient recumbent after injection to prevent postural hypotension. ■ Monitor vital signs carefully.

Maternal/Child: Category C: safety for use in pregnancy not established; benefits must outweigh risk. ■ See **Contraindications**.

DRUG/LAB INTERACTIONS

Will increase **digoxin** toxicity and may cause arrhythmias. If necessary, give small amounts very slowly. ■ Potentiated by **thiazide diuretics** (e.g., chlorothiazide [Diuril]); may cause hypercalcemia or calcium toxicity. ■ May reduce plasma levels of **atenolol** (Tenormin). ■ Antagonizes **verapamil**; can reverse clinical effects. ■ May cause metabolic alkalosis and inhibit binding of potassium with **sodium polystyrene sulfonate**.

SIDE EFFECTS

Rare when given as recommended: bradycardia, cardiac arrhythmias, cardiac arrest, heat waves, hypotension; metallic, calcium, or chalky taste; sense of oppression, syncope, tingling, and vasodilation can occur with too-rapid rate of administration. Depression of neuromuscular function, flushing, prolonged state of cardiac contraction can occur.

Overdose: Coma, intractable nausea and vomiting, lethargy, markedly elevated plasma calcium level, weakness, and sudden death.

ANTIDOTE

If side effects occur, further dilution and decrease in the rate of administration may be necessary. If side effects persist, discontinue the drug and notify the physician. IV infusion of sodium chloride (to maintain normovolemia) and furosemide (Lasix) 80 to 100 mg IV every 2 to 4 hours (with caution) are recommended in overdose. Sodium chloride competes with calcium for reabsorption in the renal tubules; furosemide enhances the activity. Together they will reduce hypercalcemia by causing a marked increase in calcium excretion. Monitoring of fluid, electrolytes, and cardiac and respiratory status is imperative. Disodium edetate may be used with extreme caution as a calcium chelating agent if overdosage is critical. For extravasation inject affected area with 1% procaine hydrochloride and hyaluronidase to reduce venospasm and dilute calcium. Use a 27- or 25-gauge needle. Warm, moist compresses may be helpful. Resuscitate as necessary.

CAPREOMYCIN **BBW**(kap-ree-oh-**MYE**-sin)**Antibacterial**
(antituberculosis)**Capastat****USUAL DOSE**

1 Gm daily, not to exceed 20 mg/kg/day. Give for 60 to 120 days, followed by 1 Gm two or three times weekly. Therapy for tuberculosis should be maintained for 12 to 24 months. Administered in combination with at least one other antituberculosis agent to which the patient's strain of tubercle bacilli is susceptible.

DOSE ADJUSTMENTS

The elderly and patients with reduced renal function should have dosage reduction based on CrCl using the guidelines in the following chart. These dosages are designed to achieve a mean steady-state capreomycin level of 10 mcg/mL. Elevation of BUN above 30 mg/dL or any other evidence of decreasing renal function warrants evaluation of patient. Dose reduction or discontinuation of therapy may be required.

Estimated Dosages to Attain Mean Steady-State Serum Capreomycin Concentration of 10 mcg/mL Based on CrCl			
CrCl (mL/min)	Dose* (mg/kg) Based on Dosing Intervals		
	24 hr	48 hr	72 hr
0 mL/min	1.29 mg/kg	2.58 mg/kg	3.87 mg/kg
10 mL/min	2.43 mg/kg	4.87 mg/kg	7.30 mg/kg
20 mL/min	3.58 mg/kg	7.16 mg/kg	10.7 mg/kg
30 mL/min	4.72 mg/kg	9.45 mg/kg	14.2 mg/kg
40 mL/min	5.87 mg/kg	11.7 mg/kg	
50 mL/min	7.01 mg/kg	14.0 mg/kg	
60 mL/min	8.16 mg/kg		
80 mL/min	10.4 mg/kg [†]		
100 mL/min	12.7 mg/kg [†]		
110 mL/min	13.9 mg/kg [†]		

*Optional dosing intervals are given. Longer intervals are expected to provide greater peaks and lower trough serum levels than shorter intervals.

[†]See Usual Dose.

DILUTION

Reconstitute each 1-Gm vial with 2 mL of NS or SWFI. Allow 2 to 3 minutes for complete dissolution. Withdraw calculated dose and further dilute in 100 mL NS.

Filters: No data available from manufacturer.

Storage: Store at CRT before reconstitution. After reconstitution, stable for 24 hours if refrigerated.

COMPATIBILITY

Specific information not available; consult pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion over 60 minutes. Neuromuscular blockade or respiratory paralysis may occur following rapid intravenous infusion. See [Precautions](#) and [Side Effects](#).

ACTIONS

A polypeptide antibiotic isolated from *Streptomyces capreolus*. Active against strains of *Mycobacterium tuberculosis*. Half-life is 4 to 6 hours in patients with normal renal function. Excreted primarily unchanged in urine. Small amounts excreted in bile. Crosses the placenta. Does not penetrate into CSF.

INDICATIONS AND USES

Used concomitantly with other appropriate antituberculosis agents to treat pulmonary infections caused by capreomycin-susceptible strains of *M. tuberculosis* when the primary agents (isoniazid, rifampin, ethambutol, aminosalicylic acid, and streptomycin) have been ineffective or cannot be used because of toxicity or the presence of resistant tubercle bacilli.

CONTRAINDICATIONS

Hypersensitivity to capreomycin.

PRECAUTIONS

Usually given IM; IV used in patients with limited muscle mass. ■ Sensitivity studies necessary to determine susceptibility of causative organism to capreomycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, capreomycin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Use with caution in patients with pre-existing auditory impairment, dehydration, or renal insufficiency or when used concomitantly with other potentially ototoxic or nephrotoxic drugs (e.g., aminoglycosides [e.g., amikacin (Amikin), gentamicin, tobramycin], colistin sulfate, polymyxin A, vancomycin). Must weigh risk of additional cranial nerve VIII (auditory and vestibular) damage or renal injury against benefit of therapy. ■ Coadministration with other parenteral antituberculosis agents (e.g., streptomycin) is not recommended. Toxicity is additive. ■ Renal injury, with tubular necrosis, elevation of BUN or SCr, and abnormal urinary sediment (casts, RBCs, WBCs), has been reported. Elderly patients, patients with abnormal renal function or dehydration, and patients receiving other nephrotoxic drugs are at increased risk for developing acute tubular necrosis. ■ Elevation of BUN above 30 mg/dL or other evidence of decreasing renal function warrants evaluation of patient. Dose reduction or discontinuation of drug may be necessary; see [Dose Adjustments](#). Clinical significance of abnormal urine sediment and slight increase in BUN or SCr during long-term therapy is not known. ■ The peripheral neuromuscular blocking action seen with other polypeptide antibiotics (colistin sulfate, polymyxin A sulfate) and aminoglycosides (e.g., kanamycin, neomycin, streptomycin) has been reported with capreomycin. ■ Cross-resistance between capreomycin and kanamycin, neomycin and viomycin reported. No cross-resistance observed between capreomycin and aminosalicylic acid, cycloserine, ethambutol, ethionamide, isoniazid, and streptomycin. ■ Use with caution in patients with allergies (especially drug allergies).

Monitor: Audiometric measurements and assessment of vestibular function should be performed before initiation of therapy and at regular intervals during treatment. ■ Obtain baseline SCr, BUN, liver function tests, and electrolytes before initiating therapy. Reduced dosage required for patients with impaired renal function; see [Dose Adjustments](#). Weekly monitoring of renal function and periodic monitoring of electrolytes and liver function tests are recommended. ■ Obtain serum calcium, potassium, and magnesium levels frequently; hypocalcemia, hypokalemia, and hypomagnesemia may occur during therapy. ■ Monitor for S/S of hypersensitivity.

Patient Education: Compliance with full course of therapy is imperative. Report any side effects promptly.

Maternal/Child: Category C: safety for use during pregnancy and breast-feeding not established. Benefits must outweigh risks. Crosses the placenta. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response similar to younger adults; however, dosing should be cautious; see [Dose Adjustments](#). ■ May be at increased risk of toxicity because of age-related de-

crease in renal function; monitor renal function. ■ More likely to have impaired hearing at baseline. Initial and periodic audiometric measurement and assessment of vestibular function is recommended. See [Precautions](#).

DRUG/LAB INTERACTIONS

Neuromuscular blockade of **nondepolarizing neuromuscular blocking agents** (e.g., vecuronium) may be enhanced with concurrent use of capreomycin because of synergistic effects and may be further enhanced by **ether or methoxyflurane anesthesia**. ■ Risk of neuromuscular blockade increased when administered concurrently or sequentially with **polymyxins or aminoglycosides** (e.g., kanamycin, neomycin, streptomycin); see [Precautions](#). ■ Neuromuscular blockade antagonized by **neostigmine**. ■ Risk of ototoxicity, nephrotoxicity, and respiratory paralysis increased when administered concurrently or sequentially with **other potentially ototoxic or nephrotoxic medications** (e.g., aminoglycosides [e.g., amikacin (Amikin), gentamicin, streptomycin, tobramycin], colistin sulfate, polymyxin A, vancomycin); see [Precautions](#).

SIDE EFFECTS

Abnormal liver function tests, abnormal urine sediment, dizziness, electrolyte disturbances resembling Bartter's syndrome, as well as hypocalcemia, hypokalemia, and hypomagnesemia, elevated BUN or SCr, eosinophilia, febrile reactions, hypersensitivity, leukocytosis, leukopenia, maculopapular skin rash, pain and induration at injection site, subclinical auditory loss (high-tone acuity), thrombocytopenia, tinnitus, toxic nephritis, urticaria, vertigo.

ANTIDOTE

Protect airway and support ventilation and perfusion. Hydrate patient to maintain urine output of 3 to 5 mL/kg/hr. Monitor fluid balance, electrolytes, renal function, vital signs, and blood gases; treat abnormalities as indicated. Hemodialysis may be useful. Resuscitate as necessary.

CARBOPLATIN **BBW**

(KAR-boh-plah-tin)

**Antineoplastic
(alkylating agent)****Paraplatin****pH 5 to 7****USUAL DOSE**

Before giving a dose in a cycle, it is recommended that platelets be above 100,000/mm³ and neutrophils above 2,000/mm³; see [Dose Adjustments](#). The Calvert formula for carboplatin dosing based on pre-existing renal function and/or desired platelet nadir determines the patient's dose.

$$\text{Total dose (mg)} = (\text{Target AUC}) \times (\text{GFR} + 25)$$

Dose is calculated in milligrams, not mg/M². The ordering physician determines the target AUC (area under the curve) and supplies the required information on the GFR (glomerular filtration rate) or CrCl, as well as the desired response. The pharmacist calculates the correct dose. See package insert for additional information.

Initial treatment of advanced ovarian cancer in combination with cyclophosphamide: Carboplatin 300 mg/M² plus cyclophosphamide 600 mg/M² on Day 1 every 4 weeks for 6 cycles or carboplatin dose targeted by Calvert equation to an AUC of 6 to 7 plus cyclophosphamide 600 mg/M² on Day 1 every 4 weeks.

Palliative treatment of recurrent ovarian cancer after prior chemotherapy: As a single agent: With normal renal function (CrCl greater than 60 mL/min), give 360 mg/M² on Day 1 every 4 weeks or a dose targeted by Calvert equation to an AUC of 4 to 6 appears to provide an appropriate dose range in these patients.

DOSE ADJUSTMENTS

Single agent or combination therapy. Dose adjustment is based on nadir after prior dose according to the chart on the next page.

Carboplatin Dose Based on Bone Marrow Suppression		
Platelets/mm³	Neutrophils/mm³	Adjusted Dose (from Prior Course)*
>100,000	>2,000	Increase to 125%
50,000-100,000	500-2,000	No adjustment
<50,000	<500	Decrease to 75%

*Percentages apply to carboplatin as a single agent or to both carboplatin and cyclophosphamide in combination.

Once the dose has been increased to 125% of the starting dose, no further dose increases are indicated. ■ With impaired renal function (CrCl 16 to 40 mL/min), give 200 mg/M²; CrCl 41 to 59 mL/min, give 250 mg/M². Dose recommendation not available for patients with a CrCl less than 16 mL/min. ■ Bone marrow suppression is more severe in patients who have had prior therapy, especially with cisplatin and when carboplatin is used with other bone marrow-suppressing therapies or radiation, and may be more severe in the elderly. Reduced dose may be indicated. Monitor carefully and manage dose and timing to reduce additive effects.

DILUTION

Specific techniques required; see [Precautions](#). Available as a premixed solution (10 mg/mL) and as a lyophilized powder. Immediately before use, reconstitute each 10-mg of carboplatin lyophilized powder with 1 mL of SWFI, D5W, or NS (50 mg with 5 mL, 150 mg with 15 mL, 450 mg with 45 mL). All yield 10 mg/mL. Both preparations may be further diluted with NS or D5W to concentrations as low as 0.5 mg/mL. Do not use needles or IV tubing with aluminum parts to mix or administer; a precipitate will form and decrease potency. Best to mix lyophilized preparation immediately before use.

Storage: Premixed solutions: Stable to the date indicated on the package stored at CRT and protected from light. Multi-dose vials maintain microbial, chemical, and physical stability for up to 14 days at RT (25° C [77° F]) following multiple-needle entries. **Lyophilized powder:** Store unopened vials at CRT. Protect from light. Reconstituted solutions are stable for 8 hours at RT (25° C [77° F]). Discard 8 hours after dilution.

COMPATIBILITY (Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Forms a precipitate if in contact with aluminum (e.g., needles, syringes, catheters).

One source suggests the following **compatibilities:**

Additive: Cisplatin (Platinol), etoposide (VePesid), ifosfamide (Ifex), paclitaxel (Taxol).
Y-site: Allopurinol (Aloprim), amifostine (Ethylol), anidulafungin (Eraxis), aztreonam (Azactam), caspofungin (Cancidas), cladribine (Leustatin), doripenem (Doribax), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), gemcitabine (Gemzar), granisetron (Kytrel), linezolid (Zyvox), melphalan (Alkeran), micalofungin (Mycamine), ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), palonosetron (Aloxi), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), propofol (Diprivan), sargramostim (Leukine), teniposide (Vumon), thiotepa, topotecan (Hycamtin), vinorelbine (Navelbine).

RATE OF ADMINISTRATION

A single dose as an infusion over a minimum of 15 minutes. Extend administration time based on amount of diluent and patient condition.

ACTIONS

An alkylating agent. Better tolerated by patients, carboplatin causes less nausea and vomiting, less neurotoxicity, and less nephrotoxicity than cisplatin. Myelosuppression is generally reversible and manageable with antibiotics and transfusions. Produces inter-strand DNA cross-links and is cell-cycle nonspecific. Not bound to plasma proteins. Half-life is 2.6 to 5.9 hours. Majority of carboplatin is excreted in the urine within 24 hours.

INDICATIONS AND USES

Initial treatment of advanced ovarian cancer in combination with other approved chemotherapeutic agents (e.g., cyclophosphamide). ■ Palliative treatment of recurrent ovarian cancer after prior chemotherapy, including patients treated with cisplatin.

Unlabeled uses: Treatment of bladder cancer, non–small-cell lung cancer, and small-cell lung cancer.

CONTRAINDICATIONS

Hypersensitivity to cisplatin or other platinum-containing compounds or mannitol; severe bone marrow suppression; significant bleeding.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Usually administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Bone marrow suppression is dose related and may be severe, resulting in infection and/or bleeding. Anemia may be cumulative and may require transfusion support. Bone marrow suppression increased in patients who have received prior therapy, especially regimens including cisplatin, and in patients with impaired kidney function. ■ Anaphylaxis has been reported and may occur within minutes of administration. ■ Risk of hypersensitivity increased in patients previously exposed to platinum therapy. Patients sensitive to other platinum compounds (e.g., cisplatin) may be sensitive to carboplatin; see [Contraindications](#). ■ Peripheral neurotoxicity is uncommon, but risk may be increased in patients over 65 years of age and in patients previously treated with cisplatin. ■ Secondary malignancies, including acute nonlymphocytic leukemia, myeloproliferation syndrome, and carcinoma have been reported in patients treated with alkylating agents. ■ See [Drug/Lab Interactions](#).

Monitor: BUN and SCr should be done before each dose. CrCl, WBC, platelet count, and hemoglobin are recommended before each dose and weekly thereafter. Platelet count recommended to be 100,000/mm³ and neutrophils 2,000/mm³ before a dose can be repeated; see [Dose Adjustments](#). Anemia is frequent and cumulative. Transfusion is often indicated. ■ Excessive hydration or forced diuresis not required, but maintain adequate hydration and urinary output. ■ Nausea and vomiting are frequently severe but less than with cisplatin; generally last 24 hours. Prophylactic administration of antiemetics is indicated. Various protocols are used. ■ Observe for symptoms of hypersensitivity reactions during administration; epinephrine, corticosteroids, and antihistamines should be available. ■ Observe closely for symptoms of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Nonhormonal birth control recommended. Manufacturer provides a patient information booklet. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. ■ Significant hearing loss has been reported in pediatric patients; occurred with higher-than-recommended doses of carboplatin in combination with other ototoxic agents.

Elderly: Neurotoxicity and myelotoxicity may be more severe. ■ Consider possibility of decreased renal function. ■ See [Dose Adjustments](#) and [Precautions](#).

DRUG/LAB INTERACTIONS

Nephrotoxicity and ototoxicity is additive when used with other **ototoxic or nephrotoxic agents** (e.g., acyclovir [Zovirax], aminoglycosides [e.g., gentamicin], cisplatin [Platinol], rifampin [Rifadin], quinidine). Use with caution. ■ Bone marrow toxicity increased with other **antineoplastic agents, radiation therapy, and/or other agents that may cause blood dyscras-**

sias (e.g., anticonvulsants [e.g., phenytoin (Dilantin)], cephalosporins, mycophenolate [CellCept], rituximab [Rituxan]). Dose adjustment of either or both drugs may be indicated. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ See *Dose Adjustments*.

SIDE EFFECTS

Allergic reactions, including anaphylaxis, can occur during administration. Alopecia (rare), anemia, anorexia, bleeding, bone marrow suppression (usually reversible), bronchospasm, bruising, changes in taste, constipation, death, decreased urine output, decreased serum electrolytes, dehydration, diarrhea, erythema, fatigue, fever, hemolytic uremic syndrome (rare, cancer associated), hypotension, infection, laboratory test abnormalities (alkaline phosphatase, aspartate aminotransferase [AST], BUN, SCr, total bilirubin), nausea and vomiting (severe), neutropenia, ototoxicity, peripheral neuropathies, pruritus, rash, stomatitis, thrombocytopenia, urticaria, visual disturbances, weakness.

ANTIDOTE

Notify physician of all side effects. Symptomatic and supportive treatment is indicated. Withhold carboplatin until myelosuppression has resolved. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) may be required. Blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Treat anaphylaxis with epinephrine, corticosteroids, oxygen, and antihistamines. There is no specific antidote.

CARFILZOMIB

(kar-FILZ-oh-mib)

**Antineoplastic
Proteasome inhibitor****Kyprolis****pH 3.5****USUAL DOSE**

Premedication: Hydration is indicated to reduce the risk of renal toxicity and tumor lysis syndrome (TLS). Hydrate patient with 250 to 500 mL of NS or other appropriate intravenous fluid before each dose in Cycle 1. Administer an additional 250 to 500 mL of intravenous fluid as needed after carfilzomib administration. Monitor fluid status and continue intravenous hydration as needed in subsequent cycles. To reduce the incidence and severity of infusion reactions, pre-medicate with **dexamethasone** 4 mg IV or PO before all doses during Cycle 1 and before all doses during the first cycle of dose escalation to 27 mg/M². If infusion reactions occur during subsequent cycles, premedication with dexamethasone should be continued.

Carfilzomib: Cycle 1: 20 mg/M². Dose is calculated using actual body surface area (BSA) at baseline. Patients with a BSA greater than 2.2 M² should receive a dose based on a BSA of 2.2 M². Dose adjustments do not need to be made for weight changes less than or equal to 20%. Administer over 2 to 10 minutes on 2 consecutive days, each week for 3 weeks (Days 1, 2, 8, 9, 15, and 16), followed by a 12-day rest period (Days 17 to 28). Each 28-day period is considered one treatment cycle.

Cycle 2: If tolerated in Cycle 1, the dose should be escalated to 27 mg/M² beginning with Cycle 2 and continued at 27 mg/M² for subsequent cycles. Treatment may be continued until disease progression or until unacceptable toxicity occurs. A summary of the dosing regimen for carfilzomib is outlined in the following table.

Carfilzomib Dosage Regimen for Patients with Multiple Myeloma										
Cycle 1										
Carfilzomib 20 mg/M ²	Week 1			Week 2			Week 3			Week 4
	Day 1	Day 2	Days 3-7	Day 8	Day 9	Days 10-14	Day 15	Day 16	Days 17-21	Days 22-28
	20 mg/M ²	20 mg/M ²	No dosing	20 mg/M ²	20 mg/M ²	No dosing	20 mg/M ²	20 mg/M ²	No dosing	No dosing
Cycle 2 and Beyond*										
Carfilzomib 27 mg/M ²	Week 1			Week 2			Week 3			Week 4
	Day 1	Day 2	Days 3-7	Day 8	Day 9	Days 10-14	Day 15	Day 16	Days 17-21	Days 22-28
	27 mg/M ²	27 mg/M ²	No dosing	27 mg/M ²	27 mg/M ²	No dosing	27 mg/M ²	27 mg/M ²	No dosing	No dosing

*If previous cycle dosage is tolerated.

DOSE ADJUSTMENTS

Dose is calculated using actual body surface area (BSA) at baseline. Patients with a BSA greater than 2.2 M² should receive a dose based on a BSA of 2.2 M². Dose adjustments do not need to be made for weight changes less than or equal to 20%. ■ Pharmacokinetics and safety of carfilzomib are not influenced by renal impairment. Because dialysis clearance of carfilzomib has not been studied, patients undergoing dialysis should receive carfilzomib after the dialysis procedure. ■ The pharmacokinetics of carfilzomib is not affected by age or gender.

Recommended actions and dose modifications based on toxicities are presented in the following table.

Dose Modifications for Toxicity During Carfilzomib Treatment	
Hematologic Toxicity	Recommended Action
Grade 3* or 4 neutropenia Grade 4 thrombocytopenia	Withhold dose. If fully recovered before next scheduled dose, continue at same dose level. If recovered to Grade 2 neutropenia or Grade 3 thrombocytopenia, reduce dose by one dose level (from 27 mg/M ² to 20 mg/M ² OR from 20 mg/M ² to 15 mg/M ²). If tolerated, the reduced dose may be escalated to the previous dose at the discretion of the physician.
Non-Hematologic Toxicity	Recommended Action
Cardiac Toxicity Grade 3 or 4, new onset or worsening of: • Congestive heart failure; • Decreased left ventricular function; or • Myocardial ischemia	Withhold until resolved or returned to baseline. After resolution, consider if restarting carfilzomib at a reduced dose is appropriate (from 27 mg/M ² to 20 mg/M ² OR from 20 mg/M ² to 15 mg/M ²). If tolerated, the reduced dose may be escalated to the previous dose at the discretion of the physician.
Pulmonary Hypertension	Withhold until resolved or returned to baseline. Restart at the dose used before the event or at a reduced dose (from 27 mg/M ² to 20 mg/M ² OR from 20 mg/M ² to 15 mg/M ²) at the discretion of the physician. If tolerated, the reduced dose may be escalated to the previous dose at the discretion of the physician.
Pulmonary Complications Grade 3 or 4	Withhold until resolved or returned to baseline. Consider restarting at the next scheduled treatment with one dose level reduction (from 27 mg/M ² to 20 mg/M ² OR from 20 mg/M ² to 15 mg/M ²). If tolerated, the reduced dose may be escalated to the previous dose at the discretion of the physician.
Hepatic Toxicity Grade 3 or 4 elevation of transaminases, bilirubin, or other liver abnormalities	Withhold until resolved or returned to baseline. After resolution, consider if restarting carfilzomib is appropriate; may be reinitiated at a reduced dose (from 27 mg/M ² to 20 mg/M ² OR from 20 mg/M ² to 15 mg/M ²) with frequent monitoring of liver function. If tolerated, the reduced dose may be escalated to the previous dose at the discretion of the physician.
Renal Toxicity Serum creatinine equal to or greater than 2 × baseline	Withhold until renal function has recovered to Grade 1 or to baseline and monitor renal function. If attributable to carfilzomib, restart at the next scheduled treatment at a reduced dose (from 27 mg/M ² to 20 mg/M ² OR from 20 mg/M ² to 15 mg/M ²). If not attributable to carfilzomib, restart at the dose used before the event. If tolerated, the reduced dose may be escalated to the previous dose at the discretion of the physician.
Peripheral Neuropathy Grade 3 or 4	Withhold until resolved or returned to baseline. Restart at the dose used before the event or at a reduced dose (from 27 mg/M ² to 20 mg/M ² OR from 20 mg/M ² to 15 mg/M ²) at the discretion of the physician. If tolerated, the reduced dose may be escalated to the previous dose at the discretion of the physician.
Other Grade 3 or 4 non-hematologic toxicities	Withhold until resolved or returned to baseline. Consider restarting at the next scheduled treatment with one dose level reduction (from 27 mg/M ² to 20 mg/M ² OR from 20 mg/M ² to 15 mg/M ²). If tolerated, the reduced dose may be escalated to the previous dose at the discretion of the physician.

*National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE) Version 3.0

DILUTION

Specific techniques required; see Precautions. Available in a 60-mg single-use vial. Remove from refrigerator just before use. Reconstitute each vial with 29 mL of SWFI. Direct the solution onto the inside wall of the vial to minimize foaming. Gently swirl and/or invert vial slowly for about 1 minute or until complete dissolution occurs. **Do not shake.** If foaming occurs, allow solution to rest in vial for about 2 to 5 minutes, until foaming subsides. Final concentration of reconstituted solution is 2 mg/mL. May withdraw reconstituted calculated dose from vial and administer without further dilution directly into the port of an IV set. Alternately, may withdraw calculated dose and dilute in 50 mL of D5W and administer as an infusion; see [Rate of Administration](#).

Filters: No data available from manufacturer.

Storage: Unopened vials should be refrigerated at 2° to 8° C (36° to 46° F). Retain in original package to protect from light. Both the reconstituted solution stored in the vial or a syringe and the solution diluted in D5W are stable for 24 hours when refrigerated and for 4 hours when stored at RT. Total time from reconstitution to administration should not exceed 24 hours. Discard any unused portion.

COMPATIBILITY

Manufacturer states, “Do not mix with or administer as an infusion with other medicinal products.”

RATE OF ADMINISTRATION

Administer intravenously over 2 to 10 minutes. **Do not** administer as a bolus. Flush line with NS or D5W immediately before and after carfilzomib administration.

ACTIONS

Carfilzomib is a proteasome inhibitor that irreversibly binds to specific sites on the 20S proteasome. Has anti-proliferative and pro-apoptotic activities in vitro in solid and in hematologic tumor cells. Actions result in cell-cycle arrest and apoptosis. Highly protein bound. Extensively metabolized via peptidase and epoxide hydrolase activities. Metabolites have no known biologic activity. Has a half-life of ≤ 1 hour on Day 1 of Cycle 1. The pathways of carfilzomib elimination have not been characterized in humans.

INDICATIONS AND USES

Treatment of patients with multiple myeloma who have received at least two prior therapies, including bortezomib and an immunomodulatory agent (e.g., thalidomide [Thalomid], lenalidomide [Revlimid]), and who have demonstrated disease progression on or within 60 days of completion of the last therapy. Approval is based on response rate. Clinical benefit, such as improvement in survival or symptoms, has not been verified.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ For IV use only; see [Rate of Administration](#). ■ Administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ New onset or worsening of pre-existing congestive heart failure with decreased left ventricular function or myocardial ischemia has been reported. Death from cardiac arrest has occurred within a day of administration. Patients with New York Heart Association Class III and IV heart failure, myocardial infarction in the preceding 6 months, and conduction abnormalities uncontrolled by medications may be at greater risk for cardiac complications and were not eligible for the clinical trials. ■ Pulmonary arterial hypertension has been reported. ■ Dyspnea was reported in close to one third of patients in clinical trials. ■ Infusion reactions can occur immediately after or up to 24 hours after administration of carfilzomib. Pre-medication with dexamethasone may reduce the incidence and severity of reaction. ■ Patients with multiple myeloma and a high tumor burden may be at increased risk for developing TLS. ■ Carfilzomib may cause elevations of serum transaminases and bilirubin. Cases of hepatic failure have been reported. Fatalities have occurred.

Safety, efficacy, and pharmacokinetics have not been studied in patients with hepatic impairment. Use caution. ■ See [Dose Adjustments](#).

Monitor: Obtain baseline CBC with differential and platelets. Obtain baseline AST, ALT, and bilirubin. ■ Maintain adequate fluid status and monitor blood chemistries closely throughout treatment. Avoid fluid overload. ■ Monitor for cardiac complications (e.g., cardiac failure, pulmonary edema, decrease in ejection fraction, ischemia) and treat promptly. ■ Monitor for S/S of pulmonary hypertension. Evaluate with cardiac imaging and/or other tests as indicated. ■ Monitor pulmonary function with new or worsening pulmonary symptoms (e.g., dyspnea). ■ Monitor for S/S of an infusion reaction (e.g., angina, arthralgia, chest tightness, chills, facial edema, facial swelling, fever, hypotension, myalgia, syncope, vomiting, and weakness). ■ Prevention and treatment of hyperuricemia due to TLS may be accomplished with adequate hydration and, if necessary, with allopurinol and alkalinization of urine. Monitor uric acid levels as indicated. ■ Carfilzomib causes thrombocytopenia. Monitor platelet counts frequently. Nadir occurs around Day 8 of each 28-day cycle. Recovery to baseline should occur by the start of the next 28-day cycle. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor serum transaminases and bilirubin frequently. ■ See [Dose Adjustments](#).

Patient Education: Avoid pregnancy. Nonhormonal birth control recommended. ■ Promptly report symptoms such as chest pain, chills, cough, dyspnea, fever, rigors, or swelling of the feet or legs. ■ May cause fatigue, dizziness, fainting, and/or a drop in blood pressure. Use caution in tasks that require alertness. ■ Avoid dehydration. Seek medical advice if dizziness, light-headedness, or fainting spells are experienced. ■ Review all medications with a physician or pharmacist. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: can cause fetal harm when administered to a pregnant woman. ■ Discontinue breast-feeding. ■ Safety and effectiveness of carfilzomib in pediatric patients have not been established.

Elderly: Differences in safety and efficacy between patients less than 65 years of age and patients 65 years of age and older have not been identified.

DRUG/LAB INTERACTIONS

Carfilzomib is primarily metabolized via peptidase and epoxide hydrolase activities and, as a result, is unlikely to be affected by concomitant administration of cytochrome P₄₅₀ inhibitors and inducers. ■ Because of IV administration and extensive metabolism, carfilzomib should not be affected by P-gp inhibitors or inducers. ■ Carfilzomib is not expected to influence exposure of other drugs.

SIDE EFFECTS

Most commonly reported adverse reactions are anemia, diarrhea, dyspnea, fatigue, fever, nausea, and thrombocytopenia. The most common serious adverse reactions are acute renal failure, congestive heart failure, fever, and pneumonia. Other adverse reactions reported in at least 10% of patients include anorexia, arthralgia, asthenia, back pain, chest wall pain, chills, constipation, cough, dizziness, edema (peripheral), elevated aspartate aminotransferase, elevated serum creatinine, headache, hypercalcemia, hyperglycemia, hypertension, hypoesthesia, hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia, insomnia, leukopenia, lymphopenia, muscle spasm, neutropenia, pain, peripheral neuropathy, upper respiratory tract infection, and vomiting. Serious but less commonly reported adverse reactions include cardiac arrest, congestive heart failure, hepatic toxicity and hepatic failure, infusion reactions, myocardial ischemia, pulmonary hypertension, and TLS.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. If signs of an infusion reaction occur, slow or interrupt the infusion and treat appropriately. Monitor patients carefully until symptoms resolve. Discontinue immediately for a serious hypersensitivity reaction. There is no specific antidote for carfilzomib. In the event of an over-

dose or with the occurrence of a serious adverse reaction, discontinue carfilzomib; see [Dose Adjustments](#). Notify the physician and provide supportive care as indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Treat hypersensitivity reactions with epinephrine, antihistamines, corticosteroids, bronchodilators, and oxygen. Resuscitate as indicated.

CARMUSTINE (BCNU) **BBW**

(kar-MUS-teen)

Antineoplastic
(alkylating agent/nitrosourea)

BiCNU

pH 5.6 to 6

USUAL DOSE

Initial dose is 150 to 200 mg/M². May be given as a single dose, or one half of the calculated dose may be given initially and repeated the next day. Repeat every 6 weeks if bone marrow is sufficiently recovered. Repeat course should not be administered until leukocytes are above 4,000/mm³ and platelets are above 100,000/mm³. Repeat doses adjusted according to hematologic response of previous dose (see [Dose Adjustments](#)).

DOSE ADJUSTMENTS

Bone marrow toxicity is cumulative. Dose adjustments must be considered **based on the nadir blood counts from the prior dose** according to the following chart.

Carmustine Dose Adjustment Based on Bone Marrow Suppression		
Nadir After Prior Dose		Percentage of Prior Dose to Be Given
Leukocytes/mm ³	Platelets/mm ³	%
≥4,000	≥100,000	100%
3,000-3,999	75,000-99,999	100%
2,000-2,999	25,000-74,999	70%
<2,000	<25,000	50%

Adjust doses accordingly when carmustine is used in combination with other myelosuppressive drugs or in patients with depleted bone marrow reserve. ■ Dosing should be cautious in the elderly. Lower-end initial doses may be indicated. Consider decrease in cardiac, hepatic, and renal function; concomitant disease; or other drug therapy; see [Elderly](#).

DILUTION

Specific techniques required; see [Precautions](#). Initially dilute 100-mg vial with supplied sterile diluent (3 mL of dehydrated alcohol injection). Further dilute with 27 mL of SWFI. Each mL will contain 3.3 mg carmustine. Withdraw desired dose and further dilute in 100 mL or more of D5W and give as an infusion. Use glass containers; loss of potency occurs in PVC containers and IV tubing.

Filters: No significant loss of potency with any size cellular ester membrane filter when reconstituted or diluted as recommended.

Storage: Must be protected from light in all forms. Store unopened vials of the dry drug (carmustine) in refrigerator (2° to 8° C [35° to 46° F]). Supplied diluent may be stored at CRT or refrigerated. After reconstitution and after further dilution to a concentration

of 0.2 mg/mL in D5W, may be stored at RT but must be used within 8 hours. Temperatures above 27° C (80° F) will cause liquefaction of the drug powder; discard immediately.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with polyvinyl chloride infusion bags; use only glass containers.

One source suggests the following **compatibilities**:

Y-site: Amifostine (Ethyol), aztreonam (Azactam), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), gemcitabine (Gemzar), granisetron (Kytril), melphalan (Alkeran), ondansetron (Zofran), piperacillin/tazobactam (Zosyn), sargramostim (Leukine), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Each single dose must be given as a slow IV infusion. Administration over fewer than 2 hours can lead to pain and burning at the injection site. Reduce rate for pain or burning at injection site, flushing of the skin, or suffusion of the conjunctiva.

ACTIONS

An alkylating agent of the nitrosourea group with anti-tumor activity, cell cycle phase nonspecific. Degraded to metabolites within 15 minutes of administration. Effectively crosses the blood-brain barrier; levels of radioactivity in the CSF are equal to or more than 50% of those measured concurrently in plasma. Excreted in changed form in urine. Small amounts excreted as respiratory CO₂.

INDICATIONS AND USES

Palliative therapy as a single agent or in established combination therapies in the treatment of brain tumors; multiple myeloma; Hodgkin's disease; and some non-Hodgkin's lymphomas.

CONTRAINDICATIONS

Hypersensitivity to carmustine.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Delayed bone marrow suppression may be severe, especially in an already compromised patient, and result in infection and/or bleeding. Anemia may be cumulative and may require transfusion support. ■ Pulmonary toxicity is dose related. Risk is increased with a cumulative dose greater than 1,400 mg/M². Delayed-onset pulmonary fibrosis has occurred up to 17 years after treatment with injectable carmustine in patients who received it in childhood or early adolescence. ■ Often used with other antineoplastic drugs in reduced doses to achieve tumor remission. ■ Secondary malignancies, including acute nonlymphocytic leukemia, myeloproliferation syndrome, and carcinoma have been reported in patients treated with alkylating agents.

Monitor: Determine absolute patency and quality of vein and adequate circulation of extremity. Severe cellulitis may result from extravasation. ■ Delayed toxicity probable in 4 to 6 weeks; wait at least 6 weeks between doses; obtain baseline CBC, including leukocyte and platelet counts, and monitor weekly. ■ Obtain baseline pulmonary function studies and monitor pulmonary function frequently during treatment. Risk of pulmonary toxicity is increased in patients with a baseline below 70% of the predicted forced vital capacity (FVC) or carbon monoxide diffusing capacity (DLco). ■ Periodic monitoring of liver and renal function tests is recommended. ■ Nausea and vomiting can be severe. Prophylactic administration of antiemetics is recommended. ■ Avoid contact of carmustine solution with the skin. ■ Observe for any signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Maintain hydration. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Nonhormonal birth control recommended. ■ Report stinging or burning at IV site promptly. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; embryotoxic and teratogenic in rats; has mutagenic potential. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Risk versus benefit must be carefully considered due to a high risk of pulmonary toxicity occurring years after treatment and resulting in death.

Elderly: Dose selection should be cautious; see [Dose Adjustments](#). ■ Toxicity may be increased. ■ Monitoring of renal function is suggested.

DRUG/LAB INTERACTIONS

Potentiated by **cimetidine** (Tagamet); increased myelosuppression (e.g., leukopenia and neutropenia) have been reported with concurrent use. ■ Inhibits **digoxin and phenytoin** (Dilantin); may reduce serum levels. ■ Do not administer **vaccines or chloroquine** to patients receiving antineoplastic drugs. ■ See [Dose Adjustments](#).

SIDE EFFECTS

Most are dose related and can be reversed. Bone marrow toxicity (especially leukopenia and thrombocytopenia) is most pronounced at 4 to 6 weeks; can be severe and cumulative with repeated dosage. Anemia, chest pain, elevated liver function test results, flushing of skin and suffusion of conjunctiva from too-rapid infusion rate, headache, hyperpigmentation and burning of skin (from actual contact with solution), hypersensitivity reactions, hypotension, nausea and vomiting, neuroretinitis, pulmonary infiltrates or fibrosis with long-term therapy, renal abnormalities, retinal hemorrhage, and tachycardia.

ANTIDOTE

Notify physician of all side effects. Most will decrease in severity with reduced dosage, increased time span between doses, or symptomatic treatment. May reduce therapeutic effectiveness. Bone marrow suppression may require withholding carmustine until recovery occurs. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) may be required. Blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity.

CASPOFUNGIN ACETATE

(kas-po-FUN-jin AS-ah-tayt)

Antifungal

Candidas

pH 6.6

USUAL DOSE

Empirical therapy: 70 mg as an infusion on Day 1. Beginning on Day 2, reduce subsequent doses to 50 mg/day. Duration of empiric therapy is based on clinical response and should continue at least until resolution of neutropenia. Patients found to have a fungal infection should be treated for a minimum of 14 days; treatment should continue for at least 7 days after both neutropenia and clinical symptoms have resolved.

Candidemia and other *Candida* infections: 70 mg as an infusion on Day 1. Beginning on Day 2, reduce subsequent doses to 50 mg/day. Duration of treatment is based on clinical and microbiologic response. Usually continued for at least 14 days after the last positive culture. Persistently neutropenic patients may require a longer course of therapy pending resolution of the neutropenia. A 150-mg dose has been studied in a small number of adult patients. Efficacy of this higher dose was not significantly better than the 50-mg dose.

Esophageal candidiasis: 50 mg daily as an infusion. Continue for 7 to 14 days after symptom resolution. A 70-mg loading dose has not been studied for this indication. Suppressive oral therapy following treatment with caspofungin may be considered to decrease the risk of relapse of oropharyngeal candidiasis in patients with HIV infections.

Invasive aspergillosis: 70 mg as an infusion on Day 1. Beginning on Day 2, reduce subsequent doses to 50 mg/day. Duration of treatment is based on severity of the underlying disease, recovery from immunosuppression, and clinical response.

PEDIATRIC DOSE

Pediatric patients 3 months to 17 years of age: 70 mg/M² as an infusion on Day 1. Beginning on Day 2, reduce subsequent doses to 50 mg/M²/day. Regardless of the patient's calculated dose, the loading dose and/or the daily maintenance dose should not exceed a maximum of 70 mg. Duration of therapy for each indication should be individualized as outlined in Usual Dose.

DOSE ADJUSTMENTS

All diagnoses: Adult and pediatric patients: Dose adjustment is not indicated based on age, gender, or race. ■ See [Drug/Lab Interactions](#).

Adults: Dose adjustment is not indicated in patients with impaired renal function or in patients with mild impaired hepatic function (Child-Pugh score 5 to 6). ■ In patients with moderate hepatic insufficiency (Child-Pugh score 7 to 9), reduce daily doses to 35 mg after the initial dose of 50 or 70 mg. ■ Dose may be increased from 50 to 70 mg daily in patients not clinically responding to the 50-mg dose; experience limited. ■ In patients receiving concurrent administration of rifampin (Rifadin), increase the daily dose to 70 mg. An increase in the daily dose to 70 mg/day should be considered in patients who are not clinically responding and are taking other inducers and/or mixed inducers/inhibitors of caspofungin clearance, specifically carbamazepine (Tegretol), dexamethasone (Decadron), efavirenz (Sustiva), nevirapine (Viramune), and phenytoin (Dilantin).

Pediatric patients: If the 50-mg/M² daily dose is well tolerated but does not provide adequate clinical response, it may be increased to 70 mg/M² (not to exceed a total dose of 70 mg). ■ There is no experience in pediatric patients with any degree of hepatic insufficiency. ■ Consider a dose of 70 mg/M² (not to exceed a total dose of 70 mg) in pediatric patients receiving inducers of caspofungin clearance, specifically carbamazepine (Tegretol), dexamethasone (Decadron), efavirenz (Sustiva), nevirapine (Viramune), phenytoin (Dilantin), and rifampin (Rifadin).

DILUTION

Available in 70-mg and 50-mg vials. Select appropriate dose and allow vial of caspofungin to come to room temperature. Reconstitute selected dose with 10.8 mL of NS, SWFI, or BWFI. Mix gently to achieve a clear solution; should dissolve completely. The 70-mg vial will yield 7 mg/mL, and the 50-mg vial will yield 5 mg/mL.

Adults: Withdraw 10 mL of reconstituted solution and add to 250 mL of NS, ½NS, ¼NS, or LR for infusion. If a 70-mg vial is not available, reconstitute two 50-mg vials and withdraw a total of 14 mL to be further diluted in 250 mL of the above solutions. When preparing a 35-mg dose, withdraw 7 mL from the reconstituted 50-mg vial and further dilute in 250 mL of the previously listed solutions. In fluid-restricted or pediatric patients, the appropriate volume of caspofungin may be added to reduced volumes of the above solutions, not to exceed a final concentration of 0.5 mg/mL.

Pediatric patients: The choice of vial used should be based on the total dose to be administered. Pediatric doses less than 50 mg should be withdrawn from a 50-mg vial to ensure accuracy. After reconstitution, withdraw the volume required to provide the correct dose, and add to a volume of NS, ½NS, ¼NS, or LR for infusion to achieve a final concentration not to exceed 0.5 mg/mL.

Storage: Refrigerate unopened vials. Reconstituted vials may be kept at CRT for 1 hour before preparing as an infusion solution. Fully diluted solutions may be stored at less than or equal to 25° C (77° F) for 24 hours or refrigerated for 48 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Manufacturer states, “Do not mix or co-infuse caspofungin with other medications. Do not use diluents containing dextrose.”

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), amikacin (Amikin), amiodarone (Nexterone), azithromycin (Zithromax), aztreonam (Azactam), bumetanide, carboplatin (Paraplatin), ciprofloxacin (Cipro IV), cisplatin (Platinol), cyclosporine (Sandimmune), daptomycin (Cubicin), daunorubicin (Cerubidine), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, dolasetron (Anzemet), dopamine, doripenem (Doribax), doxorubicin (Adriamycin), epinephrine (Adrenalin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fentanyl (Sublimaze), fluconazole (Diflucan), ganciclovir (Cytovene), gentamicin, hydroalazine, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), insulin (regular), levofloxacin (Levaquin), linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), metronidazole (Flagyl IV), midazolam (Versed), milrinone (Primacor), mitomycin (Mutamycin), morphine, mycophenolate (CellCept IV), norepinephrine (Levophed), ondansetron (Zofran), pantoprazole (Protonix IV), phenylephrine (Neo-Synephrine), potassium chloride, quinupristin/dalfopristin (Synercid), tacrolimus (Prograf), telavancin (Vibativ), tobramycin, vancomycin, vasopressin, vincristine, voriconazole (VFEND IV).

RATE OF ADMINISTRATION

A single dose as an infusion evenly distributed over 1 hour.

ACTIONS

An antifungal. An echinocandin or glucan synthesis inhibitor. It attacks the fungal cell wall and inhibits the synthesis of beta (1,3)-D-glucan, an essential component of the cell wall of susceptible *Aspergillus* and *Candida* species. Beta (1,3)-D-glucan is not found in human cells. Extensively bound to albumin (97%). After completion of an IV infusion, plasma concentrations decline in several phases, each with its own half-life (e.g., 9 to 11 hours, 40 to 50 hours). Distribution, rather than excretion or biotransformation, is the primary mechanism influencing plasma clearance. Slowly metabolized by hydrolysis and *N*-acetylation, eventually breaking down to amino acids and their degradates. Excreted in urine and feces.

INDICATIONS AND USES

Empirical therapy for presumed fungal infections in febrile, neutropenic patients. ■ Treatment of invasive aspergillosis in patients who are refractory to or intolerant of other therapies (i.e., amphotericin B [conventional], lipid formulations of amphotericin B [e.g., Abelcet, AmBisome, Amphotec], and/or itraconazole [Sporanox]). Has not been studied for initial therapy for invasive aspergillosis. ■ Treatment of esophageal candidiasis. ■ Treatment of candidemia and the following *Candida* infections: intra-abdominal abscesses, peritonitis, and pleural space infections. Has not been studied in endocarditis, osteomyelitis, and meningitis due to *Candida*.

CONTRAINDICATIONS

Known hypersensitivity to caspofungin or any of its components.

PRECAUTIONS

Concomitant use with cyclosporine is not recommended unless the potential benefit outweighs the risk; see **Monitor** and **Drug/Lab Interactions**. ■ Hepatic abnormalities, including elevated liver function tests (LFTs), clinically significant hepatic dysfunction, hepatitis, and hepatic failure have been reported. Abnormal LFTs have been seen in healthy volunteers and in adult and pediatric patients treated with caspofungin. ■ There is no clinical experience in adult patients with severe hepatic insufficiency (Child-Pugh score greater than 9) or in pediatric patients with any degree of hepatic impairment. ■ Possible histamine-related reactions and hypersensitivity reactions, including anaphylaxis, have been reported. ■ Drug resistance in patients with invasive aspergillosis has not been observed. ■ Mutants of *Candida* with reduced susceptibility to caspofungin have been identified in some patients.

Monitor: Most patients have serious underlying medical conditions (e.g., bone marrow transplant, HIV, malignancies) requiring multiple concomitant medications. Obtain baseline studies as required and repeat as indicated. ■ Monitor vital signs. ■ Observe for S/S of a histamine-related reaction (e.g., facial swelling, pruritus, rash, sensation of warmth), or a hypersensitivity reaction (e.g., chills, difficulty breathing, hypotension, rash). ■ Encourage fluids to maintain hydration. ■ Effects of severe hepatic impairment unknown; monitor liver function tests (e.g., AST, ALT) in patients with pre-existing impaired hepatic function and any time S/S suggestive of liver dysfunction develop (e.g., jaundice, lethargy). ■ Monitor liver function in patients receiving therapy with both caspofungin and cyclosporine. Monitor closely in patients who develop abnormal liver function tests. The risk/benefit of continued therapy should be evaluated. ■ See **Drug/Lab Interactions**.

Patient Education: Review all medical conditions and medications before beginning treatment. ■ Promptly report pain at infusion site, symptoms of histamine reactions (e.g., facial swelling, pruritus, rash, sensation of warmth), hypersensitivity reactions (e.g., chills, difficulty breathing, hypotension, rash), or hepatic toxicity (e.g., jaundice).

Maternal/Child: Category C: use during pregnancy only if benefits outweigh potential risks to fetus. Based on animal studies, may cause fetal harm. ■ Has been found in the milk of lactating, drug-treated rats; use caution if required during breast-feeding or discontinue breast-feeding. ■ Safety and effectiveness for use in neonates and infants under 3 months of age not studied.

Elderly: Response similar to that in younger patients. Dose adjustment is not recommended; however, use caution; may have greater sensitivity to its effects.

DRUG/LAB INTERACTIONS

Concomitant use with **cyclosporine** (Sandimmune) is not recommended unless benefit outweighs risk. By Day 10 of concomitant administration some patients had a transient ALT 2 to 3 times the upper limit of normal, and the AUC of caspofungin had increased by about 35%. ■ Pharmacokinetics of caspofungin are not altered by **amphotericin B**, **itraconazole** (Sporanox), **mycophenolate** (CellCept), **nefinavir** (Viracept), or **tacrolimus** (Prograf). ■ Serum concentrations of tacrolimus may be somewhat decreased with concomitant administration; monitor tacrolimus concentrations and adjust dose as indicated. ■ **Inducers and/or mixed inducers/inhibitors of caspofungin clearance** (e.g., carba-

mazepine [Tegretol], dexamethasone [Decadron], efavirenz [Sustiva], nevirapine [Viramune], phenytoin [Dilantin], rifampin [Rifadin]) may significantly increase caspofungin clearance and require an increase in dose; see **Dose Adjustments**. ■ Although its clearance may be affected by the enzyme inducers previously mentioned, caspofungin is not an inhibitor or inducer of any enzyme in the cytochrome P₄₅₀ (CPY) system. It is not a substrate (a substance on which an enzyme acts) for P-glycoprotein and is a poor substrate for cytochrome P₄₅₀ enzymes. It is not expected to interact with drugs metabolized by this system (e.g., amiodarone [Nexterone], calcium channel blockers [e.g., diltiazem (Cardizem), verapamil], cimetidine [Tagamet], MAO inhibitors [e.g., selegiline (Eldepryl)]).

SIDE EFFECTS

Side effect profile is similar in both adult and pediatric patients. Incidence difficult to assess because of multiple medical conditions and multiple medications. Most commonly reported side effects include chills, diarrhea, elevated liver function tests (e.g., alkaline phosphatase, ALT, AST), fever, hypokalemia, and rash. Other side effects reported include abdominal pain, ARDS, cough, diaphoresis, flushing, headache, hyperbilirubinemia, hypercalcemia, hyperglycemia, hypertension, hypomagnesemia, hypotension, increased RBCs and protein in urine, infusion-related reactions, injection site reactions, nausea, peripheral edema, phlebitis, pneumonia, pulmonary edema, radiographic infiltrates, tachycardia, and vomiting. Possible histamine-mediated symptoms (e.g., angioedema, bronchospasm, facial swelling, pruritus, rash, sensation of warmth) and hypersensitivity reactions with dyspnea, stridor, worsening of rash, and anaphylaxis have been reported.

Post-Marketing: Erythema multiforme, hepatic necrosis, hepatobiliary adverse reactions (e.g., clinically significant hepatic dysfunction, hepatitis, hepatic failure) in adult and pediatric patients with serious underlying medical conditions, pancreatitis, renal dysfunction (clinically significant), skin exfoliation, and Stevens-Johnson syndrome.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Discontinue caspofungin and notify physician of abnormal liver function tests progressing to clinical S/S of liver disease. Rash may be the first sign of an exfoliative skin disorder in immunocompromised patients; discontinue caspofungin and notify physician. Histamine-mediated reactions may require discontinuation of caspofungin and appropriate treatment. Not removed by hemodialysis. Discontinue caspofungin and treat anaphylaxis as indicated and/or resuscitate as necessary.

CEFAZOLIN SODIUM(sef-**AYZ**-oh-lin **SO**-dee-um)**Antibacterial
(cephalosporin)****Ancef, Kefzol****pH 4.5 to 7****USUAL DOSE**

250 mg to 1.5 Gm every 6 to 8 hours. Up to 6 Gm is usual, but 12 Gm in 24 hours has been used, depending on severity of infection.

Mild infections: 250 to 500 mg every 8 hours.

Moderate to severe infections: 500 mg to 1 Gm every 6 to 8 hours.

Life-threatening infections (e.g., endocarditis, septicemia): 1 to 1.5 Gm every 6 hours.

Pneumococcal pneumonia: 500 mg every 12 hours.

Uncomplicated GU infections: 1 Gm every 12 hours.

Perioperative prophylaxis: 1 Gm 30 minutes to 1 hour before incision. For lengthy procedures (e.g., 2 hours or more), 0.5 to 1 Gm may be repeated in the OR. Administer every 6 to 8 hours for 24 hours.

Endocarditis prophylaxis (unlabeled): 1 Gm 30 minutes before surgery.

PEDIATRIC DOSE

Over 1 month of age: 6.25 to 25 mg/kg of body weight every 6 hours, or 8.3 to 33.3 mg/kg every 8 hours. Do not exceed adult dose.

Endocarditis prophylaxis (unlabeled): 25 mg/kg 30 minutes before start of surgery. Do not exceed 1 Gm.

NEONATAL DOSE

See [Maternal/Child](#).

Less than 7 days of age or over 7 days but under 2,000 Gm (unlabeled): 20 mg/kg every 12 hours.

7 days to 1 month of age and 2,000 Gm or more (unlabeled): 20 mg/kg every 8 hours.

DOSE ADJUSTMENTS

Reduced doses or extended intervals may be indicated in the elderly; consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy. In impaired renal function, the initial dose in adults and pediatric patients should be as above. Reduce all subsequent doses according to the following charts.

Cefazolin Dose Guidelines in Impaired Renal Function for Adults		
CrCl or SCr	Dose	Frequency
CrCl >55 mL/min or SCr ≤1.5 mg%	Full	Normal
CrCl 35-54 mL/min or SCr 1.6 to 3 mg%	Full	q 8 hr or less frequently
CrCl 11-34 mL/min or SCr 3.1 to 4.5 mg%	½ Usual dose	q 12 hr
CrCl 10 mL/min or less or SCr ≥4.6 mg%	½ Usual dose	q 18-24 hr

Cefazolin Dose Guidelines in Impaired Renal Function for Pediatric Patients		
Creatinine Clearance (mL/min)	Dose	Frequency
>70 mL/min	Full	Normal
40-70 mL/min	60% of normal daily dose*	q 12 hr
20-40 mL/min	25% of normal daily dose*	q 12 hr
5-20 mL/min	10% of normal daily dose*	q 24 hr

*In equally divided doses.

DILUTION

Each 1 Gm or fraction thereof must be reconstituted with at least 2.5 mL of SWFI. Shake well. To reduce the incidence of thrombophlebitis, may be further diluted in 50 to 100 mL of D5W, NS, or other **compatible** infusion solutions (see chart on inside back cover or literature) and given as an intermittent infusion. Available premixed and in piggy-back vials (vent bottle before adding diluent, dilute to 50 to 100 mg, and shake well). 10-mg pharmacy bulk vials may be reconstituted with SWFI or with NS 45 mL (1 Gm/5 mL) or 96 mL (1 Gm/10 mL). May be administered through Y-tube, three-way stopcock, or additive infusion set.

Storage: Before reconstitution, protect from light and store at CRT. Give within 24 hours of preparation if stored at CRT or within 10 days if under refrigeration. Discard pharmacy bulk vials within 4 hours after initial entry.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

May be used concomitantly with aminoglycosides (e.g., amikacin [Amikin], gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer at separate sites.

One source suggests the following **compatibilities**:

Additive: Aztreonam (Azactam), clindamycin (Cleocin), famotidine (Pepcid IV), fluconazole (Diflucan), linezolid (Zyvox), meperidine (Demerol), metronidazole (Flagyl IV), verapamil.

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), alprostadil, amifostine (Ethyol), amiodarone (Nexterone), anidulafungin (Eraxis), atracurium (Tracrium), aztreonam (Azactam), bivalirudin (Angiomax), calcium gluconate, cisatracurium (Nimbex), cyclophosphamide (Cytoxan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doxapram (Dopram), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hexend), hetastarch in NS (Hespan), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), insulin (regular), labetalol, lidocaine, linezolid (Zyvox), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), midazolam (Versed), milrinone (Primacor), morphine, multivitamins (M.V.I.), nifedipine (Cardene IV), ondansetron (Zofran), palonosetron (Aloxi), pancuronium, pantoprazole (Protonix IV), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), teniposide (Vumon), theophylline, thiotepa, vancomycin, vecuronium, warfarin (Coumadin).

RATE OF ADMINISTRATION

IV injection: Each 1 Gm or fraction thereof over 3 to 5 minutes. Extend administration time as indicated by amount of solution and condition of patient.

ACTIONS

A semi-synthetic, first-generation, broad-spectrum cephalosporin antibiotic that is bactericidal through inhibition of cell wall synthesis to some gram-positive and gram-negative organisms, including staphylococci and streptococci. A number of organisms are resistant to this cephalosporin. Peak serum levels achieved by end of infusion. Widely distributed in most tissues, body fluids (CSF minimal), bone, gallbladder, myocardium, and skin and soft tissue. Serum half-life is 1.8 hours. Excreted rapidly in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious infections of the bone, joints, skin, soft tissue, respiratory tract, biliary tract, and GU tract; septicemia and endocarditis. Effective only if the causative organism is susceptible. ■ Perioperative prophylaxis. ■ Biliary tract infections. ■ Not recommended for prophylaxis in GU procedures.

Unlabeled uses: Prophylaxis of bacterial endocarditis.

CONTRAINDICATIONS

Previous hypersensitivity reaction to cephalosporins; see [Precautions](#).

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies indicated to determine susceptibility of the causative organisms to cefazolin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefazolin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for at least 2 to 3 days after all symptoms of infection subside. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with impaired renal function, allergies, or a history of GI disease (especially colitis). ■ With inappropriately high doses, seizures may occur in patients with impaired renal function. ■ May decrease prothrombin activity, especially in patients with impaired renal or hepatic function, those with a poor nutritional state, and those receiving extended courses of antimicrobial therapy. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefazolin.

Monitor: Watch for early symptoms of hypersensitivity reactions. ■ Obtain baseline PT and monitor, especially in at-risk patients (see [Precautions](#)); vitamin K may be indicated. ■ See [Drug/Lab Interactions](#); additional monitoring may be indicated (e.g., renal function, drug serum levels, PT).

Patient Education: Report promptly any bleeding or bruising, diarrhea, or symptoms of allergy (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: safety for use during pregnancy and breast-feeding not established. No problems documented. ■ Safety for use in premature infants and neonates under 1 month of age not established; immature renal function will increase blood levels.

Elderly: No specific problems documented. ■ See [Usual Dose](#) and [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics [e.g., furosemide (Lasix)]). ■ **Probenecid** inhibits excretion, resulting in elevated cefazolin levels. Dose reduction of cefazolin may be necessary. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Large amounts of **cephalosporins and/or salicylates** may induce hypoprothrombinemia (deficiency of prothrombin [factor II]). The addition of **agents that may affect platelet aggregation and/or may have GI ulcerative potential** (e.g., NSAIDs [ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)] or sulfipyrazone [Anturane]) may increase risk of hemorrhage. ■ False-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Chemstix). ■ See [Compatibility](#) and [Side Effects](#).

SIDE EFFECTS

Anorexia; CDAD; diarrhea; elevated BUN and creatinine levels; hypersensitivity reactions including anaphylaxis; leukopenia; local site pain; nausea and vomiting; neutropenia; oral thrush; phlebitis; positive direct and indirect Coombs' test; prolonged PT; transient elevation of AST, ALT, and alkaline phosphatase; seizures (large doses); thrombophlebitis; vaginal itching or discharge. Hypoprothrombinemia (rare) and hemolytic anemia may occur. Serum sickness-like reactions have occurred (e.g., arthralgia, fever, polyarthritis, skin rashes), usually after a second course of therapy. Usually resolve after cephalosporins are discontinued. Hepatitis and renal failure have been reported.

Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

ANTIDOTE

Notify the physician of any side effects. Discontinue the drug if indicated. Mild cases of CDAD may respond to discontinuation of cefazolin. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Antihistamines and corticosteroids may be indicated to manage symptoms of serum sickness. Discontinue cefazolin and treat hypersensitivity reaction as indicated (airway, oxygen, IV fluids, antihistamines [e.g., diphenhydramine], corticosteroids [e.g., hydrocortisone sodium succinate (Solu-Cortef)], epinephrine, pressor-amines [e.g., dopamine]) and resuscitate as necessary. Hemodialysis may be useful in overdose.

<p>CEFEPIME HYDROCHLORIDE (SEF-eh-pim hy-droh-KLOR-eyed)</p>	<p>Antibacterial (cephalosporin)</p>
<p>Maxipime</p>	<p>pH 4 to 6</p>

USUAL DOSE

Adults: Range is from 0.5 Gm to 2 Gm. Usually given every 12 hours. Dose based on severity of disease and/or specific susceptibility of the causative organism according to the following chart.

Cefepime Dose Guidelines			
Site and Type of Infection	Dose	Frequency	Duration (days)
Mild to Moderate Uncomplicated or complicated urinary tract infections, including pyelonephritis	0.5-1 Gm IV/IM	q 12 hr	7-10
Severe Uncomplicated or complicated urinary tract infections, including pyelonephritis	2 Gm IV	q 12 hr	10
Moderate to Severe Pneumonia	1-2 Gm IV	q 12 hr	10
Moderate to Severe Uncomplicated skin and skin structure infections	2 Gm IV	q 12 hr	10
Empiric Therapy For febrile neutropenic patients	2 Gm IV	q 8 hr	7 or until neutropenia resolves
Complicated Intra-abdominal infections	Cefepime 2 Gm IV q 12 hr in combination with metronidazole 500 mg or 7.5 mg/kg q 6 hr, not to exceed 4 Gm/24 hr of metronidazole		7-10

PEDIATRIC DOSE

Pediatric patients 2 months to 16 years; weight up to 40 kg: 50 mg/kg every 12 hours for 7 to 10 days. Increase frequency to every 8 hours for empiric monotherapy in febrile neutropenia. Do not exceed adult dose.

DOSE ADJUSTMENTS

In impaired renal function, the initial dose should be as stated earlier (except in patients undergoing hemodialysis). All remaining doses should be reduced based on CrCl according to the following chart (e.g., if the normal dose is 1 Gm every 12 hours with a CrCl greater than 60, the maintenance dose would be reduced to 1 Gm every 24 hours with a CrCl between 30 and 60 mL/min). Dose reductions should be comparable in *pediatric patients*.

Cefepime Dose Guidelines in Impaired Renal Function				
Creatinine Clearance (mL/min)	Recommended Maintenance Schedule (relative to normal dosing schedule)			
Normal Recommended Dosing Schedule (>60 mL/min)	500 mg q 12 hr	1 Gm q 12 hr	2 Gm q 12 hr	2 Gm q 8 hr
30-60 mL/min	500 mg q 24 hr	1 Gm q 24 hr	2 Gm q 24 hr	2 Gm q 12 hr
11-29 mL/min	500 mg q 24 hr	500 mg q 24 hr	1 Gm q 24 hr	2 Gm q 24 hr
<11 mL/min	250 mg q 24 hr	250 mg q 24 hr	500 mg q 24 hr	1 Gm q 24 hr
CAPD	500 mg q 48 hr	1 Gm q 48 hr	2 Gm q 48 hr	2 Gm q 48 hr
*Hemodialysis	1 Gm on Day 1, then 500 mg q 24 hr. Increase to 1 Gm q 24 hr in febrile neutropenia.			1 Gm q 24 hr

*On hemodialysis days, cefepime should be administered following hemodialysis. Whenever possible, administer at the same time each day.

Consult literature or Important IV Therapy Facts, p. xxiii, for conversion formula if dose is to be based on SCr. ■ Reduced dose may be required in the elderly based on renal function. ■ Dose adjustment not required in impaired hepatic function.

DILUTION

Available in vials (IM/IV), ADD-Vantage preparations, Duplex containers (1 or 2 Gm in 50 mL), and as Galaxy frozen premixed solutions containing 1 Gm/50 mL or 2 Gm/100 mL. **Vials** may be reconstituted (see the following chart) and then further diluted with NS, D5W, D10W, D5NS, D5LR, 1/6 M sodium lactate, Normosol-R, or D5/Normosol M. Concentrations between 1 mg/mL and 40 mg/mL are acceptable. (500 mg reconstituted with 5 mL = 100 mg/mL, further diluted with 95 mL = 5 mg/mL, with 45 mL = 10 mg/mL.)

ADD-Vantage vials must only be diluted with 50 to 100 mL of NS or D5W in ADD-Vantage infusion containers.

Duplex containers: See manufacturer’s instructions for dilution.

Galaxy frozen premixed solutions: Thaw at RT or under refrigeration. Do not force thaw by immersion in water baths or by microwave irradiation. Solution components may precipitate when frozen; should dissolve at RT. After reaching RT, shake solution. Discard if remains cloudy or a leak is detected by squeezing the container.

Cefepime Dilution Guidelines			
Single-Dose Vials for Intravenous/ Intramuscular Administration	Amount of Diluent to Be Added (mL)	Approximate Available Volume (mL)	Approximate Cefepime Concentration (mg/mL)
CEFEPIME VIAL CONTENT			
500 mg (IV)	5 mL	5.6 mL	100 mg/mL
500 mg (IM)	1.3 mL	1.8 mL	280 mg/mL
1 Gm (IV)	10 mL	11.3 mL	100 mg/mL
1 Gm (IM)	2.4 mL	3.6 mL	280 mg/mL
2 Gm (IV)	10 mL	12.5 mL	160 mg/mL
ADD-VANTAGE			
1 Gm vial	50 mL	50 mL	20 mg/mL
1 Gm vial	100 mL	100 mL	10 mg/mL
2 Gm vial	50 mL	50 mL	40 mg/mL
2 Gm vial	100 mL	100 mL	20 mg/mL

Filters: Specific information from studies not available; contact manufacturer for further information.

Storage: See manufacturer's directions. Recommendations for storing vary from CRT (20° to 25° C [68° to 77° F]) to 2° to 25° C (36° to 77° F) in the dry state; protect from light. Most reconstituted or diluted solutions are stable for 24 hours at CRT and 7 days if refrigerated (recommendations may vary with diluent).

Add-Vantage vials: Stable at concentrations of 10-40 mg/mL in D5W or NS for 24 hours at CRT or 7 days if refrigerated.

Duplex containers: Store inactivated Duplex containers at CRT; do not freeze.

Galaxy containers: Store at or below -20° C (-4° F). Once thawed, do not refreeze; handle with care; may be fragile in the frozen state. Thawed Galaxy containers are stable for 24 hours at CRT and 7 days if refrigerated.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion. May be used concomitantly with aminoglycosides (e.g., gentamicin, tobramycin), aminophylline, metronidazole (Flagyl IV), and vancomycin, but these drugs must never be mixed in the same infusion (mutual inactivation or other potential interactions). If given concurrently, administer at separate sites.

Sources suggest the following **compatibilities:**

Additive: Manufacturer lists specific concentrations of amikacin (Amikin), ampicillin, clindamycin (Cleocin), heparin, potassium chloride (KCl), theophylline, Aminosyn II 4.25% with electrolytes and calcium, and Inpersol with 4.25% dextrose. Other sources add metronidazole (Flagyl IV) and vancomycin. Do not introduce additives into Add-Vantage vials, Duplex containers, or Galaxy containers.

Y-site: Amikacin (Amikin), anidulafungin (Eraxis), bivalirudin (Angiomax), dexmedetomidine (Precedex), dobutamine, docetaxel (Taxotere), dopamine, doxorubicin liposomal (Doxil), fenoldopam (Corlopam), fluconazole (Diflucan), furosemide (Lasix), gentamicin, granisetron (Kytril), hetastarch in electrolytes (Hextend), insulin (regular), ketamine (Ketalar), methylprednisolone (Solu-Medrol), milrinone (Primacor), morphine, mycophenolate (CellCept IV), remefentanil (Ultiva), sufentanil (Sufenta), telavancin (Vibativ), tigecycline (Tygacil), tobramycin, valproate (Depacon), vancomycin.

RATE OF ADMINISTRATION

Do not use plastic containers in a series connection; could result in air embolism. May be given through Y-tube or three-way stopcock of infusion set; see [Compatibility](#).

Intermittent infusion: A single dose equally distributed over 30 minutes.

ACTIONS

A semisynthetic, extended-spectrum, fourth-generation cephalosporin antibiotic. Bactericidal to both gram-positive and gram-negative organisms, including many strains resistant to third-generation cephalosporins and aminoglycosides. Acts by inhibition of bacterial wall synthesis. Has a well-balanced spectrum with good antistaphylococcal activity, enhanced activity against gram-negative organisms, and good antipseudomonal activity. Peak serum levels achieved by end of infusion; half-life is 1.7 to 2.3 hours. Therapeutic levels last for 12 hours, allowing for twice-daily dosing. Well distributed into many body fluids and tissues. Partially metabolized; 85% excreted unchanged in urine. Secreted in breast milk.

INDICATIONS AND USES

Treatment of moderate to severe pneumonia caused by susceptible organisms, including cases associated with concurrent bacteremia. ■ Treatment of uncomplicated and complicated urinary tract infections caused by susceptible organisms, including pyelonephritis and cases associated with concurrent bacteremia. ■ Treatment of uncomplicated skin and skin structure infections caused by susceptible organisms. ■ Empiric monotherapy in the treatment of febrile neutropenic patients. ■ Treatment of complicated intra-abdominal infections in adults; used in combination with metronidazole (Flagyl). ■ See literature for list of susceptible organisms.

CONTRAINDICATIONS

Patients who have shown immediate hypersensitivity reactions to cefepime, any cephalosporin, penicillins, or other beta-lactam antibiotics; see [Precautions](#). ■ Solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to cefepime. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefepime should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Generally more resistant to hydrolysis by beta-lactamases than third-generation cephalosporins are. ■ IM injection is used only for mild to moderate urinary tract infections. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Continue for at least 2 days after all symptoms of infection subside. ■ May decrease prothrombin activity, especially in patients with impaired renal or hepatic function, those in a poor nutritional state, and those receiving extended courses of antimicrobial therapy. ■ Use caution in patients with a history of GI disease (especially colitis). ■ Serious adverse events, including encephalopathy (changes in consciousness, including confusion, hallucinations, stupor, and coma), myoclonus, nonconvulsive status epilepticus, seizures, and other life-threatening or fatal events have occurred. Patients with impaired renal function may be at greater risk, especially if doses are not properly adjusted; see [Dose Adjustments](#) and monitor closely. In most cases, neurotoxicity was reversible and resolved after cefepime was discontinued and/or after hemodialysis. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefepime. ■ Contains arginine, which may alter

glucose metabolism and elevate serum potassium. ■ Higher-end doses may increase incidence and severity of rash and require cefepime to be discontinued. ■ Insufficient data exist for monotherapy of febrile neutropenia in patients at high risk for severe infection (e.g., history of recent bone marrow transplant, hypotension on presentation, underlying hematologic malignancy, severe or prolonged neutropenia). No data are available for patients with septic shock. ■ If meningitis is suspected or documented, an alternate agent with demonstrated clinical effectiveness should be used.

Monitor: Watch for early symptoms of a hypersensitivity reaction. ■ Obtain baseline CBC with differential and platelets and SCr. ■ Obtain baseline PT and monitor, especially in at-risk patients (see [Precautions](#)); vitamin K may be indicated. ■ Monitoring of serum glucose and electrolytes (e.g., potassium, calcium) may be indicated. ■ May cause thrombophlebitis. ■ Monitor and re-evaluate frequently the need for continued antimicrobial treatment in patients whose fever resolves but who remain neutropenic for more than 7 days. ■ See [Drug/Lab Interactions](#).

Patient Education: Promptly report any bleeding or bruising or symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Promptly report neurologic S/S (e.g., change in consciousness, confusion, hallucinations, seizures, stupor).

Maternal/Child: Category B: safety for use during pregnancy, labor and delivery, and breast-feeding not established; use only if clearly needed. ■ Safety and effectiveness not established for infants under 2 months of age or for treatment of serious infections in pediatric patients in whom the suspected or proven pathogen is *Haemophilus influenzae type b*. ■ Pharmacokinetics in pediatric patients and adults are similar. Dose modification similar to adults is indicated in impaired renal function; see [Dose Adjustments](#). ■ Immature renal function of infants and small children will increase blood levels of all cephalosporins.

Elderly: No specific problems documented. Consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy; reduced dose or extended intervals may be indicated; see [Dose Adjustments](#). Monitor for hypocalcemia.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics [e.g., furosemide (Lasix)]); monitor renal function closely. ■ Risk of ototoxicity may be increased when administered with aminoglycosides (e.g., gentamicin). ■ May cause a false-positive **direct Coombs' test**. ■ May have a false-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Clinistix). ■ See [Side Effects](#). ■ Although it has not been specifically studied with cefepime, other cephalosporins have the following drug interactions. May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Large amounts of **cephalosporins and/or salicylates** may induce hypoprothrombinemia (deficiency of prothrombin [factor II]). The addition of **agents that affect platelet aggregation and/or may have GI ulcerative potential** (e.g., NSAIDs [ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)] or sulfinpyrazone [Anturane]) may increase risk of hemorrhage. ■ See [Compatibility](#).

SIDE EFFECTS

Local reactions (including phlebitis), pain and/or inflammation, and rash are most common. Full scope of hypersensitivity reactions (e.g., anaphylaxis, itching, rash, shock, urticaria). Bone marrow suppression (e.g., agranulocytosis, leukopenia, neutropenia, thrombocytopenia); CDAD; diarrhea; elevated alkaline phosphatase, AST, ALT, BUN; fever; headache; nausea and vomiting; neurotoxicity (e.g., seizures [large doses, or standard doses in renally impaired patients]); oral moniliasis; prolonged PT; vaginitis. Serum sickness-like reactions have occurred (e.g., arthralgia, fever, polyarthritis, skin rashes), usually after a second course of therapy. Usually resolve after cephalosporins are discon-

tinued. Hypoprothrombinemia (rare) and hemolytic anemia may occur. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

Overdose: Encephalopathy (disturbances of consciousness, including confusion, hallucinations, stupor, and coma), myoclonus, neuromuscular excitability, seizures.

Post-Marketing: Agranulocytosis, anaphylaxis, encephalopathy, myoclonus, seizures, non-convulsive status epilepticus.

ANTIDOTE

Notify physician of any side effects. Discontinue cefepime and treat hypersensitivity reactions as indicated (airway, oxygen, IV fluids, epinephrine, corticosteroids, pressor amines [e.g., dopamine], antihistamines [e.g., diphenhydramine]). Resuscitate as necessary. Discontinue cefepime if seizures occur and treat with anticonvulsants (e.g., diazepam [Valium]). Mild cases of CDAD may respond to discontinuation of cefepime. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Antihistamines and corticosteroids may be indicated to manage symptoms of serum sickness. Hemodialysis may be useful in overdose.

CEFOTAXIME SODIUM

(sef-oh-TAX-eem SO-dee-um)

Antibacterial
(cephalosporin)

Claforan

pH 5 to 7.5

USUAL DOSE

Range is 2 to 12 Gm/24 hr. Depends on seriousness of infection. Maximum daily dose is 12 Gm. Duration of treatment depends on the organism and infection being treated. A minimum of 10 days is recommended for infections caused by *group A beta-hemolytic streptococci* to guard against the risk of rheumatic fever or glomerulonephritis.

Uncomplicated infections: 1 Gm every 12 hours.

Moderate to severe infections: 1 to 2 Gm every 8 hours.

Serious infections and septicemia: 2 Gm every 6 to 8 hours.

Life-threatening infections: 2 Gm every 4 hours.

Higher doses often reduced with positive clinical response.

Disseminated gonococcal infections: 1 Gm every 8 hours; continue for 24 to 48 hours after symptoms improve. Transfer to oral cefixime to complete a minimum of 1 week of treatment.

Perioperative prophylaxis: 1 Gm 30 to 90 minutes before incision. Equal to or less than 60 minutes is recommended. May be repeated in a lengthy procedure. In **cesarean section** give initial dose after cord is clamped, then 1 Gm at 6 and 12 hours postoperatively.

PEDIATRIC DOSE

Maximum daily dose 12 Gm/24 hr. Differentiation between premature and normal gestational age is not necessary.

0 to 1 week of age: 50 mg/kg/dose every 12 hours.

1 to 4 weeks of age: 50 mg/kg/dose every 8 hours. One source increases the interval to every 12 hours in infants weighing less than 1,200 Gm.

1 month to 12 years, weight less than 50 kg: 50 to 180 mg/kg/24 hr equally divided into 4 to 6 doses (8.3 to 30 mg/kg/dose every 4 hours or 12.5 to 45 mg/kg/dose every 6 hours). Use higher-end doses for serious infections, including meningitis.

Weight 50 kg or more: See **Usual Dose**.

DOSE ADJUSTMENTS

In impaired renal function with a CrCl less than 20 mL/min/1.73 M², reduce dose by one half and maintain same dosing interval. ■ Reduced doses or extended intervals may be indicated in the elderly. Consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy. ■ See **Usual Dose** and **Drug/Lab Interactions**.

DILUTION

Each dose (500 mg, 1 Gm, 2 Gm) must be reconstituted with 10 mL SWFI, D5W, NS, or other **compatible** infusion solution (see chart on inside back cover or literature). Do not prepare with diluents having a pH above 7.5; see **Compatibility**. Solution color ranges from pale yellow to light amber. Available premixed and in ADD-Vantage vials for use with ADD-Vantage infusion containers. May be further diluted with 50 to 100 mL of **compatible** solutions and given as an intermittent infusion or added to larger volumes and given as a continuous infusion. (1 Gm in 14 mL of SWFI is isotonic.)

Storage: Store unopened cartons at CRT. Protect from excessive light. Stability ranges from 12 hours at RT to 10 days refrigerated depending on concentration and infusion container; see prescribing information.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

May be used concomitantly with aminoglycosides (e.g., amikacin [Amikin], gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If

given concurrently, administer at separate sites. Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion and states, “Do not add supplementary medications to premixed plastic IV containers.” Manufacturer also states, “Should not be prepared with solutions having a pH above 7.5, such as sodium bicarbonate.”

One source suggests the following **compatibilities**:

Additive: Clindamycin (Cleocin), metronidazole (Flagyl IV), verapamil.

Y-site: Acyclovir (Zovirax), alprostadil, amifostine (Ethyol), aztreonam (Azactam), bivalirudin (Angiomax), cisatracurium (Nimbex), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopan), fludarabine (Fludara), granisetron (Kytril), hetastarch in electrolytes (Hexend), hydromorphone (Dilaudid), levofloxacin (Levaquin), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), midazolam (Versed), milrinone (Primacor), morphine, ondansetron (Zofran), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), teniposide (Vumon), thiotepa, tigecycline (Tygacil), vancomycin, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

See **Compatibility**. Injection and intermittent infusion may be given through Y-tube or three-way stopcock of infusion set.

IV injection: A single dose equally distributed over a minimum of 3 to 5 minutes. Rapid bolus injections (less than 60 seconds) have caused life-threatening arrhythmias.

Intermittent IV: A single dose over 30 minutes.

Continuous infusion: 500 to 1,000 mL over 6 to 24 hours, depending on total dose and concentration.

ACTIONS

A broad-spectrum, third-generation cephalosporin antibiotic. Bactericidal to many gram-negative, gram-positive, and anaerobic organisms. Effective against many otherwise resistant organisms. Inhibits bacterial cell wall synthesis. Distributed into most body tissues and fluids, including inflamed meninges. Some metabolites formed. Half-life is approximately 1 hour. Excreted in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, urinary tract, skin and skin structure, intra-abdominal, bone and joint, CNS, gynecologic infections, and bacteremia/septicemia. Most effective against specific organisms (see literature). ■ Perioperative prophylaxis.

Unlabeled uses: Treatment of disseminated gonococcal infections and Lyme disease.

CONTRAINDICATIONS

Previous hypersensitivity reaction to cephalosporins; see **Precautions**.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to cefotaxime. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefotaxime should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for 2 to 3 days after all symptoms of infection subside. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with impaired renal function, allergies, or a history of GI disease (especially colitis). ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefotaxime. ■ Granulocytopenia and, rarely, agranulocytosis can occur, especially during prolonged therapy; see **Monitor**.

Monitor: Watch for early symptoms of a hypersensitivity reaction. ■ Monitor CBC if duration of treatment is more than 10 days. ■ May cause thrombophlebitis. Use small needles and large veins, and rotate infusion sites. ■ See [Drug/Lab Interactions](#); additional monitoring may be indicated (e.g., renal function, drug serum levels, PT).

Patient Education: Report promptly any bleeding or bruising or symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B; safety for use during pregnancy and breast-feeding not established. No problems documented. ■ Immature renal function of infants and small children will increase blood levels of all cephalosporins.

Elderly: No specific problems documented; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics [such as furosemide (Lasix)]). ■ **Probenecid** inhibits excretion of cefotaxime, decreasing clearance by approximately 50%. Limit administration of cefotaxime to no more than 6 Gm/day when given concurrently with probenecid. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ See [Compatibility](#) and [Side Effects](#). ■ May cause a positive direct **Coombs' test**. ■ May produce a false-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Chemstix).

SIDE EFFECTS

Generally well tolerated. Most common side effect is a local reaction at the injection site. Less frequent reactions include full scope of hypersensitivity reactions, including anaphylaxis; CDAD; colitis; decreased hemoglobin or decreased hematocrit; decreased platelet functions; diarrhea; dyspnea; elevation of AST, ALT, total bilirubin, alkaline phosphatase, LDH, and BUN (transient); eosinophilia; fever; leukopenia; local site pain;

nausea; oral thrush; positive direct Coombs' test; prolonged PT; seizures (large doses); thrombophlebitis; transient neutropenia; vaginitis; vomiting. Serum sickness-like reactions have occurred (e.g., arthralgia, fever, polyarthritis, skin rashes), usually after a second course of therapy. Generally resolve after cephalosporins are discontinued. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

Post-Marketing: Arrhythmia (with rapid injection), cutaneous reactions (e.g., isolated cases of erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis), encephalopathy (e.g., impairment of consciousness, abnormal movements and seizures), hematologic reactions (e.g., agranulocytosis, hemolytic anemia, thrombocytopenia), hepatic reactions (e.g., cholestasis, elevated gamma-glutamyl transferase (GGT) and bilirubin, hepatitis, jaundice), renal reactions (e.g., interstitial nephritis and transient elevations in SCr).

ANTIDOTE

Notify the physician of any side effects. Discontinue the drug if indicated. Mild cases of CDAD may respond to discontinuation of cefotaxime. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Antihistamines and corticosteroids may be indicated to manage symptoms of serum sickness. Treat hypersensitivity reactions as indicated and resuscitate as necessary. Hemodialysis may be useful in overdose.

CEFOXITIN SODIUM(seh-**FOX**-ih-tin **SO**-dee-um)**Antibacterial
(cephalosporin)****Mefoxin****pH 4.2 to 8****USUAL DOSE**

Cefoxitin Dosing Guidelines		
Type of Infection	Dose and Frequency	Total Daily Dose
Uncomplicated forms* of infections such as pneumonia, urinary tract infection, cutaneous infection	1 Gm every 6 to 8 hr	3 to 4 Gm
Moderately severe or severe infections	1 Gm every 4 hr or 2 Gm every 6 to 8 hr	6 to 8 Gm
Infections commonly needing antibiotics in higher doses (e.g., gas gangrene)	2 Gm every 4 hr or 3 Gm every 6 hr	12 Gm

*Including patients in whom bacteremia is absent or unlikely.

Perioperative prophylaxis: 2 Gm 30 minutes to 1 hour before incision. Follow with 2 Gm every 6 hours for 24 hours.

Prophylaxis during cesarean section: 2 Gm after clamping the umbilical cord. May repeat in 4 hours and again in 8 hours.

Prophylaxis during transurethral prostatectomy (unlabeled): 1 Gm before surgery. May be repeated every 8 hours for up to 5 days.

PEDIATRIC DOSE

Pediatric patients over 3 months of age: Mild to moderate infections: 80 to 100 mg/kg/24 hr in equally divided doses every 6 to 8 hours (20 to 25 mg/kg every 6 hours or 26.66 to 33.33 mg/kg every 8 hours). **Severe infections:** 100 to 160 mg/kg/24 hr in equally divided doses every 4 to 6 hours (16.66 to 26.66 mg/kg every 4 hours or 25 to 40 mg/kg every 6 hours). Do not exceed adult dose and/or 12 Gm.

Perioperative prophylaxis in pediatric patients over 3 months of age: 30 to 40 mg/kg 30 minutes to 1 hour before incision and every 6 hours for 24 hours.

NEONATAL DOSE

Use sterile cefoxitin sodium USP only. Other formulations may contain benzyl alcohol.

90 to 100 mg/kg/24 hr in equally divided doses every 8 hours (30 to 33.3 mg/kg every 8 hours).

DOSE ADJUSTMENTS

Reduced dose or extended intervals may be indicated in the elderly; consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy. ■ In impaired renal function, the initial dose should be as previously listed, but all remaining doses should be based on CrCl according to the following chart. See [Drug/Lab Interactions](#).

Cefoxitin Maintenance Dose in Adults with Impaired Renal Function		
Creatinine Clearance (mL/min)	Dose (Gm)	Frequency
30-50 mL/min	1-2 Gm	q 8-12 hr
10-29 mL/min	1-2 Gm	q 12-24 hr
5-9 mL/min	0.5-1 Gm	q 12-24 hr
<5 mL/min	0.5-1 Gm	q 24-48 hr

Hemodialysis patients should receive a loading dose of 1 to 2 Gm after each dialysis in addition to the maintenance dose listed in the previous chart.

In pediatric patients, one source recommends reducing the dose and frequency consistent with the recommendations for adults. Another source recommends increasing the dosing interval based on CrCl according to the following chart.

Cefoxitin Maintenance Dose in Pediatric Patients with Impaired Renal Function	
Creatinine Clearance (mL/min)	Frequency
>50 mL/min	q 8 hr
10-50 mL/min	q 8-12 hr
<10 mL/min	q 24-48 hr

DILUTION

Each 1 Gm or fraction thereof must be reconstituted with at least 10 mL of SWFI, D5W, or NS. A single dose may be further diluted in 50 to 100 mL of most common infusion solutions (see chart on inside back cover and literature). The use of butterfly needles and dilution in up to 1,000 mL of D5W, D5NS, or NS are preferred when administering larger doses as a continuous infusion. Available premixed and in piggyback vials. May be given through a Y-tube, three-way stopcock, additive infusion set, or as a continuous infusion.

Storage: Reconstituted solutions are stable at CRT for 6 hours and 7 days if refrigerated. Solutions diluted in 50 to 1,000 mL diluent are stable for 18 to 24 hours at CRT and up to 48 hours if refrigerated. Thaw frozen containers at CRT or under refrigeration. Do not force thaw. Stable for 21 days if refrigerated. Do not refreeze.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

May be used concomitantly with aminoglycosides (e.g., amikacin [Amikin], gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer at separate sites. Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion.

One source suggests the following **compatibilities:**

Additive: Aztreonam (Azactam), clindamycin (Cleocin), mannitol, metronidazole (Flagyl IV), multivitamins (M.V.I.), sodium bicarbonate (Neut), verapamil.

Y-site: Acyclovir (Zovirax), amifostine (Ethyol), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), cisatracurium (Nimbex), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fluconazole (Diflucan), foscarnet (Foscavir), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), linezolid (Zyvox), magnesium sulfate, meperidine (Demerol), morphine, ondansetron (Zofran), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), teniposide (Vumon), thiotepa, vancomycin.

RATE OF ADMINISTRATION

See **Compatibility**. Each 1 Gm or fraction thereof over 3 to 5 minutes or longer as indicated by amount of solution and condition of the patient. Rate of continuous infusion should be by physician order.

ACTIONS

A semisynthetic, second-generation cephalosporin antibiotic that is bactericidal to many gram-positive, gram-negative, and anaerobic organisms. Inhibits cell wall synthesis. Peak serum levels achieved by end of infusion. Widely distributed into most body tissues and fluids (CSF minimal), bone, gallbladder, myocardium, and skin and soft tissues.

Half-life is 41 to 59 minutes. Excreted rapidly in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious respiratory, GU, intra-abdominal, gynecologic, bone and joint, skin and skin structure infections and septicemia. Effective only if the causative organism is susceptible. If *C. trachomatis* is a suspected pathogen, antichlamydial coverage is indicated. ■ Perioperative prophylaxis.

Unlabeled uses: Treatment of acute pelvic inflammatory disease (CDC recommendation). ■ Treatment of oral bacterial *Eikenella corrodens*. ■ Prophylaxis during transurethral prostatectomy.

CONTRAINDICATIONS

Previous hypersensitivity reaction to cephalosporins; see **Precautions**.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to cefixitin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefixitin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for at least 2 to 3 days after all symptoms of infection subside. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with impaired renal function, allergies, or a history of GI disease (especially colitis). ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefixitin. ■ Continue treatment for group A beta-hemolytic streptococcal infections for 10 days or more to decrease the risk of rheumatic fever or glomerulonephritis.

Monitor: Watch for early symptoms of a hypersensitivity reaction. ■ Use extreme caution in the penicillin-sensitive patient; incidence of cross-sensitivity may be up to 10%. ■ Thrombophlebitis may result from prolonged or high dosage; use small needles, larger veins, and rotate infusion sites. ■ Periodic monitoring of CBC, SCr, and liver function tests is recommended during prolonged therapy. ■ See **Drug/Lab Interactions**; additional monitoring may be indicated (e.g., renal function, drug serum levels, PT).

Patient Education: Report promptly any bleeding or bruising or symptoms of allergy (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: safety for use during pregnancy and breast-feeding not established. No problems documented. ■ Do not use formulations containing benzyl alcohol in infants and children under 3 months. ■ Immature renal function will increase blood levels. ■ Eosinophilia and elevated AST associated with higher doses in infants and children.

Elderly: Response similar to that seen in younger adults. Dose selection should be cautious; see **Dose Adjustments**. Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics such as furosemide [Lasix]). ■ **Probenecid** inhibits excretion. Reduced dose of cefixitin may be required with concomitant use. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Large doses of **cephalosporins and/or salicylates** may induce hypoprothrombinemia (deficiency of prothrombin [factor II]). The addition of **agents that affect platelet aggregation and/or may have GI ulcerative potential** (e.g., NSAIDs

[ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)] or sulfinpyrazone [Anturane]) may increase risk of hemorrhage. ■ False-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Chemstix). ■ Positive **Coombs' test**. ■ False increases in **creatinine levels** with Jaffe method. ■ See [Compatibility](#) and [Side Effects](#).

SIDE EFFECTS

Local site reactions are most common. Anorexia; CDAD; colitis; flushing; hypersensitivity reactions, including anaphylaxis; eosinophilia; leukopenia; nausea and vomiting; neutropenia; oral thrush; phlebitis; prolonged PT; proteinuria; seizures (large doses); thrombophlebitis; transient elevation of AST, ALT, BUN, and alkaline phosphatase; and urticaria have occurred. Hypoprothrombinemia (rare) and hemolytic anemia may occur. Serum sickness–like reactions have occurred (e.g., arthralgia, fever, polyarthritis, skin rashes), usually after a second course of therapy. Generally resolve after cephalosporins are discontinued. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Treat hypersensitivity reactions as indicated and resuscitate as necessary. Hemodialysis may be useful in overdose. Antihistamines and corticosteroids may be indicated to manage symptoms of serum sickness.

CEFTAROLINE FOSAMIL

(cef-TAR-oh-leen FOS-a-mil)

**Antibacterial
(cephalosporin)****Teflaro****pH 4.8 to 6.5****USUAL DOSE**

600 mg every 12 hours as an IV infusion. Duration of therapy should be guided by the severity and the site of infection and the patient's clinical and bacteriologic progress as shown in the following table.

Dosage of Ceftaroline				
Infection	Dosage	Frequency	Infusion Time (hours)	Recommended Duration of Total Antimicrobial Therapy
Acute bacterial skin and skin structure infection (ABSSSI)	600 mg	q 12 hr	1 hr	5-14 days
Community-acquired bacterial pneumonia (CABP)	600 mg	q 12 hr	1 hr	5-7 days

DOSE ADJUSTMENTS

Dose adjustment required with renal impairment as outlined in the following table.

Dosage of Ceftaroline in Patients with Renal Impairment	
Estimated CrCl* (mL/min)	Recommended Dosage Regimen
>50 mL/min	600 mg q 12 hr
>30 to ≤50 mL/min	400 mg q 12 hr
≥15 to ≤30 mL/min	300 mg q 12 hr
End-stage renal disease, including hemodialysis†	200 mg q 12 hr‡

*CrCl as calculated by Cockcroft-Gault formula.

†End-stage renal disease is defined as CrCl <15 mL/min.

‡Ceftaroline is hemodialyzable; administer after hemodialysis on hemodialysis days.

- Dose adjustment is not indicated based on gender, race, or hepatic function. ■ Reduced dose may be indicated in the elderly based on age-related renal impairment.

DILUTION

Reconstitute with 20 mL of SWFI, NS, D5W, or LR as shown in the following table. Mix gently. Time to dissolution is less than 2 minutes.

Preparation of Ceftaroline for Intravenous Use			
Dosage Strength (mg)	Volume of Diluent to Be Added (mL)	Approximate Ceftaroline Concentration (mg/mL)	Amount to Be Withdrawn
400	20 mL	20 mg/mL	Total volume
600	20 mL	30 mg/mL	Total volume

Further dilute the reconstituted solution in 50 to 250 mL of NS, D5W, D2.5W, ½NS, or LR. When preparing a ceftaroline dose in a 50-mL infusion bag, withdraw 20 mL of the infusion solution before injecting the reconstituted drug into the bag. Use the same diluent for further dilution unless SWFI was used. If SWFI was used as the initial diluent,

further dilute the reconstituted solution in NS, D5W, D2.5/0.45NS, or LR. Infusion solution ranges from clear to light yellow to dark yellow depending on the concentration and the storage conditions.

Filter: Data not available.

Storage: Store unopened vials in the refrigerator at 2° to 8° C (36° to 46° F). Unrefrigerated, unconstituted ceftaroline can be stored at temperatures not exceeding 25° C (77° F) for no more than 7 days. Diluted solution should be used within 6 hours when stored at RT or within 24 hours when refrigerated.

COMPATIBILITY (Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Should not be mixed with or physically added to solutions containing other drugs.” **Compatibility** with other drugs has not been established.

One source suggests the following **compatibilities** for specific time frames; consult pharmacist:

Y-site: Acyclovir (Zovirax), amikacin (Amikin), aminophylline, amiodarone (Nexterone), azithromycin (Zithromax), bumetanide, calcium chloride, calcium gluconate, ciprofloxacin (Cipro IV), cisatracurium (Nimbex), clindamycin (Cleocin), cyclosporine (Sandimmune), dexamethasone (Decadron), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, dopamine, doripenem (Doribax), enalaprilat (Vasotec IV), esomeprazole (Nexium IV), famotidine (Pepcid IV), fentanyl (Sublimaze), fluconazole (Diflucan), furosemide (Lasix), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), insulin (regular), levofloxacin (Levaquin), lidocaine, lorazepam (Ativan), magnesium sulfate, mannitol (Osmitol), meperidine (Demerol), methylprednisolone sodium succinate (Solu-Medrol), metoclopramide (Reglan), metoprolol (Lopressor), metronidazole (Flagyl IV), midazolam (Versed), milrinone (Primacor), morphine, moxifloxacin (Avelox), multivitamin infusion (M.V.I.), norepinephrine (Levophed), ondansetron (Zofran), pantoprazole (Protonix IV), potassium chloride, promethazine (Phenergan), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sodium bicarbonate, sulfamethoxazole/trimethoprim (SMZ-TMP), tobramycin, vasopressin, voriconazole (VFEND IV).

RATE OF ADMINISTRATION

A single dose equally distributed over 1 hour.

ACTIONS

A semi-synthetic, broad-spectrum cephalosporin. Ceftaroline fosamil, a prodrug, is converted into the bioactive ceftaroline in plasma by a phosphatase enzyme. Bactericidal to many gram-negative and gram-positive organisms. Inhibits bacterial cell wall synthesis. Protein binding is minimal (20%). Ceftaroline undergoes hydrolysis, forming an inactive metabolite. Half-life is approximately 2.2 to 3 hours. Both ceftaroline and its metabolites are primarily eliminated by the kidneys.

INDICATIONS AND USES

Treatment of adults with infections caused by susceptible strains of microorganisms in conditions, including acute bacterial skin and skin structure infections (ABSSSI) and community-acquired bacterial pneumonia (CABP).

CONTRAINDICATIONS

Known serious hypersensitivity to ceftaroline or other members of the cephalosporin class.

PRECAUTIONS

Hypersensitivity reactions and serious skin reactions, including fatalities, have been reported in patients receiving beta-lactam antibiotics and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, carbapenems, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with

first-generation cephalosporins. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to ceftaroline. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ceftaroline should be used to treat only those infections proven or strongly suspected to be caused by bacteria. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ceftaroline. ■ Seroconversion from a negative to a positive direct Coombs' test occurred in approximately 10% of patients in Phase 3 trials. No adverse reactions representing hemolytic anemia were reported. If anemia develops during or after treatment with ceftaroline, drug-induced hemolytic anemia should be considered and diagnostic studies, including a direct Coombs' test, should be performed.

Monitor: Watch for early symptoms of a hypersensitivity reaction. ■ Obtain baseline CBC with differential and platelet count and SCr.

Patient Education: Promptly report S/S of a hypersensitivity reaction (e.g., rash, hives, wheezing, shortness of breath). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: safety for use during pregnancy and breast-feeding not established; use only if clearly needed. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: No specific problems documented. Efficacy and safety appear similar to that seen in younger patients. Consider age-related renal impairment; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

No clinical drug-drug interaction studies have been conducted. There is minimal potential for drug-drug interactions between ceftaroline and CYP450 substrates, inhibitors, or inducers; drugs known to undergo active renal secretion; and drugs that may alter renal blood flow.

SIDE EFFECTS

The most common side effects were diarrhea, nausea, and rash. Hypersensitivity reactions were the most frequently reported serious side effects leading to discontinuation of therapy. Other less frequently reported side effects included CDAD, constipation, hypokalemia, increased transaminases (ALT, AST), phlebitis, seroconversion from a negative to a positive direct Coombs' test, and vomiting. Several other side effects were reported in less than 2% of the population studied. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated (e.g., diphenhydramine [Benadryl], epinephrine [Adrenalin], albuterol [Ventolin]) and resuscitate as necessary. Discontinue ceftaroline for suspected drug-induced hemolytic anemia and initiate supportive therapy as indicated (e.g., transfusion). Mild cases of CDAD may respond to discontinuation of ceftaroline. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Ceftaroline is removed by hemodialysis.

CEFTAZIDIME

(sef-TAY-zih-deem)

**Antibacterial
(cephalosporin)****Fortaz, Tazicef****pH 5 to 8****USUAL DOSE**

Range is from 250 mg to 2 Gm every 8 to 12 hours. Dosage based on severity of disease, condition of the patient, and susceptibility of the causative organism.

Uncomplicated GU infections: 250 mg every 12 hours.

Complicated GU infections: 500 mg every 8 to 12 hours.

Uncomplicated pneumonia; skin and skin structure infections: 500 mg to 1 Gm every 8 hours.

Bone and joint infections: 2 Gm every 12 hours.

Severe or life-threatening infections (especially in immunocompromised patients), meningitis, serious gynecologic and intra-abdominal infections: 2 Gm every 8 hours.

Pseudomonal lung infections in cystic fibrosis patients (must have normal renal function): 30 to 50 mg/kg of body weight every 8 hours. Do not exceed 6 Gm/24 hr.

Melioidosis (unlabeled): 40 mg/kg every 8 hours.

PEDIATRIC DOSE

Use sodium carbonate formulation (Fortaz, Tazicef) only for infants and children under 12 years. Components of other formulations may be harmful. Reserve higher doses for immunocompromised pediatric patients or those with cystic fibrosis or meningitis. Do not exceed 6 Gm/24 hr.

Pediatric patients 1 month to 12 years of age: 30 to 50 mg/kg of body weight every 8 hours.

NEONATAL DOSE

Use sodium carbonate formulation only (Fortaz, Tazicef); components of other formulations may be harmful.

Neonates up to 4 weeks of age: 30 mg/kg every 12 hours.

The American Academy of Pediatrics suggests the following doses:

Less than 1 week of age weighing 2 kg or less: 50 mg/kg every 12 hours.

Less than 1 week of age weighing more than 2 kg: 50 mg/kg every 8 or 12 hours.

Neonates from 1 to 4 weeks of age: 50 mg/kg every 8 hours.

DOSE ADJUSTMENTS

Reduced dose or extended intervals may be indicated in the elderly; consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy. ■

In impaired renal function, the initial dose should be as above, but all remaining doses should be based on CrCl according to the following chart. If the normal dose would be lower than the doses in the chart, use the lower dose. Adjustment for pediatric patients is similar to adults; consider body surface or lean body mass and reduce dosing frequency.

Ceftazidime Maintenance Dose in Impaired Renal Function		
Creatinine Clearance (mL/min)	Dose	Frequency
31-50 mL/min	1 Gm	q 12 hr
16-30 mL/min	1 Gm	q 24 hr
6-15 mL/min	500 mg	q 24 hr
<5 mL/min	500 mg	q 48 hr
Hemodialysis patients	1 Gm	After each dialysis session
Peritoneal dialysis patients	500 mg	q 24 hr

In patients with impaired renal function who have severe infection (normally requiring a 6-Gm/24 hr dose), the dose in the previous chart may be increased by 50% or the dosing

Continued

frequency may be increased. In patients undergoing hemodialysis, give a loading dose of 1 Gm followed by 1 Gm after each dialysis. ■ In peritoneal dialysis patients (CAPD), give a loading dose of 1 Gm followed by 500 mg every 24 hours. ■ Dose reduction not required in impaired hepatic function.

DILUTION

IV injection: Reconstitute 0.5 Gm with 5.3 mL of SWFI. To obtain a dose of 500 mg, withdraw 5 mL from vial. Reconstitute 1 Gm or more with 10 mL of SWFI. Shake well. Dilution generates CO₂. Invert vial and completely depress plunger of syringe. Insert needle through stopper and keep it within the solution. Expel bubbles from solution in syringe before injection.

Intermittent IV: A single dose may be further diluted in 50 to 100 mL of D5W, NS, or other **compatible** infusion solutions for injection (see literature or chart on inside back cover). Also available premixed, in infusion packs, in piggyback vials, and in ADD-Vantage vials for use with ADD-Vantage infusion containers.

Storage: Store unopened vials in carton at CRT. Protect from light. Administer within 12 hours of preparation if stored at CRT, or refrigerate for up to 3 days. May be frozen for up to 3 months after initial dilution; thaw at room temperature (see instructions); do not refreeze. Will be light yellow to amber in color depending on concentration and diluent. Premixed infusion packs, piggyback vials, and ADD-Vantage vials have different storage requirements; consult prescribing information.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

May be used concomitantly with aminoglycosides (e.g., amikacin [Amikin], gentamicin, and vancomycin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer at separate sites and flush IV line before and after administration. Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion and states, "Do not add supplementary medications to premixed plastic IV containers."

One source suggests the following **compatibilities:**

Additive: Clindamycin (Cleocin), fluconazole (Diflucan), heparin, linezolid (Zyvox), metronidazole (Flagyl IV), potassium chloride, sodium bicarbonate.

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), aminophylline, anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), daptomycin (Cubicin), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, docetaxel (Taxotere), dopamine, doxapram (Dopram), enalaprilat (Vasotec IV), epinephrine (Adrenalin), esmolol (Brevibloc), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), furosemide (Lasix), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), insulin (regular), ketamine (Ketalar), labetalol, linezolid (Zyvox), melphalan (Alkeran), meperidine (Demerol), methylprednisolone (Solu-Medrol), milrinone (Primacor), morphine, nicardipine (Cardene IV), ondansetron (Zofran), paclitaxel (Taxol), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), sufentanil (Sufenta), tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepe, tigecycline (Tygacil), valproate (Depacon), vancomycin, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

See **Compatibility**. May be given through Y-tube or three-way stopcock of infusion set.

IV injection: A single dose equally distributed over 3 to 5 minutes.

Intermittent IV: A single dose over 30 minutes.

ACTIONS

A broad-spectrum, third-generation cephalosporin antibiotic. Bactericidal to selected gram-negative, gram-positive, and anaerobic organisms. Effective against many other-

wise resistant organisms, including *Pseudomonas aeruginosa*. Inhibits bacterial cell wall synthesis. Peak serum levels achieved by end of infusion. Therapeutic levels distributed into many body fluids and tissues including CSF and aqueous humor. Half-life is 1.9 hours. Excreted unchanged in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, urinary tract, skin and skin structure, bone and joint, gynecologic, intra-abdominal, CNS infections (including meningitis), and bacterial septicemia. Most effective against specific organisms (see literature).

Unlabeled uses: Treatment of melioidosis; empiric treatment of febrile neutropenia.

CONTRAINDICATIONS

Previous hypersensitivity reaction to cephalosporins; see [Precautions](#).

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Specific sensitivity studies indicated to determine susceptibility of causative organism to ceftazidime. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ceftazidime should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for at least 2 days after all symptoms of infection subside. ■ Use with caution in patients with renal impairment. Elevated levels of ceftazidime in these patients can lead to asterixis, coma, encephalopathy, myoclonia, neuromuscular excitability, and seizures; see [Dose Adjustments](#). ■ May be associated with a fall in prothrombin activity. Patients at risk include those with renal or hepatic impairment, those with poor nutritional status, those receiving a protracted course of antimicrobial therapy, and/or those previously stabilized on anticoagulant therapy; see [Monitor](#). ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with allergies or a history of GI disease (especially colitis). ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ceftazidime.

Monitor: Watch for early symptoms of a hypersensitivity reaction. ■ May cause thrombophlebitis. Use small needles and large veins, and rotate infusion sites. ■ Monitor PT and administer vitamin K as indicated; see [Precautions](#). ■ See [Drug/Lab Interactions](#); additional monitoring may be indicated (e.g., renal function, drug serum levels, PT).

Patient Education: Report promptly any bleeding or bruising or symptoms of allergy (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: safety for use during pregnancy and breast-feeding not established. No problems documented. ■ Immature renal function of infants and small children will increase blood levels of all cephalosporins. ■ Only specific solutions can be used in pediatric patients.

Elderly: No specific problems documented. ■ See [Usual Dose](#) and [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics such as furosemide [Lasix]). ■ **Probenecid** does not increase blood levels as it does with other cephalosporins. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Large amounts of **cephalosporins and/or salicylates** may induce hypoprothrombinemia (deficiency of prothrombin [factor II]). The addition of **agents that affect platelet aggregation and/or may have GI ulcerative potential** (e.g., NSAIDs [ibuprofen (Advil,

Motrin), naproxen (Aleve, Naprosyn)] or sulfinpyrazone [Anturane]) may increase risk of hemorrhage. ■ May reduce the effectiveness of **oral estrogen/progesterone contraceptives**. ■ False-positive **Coombs' test**. ■ May have a false-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Chemstix). ■ See **Compatibility** and **Side Effects**.

SIDE EFFECTS

Full scope of hypersensitivity reactions, including anaphylaxis and cardiopulmonary arrest. Aplastic anemia; burning, discomfort, and pain at injection site; CDAD; colitis; diarrhea; dizziness; elevated alkaline phosphatase, AST, ALT, GGT, and BUN; erythema multiforme; jaundice; nausea and vomiting; prolonged PT; renal impairment; seizures (large doses); Stevens-Johnson syndrome; toxic nephropathy; toxic epidermal necrolysis; urticaria. Hypoprothrombinemia (rare) and hemolytic anemia may occur. Serum sickness-like reactions have occurred (e.g., arthralgia, fever, polyarthritis, skin rashes), usually after a second course of therapy. Generally resolve after cephalosporins are discontinued. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

Overdose: Asterixis, coma, encephalopathy, neuromuscular excitability, and seizures may occur in patients with renal impairment; see **Precautions**.

Post-Marketing: Hemorrhage, hyperbilirubinemia, jaundice, toxic nephropathy.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reaction as indicated and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of ceftazidime. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis may be useful in overdose. Antihistamines and corticosteroids may be indicated to manage symptoms of serum sickness.

CEFTRIAZONE SODIUM

(sef-try-**AX**-ohn **SO**-dee-um)

Rocephin

**Antibacterial
(cephalosporin)**

pH 6.6 to 6.7

USUAL DOSE

Adults and pediatric patients over 12 years: 1 to 2 Gm/24 hr. May be given as a single dose every 24 hours or equally divided into 2 doses and given every 12 hours. For infections caused by *Staphylococcus aureus* (MSSA), recommended daily dose is 2 to 4 Gm. Do not exceed a total dose of 4 Gm/24 hr.

Meningitis: 2 Gm every 12 hours.

Disseminated gonococcal infections (unlabeled): 1 Gm daily. Continue for 24 to 48 hours after improvement. Transfer to oral dosing and continue for a minimum of 7 days.

Perioperative prophylaxis: 1 Gm IV 30 minutes to 2 hours before incision. Used primarily in patients undergoing coronary artery bypass surgery and in contaminated or potentially contaminated surgeries.

Lyme diseases (unlabeled): 2 Gm daily for 14 days (range 14 to 28 days).

PEDIATRIC DOSE

Pediatric patients 1 month to 12 years of age: See [Maternal/Child](#).

Skin and soft tissue and other serious infections (other than meningitis): 50 to 75 mg/kg of body weight/24 hr as a single dose or in equally divided doses every 12 hours (25 to 37.5 mg/kg every 12 hours). Do not exceed a total dose of 2 Gm/24 hr.

Bacterial meningitis: Begin with a loading dose of 100 mg/kg on day 1 (do not exceed a total dose of 4 Gm), follow with 100 mg/kg/day (not to exceed 4 Gm) as a single dose or in equally divided doses every 12 hours (50 mg/kg every 12 hours). An alternate regimen begins with an 80- to 100-mg/kg loading dose (not over 4 Gm); follow with 80 mg/kg at 12-hour intervals for 2 doses, then 80 to 100 mg/kg every 24 hours. Continue for 7 to 14 days depending on the causative organism. Single daily doses must be given at the same time each day to maintain adequate CSF concentrations.

Lyme diseases (unlabeled): 50 to 100 mg/kg/day for 14 days (range 10 to 28 days). Maximum dose is 2 Gm.

NEONATAL DOSE

Hyperbilirubinemic neonates, especially premature neonates, should not receive ceftriaxone; see [Contraindications](#) and [Maternal/Child](#).

Neonatal doses may also be given IM. See [Maternal/Child](#).

The American Academy of Pediatrics (AAP) recommends the following:

Less than 7 days of age: 50 mg/kg/day as a single daily dose.

1 to 4 weeks of age and weighing less than 2 kg: 50 mg/kg/day.

1 to 4 weeks of age and weighing more than 2 kg: 50 to 75 mg/kg/day.

Bacterial meningitis: Same as Pediatric Dose.

Infants born to mothers with gonococcal infections: 25 to 50 mg/kg one time only (do not exceed 125 mg).

DOSE ADJUSTMENTS

In adults with both hepatic and renal impairment, dose should not exceed 2 Gm daily unless serum concentrations of ceftriaxone are monitored. ■ Dose adjustment not required for elderly patients with doses up to 2 Gm/day. ■ See [Drug/Lab Interactions](#).

DILUTION

Initially reconstitute each 250 mg of sterile powder with 2.4 mL (500 mg with 4.8 mL, 1 Gm with 9.6 mL, 2 Gm with 19.2 mL) of SWFI, NS, D5W, D10W, D5NS, or D5/½NS for injection (see chart on inside back cover or literature for additional diluents). Each mL will contain 100 mg. A single dose must be further diluted to the desired concentration with the same solution and given as an intermittent infusion. Shake well. Concentrations of 10 mg/mL to 40 mg/mL are recommended for intermittent infusion. Sterile powder is also available in 1-Gm and 2-Gm infusion bottles. Reconstitute each 1 Gm with 10 mL of one of the above diluents, then further dilute with 50 to 100 mL of the same solution. Should not be reconstituted, further diluted, or simultaneously administered with calcium-containing IV solutions. A precipitate can form; see [Compatibility](#). Available premixed (frozen Galaxy), in Duplex containers, in ADD-Vantage vials for use with ADD-Vantage infusion containers, and in pharmacy bulk packages of 10 Gm (not for direct infusion); see prescribing information for specific dilution instructions.

Storage: See manufacturer's directions. Recommendations for storing vary from CRT (20° to 25° C [68° to 77° F]) to RT (25° C [77° F]) or below and protect from light. Stable at RT for at least 24 hours in stated solutions or selected solutions up to 10 days if refrigerated (see prescribing information). D5NS and D5/½NS should not be refrigerated. Stability and color (light yellow to amber) depend on concentration and diluent. Solutions reconstituted in D5W or NS in concentrations between 10 and 40 mg/mL and then frozen at -20° C in PVC or polyolefin containers remain stable for 26 weeks.

Add-Vantage vials: Stable at concentrations of 10 to 40 mg/mL in D5W or NS at CRT for 2 days, or 10 days if refrigerated.

Duplex containers: Store inactivated Duplex containers at CRT; do not freeze.

Galaxy containers: Store at or below -20° C (-4° F). Once thawed, do not refreeze; handle with care; may be fragile in the frozen state. Thaw frozen solutions at room tem-

perature or under refrigeration (5° C [41° F]) before use. Do not force thaw by immersion in water baths or by microwave irradiation. Thawed solution is stable for 21 days under refrigeration or 48 hours at RT. Discard unused portions.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Do not use diluents containing calcium, such as Ringer’s solution or Hartmann’s solution, to reconstitute or further dilute ceftriaxone. Particulate formation can result. Ceftriaxone and calcium-containing solutions, including continuous calcium-containing infusions such as parenteral nutrition, should not be mixed or coadministered simultaneously via a **Y-site**.” However, in patients other than neonates, ceftriaxone and calcium-containing solutions may be administered sequentially if the infusion lines are thoroughly flushed between infusions with a **compatible** fluid; see **Contraindications** and **Precautions**. Manufacturer lists as **compatible** with metronidazole (Flagyl IV) as an additive in NS or D5W if the concentration of metronidazole does not exceed 5 to 7.5 mg/mL with ceftriaxone 10 mg/mL as an admixture. Mixture is stable at RT for 24 hours. Precipitation will occur if refrigerated or if concentration of metronidazole exceeds 8 mg/mL. No studies have been done with Flagyl IV RTU. Manufacturer lists aminoglycosides (e.g., gentamicin), amsacrine (Amsidyl), fluconazole (Diflucan), and vancomycin as **incompatible** and states, “May be given sequentially with thorough flushing of the IV line with **compatible** solution between the administrations.”

One source suggests the following **compatibilities**:

Additive: Manufacturer lists metronidazole (Flagyl IV) not to exceed 5 to 7.5 mg/mL with ceftriaxone 10 mg/mL admixed in D5W or NS. Do not refrigerate; a precipitate will form.

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), amiodarone (Nexterone), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), cis-atracurium (Nimbex), daptomycin (Cubicin), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fludarabine (Fludara), foscarnet (Foscavir), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, 6% hydroxyethyl starch (Voluven), linezolid (Zyvox), melphalan (Alkeran), meperidine (Demerol), methotrexate, morphine, paclitaxel (Taxol), pantoprazole (Protonix IV), pemetrexed (Alimta), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), sodium bicarbonate, tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepa, tigecycline (Tygacil), vancomycin, warfarin (Coumadin), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Intermittent IV: A single dose over 30 minutes.

ACTIONS

A broad-spectrum, third-generation cephalosporin antibiotic. Bactericidal to selected gram-negative, gram-positive, and anaerobic organisms. Effective against many otherwise resistant organisms. Inhibits bacterial cell wall synthesis. Therapeutic concentrations achieved in many body fluids and tissues, including CSF. Highly protein bound. Has a long half-life (range is 5.8 to 8.7 hours); once-a-day dosing sufficient. Peak serum levels achieved by end of infusion. Excreted through urine, bile, and feces. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, urinary tract, skin and skin structure, bone and joint, and intra-abdominal infections. ■ Bacterial septicemia. ■ Meningitis. ■ Most effective against specific organisms (see literature). ■ Perioperative prophylaxis. ■ Given IM for additional indications (e.g., acute bacterial otitis, CDC recommendations for gonorrhea, pelvic inflammatory disease [considered treatment of choice]).

Unlabeled uses: Treatment of Lyme disease and numerous other infections. ■ Disseminated gonococcal infections. ■ IM for CDC recommendation for chancroid.

CONTRAINDICATIONS

Previous hypersensitivity reaction to cephalosporins; see [Precautions](#). ■ Hyperbilirubinemic neonates (newborn to 28 days), especially premature neonates; see [Maternal/Child](#). ■ Coadministration with calcium-containing IV solutions, including parenteral nutrition, in infants up to 28 days of age is contraindicated because of the risk of precipitation of ceftriaxone-calcium salt. Cases of fatal reactions with precipitates in lungs and kidneys have been reported in neonates. In some cases, the infusion lines and the times of administration of the ceftriaxone and calcium-containing solution differed; see [Precautions](#) and [Compatibility](#). ■ Solutions containing dextrose may be contraindicated in patients with hypersensitivity to corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with no known hypersensitivity or previous exposure, as well as those with a history of penicillin hypersensitivity or sensitivity to multiple allergens, experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies are indicated to determine susceptibility of the causative organism to ceftriaxone. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ceftriaxone should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for at least 2 to 3 days after all symptoms of infection subside. Usual course of therapy 4 to 14 days; *S. pyogenes* requires treatment for 10 days. In serious invasive infection, continue for 5 to 7 days after cultures are negative. ■ Should not be reconstituted, further diluted, or simultaneously administered with calcium-containing IV solutions. A precipitate can form; see [Compatibility](#). There are no data on potential interactions between ceftriaxone and oral calcium-containing products or between IM ceftriaxone and oral or IV calcium-containing products. ■ May be associated with a fall in prothrombin activity. Patients at risk include those with renal or hepatic impairment, those with poor nutritional status, those receiving a protracted course of antimicrobial therapy, and/or those previously stabilized on anticoagulant therapy; see [Monitor](#). ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with both impaired renal and hepatic function, allergies, or a history of GI disease (especially colitis). ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ceftriaxone. ■ Immune-mediated hemolytic anemia has been reported in both adults and pediatric patients. Fatalities have occurred. ■ Prolonged use may lead to gallbladder disease. Sonographic abnormalities in the gallbladder of patients treated with ceftriaxone have been reported. These abnormalities have been determined to be predominantly a ceftriaxone-calcium salt and may be misinterpreted as gallstones. The abnormalities appear to be transient and reversible with the discontinuation of ceftriaxone. ■ Pancreatitis, possibly secondary to biliary obstruction, has been reported.

Monitor: Watch for early symptoms of a hypersensitivity reaction. ■ Single daily dose reduces incidence of thrombophlebitis. Use of small needles, large veins, and rotation of infusion sites is preferred. ■ Monitor PT and administer vitamin K as indicated (e.g., 10 mg weekly). ■ Monitor CBC for development of cephalosporin-induced anemia. ■ See [Dose Adjustments](#) and [Drug/Lab Interactions](#); additional monitoring may be indicated (e.g., renal function, drug serum levels, PT).

Patient Education: Report promptly any bleeding or bruising or symptoms of allergy (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: safety for use during pregnancy and breast-feeding not established. No problems documented. ■ Immature renal function of infants and small chil-

dren will increase blood levels of all cephalosporins. ■ Use is contraindicated in hyperbilirubinemic neonates less than 28 days of age (especially premature neonates). Ceftriaxone can displace bilirubin from its binding sites on albumin. Risk of bilirubin encephalopathy exists; see **Contraindications** and **Precautions**.

Elderly: Response similar to other age-groups; however, greater sensitivity of the elderly cannot be ruled out; see **Dose Adjustments**.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics such as furosemide [Lasix]). ■ **Probenecid** does not increase blood levels as it does with other cephalosporins. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Large amounts of **cephalosporins and/or salicylates** may induce hypoprothrombinemia (deficiency of prothrombin [factor II]). The addition of **agents that affect platelet aggregation and/or may have GI ulcerative potential** (e.g., NSAIDs [ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)] or sulfinpyrazone [Anturane]) may increase risk of hemorrhage. ■ False-positive **Coombs' test**. ■ May produce false-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Chemstix). ■ See **Compatibility** and **Side Effects**.

SIDE EFFECTS

Full scope of hypersensitivity reactions, including anaphylaxis with fatal outcome, have been reported. Agranulocytosis, “biliary sludge” or pseudolithiasis; allergic pneumonitis; bleeding episodes; burning, discomfort, and pain at injection site; casts in urine; CDAD; colitis; diarrhea; dizziness; dysgeusia; eosinophilia; elevated alkaline phosphatase, bilirubin, BUN, creatinine, AST, and ALT; headache; leukopenia; nausea and vomiting; nephrolithiasis; pancreatitis; prolonged PT; renal precipitations; seizures; thrombophlebitis. Other hematologic reactions (e.g., anemia, hemolytic anemia, hypoprothrombinemia [rare], lymphopenia, neutropenia, thrombocytopenia) may occur. Serum sickness-like reactions have occurred (e.g., arthralgia, fever, polyarthritis, skin rashes), usually after a second course of therapy. Generally resolve after cephalosporins are discontinued. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

Post-Marketing: Dermatologic reactions (e.g., allergic dermatitis, exanthema, and isolated cases of Stevens-Johnson syndrome and toxic epidermal necrolysis), oliguria, stomatitis. Fatal cases of ceftriaxone-calcium precipitates in lungs and kidneys of neonates have been reported; see **Contraindications**, **Precautions**, and **Maternal/Child**.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated (e.g., CDAD, hypersensitivity reactions, seizures, S/S of gallbladder disease). Treat hypersensitivity reactions as indicated and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of ceftriaxone. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Vitamin K may be useful in bleeding episodes, or drug may need to be discontinued. Not removed by hemodialysis. Antihistamines and corticosteroids may be indicated to manage symptoms of serum sickness.

CEFUROXIME SODIUM(sef-your-**OX**-eem **SO**-dee-um)**Antibacterial
(cephalosporin)****Zinacef****pH 5 to 8.5****USUAL DOSE**

Dependent on seriousness of infection. Usual dose is 750 mg to 1.5 Gm every 8 hours for 5 to 10 days. Maximum dose is 3 Gm every 8 hours.

Uncomplicated infections (gonococcal, pneumonia, skin and soft tissue, urinary tract): 750 mg every 8 hours.

Severe or complicated infections and bone and joint infections: 1.5 Gm every 8 hours.

Life-threatening or infections due to less susceptible organisms: 1.5 Gm every 6 hours.

Bacterial meningitis: 3 Gm every 8 hours; see [Precautions](#).

Perioperative prophylaxis: 1.5 Gm IV 30 minutes to 1 hour before incision; then 750 mg every 8 hours during prolonged procedures. 1.5 Gm at induction of anesthesia and every 12 hours to total dose of 6 Gm in open heart surgery.

PEDIATRIC DOSE

Do not exceed adult dose.

Pediatric patients 3 months of age or older: 50 to 100 mg/kg/day in equally divided doses every 6 to 8 hours (12.5 to 25 mg/kg every 6 hours or 16.7 to 33.3 mg/kg every 8 hours). Higher-end dosing used for more serious infections.

Bone and joint infections: 50 mg/kg every 8 hours. Up to 1.5 Gm/dose has been given.

Bacterial meningitis: 200 to 240 mg/kg/day in equally divided doses every 6 to 8 hours (50 to 60 mg/kg every 6 hours or 66.7 to 80 mg/kg every 8 hours); see [Precautions](#).

NEONATAL DOSE

Neonatal doses are unlabeled; see [Maternal/Child](#).

Infants under 3 months of age: One source recommends 10 to 30 mg/kg every 12 hours.

Bacterial meningitis: 100 mg/kg/day in equally divided doses every 8 or 12 hours (33.3 mg/kg every 8 hours or 50 mg/kg every 12 hours); see [Precautions](#).

DOSE ADJUSTMENTS

Reduced doses or extended intervals may be indicated in the elderly; consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy.

Adults: Reduce total daily dose if renal function impaired according to the following chart. ■ See [Drug/Lab Interactions](#).

Cefuroxime Dose Guidelines in Impaired Renal Function in Adults		
Creatinine Clearance (mL/min)	Dose	Frequency
>20 mL/min	750 mg-1.5 Gm	q 8 hr
10-20 mL/min	750 mg	q 12 hr
<10 mL/min	750 mg	q 24 hr
Hemodialysis patients	An additional dose of 750 mg at end of each dialysis session	

Pediatric patients: In pediatric patients with impaired renal function, reduce frequency as indicated in the chart for adults.

DILUTION

Reconstitute 750 mg with 8.3 mL SWFI. Reconstitute 1.5 Gm with 16 mL SWFI. Shake well. May be further diluted to 50 or 100 mL with D5W, NS, or other **compatible** infusion solution (see chart on inside back cover or literature) and given as an intermittent infusion, or added to 500 to 1,000 mL and given as a continuous infusion. Available pre-

mixed, in piggyback vials, infusion packs, and in ADD-Vantage vials for use with ADD-Vantage infusion containers.

Storage: In dry state, store between 15° and 30° C (59° to 86° F); protect from light. Reconstituted vials are stable for 24 hours at CRT or 48 hours if refrigerated. Diluted solutions may be stable for up to 7 days if refrigerated.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

May be used concomitantly with aminoglycosides (e.g., amikacin [Amikin], gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer at separate sites. Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion and lists sodium bicarbonate **incompatible** as a diluent.

Sources suggest the following **compatibilities:**

Additive: Manufacturer lists heparin (10 and 50 units/mL in NS) and potassium chloride (10 and 40 mEq/L in NS). Other sources list clindamycin (Cleocin), furosemide (Lasix), metronidazole (Flagyl IV), midazolam (Versed).

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), amiodarone (Nexterone), anidulafungin (Eraxis), atracurium (Tracrium), aztreonam (Azactam), bivalirudin (Angiomax), cisatracurium (Nimbex), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopan), fludarabine (Fludara), foscarnet (Foscavir), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), linezolid (Zyvox), melphalan (Alkeran), meperidine (Demerol), milrinone (Primacor), morphine, ondansetron (Zofran), pancuronium, pemetrexed (Alimta), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), teniposide (Vumon), thiotepa, vancomycin, vecuronium.

RATE OF ADMINISTRATION

See **Compatibility**. Injection or intermittent infusion may be given through Y-tube or three-way stopcock of infusion set.

IV injection: A single dose equally distributed over 3 to 5 minutes.

Intermittent IV: A single dose over 30 minutes.

Continuous infusion: 500 to 1,000 mL over 6 to 24 hours, depending on total dose and concentration.

ACTIONS

A broad-spectrum, second-generation cephalosporin antibiotic. Bactericidal to selected gram-negative, gram-positive, and anaerobic organisms. Effective against many otherwise resistant organisms. Inhibits bacterial cell wall synthesis. Peak serum levels achieved by end of infusion. Widely distributed. Therapeutic concentrations found in pleural fluid, joint fluid, bile, sputum, bone, aqueous humor, and CSF. Half-life is 80 minutes. Excreted in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, urinary tract, bone and joint, skin and skin structure infections, septicemia, and meningitis. Most effective against specific organisms and when mixed organisms are present (see literature). ■ Perioperative prophylaxis. ■ Used IM to treat gonorrhea.

CONTRAINDICATIONS

Previous hypersensitivity reaction to cephalosporins; see **Precautions**.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-

generation cephalosporins. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to cefuroxime. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefuroxime should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for at least 2 to 3 days after all symptoms of infection subside. ■ Continue treatment of *Streptococcus pyogenes* infections for a minimum of 10 days to decrease the risk of rheumatic fever or glomerulonephritis. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with impaired renal function, allergies, or a history of GI disease (especially colitis). ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefuroxime. ■ May be associated with a fall in prothrombin activity. Patients at risk include those with renal or hepatic impairment, patients with poor nutritional status, patients receiving a protracted course of antimicrobial therapy, and patients previously stabilized on anticoagulant therapy; see **Monitor**. ■ Mild to moderate hearing loss has been reported in a few pediatric patients treated for meningitis.

Monitor: Watch for early symptoms of a hypersensitivity reaction. ■ May cause thrombophlebitis. Use small needles and large veins, and rotate infusion sites. ■ Monitor renal function periodically during therapy. ■ Monitor PT and administer vitamin K as indicated. ■ See **Drug/Lab Interactions**; additional monitoring may be indicated (e.g., renal function, drug serum levels).

Patient Education: Report promptly any bleeding or bruising or symptoms of allergy (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: safety for use during pregnancy and breast-feeding not established. No problems documented. ■ Is used in infants under 3 months of age, but safety not established; immature renal function will increase blood levels.

Elderly: See **Dose Adjustments**. ■ Response similar to other age-groups; however, greater sensitivity of the elderly cannot be ruled out.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics such as furosemide [Lasix]). ■ **Probenecid** inhibits excretion. Reduced dose of cefuroxime may be required with concomitant use. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); bactericidal action may be negated. ■ Large amounts of **cephalosporins and/or salicylates** may induce hypoprothrombinemia (deficiency of prothrombin [factor II]). The addition of **agents that affect platelet aggregation and/or may have GI ulcerative potential** (e.g., NSAIDs [ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)] or sulfinpyrazone [Anturane]) may increase risk of hemorrhage. ■ May reduce effectiveness of **estrogen/progesterone oral contraceptives**. ■ May cause a false-negative reaction in specific **blood glucose** tests (ferricyanide). ■ False-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Chemstix). ■ False-positive **Coombs' test**. ■ See **Compatibility** and **Side Effects**.

SIDE EFFECTS

Full scope of hypersensitivity reactions including anaphylaxis. Angioedema, CDAD, colitis, decreased hemoglobin, hematocrit, or platelet functions; diarrhea; dyspnea; elevation of AST, ALT, total bilirubin, alkaline phosphatase, LDH, and BUN (transient); eosinophilia; fever; leukopenia; local site pain; nausea; oral thrush; prolonged PT; seizures (large doses and decreased renal function); transient neutropenia; thrombocytopenia; thrombophlebitis; vaginitis; vomiting. Hypoprothrombinemia (rare) and hemolytic anemia may occur. Serum sickness-like reactions have occurred (e.g., arthralgia, fever, polyarthritis, skin rashes), usually after a second course of therapy. Generally resolve after cephalosporins are discontinued. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal

dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Treat hypersensitivity reactions and resuscitate as necessary. Hemodialysis or peritoneal dialysis may be somewhat useful in overdose. Antihistamines and corticosteroids may be indicated to manage symptoms of serum sickness.

CENTRUROIDES (SCORPION) IMMUNE F(ab')₂ (EQUINE) INJECTION

Antivenin

(SEN-troo-roy-deez [SKOR-pee-on] i-MUNE-fab-too)

Anascorp

USUAL DOSE

Initiate as soon as possible after scorpion sting in patients who develop clinically important signs of scorpion envenomation (e.g., loss of muscle control, roving or abnormal eye movements, slurred speech, respiratory distress, excessive salivation, frothing at the mouth, and vomiting).

Initial dose: Entire contents of 3 vials is the recommended initial dose based on clinical experience. Observe during and for up to 1 hour after the initial dose is administered. Desired outcome is resolution of signs of envenomation.

Repeat doses: If control of symptoms is not accomplished by the initial dose, infuse one vial at a time at intervals of 30 to 60 minutes. Observe as above for resolution of S/S of envenomation. This dose may be repeated until initial control has been established. Maximum number of doses that can be administered safely is unknown.

Summary of Dosing for Centruroides (Scorpion) Immune F(ab')₂ Equine Injection

Initial dose	3 vials	Reconstitute each vial with 5 mL of NS. Combine and further dilute to a total of 50 mL with NS. Infuse IV over 10 minutes.
Additional dose(s)	As needed	Administer one vial at a time at 30- to 60-minute intervals. Dilute to a total of 50 mL with NS. Infuse IV over 10 minutes.

PEDIATRIC DOSE

See [Usual Dose](#). Absolute venom dose following scorpion sting is expected to be the same in pediatric patients and adults; no dose adjustment for age is required. See [Maternal/Child](#).

DILUTION

Initial dose: Reconstitute each of the 3 vials with 5 mL NS. Mix by continuous gentle swirling. Combine the contents of the reconstituted vials and further dilute to a total volume of 50 mL with NS. For initial and repeat doses, the solution should be clear; do not use if turbidity is present.

Repeat doses: Reconstitute each single vial with 5 mL NS. Mix by continuous gentle swirling. Further dilute the contents of the reconstituted vial to a total volume of 50 mL with NS.

Filters: Specific information not available.

Storage: Store at RT (up to 25° C [77° F]). Temperature excursions are permitted up to 40° C (104° F). Do not freeze. Discard partially used vials.

COMPATIBILITY

Specific information not available. Consider administration through a separate line without mixing with other IV fluids or medications due to specific use and potential for anaphylaxis.

RATE OF ADMINISTRATION

A single dose equally distributed over 10 minutes.

ACTIONS

A venom-specific F(ab')₂ fragment of equine immune globulin G (IgG) obtained from horse plasma immunized with scorpion venom. Obtained by pepsin digestion of horse plasma to remove the F_c portion of immune globulin, followed by fractionation and purification steps. Binds and neutralizes venom toxins, facilitating redistribution away from target tissues and elimination from the body. Half-life ranges from 102 to 216 hours. Time from the start of injection to resolution of clinical S/S averages 1.42 hours (range 0.2 to 20.5 hours).

INDICATIONS AND USES

Treatment of adult and pediatric patients with clinical signs of scorpion envenomation.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Administer under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities and appropriate emergency drugs to monitor the patient and respond to any medical emergency. ■ Severe hypersensitivity reactions, including anaphylaxis, may occur. Patients with a known allergy to horse protein are particularly at risk for anaphylaxis. Patients who have had a previous equine antivenom/antitoxin may be sensitized to equine proteins and be at risk for severe hypersensitivity reactions. ■ Delayed hypersensitivity reactions (e.g., serum sickness) have been reported. ■ Made from equine (horse) plasma; may carry and transmit infectious agents (e.g., viruses). ■ Contains trace amounts of cresol; may cause localized reactions and generalized myalgias.

Monitor: Observe closely for S/S of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria); see **Antidote**. ■ Monitor closely during infusion and for a minimum of 1 hour to assess if clinically important signs of envenomation have resolved. ■ Follow-up visits are recommended to monitor for S/S of serum sickness (e.g., arthralgia, fever, myalgia, rash).

Patient Education: Promptly report any S/S of delayed hypersensitivity reactions or serum sickness (e.g., arthralgia, fever, joint pain, lymphadenopathy, malaise, pruritus, rash). May occur up to 14 days following discharge.

Maternal/Child: Category C: Use during pregnancy only if clearly needed. ■ Use caution; safety for use during breast-feeding not established. ■ Safety and effectiveness comparable in pediatric and adult patients. Pediatric patients generally experienced a slightly faster time to resolution (1.28 ± 0.8 hours) compared with adults (1.91 ± 1.4 hours).

Elderly: Safety and effectiveness comparable to overall patient population.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been conducted. ■ Time to resolution of symptoms was not affected by the use of sedatives.

SIDE EFFECTS

The most common side effects were fever, nausea, pruritus, rash, and vomiting. Hypersensitivity reactions, including anaphylaxis, have occurred. Less common side effects included cough, diarrhea, fatigue, headache, lethargy, myalgia, and rhinorrhea. Other rarely reported side effects included aspiration, ataxia, hypoxia, pneumonia, respiratory distress, serum sickness, and swelling of the eyes.

Post-Marketing: Chest tightness, palpitations.

ANTIDOTE

Keep the physician informed of all side effects and the extent or progression of envenomation. Discontinue the drug and treat hypersensitivity reactions and/or anaphylaxis immediately with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

CETUXIMAB **BBW**

(seh-TUX-ih-mab)

Recombinant monoclonal antibody
Antineoplastic

Erbix

pH 7 to 7.4

USUAL DOSE

Premedication: To prevent or attenuate severe infusion reactions, premedicate with diphenhydramine 50 mg IV 30 to 60 minutes before the first dose. Premedication for subsequent infusions should be based on clinical judgment and the presence/severity of previous infusion reactions.

Squamous cell carcinoma of the head and neck (SCCHN) in combination with radiation therapy or in combination with platinum-based therapy with 5-FU: *First infusion:* 400 mg/M² as an initial loading dose 1 week **before the initiation** of a course of radiation therapy or on the day of initiation of platinum-based therapy with 5-FU. Complete cetuximab administration 1 hour before beginning platinum-based therapy with 5-FU.

Subsequent infusions: 250 mg/M² once each week for the duration of radiation therapy (6 to 7 weeks) or until disease progression or unacceptable toxicity when administered with platinum-based therapy with 5-FU. Complete infusion 1 hour before radiation therapy or platinum-based therapy with 5-FU.

Squamous cell carcinoma of the head and neck as monotherapy:

First infusion: 400 mg/M² as an initial loading dose. Complete infusion 1 hour before FOLFIRI (irinotecan, 5-FU, leucovorin) for both first and subsequent infusions.

Subsequent infusions: 250 mg/M² once each week as a maintenance dose. Continue until disease progression or unacceptable toxicity.

Colorectal cancer in combination with irinotecan, FOLFIRI, or as monotherapy: Determine K-Ras mutation and epidermal growth factor receptor (EGFR)-expression status before initiating treatment; see **Indications**.

First infusion: 400 mg/M² as an initial loading dose.

Subsequent infusions: 250 mg/M² once each week as a maintenance dose. Continue until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

No dose adjustment required based on age, gender, race, or hepatic or renal function. ■ No dose adjustment indicated for mild to moderate skin toxicity. ■ If a mild or moderate (Grade 1 or 2) or non-serious (Grade 3) infusion reaction occurs (e.g., chills, dyspnea, fever), reduce the infusion rate by 50% for the balance of that infusion and for all further infusions. ■ Permanently discontinue cetuximab therapy if a serious infusion reaction requiring medical intervention and/or hospitalization occurs. ■ If a severe acneiform rash is experienced, adjust infusion schedule according to the following chart. **Dose modification is not recommended for severe radiation dermatitis.**

Cetuximab Dose Modification Guidelines for Occurrences of Severe Acneiform Rash			
Severe Acneiform Rash	Cetuximab	Outcome	Cetuximab Dose Modification
1st occurrence	Delay infusion 1 to 2 weeks	Improvement	Continue at 250 mg/M ²
		No improvement	Discontinue cetuximab
2nd occurrence	Delay infusion 1 to 2 weeks	Improvement	Reduce dose to 200 mg/M ²
		No improvement	Discontinue cetuximab
3rd occurrence	Delay infusion 1 to 2 weeks	Improvement	Reduce dose to 150 mg/M ²
		No improvement	Discontinue cetuximab
4th occurrence	Discontinue cetuximab		

DILUTION

Available in 100 mg/50 mL and 200 mg/100 mL vials (2 mg/mL). Multiple vials may be needed for each dose. May pool volume required to provide calculated dose into an empty evacuated container. Solution is clear and may contain small amounts of easily visible white particulates. **Do not shake or dilute.**

Filters: Use of a low-protein binding, 0.22-micron in-line filter is required; see [Rate of Administration](#).

Storage: Refrigerate vials at 2° to 8° C (36° to 46° F). Do not freeze. Preparations in infusion containers are chemically and physically stable for 12 hours if refrigerated or 8 hours at CRT. Discard remaining solution in the infusion container after 8 hours at CRT. Discard any unused portion of the vial.

COMPATIBILITY

Specific information not available; however, manufacturer states, “Cetuximab should be piggybacked to the patient’s infusion line.” Manufacturer recommends flushing the infusion line with NS before the infusion and at the end of the infusion to ensure delivery of the entire dose.

RATE OF ADMINISTRATION

Do not administer as an IV push or bolus. Must be given as an infusion via an infusion pump or a syringe pump. Must be administered through a low-protein binding, 0.22-micron in-line filter placed as proximal to the patient as is practical and piggybacked to the patient’s infusion line. Prime infusion line with cetuximab. Flush the infusion line with NS after the infusion.

First infusion: The initial loading dose should be infused evenly distributed over 2 hours (120 minutes). Do not exceed a rate of 10 mg/min (5 mL/min). In patients who have mild to moderate infusion reactions, decrease the rate of administration by 50% and continue this reduced rate for all subsequent infusions. See [Dose Adjustments](#).

Subsequent infusions: Weekly maintenance doses should be infused evenly distributed over 1 hour (60 minutes). Do not exceed a rate of 10 mg/min (5 mL/min). In patients who have mild to moderate infusion reactions, decrease the rate of administration by 50% and continue this reduced rate for all subsequent infusions. See [Dose Adjustments](#).

ACTIONS

An antineoplastic agent. A humanized IgG₁ monoclonal antibody produced by recombinant DNA technology. Designed to bind to the epidermal growth factor receptor (EGFR) found on the surface of both normal cells and malignant tumor cells. It interferes with the growth and survival of cancer cells by binding to tumor cells that overexpress the EGFR so that the normal (natural) EGFR cannot bind to the tumor cells and stimulate them to grow. Anti-tumor effects were not observed in tumor cells that did not express the EGFR. With the recommended dose regimen, cetuximab concentrations reached steady-state levels by the third weekly infusion with a mean half-life of 112 hours (range 63 to 230 hours). IgG antibodies may cross the placental barrier and may be secreted in breast milk.

INDICATIONS AND USES

Treatment of locally or regionally advanced SCCHN in combination with radiation therapy. ■ First-line treatment of patients with recurrent locoregional disease or metastatic SSCHN in combination with platinum-based therapy with 5-FU. ■ Used as a single agent for the treatment of patients with recurrent or metastatic SCCHN in whom platinum-based chemotherapy has failed. ■ Treatment of K-Ras mutation–negative (wild type), epidermal growth factor receptor (EGFR)–expressing metastatic colorectal cancer (mCRC) as determined by FDA-approved tests for this use. Used in combination with FOLFIRI (irinotecan, 5-fluorouracil, leucovorin) for first-line treatment. Used in combination with irinotecan (Camptosar) in patients who are refractory to irinotecan-based chemotherapy. Used as a single agent in patients who cannot tolerate irinotecan or in those who have failed treatment with both irinotecan (Camptosar) and oxaliplatin (Eloxatin) based regimens.

Limitation of use: Not recommended for treatment of K-Ras mutation-positive colorectal cancer.

CONTRAINDICATIONS

Manufacturer states, “None.” However, a repeat dose is contraindicated in any patient who has a severe infusion reaction (Grade 3 or 4). ■ Use with caution in patients with known hypersensitivity to murine proteins, cetuximab, or any of its components.

PRECAUTIONS

Do not administer as an IV push or bolus. Must be given as an infusion via an infusion pump or a syringe pump. ■ Should be administered by or under the direction of the physician specialist in a facility equipped to monitor the patient and respond to any medical emergency. ■ Severe infusion reactions and hypersensitivity reactions have occurred, and some have been fatal (less than 1 in 1,000). Most severe reactions occur with the first infusion and have occurred even with the use of prophylactic antihistamines. S/S of severe reactions may include hypotension, rapid onset of airway obstruction (e.g., bronchospasm, hoarseness, stridor), urticaria, and/or cardiac arrest. Some patients experienced their first infusion reaction during later infusions. ■ Cardiopulmonary arrest and/or sudden death has been reported in patients with SCCHN treated with cetuximab and radiation and in patients with SCCHN treated with cetuximab and a combination of platinum-based therapy with 5-FU. Carefully consider the use of cetuximab in combination with radiation therapy or platinum-based therapy with 5-FU in patients with head and neck cancer who have a history of arrhythmias, coronary artery disease, or congestive heart failure. ■ Pulmonary toxicity, including interstitial lung disease (ILD), has been reported. Interstitial pneumonitis with non-cardiogenic pulmonary edema resulted in the death of a patient. Use caution in patients with pre-existing fibrotic lung disease. ■ Severe dermatologic toxicities, including acneiform rash, skin drying, and fissuring, and inflammatory and infectious sequelae (e.g., blepharitis [inflammation of the eyelids], cellulitis [diffuse subcutaneous inflammation of connective tissues], cheilitis [inflammation of the lip], conjunctivitis, cyst, hypertrichosis, and keratitis/ulcerative keratitis with decreased visual acuity), have occurred and may be dose limiting. Complications involving *S. aureus* sepsis and abscesses requiring incision and drainage have been reported. ■ Safety for use in combination with radiation therapy and cisplatin has not been established. Death and serious cardiotoxicity have been seen in trials. ■ A protein substance, it has the potential for producing immunogenicity. However, there does not appear to be a relationship between the appearance of antibodies to cetuximab and the safety or anti-tumor activity of the molecule. ■ See [Monitor](#) and [Antidote](#).

Monitor: Expression of EGFR has been detected in nearly all patients with SCCHN. Evidence of EGFR-expressing, K-Ras mutation-negative (wild type) mCRC must be confirmed before initiating treatment in patients with colorectal cancers. Testing should be performed by a laboratory with demonstrated proficiency to avoid unreliable results. The DakoCytomation test kit was used during clinical studies. ■ Monitor VS frequently. ■ Observe patient closely during every infusion and for at least 1 hour after each infusion. Infusion reactions can occur at any time, even in patients who are premedicated with

diphenhydramine and/or who have not had infusion reactions with previous doses; see **Precautions**. S/S of Grade 1 and 2 infusion reactions include chills, fever, and dyspnea. S/S of severe reactions may include hypotension, rapid onset of airway obstruction (e.g., bronchospasm, hoarseness, stridor), loss of consciousness, MI, shock, urticaria, and/or cardiac arrest. Increase observation period for patients who experience infusion reactions. ■ Monitor magnesium, calcium, and potassium periodically during therapy and for 8 weeks following completion. Electrolyte loss may occur from days to months after initiating cetuximab. Oral or parenteral electrolyte replacement may be indicated. ■ Monitor for S/S of dermatologic toxicity such as acneiform rash (e.g., multiple follicular-pustular-appearing lesions on the face, upper chest, back, and extremities), skin drying, and fissuring. Dose adjustments or termination of therapy may be indicated; see **Dose Adjustments** and **Precautions**. The first onset of acneiform rash may occur within the first 2 weeks, may subside when treatment is discontinued, or may persist for longer periods. Inflammatory or infectious sequelae (e.g., blepharitis, cellulitis, cheilitis, cyst) may develop and should be treated promptly. ■ Monitor for S/S of interstitial lung disease (e.g., dyspnea on exertion, nonproductive cough, inspiratory crackles on chest examination). Worsening symptoms may require interruption or discontinuation of cetuximab therapy. ■ See **Dose Adjustments**, **Rate of Administration**, **Precautions**, and **Antidote**.

Patient Education: Avoid pregnancy; nonhormonal birth control recommended for both females and males during therapy and for 6 months following the last dose. See **Maternal/Child**. Women should report a suspected pregnancy immediately. ■ Review potential side effects before therapy. ■ Report any unusual or unexpected symptoms or side effects promptly, especially infusion-related reactions (e.g., dyspnea, feeling of faintness, hives, wheezing). ■ Sunlight can worsen the skin reactions that may occur. Limit exposure to the sun, and wear sunscreen, protective clothing, and hats when outdoors. ■ See Appendix D, p. 1255.

Maternal/Child: Category C: has the potential to be transferred from the mother to the developing fetus; avoid pregnancy. Use during pregnancy or in any woman not using adequate contraception methods only if benefit justifies the potential risk to the fetus. ■ Discontinue breast-feeding during treatment with cetuximab and for 60 days following the last dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Safety and effectiveness similar to younger adults.

DRUG/LAB INTERACTIONS

No evidence of pharmacokinetic interactions between cetuximab and irinotecan. ■ No other drug interaction studies have been completed. ■ The safety of combination use with **cisplatin** has not been established. Death and serious cardiotoxicity have been observed when **cetuximab, cisplatin, and radiation therapy** have been used concomitantly.

SIDE EFFECTS

The most common side effects are cutaneous adverse reactions (e.g., nail changes, pruritus, rash), diarrhea, headache, and infection. The most serious side effects are cardiopulmonary arrest, dermatologic toxicity, infusion reactions, interstitial lung disease, pulmonary embolus, radiation dermatitis, renal failure, and sepsis.

SCCHN: Confusion; dehydration; diarrhea; dry mouth; elevated ALT, AST, and alkaline phosphatase; mucositis/stomatitis/pharyngitis; and radiation dermatitis/toxicities occurred with more frequency in this group and were considered serious.

Colorectal cancer: Dehydration, diarrhea, fatigue, fever, kidney failure, neutropenia, pulmonary embolus, rash, and sepsis occurred with more frequency in this group and were considered serious.

All diagnoses: Acneiform rash, asthenia, chills, constipation, dysphagia, electrolyte abnormalities (e.g., hypocalcemia, hypokalemia, hypomagnesemia), fever, malaise, nausea and vomiting, and weight loss occur frequently. Other side effects reported include alopecia, anemia, anorexia, back pain, conjunctivitis, cough (increased), depression, dyspepsia, dyspnea, headache, insomnia, leukopenia, nail disorders (paronychia inflammation of the toes and fingers), pain, peripheral edema, pruritus, skin disorders, stomatitis.

Post-Marketing: Aseptic meningitis.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Hypersensitivity or infusion-related side effects may resolve with reduction in the rate of infusion by 50% and by continued use of pre-medication with diphenhydramine (Benadryl). Discontinue cetuximab immediately for severe infusion reactions; **do not re-challenge**. Treat hypersensitivity or infusion reactions as indicated; may require use of epinephrine, corticosteroids, diphenhydramine, bronchodilators (e.g., albuterol [Ventolin], aminophylline), IV saline, oxygen, and/or acetaminophen. Dermatologic toxicities may be dose limiting (see **Dose Adjustments**) or may be treated with topical and/or oral antibiotics as appropriate. Use of topical corticosteroids is not recommended. Interrupt cetuximab with the onset of acute or worsening pulmonary symptoms. Treat as indicated; permanently discontinue cetuximab for confirmed interstitial lung disease. Replace electrolytes as indicated. Resuscitate if indicated.

CHLORAMPHENICOL SODIUM SUCCINATE **BBW**

Antibacterial

(klor-am-FEN-ih-kohl SO-dee-um SUK-suh-nayt)

Chloromycetin

pH 6.4 to 7

USUAL DOSE

For all age levels, determine baseline blood studies before administration. Avoid repeated courses of this drug if at all possible. Treatment should not be continued longer than the time required to produce a cure with little or no risk or relapse of disease.

Adults and pediatric patients with mature metabolic processes (e.g., normal kidney and liver function): 12.5 mg/kg every 6 hours. In exceptional cases, infections due to moderately resistant organisms may require up to 25 mg/kg every 6 hours. Severe infections (e.g., bacteremia or meningitis), especially when adequate cerebrospinal fluid concentrations are desired, may require up to 25 mg/kg every 6 hours. These increased doses must be reduced to 12.5 mg/kg every 6 hours as soon as possible. Maximum dose is 4 Gm/24 hr. Change to oral form as soon as practical.

NEONATAL DOSE

See **Maternal/Child**.

Infants under 2 weeks of age or older infants with immature metabolic processes (e.g., premature infants): 6.25 mg/kg every 6 hours. Close monitoring of blood concentrations by microtechniques is recommended (information available from manufacturer).

Another source suggests a **loading dose** followed by **maintenance doses** based on age and weight. The first maintenance dose should be given 12 hours after the loading dose.

Loading dose: 20 mg/kg.

Maintenance dose: Under 7 days of age or 7 days of age or older and under 2 kg: 25 mg/kg of body weight once daily.

Over 7 days of age and over 2 kg: 25 mg/kg every 12 hours.

Infants 2 weeks of age or older with mature metabolic processes: 6.25 mg/kg every 6 hours. May increase to 12.5 mg/kg every 6 hours if indicated by severity of infection. See comments under **Adult Dose**.

DOSE ADJUSTMENTS

Reduce dose and/or initiate oral therapy as soon as feasible. ■ Reduce dose and/or extend intervals in infants and children with immature metabolic processes. See specific dose recommendations. Close monitoring of blood concentrations by microtechniques is recommended. ■ In patients with immature or impaired hepatic or renal function, dose

reduction may be required. ■ Dosing should be cautious in the elderly. Consider decreased organ function and concomitant disease or drug therapy.

DILUTION

Each 1 Gm should be reconstituted with 10 mL of SWFI or D5W to prepare a 10% solution (100 mg/mL). May be further diluted in 50 to 100 mL of D5W for intermittent infusion. Give through Y-tube, three-way stopcock, or additive infusion set.

Storage: Store at CRT. Administer within 24 hours of preparation.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Solution: Most common infusion solutions.

Additive: Amikacin (Amikin), aminophylline, ascorbic acid, calcium chloride, calcium gluconate, colistimethate (Coly-Mycin M), dimenhydrinate, dopamine, ephedrine, heparin, hydrocortisone sodium succinate (Solu-Cortef), lidocaine, lincomycin (Lincocin), magnesium sulfate, methylglucate, methylprednisolone (Solu-Medrol), nafcillin (Nallpen), oxacillin (Bactocill), oxytocin (Pitocin), penicillin G potassium and sodium, pentobarbital (Nembutal), phenylephrine (Neo-Synephrine), phytonadione (vitamin K₁), potassium chloride (KCl), ranitidine (Zantac), sodium bicarbonate, verapamil.

Y-site: Acyclovir (Zovirax), cyclophosphamide (Cytosan), enalaprilat (Vasotec IV), esmolol (Brevibloc), foscarnet (Foscavir), hydromorphone (Dilaudid), labetalol, magnesium sulfate, meperidine (Demerol), morphine, nicardipine (Cardene IV), tacrolimus (Prograf).

RATE OF ADMINISTRATION

IV injection: 1 Gm or fraction thereof over a minimum of 1 minute.

Intermittent infusion: A single dose over 10 to 30 minutes.

ACTIONS

Effective against a wide range of gram-positive and gram-negative bacteria. Primarily bacteriostatic. May be bactericidal at high concentrations or against highly susceptible organisms. Acts by inhibiting protein synthesis. Well distributed in therapeutic doses throughout the body, especially in the liver and kidneys. Lowest concentrations are found in the brain and spinal fluid; however, chloramphenicol enters cerebrospinal fluid even in the absence of meningeal inflammation, appearing in concentrations about half of those found in the blood. Partially metabolized. Excreted in urine, bile, and feces. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Only in serious infections in which potentially less dangerous drugs are ineffective or contraindicated; acute *Salmonella typhi* infections, meningial infections (e.g., *Hemophilus influenzae*), bacteremia, rickettsia, lymphogranuloma psittacosis, and other serious gram-negative infections. ■ Cystic fibrosis regimens.

CONTRAINDICATIONS

Known chloramphenicol sensitivity. Must not be used in the treatment of trivial infections.

PRECAUTIONS

Serious blood dyscrasias (e.g., aplastic anemia, hypoplastic anemia, thrombocytopenia, and granulocytopenia) resulting in irreversible bone marrow suppression and death are known to occur. Aplastic anemia resulting in leukemia has been reported. Blood dyscrasias have occurred after both short-term and longer-term therapy. Do not use if potentially less dangerous agents would be effective. ■ Administration in a hospital with facilities for monitoring the patient and responding to any medical emergency is preferred. ■ Sensitivity studies mandatory to determine susceptibility of the causative organism not only to chloramphenicol but also to other less dangerous drugs. ■ Superinfection caused by overgrowth of nonsusceptible organisms, including fungi, is possible. Treatment should not be continued longer than required to produce a cure with little or no risk of relapse of the disease. ■ For IV use only. ■ A reversible type of bone mar-

row suppression characterized by vacuolization of the erythroid cells, reduction of reticulocytes, and leukopenia is dose related and usually responds to withdrawal of chloramphenicol. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with chloramphenicol. ■ Use caution in patients with impaired hepatic and/or renal function.

Monitor: Obtain blood studies (CBC) before initiating therapy and approximately every 2 days during therapy; discontinue drug if blood studies show any indication of anemia, leukopenia, reticulocytopenia, thrombocytopenia, or any blood study findings attributable to chloramphenicol. ■ Monitor chloramphenicol serum levels at least weekly, and more often if indicated (e.g., impaired liver or kidney function, immature metabolic processes, suspicion of beginning blood dyscrasias). ■ Therapeutic levels range between 15 and 25 mcg/mL for meningitis; 10 and 20 mcg/mL for other infections. Trough levels should range between 5 and 15 mcg/mL for meningitis; 5 and 10 mcg/mL for other infections. ■ Monitor hepatic and renal function as indicated; see [Dose Adjustments](#). ■ See [Drug/Lab Interactions](#).

Patient Education: Promptly report fever, sore throat, tiredness, unusual bleeding, or bruising. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category C: no studies documented. Use during pregnancy with extreme caution; may have toxic effects on fetus. ■ Discontinue breast-feeding. ■ Blood concentration in all premature and full-term neonates under 2 weeks of age differs from that of other neonates. Use caution, lower doses, and/or extended intervals in premature infants and newborns. May cause gray syndrome (e.g., abdominal distension with or without emesis, progressive pallid cyanosis, vasomotor collapse, irregular respiration, death within a few hours of onset of symptoms); monitor serum levels; see [Precautions/Monitor](#).

Elderly: See [Dose Adjustments](#). ■ Response similar to that seen in younger patients. ■ Monitor renal function.

DRUG/LAB INTERACTIONS

May cause irreversible bone marrow suppression. Avoid concurrent therapy with **drugs that cause blood dyscrasias** (e.g., penicillins, hydantoins [phenytoin (Dilantin)]), **other bone marrow suppressants** (e.g., cytotoxic drugs, radiation therapy). ■ Increases serum levels of **oral antidiabetics** (e.g., chlorpropamide [Diabinese]) and increases hypoglycemic effects; dose reduction may be required. ■ May be synergistic with or antagonize effects of **aminoglycosides, cephalosporins, and penicillins**. (Is used with ampicillin in pediatric patients.) ■ Chloramphenicol can inhibit specific P₄₅₀ enzymes; reduced metabolism and increased serum levels may occur in agents also metabolized by that route (e.g., chlorpropamide [Diabinese], phenobarbital, phenytoin [Dilantin], tolbutamide, warfarin [Coumadin]). ■ Concurrent use with **hydantoins** (e.g., phenytoin [Dilantin]) may decrease or increase the effectiveness of chloramphenicol. Hydantoin levels may be increased, resulting in toxicity. ■ Concurrent use with **phenobarbital** may decrease chloramphenicol serum levels and increase phenobarbital serum levels, resulting in phenobarbital toxicity. Monitor serum levels of both drugs if concurrent use is indicated. ■ Concurrent administration with **anticoagulants** (e.g., heparin, warfarin [Coumadin]) may prolong PT. ■ May increase **serum iron levels**. ■ May delay response to **antianemia drugs** (e.g., iron preparations, vitamin B₁₂, folic acid). Avoid concurrent use in patients with anemia if possible. ■ **Rifampin** increases chloramphenicol metabolism and decreases its effects.

SIDE EFFECTS

Blood dyscrasias (e.g., aplastic anemia, hypoplastic anemia, granulocytopenia, thrombocytopenia) may result in irreversible bone marrow suppression and death. CDAD, confusion, depression, diarrhea, fever, gray syndrome of newborns and infants, headache, hypersensitivity reactions (e.g., angioedema, anaphylaxis, fever, rashes, urticaria), leukemia,

nausea, optic and peripheral neuritis, paroxysmal nocturnal hemoglobinuria, pseudo-membranous colitis, rashes, stomatitis, vomiting, and many others. **May be fatal.**

ANTIDOTE

Notify the physician immediately of any adverse symptoms. Discontinue the drug upon appearance of anemia, leukopenia, reticulocytopenia, thrombocytopenia, or any other blood study findings attributable to chloramphenicol. Discontinue the drug for symptoms of optic and peripheral neuritis. Monitoring of plasma levels is imperative in all patients and especially in neonates. Treat hypersensitivity reactions as indicated. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Resuscitate as necessary.

CHLORPROMAZINE HYDROCHLORIDE **BBW**

(klor-**PROH**-mah-zeen hy-droh-**KLOR**-eyed)

Phenothiazine
Antipsychotic
Antiemetic

Thorazine

pH 3 to 5

USUAL DOSE

Use of the IV route is reserved for the treatment of acute nausea and vomiting in surgery, intractable hiccups, and tetanus.

Acute nausea and vomiting in surgery: 2 mg. May repeat at 2-minute intervals as indicated. Do not exceed 25 mg. Usually given as an infusion.

Intractable hiccups: 25 to 50 mg diluted in 500 to 1,000 mL of NS. Given as a slow IV infusion with patient flat in bed. Monitor BP closely.

Tetanus: 25 to 50 mg as an infusion of at least 1 mg/mL. Individualize dose to patient response and tolerance. Repeat every 6 to 8 hours. Usually given in conjunction with barbiturates.

PEDIATRIC DOSE

See [Maternal/Child](#). IV route rarely used for pediatric patients. Not recommended for use in infants less than 6 months of age.

Acute nausea and vomiting in surgery, pediatric patients 6 months of age or older: 1 mg. May repeat at 2-minute intervals as indicated. Monitor for hypotension. Another source suggests 2.5 to 4 mg/kg/24 hr in equally divided doses every 6 to 8 hours (0.625 to 1 mg/kg every 6 hours or 0.83 to 1.33 mg/kg every 8 hours). Usual IV/IM dose does not exceed 2.5 to 4 mg/kg/24 hr or 40 mg/24 hr (whichever is less) in pediatric patients 6 months to 5 years of age or up to 50 lbs, and 75 mg/24 hr in pediatric patients 5 to 12 years of age.

Tetanus: 0.55 mg/kg of body weight (0.25 mg/lb) every 6 to 8 hours. Do not exceed 40 mg/24 hr for up to 23 kg (50 lbs) and 75 mg/24 hr for up to 50 kg (50 to 100 lbs), except in severe cases.

DOSE ADJUSTMENTS

Adjust dose to the individual and severity of condition. Reduce dose of any medication potentiated by phenothiazines by one fourth to one half. See [Drug/Lab Interactions](#). ■ Reduce dose by one fourth to one half in the elderly, debilitated patients, or emaciated patients, and increase very gradually by response.

DILUTION

Each 25 mg (1 mL) must be diluted with 24 mL of NS for injection. 1 mL will equal 1 mg. May be further diluted in 500 to 1,000 mL of NS and given as an infusion. Handle carefully; may cause contact dermatitis. Sensitive to light. Slightly yellow color does not alter potency. Discard if markedly discolored.

Storage: Store at CRT. Protect from light and freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Ascorbic acid, ethacrynic acid (Edecrin), theophylline.

Y-site: Cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), docetaxel (Taxotere), doxorubicin liposomal (Doxil), famotidine (Pepcid IV), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), ondansetron (Zofran), oxaliplatin (Eloxatin), potassium chloride (KCl), propofol (Diprivan), remifentanyl (Ultiva), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Titrate to symptoms and vital signs. See **Precautions**.

IV injection: Each 1 mg or fraction thereof over 1 minute.

Infusion: Given very slowly. Do not exceed 1 mg/min.

Pediatric rate: Do not exceed 1 mg or fraction thereof over 2 minutes.

ACTIONS

A phenothiazine derivative with effects on the central, autonomic, and peripheral nervous systems. A psychotropic agent. Decreases anxiety and tension, relaxes muscles, produces sedation, and tranquilizes. Has an antiemetic effect and potentiates CNS depressants. Has strong antiadrenergic and anticholinergic activity. Also possesses slight antihistaminic and antiserotonin activity. Onset of action is prompt and of short duration in small IV doses. Extensively metabolized in liver and kidney and excreted primarily in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

The IV route is used only for the treatment of acute nausea and vomiting in surgery, the treatment of intractable hiccups, and as an adjunct in the treatment of tetanus. ■ Used IM or PO for the treatment of schizophrenia and the management of psychotic disorders. ■ Also indicated IM, PO, or rectally to relieve restlessness and apprehension before surgery, to manage acute intermittent porphyria, to control manic episodes in manic-depressive illness, and to treat severe behavioral problems in pediatric patients.

Unlabeled uses: Treatment of phencyclidine (PCP) psychosis. ■ Treatment of migraine headaches (IV or IM). ■ To reduce choreiform movements of Huntington's disease.

CONTRAINDICATIONS

Hypersensitivity to phenothiazines, comatose or severely depressed states, or the presence of large amounts of CNS depressants (e.g., alcohol, barbiturates, narcotics).

PRECAUTIONS

Not approved for dementia-related psychosis; mortality risk in elderly dementia patients taking conventional or atypical antipsychotics is increased; most deaths are due to cardiovascular or infectious events. ■ Use of the IV route is reserved for the treatment of acute nausea and vomiting in surgery, intractable hiccups, and tetanus. IM injection preferred. ■ Use caution in patients with bone marrow suppression; glaucoma; cardiovascular, liver, renal, and chronic respiratory diseases; and acute respiratory diseases of pediatric patients. ■ Re-exposure of patients who have experienced jaundice, skin reactions, or blood dyscrasias with a phenothiazine is not recommended. Cross-sensitivity may occur. ■ May produce ECG changes (e.g., prolonged QT interval, changes in T waves). ■ Use with caution in patients with a history of seizure disorders; may lower seizure threshold. ■ Extrapyramidal symptoms caused by chlorpromazine may be confused with CNS signs of an undiagnosed disease (e.g., Reye's syndrome or encephalopathy). ■ May mask diagnosis of brain tumor, drug intoxication, and intestinal obstruction. ■ Tardive dyskinesia (potentially irreversible involuntary dyskinesic movements) may develop. Use smallest doses and shortest duration of therapy to minimize risk. ■ Neuroleptic malignant syndrome (NMS) characterized by hyperpyrexia, muscle rigidity, altered mental status, and autonomic instability has been reported; see **Antidote**. ■ May cause paradoxical excitation in

pediatric patients and the elderly. ■ Use phenothiazines with extreme caution in pediatric patients with a history of sleep apnea, a family history of SIDS, or in the presence of Reye's syndrome. ■ May contain sulfites; use caution in patients with asthma. ■ Taper dose gradually following high dose or extended therapy to prevent possible occurrence of withdrawal symptoms (e.g., dizziness, gastritis, nausea, tremors, and vomiting).

Monitor: Keep patient in supine position throughout treatment and for at least ½ hour after treatment. Ambulate slowly and carefully; may cause postural hypotension. ■ Monitor BP and pulse before and during administration and between doses. ■ Cough reflex is often depressed; monitor closely if nauseated or vomiting to prevent aspiration. ■ Anticholinergic and cardiac effects may be troublesome during anesthesia. For patients receiving phenothiazines, taper and discontinue preoperatively if they will not be continued after surgery. ■ May discolor urine pink to reddish brown. ■ Photosensitivity of skin is possible. ■ See [Drug/Lab Interactions](#).

Patient Education: Request assistance for ambulation; may cause dizziness or fainting. ■ Observe caution performing tasks that require alertness. ■ Avoid use of alcohol and other CNS depressants (e.g., diazepam [Valium], narcotics). ■ Possible eye and skin photosensitivity. Avoid unprotected exposure to sun. ■ Urine may discolor to pink or reddish brown.

Maternal/Child: See [Precautions](#) and [Contraindications](#). ■ Category C: use during pregnancy only when clearly needed. Use near term may cause maternal hypotension and adverse neonatal effects (e.g., extrapyramidal syndrome, hyperreflexia, hyporeflexia, jaundice). ■ Fetuses and infants have a reduced capacity to metabolize and eliminate; may cause embryo toxicity, increase neonatal mortality, or cause permanent neurologic damage. May contain benzyl alcohol; use not recommended in neonates. ■ Not recommended during breast-feeding. Increases risk of dystonia and tardive dyskinesia. ■ Children metabolize antipsychotic agents more rapidly than adults and are at increased risk to develop extrapyramidal actions, especially during acute illness (e.g., chickenpox, CNS infections, dehydration, gastroenteritis, measles); monitor closely.

Elderly: See [Dose Adjustments](#) and [Precautions](#). ■ Have a reduced capacity to metabolize and eliminate. May have increased sensitivity to postural hypotension, anticholinergic and sedative effects. ■ Increased risk of extrapyramidal side effects (e.g., tardive dyskinesia, parkinsonism).

DRUG/LAB INTERACTIONS

Use with **epinephrine** not recommended; may cause precipitous hypotension. ■ Use with **agents that produce hypotension** (e.g., antihypertensives, benzodiazepines, diuretics, lidocaine, paclitaxel) may produce severe hypotension. ■ Increased CNS, respiratory depression, and hypotensive effects with **CNS depressants** (e.g., narcotics, alcohol, anesthetics, and barbiturates); reduced doses of these agents usually indicated. ■ Chlorpromazine does not potentiate the anticonvulsant actions of **barbiturates**. Doses of **anticonvulsant barbiturates** should not be decreased if chlorpromazine is introduced. Instead begin chlorpromazine at a lower dose and titrate to effect. ■ Chlorpromazine may lower the seizure threshold. It may also interfere with **phenytoin and valproic acid** clearance, increasing potential for toxicity. Dose adjustment of anticonvulsants may be necessary. ■ Additive effects with **MAO inhibitors** (e.g., selegiline [Eldepryl]), **anticholinergics**, **antihistamines**, **antihypertensives**, **hypnotics**, **muscle relaxants**, **rauwolfia alkaloids**, and **thiazide diuretics**; dose adjustment may be necessary. ■ **Barbiturates** may also increase metabolism of chlorpromazine and reduce its effects. ■ Risk of cardiotoxicity increased with **pimozide** (Orap) and **sparfloxacin** (Zagam); concurrent use not recommended. ■ Risk of additive QT interval prolongation, cardiac depressant effects, and cardiac arrhythmias increased with **cisapride** (Propulsid), **disopyramide** (Norpace), **erythromycin**, **probuco** (Lorelco), **procainamide** (Pronestyl), and **quinidine**. ■ Concurrent use with **antidepressants** (e.g., fluoxetine [Prozac], paroxetine [Paxil]), **tricyclic antidepressants** (e.g., amitriptyline [Elavil], imipramine [Tofranil]), or **MAO inhibitors** (e.g., selegiline [Eldepryl]) may increase effects of both drugs; risk of NMS may be increased. ■ Use with **antithyroid drugs** may increase risk of agranulocytosis. ■ May inhibit antiparkinson effects of **levodopa**. ■ May de-

crease pressor response to **ephedrine**. ■ May increase anticholinergic effect of **orphendrine** (Norflex). ■ May decrease effects of **oral anticoagulants**. ■ Concurrent use with **haloperidol, droperidol, or metoclopramide** may cause increased extrapyramidal effects. ■ Use with **metrizamide** (Amipaque) may lower seizure threshold; discontinue chlorpromazine 48 hours before myelography and do not resume for 24 hours after test completed. ■ Metabolism and clearance of chlorpromazine is increased in cigarette **smokers**; decreased plasma levels and effectiveness may occur; dose adjustment of chlorpromazine may be indicated. ■ Decreased drowsiness may occur in cigarette **smokers**. May be offset by increased doses of chlorpromazine. ■ Use caution during anesthesia with **barbiturates** (e.g., methohexital, thiopental); may increase frequency and severity of hypotension and neuromuscular excitation. ■ Encephalopathic syndrome has been reported with concurrent use of **lithium**; monitor for S/S of neurologic toxicity. ■ Capable of innumerable other interactions. ■ May cause false-positive **pregnancy test** and false-positive **amylase, PKU, and other urine tests**.

SIDE EFFECTS

Usually transient if drug discontinued, but may require treatment if severe. Anaphylaxis, cardiac arrest, distorted Q and T waves, drowsiness, excitement, extrapyramidal symptoms (e.g., abnormal positioning, extreme restlessness, pseudoparkinsonism, weakness of extremities), fever, hematologic toxicities (e.g., agranulocytosis, aplastic anemia, leukopenia, thrombocytopenia), hypersensitivity reactions, hypertension, hypotension (occurs less frequently in smokers), melanosis, photosensitivity, tachycardia, tardive dyskinesia, and many others.

Overdose: Can cause convulsions, hallucinations, and death.

ANTIDOTE

Discontinue the drug at onset of any side effect and notify the physician. Discontinue chlorpromazine and all drugs not essential to concurrent therapy immediately if NMS occurs. Will require intensive symptomatic treatment, medical monitoring, and management of concomitant medical problems. Counteract hypotension with norepinephrine (Levophed) or phenylephrine (Neo-Synephrine) and IV fluids. Counteract extrapyramidal symptoms with benztropine (Cogentin) or diphenhydramine (Benadryl). Use diazepam (Valium) followed by phenytoin (Dilantin) for convulsions or hyperactivity. Maintain a clear airway and adequate hydration. Epinephrine is contraindicated for hypotension; further hypotension will occur. Phenytoin may be helpful in ventricular arrhythmias. Avoid analeptics such as caffeine and sodium benzoate in treating respiratory depression and unconsciousness; they may cause convulsions. Resuscitate as necessary. Not removed by dialysis.

CIDOFIVIR INJECTION **BBW**

(sih-DOF-oh-veer in-JEK-shun)

Antiviral
(nucleotide analog)**Vistide****pH 6.7 to 7.6****USUAL DOSE**

Preliminary lab work required before each dose; see **Monitor**.

A specific protocol is required; see the following chart. A 4-Gm course of oral probenecid is required on the day of each infusion of cidofovir to reduce the risk of renal impairment. Hydration with 1 to 2 liters of NS is required to help reduce proteinuria and prevent increases in SCr. Infrequent dosing schedule may eliminate need for an indwelling IV catheter, reducing discomfort and potential for infection.

Induction: 5 mg/kg in 100 mL NS once weekly for 2 consecutive weeks.

Maintenance: 5 mg/kg in 100 mL NS once every other week.

Overview of the Treatment Regimen for Cidofovir

Before Cidofovir Infusion	During Cidofovir Infusion	After Cidofovir Infusion
1. Patient takes 2 Gm of probenecid* (4 × 500 mg tablets) 3 hours before cidofovir infusion	1. Begin IV infusion of cidofovir (5 mg/kg body weight in 100 mL NS) at a constant rate over 1 hour)†	1. Patient takes 1 Gm of probenecid (2 × 500 mg tablets) 2 hours after the <i>end</i> of cidofovir infusion
2. Infuse first liter of NS over 1 to 2 hours immediately before starting cidofovir infusion	2. For patients who can tolerate the extra fluid load, infuse a second liter of NS. If administered, initiate either at the start of the cidofovir infusion or immediately afterward, and infuse over a 1- to 3-hour period	2. Patient takes 1 Gm of probenecid (2 × 500 mg tablets) 8 hours after the <i>end</i> of cidofovir infusion

*Patients receiving concomitant probenecid and zidovudine should temporarily discontinue zidovudine or decrease the zidovudine dose by 50% on days of combined zidovudine and probenecid administration.

†The recommended dosage, frequency, or infusion rate must not be exceeded.

DOSE ADJUSTMENTS

Reduce dose to 3 mg/kg for the remainder of therapy, if SCr increases by 0.3 to 0.4 mg/dL above baseline. ■ 5 mg/kg may be given to patients who develop a 2⁺ proteinuria but have a stable SCr. Encourage oral hydration; additional IV hydration may be appropriate. ■ Discontinue cidofovir if the SCr increases by 0.5 mg/dL or more above baseline or if proteinuria 3⁺ or more develops. ■ Restarting cidofovir in patients whose renal function has returned to baseline after a SCr elevation of more than 0.5 mg/dL is not recommended. ■ Discontinue cidofovir in any patient who requires therapy with a nephrotoxic agent; see **Contraindications**. Cidofovir may be restarted after other nephrotoxic therapy is complete, an adequate washout period of at least 7 days has passed, and adequate renal function (SCr less than 1.5 mg/dL) is confirmed.

DILUTION

Specific techniques required; see Precautions. A calculated dose must be diluted in 100 mL of NS.

Storage: Store unopened vials at CRT. May be refrigerated but must be used within 24 hours of dilution with NS. Allow to return to room temperature before administration. Discard partially used vials.

COMPATIBILITY

Manufacturer states, “**Compatibility** with Ringer’s solution, LR, or bacteriostatic IV fluids not evaluated; no data available to support the addition of other drugs or supplements for concurrent administration.”

RATE OF ADMINISTRATION

A single dose as an infusion at a constant rate over 1 hour. Use of an infusion pump is recommended.

ACTIONS

A nucleotide analog antiviral. Its active intracellular metabolite selectively inhibits CMV DNA synthesis. It is incorporated into the growing viral DNA chain, resulting in reductions in the rate of viral DNA synthesis. This action is independent of virus infection (acyclovir or ganciclovir require activation by a virally encoded enzyme). Elimination half-life is short (2.6 hours), but it has a long intracellular half-life, which permits infrequent dosing. Primarily excreted in urine (70% to 85% in 24 hours with concomitant doses of probenecid).

INDICATIONS AND USES

Treatment of newly diagnosed or relapsing CMV retinitis in patients with AIDS is the only approved indication.

CONTRAINDICATIONS

Pre-existing renal dysfunction (e.g., baseline SCr more than 1.5 mg/dL, calculated CrCl equal to or less than 55 mL/min, or a urine protein equal to or greater than 100 mg/dL [equivalent to a 2⁺ or more proteinuria]). ■ Patients receiving agents with nephrotoxic potential (e.g., aminoglycosides, amphotericin B, foscarnet [Foscavir], NSAIDs [ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], IV pentamidine, vancomycin). No other nephrotoxic agent should be administered within 7 days of starting cidofovir or concomitantly during cidofovir therapy. ■ Hypersensitivity to cidofovir and/or a history of clinically severe hypersensitivity (e.g., hypotension, respiratory distress) to probenecid or other sulfa-containing medications (e.g., sulfamethoxazole/trimethoprim).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist, preferably in an environment where emergency treatment is available. ■ This formulation is for IV use only; **DO NOT** use for intraocular injection. ■ Safety and effectiveness have not been established for treatment of other CMV infections (e.g., pneumonitis, gastroenteritis, congenital or neonatal CMV disease) or for CMV disease in non-HIV-infected individuals. ■ Calculated CrCl may not accurately estimate renal function in emaciated (e.g., patients with AIDS) or extremely muscular patients; a 24-hour urine collection may be required. ■ CMV resistant to ganciclovir may also be resistant to cidofovir, but may be sensitive to foscarnet (Foscavir). ■ CMV resistant to foscarnet (Foscavir) may be sensitive to cidofovir. ■ Nephrotoxicity is dose limiting and is the major toxicity of cidofovir. Do not exceed recommended dose, frequency, or rate of administration; may cause increased risk of renal toxicity. Acute renal failure requiring dialysis or contributing to death has occurred with as few as 1 or 2 doses of cidofovir. ■ Renal function may not return to baseline after treatment with cidofovir. ■ Proteinuria is an early indicator of nephrotoxicity; continued administration of cidofovir may lead to additional proximal tubular cell injury resulting in glycosuria, decreased serum phosphate, uric acid, and bicarbonate; increased SCr; and/or acute renal failure, which may necessitate dialysis. ■ May cause granulocytopenia (e.g., neutropenia). ■ Although some reference sources have published doses for patients with impaired renal function, this drug is contraindicated in such patients and should be given only to those who meet specific dosing criteria; see [Contraindications](#).

Monitor: 24 to 48 hours before each cidofovir infusion, obtain SCr, urine protein (via dipstick or quantitative urinalysis), and CBC with differential (absolute neutrophil count [ANC]). Repeat between doses if indicated. ■ Administration of probenecid as ordered and adequate hydration (oral and IV) are imperative. ■ Antiretroviral therapy may be continued with the exception of zidovudine; see [Drug/Lab Interactions](#). ■ Probenecid frequently causes fever, flushing, headache, nausea with or without emesis, and rash. Use acetaminophen for prophylaxis or treatment of fever or headache. Encourage ingestion of food before each dose of probenecid to reduce nausea; prophylactic antiemetics (e.g., ondansetron [Zofran]) are appropriate. Consider use of antihistamines (e.g., diphenhydramine [Benadryl]) for prophylaxis or treatment in

patients who develop mild hypersensitivity reactions (e.g., rash). Severe hypersensitivity reactions (e.g., laryngospasm, hypotension) have occasionally been reported with probenecid. Usually occur within several hours after patients have received probenecid even though they have received it before with no adverse reactions. Observe patient carefully for hypersensitivity reactions. Treatment for anaphylaxis (e.g., epinephrine, corticosteroids, and antihistamines) must be readily available. ■ Monitor intraocular pressure, visual acuity, and ocular symptoms with a baseline ophthalmologic exam and periodically during therapy. Uveitis or iritis has been reported; may be treated with topical steroids. Risk of increased intraocular pressure and other visual problems may be increased in patients with pre-existing diabetes mellitus. ■ Use of the Cockcroft-Gault formula is recommended if a precise estimate of CrCl measurement is indicated.

Patient Education: Not a cure for CMV retinitis. Retinitis may recur during maintenance or after treatment; regular ophthalmologic exams imperative. ■ Full compliance with regimen imperative (e.g., probenecid with food, increased IV and oral hydration, regular lab testing). ■ Report diarrhea, eye pain or change in vision, fever, headache, loss of appetite, rash, nausea, and vomiting promptly. ■ Report concomitant medication changes or additions. ■ Notify all health care personnel of treatment with probenecid to avoid interactions. ■ Consider birth control options; see [Precautions/Maternal/Child](#).

Maternal/Child: Category C: should not be used during pregnancy; embryotoxic in animals. A potential carcinogen; knowledge of effects on women unknown. ■ Women of childbearing age should use effective contraception during cidofovir therapy and for 1 month after completion. ■ Men should use barrier contraception during cidofovir therapy and for 3 months after completion. ■ Has caused reduced testicular weight and hypospermia in animals. ■ Do not administer to nursing mothers. HIV-infected mothers are advised not to breast-feed to avoid transmission to an uninfected child. ■ Safety and effectiveness for use in pediatric patients not established. Use in pediatric patients with extreme caution and only if the benefits of treatment outweigh the risks of long-term carcinogenicity and reproductive toxicity. Consult physician specialist for adjustments in probenecid and hydration.

Elderly: Effects have not been studied; monitor renal function carefully.

DRUG/LAB INTERACTIONS

Limited information available. Drug profile review by pharmacist imperative. ■ Nephrotoxicity increased by other **nephrotoxic agents** (e.g., aminoglycosides [e.g., amikacin, gentamicin], amphotericin B [conventional, Abelcet], foscarnet [Foscavir], IV pentamidine, NSAIDs [e.g., ibuprofen (Motrin)], vancomycin); see [Contraindications](#). ■ Prior treatment with **foscarnet** (Foscavir) may also increase the risk of nephrotoxicity; monitor renal function carefully. ■ **Probenecid** decreases clearance of zidovudine; temporarily discontinue or reduce dose of zidovudine by 50% on days of combined zidovudine and probenecid administration. ■ **Probenecid** may have interactions with numerous other drugs (e.g., **acetaminophen**, **acyclovir** [Zovirax], **ACE inhibitors** [e.g., enalapril (Vasotec)], **aminosalicylic acid**, **barbiturates**, **benzodiazepines** [e.g., diazepam, lorazepam (Ativan), midazolam], **bumetamide**, **chlorpropamide** [Diabinese], **clofibrate**, **ddC**, **famotidine**, **furosemide**, **methotrexate**, **NSAIDs** [e.g., ketoprofen (Orudis), ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], **theophyllines**), usually decreasing their rate of excretion and increasing toxicity. Consider withholding any drug that may interact with probenecid on the day of cidofovir administration.

SIDE EFFECTS

Nephrotoxicity is dose limiting. Metabolic acidosis (Fanconi's syndrome), neutropenia, and ocular hypotony may be dose limiting and require prompt treatment. Anorexia, asthenia, decreased intraocular pressure, decreased serum bicarbonate, chills, diarrhea, dyspnea, fever, headache, increased creatinine, infection, nausea and vomiting, ophthalmic effects (e.g., change in vision, eye pain, increased sensitivity to light, reddened eyes), pneumonia, proteinuria, rash, and unusual tiredness or weakness may occur.

ANTIDOTE

There is no specific antidote. Keep physician informed. Adequate hydration, use of probenecid, and careful monitoring will help to reduce potential for renal impairment and may minimize other side effects. Filgrastim (Neupogen) may be used to treat neutropenia. See Monitor for management of probenecid side effects. Discontinue cidofovir based on criteria in Dose Adjustments. Treat overdose for 3 to 5 days with probenecid 1 Gm three times daily and vigorous IV hydration to tolerance. Treat anaphylaxis and resuscitate as indicated. Hemodialysis may be helpful in overdose. High-flux hemodialysis has reduced serum level of cidofovir by up to 75%.

<p>CIPROFLOXACIN BBW (sip-row-FLOX-ah-sin)</p> <p>Cipro IV</p>	<p>Antibacterial (fluoroquinolone)</p> <p>pH 3.5 to 4.6</p>
--	--

USUAL DOSE

Dose based on severity and nature of the infection, susceptibility of the causative organism, integrity of host-defense mechanisms, and renal and hepatic status. Range is from 200 to 400 mg according to the following chart. Continue for 7 to 14 days (at least 2 days after all symptoms of infection subside). Bone and joint infections may require treatment for 4 to 6 weeks or more. May be transferred to oral dosing when appropriate; see Monitor.

Ciprofloxacin Dose Guidelines				
Infection	Type of Severity	Unit Dose	Frequency	Duration
Urinary tract	Mild/moderate	200 mg	q 12 hr	7-14 days
	Severe/complicated	400 mg	q 12 hr or q 8 hr	
Lower respiratory tract	Mild/moderate	400 mg	q 12 hr	7-14 days
	Severe/complicated	400 mg	q 8 hr	
Nosocomial pneumonia	Mild/moderate/ severe	400 mg	q 8 hr	10-14 days
Skin and skin structure	Mild/moderate	400 mg	q 12 hr	7-14 days
	Severe/complicated	400 mg	q 8 hr	
Bone and joint	Mild/moderate	400 mg	q 12 hr	≥4-6 weeks
	Severe/complicated	400 mg	q 8 hr	
Septicemia (Canada)		400 mg	q 12 hr	
Acute sinusitis	Mild/moderate	400 mg	q 12 hr	10 days
Chronic bacterial prostatitis	Mild/moderate	400 mg	q 12 hr	28 days
Inhalation anthrax*	Post-exposure	400 mg	q 12 hr	60 days
Intra-abdominal, complicated	Ciprofloxacin + metronidazole	400 mg	q 12 hr	7-14 days
		500 mg	q 6 hr	
Empirical therapy in febrile neutropenic patients	Ciprofloxacin + piperacillin	400 mg 50 mg/kg	q 8 hr q 4 hr	7-14 days

*Begin drug administration as soon as possible after suspected or confirmed exposure.

PEDIATRIC DOSE

Used only when alternate therapy cannot be used; see [Precautions](#) and [Maternal/Child](#).

In all situations, do not exceed an IV dose of 400 mg.

Inhalation anthrax (post-exposure): 10 mg/kg every 12 hours IV. Do not exceed 400 mg/dose IV. May transfer to oral therapy when appropriate. Dose is 15 mg/kg PO every 12 hours. Do not exceed a 500-mg dose PO. Administer for 60 days.

Complicated UTIs or pyelonephritis in patients from 1 to 17 years of age: Dosing and initial route (IV or PO) should be determined by severity of infection. 6 to 10 mg/kg IV every 8 hours. Do not exceed 400 mg/dose IV. May transfer to oral therapy with a dose of 10 to 20 mg/kg PO every 12 hours at discretion of physician. Do not exceed a 750-mg dose PO. Total duration of treatment is 10 to 21 days.

Pulmonary exacerbations of cystic fibrosis in patients from 5 to 17 years of age (unlabeled): 10 mg/kg/dose IV every 8 hours for 1 week. Do not exceed 1.2 Gm/24 hr. Follow with 20 mg/kg/dose PO every 12 hours for 3 to 14 additional days to complete a 10- to 21-day regimen; see [Monitor](#). Do not exceed 2 Gm/24 hr.

Another source suggests:

Other infections (e.g., catheter-related bloodstream infections): *Infants and children (unlabeled):*

10 to 15 mg/kg of body weight every 12 hours. Do not exceed 800 mg/24 hr.

Neonates (unlabeled): 3.5 to 20 mg/kg every 12 hours.

DOSE ADJUSTMENTS

Increase interval between doses (200 to 400 mg every 18 to 24 hours) if CrCl is less than 30 mL/min (see literature for additional information). ■ Information on dosing adjustments for pediatric patients with renal insufficiency is not available. ■ Dose reduction not required based on age; see [Elderly](#). ■ See [Drug/Lab Interactions](#).

DILUTION

Available prediluted in D5W in latex-free plastic infusion containers ready for use. A clear, colorless to slightly yellow solution. Do not hang plastic containers in a series; may cause air embolism. Also available in 20- and 40-mL vials containing 10 mg/mL (1% solution), which must be diluted with NS, D5W, SWFI, D10W, D5¹/₄NS, D5¹/₂NS, or LR to a final concentration of 1 to 2 mg/mL.

Filters: No recommendations available from manufacturer.

Storage: Store between 5° and 25° C (41° and 77° F) before dilution; protect from light, excessive heat, and freezing. Stable for up to 14 days refrigerated or at room temperature in the final diluted concentration.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion through a **Y-site** or volume control and that ciprofloxacin be administered separately and the IV line be flushed before and after administration of any other drug.

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), atracurium (Tracrium), aztreonam (Azactam), cyclosporine (Sandimmune), dobutamine, dopamine, fluconazole (Diflucan), gentamicin, lidocaine, linezolid (Zyvox), metronidazole (Flagyl IV), midazolam (Versed), norepinephrine (Levophed), pancuronium, potassium chloride (KCl), ranitidine (Zantac), tobramycin, vecuronium.

Y-site: Amifostine (Ethyol), amino acids with dextrose, amiodarone (Nexterone), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), calcium gluconate, casposfungin (Cancidas), ceftaroline (Teflaro), ceftazidime (Fortaz), cisatracurium (Nimbex), dexmedetomidine (Precedex), digoxin (Lanoxin), diltiazem (Cardizem), dimenhydrinate, diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), fenoldopam (Corlopam), gallium nitrate (Ganite), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), hetastarch in electrolytes (Hextend), 6% hydroxyethyl starch (Volu-

ven), lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, metoclopramide (Reglan), midazolam (Versed), milrinone (Primacor), potassium acetate, potassium chloride (KCl), promethazine (Phenergan), quinupristin/dalfopristin (Synercid [1 mg/mL]), ranitidine (Zantac), remifentanyl (Ultiva), sodium bicarbonate, sodium chloride, tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), thiotepa, tigecycline (Tygacil), tobramycin, vasopressin, verapamil.

RATE OF ADMINISTRATION

A single dose must be equally distributed over 60 minutes as an infusion. Too-rapid administration and/or the use of a small vein may increase incidence of local site inflammation and other side effects. May be given through a Y-tube or three-way stopcock of infusion set. Temporarily discontinue other solutions infusing at the same site.

ACTIONS

A synthetic, broad-spectrum antimicrobial agent, a fluoroquinolone. Bactericidal to a wide range of aerobic gram-negative and gram-positive organisms through interference with the enzymes needed for synthesis of bacterial DNA. Onset of action is prompt, and serum levels are dose related. Half-life averages 5 to 6 hours. Readily distributed to body fluids (saliva, nasal and bronchial secretions, sputum, skin blister fluid, lymph, peritoneal fluid, bile and prostatic secretions). Found in lung, skin, fat, muscle, cartilage, and bone. Levels in cerebrospinal fluid and eye fluids are lower than plasma levels. Limited metabolism. Excreted primarily as unchanged drug in the urine, usually within 24 hours. A small amount is excreted in the bile and feces. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of infections caused by susceptible isolates of designated organisms in the conditions and patient populations listed below. ■ Treatment of mild, moderate, severe, and complicated infections of the urinary tract and skin and skin structure. ■ Treatment of lower respiratory infections (*not* the drug of first choice in treatment of pneumonia secondary to *Streptococcus pneumoniae*). ■ Treatment of mild, moderate, and severe nosocomial pneumonia. ■ Treatment of acute sinusitis, bone and joint infections, chronic bacterial prostatitis, and septicemia (Canada). ■ Treatment of complicated intra-abdominal infections in combination with metronidazole (Flagyl). ■ Empirical therapy in febrile neutropenic patients in combination with piperacillin. ■ Reduce the incidence or progression of disease in adults or pediatric patients following exposure to aerosolized *Bacillus anthracis* (Anthrax). ■ Treatment of complicated UTI and pyelonephritis due to *Escherichia coli* in pediatric patients 1 to 17 years of age; see *Maternal/Child*. ■ Additional appropriate therapy required if anaerobic organisms are suspected of contributing to the infection. ■ Oral route of administration indicated for treatment of other infections (e.g., infectious diarrhea, typhoid fever, urethral and cervical gonococcal infections).

Unlabeled uses: Cystic fibrosis. ■ Infective endocarditis. ■ Surgical prophylaxis. ■ Tularemia.

CONTRAINDICATIONS

Known hypersensitivity to ciprofloxacin or any other quinolone antimicrobial agent (e.g., levofloxacin [Levaquin], norfloxacin [Noroxin]) or any of the product components. ■ Concomitant administration with tizanidine (Zanaflex) is contraindicated.

PRECAUTIONS

Specific culture and sensitivity studies indicated to determine susceptibility of the causative organism to ciprofloxacin. ■ The emergence of bacterial resistance to fluoroquinolones and the occurrence of cross-resistance with other fluoroquinolones have been observed and are of concern. Proper use of fluoroquinolones and other classes of antibiotics is encouraged to avoid the emergence of resistant bacteria from overuse. ■ *Pseudomonas aeruginosa* may develop resistance during treatment. Ongoing culture and sensitivity studies indicated. ■ Prolonged use may cause superinfection because of overgrowth of nonsusceptible organisms. Monitor carefully. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ciprofloxacin.

cin. ■ Convulsions, increased intracranial pressure (including pseudotumor cerebri), and toxic psychosis have been reported in patients receiving quinolones, including ciprofloxacin. Ciprofloxacin may also cause CNS events, including confusion, depression, dizziness, hallucinations, tremors and, rarely, suicidal thoughts or acts. ■ Use caution in patients with epilepsy or known or suspected CNS disorders (e.g., severe cerebral arteriosclerosis, previous history of convulsion), reduced cerebral blood flow, altered brain structure, stroke, drugs that may lower the seizure threshold, and renal dysfunction. ■ Tendinitis and tendon rupture that required surgical repair or resulted in prolonged disability have been reported in patients receiving quinolones. Most frequently involves the Achilles tendon but has also been reported with the shoulder, hand, biceps, thumb, and other tendon sites. ■ Inflammation and tendon rupture may occur during or after fluoroquinolone therapy. Has been reported within the first 48 hours of therapy and may occur bilaterally. Use caution in patients with a history of tendon disorders. Risk may be increased in patients over 60 years of age; in patients taking corticosteroids; in patients with heart, kidney, or lung transplants; with strenuous physical activity; and in patients with renal failure or previous tendon disorders such as rheumatoid arthritis. ■ Fluoroquinolones have neuromuscular blocking activity. Serious adverse events, including requirement for ventilatory support and deaths, have been reported in patients with myasthenia gravis. Avoid use in patients with a known history of myasthenia gravis; may exacerbate muscle weakness. ■ Rare cases of peripheral neuropathy (e.g., paresthesias, hypoesthesias, dysesthesias [impairment of sensitivity or touch], or weakness) have been reported. ■ Prolongation of the QT interval on ECG and infrequent cases of arrhythmia (including torsades de pointes) have been reported with the use of some fluoroquinolones. The risk of arrhythmia may be reduced by avoiding their use in patients with known prolongation of the QT interval, in the presence of hypokalemia, significant bradycardia, cardiomyopathy, or concurrent treatment with class IA antiarrhythmic agents (e.g., quinidine, procainamide [Pronestyl]) or with class III antiarrhythmic agents (e.g., amiodarone [Nexterone], sotalol [Betapace]). ■ Other serious events (sometimes fatal) due to hypersensitivity or uncertain etiology have been reported with fluoroquinolones, including ciprofloxacin; see [Side Effects, Post-Marketing](#). Discontinue ciprofloxacin at the first appearance of a skin rash, jaundice, or other signs of hypersensitivity. ■ Cases of severe hepatic toxicity, including necrosis, life-threatening hepatic failure, and fatal events have been reported. Acute liver injury is rapid in onset (range 1 to 39 days) and is often associated with hypersensitivity. ■ Moderate to severe photosensitivity/phototoxicity reactions have been reported in patients receiving quinolones; see [Patient Education](#).

Monitor: May cause anaphylaxis with the first or succeeding doses, even in patients without known hypersensitivity. Emergency equipment must always be available. ■ Monitor for S/S of peripheral neuropathy. Discontinue ciprofloxacin at the first symptoms of neuropathy (e.g., pain, burning, tingling, numbness and/or weakness) or if patient is found to have deficits in light touch, pain, temperature, position sense, vibratory sensation, and/or motor strength. ■ Maintain adequate hydration and acidity of urine throughout treatment. Will form crystals in alkaline urine. ■ Monitor hematopoietic, hepatic, and renal systems during prolonged treatment. ■ Use of large veins recommended to reduce incidence of local irritation. Symptoms of local irritation do not preclude further administration of ciprofloxacin unless they recur or worsen. Generally resolve when infusion complete. ■ Concomitant use with theophylline may cause cardiac arrest, respiratory failure, seizures, and/or status epilepticus. If concomitant use cannot be avoided, monitor serum levels of theophylline and adjust dose as indicated. ■ Doses will increase slightly with transfer to oral ciprofloxacin (e.g., 200 mg IV every 12 hours equals 250 mg PO every 12 hours; 400 mg IV every 12 hours equals 500 mg PO every 12 hours; 400 mg IV every 8 hours equals 750 mg PO every 12 hours). ■ See [Drug/Lab Interactions](#).

Patient Education: A patient medication guide is available from the manufacturer. ■ Review all prescription and non-prescription medications with your health care provider. ■ Inform physician of any history of myasthenia gravis. Patients with a history of myasthenia gravis should avoid using ciprofloxacin. ■ Consider birth control op-

tions. ■ Photosensitivity has occurred in a minimum number of patients, but it is best to avoid excessive sunlight or artificial ultraviolet light. May cause severe sunburn; wear protective clothing, use sunscreen, and wear dark glasses outdoors. Report a sunburn-like reaction or skin eruption promptly. ■ Request assistance for ambulation; may cause dizziness and light-headedness. Use caution in tasks that require alertness. ■ Effects of caffeine- or theophylline-containing preparations may be increased; promptly report difficulty breathing and/or seizures. Limit or eliminate concurrent use. Monitor if concurrent use necessary. ■ Report tendon pain or inflammation promptly; rest and refrain from exercise. ■ Promptly report skin rash or any other hypersensitivity reaction. ■ Promptly report pain, burning, tingling, numbness and/or weakness. ■ Inform physician of any history of seizures. ■ Parents should inform physician of any history of joint-related problems and should promptly report any joint-related problems that develop during or after therapy. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category C: use during pregnancy only if benefits justify potential risk to fetus and mother. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients under 18 years of age not established except for use post-exposure of inhalation anthrax and UTIs or pyelonephritis. Appropriateness based on risk/benefit assessment. ■ May erode cartilage of weight-bearing joints or cause other signs of arthropathy in infants and children. ■ Has been used in infants and children to treat serious infections unresponsive to other antibiotic regimens.

Elderly: Safety and effectiveness similar to younger adults. ■ May be at increased risk of experiencing side effects (e.g., CNS effects, drug-associated effects on the QT interval, tendinitis, tendon rupture); see **Precautions**. Half-life may be slightly extended because of age-related renal impairment; see **Dose Adjustments**. Monitoring of renal function may be useful.

DRUG/LAB INTERACTIONS

Ciprofloxacin is an inhibitor of the hepatic CYP1A2 enzyme pathway. Coadministration with other drugs metabolized by this route, such as **clozapine** (Clozaril), **methylxanthines** (e.g., theophylline), **olanzapine** (Zyprexa), **ropinirole** (Requip), or **tizanidine** (Zanaflex), results in increased plasma concentrations of these drugs, which may cause significant toxicity. **Concomitant administration with tizanidine (Zanaflex) is contraindicated** (hypotensive and sedative effects potentiated). ■ May cause serious or fatal reactions with **theophylline** (e.g., cardiac arrhythmias or arrest, respiratory failure, or seizures). If must be used concomitantly, monitor serum levels of theophylline and decrease dose as appropriate. Observe closely with **caffeine** intake; has caused similar problems. Elevated serum levels of other xanthine derivatives (e.g., pentoxifylline-containing products [e.g., Trental]) have also been seen with concurrent use. ■ Use with **cyclosporine** may cause an increase in SCr and nephrotoxic effects. ■ May potentiate **oral anticoagulants** (e.g., warfarin [Coumadin]); monitor PT/INR. ■ Potentiated by **probenicid**; may require dose adjustment based on ciprofloxacin serum levels. ■ Severe hypoglycemia has been reported with concomitant use of **oral antidiabetic agents** (e.g., glyburide [DiaBeta], glimepiride [Amaryl]); monitor serum glucose levels. ■ May increase or decrease serum **phenytoin** levels; monitor phenytoin levels with concomitant use and repeat phenytoin levels shortly after completion of ciprofloxacin therapy. ■ Two case reports suggest concurrent administration with **foscarnet** (Foscavir) may cause seizures; monitor patient carefully. ■ Risk of CNS stimulation and seizures may be increased with concurrent use of **NSAIDs** (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]) with high doses of quinolones. ■ Concurrent use with **methotrexate** requires close monitoring. May inhibit renal tubular transport of methotrexate, thereby increasing methotrexate serum levels and the risk of toxicity. ■ Coadministration with **drugs known to prolong the QT interval** (e.g., Class IA or III antiarrhythmic agents [e.g., amiodarone (Nexterone), disopyramide (Norpace), procainamide (Pronestyl), quinidine], tricyclic antidepressants [e.g., amitriptyline (Elavil), imipramine (Tofranil)], macrolide antibiotics [e.g., azithromycin (Zithromax)],

and antipsychotics [e.g., iloperidone (Fanapt), paliperidone (Invega), phenothiazines (e.g., chlorpromazine, thioridazine), ziprasidone (Geodon)]) may increase the risk of QT prolongation and life-threatening arrhythmias. ■ Pharmacologic effects of **metoprolol** (Lopressor) may be increased. Monitor cardiac function when initiating or discontinuing ciprofloxacin. ■ May increase serum concentrations of many drugs (e.g., **duloxetine** [Cymbalta], **lidocaine**, **methadone** [Dolophine], **mexiletine**, **MAO inhibitors** [e.g., rasagiline (Azilect)], **ropivacaine** [Naropin], **sildenafil** [Revatio, Viagra]). Therapeutic effects and/or side effects may be increased; dose reductions of these drugs may be indicated. ■ May cause a false-positive when **testing urine for opiates**; more specific testing methods may be indicated. ■ See **Side Effects**.

SIDE EFFECTS

Diarrhea, hepatic enzyme abnormalities (elevation of alkaline phosphatase, AST, ALT, LDH, serum bilirubin), and nausea and vomiting and rash are reported most frequently. Other less frequent reactions include allergic reactions (anaphylaxis, cardiovascular collapse, death, dyspnea, edema [facial, pharyngeal, or pulmonary], eosinophilia, fever, itching, loss of consciousness, rash, urticaria); cardiovascular effects (e.g., cardiac arrest, palpitations, QT interval prolongation, tachycardia, torsades de pointes, vasodilation, ventricular tachyarrhythmias); CDAD; CNS stimulation (confusion, hallucinations, light-headedness, restlessness, seizures, tingling, toxic psychosis, tremors); decreased hemoglobin, hematocrit, and platelet count; elevation of eosinophil and platelet counts, BUN, serum amylase, serum creatinine, serum creatine phosphokinase, serum potassium, uric acid, and triglycerides; headache; hyperglycemia; hypoglycemia; increased intracranial pressure; local site reactions; myalgias; nausea; peripheral neuropathy (e.g., pain, burning, tingling, numbness and/or weakness [see **Precautions, Monitor**]); photosensitivity/phototoxicity and vision changes; postural hypotension; respiratory failure; status epilepticus; tendinitis; and tendon rupture. Capable of numerous other reactions in fewer than 1% of patients.

Post-Marketing: Acute generalized exanthematous pustulosis (AGEP), allergic pneumonitis, arthralgia, hematologic abnormalities (agranulocytosis, anemia [hemolytic and aplastic], leukopenia, pancytopenia, thrombocytopenia, thrombotic thrombocytopenic purpura), increased INR in patients treated with vitamin K antagonists, interstitial nephritis, jaundice, liver abnormalities (e.g., acute hepatic necrosis or failure, hepatitis, jaundice), myalgia, polyneuropathy, rash, serum sickness, severe dermatologic reactions (e.g., toxic epidermal necrolysis [Lyell's syndrome], Stevens-Johnson syndrome), vasculitis.

ANTIDOTE

Death may result from some of these side effects. Discontinue ciprofloxacin at the first appearance of a skin rash or major side effect (hypersensitivity, CDAD, CNS symptoms, dermatologic reactions, phototoxicity, or tendon rupture). Treat hypersensitivity reactions with epinephrine (Adrenalin), airway management, oxygen, IV fluids, antihistamines (diphenhydramine [Benadryl]), corticosteroids (hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (dopamine) as indicated. Treat CNS symptoms as indicated. May require diazepam (Valium) for seizures. Mild cases of CDAD may respond to discontinuation of ciprofloxacin. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Drugs that inhibit peristalsis should be avoided. Keep physician informed of all side effects. Many will require symptomatic treatment; monitor closely. In overdose, observe carefully, provide supportive treatment, maintain hydration, and monitor renal function and urinary pH and acidify, if required, to prevent crystalluria. No specific antidote; up to 10% may be removed by hemodialysis or peritoneal dialysis. Maintain patient until drug excreted.

CISATRACURIUM BESYLATE **BBW**(sis-ah-trah-**KYOU**-ree-um **BES**-ih-layt)Neuromuscular blocking agent
(nondepolarizing)
Anesthesia adjunct**Nimbex, Nimbex PF**

pH 3.25 to 3.65

USUAL DOSE

Must be individualized based on previous drugs administered (e.g., fentanyl [Sublimaze], midazolam [Versed]), desired time to intubation, and anticipated length of surgery. Must be used with adequate anesthesia and/or sedation and after unconsciousness induced. Use of a peripheral nerve stimulator is indicated in all situations.

ADJUNCT TO PROPOFOL/N₂O/O₂ ANESTHESIA FOR ADULTS (IV BOLUS)

Initial dose: 0.15 to 0.2 mg/kg. 0.15 mg/kg should provide good to excellent conditions for intubation within 2 minutes and adequate muscle relaxation for 55 minutes (range 44 to 74 min). 0.2 mg/kg (7 mL [of a 2 mg/mL conc] for a 70-kg patient) should be effective within 1.5 minutes and last for 61 minutes (range 41 to 81 min). Up to 0.4 mg/kg has been used; has a dose-related length of effectiveness.

Maintenance dose: May be given by IV bolus or as a continuous infusion. Determine need for maintenance dose based on beginning symptoms of neuromuscular blockade reversal determined by a peripheral nerve stimulator. Usually required 40 to 60 minutes after a bolus dose. Do not administer before recovery begins. Repeated doses have no cumulative effect if recovery is allowed to begin before administration. See [Dose Adjustments](#).

IV bolus: 0.03 mg/kg (1 mL [of a 2 mg/mL conc] for a 70-kg patient) should provide an additional 20 minutes of muscle relaxation. Smaller or larger doses may be given based on expected duration of procedure.

Continuous infusion: Begin infusion with 3 mcg/kg/min to rapidly counteract the spontaneous recovery, then decrease to 1 to 2 mcg/kg/min. Monitor maintenance infusion with a peripheral nerve stimulator.

SUPPORT OF INTUBATED, MECHANICALLY VENTILATED, OR RESPIRATORY CONTROLLED ADULT ICU PATIENTS

After intubation is accomplished (usually with succinylcholine), an initial bolus dose of 0.1 mg/kg provides adequate neuromuscular blockade. Maintain with 3 mcg/kg/min (range 0.5 to 10.2 mcg/kg/min). Published reports describe a wide interpatient variability in dosing requirements that may change from day to day. Adjust infusion rate according to clinical assessment of the patient's response. Use of a peripheral nerve stimulator is recommended. Do not increase dose until there is a definite response to nerve stimulation. If recovery from neuromuscular block has progressed, readministration of a bolus dose may be necessary. Long-term use (beyond 6 days) has not been studied.

PEDIATRIC DOSE

See all comments under [Usual Dose](#) and [Maternal/Child](#).

ADJUNCT TO HALOTHANE OR OPIOID ANESTHESIA FOR PEDIATRIC PATIENTS 1 MONTH TO 23 MONTHS OF AGE

0.15 mg/kg. Should produce maximum block in 2 minutes and adequate muscle relaxation for 43 minutes (range is 34 to 58 minutes).

ADJUNCT TO HALOTHANE OR OPIOID ANESTHESIA FOR PEDIATRIC PATIENTS 2 TO 12 YEARS OF AGE

Initial dose: 0.1 to 0.15 mg/kg as an IV bolus. 0.1 mg/kg should provide good to excellent conditions for intubation within 2.8 minutes and adequate muscle relaxation for 28 minutes (range 21 to 38 minutes). 0.15 mg/kg should produce maximum block in 3 minutes and adequate muscle relaxation for 36 minutes (range 29 to 46 minutes).

Maintenance dose: Same as adult dosing; See all comments.

DOSE ADJUSTMENTS

Reduce initial dose to 0.02 mg/kg in any condition that may result in a prolonged neuromuscular blockade (e.g., myasthenia gravis, myasthenic syndrome, carcinomatosis, debilitation, other drugs). Use a peripheral nerve stimulator to assess the level of neuromus-

cular block and to monitor dose requirements. See Drug/Lab Interactions. ■ Increased initial and maintenance doses may be required in burn patients. Duration of action may be shortened. ■ Half-life is extended but no dose adjustment is required in patients with renal or hepatic disease or in the elderly. Time of onset may be slightly faster in patients with liver disease and slower in the elderly and patients with renal disease. Slower onset may require a delay of an additional minute before intubation. ■ Reduce maintenance dose by 30% to 40% in the presence of isoflurane or enflurane anesthesia. Larger reductions may be indicated in prolonged anesthesia. ■ May need to reduce maintenance dose by 50% in patients undergoing coronary artery bypass surgery with induced hypothermia.

DILUTION

IV bolus: May be given undiluted.

Infusion: Further dilute in NS, D5W, or D5NS to a 0.1 mg/mL or 0.4 mg/mL solution. Using the 2 mg/mL solution, 10 mg diluted in 95 mL yields 0.1 mg/mL; 40 mg diluted in 80 mL yields 0.4 mg/mL.

ICU infusion: A 20-mL vial (10 mg/mL concentration) is available for use in ICU (200 mg/vial). 200 mg in 1,000 mL yields 0.2 mg/mL, in 500 mL yields 0.4 mg/mL.

Storage: Refrigerate in carton before use; protect from light; do not freeze. Use within 21 days if at room temperature even if it was re-refrigerated. Most diluted solutions are stable refrigerated or at room temperature for 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists propofol (Diprivan) and ketorolac (Toradol) as **incompatible**. Has an acid pH and may be **incompatible** with alkaline solutions having a pH greater than 8.5 (e.g., aminophylline, barbiturates, sodium bicarbonate).

Manufacturer lists alfentanil (Alfenta), droperidol (Inapsine), fentanyl (Sublimaze), midazolam (Versed), and sufentanil (Sufenta) as **compatible** but does not specify **additive** or **Y-site**.

Another source suggests the following **compatibilities**:

Y-site: Other sources list acyclovir (Zovirax), alfentanil (Alfenta), amikacin (Amikin), aminophylline, amphotericin B (conventional), ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, cefazolin (Ancef), cefotaxime (Claforan), cefoxitin (Mefoxin), ceftaroline (Teflaro), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), clindamycin (Cleocin), dexamethasone (Decadron), dexmedetomidine (Precedex), diazepam (Valium), digoxin (Lanoxin), diphenhydramine (Benadryl), dobutamine, dopamine, doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), epinephrine (Adrenalin), esmolol (Brevibloc), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), furosemide (Lasix), ganciclovir (Cytovene), gentamicin, heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), imipenem-cilastatin (Primaxin), isoproterenol (Isuprel), ketorolac (Toradol), lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, mannitol, meperidine (Demerol), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), midazolam (Versed), morphine, nalbuphine, nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), ondansetron (Zofran), palonosetron (Aloxi), phenylephrine (Neo-Synephrine), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), procainamide (Pronestyl), prochlorperazine (Compazine), promethazine (Phenergan), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sodium bicarbonate, sufentanil (Sufenta), sulfamethoxazole/trimethoprim, theophylline, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

IV bolus: A single dose over 5 to 10 seconds.

Infusion for anesthesia adjunct or ICU: Use of a microdrip (60 gtt/mL) or volume infusion pump required. Adjust rate to desired dose based on the following charts for 0.1 mg/mL

and 0.4 mg/mL. For 0.2 mg/mL solution in ICU, multiply rates (mL/hr) of 0.1 mg/mL solution by 2 or divide rates (mL/hr) of 0.4 mg/mL solution in half.

Cisatracurium Infusion Rates for a Concentration of 0.1 mg/mL					
Patient Weight (kg)	Drug Delivery Rate (mcg/kg/min)				
	1	1.5	2	3	5
	Infusion Delivery Rate (mL/hr)				
10 kg	6 mL/hr	9 mL/hr	12 mL/hr	18 mL/hr	30 mL/hr
45 kg	27 mL/hr	41 mL/hr	54 mL/hr	81 mL/hr	135 mL/hr
70 kg	42 mL/hr	63 mL/hr	84 mL/hr	126 mL/hr	210 mL/hr
100 kg	60 mL/hr	90 mL/hr	120 mL/hr	180 mL/hr	300 mL/hr

Cisatracurium Infusion Rates for a Concentration of 0.4 mg/mL					
Patient Weight (kg)	Drug Delivery Rate (mcg/kg/min)				
	1	1.5	2	3	5
	Infusion Delivery Rate (mL/hr)				
10 kg	1.5 mL/hr	2.3 mL/hr	3 mL/hr	4.5 mL/hr	7.5 mL/hr
45 kg	6.8 mL/hr	10.1 mL/hr	13.5 mL/hr	20.3 mL/hr	33.8 mL/hr
70 kg	10.5 mL/hr	15.8 mL/hr	21 mL/hr	31.5 mL/hr	52.5 mL/hr
100 kg	15 mL/hr	22.5 mL/hr	30 mL/hr	45 mL/hr	75 mL/hr

ACTIONS

A nondepolarizing skeletal muscle relaxant with intermediate onset and duration of action. An isomer of atracurium (Tracrium) with three times its potency at a mg-for-mg dose. In contrast to most of the other neuromuscular blocking agents, cisatracurium has no clinically significant effect on HR or BP with usual doses even in patients with serious cardiovascular disease, and it also does not produce a dose-related histamine release. Causes paralysis by interfering with neural transmission at the myoneural junction. Produces maximum neuromuscular blockade within 1.5 to 3 minutes and lasts about 50 minutes in adults. Recovery to 75% usually occurs within 30 minutes. Metabolized by a process that mostly bypasses both the kidney and the liver. Forms specific metabolites (e.g., alcohol, laudanosine) that do not have neuromuscular blocking activity. Because of reduced dose requirements, laudanosine accumulation is lower than with atracurium, lowering the potential of seizures. Eliminated renally, primarily as metabolites.

INDICATIONS AND USES

Adjunctive to general anesthesia for inpatients and outpatients to facilitate endotracheal intubation and to relax skeletal muscles during surgery. ■ Relax skeletal muscles during mechanical ventilation in ICU.

CONTRAINDICATIONS

Known hypersensitivity to cisatracurium, other bis-benzylisoquinolinium compounds (e.g., atracurium), and benzyl alcohol (some preparations contain benzyl alcohol).

PRECAUTIONS

For IV use only. ■ Administered by or under the observation of the anesthesiologist. Adequate facilities, emergency resuscitation drugs and equipment, neuromuscular blocking antagonists (e.g., anticholinesterase agents [e.g., neostigmine, edrophonium]), and atropine must always be available. ■ Not recommended for rapid sequence intubation; succinylcholine is usually the drug of

choice. ■ Severe anaphylactic reactions have been reported with neuromuscular blocking agents; some have been fatal. Use caution in patients who have had an anaphylactic reaction to another neuromuscular blocking agent (depolarizing or nondepolarizing); cross-reactivity has occurred. ■ Myasthenia gravis and other neuromuscular diseases increase sensitivity to cisatracurium. Can cause critical reactions. ■ Sensitivity may be decreased in patients with burns or paralysis. See [Dose Adjustments](#) and [Monitor](#). ■ In patients with renal or hepatic disease, half-life of metabolites is longer, and concentrations may be higher with long-term administration. ■ Did not trigger malignant hypertension (MH) in susceptible pigs at doses above those required for humans, but has not been studied in MH-susceptible humans. ■ Respiratory depression with propofol (Diprivan) or morphine may be preferred in some patients requiring mechanical ventilation. ■ Will not counteract the bradycardia produced by many anesthetic agents or vagal stimulation. ■ Transient hypotension and CNS excitation (generalized muscle twitching to seizures) have been reported rarely in ICU patients undergoing prolonged therapy.

Monitor: This drug produces apnea. Controlled artificial ventilation with oxygen must be continuous and under direct observation at all times. Maintain a patent airway. ■ Use a peripheral nerve stimulator to monitor drug effect, determine the need for additional doses, confirm recovery from neuromuscular block, and avoid overdose. Place on a non-paralyzed limb in patients with paralysis. ■ Monitor vital signs and ECG continuously. ■ Has no analgesic properties or effect on consciousness. Use in conjunction with anesthesia, sedation, or analgesia as indicated. ■ Action potentiated by hypokalemia and some carcinomas. ■ Action may be potentiated or antagonized by dehydration, electrolyte imbalance, body temperature, or acid-base imbalance.

Maternal/Child: Category B: use in pregnancy only if clearly needed. Safety for use during labor and delivery not established. ■ Use caution during breast-feeding; probably best to defer breast-feeding until after full recovery. ■ Safety for use in infants under 1 month of age not established. ■ 10 mL (2 mg/mL) multiple dose vials contain benzyl alcohol; do not use in newborns. ■ In pediatric patients 2 to 12 years of age, onset is faster, duration shorter, and recovery faster than in adults. In infants 1 month to 23 months of age, onset is faster; however, duration and recovery are similar to adults. ■ For induction of anesthesia in pediatric patients 1 month to 12 years of age, intubation was facilitated more reliably when cisatracurium was used in combination with halothane anesthesia than when used in combination with opioids and nitrous oxide. ■ Rare incidences of wheezing, laryngospasm, bronchospasm, rash, and itching have been reported in pediatric patients.

Elderly: Safely administered even in patients with significant cardiac disease. ■ Response similar to that seen in younger adults; however, greater sensitivity of some older individuals cannot be ruled out. ■ Onset to complete neuromuscular block slightly slower; delay intubation until fully effective. Recovery may be slower.

DRUG/LAB INTERACTIONS

Potentiated by **general anesthetics** (e.g., enflurane, isoflurane), many **antibiotics** (e.g., aminoglycosides [kanamycin, gentamicin], lincosamides [clindamycin (Cleocin)], polypeptides [bacitracin, colistimethate], tetracyclines), **muscle relaxants**, **diuretics**, **lithium**, **local anesthetics**, **magnesium sulfate**, **procainamide** (Pronestyl), **quinidine**, **succinylcholine**, and **others**. May need to reduce initial or maintenance dose of cisatracurium; use with caution. ■ Antagonized by **acetylcholine and anticholinesterases**. ■ Duration of neuromuscular block may be shorter and dose requirements may be higher during maintenance infusion in patients stabilized on **carbamazepine** (Tegretol) or **phenytoin** (Dilantin). ■ Time to onset of maximum block is faster when **succinylcholine** is given before cisatracurium. Succinylcholine must show signs of wearing off before cisatracurium is given. Use caution.

SIDE EFFECTS

Bradycardia, bronchospasm, flushing, hypotension, and rash occurred in fewer than 1% of patients. Both inadequate and/or prolonged neuromuscular blocks have been reported. Rare reports of seizures with similar agents in ICU could be caused by accumulated laudanosine, other conditions, or medications. Excessive dosing or prolonged action may result in respiratory insufficiency or apnea. Airway closure may be caused by relaxation of epiglottis, pharynx, and tongue muscles. Hypersensitivity reactions have been reported.

ANTIDOTE

Side effects can be medical emergencies. Treat symptomatically. Maintain a patent airway and continuous controlled artificial ventilation and oxygenation until full recovery is ensured. The more profound the neuromuscular block, the longer it will take until recovery begins. Recovery from neuromuscular block must be confirmed by a peripheral nerve stimulator before anticholinesterase agents (e.g., neostigmine or edrophonium [Enlon]) can be given with an anticholinergic agent (e.g., atropine) to reverse the muscle relaxation. Neostigmine 0.04 to 0.07 mg/kg at 10% recovery in conjunction with atropine should be effective in 9 to 10 minutes. Edrophonium 1 mg/kg at 25% recovery in conjunction with atropine (Enlon-Plus is edrophonium and atropine combined) should be effective in 3 to 5 minutes. Confirm recovery by 5-second head lift and grip strength. Recovery may be inhibited by cachexia, carcinomatosis, debilitation, or the concomitant use of certain drugs; see [Drug/Lab Interactions](#). Resuscitate as necessary.

CISPLATIN **BBW**

(sis-PLAH-tin)

**Antineoplastic
(alkylating agent)****CDDP, Platinol****pH 3.5 to 6****USUAL DOSE**

Prehydration required; see **Precautions** and **Monitor**. See **Dose Adjustments**. May be given in combination with amifostine (Ethyol) to reduce nephrotoxicity and neurotoxicity of cisplatin. See amifostine monograph. Doses greater than 100 mg/M² once every 3 to 4 weeks are rarely used.

Metastatic testicular tumors: Used in combination with other approved chemotherapeutic agents. 20 mg/M² daily for 5 days per cycle.

Metastatic ovarian tumors: 75 to 100 mg/M² on Day 1 every 4 weeks. Used in combination with cyclophosphamide (Cytosan) 600 mg/M² IV on Day 1 every 4 weeks. Another regimen (unlabeled in cisplatin prescribing information) uses paclitaxel 135 mg/M² (as a 24-hour infusion) followed by cisplatin 75 mg/M². Both agents are given once every 3 weeks for 6 courses. See paclitaxel monograph; premedication required. Used as a **single agent**, the dose of cisplatin is 100 mg/M² every 4 weeks.

First-line treatment of ovarian cancer (unlabeled in cisplatin prescribing information): Given in combination with paclitaxel as follows: give paclitaxel (Taxol) 135 mg/M² as an infusion over 24 hours. Follow with cisplatin 75 mg/M² as an infusion over 6 to 8 hours. Repeat every 3 weeks. See paclitaxel monograph; premedication required. Other dose combinations and infusion times are being used.

Advanced bladder cancer: 50 to 70 mg/M² once every 3 to 4 weeks. 50 mg/M² is recommended once every 4 weeks for patients heavily pretreated with radiation or chemotherapy. Numerous other doses and combinations are used.

Non-small-cell lung cancer (unlabeled in cisplatin prescribing information): Given in combination with gemcitabine as follows: gemcitabine (Gemzar) 1,000 mg/M² as an infusion on Days 1, 8, and 15 of each 28-day cycle. Follow the gemcitabine infusion on Day 1 with cisplatin 100 mg/M². See gemcitabine monograph; other dosing schedules are in use. Another regimen uses a combination of paclitaxel and cisplatin as follows: paclitaxel 135 mg/M² as an infusion over 24 hours followed by cisplatin 75 mg/M² over 6 to 8 hours. Repeat every 3 weeks. See paclitaxel monograph; premedication required. Also used with docetaxel 75 mg/M² infused over 1 hour followed immediately by an infusion of cisplatin 75 mg/M² over 30 to 60 minutes. Repeat every 3 weeks. See docetaxel monograph; premedication required.

Fallopian tube and peritoneal cancers of ovarian origin (unlabeled): Given in combination with paclitaxel as follows. Give paclitaxel 135 to 175 mg/M² as an infusion over 3 hours (extend to 24 hours as indicated by toxicity). Follow with cisplatin 50 to 75 mg/M². Repeat every 3 to 4 weeks. See paclitaxel monograph; premedication required.

DOSE ADJUSTMENTS

All doses adjusted based on prior radiation therapy or chemotherapy. ■ Repeat doses may not be given unless SCr is below 1.5 mg/100 mL and/or BUN is below 25 mg/100 mL. Renal toxicity becomes more prolonged and severe with repeated courses. Renal function must return to normal before next dose is given. ■ Platelets should be 100,000/mm³ and leukocytes 4,000/mm³; verify auditory acuity as within normal limits. ■ Dosing should be cautious in the elderly. Lower-end initial doses may be indicated. Consider decrease in cardiac, hepatic, and renal function; concomitant disease; or other drug therapy; see **Elderly**.

DILUTION

Specific techniques required; see **Precautions.** Initially dilute each 50-mg vial with 50 mL of SWFI (1 mg/mL). Other products are available in liquid form, 1 mg/mL. Withdraw desired dose. Immediately before use, manufacturer recommends diluting a single dose

in 2 liters of D5½NS or D5⅓NS containing 37.5 Gm of mannitol. Do not use D5W. Will decompose if adequate chloride ion not available. Is also diluted in smaller amounts of NS (100 to 500 mL). Do not use needles or IV tubing with aluminum parts to administer; a precipitate will form, and potency will decrease. See **Monitor** for additional optional additives.

Storage: Cisplatin remaining in multidose vial is stable at CRT for 28 days protected from light or 7 days under fluorescent light. Do not refrigerate. Reconstituted solution is stable for 20 hours at RT. Diluted solution is stable at room temperature for at least 24 hours; protect from light if it will not be used within 6 hours. Use immediately if contains mannitol.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not use needles, IV sets, or equipment containing aluminum." Aluminum reacts with cisplatin, causing precipitate formation and loss of potency. A precipitate will form if reconstituted solutions are refrigerated.

One source suggests the following **compatibilities**:

Additive: Carboplatin (Paraplatin), cyclophosphamide (Cytosan), etoposide (VePesid), ifosfamide (Ifex), leucovorin calcium, magnesium sulfate, mannitol, ondansetron (Zofran), paclitaxel (Taxol). Another source adds carmustine (BiCNU).

Y-site: Allopurinol (Aloprim), anidulafungin (Eraxis), aztreonam (Azactam), bleomycin (Blenoxane), caspofungin (Cancidas), cladribine (Leustatin), cyclophosphamide (Cytosan), doripenem (Doribax), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), droperidol (Inapsine), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludara-bine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gemcitabine (Gemzar), granisetron (Kytril), heparin, leucovorin calcium, linezolid (Zyvox), melphalan (Alkeran), methotrexate, metoclopramide (Reglan), mitomycin (Mutamycin), ondansetron (Zofran), paclitaxel (Taxol), palonosetron (Aloxi), pemetrexed (Alimta), propofol (Diprivan), sargramostim (Leukine), teniposide (Vumon), topotecan (Hycamtin), vinblastine, vincristine, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Administer as a slow IV infusion; **should not be given as a rapid IV injection**. Rates vary based on protocol. Manufacturer suggests administering each 1 liter of infusion solution over 3 to 4 hours. Give total dose (2 liters) over 6 to 8 hours. Rate must be sufficient to maintain hydration and diuresis. Infusion times of 30 to 120 minutes are common, but infusion time has also been extended to 24 hours/dose. One source recommends a maximum rate not to exceed 1 mg/min. Too-rapid administration increases nephrotoxicity and ototoxicity.

ACTIONS

A heavy metal complex (platinum and chloride atoms). Has properties similar to alkylating agents and is cell-cycle nonspecific. Inhibits DNA synthesis by formation of DNA cross-links. Concentration is highest in liver, prostate, and kidney; somewhat lower in bladder, muscle, testicle, pancreas, and spleen; and lowest in bowel, adrenal, heart, lung, cerebrum, and cerebellum. Heavily protein bound. Only one fourth to one half of the drug is excreted in the urine by the end of 5 days. Platinum may be present in tissues for as long as 180 days after the last administration. Secreted in breast milk.

INDICATIONS AND USES

Treatment of metastatic testicular tumors; used in combination therapy with other approved chemotherapy agents in patients who have already received appropriate surgical and/or radiotherapeutic procedures. ■ Treatment of metastatic ovarian tumors; used in

combination therapy with other approved chemotherapy agents in patients who have already received appropriate surgical and/or radiotherapeutic procedures. ■ Used as a single agent as secondary treatment in patients with metastatic ovarian tumors refractory to standard chemotherapy who have not previously received cisplatin therapy. ■ Used as a single agent for treatment of patients with transitional cell bladder cancer that is no longer amenable to local treatment such as surgery and/or radiotherapy. ■ Is used in specific combinations with other chemotherapeutic drugs.

Unlabeled uses: First-line therapy for treatment of advanced cancer of the ovary in combination with paclitaxel. ■ First-line treatment of patients with inoperable, locally advanced, or metastatic non–small-cell lung cancer (NSCLC) in combination with gemcitabine, paclitaxel, or docetaxel. ■ Treatment of cancers of the brain, adrenal cortex, breast, cervix, uterus, endometrium, head and neck, esophagus, lung, and liver; osteogenic sarcomas; and numerous other malignancies.

CONTRAINDICATIONS

Hypersensitivity to cisplatin or other platinum-containing compounds, myelosuppressed patients, pre-existing impaired renal function, or hearing deficit.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Adequate facilities and emergency resuscitation equipment and supplies must always be available. ■ Renal toxicity can be cumulative and may be severe. ■ Other major dose-related toxicities include myelosuppression, nausea, and vomiting. ■ Ototoxicity (tinnitus, loss of high-frequency hearing, and/or deafness) can be significant and may be more pronounced in children. ■ Anaphylaxis has been reported and may occur within minutes of cisplatin administration. ■ Labeling changed to read, “Doses greater than 100 mg/M²/cycle once every 3 to 4 weeks are rarely used.” This is an effort to eliminate serious errors resulting from confusion with carboplatin (Paraplatin). Flip-off seal on vial now says, “Call Dr. if dose greater than 100 mg/M²/cycle.” ■ Neuropathies may occur with higher doses, greater frequency of average doses, or prolonged therapy. Usually occur after prolonged therapy but have been reported after a single dose. If symptoms of neuropathy are observed, discontinue cisplatin. ■ See [Elderly](#).

Monitor: Obtain baseline CBC, SCr, BUN, CrCl and calcium, magnesium, potassium, and sodium levels. Repeat CBC weekly and other listed labs before each subsequent cycle. ■ Hydrate patient with 1 to 2 L of infusion fluid for 8 to 12 hours before injection. Urine output should exceed 100 to 150 mL/hr. ■ Maintain adequate hydration and urine output of at least 100 to 200 mL/hr for 24 hours after each dose. ■ Avoid salt and water depletion. ■ Nausea and vomiting are frequently severe and prolonged (up to a week). Prophylactic administration of antiemetics recommended. Fosaprepitant (Emergec), ondansetron (Zofran), metoclopramide (Reglan), or dexamethasone are effective in most patients. ■ Ototoxicity is cumulative; test hearing before administration and regularly during treatment. Ototoxicity increased in pediatric patients. ■ Monitor uric acid levels before and during treatment and maintain hydration. Allopurinol may be indicated (preferred agent); see [Drug/Lab Interactions](#). Alkalinization of urine may also be indicated. ■ Monitor liver function periodically and perform neurologic exams on a regular basis. Neuropathy may present as paresthesias, areflexia, and loss of proprioception and vibratory sensation. ■ Replace depleted electrolytes as necessary. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor infusion site carefully during infusion; local soft tissue toxicity has been reported with extravasation. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Nonhormonal birth control recommended. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; will produce teratogenic effects on the fetus. Has a mutagenic potential. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. ■ Ototoxicity increased in pediatric

patients. Variants in the thiopurine *S*-methyltransferase (TPMT) gene are associated with an increased risk. All pediatric patients should have audiometric monitoring performed before initiation of therapy, before each dose, and for several years after therapy.

Elderly: Dose selection should be cautious; see **Dose Adjustments**. ■ Response (e.g., effectiveness) is similar to younger adults, but length of survival may be shorter. ■ Incidence of myelosuppression (e.g., severe leukopenia, neutropenia, thrombocytopenia), infectious complications, nephrotoxicity, and peripheral neuropathy may be increased.

DRUG/LAB INTERACTIONS

Ototoxicity and nephrotoxicity are potentiated with other **ototoxic or nephrotoxic agents** (e.g., aminoglycosides [e.g., gentamicin] and loop diuretics [e.g., furosemide (Lasix), ethacrynic acid (Edecrin)]). Concurrent use not recommended (Lasix is used to control fluid overload, use caution). ■ Serum levels of **anticonvulsant agents** (e.g., phenytoin [Dilantin]) may become subtherapeutic when used concurrently with cisplatin. Monitor anticonvulsant levels; increased doses may be indicated. ■ Bone marrow toxicity increased with **other antineoplastic agents and/or radiation therapy**. ■ Synergistic with **etoposide** (VePesid); may be beneficial. ■ May affect renal excretion and increase toxicity of many drugs (e.g., **bleomycin, methotrexate**). ■ Cisplatin may increase myelosuppressive effects of **taxane derivatives** (e.g., paclitaxel). ■ Response duration may be shortened with concurrent use of **pyridoxine (vitamin B₆) and altretamine (Hexalen)**. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents.

SIDE EFFECTS

Are frequent; can occur with the initial dose and will become more severe with succeeding doses. Dose-related and cumulative renal insufficiency, including renal failure, is the major dose-limiting toxicity (often noted during the second week following a dose). Acute leukemia, alopecia, anaphylaxis (facial edema, hypotension, tachycardia, and wheezing within minutes of administration), asthenia, cardiac abnormalities, dehydration, diarrhea, electrolyte disturbances (hypocalcemia, hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia), elevated serum amylase, hemolytic anemia, hepatotoxicity, hyperuricemia, malaise, myelosuppression, nausea and vomiting (acute or delayed), syndrome of inappropriate antidiuretic hormone (SIADH), neurotoxicity (including peripheral neuropathy that may be reversible, leukoencephalopathy, and reversible posterior leukoencephalopathy syndrome [RPLS]), ocular toxicity (e.g., blurred vision, cerebral blindness, optic neuritis, papilledema), ototoxicity including tinnitus and hearing loss in the high-frequency range, peripheral neuropathy (may be irreversible), vascular toxicities (e.g., cerebral arteritis, CVA, MI, or thrombotic microangiopathy [hemolytic-uremic syndrome (HUS)]), and vestibular toxicity.

Overdose: Deafness, intractable nausea and vomiting, kidney failure, liver failure, neuritis, ocular toxicity, significant myelosuppression, and death.

ANTIDOTE

Notify physician of all side effects. Cisplatin may have to be discontinued permanently or until recovery. Symptomatic and supportive treatment is indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Pretreatment with amifostine may reduce nephrotoxic, neurotoxic, and hematologic effects. Treat anaphylaxis with epinephrine, corticosteroids, oxygen, and antihistamines. There is no specific antidote. Hemodialysis appears to have little effect on removing platinum from the body because of the rapid and high degree of protein binding.

CLADRIBINE **BBW**

(KLAD-rih-bean)

Antineoplastic
(antimetabolite)

Leustatin

pH 6 to 6.6

USUAL DOSE

In all situations, may be administered on an outpatient basis with an appropriate pump and a central venous line in place. Administer any subsequent course with extreme caution. Hematologic recovery must be considered.

Hairy cell leukemia: 0.09 mg/kg/day equally distributed as a continuous infusion over 24 hours. Repeat daily for 7 consecutive days.

Chronic lymphocytic leukemia and Waldenström's macroglobulinemia (unlabeled): 0.1 mg/kg/day equally distributed as a continuous infusion over 24 hours for 7 consecutive days.

Acute myeloid leukemia and mantle cell lymphoma (unlabeled): 5 mg/M²/day over 2 hours for 5 days.

DOSE ADJUSTMENTS

May be required with severe bone marrow impairment, with prior radiation or myelosuppressive agents. ■ May be required in severe renal insufficiency; effects of renal or hepatic impairment on excretion of cladribine not yet clarified for humans. ■ See [Drug/Lab Interactions](#).

DILUTION

Specific techniques required; see Precautions. Available in single-use 10-mL vials containing 10 mg (1 mg/mL). Contains no preservatives; aseptic technique imperative. May develop a precipitate at low temperatures. Warm naturally to room temperature and shake vigorously. Do not heat or microwave.

Inpatient continuous infusion: Add the calculated daily dose of cladribine through a sterile 0.22-micron disposable hydrophilic syringe filter to an infusion bag containing 500 mL of NS.

Outpatient continuous infusion: A total 7-day dose is added to a calculated amount of bacteriostatic NS to make a total volume of 100 mL. Add the calculated dose of cladribine (7 days × 0.09 mg/kg or 0.09 mL/kg) to the infusion reservoir through the sterile 0.22-micron disposable hydrophilic syringe filter, then add the calculated amount of bacteriostatic NS to the reservoir through the filter. Total volume in the reservoir should equal 100 mL. Specific equipment (i.e., a sterile medication reservoir and pump capable of delivering accurate minute amounts into a central venous line [presently using SIMS Deltec medication cassette with SIMS Deltec pump]) and a specific process including the use of a 0.22-micron syringe filter are required. Preparation of cassette usually done by pharmacist. Line of cassette remains clamped until attached to central venous line and pump is functional. See literature for details and follow all specific instructions for medication pump.

Filters: To minimize the risk of microbial contamination, a 0.22-micron hydrophilic syringe filter is required in the preparation of the outpatient continuous infusion.

Storage: Protect from light. Refrigerate before reconstitution. Never refreeze. Discard any unused concentrate. **500 mL dilution** is stable for at least 24 hours at RT under normal fluorescent light; may be refrigerated for up to 8 hours after dilution. Immediate use preferred. **100 mL dilution** is stable in reservoir of medication cassette for 7 days if correctly diluted.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

D5W will cause degradation of cladribine. Manufacturer states, "Adherence to the recommended diluents and infusion systems is advised."

One source suggests the following **compatibilities**:

Y-site: Aminophylline, bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), chlorpromazine (Thorazine), cisplatin (Platinol), cyclophosphamide (Cytosan), cytarabine (ARA-C), dexamethasone (Decadron), diphenhydramine (Benadryl), dobutamine, dopamine, doxorubicin (Adriamycin), droperidol (Inapsine), enalaprilat (Vasotec IV), etoposide (VePesid), famotidine (Pepcid IV), furosemide (Lasix), gallium nitrate (Ganite), granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), leucovorin calcium, lorazepam (Ativan), mannitol, meperidine (Demerol), mesna (Mesnex), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), mitoxantrone (Novantrone), morphine, nalbuphine, ondansetron (Zofran), paclitaxel (Taxol), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, teniposide (Vumon), vincristine.

RATE OF ADMINISTRATION

Inpatient continuous infusion: A single dose properly diluted evenly distributed as an infusion over 24 hours.

Outpatient continuous infusion: Administered through a central venous line (very concentrated solution). Medication reservoir and pump required (presently using Pharmacia Deltec medication cassette and pump worn as a portable pack). Set rate for equal distribution of 100 mL over 7 days. Follow all specific instructions for pump.

ACTIONS

A chlorinated purine nucleoside analog and synthetic antineoplastic agent. Mechanism of action is not known, but it is believed to be cytotoxic by inhibiting both DNA synthesis and repair. Affects both dividing and resting cells. The 7-day course for hairy cell leukemia has resulted in complete response in a majority of patients with no evidence of persistent bone marrow disease. Crosses the blood-brain barrier. Average half-life is 4.2 to 9.2 hours. Specific methods of metabolism and routes of excretion are not known. Some drug does appear in urine.

INDICATIONS AND USES

Treatment of active hairy cell leukemia (HCL) as defined by clinically significant anemia, neutropenia, thrombocytopenia, or disease-related symptoms.

Unlabeled uses: Treatment of acute myeloid leukemia, chronic lymphocytic leukemia, mantle cell lymphoma, and Waldenström's macroglobulinemia.

CONTRAINDICATIONS

Hypersensitivity to cladribine or any of its components; neonates (7 day dilution contains benzyl alcohol).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Anticipate severe suppression of bone marrow function, including neutropenia, anemia, and thrombocytopenia; usually reversible and appears to be dose dependent. ■ Myelosuppressive effects are most notable during the first month after therapy. ■ Serious, sometimes fatal, infections have been reported (e.g., respiratory tract infections, pneumonia, viral skin infections, sepsis). ■ Neurologic toxicity, including paraparesis and quadriparesis, has been reported. Usually occurs with higher doses but has been seen with standard dosing regimens. ■ Because of the possibility of increased toxicity, use caution in known or suspected renal or hepatic insufficiency, or any severe bone marrow impairment, or prior cytotoxic or radiation therapy. ■ Acute nephrotoxicity has been observed with high doses (4 to 9 times the recommended dose for HCL). Risk of toxicity increased when given concurrently with other nephrotoxic agents and/or therapies. ■ Rare cases of tumor lysis syndrome have been reported. ■ Appears to be no relationship between serum concentrations and ultimate clinical outcome. ■ Additional courses did not improve overall response. ■ Current studies suggest that overall response rate may be decreased in patients previously treated with splenectomy, deoxycoformycin (pentostatin), and in patients re-

fractory to alpha-interferon. ■ May cause prolonged bone marrow hypocellularity; clinical significance not known.

Monitor: Obtain baseline CBC with differential and platelets before therapy. May be repeated as indicated, but usually not required again until 7 or 8 days after treatment begins; then monitor as indicated for at least 4 to 8 weeks (anemia, neutropenia, thrombocytopenia, infection [bacterial, fungal, or viral], and bleeding are common and must be treated promptly). Monitoring schedule facilitates outpatient treatment; keep in close contact with patient. ■ Consider possibility of infection if fever occurs; appropriate lab tests, x-rays, and broad-spectrum antibiotics may be indicated, especially in a febrile neutropenic patient. ■ Monitor uric acid levels before and during treatment, maintain hydration; allopurinol may be indicated (preferred agent). Alkalinization of urine may also be indicated. ■ Monitor renal and hepatic function periodically. ■ Platelet count usually returns to normal in 12 days (may be delayed if severe baseline thrombocytopenia was present), absolute neutrophil count (ANC) usually returns to normal in 5 weeks, and hemoglobin in 8 weeks. All should be normal by 9 weeks. ■ Complete response is indicated by an absence of hairy cells in bone marrow and peripheral blood and normalization of peripheral blood parameters. Confirm response with bone marrow aspiration and biopsy between 9 weeks and 4 months. ■ Prophylactic antiemetics may improve patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). Avoid constipation and avoid alcohol and aspirin (risk of GI bleeding).

Patient Education: Avoid pregnancy; consider birth control options and future fertility. ■ Report fever, bleeding, cough, edema, injection site reactions, malaise, mouth sores, rashes, shortness of breath, stomach pain, and tachycardia promptly. Maintain hydration. ■ Manufacturer supplies a patient education booklet; review thoroughly and discuss with physician and nurse. ■ Review all literature provided with pump to deliver outpatient dosing. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; has potential to cause fetal harm. Has caused suppression of testicular cells in monkeys; effect on human fertility unknown. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established. Investigationally used in higher doses to treat relapsed acute leukemia. Dose-limiting toxicity occurred.

Elderly: Geriatric-specific problems not encountered in studies to date. Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

Increased toxicity with other **myelosuppressive agents** (e.g., methotrexate). ■ May raise concentration of blood uric acid, increased doses of **antigout agents** (e.g., allopurinol [Aloprim]) may be indicated; **avoid uricosurics** (e.g., probenecid, sulfinpyrazole [Anurane]). ■ Do not administer **live attenuated vaccines** to patients receiving antineoplastic agents.

SIDE EFFECTS

Fever occurs first. Onset of thrombocytopenia begins in 7 to 10 days followed by anemia (severe) and neutropenia (severe). Fatigue, headache, injection site reactions, infection, nausea, and rash are common. Many other side effects may or may not be related to cladribine: abdominal pain, abnormal breath sounds, abnormal chest sounds, anorexia, arthralgia, asthenia, chills, constipation, cough, diaphoresis, diarrhea, dizziness, edema, epistaxis, erythema, insomnia, malaise, myalgia, pain, petechiae, pruritus, purpura, shortness of breath, tachycardia, trunk pain, weakness, vomiting.

Post-Marketing: Most of these additional side effects occurred in patients who received multiple courses of cladribine and include altered level of consciousness, aplastic anemia, conjunctivitis, elevated bilirubin and transaminases, hemolytic anemia, hypereosinophilia, hypersensitivity, myelodysplastic syndrome, neurologic toxicity, opportunistic infections, pulmonary interstitial infiltrates (usually with an infectious etiology), renal

impairment, Stevens-Johnson syndrome, toxic epidermal necrolysis, and tumor lysis syndrome.

Overdose: Acute nephrotoxicity, irreversible neurologic toxicity (paraparesis/quadruparesis), severe bone marrow suppression (anemia, neutropenia, and thrombocytopenia).

ANTIDOTE

Keep physician informed of all side effects; many will be treated symptomatically as indicated. Platelet or RBC transfusions are frequently required to treat anemia or thrombocytopenia, especially during the first month. Filgrastim (Neupogen) or pegfilgrastim (Neulasta) may be used to increase neutrophil count, although recovery is usually spontaneous. Use specific antibiotics to combat infection. Discontinue cladribine if renal toxicity, neurotoxicity, or overdose occurs. No specific antidote for overdose. Supportive therapy as indicated will help sustain the patient in toxicity. Resuscitate if indicated.

CLEVIDIPINE BUTYRATE

(klev-ID-i-peen BUE-tih-rate)

Calcium channel blocker
Antihypertensive

Cleviprex

pH 6 to 8

USUAL DOSE

Must be individualized to achieve the desired BP reduction. Titrate to patient response and BP goal.

Initial dose: 1 to 2 mg/hr (2 to 4 mL/hr) as a continuous infusion.

Dose titration: Initially, double the dose at 90-second intervals. As the BP approaches goal, increase the dose by less than doubling and lengthen the time between dose adjustments to every 5 to 10 minutes. In general, a 1- to 2-mg/hr increase in dose will produce an additional 2- to 4-mm Hg decrease in systolic pressure. The maximum dose used for most patients in studies was 16 mg/hr.

Maintenance dose: The desired therapeutic response for most patients occurs at 4 to 6 mg/hr (8 to 12 mL/hr). Doses as high as 32 mg/hr (64 mL/hr) have been administered. Data are limited. Because of lipid-load restrictions, no more than 1,000 mL or an average of 21 mg/hr (42 mL/hr) is recommended per 24-hour period. In studies, most infusions were administered for less than 24 hours. There is little experience with infusions lasting more than 72 hours at any dose.

Transition to oral therapy: Discontinue or titrate the infusion downward while establishing appropriate oral therapy. Consider the lag time of onset of oral agent's effect. See [Monitor](#).

DOSE ADJUSTMENTS

Lower-end initial doses may be indicated in the elderly. Consider the potential for decreased organ function and concomitant disease or drug therapy. ■ Patients with abnormal hepatic or renal function may receive the initial dose listed under Usual Dose.

DILUTION

Strict aseptic technique is imperative. Available as a single-dose, ready-to-use vial containing a 0.5-mg/mL phospholipid emulsion that can support microbial growth. Invert vial gently several times before use to ensure uniformity of emulsion.

Filter: No data available from manufacturer.

Storage: Refrigerate unopened vials at 2° to 8° C (36° to 46° F) or store at 25° C (77° F) for up to 2 months. Vials stored at RT should not be returned to the refrigerator. Do not freeze. Protect from light until administration. Once vial is punctured, use within 4 hours and discard any unused portion, including that which is currently being infused.

COMPATIBILITY

Manufacturer states, “Should not be administered in the same line as other medications. Should not be diluted, but can be administered via a Y-tube or medication port with SWFI, NS, D5W, D5NS, D5LR, LR, and 10% amino acid.”

RATE OF ADMINISTRATION

Administer as a continuous infusion as outlined in Usual Dose. Use of an infusion device required. May be given through a central or peripheral line.

ACTIONS

A dihydropyridine calcium channel blocker. Mediates the influx of calcium during depolarization in arterial smooth muscle. Reduces mean arterial BP by decreasing systemic vascular resistance in a dose-dependent manner. Does not reduce cardiac filling pressure (preload), confirming the lack of effect on venous capacitance vessels. Vasodilation and the resulting decrease in BP may produce a reflex increase in heart rate. Onset of effects begins within 2 to 4 minutes. Evidence of tolerance or hysteresis has not been observed in patients receiving infusions of up to 72 hours' duration. Full recovery of BP is achieved 5 to 15 minutes after the infusion is stopped. Rapidly distributed. Highly protein bound. Metabolized by hydrolysis in the blood and extravascular tissues, making its elimination unlikely to be affected by hepatic or renal dysfunction. Half-life is approximately 15 minutes. Excreted primarily in urine and, to a lesser extent, in feces.

INDICATIONS AND USES

Reduction of BP when oral therapy is not feasible or not desirable.

CONTRAINDICATIONS

Allergies to soybeans, soy products, eggs, or egg products. ■ Defective lipid metabolism such as pathologic hyperlipidemia, lipid nephrosis, or acute pancreatitis if accompanied by hyperlipidemia. ■ Severe aortic stenosis (afterload reduction can be expected to reduce myocardial oxygen delivery).

PRECAUTIONS

For IV use only. ■ Strict aseptic technique required; see [Dilution](#). ■ May produce systemic hypotension and reflex tachycardia. Dose reduction may be indicated. ■ Use caution in patients with lipid metabolism disorders. Contains approximately 0.2 Gm of lipid per mL. Lipid intake restrictions may be necessary in these patients. A reduction in the quantity of concurrently administered lipids (e.g., propofol, IV fat) may be necessary to compensate for the amount of lipid infused as part of the clevidipine formulation. See [Usual Dose](#). ■ May produce a negative inotropic effect and exacerbate heart failure. ■ Rebound hypertension may occur in patients undergoing prolonged therapy; see [Monitor](#). ■ Has not been studied for the treatment of hypertension associated with pheochromocytoma.

Monitor: Monitor BP and HR during infusion and until vital signs are stable. ■ Rebound hypertension may occur in patients who receive a prolonged infusion and are not transitioned to other antihypertensive therapies. Monitor BP for at least 8 hours after the infusion is discontinued. ■ During transition to oral therapy, continue BP monitoring until patient is stabilized. ■ Monitor heart failure patients closely.

Patient Education: Promptly report signs of a hypertensive emergency (e.g., neurologic symptoms, vision changes, evidence of CHF). ■ Continued follow-up and treatment of pre-existing hypertension required.

Maternal/Child: Category C: use during pregnancy only if potential benefit justifies potential risk to the fetus. ■ Safety in labor and delivery not established. Other calcium channel blockers suppress uterine contractions in humans. ■ Safety for use in breast-feeding not established; effects unknown. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response similar to that seen in younger adults; however, greater sensitivity in the elderly cannot be ruled out. ■ See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Formal studies have not been conducted. ■ Does not have the potential for inducing or inhibiting the cytochrome P₄₅₀ system. ■ Use of **beta-blockers** as treatment for clevidipine-induced reflex tachycardia is not recommended. Experience is limited. ■ If used concomitantly with **beta-blockers** and beta-blockers are to be discontinued, withdraw beta-blocker therapy gradually. Clevidipine will not protect against the effects of abrupt beta-blocker withdrawal.

SIDE EFFECTS

Acute renal failure, atrial fibrillation, cardiac arrest, dyspnea, flushing, headache, hypotension, myocardial infarction, nausea, peripheral edema, rebound hypertension, reflex tachycardia, syncope, and vomiting.

Post-Marketing: Decreased oxygen saturation (possible pulmonary shunting), hypersensitivity reactions, increased blood triglycerides, ileus.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Reduce dose for systemic hypotension or reflex tachycardia. Discontinue for suspected overdose. Reduction in antihypertensive effects should be seen within 5 to 15 minutes. Monitor BP and support if needed. Resuscitate as necessary.

CLINDAMYCIN PHOSPHATE **BBW**

(klin-dah-MY-cin FOS-fayt)

Antibacterial
Antiprotozoal
(lincosamide)

Cleocin Phosphate

pH 5.5 to 7

USUAL DOSE

Doses based on susceptibility of specific organisms; see literature.

Serious infections: 600 to 1,200 mg/24 hr in 2, 3, or 4 equally divided doses (300 to 600 mg every 12 hours, 200 to 400 mg every 8 hours, or 150 to 300 mg every 6 hours).

More severe infections: 1,200 to 2,700 mg/24 hr in 2, 3, or 4 equally divided doses (600 to 1,350 mg every 12 hours, 400 to 900 mg every 8 hours, or 300 to 675 mg every 6 hours).

Life-threatening infections: Up to 4.8 Gm/24 hr has been given.

Acute pelvic inflammatory disease (unlabeled): 900 mg every 8 hours for at least 4 days. Concurrent administration of 2 mg/kg of gentamicin as an initial dose and 1.5 mg/kg every 8 hours thereafter is recommended. Continue both drugs for at least 48 hours after patient improves. Complete 10- to 14-day treatment program with oral doxycycline or clindamycin.

CNS toxoplasmosis in AIDS (unlabeled): 600 mg every 6 hours. Used in combination with pyrimethamine (Daraprim).

***Pneumocystis jiroveci* pneumonia (unlabeled):** 600 mg every 6 hours or 900 mg every 8 hours. Used in combination with primaquine.

Babesiosis (unlabeled): 1,200 to 2,400 mg/24 hr in 4 equally divided doses (300 to 600 mg every 6 hours). Continue for 7 to 10 days. Used in combination with quinine.

Prophylaxis of bacterial endocarditis: 600 mg IV or PO 30 minutes before procedure.

PEDIATRIC DOSE

Pediatric patients over 1 month of age: 20 to 40 mg/kg of body weight/24 hr in 3 or 4 equally divided doses based on the seriousness of the infection (5 to 10 mg/kg every 6 hours or 6.66 to 13.3 mg/kg every 8 hours). Alternately 350 mg/M²/24 hr may be used (87.5 mg/M² every 6 hours or 116.6 mg/M² every 8 hours). 450 mg/M²/24 hr may be

used for more serious infections if necessary (112.5 mg/M² every 6 hours or 150 mg/M² every 8 hours).

Babesiosis (unlabeled): A suggested dose is 7 to 10 mg/kg every 6 to 8 hours. Continue for 7 to 10 days. Used in combination with 25 mg/kg/24 hr of oral quinine.

Prophylaxis of bacterial endocarditis: 20 mg/kg IV or PO 30 minutes before procedure. Do not exceed adult dose.

NEONATAL DOSE

See *Maternal/Child*.

Under 1 month of age, full term: 3.75 to 5 mg/kg every 6 hours or 5 to 6.7 mg/kg every 8 hours. Another source suggests:

Infants under 7 days of age weighing less than 2 kg: 5 mg/kg every 12 hours.

Infants under 7 days of age weighing over 2 kg: 5 mg/kg every 8 hours.

Infants over 7 days of age weighing less than 1.2 kg: 5 mg/kg every 12 hours.

Infants over 7 days of age weighing 1.2 to 2 kg: 5 mg/kg every 8 hours.

Infants over 7 days of age weighing over 2 kg: 5 mg/kg every 6 hours.

DOSE ADJUSTMENTS

May be required in severely impaired liver or renal function.

DILUTION

Available prediluted in 300-, 600-, and 900-mg ready-to-use Galaxy bags, in ADD-Vantage vials for use with ADD-Vantage infusion containers, as a 150 mg/mL solution in 2-mL flip-top vials, and in pharmacy bulk packages (for use only by the pharmacy). Dilute ADD-Vantage vials with 50 to 100 mL of D5W or NS. Doses prepared using the 150 mg/mL solution are most commonly diluted in 50 to 100 mL of D5W, NS, or other **compatible** infusion solution. Concentration of clindamycin in diluent should not exceed 18 mg/mL. See chart on inside back cover or product insert for additional diluents. May be further diluted in larger amounts of **compatible** infusion solutions and given as a continuous infusion after the initial dose.

Storage: Store at CRT before use; do not refrigerate. Administration as soon as possible after dilution is recommended. Stable at CRT for at least 24 hours in **compatible** diluents and infusion solutions. See manufacturer's literature for additional stability data if diluted solutions are kept at RT, refrigerated, or frozen. Frozen solutions should be thawed at room temperature and not refrozen.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **compatible** for 24 hours at RT with IV solutions containing sodium chloride, glucose, calcium, or potassium and with solutions containing vitamin B complex in concentrations usually used clinically. Manufacturer states, "No **incompatibility** has been demonstrated with the antibiotics gentamicin, kanamycin, or penicillin."

Manufacturer lists as **incompatible** with aminophylline, ampicillin, barbiturates, calcium gluconate, magnesium sulfate, phenytoin (Dilantin).

Sources suggest the following **compatibilities**:

Solution: Isolyte H, D5/Isolyte M, D5/Isolyte P, Normosol R; see chart on inside back cover.

Additive: Manufacturer states no **incompatibility** has been demonstrated with gentamicin or penicillin. Other sources list amikacin (Amikin), ampicillin, aztreonam (Azactam), cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefoxitin (Mefoxin), ceftazidime (Fortaz), cefuroxime (Zinacef), fluconazole (Diflucan), heparin, hydrocortisone sodium succinate (Solu-Cortef), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), potassium chloride (KCl), ranitidine (Zantac), sodium bicarbonate, tobramycin, verapamil.

Y-site: Acyclovir (Zovirax), amifostine (Ethyol), amiodarone (Nexterone), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin

(Angiomax), ceftaroline (Teflaro), cisatracurium (Nimbex), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), esmolol (Brevibloc), etoposide phosphate (Etopophos), fenoldopam (Corlopam), fludarabine (Fludara), foscarnet (Foscavir), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), labetalol, levofloxacin (Levaquin), linezolid (Zyvox), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), midazolam (Versed), milrinone (Primacor), morphine, multivitamins (M.V.I.), nicardipine (Cardene IV), ondansetron (Zofran), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), teniposide (Vumon), theophylline, thiotepa, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Severe hypotension and cardiac arrest can occur with too-rapid injection.

Intermittent infusion: 30 mg or fraction thereof over at least 1 minute (each 300 mg over a minimum of 10 minutes/1,200 mg over a minimum of 40 to 60 minutes). Do not give more than 1,200 mg in single 1-hour infusion.

Continuous infusion: Administer initial dose at 10 (15 or 20) mg/min over 30 minutes (rapid infusion rate). Will result in serum levels above 4 (5 or 6) mg/mL. To maintain these serum levels, continue infusion at 0.75 (1 or 1.25) mg/min.

ACTIONS

A semisynthetic antibiotic that quickly converts to active clindamycin. Bacteriostatic with activity against Gram-positive aerobes and anaerobes, as well as some Gram-negative anaerobes. It inhibits protein synthesis in the bacterial cell, producing irreversible changes in the protein-synthesizing ribosomes. Widely distributed in most body fluids, tissues, and bones. There is no clinically effective distribution to cerebrospinal fluid. Half-life is approximately 3 hours. Excreted in urine and feces in small amounts. Most excreted in inactive form in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious infections caused by susceptible anaerobic bacteria; treatment of infections due to susceptible strains of streptococcal, pneumococcal, and staphylococcal bacteria in penicillin-allergic patients; or treatment of infections that do not respond or are resistant to other less toxic antibiotics, such as penicillins or cephalosporins. Conditions indicated include septicemia and lower respiratory tract, skin and skin structure, gynecologic, intra-abdominal, and bone and joint infections.

Unlabeled uses: Alternative to sulfonamides with pyrimethamine to treat CNS toxoplasmosis in AIDS patients. ■ Treat *Pneumocystis jiroveci* pneumonia in combination with primaquine. ■ Treatment of babesiosis. ■ Prophylaxis of bacterial endocarditis. ■ Treatment of acute pelvic inflammatory disease.

CONTRAINDICATIONS

Known hypersensitivity to clindamycin or lincomycin. Treatment of minor bacterial or viral infections.

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, clindamycin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. Because its use has been associated with severe colitis, it should be used only when absolutely necessary and when an alternate drug is not acceptable. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to clindamycin. ■ Avoid prolonged use; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution with a history of GI, severe renal, or liver disease,

and in patients with a history of asthma or significant allergies. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with clindamycin. ■ Not appropriate to treat meningitis.

Monitor: Capable of causing severe, even fatal, colitis; observe for symptoms of diarrhea. ■ Periodic blood cell counts and liver and kidney studies are indicated in prolonged therapy.

Patient Education: Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Do not treat diarrhea without notifying physician.

Maternal/Child: Category B: use only if clearly needed. ■ Best to discontinue breastfeeding, even though considered acceptable by pediatricians. ■ Contains benzyl alcohol, which has been associated with a fatal “gasping syndrome” in neonates. Monitor organ system functions if used in pediatric patients.

Elderly: Monitor carefully for changes in bowel frequency; may not tolerate diarrhea well.

DRUG/LAB INTERACTIONS

May potentiate other **neuromuscular blocking agents** (e.g., atracurium [Tracrium], kanamycin, streptomycin) and cause profound respiratory depression. ■ Antagonized by **erythromycin**. ■ May decrease **cyclosporine** (Sandimmune) levels. Monitor and adjust dose if necessary.

SIDE EFFECTS

Abdominal pain, agranulocytosis, anaphylaxis, anorexia, azotemia, cardiac arrest, CDAD, diarrhea, elevated ALT, eosinophilia (transient), erythema multiforme, esophagitis, hypersensitivity reactions, hypotension, jaundice, leukopenia, metallic taste, nausea, neutropenia (transient), oliguria, polyarthritis (rare), pseudomembranous colitis, skin rashes, tenesmus (straining at stool), thrombocytopenic purpura, thrombophlebitis, urticaria, vomiting.

ANTIDOTE

Notify the physician of any side effects. Discontinue the drug if indicated (e.g., CDAD, diarrhea, hypersensitivity reactions), treat hypersensitivity reactions as indicated, and resuscitate as necessary. Mild cases may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis or CAPD will not decrease blood levels in toxicity.

CLOFARABINE(kloh-**FARE**-ah-bean)**Antineoplastic
(metabolic inhibitor)****Clolar****pH 4.5 to 7.5****PEDIATRIC DOSE**

Premedication: Consider prophylactic anti-emetic medications. Consider use of prophylactic steroids (e.g., hydrocortisone 100 mg/M² on Days 1 through 3) to mitigate or prevent the development of systemic inflammatory response syndrome (SIRS) or capillary leak syndrome (e.g., hypotension, pulmonary edema, tachycardia, tachypnea). See [Drug/Lab Interactions](#).

Clofarabine: 52 mg/M² as an infusion each day for 5 consecutive days. Dose is based on body surface area (BSA), which is calculated using the actual height and weight before the start of each cycle. Repeat every 2 to 6 weeks; see [Dose Adjustments](#). Frequency is based on recovery or return to baseline organ function. Median time between cycles during clinical studies was 28 days (range 12 to 55 days).

DOSE ADJUSTMENTS

Administer subsequent cycles no sooner than 14 days from the starting day of the previous cycle provided the patient's ANC is greater than or equal to $0.75 \times 10^9/L$. ■ Reduce dose by 50% in patients with a CrCl between 30 and 60 mL/min. Information is insufficient to make a dose recommendation in patients with a CrCl less than 30 mL/min or in patients on dialysis. ■ Reduce the dose of the next cycle by 25% in patients experiencing a Grade 4 neutropenia (ANC less than $0.5 \times 10^9/L$) that lasts 4 or more weeks. ■ Withhold clofarabine if a clinically significant infection develops. When the infection is clinically controlled, restart therapy at full dose. ■ Discontinue if hypotension develops at any time during the 5 days of administration. ■ Discontinue drug immediately if Grade 3 or higher increases in SCr occur; see [Monitor](#) and [Antidote](#). May be restarted (generally with a 25% dose reduction) when the patient is stable and organ function has returned to baseline. ■ Discontinue for Grade 3 or greater liver enzyme elevations. ■ Discontinue drug immediately if S/S of SIRS or capillary leak syndrome occur; see [Monitor](#) and [Antidote](#). May be restarted (generally with a 25% dose reduction) when the patient is stable. ■ Withhold clofarabine if a Grade 3 non-infectious nonhematologic toxicity occurs (excluding transient elevations in serum transaminases and/or serum bilirubin and/or nausea and vomiting that is controlled by antiemetics). With resolution or a return to baseline, restart clofarabine at a 25% dose reduction. ■ Discontinue therapy if a Grade 4 non-infectious nonhematologic toxicity occurs.

DILUTION

Specific techniques required; see [Precautions](#). Available in single-use 20-mL vials containing 20 mg (1 mg/mL). Contains no preservatives; aseptic technique is imperative. Calculate the exact number of vials needed to achieve the total dosing volume required.

$$\text{Total number of vials required} = \text{Total dose (mg)} \div 20 \text{ mg}$$

$$\text{Dosing volume (mL)} = \text{Total dose (mg)}$$

For example, a child with a body surface area (BSA) of 0.75 M² would need a dose of 39 mg of clofarabine ($39 \div 20 \text{ mg} = 1.95$ vials, so 2 vials of clofarabine would be needed; 39 mg equals a dosing volume of 39 mL).

Withdraw the calculated dose from the vial(s). Using a 0.2-micron syringe filter, add the calculated dose to a sufficient volume of D5W or NS to provide a final concentration between 0.15 mg/mL and 0.4 mg/mL (e.g., 39 mg [39 mL in the example above] added to 100 mL of D5W or NS will provide a final concentration of approximately 0.28 mg/mL).

Filters: Use of a 0.2-micron syringe filter is recommended for use during dilution in D5W or NS.

Storage: Store unopened vials at CRT. Diluted solutions may be stored at CRT but must be used within 24 hours.

COMPATIBILITY

Manufacturer states, “To prevent drug **incompatibilities**, no other medications should be administered through the same IV line.”

RATE OF ADMINISTRATION

A single dose properly diluted and evenly distributed as an infusion over 2 hours.

ACTIONS

A second-generation purine nucleoside analog. Acts by inhibiting DNA synthesis. Also disrupts the mitochondrial membrane, causing the release of mitochondrial proteins, cytochrome C, and apoptosis-inducing factors, which leads to cell death. Results in a rapid reduction of peripheral leukemia cells. Metabolism in the liver is very limited. Pathways of nonhepatic elimination not known. Estimated half-life is 5.2 hours. Excreted primarily in the urine.

INDICATIONS AND USES

Treatment of pediatric patients 1 to 21 years of age with relapsed or refractory acute lymphoblastic leukemia (ALL) after treatment with at least two prior regimens. Induction of a complete response is desired; increased survival or other clinical benefits have not been studied.

Unlabeled uses: Treatment of relapsed and refractory acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS).

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Most patients have hematologic impairment as a manifestation of the leukemia. Because of a pre-existing immunocompromised condition, treatment may result in prolonged and severe neutropenia and an increased risk of infection, including severe and fatal sepsis and opportunistic infections. ■ Use with great caution in patients with impaired hepatic or renal function. ■ May develop tumor lysis syndrome, cytokine release syndrome, systemic inflammatory response syndrome, capillary leak syndrome, and organ dysfunction; deaths have been reported; see **Monitor**. ■ Patients who have previously received a hematopoietic stem cell transplant (HSCT) are at higher risk for hepatotoxicity suggestive of veno-occlusive disease (VOD) following treatment with clofarabine (40 mg/M²) used in combination with etoposide (VePesid 100 mg/M²) and cyclophosphamide (Cytosan 440 mg/M²); has also been reported with monotherapy. Severe and fatal hepatotoxic events have been reported in pediatric patients with relapsed or refractory acute leukemia. ■ Safety and effectiveness in adults not established. In a Phase 1 study of adults with refractory and/or relapsed hematologic malignancies, the pediatric dose of 52 mg/M² was not tolerated.

Monitor: Obtain baseline CBC with differential and platelets and serum electrolytes. Bone marrow suppression is expected and is usually reversible (with interruption of clofarabine treatment) but can be severe; monitor regularly and more frequently in patients who develop cytopenias. Monitoring of CBC and platelets is recommended daily during the 5 days of clofarabine administration, then 1 to 2 times weekly or as clinically indicated. ■ Obtain baseline renal and hepatic function studies (e.g., SCr, bilirubin, ALT, AST), and uric acid levels. Monitor renal and hepatic function closely during the 5 days of clofarabine administration. Discontinue drug immediately if Grade 3 or higher increases in SCr or bilirubin occur; see **Antidote**. ■ Obtain baseline ECG; repeat as indicated. ■ Monitor HR, BP, and respiratory status closely during infusion. Hypotension

should be reported immediately; see **Antidote**. ■ Monitor for S/S of tumor lysis syndrome (e.g., hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure). Adequate hydration, antihyperuricemics (e.g., allopurinol), and alkalinization of urine are indicated to prevent and/or treat hyperuricemia due to tumor lysis syndrome. ■ Monitor for S/S of cytokine release (e.g., hypotension, pulmonary edema, tachycardia, tachypnea); may develop into systemic inflammatory response syndrome (SIRS)/capillary leak syndrome (rapid onset of respiratory distress, hypotension, pleural and pericardial effusion, and multi-organ failure). Close monitoring and early intervention may reduce risk; see **Antidote**. To reduce the effects of tumor lysis and other adverse events (e.g., SIRS), the continuous administration of IV fluids throughout the 5 days of clofarabine treatment is recommended. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending the result of C/S in a febrile neutropenic patient. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Avoid pregnancy; nonhormonal birth control recommended for men and women. Report a suspected pregnancy immediately. ■ Drink plenty of fluids and avoid dehydration that may be caused by diarrhea and vomiting; report promptly if significant. ■ Promptly report bleeding, decreased urine output, dizziness, fainting spells, infection, jaundice, light-headedness, rapid respiratory rate, or a rapid heart rate. ■ Review medications with pharmacist or physician. Avoid medications that may be hepatotoxic or nephrotoxic, including OTC or herbal medications. ■ Skin rash may occur; report promptly if significant. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. Also has dose-related effects on male reproductive organs in animals. ■ Discontinue breast-feeding.

Elderly: Not indicated in this patient population.

DRUG/LAB INTERACTIONS

Clinical drug-drug interactions have not been studied; however, the following cautions should be considered. ■ Primarily excreted by the kidneys; avoid drugs with known renal toxicity during the 5 days of clofarabine administration (e.g., **aminoglycosides** [e.g., gentamicin], **amphotericin B**, **NSAIDs** [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], **rifampin** [Rifadin]). ■ The liver is a known target organ for toxicity; avoid drugs known to induce hepatic toxicity (e.g., **amiodarone** [Nexterone], **NSAIDs** [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], **phenothiazines** [e.g., prochlorperazine (Compazine)], **zidovudine** [AZT, Retrovir]). ■ Close monitoring is required with concomitant administration of medications affecting blood pressure or cardiac function (e.g., **diuretics** [furosemide (Lasix)], **calcium channel blockers** [diltiazem (Cardizem)], **and other antihypertensives**). ■ Cytochrome P₄₅₀ inhibitors (e.g., cimetidine [Tagamet], erythromycins, antifungal agents [e.g., itraconazole (Sporanox)], ritonavir [Norvir], verapamil) and cytochrome P₄₅₀ inducers (e.g., carbamazepine [Tegretol], phenobarbital, phenytoin [Dilantin], rifampin [Rifadin]) are unlikely to affect the metabolism of clofarabine. The effect on cytochrome P₄₅₀ substrates has not been studied.

SIDE EFFECTS

Bone marrow suppression (e.g., anemia, leukopenia, neutropenia, thrombocytopenia) is anticipated, appears to be dose dependent, and is usually reversible. Anxiety, diarrhea, fatigue, febrile neutropenia, fever, flushing, headache, mucosal inflammation, nausea and vomiting, palmar-plantar erythrodysesthesia syndrome, pruritus, and rash occur most frequently. Cardiac toxicity (e.g., left ventricular systolic dysfunction, pericardial effusion, tachycardia) has been reported. SIRS/capillary leak syndrome (e.g., rapid onset of respiratory distress, hypotension, pleural and pericardial effusion, and multi-organ failure) has occurred and can be fatal. Hepatotoxicity, renal toxicity, and venous occlusive disease of the liver have occurred. Numerous additional side effects may occur and include abdominal pain, anorexia, arthralgia, back pain, confusion, constipation, cough,

depression, dermatitis, dizziness, dyspnea, edema, elevated creatinine, epistaxis, erythema, gingival bleeding, hematuria, hepatobiliary toxicity (e.g., elevated AST, ALT, bilirubin), hepatomegaly, hypertension, hypotension, infections (e.g., bacteremia, cellulitis, herpes simplex, oral candidiasis, pneumonia, sepsis, staphylococcal), injection site pain, irritability, jaundice, lethargy, myalgia, pain, petechiae, pleural effusion, renal toxicity, respiratory distress, rigors, somnolence, sore throat, transfusion reaction, tremor, weight loss.

Post-Marketing: Bone marrow failure, GI hemorrhage (including fatalities), Stevens-Johnson syndrome, toxic epidermal necrolysis, and veno-occlusive disease.

ANTIDOTE

Keep physician informed of all side effects; most will be treated symptomatically as indicated. Discontinue if hypotension develops at any time during the 5 days of administration. Discontinue clofarabine immediately if early S/S of SIRS or capillary leak (e.g., hypotension) appear. Use of albumin, diuretics, and steroids may be indicated. May consider restarting (usually at a lower dose) after the patient is stabilized and organ function has returned to baseline. Discontinue clofarabine immediately if substantial increases in SCr, liver enzymes, or bilirubin occur. May be restarted (possibly at a lower dose) when the patient is stable and organ function has returned to baseline. Bone marrow suppression must be resolved before additional doses can be given. Administration of whole blood products (e.g., packed RBCs, platelets, or leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Blood modifiers can be used at the physician's discretion; however, they are not recommended for use during the 5-day clofarabine administration cycle. Use specific antibiotics to combat infection. No specific antidote for overdose. Supportive therapy as indicated will help sustain the patient in toxicity. Should a hypersensitivity reaction occur, treat with antihistamines, corticosteroids, epinephrine, and oxygen as indicated. Resuscitate if indicated.

COAGULATION FACTOR VIIa (RECOMBINANT) RTS **BBW**

Antihemorrhagic

(ko-ag-yew-LA-shun **FAK**-ter 7a [re-KOM-be-nant])

NovoSeven RT

pH 5.5

USUAL DOSE

HEMOPHILIA A OR B PATIENTS WITH INHIBITORS

Bleeding episodes: 90 mcg/kg every 2 hours until hemostasis is achieved or until the treatment has been judged to be ineffective. Doses between 35 and 120 mcg/kg have been used successfully. Minimum effective dose has not been established. The dose and dosing interval may be adjusted based on the severity of the bleeding and the degree of homeostasis achieved. In clinical studies, a decision on outcome was reached for a majority of patients with joint or muscle bleeds within 8 doses, although more doses were required for severe bleeds. For severe bleeds, dosing should continue at 3- to 6-hour intervals after hemostasis is achieved to maintain the hemostatic plug. The appropriate duration of post-hemostatic dosing has not been studied and should be minimized; see [Precautions](#). If a new bleeding episode or rebleeding occurs, return to 2-hour dosing intervals.

Surgical intervention: 90 mcg/kg immediately before the intervention. Repeat every 2 hours during intervention. **For minor surgery**, post-surgical dosing should be administered every 2 hours for 48 hours and then every 2 to 6 hours until healing has occurred. **For major surgery**, post-surgical dosing should be administered every 2 hours for 5 days and then every 4 hours until healing has occurred. Additional doses may be given if required.

CONGENITAL FACTOR VII DEFICIENCY PATIENTS

Bleeding episodes and surgical intervention: 15 to 30 mcg/kg every 4 to 6 hours until hemostasis is achieved. Doses as low as 10 mcg/kg have been effective. Dose and dosing interval should be adjusted to each individual based on the severity of bleeding and the degree of hemostasis achieved. Minimal effective dose has not been determined.

ACQUIRED HEMOPHILIA

70 to 90 mcg/kg every 2 to 3 hours until hemostasis is achieved. Minimum effective dose has not been determined.

PEDIATRIC DOSE

See [Usual Dose](#). Clinical studies were conducted with dosing determined according to body weight and not according to age. See [Maternal/Child](#).

DOSE ADJUSTMENTS

Dose and administration interval may be adjusted based on the severity of the bleeding and the degree of hemostasis achieved. If patient develops intravascular coagulation or thrombosis, dosage should be reduced or treatment stopped; see [Monitor](#).

DILUTION

NovoSeven RT is room temperature stable (RTS); aseptic technique is imperative. Available in packages that contain 1-, 2-, or 5-mg vials with a specified volume of histidine diluent. Select the appropriate vial package based on the calculated dose. Bring vial and diluent to RT. Do not exceed 37° C (98.6° F). Reconstitute powder with provided diluent, aiming the needle (20- to 26-gauge needle recommended) and the stream of diluent against the side of the vial. Do not inject the diluent directly on the powder. Do not use SWFI or other diluents. Gently swirl vial until powder is completely dissolved. Final concentration of reconstituted solution is 1 mg/mL (1,000 mcg/mL).

Storage: Before reconstitution, refrigerate or store between 2° and 25° C (36° and 77° F). Avoid exposure to direct sunlight. Do not freeze. After reconstitution, store at RT or refrigerate. Should be used within 3 hours. Do not freeze reconstituted product or store in syringe. Discard unused product.

COMPATIBILITY

Manufacturer states, “Intended for IV injection only and should not be mixed with infusion solutions. Do not store reconstituted solution in syringes.” If line needs to be flushed before or after NovoSeven RT administration, use NS.

RATE OF ADMINISTRATION

A single dose as a slow IV injection over 2 to 5 minutes, depending on dose administered.

ACTIONS

A vitamin K–dependent glycoprotein structurally similar to human plasma–derived factor VIIa. Produced by recombinant DNA technology. Promotes hemostasis by activating the extrinsic pathway of the coagulation cascade. When complexed with tissue factor, can activate coagulation factor X to factor Xa, and coagulation factor IX to factor IXa. Factor Xa, in complex with other factors, then converts prothrombin to thrombin. This leads to the formation of a hemostatic plug by converting fibrinogen to fibrin. Half-life is 2.3 hours. Duration of action is 3 hours.

INDICATIONS AND USES

Treatment of bleeding episodes or prevention of bleeding in surgical interventions or invasive procedures in hemophilia A or B patients with inhibitors to factor VIII or factor IX and in patients with acquired hemophilia. ■ Treatment of bleeding episodes or prevention of bleeding in surgical interventions or invasive procedures in patients with congenital FVII deficiency.

CONTRAINDICATIONS

Manufacturer states, “None.” Use with caution in patients with known hypersensitivity to coagulation factor VIIa (recombinant), any of its components, and in patients with known hypersensitivity to mouse, hamster, or bovine proteins.

PRECAUTIONS

For intravenous bolus administration only. ■ Should be administered to patients only under the direct supervision of a physician experienced in the treatment of bleeding disorders. ■ Thrombotic events have been reported in clinical trials as well as through post-marketing surveillance following coagulation factor VIIa (recombinant) RTS use for each of the approved indications. Patients with disseminated intravascular coagulation (DIC), advanced atherosclerotic disease, crush injury, septicemia, or concomitant treatment with aPCCs/PCCs (activated or non-activated prothrombin complex concentrates) may have an increased risk of developing thrombotic events due to circulating tissue factor or predisposing coagulopathy. Use caution in patients with an increased risk of thromboembolic complications. These include, but are not limited to, patients with a history of coronary artery disease (CAD), liver disease, DIC, or postoperative immobilization; elderly patients; and neonates. ■ Coagulation factor VIIa has been studied in placebo-controlled trials outside the approved indications to control bleeding in intracranial hemorrhage, advanced liver disease, trauma, cardiac surgery, spinal surgery, and other therapeutic areas. Safety and effectiveness have not been established in these settings, and the use is not approved by the FDA. Arterial and venous thrombotic and thromboembolic events have been reported during post-marketing surveillance. Studies have shown an increased risk of arterial thromboembolic adverse events (e.g., MI, myocardial ischemia, cerebral infarction, and cerebral ischemia) with coagulation factor VIIa when administered outside the current approved guidelines. ■ Biologic and clinical effects of prolonged elevated levels of factor VIIa have not been studied; therefore, the duration of post-hemostatic dosing should be minimized, and patients should be appropriately monitored by a physician experienced in the treatment of hemophilia during this time period.

Monitor: Evaluation of hemostasis should be used to determine the effectiveness of therapy and to provide a basis for modification of the treatment schedule; coagulation parameters do not necessarily correlate with or predict the effectiveness of therapy. Coagulation parameters (e.g., PT, aPTT, plasma FVII clotting activity [FVII:C]) may be used as an adjunct to the clinical evaluation of hemostasis in monitoring the effectiveness and treatment schedule, although these parameters have shown no direct correlation to achieving hemostasis. ■ Patients with factor VII deficiency should be monitored for PT and factor

VII coagulant activity before and after treatment. If the factor VIIa activity fails to reach the expected level, if PT is not corrected, or if bleeding is not controlled after treatment with the recommended doses, antibody formation should be suspected and analysis for antibodies should be performed. ■ The normal factor VII plasma concentration is 0.5 mcg/mL. Factor VIIa levels of 15% to 25% (0.075 to 0.125 mcg/mL) are generally sufficient to achieve normal hemostasis. ■ Monitor patients for the development of signs or symptoms of activation of the coagulation system or thrombosis. When there is laboratory confirmation of intravascular coagulation or presence of clinical thrombosis, dosage should be reduced or the treatment stopped, depending on the patient's symptoms; see [Dose Adjustments](#).

Patient Education: Discuss benefits versus risk of therapy and signs of hypersensitivity reactions including hives, urticaria, chest tightness, wheezing, hypotension, and anaphylaxis. ■ Signs of bleeding may be similar to signs of thrombosis and can include new-onset swelling and pain in the limbs or abdomen, new-onset chest pain, shortness of breath, loss of sensation or motor power, or altered consciousness or speech.

Maternal/Child: Category C: safety for use during pregnancy not established. Use only if clearly indicated and benefit justifies potential risk to the fetus. ■ Discontinue breastfeeding. ■ Thrombotic events have been reported in women without a prior diagnosis of bleeding disorders who have received coagulation factor VIIa for uncontrolled postpartum hemorrhage. ■ A decision should be made whether to discontinue nursing or to discontinue the drug. ■ The safety and effectiveness has not been studied to determine if there are differences among various age-groups from infants to adolescents (0 to 16 years of age); see [Pediatric Dose](#).

Elderly: Numbers in clinical studies insufficient to determine if the elderly respond differently than younger subjects.

DRUG/LAB INTERACTIONS

The risk of potential interaction between factor VIIa and coagulation factor concentrates has not been adequately evaluated. Simultaneous use of **activated prothrombin complex concentrates** (e.g., anti-inhibitor coagulant complex [Feiba NF]) or **prothrombin complex concentrates** (e.g., factor IX [AlphaNine SD, Benefix]) should be avoided.

SIDE EFFECTS

Generally well tolerated. The majority of patients reporting side effects received more than 12 doses. The most common side effects are arthralgia, edema, fever, headache, hemorrhage, hypertension, hypotension, injection site reaction, nausea, pain, rash, and vomiting. Most serious adverse reactions are thrombotic events; however, the risk in patients with hemophilia and inhibitors is considered to be low. **Fatal and non-fatal thrombotic events have been reported when used for both labeled and off-label indications.** Other side effects include arthrosis, bradycardia, coagulation disorder, DIC, decreased fibrinogen plasma, decreased prothrombin, decreased therapeutic response, hemarthrosis, hypersensitivity reactions, increased fibrinolysis, pneumonia, pruritus, purpura, renal function abnormalities, shock, subdural hematoma, thrombosis, urticaria.

Post-Marketing: High D-dimer levels and consumptive coagulopathy, thromboembolic events including myocardial ischemia and/or infarction, cerebral ischemia and/or infarction, thrombophlebitis, arterial thrombosis, deep vein thrombosis and related pulmonary embolism, and isolated cases of hypersensitivity reactions including anaphylaxis have occurred following use in both labeled and unlabeled indications.

ANTIDOTE

Discontinue drug and notify physician of any major side effects. Treat hypersensitivity reactions as indicated. For thrombosis or DIC, anticoagulation with heparin may be indicated.

CONIVAPTAN HYDROCHLORIDE

(kon-ih-VAP-tan hy-droh-KLOR-eyed)

Arginine vasopressin antagonist

Vaprisol

pH 3 to 3.8

USUAL DOSE

Loading dose: 20 mg as an IV infusion over 30 minutes. Follow with 20 mg administered as a **continuous infusion** evenly distributed over 24 hours. May be administered for an additional 1 to 3 days as a continuous infusion of 20 mg/day. The total duration of infusion (after the loading dose) should not exceed 4 days.

DOSE ADJUSTMENTS

If the serum sodium does not rise at the desired rate, the dose may be titrated up to 40 mg as a continuous infusion over 24 hours. 40 mg is the maximum daily dose. ■ A reduced dose may be required if the patient experiences an undesirably rapid rate of rise of serum sodium; see **Precautions**. ■ If hyponatremia persists or recurs (after initial interruption of therapy) and the patient has no evidence of neurologic sequelae, conivaptan may be resumed at a reduced dose; see **Monitor**. ■ A reduced dose may also be required in patients who develop hypotension or hypovolemia; see **Monitor**. ■ No dose adjustment indicated in patients with mild hepatic impairment. ■ Reduced dose required in patients with moderate hepatic impairment. Initiate with a loading dose of 10 mg. Follow with a continuous infusion of 10 mg over 24 hours for 2 days to a maximum of 4 days. If sodium is not rising at the desired rate, the conivaptan dose may be titrated up to 20 mg/day. ■ Use in patients with severe renal impairment (CrCl less than 30 mL/min) is not recommended; see **Contraindications**.

DILUTION

Available in a single-use, ready-to-use (RTU) plastic container containing 20 mg conivaptan in 100 mL D5W. If the RTU container is being administered as a 40-mg dose, administer two consecutive 20 mg/100 mL containers over 24 hours.

Storage: Store in carton at CRT. Protect from light and freezing. Do not remove container from overwrap until ready to use. Overwrap is a moisture and light barrier.

COMPATIBILITY

Manufacturer states, "Should not be mixed or administered with lactated Ringer's or furosemide (Lasix). Should not be combined with any other product in the same intravenous line or bag."

RATE OF ADMINISTRATION

Loading dose: A single dose equally distributed over 30 minutes as an infusion.

Continuous infusion: A single dose equally distributed over 24 hours.

ACTIONS

A nonpeptide, dual antagonist of arginine vasopressin (AVP) V_{1A} and V_2 receptors. The level of AVP in the blood is critical for the regulation of water and electrolyte balance and is usually elevated in both euvolemic and hypervolemic hyponatremia (in euvolemic hyponatremia there is an increase in total body water, but the sodium content remains the same; in hypervolemic hyponatremia both sodium and water content in the body increase, but the water gain is greater). AVP excess is associated with hyponatremia without edema. The AVP effect is mediated through V_2 receptors that help maintain plasma osmolality. Conivaptan blocks V_2 receptors in the renal collecting ducts, resulting in aquaresis (excretion of free water). This is generally accompanied by increased net fluid loss, increased urine output, and decreased urine osmolality. Conivaptan is highly protein bound. It is metabolized in the liver by the cytochrome P_{450} isoenzyme, CYP3A. Its half-life is 5.3 to 8.1 hours, depending on dose. Primarily excreted in the feces and, to a lesser extent, in urine. Crosses the placenta in animals.

INDICATIONS AND USES

For use in the hospitalized patient to treat euvolemic and hypervolemic hyponatremia. Euvolemic hyponatremia may occur in the syndrome of inappropriate secretion of antidiuretic hormone (SIADH, an inability of the body to excrete dilute urine) or in the setting of certain conditions, including hypothyroidism, adrenal insufficiency, and pulmonary disorders. ■ Not indicated for the treatment of the S/S of heart failure. Raising serum sodium with conivaptan has not been shown to provide a symptomatic benefit.

CONTRAINDICATIONS

Patients with hypovolemic hyponatremia. ■ Hypersensitivity to conivaptan or any of its components (propylene glycol, ethanol, lactic acid). ■ Coadministration with potent CYP3A inhibitors, such as clarithromycin, indinavir, itraconazole, ketoconazole, and ritonavir; see [Drug Interactions](#). ■ Premixed solution contains dextrose, which may be contraindicated in patients with a known allergy to corn or corn products. ■ Anuria (no benefit expected).

PRECAUTIONS

For IV use only. ■ Use only in hospitalized patients. ■ Safety for use in hypovolemic hyponatremic patients with underlying CHF has not been established. Should be used to raise sodium in these patients only after other treatment options have been considered. Incidence of adverse cardiac events may be increased. ■ An overly rapid increase in serum sodium concentration (more than 12 mEq/L/24 hr) may result in serious sequelae. Although not observed in clinical trials, osmotic demyelination syndrome (brain cell dehydration) has been reported following rapid correction of low serum sodium concentration. Osmotic demyelination results in dysarthria, lethargy, affective changes, spastic quadriparesis, seizures, coma, or death. Patients with severe malnutrition, alcoholism, or advanced liver disease may be at increased risk; use slower rates of correction; see [Monitor](#). ■ Reduced doses required in patients with moderate hepatic impairment; see [Dose Adjustments](#). Impact of severe hepatic impairment has not been studied. ■ May cause significant infusion site reaction; see [Monitor](#).

Monitor: Administer via a large vein. Monitor infusion site and rotate every 24 hours. ■ Monitor serum sodium concentration and neurologic status closely during therapy. If an overly rapid increase in serum sodium concentration occurs (greater than 12 mEq/L/24 hr), administration should be discontinued. If the sodium continues to rise, administration should not be resumed. If hyponatremia persists or recurs (after initial interruption of therapy) and the patient has no evidence of neurologic sequelae, conivaptan may be resumed at a reduced dose. ■ Monitor vital signs, urine output and osmolality, and volume status of patient. Discontinue therapy in patients who develop hypotension or hypovolemia. Once the patient is again euvolemic and is no longer hypotensive, therapy may be resumed at a reduced dose; see [Dose Adjustments](#).

Patient Education: Promptly report any burning at the infusion site or other side effects. ■ Request assistance for ambulation. ■ Review list of allergies and medications with physician or pharmacist.

Maternal/Child: Category C: use during pregnancy only if benefits justify risk to the fetus. Has been shown to cause fetal harm in animals. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients has not been studied.

Elderly: Response similar to that seen in the general study population.

DRUG/LAB INTERACTIONS

A substrate of CYP3A. Coadministration with inhibitors of this enzyme could lead to an increase in conivaptan concentrations, the effect of which is unknown. Concomitant use with **potent CYP3A4** inhibitors such as clarithromycin (Biaxin), indinavir (Crixivan), itraconazole (Sporanox), ketoconazole (Nizoral), and ritonavir (Norvir) is contraindicated. ■ A potent inhibitor of CYP3A. May increase plasma concentrations of drugs that

are primarily metabolized by this enzyme. Coadministration with **amlodipine** (Norvasc), **midazolam** (Versed), and **simvastatin** (Zocor) resulted in increased concentrations of each of the drugs. Two cases of rhabdomyolysis occurred in patients who were receiving a **CYP3A4-metabolized HMG-CoA reductase inhibitor** (e.g., simvastatin [Zocor]). Avoid concomitant use with drugs eliminated primarily by **CYP3A4-mediated metabolism**. Do not initiate subsequent therapy with **CYP3A4 substrate drugs** until at least 1 week after an infusion of conivaptan. ■ May decrease clearance and increase serum concentration of **digoxin**. Monitor digoxin levels. ■ Captopril (Capoten) and furosemide (Lasix) do not appear to affect the pharmacokinetics of conivaptan. ■ Does not appear to affect PT/INR when coadministered with warfarin (Coumadin). ■ Does not appear to affect the QT interval.

SIDE EFFECTS

The most common adverse reactions are infusion site reactions (e.g., erythema, pain, phlebitis), fever, headache, hypokalemia, orthostatic hypotension, peripheral edema. Other reactions that occurred in more than 2% of patients include anemia, atrial fibrillation, confusion, constipation, diarrhea, hypertension, hypomagnesemia, hyponatremia, hypotension, insomnia, nausea, pharyngolaryngeal pain, pneumonia, pruritus, pyrexia, ST segment depression on ECG, thirst, urinary tract infection, and vomiting.

ANTIDOTE

Notify physician of any side effects. Most will be treated symptomatically. Discontinue therapy if there is an overly rapid increase in serum sodium concentration or if the patient experiences hypotension or hypovolemia. Discontinue therapy permanently if neurologic sequelae are present; see [Precautions](#), [Monitor](#), and [Dose Adjustments](#). Resuscitate as necessary.

CONJUGATED ESTROGENS **BBW**

(KON-jyou-gay-ted ES-troh-jens)

Hormone (estrogen)

Antihemorrhagic

Premarin Intravenous

pH 7.2 to 7.4

USUAL DOSE

25 mg in 1 injection. May be repeated in 6 to 12 hours if indicated.

DILUTION

Reconstitute with 5 mL SWFI, directing the flow of diluent gently against the side of the vial. Agitate gently. Do not shake violently. Do not use if discolored or if precipitate is present. Dilution in an IV infusion is not recommended.

Storage: Refrigerate prior to use. Use immediately after reconstitution.

COMPATIBILITY

*Consider any drug NOT listed as compatible to be **INCOMPATIBLE** until consulting a pharmacist; specific conditions may apply.*

Manufacturer lists as **incompatible** with ascorbic acid, protein hydrolysate, or any solution with an acid pH.

According to the manufacturer, infusion with other agents is not generally recommended. May be given at Y-tube if **compatible** solutions are infusing (NS, dextrose, and invert sugar solutions). According to one source, it is **compatible** at the **Y-site** with heparin, hydrocortisone sodium succinate (Solu-Cortef), and potassium chloride (KCl).

RATE OF ADMINISTRATION

5 mg or fraction thereof over 1 minute. Must be given direct IV or through IV tubing close to needle site. Infusion solution must be **compatible**. Too-rapid injection may cause flushing.

ACTIONS

A mixture of conjugated estrogens obtained from natural sources. Administration provides a rapid and temporary increase in estrogen levels. Acts at several points on the clotting cascade, enhancing coagulability of the blood, especially in the capillary beds. Promptly corrects bleeding due to estrogen deficiency. Widely distributed in the body. Metabolized primarily in the liver and excreted in the urine. Secreted in breast milk.

INDICATIONS AND USES

Treatment of abnormal uterine bleeding caused by hormonal imbalance in the absence of organic pathology. Indicated for short-term use only to provide a rapid and temporary increase in estrogen levels.

Unlabeled uses: Postcoital contraception.

CONTRAINDICATIONS

Known, suspected, or history of breast cancer, active deep venous thrombosis, or pulmonary embolism. ■ A history of or active arterial thromboembolic disease (e.g., stroke, MI). ■ Known or suspected estrogen-dependent neoplasia, pregnancy, undiagnosed abnormal genital bleeding, liver dysfunction or disease. ■ Hypersensitivity to this product or its ingredients (e.g., known anaphylactic reaction and angioedema). ■ Known protein C, protein S, or antithrombin deficiency, or other known thrombophilic disorders. ■ Other specific contraindications for estrogens must be considered.

PRECAUTIONS

IV therapy with conjugated estrogens is indicated for short-term use. However, warnings and precautions associated with oral therapy should be considered (e.g., changes in vaginal bleeding, headache, hypersensitivity reactions, skin reactions, and many more); see [Precautions](#) and prescribing information. ■ Estrogens with or without progestins should not be used for the prevention of cardiovascular disease or dementia. ■ Even though bleeding is controlled, the etiology of the bleeding must be determined and definitive therapy instituted. ■ May cause fluid retention. Use with caution in patients with cardiac or renal dysfunction. ■ Use with caution in asthma, diabetes, endometriosis, epilepsy, hepatic

hemangiomas, hepatic or gallbladder disease, hypercalcemia or hypocalcemia, hypercholesterolemia, hypertriglyceridemia, hypertension, hypoparathyroidism, migraines, obesity, porphyria, systemic lupus erythematosus, or tobacco use; may exacerbate condition.

- May induce or exacerbate symptoms of angioedema, particularly in women with hereditary angioedema.
- Retinal vascular thrombosis has been reported in patients receiving estrogen therapy. Discontinue therapy and obtain ophthalmologic exam if visual disturbances occur.
- Patients dependent on thyroid hormone replacement therapy (e.g., levothyroxine [Synthroid]) who are also receiving estrogen may require dose adjustment of thyroid replacement medication.
- Estrogens may increase the risk of deep venous thrombosis, MI, pulmonary embolism, stroke, breast cancer, endometrial cancer, and dementia.
- Follow immediately with oral estrogens as recommended for dysfunctional uterine bleeding.

Monitor: Monitor VS; may cause a temporary BP elevation.

Patient Education: Review health history and disease states with physician before beginning treatment with conjugated estrogens. ▪ Review possible side effects with physician and report any side effects promptly.

Maternal/Child: Category X: avoid pregnancy. ▪ Use caution during breast-feeding. Detectable amounts have been found in breast milk and may decrease quantity and quality of milk. ▪ Safety for use in pediatric patients not established. Extended use may accelerate epiphyseal closure, which could result in short adult stature.

Elderly: Differences in response compared to younger adults not identified.

DRUG/LAB INTERACTIONS

May decrease effects of **oral antidiabetics**. ▪ **Barbiturates** (e.g., phenobarbital), **carbamazepine** (Tegretol), **phenytoin** (Dilantin), **rifampin** (Rifadin), and **St. John's wort** increase metabolism and decrease serum levels and effects. ▪ Plasma concentrations may be increased with coadministration of **clarithromycin** (Biaxin), **erythromycin**, **itraconazole** (Sporanox), **ketoconazole** (Nizoral), **ritonavir** (Norvir), and **grapefruit juice**. ▪ May decrease metabolism and increase serum levels of **cyclosporine**. May increase risk of cyclosporine toxicity. ▪ Increased risk of hepatotoxicity with **other hepatotoxic agents** (e.g., dantrolene [Dantrium]). ▪ May increase **blood glucose** levels and **serum lipids**. ▪ May reduce response to **metyrapone test**. ▪ May alter numerous **coagulation tests, glucose tolerance, and thyroid and other protein-binding tests**.

SIDE EFFECTS

Rare when used as directed; flushing, nausea, vomiting. IV therapy with conjugated estrogens is indicated for short-term use. However, the numerous adverse reactions associated with oral therapy should be considered (e.g., changes in vaginal bleeding, headache, hypersensitivity reactions, skin reactions, and many more); see **Precautions** and prescribing information.

Post-Marketing: Anaphylaxis within minutes to hours of infusion, angioedema involving the face, tongue, larynx, hands, and feet.

ANTIDOTE

No toxicity has been reported throughout years of clinical use. Discontinue if jaundice occurs. Discontinue immediately if DVT, MI, PE, stroke, or venous thromboembolism occurs.

COSYNTROPIN

(koh-SIN-troh-pin)

Diagnostic agent
(adrenocorticotrophic)**Cortrosyn**

pH 5.5 to 7.5

USUAL DOSE

250 mcg (0.25 mg). Up to 750 mcg (0.75 mg) has been used.

PEDIATRIC DOSE**Pediatric patients over 2 years of age:** May use adult dose, but 125 mcg (0.125 mg) is usually adequate.**Pediatric patients 2 years of age or less:** 125 mcg (0.125 mg). Usually given IM.**DILUTION**

Available as a lyophilized powder or as a solution. Reconstitute powder with 1 mL NS. For IV use, both formulations should be diluted with 2 to 5 mL of NS. May be given directly IV after this initial dilution or further diluted in D5W or NS and given as an infusion (250 mcg in 250 mL equals 1 mcg/mL).

Storage: Lyophilized powder: Store at CRT. **Liquid formulation:** Store at 2° to 8° C (36° to 46° F); protect from light and freezing. Discard any unused drug.**COMPATIBILITY**

Manufacturer states, "Should not be added to blood or plasma; may be inactivated by enzymes." Consider specific use.

RATE OF ADMINISTRATION**IV injection:** A single dose over 2 minutes.**Infusion:** A single dose at a rate of approximately 40 mcg/hr over 6 hours.**ACTIONS**

A synthetic form of adrenocorticotrophic hormone (ACTH). Stimulates the adrenal cortex to secrete adrenocortical hormone. Does not increase cortisol secretion in patients with primary adrenocortical insufficiency. Peak plasma cortisol levels occur in 1 to 2 hours depending on formulation used.

INDICATIONS AND USES

Diagnostic aid for adrenocortical insufficiency.

CONTRAINDICATIONS

Hypersensitivity to cosyntropin.

PRECAUTIONS

The liquid formulation of cosyntropin is for IV use only. Cortrosyn may be used IV or IM. ■ Preferable to ACTH because it is less likely to cause hypersensitivity reactions; however, hypersensitivity reactions have occurred. Administer in a facility equipped to monitor the patient and respond to any medical emergency. ■ May be used in patients who have had a hypersensitivity reaction to ACTH.

Monitor: Continuous observation for at least the first 30 minutes is mandatory. Observe frequently thereafter. ■ Check BP frequently; may cause elevated BP and salt and water retention. ■ Monitor correct collection of specimens; see prescribing information for specific details. ■ See [Drug/Lab Interactions](#).**Patient Education:** Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face).**Maternal/Child:** Category C: use during pregnancy only if benefits outweigh risks. ■ Use with caution during breast-feeding.**DRUG/LAB INTERACTIONS**Plasma cortisol may be falsely elevated with **cortisone, hydrocortisone, or spironolactone**. Patients receiving cortisone, hydrocortisone, or spironolactone should omit their pre-test doses on the day of testing. ■ Abnormally high basal plasma cortisol levels may also occur in patients taking inadvertent doses of **cortisone or hydrocortisone** on the test day

and in women taking drugs that contain **estrogen**. ■ Many drug reactions are possible with corticosteroids, but usually not a concern with specific diagnostic use. ■ May accentuate electrolyte loss associated with **diuretic therapy**.

SIDE EFFECTS

Bradycardia, hypertension, peripheral edema, rash, tachycardia have been reported. Hypersensitivity reactions, including anaphylaxis (rare), have occurred.

ANTIDOTE

Notify the physician of any side effect. Keep epinephrine and diphenhydramine available to treat anaphylaxis. Resuscitate as necessary.

CYCLOPHOSPHAMIDE

(syeh-kloh-FOS-fah-myed)

Antineoplastic
(alkylating agent/
nitrogen mustard)

Lyophilized Cytosan,  Procytox

pH 3 to 7.5

USUAL DOSE

Although effective alone in susceptible malignancies, cyclophosphamide is more frequently used concurrently or sequentially with other antineoplastic agents. See **Monitor**. Doses may be expressed in mg/mL or mg/M².

Malignant diseases (adult and pediatric patients): As a single agent: The initial dose may be 40 to 50 mg/kg of body weight, usually given in divided doses over 2 to 5 days. Alternate dosing schedules are 3 to 5 mg/kg twice weekly or 10 to 15 mg/kg every 7 to 10 days. Higher doses have been used with some protocols based on the condition being treated. Adequate hydration is indicated, and the use of mesna can be considered to attenuate or reduce the incidence of hemorrhagic cystitis. **Combination protocols:** Numerous combination therapies are in use. Has been used with bleomycin, bortezomib, carboplatin, cisplatin, cytarabine, dacarbazine, dactinomycin, dexamethasone, doxorubicin, epirubicin, etoposide, fludarabine, fluorouracil, ifosfamide, methotrexate, prednisone, procarbazine, rituximab, and vincristine.

Adjuvant treatment of operable node-positive breast cancer: Treatment protocol includes cyclophosphamide, doxorubicin, and docetaxel. Administer cyclophosphamide 500 mg/M² and doxorubicin 50 mg/M². One hour later, give docetaxel 75 mg/M². Repeat every 3 weeks for 6 cycles. See docetaxel (Taxotere) and doxorubicin (Adriamycin) monographs.

PEDIATRIC DOSE

Malignant diseases: See **Usual Dose**.

DOSE ADJUSTMENTS

Reduced dose may be required in the adrenalectomized patient and in impaired hepatic function. ■ Dosing should be cautious in the elderly. Lower-end initial doses may be indicated. Consider decrease in cardiac, hepatic, and renal function; concomitant disease; or other drug therapy; see **Elderly**. ■ The total leukocyte count is a good objective guide for regulating dosage. Transient decreases in the total WBC to 2,000 cells/mm³ (following short courses) or more persistent reduction to 3,000 cells/mm³ (with continuing therapy) are tolerated without serious risk of infection if there is no marked granulocytopenia. ■ Often used with other antineoplastic drugs in reduced doses to achieve tumor remission.

DILUTION

Specific techniques required; see Precautions. Contains no preservatives; aseptic technique imperative. Each 100 mg must be diluted with 5 mL of NS or SWFI; yields 20 mg/mL

(a 2% solution). Shake solution gently and allow to stand until clear. A 2% solution reconstituted with NS may be injected directly or further diluted to a minimum concentration of 0.2% (2 mg/mL) for infusion. A 2% solution reconstituted with SWFI is hypotonic and should not be injected directly. It **must** be further diluted to a minimum concentration of 0.2% (2 mg/mL). D5W, ½NS, and D5NS are **compatible** diluents. Do not use heat to facilitate dilution. See **Monitor**.

Filters: May be filtered through available micron sizes of cellulose ester membrane filters.

Storage: Store unopened vials at or below 25° C (77° F). Reconstituted or diluted solution must be used within 24 hours when stored at RT. Solutions reconstituted in NS or further diluted in ½NS are stable up to 6 days if refrigerated. Solutions further diluted in D5W or D5NS are stable for 36 hours if refrigerated. Do not use cyclophosphamide vials if there are signs of melting (clear or yellowish viscous liquid or droplets).

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Bleomycin (Blenoxane), cisplatin (Platinol), fluorouracil (5-FU), mesna (Mesnax), methotrexate, mitoxantrone (Novantrone), ondansetron (Zofran).

Y-site: Allopurinol (Aloprim), amifostine (Ethylol), amikacin (Amikin), ampicillin, anidulafungin (Eraxis), aztreonam (Azactam), bleomycin (Blenoxane), cefazolin (Ancef), cefotaxime (Claforan), cefoxitin (Mefoxin), cefuroxime (Zinacef), chloramphenicol (Chloromycetin), cisplatin (Platinol), cladribine (Leustatin), clindamycin (Cleocin), doripenem (Doribax), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), doxycycline, droperidol (Inapsine), erythromycin (Erythrocin), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), gallium nitrate (Ganite), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, idarubicin (Idamycin), leucovorin calcium, linezolid (Zyvox), melphalan (Alkeran), methotrexate, metoclopramide (Reglan), metronidazole (Flagyl IV), mitomycin (Mutamycin), nafcillin (Nallpen), ondansetron (Zofran), oxacillin (Bactocill), oxaliplatin (Eloxatin), paclitaxel (Taxol), palonosetron (Aloxi), pemetrexed (Alimta), penicillin G potassium, piperacillin/tazobactam (Zosyn), propofol (Diprivan), sargramostim (Leukine), sodium bicarbonate, sulfamethoxazole/trimethoprim, teniposide (Vumon), thiotepa, ticarcillin/clavulanate (Timentin), tobramycin, topotecan (Hycamtin), vancomycin, vinblastine, vincristine, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Rate may vary depending on protocol. May be given by IV push or as an intermittent or continuous infusion.

Injection: Doses equal to or less than 1 Gm of properly diluted solution (20 mg/mL in NS) may be given by slow IVP through Y-tube or three-way stopcock of a free-flowing IV or as a direct IV injection followed with a NS flush.

Infusion: Doses greater than 500 mg to approximately 2 Gm may be given over 20 to 30 minutes, or a single dose may be administered over 1 to 24 hours. Must be properly diluted as a minimum 2% solution. Additional diluent is preferred (e.g., 0.2% solution). See **Monitor**.

ACTIONS

An alkylating agent of the nitrogen mustard group with anti-tumor activity; cell cycle phase nonspecific, but most effective in S phase. Cyclophosphamide is a prodrug that is activated by hepatic microsomal enzymes. It is thought to prevent cell division by cross-linking DNA strands and preventing DNA synthesis. Elimination half-life is 3 to 12 hours. Metabolized in the liver, it or its metabolites are excreted in the urine. Secreted in breast milk.

INDICATIONS AND USES

Although effective alone in susceptible malignancies, cyclophosphamide is more frequently used concurrently or sequentially with other antineoplastic agents. Cyclophosphamide has been used in the treatment of the following malignancies: malignant lymphomas (e.g., Hodgkin's disease, lymphocytic lymphoma, mixed-cell type lymphomas, histiocytic lymphoma, Burkitt's lymphoma), multiple myeloma, leukemias (e.g., chronic lymphocytic leukemia, chronic granulocytic leukemia, acute myelogenous and monocytic leukemia, acute lymphoblastic [stem cell] leukemia in children), mycosis fungoides, neuroblastoma, adenocarcinoma of the ovary, retinoblastoma, and carcinoma of the breast. ■ Adjuvant treatment of operable node-positive breast cancer in combination with doxorubicin and docetaxel. ■ Used orally to treat many other indications, including biopsy-proven nephrotic syndrome, in pediatric patients when disease fails to respond to primary therapy or primary therapy causes intolerable side effects.

Unlabeled uses: Ewing's sarcoma, granulomatosis with polyangiitis (GPA, Wegener's granulomatosis), lupus nephritis, non-Hodgkin's lymphoma, severe rheumatologic conditions. ■ Transplant conditioning and many others; see literature.

CONTRAINDICATIONS

Previous hypersensitivity, severely depressed bone marrow function.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Development of secondary malignancies has been reported in patients treated with cyclophosphamide used alone or in association with other antineoplastic agents. May develop several years after treatment has been discontinued. ■ Use caution in cases of leukopenia, thrombocytopenia, bone marrow infiltrated with malignant cells, previous radiation therapy, previous cytotoxic therapy, and impaired hepatic or renal function. ■ May interfere with normal wound healing. ■ Do not administer any live virus vaccine to patients receiving antineoplastic drugs. ■ May result in hemorrhagic cystitis. Fatalities have occurred. Fibrosis of the urinary bladder, with or without cystitis, has also been reported. ■ Possible cross-sensitivity with other alkylating agents has been reported. ■ Anaphylaxis resulting in death has been reported. ■ Acute cardiac toxicity without determination of a causal relationship has been reported. Usually seen when cyclophosphamide is used as a component of an intensive antineoplastic multidrug regimen or in conjunction with transplantation procedures. Severe and sometimes fatal CHF has been reported after the first cyclophosphamide dose when high doses are used. Has been reported to potentiate doxorubicin-induced cardiotoxicity. ■ Serious, sometimes fatal, infections may develop in severely immunocompromised patients.

Monitor: Prehydration with 500 to 1,000 mL NS recommended, especially with higher doses. ■ Marked leukopenia will occur after the initial dose. Recovery should begin in 7 to 10 days. ■ Monitor neutrophils and platelets and examine urine for RBCs on a regular basis. ■ Maintenance doses are regulated by an acceptable leukocyte count (2,500 to 4,000 cells/mm³) and the absence of serious side effects. The maximum effective maintenance dose should be used; see [Dose Adjustments](#). ■ Observe continuously for infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Use antiemetics for patient comfort. ■ Acute hemorrhagic cystitis occurs in 7% to 12% of patients; administer before 4 PM to decrease amount of drug remaining in bladder overnight. Encourage fluid intake (2 or 3 L of fluids per day [PO or IV] are recommended, especially with doses over 1,000 mg). Encourage frequent voiding to prevent cystitis. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Nonhormonal birth control recommended. ■ Interferes with oogenesis and spermatogenesis. May cause sterility in both sexes. ■ Increase fluid intake and void frequently. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: may produce teratogenic effects on the fetus. Has a mutagenic potential; see [Patient Education](#). ■ Discontinue breast-feeding. ■ When given in remission, has been effective in prolonging the duration of the remission in pediatric patients with acute lymphoblastic (stem-cell) leukemia. ■ Safety profile in pediatric patients similar to that of adults.

Elderly: Consider age-related organ impairment. Dose selection should be cautious; see [Dose Adjustments](#). Toxicity may be increased. Monitoring of renal function is suggested.

DRUG/LAB INTERACTIONS

Chloramphenicol may inhibit the metabolism of cyclophosphamide, decreasing the conversion to its active metabolites. ■ **Thiazide diuretics** (e.g., chlorothiazide [Diuril]) may prolong bone marrow suppression. ■ May increase or decrease activity of **anticoagulants** (e.g., warfarin [Coumadin]); monitor INR and adjust dose as indicated. ■ May reduce serum **digoxin** levels. ■ Can potentiate **doxorubicin**-induced cardiotoxicity. ■ May prolong neuromuscular blockade and prolonged respiratory depression caused by **succinylcholine**. These effects are dose dependent and may occur up to several days after cyclophosphamide is discontinued. ■ May decrease effectiveness of oral **quinolone antibiotics** (e.g., ciprofloxacin [Cipro]). ■ **Allopurinol** (Aloprim) may enhance the myelosuppressive side effect of cyclophosphamide, increasing the risk of bleeding or infection. ■ Chronic administration of high doses of **phenobarbital** may increase metabolism of cyclophosphamide and decrease its effectiveness. ■ Capable of many other interactions.

SIDE EFFECTS

Abdominal pain, alopecia (regrowth may be slightly darker), amenorrhea, anorexia, diarrhea, gonadal suppression, leukopenia (see [Precautions](#)), malaise, mucosal ulcerations, nausea and vomiting, darkening of skin and fingernails, susceptibility to infection.

Major: Anaphylaxis, bone marrow suppression (anemia, leukopenia, thrombocytopenia), hemorrhagic cystitis or ureteritis (reversible), infection, pulmonary fibrosis, rash, renal tubular necrosis (reversible), secondary neoplasia, SIADH, urinary bladder fibrosis.

Post-Marketing: Asthenia, interstitial pneumonitis, malaise and, rarely, Stevens-Johnson syndrome and toxic epidermal necrolysis.

ANTIDOTE

No specific antidote available. Minor side effects will be treated symptomatically if necessary. Discontinue the drug and notify the physician of hematuria immediately. Mesna has been used to decrease the incidence of cystitis. Interrupt therapy, reduce dose, or discontinue in patients who have or who develop potentially serious infections. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Cyclophosphamide and its metabolites are dialyzable.

CYCLOSPORINE **BBW**

Immunosuppressant

(sye-kloh-**SPOR**-een)**Sandimmune****USUAL DOSE**

5 to 6 mg/kg of body weight as a single dose 4 to 12 hours before transplantation. Repeat once each day until oral dosage form can be tolerated. Individualized adjustment is imperative and may be required on a daily basis. Administered at $\frac{1}{3}$ of the oral dose in patients temporarily unable to take oral cyclosporine. Administered in conjunction with adrenal corticosteroids; different regimens used; see prescribing information.

PEDIATRIC DOSE

Same as adult dose; however, higher doses may be required. See [Maternal/Child](#).

DOSE ADJUSTMENTS

Reduced dose may be required in impaired renal function and in patients with severe hepatic impairment. ■ Higher doses may be required in pediatric patients. ■ Lower-end doses may be indicated in the elderly. Consider impaired organ function and concomitant disease or other drug therapy. ■ Cyclosporine (Sandimmune) is not bioequivalent to Neoral (a brand of cyclosporine oral solution). Conversion from Neoral dosing to Sandimmune may result in lower cyclosporine blood concentrations. Blood concentration monitoring is indicated to avoid potential underdosing. ■ See [Monitor](#) and [Drug/Lab Interactions](#).

DILUTION

Each 50 mg should be diluted immediately before use with 20 to 100 mL of NS or D5W and given as an infusion. May leach phthalate from polyvinylchloride containers; use diluents in glass infusion bottles. Dilute immediately before use and discard unused portion.

Filters: Filtered through a 0.45-micron polypropylene filter during manufacturing. Has a high ethanol content, which the filter must accommodate. A large-bore needle filter may be used when withdrawing cyclosporine from an ampule. Adsorption should be negligible, but if there is concern, draw diluent through the same filter. In-line filtering is acceptable. Manufacturer indicates that cyclosporine molecules are small enough to pass through an in-line filter as small as 0.22 microns. Loss of potency is not expected. Another source used 0.22- and 0.45-micron filters and indicates an initial loss of potency that recovered to full concentration.

Storage: Before use, store ampules at CRT. Protect from light. Discard diluted solution after 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Leaches out plasticizers, including DEHP from PVC infusion bags and IV tubing; use of non-PVC containers and IV tubing recommended.

One source suggests the following **compatibilities**:

Additive: Ciprofloxacin (Cipro IV).

Y-site: Anidulafungin (Eraxis), caspofungin (Cancidas), ceftaroline (Teflaro), doripenem (Doribax), linezolid (Zyvox), meropenem (Merrem IV), micafungin (Mycamine), propofol (Diprivan), sargramostim (Leukine), telavancin (Vibativ).

RATE OF ADMINISTRATION

A single dose properly diluted as a slow IV infusion equally distributed over 2 to 6 hours.

ACTIONS

A potent immunosuppressive agent. Interferes with IL-2 production and blocks T-cell proliferative signals during early T-cell activation. Prolongs survival of kidney, liver, and heart allogeneic transplants in the human. Measured by specific or nonspecific assays.

Extensively metabolized by the cytochrome P₄₅₀ hepatic enzyme system. Half-life is 19 hours (range 10 to 27 hours). Primarily excreted in bile and to a small extent in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Prophylaxis of organ rejection in kidney, liver, and heart allogeneic transplants in conjunction with adrenocortical steroids. ■ Treatment of chronic rejection in patients previously treated with other immunosuppressive agents. Reserve parenteral formulation for when oral administration not feasible.

Unlabeled uses: Decrease frequency of pancreatic or corneal allograft rejection. ■ Prevention of acute graft versus host disease. ■ Crohn's disease.

CONTRAINDICATIONS

Hypersensitivity cyclosporine or to Cremophor EL (polyoxyethylated castor oil).

PRECAUTIONS

Anaphylactic reactions have been reported with the IV formulation. These reactions may be related to the IV vehicle Cremophor EL; patients who experienced these reactions have subsequently been treated with the oral formulation of cyclosporine without incident. Because of the risk of anaphylaxis, IV cyclosporine should be reserved for patients who are unable to take oral therapy. ■ Usually administered in the hospital by or under the direction of a physician experienced in immunosuppressive therapy and management of organ transplant patients. ■ Adequate laboratory and supportive medical resources must be available. ■ All formulations may be given concomitantly with adrenocortical steroids. Manufacturer has a Black Box Warning. **Do not administer cyclosporine with any other immunosuppressive agent except adrenocortical steroids.** ■ Can cause hepatotoxicity and nephrotoxicity; see **Monitor**. In impaired renal function, if rejection is severe, try other immunosuppressive therapy or allow rejection and removal of the kidney rather than increase dose of cyclosporine. ■ May cause lymphomas and other malignancies, particularly those of the skin. Increased risk of developing a malignancy appears to be related to the intensity and duration of immunosuppression. Some malignancies may be fatal. ■ Patients receiving immunosuppressive therapies, including cyclosporine and cyclosporine-containing regimens, are at increased risk for infections (viral, bacterial, fungal, protozoal). Both generalized and localized infections can occur. Opportunistic infections include polyomavirus infections (e.g., JC virus-associated progressive multifocal leukoencephalopathy [PML]; polyoma virus-associated nephropathy [PVAN], especially due to BK virus infection). Pre-existing infections may be aggravated. Latent infections may be reactivated. Fatal outcomes have been reported. ■ Encephalopathy has been reported, including posterior reversible encephalopathy syndrome (PRES). May be manifest as impaired consciousness, convulsions, visual disturbances (including blindness), loss of motor function, movement disorders, and psychiatric disturbances. Predisposing factors may include hypertension, hypomagnesemia, hypocholesterolemia, high-dose corticosteroids, high cyclosporine blood levels, and graft-versus-host disease. Patients receiving liver transplants may be more susceptible to encephalopathy than patients receiving kidney transplants. Reversal of encephalopathy has occurred after discontinuation or dose reduction of cyclosporine. ■ Convulsions have been reported, particularly in patients receiving concomitant therapy with high-dose methylprednisolone. ■ Significant hyperkalemia (sometimes associated with hyperchloremic acidosis) and hyperuricemia has been reported. ■ A syndrome of thrombocytopenia and microangiopathic hemolytic anemia that may result in graft failure has been reported. ■ Optic disc edema, including papilledema, with possible visual impairment secondary to benign intracranial hypertension has been reported. ■ See **Drug/Lab Interactions**.

Monitor: Observe for S/S of an anaphylactic reaction (e.g., blood pressure changes; bronchospasm; dyspnea; edema of face, tongue, or throat; itching; rash; tachycardia; wheezing). Monitor continuously for the first 30 minutes of the infusion and frequently thereafter. ■ Can cause hepatotoxicity and nephrotoxicity. Monitor BUN, SCr, serum bilirubin, and liver enzymes frequently. Timing and amount of rise in BUN and creatinine

and degree of nephrotoxicity or hepatotoxicity distinguish between need for dose reduction or symptoms of organ rejection. ■ May be difficult to distinguish between nephrotoxicity and rejection. Up to 20% of patients may have simultaneous nephrotoxicity and rejection. See package insert for a table discussing differential diagnoses for each. ■ Monitor cyclosporine blood levels. Measured by specific or nonspecific assay. 24-hour specific trough values of 100 to 200 ng/mL of whole blood or 24-hour nonspecific trough values of 250 to 800 ng/mL of whole blood minimize side effects and rejection events. Nonspecific assays trough values are higher because they include metabolites. Plasma levels may range from $\frac{1}{2}$ to $\frac{1}{5}$ of whole blood levels. Consistent use of one assay is recommended. Confirm assay method to evaluate appropriately. ■ Observe constantly for signs of infection (fever, sore throat, tiredness) or unusual bleeding or bruising. ■ Prophylactic antibiotics may be indicated pending results of C/S. ■ Monitor for development of PVAN and BK virus-associated nephropathy (e.g., deteriorating renal function and renal graft loss). Dose reduction may be indicated. ■ Monitor for development of PML (e.g., apathy, ataxia, cognitive deficiencies, confusion, hemiparesis). If symptoms appear, consultation with a neurologist may be indicated. ■ Monitor BP. Hypertension is a common side effect. Initiation or modification of antihypertensive therapy may be indicated; do not use potassium-sparing diuretics (e.g., spironolactone [Aldactone]); may increase risk of hyperkalemia. ■ Monitor for S/S of encephalopathy and/or PRES. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Use nonhormonal birth control. Do not use oral contraceptives. See Appendix D, p. 1255. ■ Do not make any changes in formulation (e.g., IV, capsules, oral solution) without physician direction; products are not equivalent. May require dose adjustment. ■ Review side effects with a health care professional and report all side effects promptly. ■ Capable of multiple drug-drug interactions; obtain physician approval before adding or stopping medications. ■ Compliance with frequent laboratory tests is imperative.

Maternal/Child: Category C: safety for use in pregnancy not established. Should not be used unless benefit to the mother justifies potential risk to the fetus. Use in men and women capable of conception not established. Reported outcomes of pregnancies in women who received cyclosporine are difficult to evaluate. It is not possible to separate the effects of cyclosporine from the effects of other medications, underlying maternal disorders, or other aspects of the transplantation process. Negative outcomes included prematurity, low birth weight, fetal loss, and various malformations. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established but has been used in patients as young as 6 months. Accidental parenteral overdose in premature neonates has caused serious symptoms of intoxication.

Elderly: Dose selection should be cautious; see [Dose Adjustments](#). ■ Differences in response compared to younger adults not identified.

DRUG/LAB INTERACTIONS

Interactions are numerous and potentially life threatening. Review of drug profile by pharmacist imperative. ■ Risk of nephrotoxicity increased when given with other drugs that may potentiate renal dysfunction. Use extreme caution and monitor renal function closely. If impairment of renal function is significant, either reduce the dose of cyclosporine and/or the coadministered drug, or consider an alternative treatment. Manufacturer lists **antibiotics** (e.g., ciprofloxacin [Cipro], gentamicin, tobramycin, sulfamethoxazole/trimeoprim, vancomycin), **antifungals** (e.g., amphotericin B, ketoconazole [Nizoral]), **anti-inflammatory drugs** (e.g., azapropazon [Rheumox], colchicine, diclofenac [Voltaren, Cataflam], naproxen [Aleve, Naprosyn], sulindac [Clinoril]), **H₂ antagonists** (e.g., cimetidine [Tagamet], ranitidine [Zantac]), **immunosuppressives** (e.g., tacrolimus [Prograf]), **antineoplastics** (e.g., melphalan [Alkeran], methotrexate), and **fibrin acid derivatives** (e.g., fenofibrate [Tricor]). Other sources list **acyclovir** (Zovirax), **foscarnet** (Foscavir), **selected quinolones** (e.g., norfloxacin [Noroxin]), and **numerous other nephrotoxic drugs**. ■ Concurrent administration with **colchicine** may cause cyclosporine toxicity (e.g., GI, hepatic,

renal, and neuromuscular toxicity). Cyclosporine may decrease the clearance and increase the toxic effects of colchicine (e.g., myopathy, neuropathy), especially in patients with renal impairment. With concurrent use, close clinical observation is required. Reduce colchicine dose, or discontinue as indicated. ■ May increase **diclofenac** (Voltaren) serum levels with concomitant administration; initiate diclofenac dose at the lower end of the therapeutic range. ■ Cyclosporine is extensively metabolized by CYP3A4 and is a substrate of the multidrug efflux transporter P-glycoprotein. **Drugs that inhibit or induce CYP3A4, P-glycoprotein transporter, or both** will result in an alteration of cyclosporine concentrations. Toxicity or allograft rejection may occur. ■ Cyclosporine plasma levels may be increased with concurrent use of **protease inhibitors** (e.g., boceprevir [Victrelis], indinavir [Crixivan], nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase], telaprevir [Incivek]), which are metabolized by cytochrome P₄₅₀ 3A; use caution. ■ Drugs that inhibit the cytochrome P₄₅₀ system may decrease the metabolism of cyclosporine and increase its serum concentrations. Manufacturer lists **allopurinol** (Aloprim), **amiodarone** (Nexterone), **antibiotics** (e.g., azithromycin [Zithromax], clarithromycin, erythromycin, quinupristin/dalfopristin [Synercid]), **antifungals** (e.g., fluconazole [Diflucan], itraconazole [Sporanox], ketoconazole [Nizoral]), voriconazole [VFEND]), **bromocriptine** (Parlodel), **calcium channel blockers** (e.g., diltiazem [Cardizem], nicardipine [Cardene], verapamil), **colchicine**, **danazol** (Danocrine), **glucocorticoids** (e.g., methylprednisolone [Solu-Medrol]), **imatinib** (Gleevec), **metoclopramide** (Reglan), **nefazodone**, and **oral contraceptives**. Monitor blood levels with concurrent use to avoid cyclosporine toxicity. ■ Drugs that decrease cyclosporine concentrations should be avoided. Manufacturer lists **antibiotics** (e.g., nafcillin [Nallpen], rifampin [Rifadin]), **anticonvulsants** (e.g., carbamazepine [Tegretol], oxcarbazepine [Trileptal], phenobarbital [Luminal], phenytoin [Dilantin]), **bosentan** (Tracleer), **octreotide** (Sandostatin), **orlistat** (Alli, Xenical), **terbinafine** (Lamisil), **ticlopidine** (Ticlid), **St. John's wort**, and **sulfinpyrazone** (Anturane). Other sources list **sulfamethoxazole/trimethoprim**; monitor levels and adjust cyclosporine dose as indicated to avoid transplant rejection. ■ **Rifabutin** (Mycobutin) may increase metabolism of cyclosporine; use care with concomitant use. ■ Cyclosporine inhibits CYP3A4 and the multidrug efflux transporter P-glycoprotein and may increase plasma concentrations of co-medications that are substrates of CYP3A4, P-glycoprotein, or both. Cyclosporine reduces clearance and may increase blood levels of **ambrisentan** (Letairis), **bosentan** (Tracleer), **colchicine**, **digoxin**, **etoposide**, **methotrexate**, and **prednisolone**; in addition, it may decrease the volume distribution of digoxin and cause toxicity rather quickly. With concurrent use, monitor digoxin levels, reduce digoxin dose, or discontinue as indicated. ■ Cyclosporine may decrease the clearance of **HMG-CoA reductase inhibitors (statins)** such as atorvastatin (Lipitor), lovastatin (Mevacor), pravastatin (Pravachol), simvastatin (Zocor) and, rarely, fluvastatin (Lescol). Cases of myotoxicity (including muscle pain and weakness, myositis, and rhabdomyolysis) have been reported with concomitant use. Dose reduction of statins is indicated. Statins may be temporarily withheld or discontinued in patients with S/S of myopathy or potential for renal injury, including renal failure, secondary to rhabdomyolysis. ■ Coadministration with **aliskiren** (Tekturna) is not recommended. ■ May decrease **mycophenolate** (CellCept) levels. Monitor levels closely when cyclosporine is added or removed from a drug regimen containing mycophenolate. ■ Concurrent use of cyclosporine with **imipenem-cilastatin** (Primaxin) may increase CNS toxicity of both agents. ■ Potentiates **nondepolarizing muscle relaxants** (e.g., atracurium [Tracrium]); will prolong neuromuscular blockade. ■ Do not use **potassium-sparing diuretics** (e.g., spironolactone [Aldactone]); may increase risk of hyperkalemia. Use caution when coadministered with **other potassium-sparing drugs** (e.g., angiotensin-converting inhibitors [e.g., enalapril (Vasotec), lisinopril (Zestril)], angiotensin II receptor antagonists [e.g., losartan (Cozaar), valsartan (Diovan)]), **potassium-containing drugs**, and/or in patients on a **potassium-rich diet**. Hyperkalemia can occur. ■ May cause convulsions with high doses of **methylprednisolone**. ■ May be given in combination with **steroids** but has additive effects with other **immunosuppressive agents**; may increase risk of lymphoma. ■ Concurrent administration with **sirolimus** (Rapamune) increases blood

levels of sirolimus. To minimize the effect on blood levels, administer sirolimus 4 hours after cyclosporine dose. ■ Elevations in SCr have been reported with coadministration of **sirolimus** and cyclosporine. Effect is usually reversible with cyclosporine dose reduction. ■ Serum levels may increase with **chloroquine** (Aralen). ■ Avoid use in psoriasis patients receiving **other immunosuppressive agents or radiation therapy, including PUVA and UVB**. Immunosuppression may be excessive. ■ May increase the plasma concentrations of **repaglinide** (Prandin), which increases the risk for hypoglycemia. Monitor blood glucose levels closely. ■ Concurrent use with **nifedipine** (Procardia) has caused gingival hyperplasia; avoid use in patients who develop gingival hyperplasia. ■ High doses of cyclosporine (e.g., IV doses of 16 mg/kg/day) may increase the exposure to **anthracycline antibiotics** (e.g., daunorubicin, doxorubicin, mitoxantrone) in cancer patients. ■ Vaccinations may be less effective. Avoid use of **live virus vaccines** in patients receiving cyclosporine. ■ **Grapefruit juice** may affect certain enzymes of the P₄₅₀ enzyme system and should be avoided.

SIDE EFFECTS

The most common side effects include gum hyperplasia, hirsutism, hypertension, renal dysfunction, and tremor. Other side effects include acne, convulsions, cramps, diarrhea, encephalopathy, glomerular capillary thrombosis, headache, hepatotoxicity, hyperkalemia, hyperuricemia, hypomagnesemia, infection, leukopenia, lymphoma, microangiopathic hemolytic anemia, nausea and vomiting, paresthesia, skin rash, and thrombocytopenia. Hypersensitivity reactions including anaphylaxis have occurred. Stevens-Johnson syndrome and toxic epidermal necrolysis have occurred rarely.

Post-Marketing: Headache, including migraine; hepatotoxicity and liver injury, including cholestasis, hepatitis, jaundice, and liver failure with serious and/or fatal outcomes; JC virus–associated PML, sometimes fatal; and PVAN, especially due to BK virus infection, resulting in graft loss.

ANTIDOTE

Notify physician of all side effects. Most can be treated symptomatically. Drug may be decreased or discontinued or other immunosuppressive agents utilized. Consider reducing total immunosuppression in transplant patients who develop PML or PVAN; may place graft at risk. Discontinue infusion at the first sign of a severe hypersensitivity reaction. Treat hypersensitivity as indicated; may require oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and/or ventilation equipment. Nephrotoxicity, hepatotoxicity, encephalopathy (including PRES), or hematopoietic depression may require temporary reduction of dosage or permanent withholding of treatment. Dialysis is not effective in overdose.

CYTARABINE **BBW**(sye-**TAIR**-ah-bean)Antineoplastic
(antimetabolite)ARA-C, Cytosar[®], Cytosar-U[®]

pH 5

USUAL DOSE

Acute nonlymphocytic leukemia in adult and pediatric patients: *Single agent:* 200 mg/M²/24 hr as a continuous infusion for 5 days. Repeat every 2 weeks. *Combination chemotherapy:* Dose is variable depending on specific regimen or protocol. Examples are 100 mg/M²/24 hr as a continuous infusion or 100 mg/M² as an IV injection every 12 hours. Repeat daily on days 1 through 7. Another regimen uses 100 to 200 mg/M² or 2 to 6 mg/kg/24 hr as a continuous infusion or equally divided into 2 or 3 doses and given by IV injection or intermittent infusion. Given for 5 to 10 days. Maintain treatment until therapeutic effect or toxicity occurs. Modify on a day-to-day basis for maximum individualized effectiveness.

Acute myelocytic leukemia or erythroleukemia in adult and pediatric patients: As a single agent, 100 to 200 mg/M²/24 hr or 3 mg/kg/24 hr for 5 to 10 days as a continuous infusion or in divided doses by IV injection. Total dose is 1,000 mg/M². Repeat every 2 weeks.

DOSE ADJUSTMENTS

Dose (mg/kg) based on average weight in presence of edema or ascites. ■ Dose reduction may be indicated in impaired hepatic or renal function. ■ See [Precautions/Monitor](#). ■ Usually used with other antineoplastic drugs in specific doses to achieve tumor remission. ■ Withhold or modify dose based on degree of bone marrow suppression; see [Monitor](#).

DILUTION

Specific techniques required; see [Precautions](#). Some preparations are liquid and do not require reconstitution or each 100 mg must be reconstituted with 5 mL (500 mg with 10 mL) of SWFI with benzyl alcohol 0.9%. Solution pH about 5. May be given by IV injection as is or further diluted in NS or D5W and given as an infusion. IV injection should be through a free-flowing IV tubing. Use only clear solutions.

Storage: Stable at room temperature for 48 hours.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Additive: Daunorubicin (Cerubidine), gentamicin, hydrocortisone sodium succinate (Solu-Cortef), lincomycin (Lincocin), methotrexate, methylprednisolone (Solu-Medrol), mitoxantrone (Novantrone), ondansetron (Zofran), potassium chloride (KCl), sodium bicarbonate, vincristine.

Y-site: Amifostine (Ethyol), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), aztreonam (Azactam), cladribine (Leustatin), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), hydrocortisone sodium succinate (Solu-Cortef), idarubicin (Idamycin), linezolid (Zyvox), melphalan (Alkeran), methotrexate, methylprednisolone (Solu-Medrol), ondansetron (Zofran), paclitaxel (Taxol), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), propofol (Diprivan), sargramostim (Leukine), sodium bicarbonate, teniposide (Vumon), thiotepe, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

IV injection: Each 100 mg or fraction thereof over 1 to 3 minutes.

IV infusion: Single daily dose properly diluted over 30 minutes to 24 hours, depending on amount of infusion solution and dosage regimen.

ACTIONS

An antimetabolite and pyrimidine antagonist that interferes with the synthesis of DNA. Cell cycle specific for S phase. Through various chemical processes this deprivation acts more quickly on rapidly growing cells and causes their death. Cytotoxic and cytostatic. A potent bone marrow suppressant. Crosses the blood-brain barrier. Serum half-life averages 1 to 3 hours. Metabolized in the liver and excreted in the urine.

INDICATIONS AND USES

Induction and maintenance of remission in acute nonlymphocytic leukemia in adults and pediatric patients. Also used for treatment of acute lymphocytic leukemia (ALL), the blast phase of chronic myelocytic leukemia, and acute myelocytic leukemia (AML). ■ Is used intrathecally in the treatment of meningeal leukemia. A liposomal formulation (DepoCyt) is available for intrathecal use only, liposome molecules contained in this product are much too large for IV use.

CONTRAINDICATIONS

Hypersensitivity to cytarabine, pre-existing drug-induced bone marrow suppression.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Remissions induced by cytarabine are brief unless followed by maintenance therapy. ■ Use caution with impaired liver or renal function. ■ Severe GI, pulmonary, or CNS toxicity has occurred with experimental cytarabine regimens. Toxicities are different (e.g., reversible corneal toxicity, hemorrhagic conjunctivitis, cerebral and cerebellar dysfunction, severe GI ulceration) from those seen with conventional therapy. Deaths have been reported. ■ Benzyl alcohol may cause a fatal “gasping syndrome” in premature infants.

Monitor: Leukocyte and platelet counts should be monitored daily. ■ During induction therapy, WBC depression is biphasic with the first nadir occurring at days 7 to 9 and a deeper fall at days 15 to 24. Platelet depression begins around day 5 and reaches a nadir at days 12 to 15. ■ Hold or modify therapy for platelet count less than 50,000 or polymorphonuclear granulocytes less than 1,000 cells/mm³. Restart therapy when bone marrow recovery is confirmed. ■ Monitor bone marrow, liver, and renal function at regular intervals during therapy. ■ Higher doses tolerated by IV injection compared with IV infusion, but the incidence and intensity of nausea and vomiting are increased. ■ Prophylactic administration of antiemetics recommended. ■ Be alert for signs of bone marrow suppression, bleeding, infection, or neurotoxicity. These side effects are dose- and schedule-dependent. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor uric acid levels; maintain hydration; allopurinol may be indicated.

Patient Education: Nonhormonal birth control recommended. ■ See Appendix D, p. 1255. ■ Promptly report early signs of neurotoxicity (e.g., ataxia, confusion, lethargy).

Maternal/Child: Category D: avoid pregnancy. May produce teratogenic effects on the fetus, especially during the first trimester. ■ Discontinue breast-feeding. ■ See [Drug/Lab Interactions](#).

Elderly: Consider age-related organ impairment; toxicity may be increased.

DRUG/LAB INTERACTIONS

May inhibit **digoxin** absorption. ■ Do not administer any **live virus vaccines** to patients receiving antineoplastic drugs. ■ May cause acute pancreatitis in patients who previously received **L-asparaginase**. ■ May antagonize action of **gentamicin** against *Klebsiella*. ■ May antagonize antifungal actions of **flucytosine** (Ancobon). ■ Clearance decreased and toxicity increased with **nephrotoxic agents** (e.g., aminoglycosides [gentamicin]); may cause neurotoxic symptoms (e.g., ataxia, confusion, lethargy). ■ Concurrent use of high doses of **cytarabine** with cisplatin may increase ototoxicity.

SIDE EFFECTS

Abdominal pain, bone marrow suppression (e.g., anemia, leukopenia, thrombocytopenia), bone pain, cardiomyopathy, chest pain, conjunctivitis, diarrhea, esophagitis, fever, hepatic dysfunction, hypersensitivity reactions, hyperuricemia, malaise, megaloblastosis, mucosal bleeding, myalgia, nausea, oral ulceration, pancreatitis, peripheral motor and sensory neuropathies, rash, stomatitis, thrombophlebitis, vomiting. Higher than usual dose regimens may cause severe coma, GI ulcerations and peritonitis, personality changes, pulmonary toxicity, somnolence, or death.

ANTIDOTE

Notify the physician of all side effects. Most will be treated symptomatically. Some toxicity is necessary to produce remission. Discontinue the drug for serious bone marrow suppression. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes), and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epoen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Drug must be restarted as soon as signs of bone marrow recovery occur, or its effectiveness will be lost. Use corticosteroids for cytarabine syndrome (fever, myalgia, bone pain, occasional chest pain, maculopapular rash, conjunctivitis, malaise). Usually occurs in 6 to 12 hours after administration. Continue cytarabine if patient responds to corticosteroids. There is no specific antidote; supportive therapy as indicated will help to sustain the patient in toxicity.

CYTOMEGALOVIRUS IMMUNE GLOBULIN INTRAVENOUS (HUMAN) **BBW***

(sigh-toh-meg-ah-lo-VIGH-rus ih-MUNE GLAW-byoo-lin)

Passive immunizing agent
Antibacterial
Antiviral

CMV-IGIV, CytoGam

*This drug is on the Black Box Warning list; however, a BBW is not provided in the parenteral prescribing information.

USUAL DOSE

150 mg/kg is the maximum recommended dose per infusion.

Kidney transplant: 150 mg/kg of body weight as an IV infusion. This initial dose must be given within 72 hours of transplant. Additional infusions of 100 mg/kg are given at 2, 4, 6, and 8 weeks post-transplant, then reduced to 50 mg/kg at 12 and 16 weeks post-transplant.

Heart, liver, lung, and pancreas transplants: 150 mg/kg of body weight as an IV infusion. This initial dose must be given within 72 hours of transplant. Consider use in combination with ganciclovir (Cytovene) 10 mg/kg/day for 14 days. Additional infusions of cytomegalovirus IGIV containing 150 mg/kg are given at 2, 4, 6, and 8 weeks post-transplant, then reduced to 100 mg/kg at 12 and 16 weeks post-transplant.

DILUTION

Absolute sterile technique required; contains no preservatives. Available in 20- and 50-mL vials (50 mg/mL); multiple vials may be required. Use only if clear and colorless. Enter vial only once and initiate infusion within 6 hours. Must be completely infused within 12 hours of dilution. See [Rate of Administration](#).

Filters: Use of an in-line filter (pore size 15 microns [0.2 microns acceptable]) is required; see [Rate of Administration](#).

Storage: Store dry powder in refrigerator between 2° and 8° C (35° to 46° F).

COMPATIBILITY

Administration through a separate infusion line recommended. If absolutely necessary, may be piggybacked in a pre-existing line containing NS, ½NS, dextrose 2.5%, 5%, 10%, or 20% in water or saline. Do not dilute CMV-IGIV more than one part to two parts of any of these solutions.

RATE OF ADMINISTRATION

Use of an in-line filter (pore size 15 microns [0.2 microns acceptable]) and a constant infusion pump (e.g., IVAC) is required. Begin with a rate of 15 mg/kg/hr. May be increased to 30 mg/kg/hr in 30 minutes if no discomfort or adverse effects. May be increased in another 30 minutes to 60 mg/kg/hr if no discomfort or adverse effects. Do not exceed the 60 mg/kg/hr rate or allow the volume infused to exceed 75 mL/hr regardless of mg/kg/hr dose. Slow rate of infusion at onset of patient discomfort or any adverse reactions. Infusion must be complete within 12 hours of dilution. Subsequent doses may be increased at 15-minute intervals using the same mg/kg/hr rates and adhering to the volume maximum of 75 mL/hr.

ACTIONS

A sterile solution of immunoglobulin Gm (IgG). Derived from pooled adult human plasma selected for high titers of antibody for cytomegalovirus (CMV). Purified by a specific process. Can raise the relevant antibody levels sufficiently to attenuate or reduce the incidence of serious CMV disease. Antibody levels will last 2 to 3 weeks. Recent studies of combined prophylaxis with CMV-IGIV and ganciclovir have shown reductions in the incidence of serious CMV-associated disease in CMV-seronegative recipients of CMV-seropositive organs below that expected from one drug alone.

INDICATIONS AND USES

Prophylaxis of CMV disease associated with transplantation of kidney, heart, liver, lung, and pancreas. In transplants of these organs other than kidney from CMV-seropositive donors to seronegative recipients, prophylactic CMV-IGIV should be considered in combination with ganciclovir.

CONTRAINDICATIONS

History of a prior severe reaction associated with any human immunoglobulin preparations. Individuals with selective immunoglobulin A deficiency may develop antibodies to IgA and are at risk for anaphylaxis.

PRECAUTIONS

75% of untreated recipients would be expected to develop CMV disease. Use of CMV-IGIV has effected a 50% reduction in this disease rate. Effective results have been obtained with a variety of immunosuppressive regimens (e.g., combinations of azathioprine, cyclosporine, prednisone). ■ A fatal CMV infection occurred even with ganciclovir treatment in one patient, who inadvertently missed a single injection.

Monitor: Continuous monitoring of vital signs is preferred. Must be monitored before infusion, at every rate change, the midpoint, at the conclusion, and several times after completion. ■ All supplies for emergency treatment of acute anaphylactic reaction must be available; see [Antidote](#).

Patient Education: Adherence to the prescribed regimen is imperative.

Maternal/Child: Category C: safety for use during pregnancy or breast-feeding not established. Use only if clearly needed.

DRUG/LAB INTERACTIONS

Defer vaccination with any **live virus vaccine** (e.g., measles, mumps, rubella) until 3 months after CMV-IGIV administration.

SIDE EFFECTS

Incidence related to rate of administration; back pain, chills, fever, flushing, hypotension, muscle cramps, nausea, vomiting, wheezing. Hypersensitivity reactions, including anaphylaxis, are possible.

ANTIDOTE

With onset of any minor side effect, reduce rate of infusion immediately or discontinue temporarily. Discontinue CMV-IGIV if symptoms persist and notify the physician. May be treated symptomatically and infusion resumed at a slower rate if symptoms subside. Discontinue CMV-IGIV if hypotension or anaphylaxis occur and treat immediately. Epinephrine (Adrenalin), diphenhydramine (Benadryl), oxygen, vasopressors (e.g., dopamine), corticosteroids, and ventilation equipment must always be available. Resuscitate as necessary.

DACARBAZINE **BBW**

(dah-KAR-bah-zeen)

Antineoplastic
(alkylating agent)

DTIC, DTIC-Dome

pH 3 to 4

USUAL DOSE

Malignant melanoma: 2 to 4.5 mg/kg of body weight/24 hr for 10 days. May be repeated at 4-week intervals. May administer 250 mg/M² daily for 5 days. Repeat in 3 weeks. Has proved as effective in lesser doses as in larger doses. Individualized response determines dosage of subsequent treatments.

Hodgkin's disease: 150 mg/M²/24 hr for 5 days. Repeat every 4 weeks. Used in combination with other drugs in a specific regimen. An alternate regimen is 375 mg/M² on Days 1 and 15 every 4 weeks or 100 mg/M²/day for 5 days. Given as part of a specific protocol.

DOSE ADJUSTMENTS

Dose (mg/kg) based on average weight in presence of edema or ascites. ■ Used with other antineoplastic drugs and radiation therapy in reduced doses to achieve tumor remission. ■ Dose reduction may be required in impaired liver and renal function.

DILUTION

Specific techniques required; see Precautions. Each 100-mg vial is diluted with 9.9 mL (200 mg with 19.7 mL) of SWFI (10 mg/mL). Further dilution in 50 to 250 mL of D5W or NS for infusion is preferred. May be given through Y-tube or three-way stopcock of infusion set through a free-flowing IV.

Storage: Discard in 6 to 8 hours if kept at room temperature. Reconstituted solution stable for 72 hours, diluted solution for 24 hours if refrigerated at 4° C (39° F).

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Additive: Ondansetron (Zofran).

Y-site: Amifostine (Ethyol), aztreonam (Azactam), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), filgrastim (Neupogen), fludarabine (Fludara), granisetron (Kytril), heparin, melphalan (Alkeran), ondansetron (Zofran), paclitaxel (Taxol), palonosetron (Aloxi), sargramostim (Leukine), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Total dose over 30 to 60 minutes. More rapid rate may cause severe venous irritation.

ACTIONS

An antineoplastic agent. Exact mechanism of action is not known; may inhibit DNA and RNA synthesis. It is an alkylating agent, cell cycle phase nonspecific. Probably localizes in the liver and is excreted in the urine.

INDICATIONS AND USES

Metastatic malignant melanoma. ■ Hodgkin's disease. ■ Soft-tissue sarcomas.

Unlabeled uses: Treatment of malignant pheochromocytoma with cyclophosphamide and vincristine. ■ Treatment of metastatic malignant melanoma with tamoxifen.

CONTRAINDICATIONS

Known hypersensitivity to dacarbazine.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Bone marrow suppression is the most common toxicity. ■ Hepatic necrosis has been reported. ■ Consider potential for therapeutic benefit versus risk for toxicity. ■ Use caution in impaired liver and renal function.

Monitor: Determine absolute patency of vein; a stinging or burning sensation indicates extravasation; severe cellulitis and tissue necrosis will result. Discontinue injection; use another vein. ■ Monitor bone marrow function, white and RBC count, and platelet count frequently. ■ Nausea and vomiting may be reduced by restricting oral intake of fluid and foods for 4 to 6 hours before administration. Use prophylactic antiemetics. ■ Be alert for signs of bone marrow suppression, bleeding, or infection. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient.

Patient Education: Protect skin surfaces; may cause photosensitive skin reactions. ■ Non-hormonal birth control recommended. ■ Report burning or stinging at IV site promptly. ■ See Appendix D, p. 1255.

Maternal/Child: Category C: safety for use in pregnancy or breast-feeding and in men and women capable of conception not established. ■ Carcinogenic and teratogenic in animals. ■ Discontinue breast-feeding.

Elderly: Consider age-related organ impairment; toxicity may be increased.

DRUG/LAB INTERACTIONS

Do not administer any **live virus vaccines** to patients receiving antineoplastic drugs. ■ Inhibited by **phenobarbital and phenytoin** (Dilantin). ■ Potentiates **allopurinol**. ■ Effects of dacarbazine may be increased with **ciprofloxacin** (Cipro), **isoniazid** (INH), **fluvoxamine** (Luvox), **ketoconazole** (Nizoral), **miconazole** (Monistat), and **norfloxacin** (Noroxin). Effects may be decreased with **carbamazepine** (Tegretol), **phenobarbital**, and **rifampin** (Rifadin).

SIDE EFFECTS

Leukopenia and thrombocytopenia may be serious enough to cause death. Alopecia, anaphylaxis, anorexia, facial flushing, facial paresthesias, fever, hepatotoxicity, malaise, myalgia, nausea, skin necrosis, vomiting.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Bone marrow suppression may require temporary or permanent withholding of treatment. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. For extravasation, elevate extremity; consider injection of long-acting dexamethasone (Decadron LA) throughout extravasated tissue. Use a 27- or 25-gauge needle. Apply moist, warm compresses.

DACTINOMYCIN **BBW**

(dack-tin-oh-MY-sin)

**Antineoplastic
(antibiotic)****Cosmegen****pH 5.5 to 7****USUAL DOSE**

Dose will depend on tolerance of the patient, the size and location of the tumor, and the use of other forms of therapy. Calculate each dose carefully before administration. Calculation of the dose for obese or edematous patients should be based on body surface area. The dose intensity per 2-week cycle for adult and pediatric patients should not exceed 15 mcg/kg/day (0.015 mg/kg/day) or 400 to 600 mcg/M²/day (0.4 to 0.6 mg/M²/day) for 5 days.

Wilms' tumor, childhood rhabdomyosarcoma, and Ewing's sarcoma: 15 mcg/kg/day for 5 days, not to exceed 0.5 mg/day. May be administered in various combinations and schedules with other chemotherapeutic agents.

Metastatic nonseminomatous testicular cancer: 1,000 mcg/M² (1 mg/M²) on Day 1 as part of a combination regimen with cyclophosphamide, bleomycin, vinblastine, and cisplatin.

Gestational trophoblastic neoplasia: 12 mcg/kg/day for 5 days as a single agent or 500 mcg on Days 1 and 2 as part of a combination regimen with etoposide, methotrexate, folinic acid, vincristine, cyclophosphamide, and cisplatin.

PEDIATRIC DOSE

Same as Usual Dose for adults; see [Contraindications](#).

DOSE ADJUSTMENTS

Calculate dose based on body surface area in presence of edema or ascites. ■ Used with other antineoplastic drugs in reduced doses to achieve tumor remission. ■ Reduce dose of dactinomycin and radiation therapy when used concurrently, if either has been used previously, or if previous chemotherapy has been employed. ■ Dose selection should be cautious in the elderly. Consider potential for decreased cardiac, hepatic, and renal function, and concomitant disease or drug therapy; see [Elderly](#).

DILUTION

Specific techniques required; see [Precautions](#). Highly toxic. Both powder and solution must be handled with care. Dilute each 0.5-mg vial with 1.1 mL of preservative-free SWFI (0.5 mg/mL). Reconstituted product is a clear, gold-colored solution. SWFI with preservative (benzyl alcohol or paraben) will cause precipitation. Very corrosive to soft tissue. Use sterile two-needle technique if given by IV injection; one needle to dilute and withdraw and one needle to inject into the vein (rinse with blood or IV solution before removing). May be given by IV injection, through the Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS, or further diluted in one of the above solutions for infusion to a final concentration of 10 mcg/mL or higher.

Filters: Manufacturer states, "Use of some in-line cellulose ester membrane filters have resulted in loss of potency." Another source suggests no loss of drug potency with a 5-micron stainless steel depth filter.

Storage: Store at 25° C (77° F). Protect from light and humidity. Prepared product must be used within 4 hours of initial reconstitution when stored at ambient RT. Discard any unused portion.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Forms a precipitate with SWFI that contains preservatives. Cellulose ester membrane filters may reduce dose by partial removal of dactinomycin.

One source suggests the following **compatibilities**:

Y-site: Allopurinol (Aloprim), amifostine (Ethylol), aztreonam (Azactam), etoposide phosphate (Etopophos), fludarabine (Fludara), gemcitabine (Gemzar), granisetron (Ky-

tril), melphalan (Alkeran), ondansetron (Zofran), sargramostim (Leukine), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

IV injection: A single dose over 2 to 3 minutes.

IV infusion: A single dose over 10 to 15 minutes.

ACTIONS

A highly toxic antibiotic antineoplastic agent, cell cycle phase nonspecific. Cytotoxic, it interferes with cell division by binding DNA to slow production of RNA. Found in high concentrations in the kidney, liver, and spleen. Does not penetrate the blood-brain barrier. Minimally metabolized. Elimination half-life is approximately 36 hours. Excreted as unchanged drug in bile and urine.

INDICATIONS AND USES

As part of a combination chemotherapy and/or multi-modality regimen for treatment of Wilms' tumor, childhood rhabdomyosarcoma, Ewing's sarcoma, and metastatic non-seminomatous testicular cancer. ■ Alone or in combination with other chemotherapeutic agents for the treatment of gestational trophoblastic neoplasia.

Unlabeled uses: Treatment of osteosarcoma, malignant melanoma, Paget's disease of the bone.

CONTRAINDICATIONS

Exposure to chickenpox, herpes zoster, known sensitivity to dactinomycin, infants under 6 to 12 months of age.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. Review guidelines before handling and follow diligently. See Appendix A, p. 1251. ■ For IV use only. Do not administer IM or SC. ■ Highly toxic; both the powder and solution must be handled and administered with care. Inhalation of dust or vapors and contact with skin or mucous membranes, especially those of the eyes, must be avoided. If eye contact occurs, rinse for at least 15 minutes with water, saline or a balanced salt ophthalmic solution and then seek immediate ophthalmologic consultation. If skin contact occurs, remove contaminated clothing and rinse area for 15 minutes. Medical attention should be sought immediately and clothes should be destroyed. ■ Administered by or under the direction of a physician specialist. ■ In general, dactinomycin should not be administered concomitantly with radiation therapy in the treatment of Wilms' tumor unless the benefit outweighs the risk. Hepatomegaly and elevated AST levels have been reported. ■ Hepatic veno-occlusive disease that may be associated with intravascular clotting disorder and multi-organ failure has been reported. Pediatric patients younger than 48 months of age may be at increased risk. ■ May have increased incidence of second primary tumors following treatment with dactinomycin and radiation. Long-term follow-up of cancer survivors is indicated.

Monitor: Very corrosive to soft tissue; determine absolute patency of vein. If extravasation occurs, severe damage to soft tissue will result. A stinging or burning sensation indicates extravasation; severe cellulitis and tissue necrosis will result. Discontinue injection; use another vein. Close observation and reconstructive surgery consultation are recommended. ■ Monitor renal, hepatic, and bone marrow function frequently. ■ Except for immediate nausea and vomiting, side effects may not appear for 2 to 4 days and may not peak for 1 to 2 weeks. Always observe closely. Use prophylactic antiemetics. ■ If stomatitis, diarrhea, or severe hematopoietic depression appears, discontinue therapy until the patient has recovered. ■ An increased incidence of GI toxicity, bone marrow suppression, and skin and mucosal reactions has been reported when dactinomycin is administered in combination with radiation therapy. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Allopurinol, increased fluid intake, and alkalinization of urine may be required to reduce uric acid levels. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient.

Patient Education: Nonhormonal birth control recommended. ■ Report burning or stinging at IV site promptly. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. May produce teratogenic effects on the fetus; use caution in men and women capable of conception. ■ Discontinue breastfeeding. ■ Greater frequency of toxic effects seen in infants. See **Contraindications and Precautions**.

Elderly: Response similar to that in younger adults; however, recent studies suggest elderly may be at increased risk for myelosuppression; see **Dose Adjustments**.

DRUG/LAB INTERACTIONS

Dactinomycin potentiates the effects of **radiation therapy**; use with caution in patients receiving radiation therapy. Reduced doses are indicated with simultaneous use; risk of GI toxicity and myelosuppression increased. ■ Dactinomycin alone may reactivate erythema from **previous radiation therapy**. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Inhibits action of **penicillin**. ■ See **Dose Adjustments**. ■ May interfere with **bioassay procedures** used in determining antibacterial drug levels.

SIDE EFFECTS

Toxic reactions are frequent, may be severe, and may be dose limiting; however, the severity of toxicity varies markedly and is only partly dependent on the dose administered. Abdominal pain, acne, alopecia, anaphylaxis, anorexia, bone marrow suppression (e.g., anemia, aplastic anemia, agranulocytosis, febrile neutropenia, leukopenia, neutropenia, thrombocytopenia), cheilitis, diarrhea, dysphagia, erythema flare-up, erythema multiforme, esophagitis, fatigue, fever, GI ulceration, hypocalcemia, lethargy, liver toxicity (ascites, hepatitis, hepatic failure with reports of death, hepatic veno-occlusive disease, hepatomegaly, and liver function test abnormalities), malaise, myalgia, nausea, pharyngitis, pneumonitis, proctitis, sepsis (including neutropenic sepsis), skin eruptions, ulcerative stomatitis, vomiting.

Post-Marketing: Stevens-Johnson syndrome, toxic epidermal necrolysis.

ANTIDOTE

Any side effect can result in death. Notify the physician of all side effects. Most will be treated symptomatically. Bone marrow suppression may require withholding dactinomycin until recovery occurs. No specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epoen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. For extravasation, discontinue immediately and elevate extremity. Apply ice to site four times daily for 3 days. Close observation and reconstructive surgery consultation recommended.

DANTROLENE SODIUM

(DAN-troh-leen SO-dee-um)

Skeletal muscle relaxant
(direct acting)

Dantrium

pH 9.5

USUAL DOSE

In patients known to be susceptible to malignant hyperthermia, oral dantrolene is indicated prophylactically preoperatively and postoperatively for 1 to 3 days following therapeutic IV treatment. Postoperative dosing is indicated after emergency treatment.

Prophylactic dose: 2.5 mg/kg as an infusion. Begin administration 1¼ hours before anesthesia, and administer over 1 hour. Oral dantrolene may be used.

Therapeutic or emergency dose: 1 mg/kg of body weight as an initial dose. Repeat as necessary until symptoms subside or a cumulative dose of 10 mg/kg is reached. Entire regimen may be repeated if symptoms reappear. Dose required depends on degree of susceptibility to malignant hyperthermia, length of time of exposure to triggering agent, and time lapse between onset of crisis and beginning of treatment. Discontinue all anesthetic agents at the first sign of a malignant hyperthermia reaction. Administration of 100% oxygen is recommended.

Post-crisis follow-up: An oral dose of 4 to 8 mg/kg/day for 1 to 3 days to prevent recurrences. If oral dosing not feasible, begin IV dose at 1 mg/kg and individualize by increasing based on patient response.

PEDIATRIC DOSE

Prophylactic, therapeutic, and post-crisis follow-up doses are the same as for adults; see *Maternal/Child*.

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Each 20 mg must be diluted with 60 mL SWFI without a bacteriostatic agent. Shake until solution is clear. May be administered through a Y-tube or three-way stopcock of infusion tubing. If large volumes will be used, transfer to plastic infusion bags; do not use glass bottles; see *Compatibility*.

Storage: Store undiluted vials at CRT and protect from light. Protect diluted solution from direct light and discard after 6 hours.

COMPATIBILITY

Manufacturer states, "D5W, NS, and acidic solutions are **not compatible** and should not be used." May form a precipitate with glass bottles; use of plastic IV bags recommended.

RATE OF ADMINISTRATION

Prophylactic dose: A single dose as an infusion distributed over 1 hour.

Therapeutic or emergency dose: Each single dose should be given by rapid continuous IV push. Follow immediately with subsequent doses as indicated.

Follow-up dose: Each single dose over 2 to 3 minutes.

ACTIONS

A direct-acting skeletal muscle relaxant. Inhibits excitation-contraction coupling by interfering with the release of the calcium ion from the sarcoplasmic reticulum to reverse the physiologic cause of malignant hyperthermia. Has no appreciable effect on cardiovascular or respiratory function. Onset of action is prompt and lasts about 5 hours. Half-life is 4 to 8 hours. Metabolized in the liver and excreted in urine. Readily crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Management of the fulminant hypermetabolism of skeletal muscle characteristics of malignant hyperthermic crises in patients of all ages. ■ Perioperatively to prevent, treat,

or minimize the severity of clinical and laboratory signs of malignant hyperthermia in individuals who may be or are known to be susceptible.

CONTRAINDICATIONS

None when used as indicated for malignant hyperthermia crisis.

PRECAUTIONS

Use caution in patients with impaired pulmonary or cardiac function or history of liver disease. ■ Discontinue all anesthetic agents immediately when onset of malignant hyperthermia is recognized. S/S of the fulminant hypermetabolism of skeletal muscle characteristic of malignant hyperthermia crisis are tachycardia, tachypnea, central venous desaturation, hypercapnia, metabolic acidosis, skeletal muscle rigidity, cyanosis, mottling of skin, fever, increased use of anesthesia circuit CO₂ absorber. ■ Hepatotoxicity has been reported.

Monitor: Monitor ECG, vital signs, electrolytes, and urine output continuously. ■ Oxygen needs are increased. ■ Manage metabolic acidosis. ■ Institute cooling measures. ■ Confirm absolute patency of vein; avoid extravasation. ■ Monitor hepatic function frequently, including ALT, AST. ■ S/S of malignant hyperthermia crises include central venous desaturation, cyanosis and mottling of the skin, hypercarbia, increased utilization of anesthesia circuit carbon dioxide absorber, metabolic acidosis, skeletal muscle rigidity, tachycardia, tachypnea and, in many cases, fever.

Patient Education: May experience decreased grip strength, weakness in leg muscles, and light-headedness postoperatively. May persist for 48 hours. ■ Request assistance for ambulation. ■ Use caution when eating; choking and difficulty swallowing has been reported on day of administration. ■ Avoid alcohol and other CNS depressants (e.g., diazepam [Valium]). ■ Avoid tasks that require alertness. ■ Promptly report bloody or tarry stools, itching, jaundice (yellow color) of eyes and skin, or skin rash.

Maternal/Child: Category C: embryocidal with larger doses in rats. Benefits must outweigh risks. ■ Discontinue breast-feeding. ■ Use caution in pediatric patients under 5 years; safety not established.

Elderly: Dose selection should be cautious; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Ability to bind to plasma proteins inhibited by **warfarin and clofibrate**; increased by **tolbutamide**. ■ Avoid concurrent use of **calcium channel blockers** (e.g., diltiazem [Cardizem]) and **dantrolene**. Myocardial depression, arrhythmias, and hyperkalemia have been reported. ■ May potentiate **vecuronium**-induced neuromuscular blockade. ■ May cause hepatotoxicity with **estrogens**, especially in women over 35 years of age.

SIDE EFFECTS

Dizziness, drowsiness, erythema, injection site reactions, loss of grip strength, pulmonary edema, thrombophlebitis, urticaria, and weakness. Anaphylaxis has been reported.

ANTIDOTE

No specific antidote is available or needed when used correctly. Notify physician and initiate supportive measures (adequate airway and ventilation, monitor ECG) in overdose. Discontinue all anesthetic agents at the first sign of a malignant hyperthermia reaction. Administration of 100% oxygen is recommended. Large amounts of IV fluids may be needed to prevent crystalluria. Treat anaphylaxis and resuscitate as necessary.

DAPTOMYCIN

(dap-toe-MY-sin)

Antibacterial
(cyclic lipopeptide)**Cubicin****USUAL DOSE**

Complicated skin and skin structure infections: 4 mg/kg once every 24 hours for 7 to 14 days. Do not administer more frequently than once daily.

Staphylococcus aureus bloodstream infections (bacteremia), including those with right-sided endocarditis: 6 mg/kg once every 24 hours for 2 to 6 weeks. Duration of treatment is dependent on diagnosis. Safety data for use more than 28 days is limited. Do not administer more frequently than once daily.

DOSE ADJUSTMENTS

Dose adjustment required in patients with severe renal impairment. In patients with CrCl less than 30 mL/min, including patients undergoing hemodialysis or CAPD, administer a single dose (4 or 6 mg/kg) every 48 hours. If possible, administer dose following completion of hemodialysis on hemodialysis days. ■ No specific dose adjustments required based on age, gender, obesity, or mild to moderate hepatic impairment. Has not been studied in patients with severe hepatic impairment.

DILUTION

Available in 500-mg vials. Reconstitute each 500-mg vial by slowly directing 10 mL of NS to vial sides (50 mg/mL). Ensure wetting of entire daptomycin product. Allow vial to stand for 10 minutes, then gently rotate to ensure complete dilution. **To minimize foaming, avoid vigorous agitation or shaking during or after reconstitution.** Freshly reconstituted solutions range in color from pale yellow to light brown. May be administered as a 50 mg/mL reconstituted solution or may be further diluted with 50 mL of NS before administration and given as an infusion.

Filters: No data available from manufacturer.

Storage: Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Both reconstituted and diluted solutions are stable for 12 hours at RT or up to 48 hours refrigerated. The combined time (vial and infusion bag) at RT should not exceed 12 hours. Combined refrigeration time (vial and infusion bag) should not exceed 48 hours.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Additives or other medications should not be added to daptomycin single-use vials or infused simultaneously through the same intravenous line. If the same intravenous line is used for sequential infusion of several different drugs, the line should be flushed with a **compatible** infusion solution before and after infusion with daptomycin.” ■ Manufacturer states, “Daptomycin is **compatible** with NS and LR but is **incompatible** with dextrose-containing diluents.” ■ Do not use in conjunction with ReadyMED® elastomeric infusion pumps (Cardinal Health, Inc.); an **incompatibility** occurs because of an impurity leaching from this pump system into the daptomycin solution.

One source suggests the following **compatibilities**:

Y-site: Aztreonam (Azactam), casprofungin (Cancidas), ceftazidime (Fortaz), ceftriaxone (Rocephin), dopamine, doripenem (Doribax), fluconazole (Diflucan), gentamicin, heparin, levofloxacin (Levaquin), lidocaine.

RATE OF ADMINISTRATION

See **Compatibility**. Flushing of the IV line before and after infusion may be indicated.

Injection: A single dose properly reconstituted over 2 minutes.

Infusion: A single dose properly diluted over 30 minutes.

ACTIONS

A cyclic lipopeptide antibacterial agent. Binds to bacterial membranes and causes a rapid depolarization of the membrane potential. Loss of the membrane potential leads to inhibition of protein, DNA and RNA synthesis, which results in bacterial cell death. Exhibits bactericidal activity against aerobic gram-positive bacteria and has been shown to retain potency against antibiotic-resistant, gram-positive bacteria, including isolates resistant to methicillin, vancomycin, and linezolid. Cross-resistance between daptomycin and other antibacterial agents has not been reported. Highly protein bound, primarily to albumin. Site of metabolism has not been identified. Half-life is approximately 7 to 9 hours. Is excreted primarily by the kidney. A small fraction is excreted through the feces. Secreted in breast milk.

INDICATIONS AND USES

Treatment of complicated skin and skin structure infections caused by susceptible strains of several aerobic gram-positive microorganisms and *Staphylococcus aureus* bloodstream infections (bacteremia), including those with right-sided infective endocarditis caused by methicillin-susceptible and methicillin-resistant isolates. The effectiveness of daptomycin in patients with left-sided endocarditis due to *S. aureus* has not been demonstrated. See manufacturer's literature.

Limitation of use: Daptomycin is not indicated for treatment of left-sided infective endocarditis due to *S. aureus* and has not been studied in patients with prosthetic valve endocarditis. ■ **Not** indicated for treatment of pneumonia. In phase 3 studies of community-acquired pneumonia, the death rate and rates of serious cardiorespiratory adverse events were higher in daptomycin-treated patients than in patients treated with a comparator agent. These differences resulted from the lack of therapeutic effectiveness of daptomycin in the treatment of community-acquired pneumonia.

CONTRAINDICATIONS

Known hypersensitivity to daptomycin.

PRECAUTIONS

C/S indicated to determine susceptibility of causative organism to daptomycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, daptomycin should be used to treat or prevent only those infections that are proven or strongly suspected to be caused by susceptible bacteria. ■ Combination therapy may be clinically indicated if the documented or presumed pathogens include Gram-negative or anaerobic organisms. ■ Eosinophilic pneumonia has been reported. Onset is usually 2 to 4 weeks after initiation of daptomycin and improves when therapy is discontinued. Patient may present with fever, dyspnea with hypoxic respiratory insufficiency, and diffuse pulmonary infiltrates. ■ Superinfection caused by the overgrowth of nonsusceptible organisms may occur with antibiotic use. Treat as indicated. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with daptomycin. ■ Skeletal muscle effects associated with daptomycin have been observed. Elevations in serum creatine phosphokinase (CPK); myopathy; and rhabdomyolysis, with or without acute renal failure, have been reported. Some cases involved patients treated concurrently with daptomycin and HMG-CoA reductase inhibitors; see [Drug/Lab Interactions](#). ■ Adverse events, possibly reflective of peripheral or cranial neuropathy (e.g., paresthesias, Bell's palsy), have been reported rarely. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. ■ In clinical trials, decreased efficacy was observed in patients with moderate baseline renal impairment (CrCl less than 50 mL/min).

Monitor: Obtain baseline and weekly Scr, BUN, and CPK levels. Patients who received recent, prior, or concomitant therapy with an HMG-CoA reductase inhibitor (e.g., simvastatin [Zocor], lovastatin [Mevacor]), patients with renal insufficiency, and patients who develop unexplained elevations in CPK while receiving daptomycin should be monitored more frequently. See [Precautions](#) and [Antidote](#). ■ Monitor for S/S of hypersensitivity reactions (e.g., dyspnea, fever, flushing, hypotension, nausea, pruritus, rash,

urticaria). ■ Monitor for the development of muscle pain or weakness, particularly in the distal extremities. ■ Monitor for S/S of neuropathy. ■ Repeat blood cultures indicated in patients with persisting or relapsing *S. aureus* infection or poor clinical response. MIC (minimum inhibitory concentration) susceptibility testing and diagnostic evaluation to rule out sequestered foci of infection may be indicated. Surgical intervention (e.g., débridement, removal of prosthetic device) may be required. ■ Monitor for S/S of eosinophilic pneumonia (e.g., cough, fever, difficulty breathing, shortness of breath). Treatment with systemic steroids is recommended.

Patient Education: Review side effects with physician. Promptly report muscle pain or weakness, S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face), S/S of neuropathy (e.g., tingling or numbness, especially in the forearm or lower leg), or new or worsening cough or fever. ■ Review medications (prescription and non-prescription) with health care provider. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: use during pregnancy only if clearly needed. ■ Use caution during breastfeeding. Is present in breast milk, but oral bioavailability is poor. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly: Lower clinical success rates were seen in patients 65 years of age or older. In addition, adverse events were more common in this age-group. Consider age-related renal impairment. See [Dose Adjustment](#).

DRUG/LAB INTERACTIONS

Daptomycin does not appear to inhibit or induce the activities of the cytochrome P₄₅₀ isoforms: 1A2, 2A6, 2C9, 2C19, 2D6, 2E1, and 3A4. It is unlikely that it will inhibit or induce the metabolism of drugs metabolized by this system. ■ *In vitro* synergistic interactions occurred with **aminoglycosides, beta-lactam antibiotics, and rifampin** (Rifadin) against some isolates of staphylococci and enterococci, including some methicillin-resistant *Staphylococcus aureus* (MRSA) isolates and some vancomycin-resistant enterococci isolates. ■ Has been administered with **warfarin**. Does not appear to affect the pharmacokinetics of either drug. However, daptomycin can cause a significant concentration-dependent false prolongation of PT and elevation of INR when certain recombinant thromboplastin reagents are used for the assay. This drug-lab interaction can be minimized by drawing specimens for PT/INR near the time of trough plasma concentrations of daptomycin. Evaluation of PT/INR using an alternative method may be required. ■ Inhibitors of **HMG-CoA reductase** (e.g., simvastatin [Zocor], atorvastatin [Lipitor]) may cause myopathy, which is manifested as muscle pain or weakness associated with elevated levels of CPK and possible rhabdomyolysis. Consider temporarily suspending the use of HMG-CoA reductase inhibitors in patients receiving daptomycin. ■ Has been used concomitantly with aztreonam (Azactam). No dose adjustment for either antibiotic was required. ■ No dose adjustment is required when given concomitantly with probenecid.

SIDE EFFECTS

Most side effects are mild to moderate in intensity. Side effects occurring in 2% or more of patients include abnormal liver function tests, anemia, anxiety, arthralgia, asthenia, back pain, constipation, diarrhea, dizziness, dyspepsia, dyspnea, edema, elevated CPK, fever, fungal infections, gram-negative infections, headache, hyperkalemia, hypertension, hypokalemia, hypotension, injection site pain, insomnia, limb pain, nausea and vomiting, pruritus, rash, renal failure, sweating, and urinary tract infections. Less frequently reported side effects include abdominal pain, anxiety, back pain, *Candida* infections, cardiac failure, CDAD, cellulitis, chest pain, confusion, cough, decreased appetite, edema, elevated alkaline phosphatase, hyperglycemia, hypoglycemia, hypokalemia, and sore throat. Muscle pain or weakness, rhabdomyolysis, and peripheral neuropathy have been reported rarely. See [Precautions](#). Hypersensitivity reactions including anaphylaxis, difficulty swallowing, hives, pruritus, shortness of breath, and truncal erythema have

been reported. Other reactions have been reported in fewer than 1% of study patients. See manufacturer's literature.

Post-Marketing: Pulmonary eosinophilia.

ANTIDOTE

Notify physician of any side effects. Discontinue drug in patients with unexplained S/S of myopathy in conjunction with CPK elevation greater than 1,000 units/L (approximately 5 times the upper limit of normal) or in patients without reported symptoms who have marked elevation in CPK (equal to or greater than 10 times the upper limit of normal). In animal studies, skeletal muscle effects and neuropathies were reversible with discontinuation of the drug. Discontinue daptomycin at the first sign of eosinophilic pneumonia. Treatment with systemic steroids is recommended. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Treat hypersensitivity reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Approximately 15% of daptomycin is removed during a 4-hour hemodialysis run. Approximately 11% is recovered over 48 hours with peritoneal dialysis. Use of a high-flux dialysis membrane may increase the amount of drug removal. Resuscitate as necessary.

DARBEPOETIN ALFA **BBW**

(DAR-beh-poh-eh-tin AL-fah)

Antianemic agent

Aranesp

pH 5.7 to 6.4

USUAL DOSE

Adult and pediatric patients: Rate of hemoglobin increase is dose dependent and varies among patients. Availability of iron stores, baseline hemoglobin, and concurrent medical problems affect the rate and extent of response. In controlled clinical trials, patients experienced greater risks for death, serious adverse cardiovascular reactions, and stroke when administered erythropoiesis-stimulating agents (ESAs) to target a hemoglobin level of greater than 11 Gm/dL. Use the lowest dose for each patient that will gradually increase the hemoglobin concentration to avoid the need for RBC transfusion. If a patient fails to respond or maintain a response, other etiologies should be considered and evaluated. See [Monitor](#), [Precautions](#), and [Maternal/Child](#).

Anemia associated with chronic kidney disease (CKD) for patients on dialysis: Initiate darbepoetin when the hemoglobin level is less than 10 Gm/dL: **Starting dose:** 0.45 mcg/kg of body weight once per week or 0.75 mcg/kg once every 2 weeks as appropriate. May be given by IV or SC injection. The IV route is recommended for patients on hemodialysis; see [Precautions](#). See [Dose Adjustments](#) and [Maternal/Child](#).

Anemia associated with chronic kidney disease (CKD) for patients NOT on dialysis: Consider initiating darbepoetin only when the hemoglobin level is less than 10 Gm/dL and the following two considerations apply: (1) the rate of hemoglobin decline indicates the likelihood of requiring a RBC transfusion, and (2) reducing the risk of alloimmunization and/or other RBC transfusion-related risks is a goal. **Starting dose:** 0.45 mcg/kg of body weight IV or SC given once every 4 weeks as appropriate.

Conversion from epoetin alfa to darbepoetin alfa in patients with CKD on dialysis: Estimate starting weekly dose of darbepoetin for adult and pediatric patients based on the weekly dose of epoetin alfa at the time of substitution as shown in the following chart. Administer darbepoetin once per week in patients who were receiving epoetin alfa 2 to 3 times a week and once every 2 weeks in patients who were receiving epoetin alfa once per week. The route of administration (IV or SC) should remain the same.

Estimated Darbepoetin Alfa Starting Dose Based on Previous Epoetin Alfa Dose for Patients with CKD on Dialysis		
Previous Weekly Epoetin Alfa Dose (units/week)	Weekly Darbepoetin Alfa Dose (mcg/week)	
	Adult	Pediatric
<1,500 units/week	6.25 mcg/week	See *
1,500 to 2,499 units/week	6.25 mcg/week	6.25 mcg/week
2,500 to 4,999 units/week	12.5 mcg/week	10 mcg/week
5,000 to 10,999 units/week	25 mcg/week	20 mcg/week
11,000 to 17,999 units/week	40 mcg/week	40 mcg/week
18,000 to 33,999 units/week	60 mcg/week	60 mcg/week
34,000 to 89,999 units/week	100 mcg/week	100 mcg/week
≥90,000 units/week	200 mcg/week	200 mcg/week

*Data insufficient to determine a darbepoetin alfa conversion dose in pediatric patients receiving a weekly epoetin alfa dose of less than 1,500 units/week.

Conversion from epoetin alfa to darbepoetin alfa in patients with CKD NOT on dialysis: The dose conversion shown in the previous table (for patients with CKD on dialysis) does not accurately estimate the once-monthly dose of darbepoetin.

Anemia associated with chemotherapy in cancer patients: ESAs shortened overall survival and/or increased the risk of tumor progression or recurrence in clinical studies of patients with certain types of cancer; see **Precautions**. Initiate darbepoetin in patients undergoing cancer chemotherapy only if the hemoglobin is less than 10 Gm/dL and there is a minimum of 2 additional months of planned chemotherapy. Use the lowest dose necessary to avoid RBC transfusions.

Starting dose: 2.25 mcg/kg of body weight SC every week until completion of chemotherapy course. An alternative schedule is 500 mcg SC every 3 weeks until completion of chemotherapy course.

DOSE ADJUSTMENTS

All patients with CKD: When adjusting therapy, consider hemoglobin rate of rise, hemoglobin rate of decline, ESA responsiveness, and hemoglobin variability. A single hemoglobin excursion may not require a dose adjustment. Dose should be started slowly and adjusted for each patient to achieve and maintain the lowest hemoglobin level sufficient to avoid the need for RBC transfusion. Allow sufficient time before adjusting a dose; increased hemoglobin levels may not be observed for 2 to 6 weeks. ■ Do not increase the dose more frequently than once every 4 weeks. Decreases in dose can occur more frequently. ■ If the hemoglobin rises rapidly (e.g., more than 1 Gm/dL in any 2-week period), reduce the dose by 25% or more as needed to reduce rapid responses. ■ For patients who do not respond adequately (e.g., the hemoglobin has not increased by more than 1 Gm/dL) after 4 weeks of therapy, increase the dose by 25%. ■ For patients who do not respond adequately over a 12-week escalation period, increasing the dose further is unlikely to improve response and may increase risks. Discontinue darbepoetin if responsiveness does not improve.

Patients with CKD on dialysis: If the hemoglobin level approaches or exceeds 11 Gm/dL, reduce or interrupt the dose of darbepoetin.

Patients with CKD NOT on dialysis: If the hemoglobin level exceeds 10 Gm/dL, reduce or interrupt the dose of darbepoetin.

Continued

Anemia associated with chemotherapy in cancer patients:

Dose Adjustment in Patients Undergoing Cancer Chemotherapy		
Dose Adjustment	Weekly Schedule	Every-3-Week Schedule
If hemoglobin increases greater than 1 Gm/dL in any 2-week period or If hemoglobin reaches a level needed to avoid RBC transfusion	Reduce dose by 40%	Reduce dose by 40%
If hemoglobin exceeds a level needed to avoid RBC transfusion	Withhold dose until hemoglobin approaches a level at which RBC transfusions may be required Reinitiate at a dose 40% below the previous dose	Withhold dose until hemoglobin approaches a level at which RBC transfusions may be required Reinitiate at a dose 40% below the previous dose
If hemoglobin increases by less than 1 Gm/dL and remains below 10 Gm/dL after 6 weeks of therapy	Increase dose to 4.5 mcg/kg/week	No dose adjustment
If there is no response as measured by hemoglobin levels or if RBC transfusions are still required after 8 weeks of therapy Following completion of a chemotherapy course	Discontinue darbepoetin	Discontinue darbepoetin

DILUTION

Available in numerous concentrations and in two formulations (polysorbate or albumin solutions). Supplied in vials or pre-filled syringes with needle guards (needle cover contains a derivative of latex). Check labeling carefully to confirm IV use. Must be given undiluted as an IV injection. Do not administer in conjunction with other drug solutions. **Do not shake** and keep covered to protect from room light until administration. Vigorous shaking or exposure to light will render solution biologically inactive. Single-dose vial contains no preservatives. Use only 1 dose per vial, then discard.

Filters: Not required; however, it was filtered during manufacturing with 0.2-micron filters. No significant loss of potency expected with use of non-protein binding filters of a similar size or larger.

Storage: Store at 2° to 8° C. Do not freeze or shake. Protect from light.

COMPATIBILITY

Manufacturer states, "Do not administer in conjunction with other drug solutions."

RATE OF ADMINISTRATION

A single dose over at least 1 minute.

ACTIONS

An erythropoiesis-stimulating protein produced by recombinant DNA technology. Closely related to human erythropoietin. Production of endogenous erythropoietin is impaired in patients with chronic renal failure, and erythropoietin deficiency is the primary cause of their anemia. Darbepoetin has the same biologic effects as erythropoietin produced naturally by the kidneys. Stimulates bone marrow to produce RBCs, increasing the reticulocyte count within 10 days and the red cell count, hemoglobin, and hematocrit within 2 to 6 weeks. Normal iron stores are necessary because it steps up RBC production to a rate above what the body usually makes. New cells need iron, which is quickly

depleted. Distribution is confined to the vascular space. Half-life is approximately 21 hours. Continued therapy will maintain improved RBC levels and decrease the need for transfusions.

INDICATIONS AND USES

Treatment of anemia associated with chronic kidney disease, including patients receiving dialysis and patients not receiving dialysis. ■ As a SC injection to treat chemotherapy-induced anemia in adult cancer patients who have non-myeloid malignancies in which anemia is a result of the effect of concomitant myelosuppressive chemotherapy and who, upon initiation of therapy, have a minimum of 2 additional months of planned chemotherapy.

Limitation of use: Not indicated for use in patients with cancer receiving hormonal agents, therapeutic biologic products, or radiotherapy unless receiving concomitant myelosuppressive chemotherapy. ■ Not indicated for patients receiving myelosuppressive therapy when the anticipated outcome is cure; see [Precautions](#). ■ Has not been shown to improve symptoms of anemia, quality of life, fatigue, or patient well-being; see [Precautions](#). ■ Not indicated for reduction in allogeneic RBC transfusions in patients scheduled for surgical procedures. ■ Not indicated as a substitute for a RBC transfusion in patients who require immediate correction of anemia.

CONTRAINDICATIONS

Known hypersensitivity to albumin, polysorbate, or darbepoetin. ■ Uncontrolled hypertension. ■ Pure red cell aplasia (PRCA) that begins after treatment with darbepoetin or other erythropoietin agents.

PRECAUTIONS

May be given IV or SC to patients not receiving dialysis. ■ Erythropoiesis-stimulating agents (ESAs) increase the risk of death, MI, stroke, venous thromboembolism, and thrombosis of vascular access. Patients experienced greater risks of these adverse events when ESAs were administered to target a hemoglobin of greater than 11 Gm/dL. No trial has identified a hemoglobin target level, a darbepoetin dose, or a dosing strategy that does not increase these risks. Use the lowest darbepoetin dose sufficient to reduce the need for RBC transfusions. ■ Use with caution in patients with coexistent cardiovascular disease and stroke. Patients with CKD and an insufficient hemoglobin response to ESA therapy may be at even greater risk for cardiovascular reactions and mortality than other patients. ■ In clinical trials, ESAs increased the risk of death in patients undergoing CABG surgery and the risk of deep venous thrombosis in patients undergoing orthopedic procedures. ■ Increases in hemoglobin of greater than 1 Gm/dL during any 2-week period have been associated with an increased incidence of cardiac arrest, neurologic events (e.g., seizures, stroke), exacerbations of hypertension, congestive heart failure (CHF), vascular thrombosis/ischemia/infarction, acute MI, deep vein thrombosis (DVT), pulmonary embolus, hemodialysis graft occlusion, and fluid overload/edema. See [Dose Adjustments](#). ■ Administration of erythropoiesis-stimulating agents (ESAs) to cancer patients shortened the overall survival time and/or increased the risk of tumor progression or recurrence in clinical studies of some patients with breast, cervical, head and neck, lymphoid, and non-small cell lung malignancies. To minimize these risks, as well as the risks of serious cardiovascular and thrombovascular events, use the lowest dose needed to avoid a red blood cell transfusion. Use only to treat anemia due to concomitant myelosuppressive chemotherapy and discontinue after completion of a chemotherapy course. Prescribers and hospitals are now required to enroll in and comply with the ESA APPRISE Oncology Program to prescribe and/or dispense ESAs to patients with cancer. See prescribing information Black Box Warning. ■ BP may increase during therapy with darbepoetin. Hypertensive encephalopathy and seizures have been observed. ■ Patients with uncontrolled hypertension should not be treated with darbepoetin until BP has been adequately controlled. ■ In addition to low baseline hemoglobin and inadequate iron stores, delayed or diminished response may result from concurrent medical problems (e.g., infections, inflammatory or malignant processes, occult blood loss, underlying hematologic disease, folic acid or vitamin B₁₂ deficiency, hemolysis, aluminum intoxication, osteofibrosis cystica, bone marrow fibrosis, pure red cell aplasia [PRCA], or anti-

erythropoietin antibody-associated anemia). Correct or exclude other causes of anemia before initiating therapy. Not intended for use in anemia caused by iron or folate deficiencies, hemolysis, or GI bleeding or for use in treating symptoms of anemia, including dizziness, fatigue, low energy, poor quality of life, or shortness of breath. ■ Safety and efficacy have not been established in patients with underlying hematologic diseases (e.g., hemolytic anemia, sickle cell anemia, thalassemia, porphyria). ■ Therapy results in an increase in RBCs and a decrease in plasma volume, which could reduce dialysis efficiency; adjustment of dialysis prescription may be necessary. ■ Darbepoetin increases the risk of seizures in patients with CKD. Use with caution in patients with epilepsy. ■ As with all proteins, there is a potential for immunogenicity. The incidence of antibody development in patients receiving darbepoetin has not been determined. Use caution; hypersensitivity reactions and/or anaphylaxis can occur. ■ Pure red cell aplasia (PRCA) and severe anemia, with or without other cytopenias, in association with neutralizing antibodies to erythropoietin has been observed. Most often reported in CKD patients receiving epoetin alfa by SC injection. Evaluate any patient who develops a sudden loss of response to darbepoetin alfa accompanied by severe anemia and low reticulocyte count. Physicians may contact the manufacturer (Amgen) for help with evaluation of these patients. ■ The formulation containing albumin carries a risk for transmission of viral diseases or Creutzfeldt-Jakob disease. Donor screening and manufacturing processes make this risk extremely remote. ■ Darbepoetin is a growth factor that stimulates RBC production. Erythropoietin receptors are also found on the surfaces of normal, non-hematopoietic tissue and some malignant cell lines. The possibility that darbepoetin can act as a growth factor for any tumor type cannot be ruled out.

Monitor: Monitor hemoglobin weekly in patients who are initiating therapy. Continue until stable and the maintenance dose has been established, then monitor at regular intervals. ■ Monitor hemoglobin weekly for at least 4 weeks following adjustment of therapy. Once stabilized, continue to monitor at regular intervals. ■ Monitor BP routinely. Initiation or intensification of antihypertensive therapy and dietary restrictions may be necessary. If BP is difficult to control by pharmacologic or dietary measures, the dose of darbepoetin should be reduced or withheld. ■ Monitor for the presence of premonitory neurologic symptoms during initiation of therapy or when dose is adjusted. Seizures have been reported; see [Precautions](#). ■ Predialysis patients may be more responsive to the effects of therapy. Monitor BP, hemoglobin, renal function, and fluid and electrolyte balance. During the transition period onto dialysis, hemoglobin and BP should be monitored carefully; see [Dose Adjustments](#). ■ Normal iron stores required to support epoetin-stimulated erythropoiesis. Transferrin saturation should be at least 20% and ferritin at least 100 ng/mL (100 mcg/L). Monitor before and during therapy. Supplemental iron is usually required to increase and maintain transferrin saturation. Administration of parenteral iron may be necessary in some patients.

Patient Education: Risk of seizures, especially for first several months of therapy. Do not drive or operate heavy equipment. ■ Stress the importance of compliance with diet, iron and vitamin (e.g., folic acid, B₁₂) supplementation, BP control, and dialysis regimen. ■ Close monitoring of BP and hemoglobin is imperative. ■ Promptly report S/S of a hypersensitivity reaction, pain or swelling in the legs, shortness of breath (SOB), increase in BP, dizziness, or loss of consciousness. ■ Menses may resume; possibility of pregnancy. Contraception may be indicated. ■ Additional instruction (e.g., equipment, techniques) will be required in patients who will self-administer (manufacturer supplies brochure). ■ Increased risk of mortality, serious cardiovascular events, thromboembolic events, and tumor progression or recurrence. ■ Read medication guide carefully. All patients should discuss the risks of using an ESA with a health care professional. ■ Cancer patients must sign a patient–health care provider acknowledgment form through the APPRISE Oncology Program before initiating therapy; see [Precautions](#).

Maternal/Child: Category C: may present risk to fetus; benefits must justify risk. ■ Use caution in nursing mothers. ■ Safety and effectiveness not established for use in the

initial treatment of anemic pediatric patients with CKD or in the transition from another erythropoietin to darbepoetin in pediatric CKD patients less than 1 year of age. Safety and effectiveness similar to adult conversion studies in pediatric CKD patients over 1 year of age. ■ Safety and effectiveness for use in pediatric cancer patients not established. ■ Half-life and plasma concentrations in pediatric patients 3 years of age and older are similar to those seen in adults. See package insert.

Elderly: Response similar to that found in younger patients; however, the elderly may have a greater sensitivity to its effects. ■ Monitor blood chemistry and BP carefully due to increased risk of renal and/or cardiovascular complications.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Chronic kidney disease patients: Commonly reported *serious* adverse reactions include angina, cardiac arrhythmia, CHF, sepsis, vascular access thrombosis. Other commonly reported side effects were diarrhea, fever, headache, hypertension, hypotension, infection (e.g., abscess, bacteremia, peritonitis, pneumonia, sepsis), myalgia, nausea. Less commonly reported side effects include abdominal pain, angina, arthralgia, asthenia, back pain, constipation, cough, dizziness, fatigue, flu-like symptoms, fluid overload, hypersensitivity reactions (e.g., rash, urticaria), injection site reactions (infection, hemorrhage), limb pain, peripheral edema, upper respiratory tract infection, vomiting. PRCA and severe anemia, with or without other cytopenias, in association with neutralizing antibodies has been reported; see [Precautions](#). Cardiac arrest and death have been reported.

Cancer patients receiving chemotherapy: The most frequently reported *serious* adverse events include death, dehydration, dyspnea, fever, pneumonia, and vomiting. Other commonly reported side effects include diarrhea, edema, fatigue, and nausea. Arthralgia, constipation, dizziness, headache, hypertension, myalgia, rash, seizures, and thrombotic events (e.g., pulmonary embolism, thrombosis) are less commonly reported.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Excessive hypertension may require discontinuation of darbepoetin until BP is controlled or may respond to a reduction in dose of darbepoetin or to an increase in antihypertensive therapy. Reduce dose of darbepoetin in patients with an increase in hemoglobin of more than 1 Gm/dL in 2 weeks. May need to withhold darbepoetin until hemoglobin falls to desired goal. Consider phlebotomy in the event of overdose or polycythemia. If overdose or polycythemia does occur, monitor closely for cardiovascular events and hematologic abnormalities. When resuming therapy, monitor closely for evidence of rapid increases in hemoglobin concentration (greater than 1 Gm/dL within 14 days) and reduce dose as indicated. Adjustments in dialysis prescription may be required during dialysis to prevent clotting. Permanently discontinue therapy in patients with antibody-mediated anemia. Patients should not be switched to other erythropoietic proteins, because antibodies may cross-react. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary.

(daw-noh-ROO-bih-sin hy-droh-KLOR-eyed)
 (daw-noh-ROO-bih-sin SIH-trate LIP-oh-sohm-ul)

Cerubidine ■ DaunoXome

pH 4.5 to 6.5 ■ 4.9 to 6

USUAL DOSE

CONVENTIONAL DAUNORUBICIN

Adult acute nonlymphocytic leukemia: 45 mg/M²/day on Days 1, 2, and 3 in adults under age 60 (adults over age 60 may require reduction to 30 mg/M²/day). Used in specific protocol combination therapy (e.g., cytarabine 100 mg/M²/day for 7 days). Regimen repeated every 3 to 4 weeks. In these subsequent courses, repeat daunorubicin, 30 to 45 mg/M²/day (depending on age) for only 2 days and cytarabine for only 5 days. To obtain a normal-appearing bone marrow may require up to 3 courses.

Adult acute lymphocytic leukemia: 45 mg/M²/day on Days 1, 2, and 3. Used in combination therapy (e.g., vincristine, prednisone, and L-asparaginase). In all situations, when remission is complete, an individual maintenance program should be established.

DAUNOXOME (LIPOSOMAL INJECTION)

Advanced, HIV-associated Kaposi's sarcoma: 40 mg/M² as an IV infusion. Repeat every 2 weeks. Continue treatment until there is evidence of disease progression (specifics outlined in package insert).

PEDIATRIC DOSE

CONVENTIONAL DAUNORUBICIN

See [Maternal/Child](#).

Acute lymphocytic leukemia in pediatric patients 2 years of age and older: 25 mg/M²/day on Day 1 each week, vincristine 1.5 mg/M² on Day 1 each week, and prednisone 40 mg/M² PO daily. Remission should be obtained in 4 weeks. If a partial remission is obtained after 4 weeks, 1 or 2 more weeks of treatment may produce a complete remission.

Acute lymphocytic leukemia in infants and children less than 2 years of age or less than 0.5 M² body surface: Calculate dose based on weight instead of body surface area: 1 mg/kg.

DAUNOXOME: Safety for use in pediatric patients not established.

DOSE ADJUSTMENTS

ALL DAUNORUBICINS: See [Precautions/Monitor](#).

CONVENTIONAL DAUNORUBICIN: Profound bone marrow suppression is usually required to eradicate the leukemic cells and induce a complete remission. Evaluate bone marrow and peripheral blood to determine need for additional courses. ■ See [Usual Dose](#) for adults over 60 years of age. ■ Reduce dose in impaired hepatic or renal function according to the following chart.

Daunorubicin Dosing in Impaired Hepatic or Renal Function		
Serum Bilirubin	Serum Creatinine	Dose Reduction
1.2 to 3.0 mg	—	25%
>3 mg	—	50%
—	>3 mg	50%

DAUNOXOME: Reduce dose to 75% of normal (30 mg/M²) if serum bilirubin is 1.2 to 3 mg/dL. Reduce dose to 50% of normal (20 mg/M²) if serum bilirubin or creatinine is greater than 3 mg/dL. ■ Withhold dose if absolute granulocyte count is less than 750 cells/mm³.

DILUTION

Specific techniques required; see Precautions.

Conventional daunorubicin: Each 20 mg must be diluted with 4 mL of SWFI (5 mg/mL). Agitate gently to dissolve completely. Further dilute each dose with 10 to 15 mL of NS. Must be given through Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS. May be added to 100 mL NS and given as an infusion. Use extreme caution.

DaunoXome: Dilute each single dose with an equal amount of D5W. Available as a 2 mg/mL preservative-free solution. Withdraw calculated volume (dose of DaunoXome) from vial; transfer to a sterile infusion bag that contains an equal volume of D5W. Desired concentration is 1 mg/mL. Do not use any other diluent. A translucent red liposomal dispersion; do not use if opaque. Do not use in-line filters for infusion. See **Compatibility**.

Filters: DaunoXome: Manufacturer states, “Do not use in-line filters for infusion.”

Storage: Conventional daunorubicin: Protect from sunlight. Diluted solution stable 24 hours at room temperature, 48 hours if refrigerated; then discard.

DaunoXome: Refrigerate unopened vials; avoid freezing. Protect from light. Discard unused drug. Reconstituted solutions may be refrigerated for a maximum of 6 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

CONVENTIONAL DAUNORUBICIN

Manufacturer states, “Should not be administered mixed with other drugs or heparin.”

One source suggests the following **compatibilities**:

Additive: Not recommended by manufacturer. Cytarabine (ARA-C), etoposide (VePesid), hydrocortisone sodium succinate (Solu-Cortef).

Y-site: Amifostine (Ethyol), anidulafungin (Eraxis), casposfungin (Cancidas), etoposide phosphate (Etopophos), filgrastim (Neupogen), gemcitabine (Gemzar), granisetron (Kytril), melphalan (Alkeran), methotrexate, ondansetron (Zofran), sodium bicarbonate, teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

DAUNOXOME

Manufacturer states, “The only fluid that may be mixed with DaunoXome is D5W. Must not be mixed with saline, bacteriostatic agents such as benzyl alcohol, or any other solution.”

RATE OF ADMINISTRATION**CONVENTIONAL DAUNORUBICIN**

IV injection: A single dose of properly diluted medication over 3 to 5 minutes.

IV infusion: A single dose evenly distributed over 30 to 45 minutes.

DAUNOXOME

A single dose as an infusion evenly distributed over 60 minutes. Do not use an in-line filter. Back pain, flushing, and chest tightness may occur. Usually subsides if infusion is stopped, and usually does not recur if infusion is restarted at a slower rate after symptoms subside.

ACTIONS

CONVENTIONAL DAUNORUBICIN: A highly toxic antibiotic antineoplastic agent. Rapidly cleared from plasma, it inhibits synthesis of DNA. Cell cycle specific for S phase; exact method of action is unknown; antimetabolic, cytotoxic, and immunosuppressive. Widely distributed in tissues, with the highest concentrations occurring in the spleen, kidneys, liver, lungs, and heart. Does not cross blood-brain barrier. Metabolized in the liver and other tissues. Elimination half-life is 18 to 30 hours. Slowly excreted in bile and urine.

DAUNOXOME: A liposomal preparation of daunorubicin formulated to maximize selectivity for solid tumors. In the circulation, the liposomal preparation protects the entrapped daunorubicin from chemical and enzymatic degradation, minimizes protein binding, and generally decreases uptake by normal (non-reticuloendothelial system) tissues. The mechanism of delivery is not known, but may be through the often altered and/or compromised vasculature of tumors. In animals, it has been shown to accumulate in tumors to a greater extent than conventional daunorubicin. Released over time within the cells of the solid tumor. Persists at high levels within tumor tissue for several days. It differs

from conventional daunorubicin because it mostly confines itself to vascular fluid volume. Plasma clearance is slower and the AUC (area under the curve) is larger.

INDICATIONS AND USES

CONVENTIONAL DAUNORUBICIN: Treatment of acute nonlymphocytic leukemia in adults (myelogenous, monocytic, erythroid). ■ Combination therapy for induction of remission in acute lymphocytic leukemia in adults and pediatric patients.

DAUNOXOME: Currently approved only for first-line cytotoxic therapy for advanced HIV-associated Kaposi's sarcoma.

CONTRAINDICATIONS

CONVENTIONAL DAUNORUBICIN: Hypersensitivity to daunorubicin or any of its components. **Not absolute;** pre-existing bone marrow suppression, impaired cardiac function, pre-existing infection; see [Precautions](#).

DAUNOXOME: History of hypersensitivity reaction to previous treatment with DaunoXome or any of its components (includes conventional daunorubicin). Not recommended in patients with less than advanced HIV-related Kaposi's sarcoma.

PRECAUTIONS

ALL DAUNORUBICINS: Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist with facilities for monitoring the patient and responding to any medical emergency. ■ For IV use only; do not give IM or SC. ■ Severe myelosuppression may occur and may lead to infection or hemorrhage. ■ Use extreme caution in pre-existing drug-induced bone marrow suppression, existing heart disease, previous treatment with other anthracyclines (e.g., doxorubicin [Adriamycin]), or radiation therapy encompassing the heart. ■ Incidence of myocardial toxicity increases after a total cumulative dose that exceeds 400 to 550 mg/M² in adults, 300 mg/M² in pediatric patients more than 2 years of age, or 10 mg/kg in pediatric patients less than 2 years of age. Potentially fatal congestive heart failure may occur either during therapy or months to years after therapy is complete. ■ Urine may be reddish color (from dye, not hematuria).

Monitor: ALL DAUNORUBICINS: Monitor CBC including differential and platelet count before each dose. ■ Monitoring of liver function, kidney function, ECG, chest x-ray, echocardiography, and systolic ejection fraction indicated before and during therapy; recommended before each course. ■ Evaluation of cardiac function by medical history and physical exam is recommended before each dose; see [Precautions](#). ■ Monitor closely for S/S of hemorrhage or infection; may be life threatening. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Determine absolute patency of vein. A stinging or burning sensation indicates extravasation; discontinue injection and use another vein. Severe cellulitis and tissue necrosis will result from extravasation with conventional daunorubicins; has not been observed with DaunoXome. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Monitor uric acid levels; maintain hydration; alkalinization of urine or allopurinol may be indicated. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

CONVENTIONAL DAUNORUBICIN: May cause acute congestive heart failure with total cumulative doses over 550 mg/M² in adults (400 mg/M² if previous treatment with doxorubicin or radiation therapy in area of heart), 300 mg/M² in pediatric patients over 2 years, and 10 mg/kg in pediatric patients under 2 years.

DAUNOXOME: May also cause cardiomyopathy. Monitoring of LVEF recommended at total cumulative doses of 320 mg/M², 480 mg/M², and every 240 mg/M² thereafter.

Patient Education: Nonhormonal birth control recommended. ■ Report IV site burning or stinging promptly. ■ Secondary leukemias have been reported. ■ See Appendix D, p. 1255.

Maternal/Child: ALL DAUNORUBICINS: Category D: can cause fetal harm. Avoid pregnancy. ■ Safety for use in breast-feeding not established; discontinue breast-feeding. ■ Cardiotoxicity may be more frequent and occur at lower cumulative doses in pediatric patients. ■ See [Monitor](#).

DAUNOXOME: Safety for use in pediatric patients not established.

Elderly: Cardiotoxicity and myelotoxicity may be more severe. Consider age-related renal impairment. Safety of DaunoXome for use in the elderly has not been established.

DRUG/LAB INTERACTIONS

Concurrent use with **cyclophosphamide** (Cytoxan) may increase cardiotoxicity. ■ Dose reduction may be required with concurrent use of **other myelosuppressive agents**. ■ Concurrent use with **hepatotoxic agents** (e.g., high-dose methotrexate) may increase risk of toxicity. ■ Risk of cardiotoxicity increased in patients previously treated with maximum cumulative doses of **other anthracyclines** (e.g., doxorubicin [Adriamycin], idarubicin [Idamycin]) **and/or radiation encompassing the heart**. ■ Do not administer **vaccines or chloroquine** to patients receiving antineoplastic drugs. ■ See **Precautions**.

SIDE EFFECTS

ALL DAUNORUBICINS: Bone marrow suppression and cardiotoxicity are dose related and dose limiting.

CONVENTIONAL DAUNORUBICIN: Acute congestive heart failure, alopecia (reversible), bone marrow suppression (marked with average doses), chills, decrease in systolic ejection fraction, depressed QRS voltage, diarrhea, fever, gonadal suppression, mucositis, myocarditis, nausea, pericarditis, skin rash, vomiting.

DAUNOXOME: Granulocytopenia is most common. Symptoms common to conventional daunorubicin may also occur. Infusion related back pain, chest tightness, and flushing may be related to liposomal formulation.

Overdose: Will cause increased severity of myelosuppression, fatigue, nausea, and vomiting.

ANTIDOTE

Most side effects will be tolerated or treated symptomatically. Keep physician informed. Close monitoring of cumulative dosage, bone marrow, ECG, chest x-ray, echocardiography, and systolic ejection fraction may prevent most serious and potentially fatal side effects. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epo-gen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. For extravasation, aspirate as much infiltrated drug as possible, flood site with normal saline, and inject hydrocortisone sodium succinate (Solu-Cortef) or hyaluronidase (Wydase) throughout extravasated tissue. Use a 27- or 25-gauge needle. Cold, moist compresses may be helpful; elevate extremity. Site should be observed promptly by a reconstructive surgeon.

DECITABINE FOR INJECTION

(deh-SIGHT-ah-been for in-JEK-shun)

Antineoplastic
(miscellaneous)

Dacogen

pH 6.7 to 7.3

USUAL DOSE

There are two treatment options. With either regimen, treatment for a minimum of 4 cycles is recommended. A complete or partial response may take longer than 4 cycles.

Premedication: Standard anti-emetic therapy is indicated.

Option 1: 15 mg/M² as an infusion over 3 hours. Repeat every 8 hours for 3 days. Repeat this complete cycle every 6 weeks. See [Dose Adjustments](#) and [Monitor](#).

Option 2: 20 mg/M² as an infusion over 1 hour. Repeat once each day for 5 days. Repeat this complete cycle every 4 weeks. See [Dose Adjustments](#) and [Monitor](#).

DOSE ADJUSTMENTS

Option 1 and Option 2: Hematologic recovery to at least an ANC equal to or greater than 1,000 cells/mm³ and platelets equal to or greater than 50,000 cells/mm³ is required before subsequent cycles are administered. ■ If a SCr equal to or greater than 2 mg/dL, an ALT or a total bilirubin equal to or greater than 2 times the ULN, and/or an active or uncontrolled infection occur, do not restart decitabine therapy until the toxicity is resolved. ■ No additional dose reductions are indicated based on age, gender, or race; see [Precautions](#) and [Elderly](#).

Option 1: If hematologic recovery requires more than 6 weeks but less than 8 weeks, delay repeat cycle of decitabine for up to 2 weeks. When therapy is restarted, reduce dose for that cycle to 11 mg/M² every 8 hours (33 mg/M²/day, 99 mg/M²/cycle). ■ If hematologic recovery requires more than 8 weeks but less than 10 weeks, assess the patient for disease progression (by bone marrow aspirates). If disease progression has not occurred, delay repeat cycle of decitabine for up to 2 more weeks to allow for hematologic recovery. When therapy is restarted, reduce dose for that cycle to 11 mg/M² every 8 hours (33 mg/M²/day, 99 mg/M²/cycle). In subsequent cycles, maintain or increase dose based on hematologic recovery.

DILUTION

Specific techniques required; see [Precautions](#). Reconstitute a single vial (50 mg) with 10 mL SWFI (each mL contains 5 mg of decitabine at a pH of 6.7 to 7.3). Further dilute immediately with NS, D5W, or LR to a final concentration of 0.1 to 1 mg/mL (further dilute each mL with 4 mL additional diluent for a 1 mg/mL concentration or 49 mL for a 0.1 mg/mL concentration). Must be used within 15 minutes of reconstitution. If decitabine will not be used within 15 minutes of reconstitution, it must be diluted using cold (2° C to 8° C) infusion fluids and stored at 2° C to 8° C (36° F to 46° F) for up to a maximum of 7 hours.

Filters: Specific information not available.

Storage: Store unopened vials at 25° C (77° F); excursions permitted to 15° to 30° C (59° to 86° F). Use of reconstituted and/or diluted solution within 15 minutes of reconstitution is preferred or a specific process is required; see [Dilution](#).

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Option 1: A single dose as an infusion equally distributed over 3 hours.

Option 2: A single dose as an infusion equally distributed over 1 hour.

ACTIONS

A hypomethylating antineoplastic agent. Cytotoxic to proliferating cells through a process that incorporates it into DNA, inhibits the enzyme DNA methyltransferase, and causes hypomethylation of DNA, leading to cell disintegration and/or death. This hypomethylation in neoplastic cells may restore normal function to genes that are critical for

the control of cellular differentiation and proliferation and allow the formation of normal RBCs and platelets. Patients with myelodysplastic syndromes who have responded to decitabine have become transfusion independent. Terminal half-life range is 0.21 to 0.82 hours. Extensively metabolized by an unknown route(s). Protein binding is negligible.

INDICATIONS AND USES

Treatment of patients with myelodysplastic syndromes (MDS), including previously treated and untreated *de novo* and secondary MDS of all French-American-British subtypes (refractory anemia, refractory anemia with ringed sideroblasts, refractory anemia with excess blasts, refractory anemia with excess blasts in transformation, and chronic myelomonocytic leukemia) and intermediate-1, intermediate-2, and high-risk International Prognostic Scoring System groups.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ The effects of age, gender, race, or renal or hepatic impairment on the pharmacokinetics of decitabine have not been studied. ■ Myelosuppression and worsening neutropenia may occur more frequently in the first or second treatment cycles and may not indicate progression of underlying MDS. Neutropenia and thrombocytopenia may be dose-limiting toxicities. ■ Patients with MDS produce poorly functioning and immature blood cells and experience anemia, bleeding, fatigue, infection, and weakness. High-risk MDS patients may experience bone marrow failure, which may lead to death from bleeding and infection. ■ MDS can progress to acute leukemia (AML). ■ Use caution in patients with renal or hepatic impairment. Use has not been studied.

Monitor: Obtain a baseline CBC with platelets and monitor before each dosing cycle and as indicated between cycles. ■ Consider early institution of growth factors as indicated. ■ Obtain a baseline and monitor renal and hepatic function (BUN, SCr, bilirubin) as indicated. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Monitor for S/S of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Avoid administration of live virus vaccine to immunocompromised patients. ■ Observe for S/S of a hypersensitivity reaction; specific information not available. ■ See [Precautions and Antidote](#).

Patient Education: Avoid pregnancy; nonhormonal birth control recommended for both males and females; see [Maternal/Child](#). Women should report a suspected pregnancy immediately. ■ Discuss possible liver or kidney disease with a health care professional. ■ Report S/S of infection (e.g., fever, sore throat), bruising, bleeding, or other suspected side effects.

Maternal/Child: Category D: avoid pregnancy; may cause fetal harm. Females should use birth control until at least 1 month after treatment with decitabine is discontinued. Males should not father a child until at least 2 months after treatment with decitabine is discontinued. ■ Discontinue breast-feeding; has potential for serious harm to nursing infants. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: The majority of patients in clinical trials were over 65 years of age. Safety and effectiveness similar to younger adults; however, greater sensitivity of some older individuals should be considered.

DRUG/LAB INTERACTIONS

Formal drug interactions studies have not been completed. In vitro studies suggest that decitabine is unlikely to inhibit or induce the activities of human hepatic cytochrome P₄₅₀ isoenzymes. ■ Plasma protein binding is negligible; interactions due to displacement of

more highly protein bound drugs from plasma proteins are not expected. ■ Do not administer **live virus vaccines** to immunocompromised patients who are receiving antineoplastic agents.

SIDE EFFECTS

Cough, constipation, diarrhea, fatigue, fever, hyperglycemia, nausea, and petechiae have been reported most commonly. Bone marrow suppression (anemia, neutropenia, thrombocytopenia) was the most frequent cause of dose reduction, delay, and discontinuation. Grade 3 or 4 adverse events included febrile neutropenia, leukopenia, neutropenia, and thrombocytopenia. During clinical trials, therapy was also discontinued because of abnormal liver function tests, cardiopulmonary arrest, intracranial hemorrhage, *Mycobacterium avium* complex infection, and pneumonia. Atrial fibrillation, central line infection, febrile neutropenia, neutropenia, and pulmonary edema also resulted in delayed doses; bone marrow suppression (anemia, neutropenia, thrombocytopenia), depression, edema, lethargy, pharyngitis, and tachycardia resulted in reduced doses. Numerous other side effects may occur.

Post-Marketing: Acute febrile neutrophilic dermatosis (Sweet's syndrome) has been reported.

Overdose: Increased myelosuppression, including prolonged neutropenia and thrombocytopenia.

ANTIDOTE

Notify physician of any side effects. Most will be treated symptomatically. Dosage may be delayed for hematologic toxicity. Hematologic recovery to at least an ANC equal to or greater than 1,000 cells/mm³ and platelets equal to or greater than 50,000 cells/mm³ between cycles is required; see **Dose Adjustments**. If a SCr equal to or greater than 2 mg/dL, an ALT or a total bilirubin equal to or greater than 2 times the ULN, and/or an uncontrolled infection occur, discontinue decitabine therapy until the toxicity is resolved. Blood and blood products, antibiotics, and other adjunctive therapies must be available. Blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. No known antidote; provide supportive care in overdose. ■ Resuscitate as necessary.

DEFEROXAMINE MESYLATE

(deh-fer-**OX**-ah-meen **MES**-ih-layt)

Desferal

Antidote
Chelating agent

pH 4 to 6

USUAL DOSE

Acute iron intoxication in adults and pediatric patients over 3 years of age: IM use preferred for all patients not in shock; see [Precautions](#). Administer an initial dose of 1,000 mg at a rate not to exceed 15 mg/kg/hr. May be followed with 500 mg every 4 hours for 2 doses at a rate not to exceed 125 mg/hr (adults) or 15 mg/kg/hr (pediatric patients). Depending on clinical response, subsequent doses of 500 mg every 4 to 12 hours may be administered. **Do not exceed 6 Gm in 24 hours by way of any or all routes—IV, IM, clysis, or oral.** As soon as clinical condition permits, IV route should be changed to IM.

Chronic iron overload in adults: 40 to 50 mg/kg/day over 8 to 12 hours for 5 to 7 days per week. Average dose should not exceed 60 mg/kg/day. Alternately, 500 to 1,000 mg daily may be given as an IM injection. In poorly compliant patients, deferoxamine may be administered *before or following* same-day blood transfusion (e.g., 1,000 mg over 4 hours on the day of transfusion); however, the contribution to iron balance is limited. Should not be administered concurrently with blood to avoid confusion about the source of side effects (e.g., anaphylaxis, hypotension, rash).

Aluminum toxicity (unlabeled): Dose must be individualized. One source recommends 5 to 10 mg/kg 4 to 6 hours before dialysis. May repeat every 7 to 10 days as needed. 100 mg can bind 4.1 mg of aluminum.

PEDIATRIC DOSE

Acute iron intoxication in pediatric patients over 3 years of age: See [Usual Dose](#). **Do not exceed a rate of 15 mg/kg/hr or a total dose of 6 Gm in 24 hours.**

Chronic iron overload: 20 to 40 mg/kg/day over 8 to 12 hours for 5 to 7 days per week. Average dose should not exceed 40 mg/kg/day until growth has ceased. **Do not exceed a rate of 15 mg/kg/hr or a total dose of 6 Gm in 24 hours.**

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Each 500 mg must be reconstituted in 5 mL of SWFI. When completely dissolved, deferoxamine must be further diluted in an IV solution; $\frac{1}{2}$ NS, NS, D5W, D10W, and LR are **compatible**. Dissolve completely before use.

Storage: Store unopened vial at room temperature. Reconstituted solution may be stored at room temperature for 24 hours if it has been prepared in a sterile laminar flow hood. Do not refrigerate reconstituted solution. Single-dose vial. Discard unused portion of vial.

COMPATIBILITY

Manufacturer states, "Reconstituting in solvents or under conditions other than indicated may result in precipitation. Turbid solutions should not be used."

RATE OF ADMINISTRATION

Initial 1,000 mg may be administered at a rate not to exceed 15 mg/kg/hr. Follow with 500 mg over 4 hours for 2 doses. Depending on clinical response, subsequent 500-mg doses may be given over 4 to 12 hours. In these subsequent doses, do not exceed a rate of 125 mg/hr (adults) or 15 mg/kg/hr (pediatric patients); see [Precautions](#), [Side Effects](#), [Overdose](#).

ACTIONS

A heavy metal antagonist that chelates iron and aluminum. As an iron-chelating agent, deferoxamine complexes with iron to form ferrioxamine, a stable chelate that prevents the iron from entering into further chemical reactions. Chelates iron from ferritin and

hemosiderin but not readily from transferrin, hemoglobin, or cytochromes. 1 Gm of deferoxamine can theoretically sequester 85 mg of iron (as the ferric ion); however, the rate of complex formation is pH dependent. Metabolized by plasma enzymes via unknown pathways. Chelate is readily soluble in water and passes easily through the kidneys, giving the urine a characteristic reddish color. Also excreted in feces through the bile.

INDICATIONS AND USES

To facilitate the removal of iron in the treatment of acute iron intoxication. Is an adjunct to, not a substitute for, standard measures used to treat acute iron intoxication. Such measures may include induction of emesis and/or gastric lavage; suction and maintenance of a clear airway; control of shock with IV fluids, blood, oxygen, and vasopressors; and correction of acidosis. ■ Treatment of chronic iron overload due to transfusion-dependent anemias.

Limitation of use: Not indicated for primary hemochromatosis; phlebotomy is the method of choice for removing excess iron in the blood.

Unlabeled uses: Diagnosis and management of aluminum toxicity associated with chronic kidney disease (CKD).

CONTRAINDICATIONS

Severe renal disease or anuria. ■ Hypersensitivity to deferoxamine.

PRECAUTIONS

IM administration is preferred and should be used for all patients not in shock. May be given SC by hypodermoclysis. IV administration should be used only in a state of cardiovascular shock or chronic iron overload and then only by slow IV infusion. Flushing, urticaria, hypotension, and shock have occurred with rapid infusion. ■ Ocular and auditory disturbances have been reported with high doses, in patients with low ferritin levels, or when the drug is administered over a prolonged period of time. Disturbances may be reversible with early detection and immediate cessation of therapy. ■ Increases in SCr, renal tubular disorders, and acute renal failure have been reported. ■ High doses in patients with concomitant low ferritin levels have been associated with growth retardation. Growth velocity may partially resume to pretreatment rates with dose reduction; see [Maternal/Child](#). ■ Acute respiratory distress syndrome (ARDS) has been reported following treatment with excessively high intravenous doses in patients with acute iron intoxication or thalassemia. ■ Rare cases of mucormycosis (some fatal) and generalized infections with *Yersinia enterocolitica* and *Yersinia pseudotuberculosis* have been reported. Discontinue therapy, obtain cultures, and institute proper therapy at first sign of infection. ■ Impairment of cardiac function has been reported following concomitant treatment with deferoxamine and vitamin C (more than 500 mg daily). However, patients with chronic iron overload may become vitamin C deficient. Cautious vitamin C supplementation may be required. Begin supplementation only after initial month of deferoxamine therapy. Limit daily dose to 200 mg given in divided doses. Avoid concomitant use of vitamin C and deferoxamine in patients with pre-existing cardiac failure. ■ Treatment with deferoxamine in the presence of aluminum overload may result in decreased serum calcium and aggravation of hyperparathyroidism. In patients with aluminum-related encephalopathy who are undergoing dialysis, deferoxamine may cause neurologic dysfunction (seizures). May precipitate onset of dialysis dementia. ■ Studies have not been performed in patients with impaired hepatic function. ■ See [Drug/Lab Interactions](#).

Monitor: Deferoxamine is adjunctive therapy; see [Precautions](#) for standard measures for treating acute iron intoxication. ■ Monitor for development of ocular disturbances. May include blurred vision; development of cataracts after prolonged administration in chronic iron overload; decreased visual acuity (including vision loss; vision defects; scotoma; impaired peripheral, color, and night vision; optic neuritis; cataracts; corneal opacities; and retinal pigmentary abnormalities). Periodic visual acuity tests, slit-lamp examinations, and funduscopy are recommended with prolonged therapy. ■ Monitor for development of auditory disturbances. May include tinnitus and hearing loss, including high-frequency sensorineural hearing loss. Periodic audiometry is recommended with prolonged therapy. ■ Monitor cardiac function in patients receiving concomitant therapy

with vitamin C and deferoxamine. Cardiac dysfunction may be reversible with discontinuation of vitamin C. ■ Monitor serum ferritin and serum iron. ■ In acute iron intoxication, larger-than-normal amounts of IV fluids are required to maintain intravascular volume and prevent kidney damage. Monitor renal function. ■ Monitor blood gases, central venous pressure (CVP), and cardiac output as indicated to assess the effects of absorbed iron.

Patient Education: Report any hearing or vision changes. ■ Do not take vitamin C unless prescribed by physician. ■ Do not drive or operate hazardous machinery if dizziness, visual or auditory impairment, or other nervous system disturbances are experienced. ■ May cause reddish discoloration of urine.

Maternal/Child: Category C: use only if potential benefit justifies potential risk to fetus. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 3 years of age not established. ■ Monitor body weight and growth every 3 months in pediatric patients; see [Precautions](#). ■ Supplementation may be required in pediatric patients who become vitamin C deficient. In general, 50 mg daily is sufficient for pediatric patients under 10 years of age. 100 mg is sufficient in older pediatric patients; see [Precautions](#) and [Drug/Lab Interactions](#).

Elderly: See [Dose Adjustments](#) and [Drug/Lab Interactions](#). ■ Risk of cardiac decompensation increased. ■ Post-marketing reports suggest a possible increased risk of eye disorders (color blindness, maculopathy, and scotoma) and an increased risk of hearing loss or deafness.

DRUG/LAB INTERACTIONS

Risk of cardiac decompensation is increased when given concurrently with large doses (greater than 200 mg) of **vitamin C** (ascorbic acid). However, vitamin C increases the availability of iron for chelation. Small doses of a vitamin C supplement may be required. ■ Concurrent treatment with **prochlorperazine** (Compazine) may lead to a temporary impairment in consciousness. ■ Discontinue deferoxamine 48 hours before **scintigraphy with gallium-67**. Imaging results may be distorted because of rapid urinary excretion of deferoxamine-bound gallium-67.

SIDE EFFECTS

Occur more frequently with too-rapid administration; abdominal discomfort, acute respiratory distress syndrome (ARDS), arthralgia, diarrhea, dysuria, fever, flushing of the skin, growth retardation and bone changes, headache, high-frequency sensorineural hearing loss and/or tinnitus, hypersensitivity reactions (anaphylaxis, angioedema, generalized rash, urticaria), hypotension, impaired hepatic and/or renal function, increased ALT and AST, infection (mucormycosis, *Yersinia*), injection site reactions, muscle spasms, myalgia, nausea, neurologic disturbances (dizziness; peripheral sensory, motor, or mixed neuropathy; paresthesias; exacerbation or precipitation of aluminum-related dialysis encephalopathy), seizures, shock, tachycardia, visual disturbances (blurred vision, decreased acuity or loss of vision, retinopathy, scotoma, and others). Blood dyscrasias (e.g., leukopenia, thrombocytopenia) have been reported. See [Precautions](#).

Post-Marketing: Increased SCr, acute renal failure, and renal tubular disorders.

Overdose: Acute transient loss of vision, acute renal failure, agitation, aphasia, bradycardia, CNS depression including coma, headache, hypotension, GI disturbances, nausea, and tachycardia may occur with too rapid administration, inadvertent IV bolus, or overdose.

Post-Marketing: Renal dysfunction (e.g., increased SCr, renal tubular disorders, acute renal failure).

ANTIDOTE

At first sign of side effects, decrease rate of administration. If side effects persist, discontinue drug and notify physician. Further dilution and decrease in rate of administration may be necessary. Readily dialyzable. Resuscitate as indicated.

DENILEUKIN DIFTITOX **BBW**(den-ih-**LOO**-kin **DIF**-tih-tox)**Antineoplastic**
Biological response modifier**Ontak****pH 6.9 to 7.2****USUAL DOSE**Pretesting indicated; see **Monitor**.**Premedication:** Premedicate with an antihistamine (e.g., diphenhydramine [Benadryl]) and acetaminophen (Tylenol) before each infusion.**Denileukin diftiox:** 9 or 18 mcg/kg/day administered as an IV infusion for 5 consecutive days. Repeat course every 21 days for 8 cycles.**DOSE ADJUSTMENTS**In patients with hypoalbuminemia, administration of denileukin diftiox should be delayed until serum albumin levels are at least 3 Gm/dL; see **Monitor**.**DILUTION**

Each 2-mL vial contains 300 mcg (150 mcg/mL) of frozen recombinant denileukin diftiox. Thaw in refrigerator (2° to 8° C) for not more than 24 hours or at CRT for 1 to 2 hours. Bring to CRT before preparing dose. Do not heat. Gently swirl contents of vial. Do not shake. Solution may be hazy initially. Haze should clear as solution reaches CRT. The concentration of denileukin diftiox must be at least 15 mcg/mL during all steps in the preparation of the infusion solution. This is best accomplished by aseptically withdrawing the calculated dose of denileukin diftiox and injecting it into an empty infusion bag. For each 1 mL of denileukin diftiox from the vial(s), no more than 9 mL of sterile NS without preservative should then be added to the bag. For example: A 70-kg patient receiving a 9-mcg/kg dose would require 630 mcg of denileukin diftiox (or 4.2 mL). Withdraw 4.2 mL of denileukin diftiox from vials and inject into an empty infusion bag. Add no more than 37.8 mL (9×4.2 mL) of preservative-free NS to infusion bag. The final solution will be 630 mcg in 42 mL of solution, which equals the desired concentration of 15 mcg/mL. Diluted denileukin diftiox must be prepared and stored in a plastic syringe or soft plastic IV infusion bag. Do not use a glass container; see **Compatibility**.

Filters: Manufacturer states, "Do not administer through an in-line filter."**Storage:** Store unopened vials in freezer at or below -10° C (14° F). Prepared solutions should be administered within 6 hours. Discard unused solution. Do not refreeze.**COMPATIBILITY**

Manufacturer states, "Do not physically mix denileukin diftiox with other drugs." Do not mix in glass. Adsorption to glass may occur in the dilute state.

RATE OF ADMINISTRATION

A single dose evenly distributed over 30 to 60 minutes. Administer via peripheral or central vein by a pump device or IV infusion bag. Do not administer as a bolus injection. Do not administer through an in-line filter. If adverse reactions occur during the infusion, the infusion should be discontinued or the rate should be reduced depending on the severity of the reaction. There is no clinical experience with infusion times lasting more than 80 minutes.

ACTIONS

A recombinant DNA-derived cytotoxic protein. A fusion protein that utilizes both the cytotoxic action of diphtheria toxin and the cell-targeting ability of human interleukin-2 (IL-2) to kill certain leukemia and lymphoma cells. Targets specific receptors (IL-2 receptors) on malignant cells while minimizing damage to normal cells that do not express the receptor. Ex vivo studies suggest that denileukin diftiox interacts with the high-affinity IL-2 receptor on the cell surface and inhibits cellular protein synthesis, resulting in cell death within hours. No differences in pharmacologic action noted based on age,

gender, and/or race. Half-life in lymphoma patients is 70 to 80 minutes. Development of antibodies to denileukin diftitox has been shown to increase clearance; see [Precautions](#).

INDICATIONS AND USES

Treatment of patients with persistent or recurrent cutaneous T-cell lymphoma whose malignant cells express the CD25 component of the IL-2 receptor. The safety and efficacy of denileukin diftitox in patients with CTCL whose malignant cells do not express the CD25 component of the IL-2 receptor have not been examined.

CONTRAINDICATIONS

Hypersensitivity to denileukin diftitox, any of its components, diphtheria toxin, or interleukin-2.

PRECAUTIONS

Administered under the supervision of a physician experienced in the use of antineoplastic therapy and the management of patients with cancer. ■ Administer in a facility equipped and staffed for cardiopulmonary resuscitation and in which the patient can be properly monitored. ■ Infusion and/or hypersensitivity reactions, defined as symptoms occurring within 24 hours of infusion and resolving within 48 hours of the last infusion in that course, have been reported and may be serious or life threatening. Deaths have occurred. Incidence of infusion reactions appears to decrease after the first 2 courses of therapy. ■ Capillary leak syndrome (CLS) has resulted in death. CLS characterized by at least two of the following three symptoms (edema, hypoalbuminemia [3 Gm/dL or less], hypotension), has been reported. Symptoms are not required to occur simultaneously to be described as capillary leak syndrome. Onset can occur at any time. Usually occurs within 2 weeks of the infusion but may be delayed. Patients with edema or pre-existing low serum albumin levels may be predisposed to this syndrome. Symptoms may persist or worsen after denileukin diftitox is discontinued; treatment and/or hospitalization may be required; deaths have been reported. Use special caution in patients with pre-existing cardiovascular disease. ■ A significant percentage of patients treated with denileukin diftitox tested positive for antibodies at baseline, probably due to a prior exposure to diphtheria toxin or its vaccine. With each subsequent course, the percent of patients who tested positive increased, C_{max} and AUC decreased, and clearance increased with increasing antibody formation. The formation of neutralizing antibodies was assessed in a number of patients. Evidence of inhibited functional activity in the cellular assay was seen. ■ Loss of visual acuity (usually with loss of color vision, with or without retinal pigment mottling) has been reported. Some patients recover; however, most report persistent visual impairment.

Monitor: Before administration of denileukin diftitox, the patient's malignant cells should be tested for CD25 expression. A testing service for the assay of CD25 on skin biopsy samples is available; see manufacturer's prescribing information. ■ Consider baseline and periodic monitoring of CBC and a blood chemistry panel, including liver and renal function, before therapy and weekly during therapy. ■ Monitor serum albumin levels before each course of therapy. Nadir occurs 1 to 2 weeks after administration. Delay administration if necessary until serum albumin levels are at least 3 Gm/dL. Note Dose Adjustments. ■ Observe for capillary leak syndrome. Monitor weight, edema, BP, and serum albumin levels on an outpatient basis. ■ Monitor for signs and symptoms of infection. Patients with CTCL have a predisposition to cutaneous infections, and binding of denileukin diftitox to activated lymphocytes and macrophages may lead to cell death and may impair patient's immune system. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor injection site. To minimize occurrence or phlebitis, change the injection site frequently. ■ See [Precautions](#), [Side Effects](#), and [Antidote](#).

Patient Education: Promptly report orthostatic hypotension (dizziness), weight gain, or edema following infusion. ■ Weigh self daily. ■ Report breathing problems, chest pain, chills, fever, tachycardia, and/or urticaria following infusion. ■ Report vision changes. ■ Keep physician informed of all side effects.

Maternal/Child: Safety for use in pregnancy not established. Use only if clearly needed. ■ Discontinue breast-feeding. ■ Safety and effectiveness in pediatric patients not established.

Elderly: Numbers in clinical studies insufficient to determine if the elderly respond differently than do younger adults.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been conducted.

SIDE EFFECTS

All patients experienced at least one adverse event. The occurrence of side effects tended to diminish in frequency and severity after the first two courses of therapy. ■ The most common side effects were cough, diarrhea, dyspnea, edema, fatigue, fever, headache, nausea, peripheral edema, pruritus, and rigors. The most common serious side effects were capillary leak syndrome, infusion reactions, and vision changes, including loss of visual acuity. During initial studies the most common reasons for discontinuation of therapy were systemic flu-like symptoms (e.g., anorexia, asthenia, chills, fever, malaise, nausea, and vomiting), hypoalbuminemia, infection, rash, respiratory events (e.g., dyspnea, apnea, pulmonary edema, or pneumonia), and capillary leak syndrome. The most common reasons for therapy-related hospitalization were evaluation of fever, management of capillary leak syndrome, or dehydration secondary to gastrointestinal toxicity. ■ Other reported side effects include anorexia, arthralgia, asthenia, back pain, chest pain, dizziness, dysgeusia, hypotension, myalgia, pain, rash, upper respiratory tract infection, and vomiting.

Post-Marketing: Hyperthyroidism, hypothyroidism, thyroiditis, thyrotoxicosis, visual acuity loss.

ANTIDOTE

Notify physician of any side effects. If adverse reactions occur during administration, the infusion should be discontinued or the rate should be reduced depending on the severity of the reaction. If a serious infusion reaction occurs, immediately stop and permanently discontinue denileukin diftiox. IV antihistamines, corticosteroids, and/or epinephrine may be required. Most symptoms of the flu-like syndrome will respond to treatment with antipyretics and/or antiemetics (e.g., promethazine [Phenergan] or prochlorperazine [Compazine]). Pre-medication with acetaminophen and an antihistamine 30 to 60 minutes before each infusion may help reduce the frequency and/or severity of symptoms. While on therapy, patients may continue to receive acetaminophen every 4 to 6 hours while awake. Fever, chills, and/or pain not controlled with acetaminophen alone may be treated with an NSAID. Rigors may be treated with meperidine. Skin rashes may require treatment with topical and/or oral corticosteroids. Treatment of capillary leak syndrome depends on whether edema or hypotension is the primary clinical problem. Patients who present with dehydration should be considered for IV fluid replacement therapy. If BP is still not adequate after replacement therapy, pressor agents (e.g., dopamine) should be considered. Use of diuretics should be avoided in patients whose intravascular depletion has not been corrected. However, patients who present primarily with edema may benefit from diuretic therapy. Continuous monitoring of fluid status, weight, and BP is essential. If overdose occurs, hepatic and renal function and overall fluid status should be closely monitored. Resuscitate as necessary.

DESMOPRESSIN ACETATE

(des-moh-PRESS-in AS-ah-tayt)

Hormone
Antidiuretic
Antihemorrhagic

DDAVP, 1-Deamino-8-D-Arginine Vasopressin

pH 3.5 to 4

USUAL DOSE

Diabetes insipidus: 2 to 4 mcg daily in 2 divided doses. Adjust each dose individually for an adequate diurnal rhythm of water turnover. IV dose has 10 times the antidiuretic effect of intranasal desmopressin. Available as a tablet to manage cranial central diabetes insipidus.

Hemophilia A and von Willebrand's disease (type 1): 0.3 mcg/kg of body weight. Administer 30 minutes preoperatively.

DOSE ADJUSTMENTS

Many specific requirements depending on diagnosis; see [Precautions](#), [Monitor](#). ■ Dosing should be cautious in the elderly. Consider potential for decreased organ function and concomitant disease or drug therapy. See [Elderly](#) and [Contraindications](#). ■ Reduce dose accordingly when transferring from intranasal to IV administration.

DILUTION

Diabetes insipidus: May be given undiluted.

Hemophilia A and von Willebrand's disease (type 1): Dilute a single dose in 10 mL of NS for pediatric patients under 10 kg; 50 mL for adults and pediatric patients over 10 kg. Must be given as an infusion.

Storage: Refrigerate at 2° to 8° C (36° to 46° F). Use diluted product promptly.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Diabetes insipidus: A single dose by IV injection over 1 minute.

Hemophilia A and von Willebrand's disease (type 1): A single dose as an infusion over 15 to 30 minutes.

ACTIONS

A synthetic analog of the natural hormone arginine vasopressin (human antidiuretic hormone—ADH). It is more potent than arginine vasopressin in increasing plasma levels of factor VIII activity in patients with hemophilia A and von Willebrand's disease (Type 1). Produces dose-related increase in factor VIII levels within 30 minutes and peaks in 90 to 120 minutes. Duration of anti-hemorrhagic action is 4 to 24 hours in mild hemophilia A and 3 hours in von Willebrand's disease. Onset of action as an antidiuretic is prompt. Half-life is biphasic (7.8 minutes for fast phase and 75.5 minutes for slow phase). Increases water resorption in the kidney, increases urine osmolality, and decreases urine output. Clinically effective antidiuretic doses are usually below the levels needed to affect vascular or visceral smooth muscle. Excreted in urine.

INDICATIONS AND USES

Antidiuretic replacement therapy in the management of central (cranial) diabetes insipidus. ■ Management of the temporary polyuria and polydipsia following head trauma or surgery in the pituitary region. ■ Maintenance of hemostasis in patients with hemophilia A or von Willebrand's disease during surgical procedures and postoperatively. ■ To stop bleeding in patients with hemophilia A or von Willebrand's disease with episodes of spontaneous or trauma-induced injuries.

CONTRAINDICATIONS

Infants under 3 months in hemophilia A or von Willebrand's disease, known hypersensitivity to desmopressin, patients with moderate to severe renal impairment (CrCl less than 50 mL/min), and patients with hyponatremia or a history of hyponatremia.

PRECAUTIONS

Use caution in patients with coronary artery insufficiency or hypertension. ■ When administered to patients who do not have a need for the antidiuretic effect, fluid intake should be adjusted downward to decrease the potential occurrence of water intoxication and hyponatremia. S/S may include headache, nausea and vomiting, decreased serum sodium, weight gain, restlessness, fatigue, lethargy, disorientation, depressed reflexes, loss of appetite, irritability, muscle weakness, muscle spasms, and abnormal mental status (e.g., confusion, decreased consciousness, hallucinations). Pediatric and elderly patients may be at increased risk. ■ Use with caution in patients with habitual or psychogenic polydipsia. May be more likely to drink excessive amounts of water, increasing their risk of hyponatremia. ■ Excessive fluid intake may result in an extreme decrease in plasma osmolality. May lead to seizures, coma, and respiratory arrest. ■ Use with caution in patients predisposed to thrombus formation. ■ Use with caution in patients with conditions associated with fluid and electrolyte imbalance (e.g., cystic fibrosis, CHF, renal disorders). ■ Severe hypersensitivity reactions, including anaphylaxis, have been reported. ■ See [Drug Interactions](#).

Monitor: Diabetes insipidus: Not effective for the treatment of nephrogenic diabetes insipidus. ■ Confirm diagnosis of diabetes insipidus by the water deprivation test, the hypertonic saline infusion test, and the response to ADH. ■ Monitor continued response by measuring urine volume and osmolality. ■ Plasma osmolality may be needed. Monitor serum electrolytes in therapy lasting longer than 7 days. ■ Accuracy and effectiveness of dose measured by duration of sleep and adequate, not excessive, water turnover.

Hemophilia A: May be considered for use in patients with factor VIII activity levels from 2% to 5% with careful monitoring. Generally used only when the factor VIII activity level is above 5%. ■ Not indicated in patients with hemophilia B or those with factor VIII antibodies. ■ Monitor factor VIII coagulant, factor VIII antigen, factor VIII ristocetin cofactor, and aPTT.

von Willebrand's disease (type 1): Most effective when factor VIII activity level above 5%. ■ Monitor bleeding time, factor VIII activity levels, ristocetin cofactor activity, and von Willebrand factor antigen during therapy to ensure adequate levels. ■ Not indicated for treatment of severe classic von Willebrand's disease (Type 1), Type IIB von Willebrand's disease (will induce platelet aggregation), or if there is evidence of an abnormal molecular form of factor VIII antigen.

Hemophilia and von Willebrand's disease: Sometimes used with aminocaproic acid. ■ Monitor BP and pulse during infusion. ■ Determine need for repeat administration of desmopressin or use of blood products by laboratory response as well as the clinical condition of the patient. Tachyphylaxis (lessening of response; i.e., a gradual diminution of the factor VIII activity increase) has been seen when given more frequently than every 48 hours.

Patient Education: When antidiuretic effect is not needed, caution patients (especially the young and the elderly) to limit fluid intake to satisfy thirst needs only; this decreases potential occurrence of water intoxication and hyponatremia.

Maternal/Child: Category B: use only when clearly indicated in pregnancy and breastfeeding. ■ Risk of hyponatremia and water intoxication increased in pediatric patients. Restrict fluid intake. ■ Safety for use in pediatric patients under 12 years of age with diabetes insipidus not established. ■ See [Contraindications](#).

Elderly: Risk of hyponatremia and water intoxication increased. Use caution and careful fluid intake restriction. ■ Response similar to that seen in younger adults. Dosing should be cautious in the elderly. Monitor renal function; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

May produce hypertension with other **vasopressors** (e.g., dopamine). ■ Antidiuretic effect may be potentiated by **chlorpropamide** (Diabinese) or **carbamazepine** (Tegretol). ■ Use caution when administered concurrently with other medications that can increase the risk of water intoxication with hyponatremia (e.g., **carbamazepine** [Tegretol], **chlorpromazine** [Thorazine], **lamotrigine** [Lamictal], **NSAIDs** [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], **opiate analgesics**, **selective serotonin reuptake inhibitors** [e.g., sertraline (Zoloft)], **tricyclic antidepressants** [e.g., imipramine (Tofranil)]). ■ Desmopressin may increase the levels and/or effects of **lithium**. **Lithium** may decrease the levels and/or effects of desmopressin. ■ Hyponatremic convulsions have been reported with concomitant use with **oxybutynin** (Ditropan) and **imipramine** (Tofranil-PM).

SIDE EFFECTS

Are infrequent. High doses may produce facial flushing, headache, hypertension (slight), hypotension with a compensatory tachycardia, mild abdominal cramps, nausea, thrombotic events (cerebrovascular thrombosis, MI), and vulval pain. May cause burning, local erythema, and swelling at site of injection; hyponatremia with resultant sequelae (see [Precautions](#)); and water intoxication. Anaphylaxis has been reported.

ANTIDOTE

Notify physician of all side effects. Most will respond to reduction of dose or rate of administration, or symptomatic treatment. May need to discontinue drug. Resuscitate as necessary.

DEXAMETHASONE SODIUM PHOSPHATE

(dex-ah-METH-ah-zohn SO-dee-um FOS-fayt)

Hormone (corticosteroid)
Anti-inflammatory
Antiemetic
Immunosuppressant
Diagnostic agent

Decadron, Decadron Phosphate

pH 7 to 8.5

USUAL DOSE

Average dose range is 0.5 to 24 mg daily. May be divided into 2 to 4 doses. IV dexamethasone is usually given in an emergency situation or when oral dosing is not feasible. Larger doses may be justified by patient condition. Repeat until adequate response, then decrease dose as indicated. Total dose usually does not exceed 80 mg/24 hr. Dosage must be individualized. High-dose treatment is utilized until patient condition stabilizes, usually no longer than 48 to 72 hours. Doses similar by IV or oral route.

Anti-inflammatory: See average dose range above.

Shock: Several regimens have been suggested:

1 to 6 mg/kg as a single injection; *or*

40 mg. Repeat every 2 to 6 hours as needed; *or*

20 mg as a **loading dose**, followed by a continuous infusion of 3 mg/kg equally distributed over 24 hours.

Cerebral edema: Loading dose: 10 mg. **Maintenance dose:** 4 mg every 6 hours (usually given IM). Reduce dose after 2 to 4 days. Discontinue gradually over 5 to 7 days. A brain tumor requiring treatment before dexamethasone can be discontinued is the exception.

Cerebral edema (ICP) in recurrent or inoperable brain tumors: 2 mg every 8 to 12 hours (usually given IM). Adjust based on patient response.

Antiemetic in management of emesis-inducing chemotherapy: Several regimens have been used:

10 to 20 mg before chemotherapy. Lower doses may be given over the next 24 to 72 hours if necessary; *or*

Give a loading dose of 4 to 8 mg/M². May repeat 2 to 4 mg/M² every 6 hours; *or*

20 mg combined with 8 mg of ondansetron (Zofran) in 50 mL D5W before chemotherapy; *or*

20 mg 40 minutes before administration of chemotherapeutic agent. Given concurrently with metoclopramide and lorazepam or diphenhydramine; *or*

10 mg 30 minutes before administration of chemotherapeutic agent. Given concurrently with oral dexamethasone 8 mg beginning prior evening, 4 mg every 4 to 6 hours continuing through treatment day, with droperidol or haloperidol.

Airway edema: Adult and pediatric patients: 0.5 to 2 mg/kg/24 hr in equally divided doses every 6 hours (0.125 to 0.5 mg/kg every 6 hours) for croup or beginning 24 hours before elective extubation. Repeat for 4 to 6 doses. Up to 1 mg/kg/24 hr may be given in divided doses before and after extubation.

Allergic conditions: (Usually given IM or PO) 4 to 8 mg on the first day, then PO in decreasing doses (1.5 mg every 12 hours on Days 2 and 3; 0.75 mg every 12 hours on Day 4; and 0.75 mg on Days 5 and 6).

Meningitis: Adult and pediatric patients: 0.15 mg/kg/dose every 6 hours for 4 days.

Primary or secondary adrenocortical insufficiency (physiologic replacement): 0.03 to 0.15 mg/kg/24 hr or 0.6 to 0.75 mg/M²/24 hr given in divided doses every 6 to 12 hours (0.015 to 0.075 mg/kg every 12 hours, or 0.0075 to 0.0375 mg/kg every 6 hours, or 0.3 to 0.375 mg/M² every 12 hours, or 0.15 to 0.1875 mg/M² every 6 hours). Usually given IM. Dexamethasone has minimal mineralocorticoid properties; may require a concomitant mineralocorticoid (e.g., hydrocortisone IV or PO). Hydrocortisone is the drug of choice for this indication.

PEDIATRIC DOSE

See **Maternal/Child**.

Cerebral edema: Loading dose: 1 to 2 mg/kg of body weight for 1 dose.

Maintenance dose: 1 to 1.5 mg/kg/24 hr in equally divided doses every 4 to 6 hours (0.17 to 0.25 mg/kg every 4 hours or 0.25 to 0.375 mg/kg every 6 hours) for 5 days, then gradually decrease. Maximum dose is 16 mg/24 hr.

Airway edema: See **Usual Dose**.

Antiemetic: Loading dose: 4 to 8 mg/M². May repeat 2 to 4 mg/M² every 6 hours.

Anti-inflammatory: 0.03 to 0.15 mg/kg/24 hr in equally divided doses every 6 to 12 hours (0.015 to 0.075 mg/kg every 12 hours or 0.0075 to 0.0375 mg/kg every 6 hours).

Meningitis: See **Usual Dose**.

DOSE ADJUSTMENTS

Reduced dose may be required in the elderly and with cyclophosphamide. ■ See **Drug/Lab Interactions**.

DILUTION

May be given undiluted or added to IV glucose or saline solutions and given as an infusion. 24 mg/mL product for IV use only; 4 mg/mL may be used IM/IV.

Storage: Use diluted solutions within 24 hours. Sensitive to heat. Protect from freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), aminophylline, bleomycin (Blenoxane), furosemide (Lasix), granisetron (Kytril), lidocaine, meropenem (Merrem IV), mitomycin (Mutamycin), nafcillin (Nallpen), ondansetron (Zofran), palonosetron (Aloxi), prochlorperazine (Compazine), ranitidine (Zantac), verapamil.

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), aztreonam (Azactam), bivalirudin (Angiomax), ceftaroline (Teflaro), cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), docetaxel (Taxotere), doripenem (Doribax), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fentanyl (Sublimaze), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), foscarnet (Foscavir), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), levofloxacin (Levaquin), linezolid (Zyvox), lorazepam (Ativan), melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), methadone (Dolophine), milrinone (Primacor), morphine, ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCI), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), sodium bicarbonate, tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepe, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose over 1 minute or less if necessary. As an IV infusion, give at prescribed rate.

ACTIONS

An anti-inflammatory glucocorticoid. A synthetic adrenocortical steroid with little sodium retention. Very soluble in water. Seven times as potent as prednisolone and 20 to 30 times as potent as hydrocortisone. Has minimal mineralocorticoid activity. Primarily used for anti-inflammatory and immunosuppressive effects. May be used in conjunction with other forms of therapy, such as epinephrine for acute hypersensitivity reactions or antibiotics for acute infections. Metabolized primarily in the liver and excreted as inactive metabolites in urine. Crosses the placental barrier. Excreted in urine and breast milk.

INDICATIONS AND USES

Supplementary therapy for severe allergic/hypersensitivity reactions. ■ Reduction of acute edematous states (cerebral edema, airway edema). ■ Shock unresponsive to con-

ventional therapy. ■ Acute exacerbations of disease for patients receiving steroid therapy. ■ Adrenocortical insufficiency; total, relative, and operative. ■ Antiemetic for chemotherapy-induced vomiting (e.g., cisplatin). Has numerous other uses by other routes of administration (e.g., IM, intra-articular, intralesional, intrasynovial, soft-tissue injection, oral inhalant).

Unlabeled uses: Adjunct to treatment of meningitis with antibiotics (to reduce incidence of ototoxicity). ■ Dexamethasone or betamethasone are given IM to the mother to accelerate the production of lung surfactant in utero in the prevention of respiratory distress syndrome of premature infants.

CONTRAINDICATIONS

Hypersensitivity to any product component including sulfites, cerebral malaria, systemic fungal infections.

Relative contraindications: Active or latent peptic ulcer, acute or healed tuberculosis, acute or chronic infections (especially chickenpox), acute psychoses, diabetes mellitus, diverticulitis, fresh intestinal anastomoses, myasthenia gravis, ocular herpes simplex, osteoporosis, pregnancy, psychotic tendencies, renal insufficiency, thromboembolic tendencies.

PRECAUTIONS

Withdrawal from therapy should be gradual to avoid precipitation of symptoms of adrenal insufficiency. The patient is observed, especially under stress, for up to 2 years. ■ Prophylactic antacids may prevent peptic ulcer complications. ■ Use with caution in hypothyroidism and cirrhosis.

Monitor: May increase insulin needs in diabetes. ■ Monitor electrolytes periodically. May cause sodium retention and potassium and calcium excretion. May cause hypertension secondary to fluid and electrolyte disturbances. ■ May mask signs of infection. ■ Administer a single dose before 9 AM to reduce suppression of individual's adrenocortical activity. ■ Periodic ophthalmic exams may be necessary with prolonged treatment. ■ See [Drug/Lab Interactions](#).

Patient Education: Report edema, tarry stools, or weight gain promptly. Anorexia, diarrhea, dizziness, fatigue, low blood sugar, nausea, weakness, weight loss, and vomiting promptly. May indicate adrenal insufficiency after dose reduction or discontinuing therapy; report any of these symptoms. ■ May mask signs of infection and/or decrease resistance. ■ Patients with diabetes may have an increased requirement for insulin or oral hypoglycemics. ■ Avoid immunization with live virus vaccines. ■ Carry ID stating steroid dependent if receiving prolonged therapy.

Maternal/Child: Category C: has caused birth defects; benefits must outweigh risks. ■ Observe newborn for hypoadrenalism if mother has received large doses. ■ Monitor growth and development of pediatric patients receiving prolonged treatment. ■ Use of a preservative-free solution recommended for neonates.

Elderly: Reduced muscle mass and plasma volume may necessitate a reduced dose. Monitor BP, blood glucose, and electrolytes carefully. ■ Increased risk of hypertension. ■ Higher risk of glucocorticoid-induced osteoporosis. ■ Avoid aluminum-based antacids (risk of Alzheimer's disease).

DRUG/LAB INTERACTIONS

Some sources list additional interactions; review drug profile with pharmacist.

Aminoglutethimide (Cytadren) and **mitotane** (Lysodren) suppress adrenal function and increase metabolism of dexamethasone two-fold. Not recommended for concurrent use, or dexamethasone dose may require doubling to be effective. Use of hydrocortisone suggested. ■ Metabolism increased and effects reduced by **hepatic enzyme-inducing agents** (e.g., alcohol, barbiturates [e.g., phenobarbital], hydantoins [e.g., phenytoin (Dilantin)], rifampin [Rifadin]); dose adjustments may be required when adding or deleting from drug profile. ■ Risk of hypokalemia increased with **amphotericin B** or **potassium-depleting diuretics** (e.g., thiazides, furosemide, ethacrynic acid). Monitor potassium levels and cardiac function. ■ Increased risk of **digoxin** toxicity secondary to hypokalemia. ■ May

also decrease effectiveness of **potassium supplements**; monitor serum potassium. ■ **Diuretics** decrease sodium and fluid retention effects of corticosteroids; corticosteroids decrease sodium excretion and diuretic effects of diuretics. ■ Clearance increased and effects decreased with **ephedrine**. ■ May antagonize effects of **anticholinesterases** (e.g., neostigmine), **isoniazid**, **salicylates**, and **somatrem**; dose adjustments may be required. ■ Clearance decreased and effects increased with **estrogens**, **oral contraceptives**, and **ketoconazole** (Nizoral). ■ May interact with **anticoagulants**, **nondepolarizing muscle relaxants** (e.g., atracurium [Tracrium]), or **theophyllines**; may inhibit or potentiate action; monitor carefully. ■ Monitor patients receiving **insulin or thyroid hormones** carefully; dose adjustments of either or both agents may be required. ■ Do not vaccinate with **attenuated virus vaccines** (e.g., smallpox) during therapy. ■ **Altered protein-binding capacity** will impact effectiveness of this drug. ■ **Smoking** may antagonize therapeutic effects. ■ See **Precautions**. ■ Decreases uptake of **radioactive material** in cerebral edema; will alter brain scan.

SIDE EFFECTS

Do occur but are usually reversible: burning, Cushing's syndrome, electrolyte imbalance, euphoria, glycosuria, headache, hyperglycemia, hypersensitivity reactions including anaphylaxis, hypertension, insomnia, menstrual irregularities, mood swings, peptic ulcer, perforation and hemorrhage, protein catabolism, sweating, thromboembolism, tingling, weakness, and many others.

ANTIDOTE

Notify the physician of any side effect. Treat side effects as indicated. Resuscitate as necessary for anaphylaxis and notify physician. Keep epinephrine immediately available.

DEXMEDETOMIDINE HYDROCHLORIDE

(dex-med-ih-TOM-ih-deen hy-droh-KLOR-eyed)

Alpha₂-adrenoceptor
agonist
Sedative-hypnotic

Precedex

pH 4.5 to 7.0

USUAL DOSE

Dosing should be individualized and titrated to desired clinical response.

ICU sedation: Loading dose: 1 mcg/kg as an infusion over 10 minutes. A loading dose may not be necessary in patients who are being converted from alternate sedative therapy. See [Dose Adjustments](#).

Maintenance infusion: 0.2 to 0.7 mcg/kg/hr. Adjust rate to achieve the desired level of sedation; see [Monitor](#). Dexmedetomidine is **not** indicated for infusions lasting longer than 24 hours. Has been infused in mechanically ventilated patients before, during, and after extubation provided the infusion does not exceed 24 hours. See [Dose Adjustments](#).

Procedural sedation: Loading dose for both adult and/or awake fiber optic intubation patients: 1 mcg/kg as an infusion over 10 minutes. For less invasive procedures (e.g., ophthalmic surgery), a loading dose of 0.5 mcg/kg as an infusion over 10 minutes may be sufficient. See [Dose Adjustments](#).

Maintenance infusion for adult patients: Begin with 0.6 mcg/kg/hr. Titrate to achieve desired level of sedation. Usual range is 0.2 to 1 mcg/kg/hr. See [Dose Adjustments](#).

Maintenance infusion for awake fiber optic intubation patients: A dose of 0.7 mcg/kg/hr is recommended until the endotracheal tube is secured, then titrate to achieve desired level of sedation as above. See [Dose Adjustments](#).

DOSE ADJUSTMENTS

Reduced doses may be required in patients with hepatic impairment and in the elderly. ■ For patients over 65 years of age, reduce the loading dose for procedural sedation to 0.5 mcg/kg/hr. ■ Dose reduction of either or both agents may be required when coadministered with anesthetics, sedatives, hypnotics, or opioids; see [Drug Interactions](#).

DILUTION

Supplied in single-use vials containing 200 mcg/2 mL. Must be diluted before administration. Preparation of the solution is the same, whether for loading dose or maintenance infusion. Withdraw 2 mL of dexmedetomidine and add to 48 mL of NS for a final concentration of 4 mcg/mL. Shake gently.

Storage: Store unopened vials at CRT.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

According to the manufacturer, the **compatibility** of dexmedetomidine with blood, serum, or plasma has not been established; avoid coadministration. Manufacturer lists as **incompatible** with amphotericin B and diazepam (Valium). Adsorption of dexmedetomidine to some types of natural rubbers may occur. Although dexmedetomidine is dosed to effect, it is advisable to use administration components that are made with synthetic or coated natural rubber gaskets.

Manufacturer lists the following **compatibilities:** NS, D5W, 20% mannitol, LR, magnesium sulfate (100 mg/mL), and 0.3% potassium chloride solution.

One source suggests the following **compatibilities:**

Y-site: Alfentanil (Alfenta), amikacin (Amikin), aminophylline, amiodarone (Nexterone), ampicillin, ampicillin/sulbactam (Unasyn), atracurium (Tracrium), atropine, azithromycin (Zithromax), aztreonam (Azactam), bumetanide, butorphanol (Stadol), calcium gluconate, cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), clinda-

mycin (Cleocin), dexamethasone (Decadron), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, dolasetron (Anzemet), dopamine, doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), ephedrine, epinephrine (Adrenalin), erythromycin (Erythrocin), esmolol (Brevibloc), etomidate (Amidate), famotidine (Pepcid IV), fenoldopam (Corlopan), fentanyl (Sublimaze), fluconazole (Diflucan), furosemide (Lasix), gentamicin, glycopyrrolate (Robinul), granisetron (Kytrel), heparin, hydromorphone (Dilaudid), isoproterenol (Isuprel), ketorolac (Toradol), labetalol, levofloxacin (Levaquin), lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium, meperidine (Demerol), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), midazolam (Versed), milrinone (Primacor), morphine, nalbuphine, nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), ondansetron (Zofran), pancuronium, phenylephrine (Neo-Synephrine), piperacillin/tazobactam (Zosyn), potassium chloride, procainamide (Pronestyl), prochlorperazine (Compazine), promethazine (Phenergan), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), rocuronium (Zemuron), sodium bicarbonate, succinylcholine (Anectine), sufentanil (Sufenta), sulfamethoxazole/trimethoprim, theophylline, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vecuronium, verapamil.

RATE OF ADMINISTRATION

Administer using a controlled infusion device. Rapid IV or bolus administration may result in bradycardia and sinus arrest.

Loading dose: Infuse over 10 minutes. Increase infusion time (decrease infusion rate) if transient hypertension develops; see [Monitor](#) and [Antidote](#).

Maintenance infusion: See [Usual Dose](#). Titrate to desired clinical effect.

ACTIONS

A relatively selective α_2 -adrenoceptor agonist with sedative properties. In animal studies, the desired α_2 selectivity is seen following slow IV infusions of low and medium doses (10 to 300 mcg/kg), but both α_1 and α_2 activity are seen following slow IV infusion of high doses (equal to or greater than 1,000 mcg/kg) or with rapid IV administration. Appears to have both sedative and moderate analgesic activity and may decrease the requirement for concomitant sedation and analgesia when used as a short-term infusion in the ICU setting. Other actions include reduced BP, HR, and reduced salivation. Highly protein bound. Almost completely metabolized in the liver via direct glucuronidation and cytochrome P₄₅₀-mediated metabolism. Metabolites excreted primarily in urine and to a small extent in feces. Half-life is approximately 2 hours. Pharmacokinetics not altered by age or gender.

INDICATIONS AND USES

Sedation of initially intubated and mechanically ventilated patients during treatment in an intensive care setting. Should be administered by continuous infusion not to exceed 24 hours. ■ Sedation of non-intubated patients before and/or during surgical and other procedures.

CONTRAINDICATIONS

None noted.

PRECAUTIONS

Administered by persons skilled in the management of patients in the intensive care or operating room setting. ■ Clinically significant episodes of bradycardia and sinus arrest have been reported in young, healthy volunteers with high vagal tone or with different routes of administration, including rapid intravenous or bolus administration; see [Rate of Administration](#). ■ Hypotension and bradycardia have been reported. Decreases sympathetic nervous system activity. Use caution in patients with advanced heart block, severe ventricular dysfunction, diabetes mellitus, chronic hypertension, hypovolemia, and the elderly; hypotension and/or bradycardia may be more pronounced. Clinical intervention may be required; see [Antidote](#). ■ Patients may be arousable and alert when stimulated. This alone should not be considered as evidence of lack of effectiveness in the absence of other clinical signs and symptoms. ■ Dexmedetomidine should not be administered for longer than 24 hours. Adverse events related to withdrawal (e.g., agitation, hyperten-

sion, nausea and vomiting, tachycardia) have been reported with prolonged infusions. Most withdrawal-related events were seen 24 to 48 hours following discontinuation of the infusion. Withdrawal symptoms have not been seen with discontinuation of short-term infusions (less than 6 hours). ■ Use beyond 24 hours has been associated with tolerance and tachyphylaxis and a dose-related increase in adverse reactions. ■ Use with caution in patients with hepatic impairment. Clearance of dexmedetomidine is decreased; see [Dose Adjustments](#).

Monitor: Continuous monitoring of VS, oxygenation, and cardiac and fluid status imperative. ■ Hypovolemia may increase risk of hypotension. ■ Use of a sedation scale (e.g., Ramsay) recommended for monitoring of sedative effect. ■ Transient hypertension has been observed primarily during the loading dose in association with initial peripheral vasoconstrictive effects. Treatment is generally not required; see [Antidote](#). ■ See [Precautions](#).

Patient Education: Report abdominal pain, agitation, confusion, constipation, diarrhea, dizziness, excessive sweating, headache, nervousness, salt cravings, weakness, or weight loss that occur within 48 hours.

Maternal/Child: Category C: safety for use in pregnancy not established. Studies suggest fetal exposure should be expected. ■ Safety for use during labor and delivery and with breast-feeding not established. Use only when clearly indicated. ■ Safety and effectiveness in pediatric patients under 18 years of age not established.

Elderly: In patients older than 65 years, a higher incidence of bradycardia and hypotension was observed following administration of dexmedetomidine. ■ Consider age-related organ impairment and history of previous or concomitant disease or drug therapy. ■ See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

In vitro studies showed no evidence of cytochrome P₄₅₀-mediated drug interactions that are likely to be of clinical significance. ■ Potentiated by **anesthetics** (e.g., enflurane, isoflurane, sevoflurane), **sedatives or hypnotics** (e.g., barbiturates, benzodiazepines [e.g., diazepam (Valium), midazolam (Versed)], propofol [Diprivan]), and **opioids** (e.g., alfentanil, meperidine, morphine). Reduced doses of both drugs may be indicated. See [Dose Adjustments](#). ■ Concurrent use with other **vasodilators** (e.g., nitroglycerin, nitroprusside sodium) or **negative chronotropic agents** (e.g., beta blockers [e.g., metoprolol (Lopressor)], calcium channel blockers [e.g., diltiazem (Cardizem)]) may have an additive effect; use with caution.

SIDE EFFECTS

The most common treatment-emergent side effects, occurring in more than 2% of patients in both ICU and procedural sedation studies, included bradycardia, dry mouth, and hypotension. Other frequently reported side effects requiring treatment were anemia, fever, hypertension, hypoxia, nausea, tachycardia, and vomiting. Less frequently reported side effects include abnormal vision, acidosis, agitation, apnea, arrhythmia (e.g., atrial fibrillation), bronchospasm, confusion, delirium, dizziness, dyspnea, hallucination, headache, heart block, hypercapnia, hyperkalemia, hypoventilation, increased alkaline phosphatase, increased GGT (gamma glutamyltransferase), increased ALT, increased AST, increased sweating, infection, light anesthesia, neuralgia, neuritis, pain, pleural effusion, pulmonary edema, rigors, sinus arrest, somnolence, and speech disorder.

Overdose: Bradycardia, cardiac arrest, first-degree AV block, hypotension, second-degree heart block.

ANTIDOTE

Keep physician informed of all side effects. Hypotension and bradycardia may be treated by slowing or stopping the dexmedetomidine infusion, increasing the rate of IV fluid administration, elevation of the lower extremities, or use of pressor amines (e.g., dopamine). Administration of anticholinergic agents (e.g., atropine or glycopyrrolate) may be considered to modify vagal tone. Transient hypertension during loading dose may be treated by decreasing the rate of the infusion. Resuscitate as necessary.

DEXRAZOXANE

(dex-rah-ZOX-ayn)

Antidote
Antineoplastic adjunct
Chelating agent

Totect, Zinecard

pH 3.5 to 5.5

USUAL DOSE

TOTECT

Administer once daily for 3 consecutive days. Initiate treatment as soon as possible and within 6 hours of extravasation. Doses should be given 24 hours apart (+ or – 3 hours); see [Precautions](#). Recommended regimen is:

Day 1 and Day 2: 1,000 mg/M² not to exceed 2,000 mg.

Day 3: 500 mg/M² not to exceed 1,000 mg.

ZINECARD

Administered in conjunction with doxorubicin. Dose ratio of dexrazoxane to doxorubicin (Adriamycin) is 10:1 (e.g., 500 mg/M² dexrazoxane to 50 mg/M² doxorubicin). Doxorubicin dose must be given within 30 minutes of starting the dexrazoxane injection, but only after the full dose of dexrazoxane is administered.

DOSE ADJUSTMENTS

TOTECT AND ZINECARD

Decrease the recommended dose of dexrazoxane by 50% in patients with moderate to severe renal impairment (CrCl less than 40 mL/min). Ratio of Zinecard to doxorubicin will be 5:1 (e.g., 250 mg/M² dexrazoxane to 50 mg/M² doxorubicin). ■ Consider age-related impaired organ function and concomitant disease or drug therapy in the elderly; see [Elderly](#). ■ See [Antidote](#). ■ Has not been evaluated in hepatic insufficiency.

ZINECARD

When administering Zinecard, the dose of dexrazoxane is dependent on the dose of doxorubicin. When the dose of doxorubicin is reduced (e.g., patients with hyperbilirubinemia), adjust the dexrazoxane dose accordingly. Maintain a 10:1 ratio (dexrazoxane to doxorubicin) except in patients with CrCl less than 40 mL/min.

DILUTION

Specific techniques required; see [Precautions](#).

TOTECT

Reconstitute each 500-mg vial with 50 mL of provided diluent (10 mg/mL). Further dilute the calculated dose in 1,000 mL of NS. Up to 10 vials of Totect and 10 vials of diluent may be needed to complete 3 days of treatment.

ZINECARD

Initially reconstitute each 250 mg (500 mg) with 25 mL (50 mL) of SWFI (10 mg/mL). This initial dilution has a pH of 1 to 3. Must be further diluted with LR. Concentration should range from 1.3 to 3 mg/mL. Further dilution of each 250-mg (500-mg) vial with 75 mL (150 mL) of LR would yield 2.5 mg/mL. Fully diluted solution has a pH of 3.5 to 5.5.

Storage: Totect and Zinecard: Store unopened vials at CRT. **Totect:** Protect unopened kit from light. Reconstituted solution should be used immediately (within 2 hours). Diluted product stable for 4 hours from time of reconstitution and dilution when stored below 25° C (77° F). **Zinecard:** Reconstituted solution stable for 30 minutes at RT or, if necessary, up to 3 hours from the time of reconstitution under refrigeration at 2° to 8° C (36° to 46° F). Fully diluted solutions in LR are stable for 1 hour at RT or up to 4 hours if refrigerated at 2° to 8° C (36° to 46° F). Discard unused solutions.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be mixed or administered with other drugs"; degrades rapidly at a pH above 7.

One source suggests the following **compatibilities**:

Y-site: Gemcitabine (Gemzar) and pemetrexed (Alimta).

RATE OF ADMINISTRATION**TOTECT**

Administer a single dose as an IV infusion equally distributed over 1 to 2 hours. Infuse at RT with normal lighting.

ZINECARD

A single dose as a rapid infusion (given over 10 to 15 minutes in one study). Do not administer by IV push. Complete dexrazoxane dose but begin doxorubicin within 30 minutes of beginning dexrazoxane.

ACTIONS**DEXRAZOXANE**

Rapidly distributed, at least partly metabolized. Elimination half-life is 2.5 hours. Primarily excreted in urine. See [Drug/Lab Interactions](#).

TOTECT

Diminishes tissue damage resulting from extravasation of anthracycline drugs. Exact mode of action unknown. May inhibit topoisomerase II reversibly.

ZINECARD

A cardioprotective agent. A potent intracellular chelating agent that readily penetrates cell membranes and interferes with iron-mediated free radical generation thought to be, in part, responsible for anthracycline-induced cardiomyopathy. Reduces the incidence of doxorubicin cardiomyopathy.

INDICATIONS AND USES**TOTECT**

Treatment of extravasation resulting from IV anthracycline chemotherapy.

ZINECARD

Reduce the incidence and severity of cardiomyopathy associated with cumulative doses of doxorubicin exceeding 300 mg/M². Currently approved only for use in women with metastatic breast cancer who would benefit from continuing doxorubicin therapy above this cumulative dose. Cardioprotective effect permits a greater number of patients to be treated with extended doxorubicin therapy. ■ **Not recommended for use with the initiation of doxorubicin therapy.**

CONTRAINDICATIONS**TOTECT**

None known.

ZINECARD

Do not use with chemotherapy regimens that do not contain an anthracycline or in the initiation of doxorubicin therapy.

PRECAUTIONS**TOTECT AND ZINECARD**

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Usually administered by or under the direction of the physician specialist. ■ For IV infusion only; do not administer IV push. ■ Use with caution in patients with renal or hepatic impairment; see [Dose Adjustments](#).

TOTECT

Cytotoxic when administered to patients receiving anthracycline-containing chemotherapy; additive myelosuppression (leukopenia, neutropenia, thrombocytopenia) may occur. ■ Administer in a large vein in an extremity/area other than the one affected by extravasation. Cooling procedures such as ice packs, if used, should be removed from the

area at least 15 minutes before administration to allow sufficient blood flow to the extravasated area.

ZINECARD

May add to myelosuppression caused by chemotherapeutic agents. ■ Evidence indicates that the use of dexrazoxane with the initiation of fluorouracil, doxorubicin, and cyclophosphamide (FAC) therapy interferes with the anti-tumor efficacy of the regimen. In one breast cancer trial, a lower response rate and a shorter time to progression were seen in patients who received dexrazoxane with their first cycle of FAC therapy. This use is not recommended; see [Indications](#) and [Contraindications](#). ■ Secondary malignancies (e.g., acute myeloid leukemia [AML] and myelodysplastic syndrome [MDS]) have been reported in pediatric patients and adults (not indicated for use in pediatric patients).

Monitor: **TOTECT AND ZINECARD:** Use of prophylactic antiemetics may be indicated.

TOTECT: Monitor CBC and differential and platelet count for increased bone marrow suppression. ■ Obtain baseline and periodic renal and liver function tests as indicated.

ZINECARD: Obtain baseline ECG, serum levels of iron and zinc, and liver and renal function tests. Monitor at intervals. Baseline left ventricular ejection fraction (LVEF) helpful. ■ Obtain baseline CBC and differential and platelet count. Monitor for increased bone marrow suppression. ■ Reduces but does not eliminate the risk of doxorubicin-induced cardiotoxicity. Monitor for signs of congestive heart failure (e.g., basilar rales, S₃ gallop, paroxysmal nocturnal dyspnea, significant dyspnea on exertion, cardiomegaly by x-ray, or progressive decline from baseline of LVEF). A decline in QRS voltage on a 6-lead ECG of more than 30% may indicate cardiomyopathy.

Patient Education: Nonhormonal birth control recommended. Report a suspected pregnancy; see [Maternal/Child](#). ■ Report pain at injection site promptly.

Maternal/Child: **TOTECT AND ZINECARD:** Category D: avoid pregnancy. Can cause fetal harm. ■ Embryotoxic and teratogenic in rats at doses lower than required for humans. May cause testicular atrophy. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established.

ELDERLY: Response similar to that seen in younger patients. ■ Monitor renal function; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

TOTECT AND ZINECARD

May have additive bone marrow suppressant effects with **other bone marrow suppressants** (e.g., fluorouracil [5-FU], cyclophosphamide [Cytoxan]). ■ Does not affect pharmacokinetics of **doxorubicin**.

TOTECT

Dimethylsulfoxide (DMSO) should not be used in patients who are receiving dexrazoxane for treatment of anthracycline-induced extravasation.

ZINECARD

Not indicated for use in initiation of doxorubicin therapy; may interfere with anti-tumor effects of combination regimens.

SIDE EFFECTS

Administered to patients receiving chemotherapeutic agents; side effect profile reflects a combination of dexrazoxane, underlying disease, and chemotherapy. Most common side effects are fever, injection site pain, nausea, and vomiting. Increased myelosuppression (e.g., granulocytopenia, leukopenia, and thrombocytopenia); may be dose limiting. Coagulation abnormalities, decreased serum zinc, increased serum iron, increased AST and ALT, and increased serum triglycerides do occur. Alopecia, anorexia, diarrhea, and stomatitis, as well as other side effects, may occur.

ANTIDOTE

Keep physician informed of side effects; most will be treated symptomatically. Recovery from myelosuppression similar with or without dexrazoxane. A reduced dose may be indicated if coagulation abnormalities develop. Hemodialysis or peritoneal dialysis may be useful in overdose.

DEXTRAN HIGH MOLECULAR WEIGHT

Plasma volume expander

(DEX-tran hi mo-LEK-u-ler)

Dextran 70, Dextran 75, Gentran 75

pH 3 to 7

USUAL DOSE

Variable, depending on amount of fluid loss and resultant hemoconcentration. Initially 30 Gm (500 mL). Total dose should not exceed 1.2 Gm/kg (20 mL/kg) of body weight in the first 24 hours for adult and pediatric patients. May give 0.6 Gm/kg (10 mL/kg) every 24 hours thereafter if indicated. **Use of Dextran 1 is indicated for prophylaxis of serious anaphylactic reactions.**

DILUTION

Available as a 6% solution in 500-mL bottles properly diluted in NS or D5W and ready for use. Dextran 70 (Cutter) is available in a 250-mL bottle. Use only clear solution. Crystallization of dextran can occur at low temperatures. Submerge in warm water and dissolve all crystals before administration.

Storage: Store at constant temperature not above 25° C (76° F). Discard partially used solution; no preservative added.

COMPATIBILITY

One source suggests that drugs should not be added to a dextran solution.

RATE OF ADMINISTRATION

Variable, depending on indication, present blood volume, and patient response. Initial 500 mL may be given at 20 to 40 mL/min if hypovolemic. If additional high molecular weight dextran is required, reduce flow to lowest rate possible to maintain hemodynamic status desired. In normovolemic patients, rate should not exceed 4 mL/min.

ACTIONS

A glucose polymer that approximates colloidal properties of human albumin. Provides hemodynamically significant plasma volume expansion in excess of the amount infused for about 24 hours. Dilutes total serum proteins and hematocrit values. Smaller dextran molecules are eliminated in urine; larger molecules are degraded to glucose.

INDICATIONS AND USES

Adjunct in treatment of shock or impending shock caused by burns, hemorrhage, surgery, or trauma.

Unlabeled uses: Treatment of nephrosis, toxemia of late pregnancy, and prevention of postoperative deep vein thrombosis.

CONTRAINDICATIONS

Severe bleeding disorders; marked hemostatic defects (e.g., thrombocytopenia, hypofibrinogenemia), even if drug-induced (e.g., heparin, warfarin); known hypersensitivity to dextran; breast-feeding and pregnancy unless a lifesaving measure; severe congestive cardiac failure; renal failure.

PRECAUTIONS

For IV use only. ■ Used when whole blood or blood products are not available. Not a substitute for whole blood or plasma proteins. ■ Use extreme caution in heart disease, impaired hepatic or renal function, congestive heart failure, pulmonary edema, in patients with edema and sodium retention of pathologic abdominal conditions, and in patients receiving anticoagulants or corticosteroids.

Monitor: Monitor pulse, BP, central venous pressure, and urine output every 5 to 15 minutes for the first hour and hourly thereafter while indicated. ■ Maintain hydration of patient with additional IV fluids; dextran promotes tissue dehydration. Avoid overhydration with dilution of electrolyte balance. ■ Change IV tubing or flush well with normal saline before infusing blood. Dextran will promote coagulation of blood in the tubing

(glucose content). ■ May reduce coagulability of the circulating blood. Observe patient for increased bleeding; maintain hematocrit above 30%. ■ Hemoglobin, hematocrit, electrolyte, and serum protein evaluations are necessary during therapy. ■ 500 mL contains 77 mEq of sodium and chloride. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding not established.

DRUG/LAB INTERACTIONS

Draw blood for **laboratory tests and type and cross-match** before giving dextran, or notify laboratory of its use. May alter type and cross-match, blood sugar, total protein, and total bilirubin evaluation. ■ May produce elevated **urine specific gravity** (also symptom of dehydration) and increase **AST and ALT**. ■ See [Monitor](#) for interaction with blood.

SIDE EFFECTS

Bleeding, dehydration, fever, hypotension, joint pain, nausea, overhydration, tightness of the chest, urticaria, vomiting, wheezing. Severe anaphylaxis and death have occurred. Excessive doses have caused wound hematoma, seroma, and bleeding; distant bleeding (hematuria, melena); and pulmonary edema.

ANTIDOTE

Notify physician of any side effect. Discontinue the drug immediately at the first sign of a hypersensitivity reaction, provided other means of sustaining the circulation are available. Use epinephrine (Adrenalin) and/or antihistamines (diphenhydramine [Benadryl]) as indicated. Factor VIII infusion may reverse excessive bleeding. Resuscitate as necessary.

DEXTRAN LOW MOLECULAR WEIGHT

Plasma volume expander

(DEX-tran lo mo-LEK-u-ler)

Dextran 40, Gentran 40, L.M.D. 10%, Rheomacrodex

pH 3 to 7

USUAL DOSE

Adjunct in shock: Variable, depending on amount of fluid loss and resultant hemoconcentration. Do not exceed 2 Gm/kg (20 mL) of body weight total over first 24 hours and 1 Gm/kg (10 mL) total over each succeeding 24 hours. Discontinue infusion after 5 days of therapy. **Dextran 1 is indicated for prophylaxis of serious anaphylactic reactions.**

Prophylaxis of venous thrombosis and/or pulmonary embolism: 10 mg/kg of body weight on day of surgery. 500 mL daily for 2 to 3 days, then 500 mL every 2 to 3 days up to 2 weeks. Length of treatment based on risk of thromboembolic complication. **Note previous comment on use of dextran 1.**

As priming fluid: 10 to 20 mL/kg of body weight. Do not exceed this dose. May be used in conjunction with other priming fluids.

DILUTION

Available as a 10% solution in 500-mL bottles properly diluted in NS or D5W and ready for use. Use only clear solution. Crystallization of dextran can occur at low temperatures. Submerge in warm water and dissolve all crystals before administration.

Storage: Store at constant temperature not above 25° C (76° F). Discard partially used solution; no preservative added.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests that drugs should not be added to a dextran solution. Another source suggests the following **compatibilities**:

Y-site: Enalaprilat (Vasotec IV), famotidine (Pepcid IV), and nicardipine (Cardene IV).

RATE OF ADMINISTRATION

Initial 500 mL may be given rapidly. Remainder of any desired daily dose should be evenly distributed over 8 to 24 hours depending on use. Slow rate or discontinue dextran for rapid increase of central venous pressure.

ACTIONS

A low-molecular-weight, rapid, but short-acting plasma volume expander. A colloid hypertonic solution, it increases plasma volume by once or twice its own volume. Helps to restore normal circulatory dynamics, increasing arterial and pulse pressure, central venous pressure, and cardiac output. Improves microcirculatory flow and prevents sludging in venous channels. Mobilizes water from body tissues and increases urine output.

INDICATIONS AND USES

Adjunctive therapy in the treatment of shock caused by hemorrhage, burns, trauma, or surgery. ■ Prophylaxis during surgical procedures with a high incidence of venous thrombosis and pulmonary embolism. ■ Pump priming during extracorporeal circulation.

CONTRAINDICATIONS

Severe bleeding disorders, marked hemostatic defects (e.g., thrombocytopenia, hypofibrinogenemia) even if drug-induced (e.g., heparin, warfarin), known hypersensitivity to dextran, breast-feeding and pregnancy unless a lifesaving measure, severe congestive cardiac failure, renal failure.

PRECAUTIONS

For IV use only. ■ Use caution in heart disease, renal shutdown, congestive heart failure, pulmonary edema, patients with edema and sodium retention, and patients taking corticosteroids.

Monitor: Monitor pulse, BP, central venous pressure (if possible), and urine output every 5 to 15 minutes for the first hour and hourly thereafter while indicated. ■ Slow rate or discontinue dextran for rapid increase of central venous pressure (normal 7 to 14 mm H₂O pressure). ■ If anuric or oliguric after 500 mL of dextran, discontinue the dextran. Mannitol may help increase urine flow. ■ Maintain hydration of patient with additional IV fluids; dextran promotes tissue dehydration. Avoid overhydration and dilution of serum electrolytes. ■ Change IV tubing or flush well with normal saline before superimposing blood. Dextran will promote coagulation of blood in the tubing (glucose content). ■ May reduce coagulability of the circulating blood slightly. Observe for bleeding complications, particularly following surgery or if patient is being anticoagulated. Maintain hematocrit above 30%. ■ 500 mL contains 77 mEq of sodium and chloride. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding not established.

DRUG/LAB INTERACTIONS

Draw blood for **laboratory tests and type and cross-match** before giving dextran, or notify laboratory of its use. May alter type and cross-match, blood sugar, total protein, and total bilirubin evaluation. ■ May produce elevated **urine specific gravity** (also a symptom of dehydration) and increase **AST and ALT**. ■ See [Monitor](#) for interaction with blood.

SIDE EFFECTS

Bleeding, dehydration, fever, hypotension, joint pain, nausea, overhydration, tightness of chest, urticaria, vomiting, wheezing. Severe anaphylaxis and death can occur. Excessive doses have caused wound hematoma, wound seroma, wound bleeding, distant bleeding (hematuria, melena), and pulmonary edema.

ANTIDOTE

Notify the physician of any side effect. Discontinue the drug immediately at the first sign of a hypersensitivity reaction, provided other means of sustaining the circulation are available. Use epinephrine (Adrenalin) and/or antihistamines (diphenhydramine [Benadryl]) as indicated. Factor VIII infusion may reverse excessive bleeding. Resuscitate as necessary.

DEXTROSE

(DEX-trohs)

GlucoseNutritional
(carbohydrate)

pH 3.5 to 6.5

USUAL DOSE

Depends on use and age, weight, and clinical condition of the patient. The average normal adult requires 2 to 3 L of fluid daily to replace water loss through perspiration and urine.

2½% (25 Gm/L) or 5% (50 Gm/L) dextrose: 50 to 1,000 mL. May be repeated as indicated. Consider total amount of fluid.

10% dextrose (100 Gm/L): 5 mL. May repeat as necessary or 500 to 1,000 mL once or twice every 24 hours as indicated.

20% dextrose (200 Gm/L): 500 mL once or twice every 24 hours as indicated.

50% dextrose (500 Gm/L): 20 mL (10 Gm) to 50 mL (25 Gm). May repeat if indicated in *insulin-induced hypoglycemia*.

10% (100 Gm/L), 20% (200 Gm/L), 30% (300 Gm/L), 38.5% (385 Gm/L), 40% (400 Gm/L), 50% (500 Gm/L), 60% (600 Gm/L), 70% (700 Gm/L): 500 to 1,500 mL/24 hr as an infusion after admixture with other solutions such as amino acids or fat emulsion. Used for nutritional support.

PEDIATRIC DOSE

Dose is dependent on use, weight, clinical condition, and laboratory results. See [Rate of Administration](#), [Precautions](#), [Monitor](#), and [Maternal/Child](#).

NEONATAL DOSE

Dose is dependent on use, weight, clinical condition, and laboratory results. See [Rate of Administration](#), [Precautions](#), [Monitor](#), and [Maternal/Child](#).

Acute symptomatic hypoglycemia: 250 to 500 mg/kg of body weight of 10% to 25% dextrose.

DOSE ADJUSTMENTS

Dosing should be cautious in the elderly. Lower-end initial doses may be indicated. Consider decrease in organ function, concomitant disease, or other drug therapy. See [Rate of Administration](#) and [Precautions](#).

DILUTION

May be given undiluted in prepared solutions or further diluted to achieve desired final concentration. Check label for aluminum content; see [Precautions](#). Dextrose solutions are excellent media for bacterial growth. Do not use unless the solution is entirely clear and the vial is sterile. Do not store after adding additives.

Storage: Store at 20° to 25° C (68° to 77° F). Protect from freezing.

COMPATIBILITY

Will cause pseudoagglutination of red blood cells if administered simultaneously with whole blood. Consult pharmacist or refer to individual drug monograph before admixing with other drugs or solutions. Mix thoroughly.

RATE OF ADMINISTRATION

2½% and 5% solution, rate dependent on amount.

10% solution, 5 mL over 10 to 15 seconds.

10% solution, 1,000 mL over at least 3 hours.

20% solution, 500 mL over 30 to 60 minutes.

50% solution, 3 mL over 1 minute.

500 mL of 30% to 70% solution over 4 to 12 hours, depending on body weight. A rate of 0.5 Gm/kg/hr will not cause glycosuria. At 0.8 Gm/kg/hr 95% is retained and will cause glycosuria. May cause hyperosmolar syndrome.

Excessive or rapid administration in very-low-birth-weight infants may cause hyperglycemia, hypoglycemia, or increased serum osmolality and possible intracerebral hemorrhage.

ACTIONS

A parenteral fluid and nutrient replenisher. A monosaccharide, it provides glucose calories for metabolic needs. Metabolized to CO₂ and water. Its oxidation provides water to sustain volume and may help lower excess ketone production. Restores blood glucose levels. May help minimize liver glycogen depletion and may exert a protein-sparing action. Hypertonic solutions (20% to 50%) act as diuretics and reduce CNS edema. Readily excreted by the kidneys, producing diuresis.

INDICATIONS AND USES

Provide calories and fluid by peripheral infusion when calories and fluid are required (2½%, 5%, 10%). ■ Provide calories by central IV infusion in conditions requiring a minimum volume of fluid (20%). ■ Provide calories by central IV infusion in combination with other amino acid solutions as total parenteral nutrition (10% to 70%). ■ Treatment of insulin-induced hypoglycemia (50%). ■ Treatment of acute symptomatic episodes of hypoglycemia in the neonate and infant (25%). ■ Shock (sustain blood volume). ■ Diuresis (20% to 50% solution). ■ Hyperkalemia (20% solution). ■ As a diluent for IV administration of medications (2½% to 10% solutions usually). ■ A sclerosing solution (25% to 50% solution, 3 to 20 mL).

CONTRAINDICATIONS

Delirium tremens with dehydration; diabetic coma while blood sugar is excessive; hepatic coma intracranial or intraspinal hemorrhage; glucose-galactose malabsorption syndrome. Solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Use caution in severe kidney damage. ■ 50% dextrose can be used as a sclerosing agent and will cause thrombosis. ■ Use caution in infants of diabetic mothers, in patients with carbohydrate intolerance or subclinical or overt diabetes, and in patients receiving corticosteroids. ■ Use dextrose with extreme caution in low-birth-weight or septic infants. May cause severe hyperglycemia, may increase serum osmolality, and may cause intracerebral hemorrhage. ■ To prevent hypokalemia, fasting patients with good renal function (especially patients undergoing digoxin therapy) should have adequate amounts of potassium added to hypertonic dextrose solutions. ■ Some solutions may contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive greater than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. ■ Concentrated dextrose solutions, if administered too rapidly, may result in significant hyperglycemia and possible hyperosmolar syndrome characterized by mental confusion and loss of consciousness. Fatty infiltration of the liver, acute respiratory failure, and difficulty in weaning hypermetabolic patients from the respirator may be caused by excessive carbohydrate calories.

Monitor: Adult and pediatric patients: Do not use as a diluent for blood or administer simultaneously through the same infusion set; dextrose in any dilution causes clumping of RBCs unless sodium chloride is added. ■ For concentrations over 12.5% (hypertonic) very large (central) veins and slow administration are absolutely necessary. ■ Confirm

patency of vein; avoid extravasation. ■ Use with caution in patients with known sub-clinical or overt diabetes. Insulin requirements may be increased. Monitor blood glucose. ■ Monitor changes in fluid balance, electrolyte concentrations, and acid-base balance during prolonged therapy or as indicated by patient condition. ■ Potassium and vitamins are readily depleted. Watch for any signs of beginning deficiency and replace as needed. Add other electrolytes and minerals as required by fluid and electrolyte status. ■ Can cause fluid or solute overload. May result in dilution of serum electrolyte concentrations, overhydration, congested states, or pulmonary edema. ■ Rapid administration of hypertonic solutions will cause hyperglycemia (over 0.5 Gm/kg/hr) and may cause hyperosmolar syndrome. ■ Concentrated dextrose solutions must not be withdrawn abruptly. Will cause reactive hypoglycemia. Reduce rate of administration gradually and then follow with administration of 5% or 10% dextrose solution. ■ See [Rate of Administration](#) and [Precautions](#).

Pediatric patients: Monitor serum glucose frequently, especially in infants, neonates, and low-birth-weight infants. ■ Small volumes of fluid may affect fluid and electrolyte balance in very small infants and neonates. Renal function may be immature and the ability to excrete fluid and solute loads limited. Monitor fluid intake, urine output, and serum electrolytes closely in infants, neonates, and low-birth-weight infants.

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding not established. Benefits must outweigh risks. Use caution and monitor fluid balance, glucose and electrolyte concentrations, and acid-base balance of both mother and fetus as indicated by their conditions. ■ See [Precautions](#).

Elderly: Lower-end initial doses may be indicated; see [Dose Adjustments](#). Monitoring of renal function may be useful. Specific age-related differences in response have not been identified.

DRUG/LAB INTERACTIONS

See [Monitor](#).

SIDE EFFECTS

Rare in small doses administered slowly: acidosis, alkalosis, febrile reactions, fluid overload (congested states, pulmonary edema, overhydration, dilution of serum electrolyte concentrations), hyperglycemia (during infusion), hyperosmolar syndrome (mental confusion, loss of consciousness), hypersensitivity reactions (e.g., anaphylaxis; coughing; difficulty breathing; periorbital, facial, and/or laryngeal edema; pruritus; sneezing; and urticaria), hypokalemia, hypovitaminosis, infection at injection site, reactive hypoglycemia (after infusion), venous thrombosis or phlebitis.

ANTIDOTE

Discontinue the drug and notify the physician of the side effect. Symptomatic treatment is probable.

DIAZEPAM(dye-**AYZ**-eh-pam)

Benzodiazepine
 Sedative-hypnotic
 Antianxiety agent
 Anticonvulsant
 Amnestic
 Skeletal muscle relaxant (adjunct)

Valium ■ Diazemuls 

pH 6.2 to 6.9 ■ pH 8

USUAL DOSE

Maximum dose except in status epilepticus is 30 mg in 8 hours. Note some changes in times of administration between conventional diazepam (Valium) and emulsified forms (e.g., Diazemuls). The emulsified form is no longer available in the United States.

PREOPERATIVE MEDICATION

Conventional diazepam (Valium): 5 to 10 mg before surgery.

Emulsified diazepam (Diazemuls): 10 mg 1 to 2 hours before surgery.

MODERATE ANXIETY DISORDERS AND SYMPTOMS OF ANXIETY

All formulations: 2 to 5 mg. Repeat in 3 to 4 hours if necessary.

SEVERE ANXIETY DISORDERS AND SYMPTOMS OF ANXIETY

All formulations: 5 to 10 mg. Repeat in 3 to 4 hours if necessary.

ACUTE ALCOHOL WITHDRAWAL

All formulations: 10 mg initially, then 5 to 10 mg in 3 to 4 hours if necessary.

STATUS EPILEPTICUS

All formulations: 5 to 10 mg. May be repeated at intervals of 10 to 15 minutes up to a total dose of 30 mg. May repeat in 2 to 4 hours. Another source suggests 0.2 to 0.5 mg/kg every 15 to 30 minutes for 2 or 3 doses. Some specialists start with 20 mg and titrate the total dose over 10 minutes or until seizures stop. Maximum dose in 24 hours is 100 mg.

CARDIOVERSION

Conventional diazepam (Valium): 5 to 15 mg 5 to 10 minutes before procedure begins.

Emulsified diazepam (Diazemuls): 5 to 15 mg 10 to 20 minutes before procedure begins.

ENDOSCOPY

Conventional diazepam (Valium): 10 mg or less is usually effective given immediately before procedure begins; titrate to desired sedation (e.g., slurred speech). Up to 20 mg may be indicated if a narcotic is not used.

Emulsified diazepam (Diazemuls): 5 to 10 mg 30 minutes before the procedure begins; titrate to desired sedation (e.g., slurred speech). Up to 20 mg may be indicated if a narcotic is not used.

MUSCLE SPASM

All formulations: 5 to 10 mg. Repeat in 3 to 4 hours if necessary. Larger doses may be required in tetanus.

PEDIATRIC DOSE

Safety for use in neonates not established but is used. Neonates have reduced or immature organ function; may be susceptible to prolonged CNS depression. Avoid small veins (e.g., dorsum of hand or wrist); see [Monitor](#). Use in infants and children is most frequent in tetany, status epilepticus, or hypersensitivity reactions. Use of longer-acting anticonvulsants (e.g., phenobarbital, phenytoin) following diazepam may be indicated. Not recommended but is used for other general indications.

SEDATIVE/MUSCLE RELAXANT

All formulations: 0.04 to 0.2 mg/kg every 2 to 4 hours. Maximum dose 0.6 mg/kg in 8 hours.

TETANUS IN PEDIATRIC PATIENTS FROM 30 DAYS OF AGE TO 5 YEARS OF AGE

Respiratory assistance must be available.

All formulations: 1 to 2 mg every 3 to 4 hours.

Conventional diazepam (Valium): One source suggests a maximum single dose not to exceed 0.25 mg/kg; repeat in 15 to 30 minutes if necessary. A third dose may be given, but if it does not relieve symptoms, consider alternative therapy.

TETANUS IN PEDIATRIC PATIENTS 5 YEARS OF AGE OR OLDER

Respiratory assistance must be available.

All formulations: 5 to 10 mg every 3 to 4 hours.

Conventional diazepam (Valium): One source suggests a maximum single dose not to exceed 0.25 mg/kg; repeat in 15 to 30 minutes if necessary. A third dose may be given, but if it does not relieve symptoms, consider alternative therapy.

STATUS EPILEPTICUS IN NEONATES (UNLABELED)

All formulations: 0.3 to 0.75 mg/kg every 15 to 30 minutes for 2 to 3 doses. Maximum total dose is 5 mg.

STATUS EPILEPTICUS IN PEDIATRIC PATIENTS FROM 30 DAYS OF AGE TO 5 YEARS OF AGE

All formulations: 0.2 to 0.5 mg every 2 to 5 minutes to a maximum 5-mg dose. May repeat in 2 to 4 hours. Another source suggests 0.2 to 0.5 mg/kg every 15 to 30 minutes to a maximum 5-mg dose.

STATUS EPILEPTICUS IN PEDIATRIC PATIENTS 5 YEARS OF AGE OR OLDER

All formulations: 1 mg every 2 to 5 minutes to a maximum 10-mg dose. May repeat in 2 to 4 hours. Another source suggests 0.2 to 0.5 mg/kg every 15 to 30 minutes to a maximum 10-mg dose.

DOSE ADJUSTMENTS

Reduce dose by one half for the elderly or debilitated, in impaired liver or renal function, in patients with limited pulmonary reserve, and in the presence of other CNS depressants. Begin with a small dose and increase in gradual increments. ■ See *Drug/Lab Interactions*.

DILUTION

All formulations: Do not dilute or mix with any other drug. Should be given directly into the vein. Inject into IV tubing close to vein site only when direct IV injection is not feasible. Consider heparin lock for frequent injection. Change site every 2 to 3 days. Some precipitation or adsorption into plastic tubing may occur.

Conventional diazepam: *Not soluble in any solution.* If dilution is imperative, add dilution solution to diazepam, not diazepam to solution; consult pharmacist. Direct IV administration is preferred but can be administered at a Y-tube injection site.

Emulsified diazepam: May be diluted with their emulsion base (Intralipid or Nutralipid). Mixture should be used within 6 hours. In any other solution, *emulsion may be destabilized and may not be visually apparent. Incompatible* with polyvinylchloride infusion sets. If a filter is used for emulsified forms, it must have a pore size of 5 microns or more so as not to break down the emulsion. Emulsified forms eliminate the use of nonphysiologic, potentially irritating solvents.

Filters: *Emulsified diazepam:* If a filter is used for emulsified forms, it must have a pore size of 5 microns or more to prevent breakdown of the emulsion.

Storage: *Conventional diazepam (Valium):* Store at CRT in cartons to protect from light. Do not freeze.

Emulsified diazepam (Diazemuls): Store below 25° C (77° F) unless manufacturer suggests refrigeration. Do not freeze. Protect from light. Note expiration date.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturers for all preparations recommend not mixing with any other drug or solution in syringe or solution. Precipitation can occur. Emulsified forms are *incompatible* with polyvinylchloride infusion sets. *Emulsion may be destabilized and may not be visually apparent.* See *Dilution*.

One source suggests the following **compatibilities:**

CONVENTIONAL DIAZEPAM

Additive: Verapamil.

Y-site: Cisatracurium (Nimbex), dobutamine, fentanyl (Sublimaze), hydromorphone (Dilaudid), methadone (Dolophine), morphine, nafcillin (Nallpen), quinidine gluconate, remifentanyl (Ultiva).

EMULSIFIED DIAZEPAM

Additive: Intralipid, Nutralipid; see *Dilution*.

RATE OF ADMINISTRATION

If a filter is used for emulsified forms, it must have a pore size of 5 microns or more so as not to break down the emulsion.

Adults: 5 mg (1 mL) or fraction thereof over 1 minute.

Infants and other pediatric patients: Give total dose over a minimum of 3 minutes, but do not exceed a rate of 0.25 mg/kg over 3 minutes.

ACTIONS

A benzodiazepine that depresses the central, autonomic, and peripheral nervous systems in an undetermined manner. Exerts antianxiety, sedative/hypnotic, amnesic, anticonvulsant, skeletal muscle relaxant, and antitremor effects. Diminishes patient recall. Metabolized in the liver; stays in the body in appreciable amounts for several days and is excreted very slowly in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Management of moderate to severe anxiety disorders or short-term relief of symptoms of anxiety. ■ Acute alcohol withdrawal. ■ Acute stress reactions. ■ Muscle spasm. ■ Status epilepticus and severe recurrent convulsive seizures, including tetany. ■ Preoperative medication, including endoscopic procedures. ■ Cardioversion.

Unlabeled uses: Conscious sedation in dental procedures, treatment of panic disorders.

CONTRAINDICATIONS

Known hypersensitivity, open-angle glaucoma unless receiving appropriate therapy, shock, coma, acute alcoholic intoxication with depression of vital signs. Emulsion in Dizac contains soybean oil; do not use in patients with known hypersensitivity to soy protein.

PRECAUTIONS

Check label carefully. Some preparations are for IV use only (e.g., Diazemuls); others can be given IM/IV (e.g., Valium). ■ Drug of choice for initial treatment of status epilepticus or seizures resulting from drug overdose or poisoning. Some specialists administer phenytoin simultaneously to facilitate long-term control (onset of action is not as immediate as diazepam). Oral phenytoin or phenobarbital may be used for maintenance. ■ May not be effective if seizures are due to acute brain lesions. ■ Not recommended for treatment of petit mal or petit mal variant seizures; may cause tonic state epilepticus. ■ Use caution in the elderly, those who are very ill, and those with limited pulmonary reserve (e.g., chronic lung disease) or unstable cardiac status. ■ Withdrawal symptoms will occur for several weeks after extended or large doses. ■ Hypoalbuminemia may increase the incidence of side effects. ■ Intended for short-term use only. ■ Available PO and as a rectal gel.

Monitor: See *Dilution*. ■ To reduce the incidence of thrombophlebitis, avoid smaller veins. Extravasation or arterial administration hazardous. ■ Oxygen, respiratory assistance, and flumazenil (Romazicon) must always be available. ■ Bed rest required for a minimum of 3 hours after IV injection.

Patient Education: May produce drowsiness or dizziness. Request assistance with ambulation and use caution performing tasks that require alertness. Do not drive or operate hazardous machinery until all effects have subsided. ■ Avoid use of alcohol or other CNS depressants (e.g., antihistamines, barbiturates). ■ May be habit-forming with long-term use or high-dose therapy. ■ Has amnesic potential; may impair memory. ■ Consider birth control options.

Maternal/Child: Category D: has caused birth deformities, especially in the first trimester. ■ Not recommended during pregnancy, childbirth, or while breast-feeding.

Elderly: See *Dose Adjustments*. Start with a small dose and increase gradually based on response. ■ More sensitive to therapeutic and adverse effects (e.g., ataxia, dizziness,

oversedation). ■ IV injection may be more likely to cause apnea, bradycardia, hypotension, and cardiac arrest. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

DRUG/LAB INTERACTIONS

Concurrent use with other **CNS depressants** (e.g., alcohol, antihistamines, barbiturates, MAO inhibitors [e.g., selegiline (Eldepryl)], narcotics [e.g., morphine, meperidine (Demerol), fentanyl], phenothiazines [e.g., prochlorperazine (Compazine)], tricyclic antidepressants [e.g., imipramine (Tofranil-PM)]) may result in additive effects for up to 48 hours. Reduced doses of both drugs may be indicated. ■ May increase serum concentrations of **digoxin and phenytoin** (Dilantin); monitor digoxin and phenytoin serum levels. ■ **Ritonavir** (Norvir) may increase risk of prolonged sedation and respiratory depression. Concurrent use not recommended. Benzodiazepines metabolized by alternate routes may be safer (e.g., lorazepam [Ativan], oxazepam [Serax], temazepam [Restoril]). ■ Concurrent use with **beta-blockers** (e.g., metoprolol [Lopressor], propranolol [Inderal]), **cimetidine** (Tagamet), **disulfiram** (Antabuse), **estrogen-containing oral contraceptives**, **fluoxetine** (Prozac), **isoniazid** (INH), **itraconazole** (Sporanox), **ketoconazole** (Nizoral), **omeprazole** (Prilosec), **probenecid**, and **valproic acid** (Depakene) may inhibit hepatic metabolism, resulting in increased plasma concentrations of benzodiazepines. ■ Diazepam decreases clearance and increases toxicity of **zidovudine** (AZT, Retrovir). ■ May increase clearance and decrease effectiveness of **levodopa**. ■ Hypotensive effects of benzodiazepines may be increased by **any agent that induces hypotension** (e.g., antihypertensives, CNS depressants, diuretics, lidocaine, paclitaxel). ■ Use with **rifampin** (Rifadin) increases clearance and reduces effects of diazepam. ■ **Theophyllines** (e.g., Aminophylline) antagonize sedative effects of benzodiazepines. ■ **Smoking** increases metabolism and clearance of diazepam, decreasing plasma levels and sedative effects. ■ **Clozapine** (Leponex) has caused respiratory distress or cardiac arrest in a few patients; use concurrently with extreme caution. ■ Decreased drowsiness may occur in cigarette **smokers**, especially if elderly. ■ **Grapefruit juice** may affect certain enzymes of the P₄₅₀ enzyme system and should be avoided.

SIDE EFFECTS

Apnea, ataxia, blurred vision, bradycardia, cardiac arrest, cardiovascular collapse, coma, confusion, coughing, depressed respiration, depression, diminished reflexes, drowsiness, dyspnea, headache, hiccups, hyperexcited states, hyperventilation, laryngospasm, neutropenia, nystagmus, somnolence, syncope, venous thrombosis and phlebitis at injection site, vertigo.

ANTIDOTE

Notify the physician of all side effects. Reduction of dosage may be required. Discontinue the drug for major side effects or paradoxical reactions, including hyperexcitability, hallucinations, and acute rage. Flumazenil (Romazicon) will reverse all sedative effects of benzodiazepines. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. May cause emesis; observe closely. Treat hypersensitivity reaction, or resuscitate as necessary.

DIGOXIN(dih-**JOX**-in)

Cardiac glycoside
 Antiarrhythmic
 Inotropic agent

Digoxin Pediatric, Lanoxin, Lanoxin Pediatric

pH 6.8 to 7.2

USUAL DOSE

Calculate dose based on lean body weight (LBW), CrCl, age, as well as concomitant disease states, concurrent medications, and other factors that may alter the effects of digoxin. In general, the dose of digoxin used should be determined on clinical grounds. When changing from IV or oral dosing, increase oral dose by 20% to 25%.

Rapid digitalization (heart failure): An example of a usual **loading** dose is 400 to 600 mcg (0.4 to 0.6 mg), followed cautiously by 100 to 300 mcg (0.1 to 0.3 mg) at 6- to 8-hour intervals until clinical evidence of adequate effect. Assess clinical response (e.g., increased cardiac output, decreased heart rate) before each additional dose. To achieve the expected 8 to 12 mcg/kg peak body stores in a 70-kg patient, 600 to 1,000 mcg (0.6 to 1 mg) is usually required; see **Monitor**.

Maintenance dose: May range from 100 to 400 mcg IV (0.1 to 0.4 mg) once daily. Oral dose may range from 125 to 500 mcg (0.125 to 0.5 mg) once daily. 250 mcg (0.25 mg) is suggested once daily for patients under age 70 with good renal function, 125 mcg (0.125 mg) for patients over age 70 or with impaired renal function, and 62.5 mcg (0.0625 mg) in patients with marked renal impairment.

Gradual digitalization: An example for a 70-kg patient with a CrCl of 60 mL/min is a dose of 175 mcg (0.175 mg) daily. Steady state should be achieved in approximately 11 days. See prescribing information for a formula based on peak body stores lost each day through elimination and additional doses based on CrCl and lean body weight.

Atrial fibrillation in adult and pediatric patients: Peak digoxin body stores larger than the 8 to 12 mcg/kg required for most patients with heart failure and NSR may be required to control AF. Titrate to the minimum dose that achieves the desired ventricular rate without undesirable side effects. Data not available to determine appropriate resting or exercise target rates.

Slow ventricular response in atrial fibrillation/atrial flutter or alternative drug for re-entry SVT (AHA states, "May be of limited use"): AHA guidelines recommend a loading dose of 4 to 6 mcg/kg over 5 minutes. Second and third boluses of 2 to 3 mcg/kg to follow at 4- to 8-hour intervals (total loading dose of 8 to 12 mcg/kg is divided over 8 to 16 hours). Monitor HR and ECG. Check digoxin levels no sooner than 6 to 8 hours after an IV dose.

PEDIATRIC DOSE

Use 0.1 mg/mL pediatric injection (100 mcg/mL).

Rapid digitalizing dose (heart failure): Give one half of total daily dose initially; additional fraction of the planned total dose may be given at 4- to 8-hour intervals. Assess clinical response before each additional dose. Carefully titrate dose based on clinical response in pediatric patients with renal disease. If using a tuberculin syringe to measure a pediatric dose, do not flush syringe with parenteral solution after contents are injected; may result in an overdose.

Usual Digitalizing and Maintenance Dosages of Digoxin in Pediatric Patients with Normal Renal Function Based on Lean Body Weight		
Age	Digitalizing Dose (mcg/kg)*	Daily IV Maintenance Dose (mcg/kg)†
Premature	15-25 mcg/kg	20%-30% of IV loading dose‡ divided
Full-term	20-30 mcg/kg	25%-35% of IV loading dose‡ divided
1-24 months	30-50 mcg/kg	
2-5 years	25-35 mcg/kg	
5-10 years	15-30 mcg/kg	
Over 10 years	8-12 mcg/kg	

*IV digitalizing doses are 80% of oral digitalizing doses; see Pediatric Dose for correct division of digitalizing dose.

†Divided daily dosing is recommended for pediatric patients under 10 years of age.

‡Projected or actual digitalizing dose providing clinical response.

DOSE ADJUSTMENTS

Reduce dose in partially digitalized patients, in patients with impaired renal function, and in the elderly. ■ Dose reduction may be required before cardioversion. ■ See [Drug/Lab Interactions](#); adjustments may be required with numerous drugs. ■ Reduced doses may be indicated in advanced heart failure, myocardial infarction, severe carditis, or severe pulmonary disease. ■ Renal clearance diminished in neonates, including premature infants; adjust dose as indicated. ■ See [Precautions](#).

DILUTION

May be given undiluted or each 1 mL may be diluted in 4 mL SWFI, NS, or D5W. Less diluent may cause precipitation. Use diluted solution immediately. Give through Y-tube or three-way stopcock of IV infusion set. See [Pediatric Dose](#).

Storage: Store unopened vials at CRT protected from light.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends not mixing with other drugs in the same container and not administering simultaneously via the same IV line.

One source suggests the following **compatibilities (not recommended by manufacturer):**

Additive: Furosemide (Lasix), lidocaine, ranitidine (Zantac), verapamil.

Y-site: Anidulafungin (Eraxis), bivalirudin (Angiomax), ceftaroline (Teflaro), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), dexmedetomidine (Precedex), diltiazem (Cardizem), doripenem (Doribax), famotidine (Pepcid IV), fenoldopam (Corlopam), hetastarch in electrolytes (Hextend), insulin (regular), linezolid (Zyvox), meperidine (Demerol), meropenem (Merrem IV), midazolam (Versed), milrinone (Primacor), morphine, nesiritide (Natrecor), potassium chloride (KCl), remifentanyl (Ultiva), tacrolimus (Prograf).

RATE OF ADMINISTRATION

Each single dose over a minimum of 5 minutes. Rapid administration may cause systemic and coronary arteriolar constriction.

ACTIONS

A cardiac glycoside obtained from *Digitalis lanata*. Onset of action is within 5 to 30 minutes. Half-life is 1.5 to 2 days and duration of action is 2 to 3 days. It has positive inotropic action, increasing the strength of myocardial contraction. It also decreases the degree of activation of the sympathetic nervous system and the renin-angiotensin system and decreases conduction velocity through the AV node, thereby decreasing heart rate. Results are a slower, stronger heartbeat with an increase in cardiac output and left ventricular ejection fraction and a decrease in pulmonary artery pressure, pulmonary capillary wedge pressure, and systemic vascular resistance. In atrial fibrillation, digoxin slows rapid ventricular response in a linear dose-dependent manner. Widely distributed

throughout the body. Minimal metabolism. Rapidly excreted in urine; primarily as unchanged drug. Crosses the placenta and is secreted in breast milk.

INDICATIONS AND USES

Treatment of mild to moderate heart failure. ■ Control of ventricular response rates in patients with chronic atrial fibrillation; see [Precautions](#).

CONTRAINDICATIONS

Ventricular fibrillation and known hypersensitivity to digoxin or other digitalis preparations.

PRECAUTIONS

IV administration is the preferred parenteral route. Used only when oral therapy is not feasible or rapid therapeutic effect is necessary. ■ Calcium channel blockers (e.g., diltiazem [Cardizem], verapamil) or beta blockers (e.g., atenolol [Tenormin], metoprolol [Lopressor]) generally preferred to treat atrial fibrillation; adenosine (Adenocard, Adenoscan) preferred to treat PSVT. ■ Commonly prolongs the PR interval; may cause severe sinus bradycardia or sinoatrial block in patients with pre-existing sinus node disease and may cause advanced or complete heart block in patients with pre-existing incomplete AV block. Consider insertion of a pacemaker before treatment with digoxin in these patients. ■ Use in patients with an accessory AV pathway (Wolff-Parkinson-White syndrome) is not recommended unless the conduction down the accessory pathway has been blocked either pharmacologically or by surgery. Cardioversion is usually used to treat PSVT in these patients. ■ Avoid use in patients with heart failure associated with preserved left ventricular systolic function (e.g., acute cor pulmonale, amyloid heart disease, constrictive pericarditis, idiopathic hypertrophic subaortic stenosis, restrictive cardiomyopathy). Has been used in select patients with these diagnoses to treat chronic atrial fibrillation. ■ Avoid use in patients with myocarditis; may precipitate vasoconstriction. ■ Use with caution in patients with impaired renal function; risk of toxicity increased; see [Dose Adjustments](#). ■ Use caution in patients with electrolyte disorders because potassium or magnesium depletion sensitizes the myocardium to digoxin; toxicity may occur with serum digoxin concentrations below 2 ng/mL. ■ Patients with beriberi heart disease may fail to respond adequately to digoxin if the underlying thiamine deficiency is not treated concomitantly. ■ Some clinicians suggest stopping digoxin 12 hours before surgery to reduce risk of perioperative arrhythmias in digitalized patients. The exception is patients with supraventricular tachyarrhythmias; they should receive a dose the morning of surgery. ■ Use with caution in patients with hypercalcemia or liver or kidney disease; see [Dose Adjustments](#). ■ Hypocalcemia may nullify effect of digoxin. If calcium levels need to be restored to normal, give calcium slowly and in small amounts. Death has occurred in digitalized patients receiving calcium. ■ Hypothyroidism may reduce requirements for digoxin. Addressing the underlying condition is suggested in patients with heart failure and/or atrial arrhythmias resulting from hypermetabolic or hyperdynamic states (e.g., hyperthyroidism, hypoxia, or arteriovenous shunt). ■ Use caution in patients with myocardial infarction. May cause an increase in myocardial oxygen demand and ischemia. ■ Some clinicians suggest reducing the dose of digoxin for 1 to 2 days before an elective cardioversion. If countershock is necessary (last-resort treatment of life-threatening arrhythmias), begin with low voltage levels and increase gradually to avoid ventricular arrhythmias. ■ See [Drug/Lab Interactions](#).

Monitor: Hypomagnesemia, hypokalemia, and hypercalcemia may predispose patient to digoxin toxicity. Monitor electrolytes frequently during therapy. Avoid rapid changes. Supplements indicated to maintain normal serum electrolyte levels. ■ Monitor HR and BP. ■ Baseline and periodic ECG monitoring suggested. May prolong the PR interval and cause depression of the ST segment on ECG. ■ ECG monitoring recommended in pediatric patients to avoid intoxication. ■ Monitor digoxin levels. Draw at least 6 to 8 hours after last dose, preferably just before next dose. Therapeutic effects usually achieved with serum levels in a range from 0.8 to 1.5 ng/mL. Toxic threshold is equal to or greater than 2 ng/mL. ■ Monitor renal function. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Maternal/Child: Category C: use only if clearly needed. ■ Has been used to treat fetal tachycardia. ■ Use caution during breast-feeding. ■ Carefully titrate dose based on clinical response in pediatric patients with renal disease. ■ Renal clearance diminished in neonates, including premature infants; see [Dose Adjustments](#).

Elderly: Monitor carefully. Reduced dose may be indicated. Consider reduced body mass and reduced kidney function.

DRUG/LAB INTERACTIONS

Monitor serum levels carefully and adjust doses as indicated. ■ **Potassium-depleting diuretics** (e.g., furosemide [Lasix], chlorothiazide [Diuril]) are a major contributing factor to digitalis toxicity. ■ **Calcium** may produce serious arrhythmias in digitalized patients, particularly with too-rapid IV administration. ■ **Alprazolam** (Xanax), **amiodarone** (Nexterone), **indomethacin** (Indocin), **itraconazole** (Sporanox), **propafenone** (Rythmol), **quinidine**, **spironolactone** (Aldactone), and **verapamil** may raise serum digoxin concentration due to a reduction in clearance and/or in volume of distribution of digoxin. AHA states, "Reduce digoxin dose by 50% when used with **amiodarone** (Nexterone)." ■ Synergistic with **beta-blockers** (e.g., atenolol [Tenormin], metoprolol [Lopressor]) and **calcium channel blockers** (e.g., verapamil, diltiazem [Cardizem]). Additive effects on AV node conduction may result in advanced or complete heart block. ■ Both **digitalis glycosides** and **beta-blockers** slow AV conduction and decrease heart rate; concomitant use may increase risk of bradycardia. ■ Concurrent administration with **carvedilol** (Coreg) increases digoxin concentrations. Monitor digoxin with changes in carvedilol dosing. ■ **Succinylcholine** may cause a sudden extrusion of potassium from muscle cells; may cause arrhythmias in digitalized patients. ■ Increased risk of arrhythmias with **sympathomimetic amines** (e.g., epinephrine). ■ Initiation of **thyroid treatment** may require an increase in digoxin dose. ■ Serum levels and therapeutic effects may be reduced by **rifampin** (Rifadin). Impact may be increased in impaired renal function because nonrenal clearance of digoxin is increased. ■ See [Precautions and Monitor](#).

SIDE EFFECTS

Seldom last more than 3 days after drug is discontinued. Any form of digoxin may cause partial or AV block and almost any arrhythmia, including paroxysmal tachycardia, atrial tachycardia, fibrillation, or standstill.

First ECG signs of toxicity are ST segment sagging, PR prolongation, and possible bigeminal rhythm. **The most common clinical signs of toxicity in adults** are GI and cardiac disturbances. CNS side effects are less common. Other side effects include anorexia, blurred vision, confusion, diarrhea, disturbed color (yellow) vision, dizziness, headache, mental disturbances (e.g., anxiety, delirium, depression, hallucination), nausea, photopsia (points of light in peripheral vision), rash, vomiting, and weakness. Toxicity can cause death. The **most common manifestation of excessive dosing in pediatric patients** is the appearance of cardiac arrhythmias, including sinus bradycardia.

ANTIDOTE

Discontinue the drug at the first sign of toxicity and notify the physician. Dosage may be decreased or discontinued. For severe toxicity, digoxin immune Fab is a specific antidote. Consider causes of toxicity (electrolyte disturbances, thyroid, concurrent medications) and treat as indicated. Serum potassium must be obtained before administering potassium salts. See [Precautions](#). Peritoneal dialysis or hemodialysis not effective in overdose.

DIGOXIN IMMUNE FAB (OVINE)(dih-**JOX**-in im-**MYOUN** fab)**Antidote**
(digoxin intoxication)**Digibind, DigiFab****pH 6 to 8****USUAL DOSE**

Testing for sensitivity to sheep serum and/or premedication may be indicated; see **Contraindications** and **Monitor**.

Acute toxicity in adults and pediatric patients: Determine dose by symptoms and clinical findings. Serum concentration may not reflect actual toxicity for 6 to 12 hours. Symptoms of life-threatening toxicity due to digoxin overdose include severe arrhythmias (e.g., VT, VF), progressive bradycardia, second- or third-degree heart block not responsive to atropine, and/or serum potassium levels exceeding 5 to 5.5 mEq/L in adults and 6 mEq/L in pediatric patients.

Dose in numbers of vials based on ingested dose is calculated by dividing the body load of digoxin in milligrams by 0.5. Each vial of **Digibind** contains 38 mg/vial and will bind 0.5 mg digoxin. Each vial of **DigiFab** contains 40 mg/vial and will bind 0.5 mg of digoxin. Dose may also be based on serum digoxin levels (see package insert; has charts for adults and pediatric patients).

An initial dose of up to 20 vials has been used. 20 vials will bind approximately 50 (0.25 mg) tablets of Lanoxin and should provide adequate treatment of most life-threatening ingestions in adult and pediatric patients. If ingested substance is unknown, if serum digoxin level is not available, or if there is concern about sensitivity to the serum, consider giving 10 vials. Observe clinical response and repeat if indicated. In clinical trials of Digibind the average dose was 10 vials. A single dose may be repeated in several hours if toxicity has not reversed or appears to recur. Febrile reactions are dose related.

Toxicity in chronic therapy: Adults: 6 vials should be adequate to reverse most cases of toxicity in adults in acute distress or if a serum digoxin concentration is not available.

Pediatric patients: less than 20 kg: 1 vial should be adequate if signs of toxicity are present.

DILUTION

Each vial must be diluted with 4 mL of SWFI (results in 9.5 mg/mL for Digibind and 10 mg/mL for DigiFab). Mix gently. May be given in this initial dilution or may be further diluted with any desired amount of NS (with **Digibind**, 34 mL NS/vial yields 1 mg/mL; with **DigiFab**, 36 mL NS/vial yields 1 mg/mL). Consider volume overload in pediatric patients when further diluting in NS. Administer to infants after initial dilution using a tuberculin syringe to deliver an accurate dose with less volume; for extremely small doses, dilute to 1 mg/mL before administration.

Filters: Digibind: Must be given through a 0.22-micron membrane filter.

Storage: Refrigerate unreconstituted vials. Use reconstituted solution promptly or store in refrigerator for up to 4 hours.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Decrease the rate of infusion or discontinue temporarily if an infusion reaction occurs. Do not give as an IV bolus injection unless cardiac arrest is imminent. Be prepared to treat anaphylaxis.

Digibind: Must be given through a 0.22-micron membrane filter. A single dose as an IV infusion equally distributed over 15 to 30 minutes.

DigiFab: A single dose as an infusion over 30 minutes.

ACTIONS

Antigen-binding fragments (Fab) prepared from specific antidigoxin antibodies produced in sheep are isolated and purified. Fab fragments bind molecules of digoxin and make

them unavailable for binding at their site of action. Freely distributed in extracellular space. Reduces the level of free digoxin in the serum. Onset of action is prompt, with improvement in symptoms of toxicity within 30 minutes. Fab-digoxin complexes are cleared by the kidney. DigiFab is also cleared in the reticuloendothelial system.

INDICATIONS AND USES

Digibind: Treatment of patients with life-threatening digoxin intoxication or overdose (digoxin).

DigiFab: Treatment of patients with life-threatening or potentially life-threatening digoxin toxicity or overdose. Not indicated for milder cases of digoxin toxicity.

All formulations: Indicated for known suicidal or accidental consumption of fatal doses of digoxin, including ingestion of 10 mg or more of digoxin in previously healthy adults, 4 mg (or more than 0.1 mg/kg) in previously healthy pediatric patients, or ingestion causing steady-state serum concentrations greater than 10 ng/mL. ■ Indicated for chronic ingestions causing steady-state serum digoxin concentrations exceeding 6 ng/mL in adults or 4 ng/mL in pediatric patients. ■ Indicated for manifestations of life-threatening toxicity due to digoxin overdose, including severe ventricular arrhythmias (such as VT or VF), progressive bradycardia, or third-degree heart block not responsive to atropine. ■ Also indicated when potassium concentrations are above 5 to 5.5 mEq/L in adults or 6 mEq/L in pediatric patients with rapidly progressive S/S of digoxin toxicity. ■ See [Precautions](#) and [Maternal/Child](#).

CONTRAINDICATIONS

None known when used for specific indications. If hypersensitivity exists and treatment is necessary, premedicate with corticosteroids and diphenhydramine and prepare to treat anaphylaxis.

PRECAUTIONS

Administered under the direction of the physician specialist with facilities for monitoring the patient and responding to any medical emergency. Cardiac arrest can result from ingestion of more than 10 mg digoxin by healthy adults, 4 mg digoxin by healthy pediatric patients, or serum digoxin levels above 10 ng/mL. ■ Larger doses of digoxin immune Fab act more quickly but increase the possibility of febrile or hypersensitivity reactions. ■ Use caution in impaired cardiac function. Inability to use cardiac glycosides may endanger patient. Support with dopamine or vasodilators. ■ The clinical problem may not be caused by digoxin toxicity if the patient fails to respond to digoxin immune Fab. ■ Consider that multiple drugs may have been used and are producing toxicity in suicide attempts. ■ See [Monitor](#) and [Drug/Lab Interactions](#).

Monitor: Although allergy testing is not required before treating life-threatening digoxin toxicity, patients allergic to ovine proteins or those who have previously received antibodies or Fab fragments produced from sheep are at risk. Determine patient response to any previous injections of serum of any type and history of any allergic-type reactions. In addition, *DigiFab* considers that patients with allergies to papain, chymopapain, other papaya extracts, or the pineapple enzyme bromelain may be at risk. *Digibind* provides the information below on sensitivity testing; that information is not included in the package insert for *DigiFab*. ■ Test for sensitivity if indicated. Make a 1 : 100 solution by diluting 0.1 mL of reconstituted solution (10 mg/mL) with 9.9 mL sterile NS (100 mcg/mL).

Scratch test: Make a ¼-inch skin scratch through a drop of 1 : 100 dilution in NS. Inspect the site in 20 minutes. An urticarial wheal surrounded by a zone of erythema is a positive reaction.

Skin test: Inject 0.1 mL (10 mcg) of 1 : 100 dilution intradermally. Inspect the site in 20 minutes. A urticarial wheal surrounded by a zone of erythema is a positive reaction.

Concomitant use of antihistamines may interfere with sensitivity tests. If skin testing causes a systemic reaction, place a tourniquet above the testing site and treat anaphylaxis.

■ Standard treatment of digoxin intoxication includes withdrawal of the intoxicating agent, correction of electrolyte disturbances (especially hyperkalemia), acid-base imbalances, hypoxia, and treatment of cardiac arrhythmias. ■ Monitor VS, ECG, and potas-

sium concentration frequently during and after drug administration. ■ Monitor for S/S of an acute hypersensitivity reaction (e.g., angioedema, bronchospasm with wheezing or cough, erythema, hypotension, laryngeal edema, pruritus, stridor, tachycardia, urticaria). ■ Obtain serum digoxin concentrations if possible. High margin of error will occur if drawn soon after ingestion. 6 to 8 hours are required after the last digoxin dose to obtain an accurate serum concentration. ■ Potassium may be shifted from inside to outside the cell, causing increased renal excretion. May appear to have hyperkalemia while there is a total body deficit of potassium. When the digoxin effect is reversed, hypokalemia may develop rapidly. ■ Do not redigitalize until all Fab fragments have been eliminated from the body. May take several days. May take longer in severe renal impairment, and re intoxication may occur by release of newly unbound digoxin into the blood. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Maternal/Child: Category C: use only when clearly indicated and benefits outweigh risks in pregnancy, breast-feeding, and infants. ■ **Digibind** indicates that it should be used in infants and children if more than 0.3 mg of digoxin is ingested, if serum digoxin levels equal to or greater than 6.4 nmol/L, or if there is underlying heart disease.

Patient Education: Contact the physician immediately if S/S of a delayed hypersensitivity reaction or serum sickness occur (e.g., rash, pruritus, urticaria).

Elderly: Consider age-related impaired renal function; monitor closely for recurrent toxicity; see [Monitor](#).

DRUG/LAB INTERACTIONS

Will cause a precipitous rise in **total serum digoxin**, but most will be bound to the Fab fragment. Will interfere with digoxin immunoassay measurements until Fab fragment is completely eliminated. ■ **Catecholamines** (e.g., epinephrine) may aggravate digoxin arrhythmias. ■ See [skin test in Monitor](#).

SIDE EFFECTS

Acute anaphylaxis with urticaria, respiratory distress, and vascular collapse are possible. Exacerbation of congestive heart failure and low cardiac output states and increased ventricular response in atrial fibrillation may occur due to withdrawal of digoxin effects. Hypokalemia may be life threatening.

ANTIDOTE

Notify the physician of all side effects. Discontinue the drug and treat anaphylaxis immediately. Corticosteroids, epinephrine (Adrenalin [see [Drug/Lab Interactions](#)]), diphenhydramine (Benadryl), oxygen, IV fluids, vasopressors (dopamine), and ventilation equipment must always be available. Resuscitate as necessary. Treat hypokalemia cautiously when necessary. Support exacerbated cardiac conditions as necessary.

DIHYDROERGOTAMINE MESYLATE **BBW**

(dye-hy-droh-er-GOT-ah-meen MES-ih-layt)

pH 3.2 to 4

USUAL DOSE

Abort or prevent headaches: 1 mg (1 mL). May be repeated in 1 hour. No more than 2 doses (2 mg total) may be given IV in 24 hours. Do not exceed 6 mg in 1 week; see **Precautions**. Administration of an antiemetic (e.g., metoclopramide [Reglan] 10 mg) PO 1 hour before dihydroergotamine is recommended.

Chronic intractable headache: 0.5 mg (0.5 mL). Administer an antiemetic IV (e.g., metoclopramide) about 10 minutes before injection.

Prevention of orthostatic hypotension associated with spinal or epidural anesthesia (unlabeled): 0.5 mg (0.5 mL). Give a few minutes before anesthetic.

PEDIATRIC DOSE

See **Maternal/Child**. Administration of an antiemetic (e.g., metoclopramide, prochlorperazine), usually PO, 1 hour before dihydroergotamine is recommended.

Pediatric patients 6 to 9 years of age: 100 to 150 mcg (0.1 to 0.15 mg).

Pediatric patients 9 to 12 years of age: 200 mcg (0.2 mg).

Pediatric patients 12 to 16 years of age: 250 to 500 mcg (0.25 to 0.5 mg).

For all age ranges, repeat up to 2 doses at 20-minute intervals if necessary. Another source suggests 250 mcg (0.25 mg) at the start of the attack. Repeat in 1 hour if necessary.

DILUTION

May be given undiluted.

Storage: Protect ampules from light and heat.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

1 mg or fraction thereof over 1 minute.

ACTIONS

An alpha-adrenergic blocking agent that causes constriction of both peripheral and cerebral blood vessels and produces depression of central vasomotor centers. Metabolized by the liver. Metabolites eliminated primarily in feces. Secreted in breast milk.

INDICATIONS AND USES

To abort or prevent vascular headaches (migraine, histamine cephalgia). Used when rapid control is desired or other routes not feasible. ■ Treatment of chronic intractable headache.

Unlabeled uses: To prevent orthostatic hypotension associated with spinal or epidural anesthesia. Use SC to enhance heparin effects in preventing postoperative deep vein thrombosis after abdominal, thoracic, or pelvic surgeries or total hip replacement and IM or SC to treat orthostatic hypotension.

CONTRAINDICATIONS

Breast-feeding, coronary artery disease, hepatic or renal disease, hypersensitivity, uncontrolled hypertension, peripheral vascular disease, pregnancy or women who may become pregnant, sepsis. ■ Coadministration with potent CYP3A4 inhibitors, including protease inhibitors and macrolide antibiotics, is contraindicated; see **Drug/Lab Interactions**.

PRECAUTIONS

IM or SC use is preferred but may be given IV to obtain a more rapid effect. ■ Coadministration with potent CYP3A4 inhibitors, including protease inhibitors and macrolide antibiotics, increases the risk of vasospasm, leading to cerebral ischemia and/or ischemia of the extremities (peripheral). May be serious and/or life threatening; see **Contraindications** and **Drug/Lab Interactions**. ■ Use

only when a clear diagnosis of migraine has been established. Do not exceed dosing guidelines or use for chronic daily administration; see [Usual Dose](#).

Monitor: Monitor vital signs; observe closely. ■ See [Drug/Lab Interactions](#).

Patient Education: Consider birth control options. ■ Take only as directed. ■ Report ineffectiveness or an increase in frequency or severity of headaches. ■ Report chest pain, increased HR, itching, muscle pain or weakness of arms or legs, numbness or tingling of extremities, or swelling.

Maternal/Child: Category X: avoid pregnancy. See [Contraindications](#). ■ Safety for use in pediatric patients not established. Severe side effects (e.g., extrapyramidal reactions may occur). Pretreatment with an antiemetic may be helpful. Limit pediatric use to patients who have not responded to less toxic treatment.

Elderly: Increased risk of hypothermia and ischemic complications (e.g., cardiac, peripheral). ■ Consider age-related renal impairment.

DRUG/LAB INTERACTIONS

Contraindicated with potent CYP3A4 inhibitors, including **antifungals** (itraconazole [Sporanox], ketoconazole [Nizoral]), **protease inhibitors** (ritonavir [Norvir], nelfinavir [Viracept], and indinavir [Crixivan]), and **macrolide antibiotics** (clarithromycin [Biaxin], erythromycin, and troleandomycin [TAO]); see [Contraindications](#) and [Precautions](#). ■ Administer less potent CYP3A4 inhibitors with caution as vasospasm may occur. **Less potent inhibitors** include, but are not limited to, saquinavir (Invirase), nefazodone, fluconazole (Diflucan), grapefruit juice, fluoxetine (Prozac), fluvoxamine (Luvox), zileuton (Zyflo), and clotrimazole (Gyne-Lotrimin, Mycelex). ■ Opposes vasodilating effects of **nitrates** (e.g., nitroglycerin), decreasing their effectiveness. ■ May cause hypertensive crisis in combination with other **vasopressors** (e.g., epinephrine). ■ May cause peripheral vasoconstriction with ischemia and/or cyanosis with **beta-adrenergic blockers** (e.g., propranolol [Inderal]) and **nicotine**.

SIDE EFFECTS

Rare in therapeutic doses, but may include angina pectoris, blindness, gangrene, muscle pains, muscle weakness, nausea, numbness and tingling of the fingers and toes, pleural and retroperitoneal fibrosis, thirst, uterine bleeding, and vomiting.

ANTIDOTE

Discontinue the drug and notify the physician of any side effects. Another drug will probably be chosen if further treatment is indicated. Vasodilators (nitroprusside sodium) and CNS stimulants (e.g., caffeine and sodium benzoate) are indicated as an antidote. Heparin and low-molecular-weight dextran may be used to reduce thrombosis due to excessive vasoconstriction. Hemodialysis may be indicated. Resuscitate as necessary.

DILTIAZEM HYDROCHLORIDE

(dill-TYE-a-zem hy-droh-KLOR-eyed)

**Calcium channel blocker
Antiarrhythmic****Cardizem****pH 3.7 to 4.1****USUAL DOSE**

0.25 mg/kg of body weight initially (20 mg for the average patient). Some patients may respond to an initial dose of 0.15 mg/kg. A second dose of 0.35 mg/kg may be given in 15 minutes if needed to achieve HR reduction (25 mg for the average patient). Any additional bolus doses used to achieve an appropriate response must be individualized to each patient. Patients with PSVT will probably respond to bolus doses and may not require an infusion, but to maintain reduction in HR in patients with atrial fibrillation or atrial flutter, immediately follow with an intravenous infusion at an initial rate of 10 mg/hr. May only be used for up to 24 hours. Some patients may maintain response with an initial rate of 5 mg/hr. Infusion may be increased by 5 mg/hr increments to a maximum dose of 15 mg/hr. Discontinue infusion within 24 hours. Oral antiarrhythmic agents (e.g., digoxin, quinidine, procainamide, calcium channel blockers [e.g., diltiazem, verapamil], beta blockers [e.g., atenolol, metoprolol, propranolol]) to maintain reduced HR are usually started within 3 hours of initial bolus of diltiazem.

DOSE ADJUSTMENTS

Specific mg/kg dose must be used for patients with low body weights. ■ Reduced dose may be indicated in impaired hepatic or renal function. ■ Dose selection should be cautious in the elderly. Reduced doses may be indicated based on potential for decreased organ function and concomitant disease or drug therapy. ■ See [Drug/Lab Interactions](#).

DILUTION

Available as a solution in 25- or 50-mg vials (5 mg/mL), as a powder with supplied diluent (Lyo-ject syringe 25 mg [5 mg/mL]), and in a piggyback monovial containing 100 mg (with transfer needle set to facilitate preparation of an infusion). Dilute according to the following charts.

Cardizem Injectable or Cardizem Lyo-Ject Syringe				
Diluent Volume	Quantity of Cardizem (Diltiazem) Injection	Final Concentration	Administration	
			Dose	Infusion Rate
100 mL	125 mg (25 mL)	1 mg/mL	5 mg/hr 10 mg/hr 15 mg/hr	5 mL/hr 10 mL/hr 15 mL/hr
250 mL	250 mg (50 mL)	0.83 mg/mL	5 mg/hr 10 mg/hr 15 mg/hr	6 mL/hr 12 mL/hr 18 mL/hr
500 mL	250 mg (50 mL)	0.45 mg/mL	5 mg/hr 10 mg/hr 15 mg/hr	11 mL/hr 22 mL/hr 33 mL/hr
100 mL	100 mg (1 monovial)	1 mg/mL	5 mg/hr 10 mg/hr 15 mg/hr	5 mL/hr 10 mL/hr 15 mL/hr
250 mL	200 mg (2 monovials)	0.8 mg/mL	5 mg/hr 10 mg/hr 15 mg/hr	6.25 mL/hr 12.5 mL/hr 18.8 mL/hr
500 mL	200 mg (2 monovials)	0.4 mg/mL	5 mg/hr 10 mg/hr 15 mg/hr	12.5 mL/hr 25 mL/hr 37.5 mL/hr

IV injection: May be given undiluted through Y-tube or three-way stopcock of tubing containing NS, D5W, or D5¹/₂NS.

Infusion: May be further diluted for infusion in any of the above solutions.

Filters: No data available from manufacturer.

Storage: Vials may be stored at room temperature for up to 1 month, then discarded. Refrigeration before and after dilution preferred. Use within 24 hours of dilution. Discard unused medication and/or solution. Do not freeze.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends that **all formulations** not be mixed with any other drugs in the same container and, if possible, that they not be co-infused in the same IV line.

Cardizem Lyo-Ject Syringe is listed by the manufacturer as **incompatible** at the **Y-site** with acetazolamide (Diamox), acyclovir (Zovirax), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), diazepam (Valium), furosemide (Lasix), hydrocortisone sodium succinate (Solu-Cortef), methylprednisolone (Solu-Medrol), mezlocillin (Mezlin), nafcillin (Nallpen), phenytoin (Dilantin), rifampin (Rifadin), sodium bicarbonate. **Cardizem** is listed as **incompatible** with all of the above and insulin (regular).

Cardizem Monovial is listed by the manufacturer as **incompatible** at the **Y-site** with acetazolamide (Diamox), acyclovir (Zovirax), diazepam (Valium), furosemide (Lasix), phenytoin (Dilantin), rifampin (Rifadin).

Manufacturer lists **Cardizem Lyo-Ject Syringe** as **compatible** at the **Y-site** with insulin (regular) and lists the **Cardizem Monovial** (1 mg/mL) in NS as **compatible** at the **Y-site** with aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), hydrocortisone sodium succinate (Solu-Cortef), insulin (regular), methylprednisolone (Solu-Medrol), mezlocillin (Mezlin), nafcillin (Nallpen), sodium bicarbonate.

One source lists the following **compatibilities** but does not differentiate formulations:
Y-site: Acetazolamide (Diamox), acyclovir (Zovirax), albumin, amikacin (Amikin), aminophylline, amphotericin B (conventional), ampicillin, ampicillin/sulbactam (Unasyn), argatroban, aztreonam (Azactam), bivalirudin (Angiomax), bumetanide, caspofungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftazoline (Teflaro), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), ciprofloxacin (Cipro IV), clindamycin (Cleocin), dexmedetomidine (Precedex), digoxin (Lanoxin), dobutamine, dopamine, doripenem (Doribax), doxycycline, epinephrine (Adrenalin), erythromycin (Erythrocin), esmolol (Brevibloc), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), gentamicin, heparin, hetastarch in electrolytes (Hextend), hetastarch in NS (Hespan), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), imipenem-cilastatin (Primaxin), labetalol, lidocaine, lorazepam (Ativan), meperidine (Demerol), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metoprolol (Lopressor), metronidazole (Flagyl IV), midazolam (Versed), milrinone (Primacor), morphine, multivitamins (M.V.I.), nafcillin (Nallpen), nesiritide (Natrecor), nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), oxacillin (Bactocill), penicillin G potassium, pentamidine, potassium chloride (KCl), potassium phosphates, procaainamide (Pronestyl), ranitidine (Zantac), sodium bicarbonate, sulfamethoxazole/trimethoprim, telavancin (Vibativ), theophylline, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vasopressin, vecuronium.

RATE OF ADMINISTRATION

IV injection: Each single dose equally distributed over 2 minutes.

Infusion: 5 mg to 15 mg/hr based on patient response. See **charts under Dilution** for diluent, dose, and infusion rate information. Use of a metriset (60 gtt/min) required; volumetric infusion pump preferred.

ACTIONS

Directly inhibits the influx of calcium ions through slow channels during membrane depolarization of cardiac and vascular smooth muscle. Effective in supraventricular

tachycardias because it slows conduction through the AV node, prolongs the effective refractory period, reduces ventricular rates, and helps to prevent embolic complications. Also slows conduction through the SA node. Prevents reentry phenomena through the AV node. Reduces HR (10% with a single dose, 20% at peak effectiveness), systolic and diastolic BP, systemic vascular resistance, pulmonary artery systolic and diastolic BPs, and coronary vascular resistance with no significant effect on contractility, left ventricular end diastolic pressure, right atrial pressure, or pulmonary capillary wedge pressure. Increases cardiac output and stroke volume. Has little or no effect on normal AV nodal conduction at normal HRs. Produces less myocardial depression than verapamil. Effective within 3 minutes; maximum effect should occur within 2 to 7 minutes and last for 1 to 3 hours. 70% to 80% bound to plasma proteins. Metabolized in the liver. Half-life is approximately 3.4 hours following a bolus injection and increases to 4.1 to 4.9 hours with continuous infusion. Excreted in urine and bile. Secreted in breast milk.

INDICATIONS AND USES

Temporary control of rapid ventricular rate in atrial fibrillation or atrial flutter unless associated with an accessory bypass tract (e.g., Wolff-Parkinson-White syndrome or short PR syndrome). ■ Rapid conversion of paroxysmal supraventricular tachycardia (PSVT) to normal sinus rhythm including AV nodal reentrant tachycardias and reciprocating tachycardias associated with an extranodal accessory pathway (e.g., Wolff-Parkinson-White syndrome or short PR syndrome).

CONTRAINDICATIONS

Atrial fibrillation or flutter when associated with an accessory bypass tract (e.g., Wolff-Parkinson-White or short PR syndrome), cardiogenic shock, congestive heart failure (severe) unless secondary to supraventricular tachyarrhythmia treatable with diltiazem, known sensitivity to diltiazem, second- or third-degree AV block or sick sinus syndrome (unless functioning ventricular pacemaker in place), severe hypotension, patients receiving IV beta-adrenergic blocking agents (e.g., atenolol [Tenormin], propranolol [Inderal]) within 2 to 4 hours, ventricular tachycardia. Not recommended for wide QRS tachycardias of uncertain origin or for tachycardias induced by drugs or poisons.

PRECAUTIONS

For short-term use only. ■ Initial administration of IV diltiazem should take place in a facility with adequate personnel, equipment, and supplies to monitor the patient and respond to any medical emergency. ■ While diltiazem will effectively decrease HR, cardioversion will probably be required to convert atrial fibrillation or atrial flutter to a normal sinus rhythm. ■ Valsalva maneuver recommended before use of diltiazem in all paroxysmal supraventricular tachycardias if clinically appropriate. ■ Use IV diltiazem with caution in patients with pre-existing impaired ventricular function (e.g., congestive heart failure, acute myocardial infarction or pulmonary congestion documented by x-ray); may exacerbate disease. Use of oral diltiazem in these patients is contraindicated. ■ May cause second- or third-degree AV block in sinus rhythm; discontinue diltiazem if AV block occurs. ■ Can cause life-threatening tachycardia with severe hypotension in atrial fibrillation or flutter in patients with an accessory bypass tract and periods of asystole in patients with sick sinus syndrome. ■ Use with caution in impaired renal or hepatic function. ■ Ventricular premature beats (VPBs) may occur on conversion of PSVT to sinus rhythm; considered to have no clinical significance. ■ Continue regular dosing on day of OR and thereafter unless otherwise specified by physician. If discontinued, may cause severe angina or MI.

Monitor: Accurate pretreatment diagnosis differentiating wide-complex QRS tachycardia of supraventricular origin from ventricular origin is imperative. ■ ECG monitoring during administration preferred; must be available. ■ Monitor BP and HR closely. ■ Emergency resuscitation drugs and equipment must always be available. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: large doses (5 to 10 times mg/kg dose) have resulted in embryo and fetal death and skeletal abnormalities in animals. ■ Discontinue breastfeeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: See *Dose Adjustments*. ■ Half-life may be prolonged. ■ May cause tinnitus.

DRUG/LAB INTERACTIONS

Do not give concomitantly (within a few hours) with IV **beta-adrenergic blocking agents** (e.g., atenolol [Tenormin], propranolol [Inderal]); see *Contraindications*. May result in bradycardia, AV block, and/or depression of contractility. Use extreme caution if these drugs are administered orally or if patient has received before admission; usually tolerated. ■ May result in additive effects with **any agent known to affect cardiac contractility and/or SA or AV node conduction** (e.g., digoxin [Lanoxin], disopyramide [Norpace], procainamide [Pronesty], beta-blockers [e.g., propranolol], quinidine). ■ Is used with **digoxin**, but monitor for excessive slowing of HR and/or AV block. ■ Coadministration with **amiodarone** (Nexterone) may result in bradycardia and decreased cardiac output. Monitor closely. ■ May increase effects of certain **benzodiazepines** (e.g., midazolam [Versed], triazolam [Halcion]), **buspirone** (BuSpar), **methylprednisolone** (Solu-Medrol). ■ May increase serum concentrations of **digoxin**, **HMG-CoA reductase inhibitors** (e.g., atorvastatin [Lipitor], simvastatin [Zocor]), **imipramine** (Tofranil), **sirolimus** (Rapamune), and **tacrolimus** (Prograf). Monitor serum levels and/or monitor for S/S of toxicity. ■ May potentiate **anesthetics**; titrate both drugs carefully. ■ May decrease metabolism and increase serum concentrations and toxicity of **drugs metabolized by the cytochrome P₄₅₀ enzyme system** (e.g., amlodipine [Norvasc], carbamazepine [Tegretol], cyclosporine [Sandimmune], quinidine, theophylline, valproate [Depacon]). ■ Metabolism may be decreased and serum concentrations increased by **cimetidine** (Tagamet) and **ranitidine** (Zantac). ■ Metabolism may be increased and serum concentrations decreased by **rifampin** (Rifadin). Adjust dose as needed. ■ May increase **moricyzine** (Ethmozine) serum concentrations. Moricyzine may decrease diltiazem concentrations. ■ May increase **nifedipine** (Procardia) serum concentrations; nifedipine may increase diltiazem serum concentrations. ■ Variable effects when administered with **lithium**. Has caused decreased effectiveness of lithium and may cause neurotoxicity. ■ **Any drug metabolized in the liver** may cause competitive inhibition of metabolism (e.g., insulin).

SIDE EFFECTS

Arrhythmia (junctional rhythm or isorhythmic dissociation), flushing, hypotension (asymptomatic and symptomatic), and injection site reactions (burning, itching) occurred most frequently and were most often mild and transient but could have serious potential. Amblyopia, asthenia, atrial flutter, AV block (first- or second-degree), bradycardia, chest pain, congestive heart failure, constipation, dizziness, dry mouth, dyspnea, edema, elevated alkaline phosphatase and AST, headache, hyperuricemia, nausea, paresthesia, pruritus, sinus node dysfunction, sinus pause, skin eruptions (including rare reports of exfoliative dermatitis or Stevens-Johnson syndrome), sweating, syncope, ventricular arrhythmias, ventricular fibrillation, ventricular tachycardia, and vomiting have occurred.

ANTIDOTE

Discontinue diltiazem if a high-degree AV block occurs in sinus rhythm. Notify physician promptly of all side effects. Treatment will depend on clinical situation; maintain IV fluids as indicated. Rapid ventricular response in atrial flutter/fibrillation should respond to cardioversion, procainamide, and/or lidocaine. Treat bradycardia, AV block, and asystole with standard AHA protocol (atropine, isoproterenol, pacing). Treat cardiac failure with inotropic agents (isoproterenol, dopamine, or dobutamine) and diuretics. Calcium chloride will reverse effects of verapamil; may be useful with diltiazem. Dopamine or norepinephrine (levarterenol) and Trendelenburg position should reverse hypotension. Treat hypersensitivity reactions or resuscitate as necessary. Not removed by hemodialysis.

DIPHENHYDRAMINE HYDROCHLORIDE

(dye-fen-**HY**-drah-meen
hy-droh-**KLOR**-eyed)

Antihistamine
Antidyskinetic/antiparkinsonism
Antiemetic
Antivertigo agent
Sedative-hypnotic

Benadryl, Benadryl PF, Diphenhydramine PF

pH 5 to 6

USUAL DOSE

10 to 50 mg. Up to 100 mg may be given. Individualize dose based on patient symptoms and response. Total dosage should not exceed 400 mg/24 hr.

PEDIATRIC DOSE

See [Contraindications](#) and [Maternal/Child](#).

Pediatric patients after neonatal period: 1.25 mg/kg/dose every 6 hours as needed or 150 mg/M²/24 hr in equally divided doses given every 6 hours (37.5 mg/M² every 6 hours). Never exceed a total dosage of 300 mg/24 hr.

Anaphylaxis or phenothiazine overdose: 1 to 2 mg/kg IV slowly.

DOSE ADJUSTMENTS

Reduce dose for the elderly or debilitated. ■ See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted.

Filters: No data available from manufacturer.

Storage: Store below 40° C (104° F), preferably between 15° and 30° C (59° and 86° F). Protect from light and freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Amikacin (Amikin), aminophylline, ascorbic acid, bleomycin (Blenoxane), colistimethate (Coly-Mycin M), erythromycin (Erythrocin), lidocaine, methylodopate, nafcillin (Nallpen), penicillin G potassium and sodium.

Y-site: Abciximab (ReoPro), acyclovir (Zovirax), aldesleukin (Proleukin), amifostine (Ethyol), argatroban, azithromycin (Zithromax), aztreonam (Azactam), bivalirudin (Angiomax), caspofungin (Cancidas), ceftaroline (Teflaro), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), docetaxel (Taxotere), doripenem (Doribax), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopan), fentanyl (Sublimaze), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), gallium nitrate (Ganite), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), linezolid (Zyvox), melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), methadone (Dolophine), morphine, ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), teniposide (Vumon), thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

25 mg or fraction thereof over 1 minute. Extend injection time in nonemergency situations and pediatric patients. See [Maternal/Child](#).

ACTIONS

A potent antihistamine, it is capable of blocking the effects of histamine at various receptor sites, either eliminating a hypersensitivity reaction or greatly modifying it. It also has anticholinergic (antispasmodic), antiemetic, antvertigo, and sedative effects. It has rapid onset of action and is widely distributed throughout the body, including the CNS. A portion of this drug is metabolized in the liver; the rest is excreted unchanged in the urine. Half-life is 1 to 4 hours. Some secretion may occur in breast milk.

INDICATIONS AND USES

Allergic reactions to blood or plasma. ■ Supplemental therapy to epinephrine in anaphylaxis and other uncomplicated allergic/hypersensitivity reactions requiring prompt treatment (e.g., angioedema, pruritus, urticaria). ■ Preoperative or generalized sedation. ■ Management of parkinsonism, including drug-induced (e.g., phenothiazines [e.g., prochlorperazine (Compazine)]). ■ Severe nausea and vomiting. ■ Motion sickness. ■ To replace oral therapy when it is impractical or contraindicated.

CONTRAINDICATIONS

Breast-feeding, hypersensitivity to antihistamines, newborn or premature infants.

PRECAUTIONS

IV route used only in emergency situations. ■ Avoid SC or perivascular injection. ■ Use with extreme caution in infants, children, elderly or debilitated individuals, asthmatic attack, bladder neck obstruction, narrow-angle glaucoma, lower respiratory tract infections, prostatic hypertrophy, pyloroduodenal obstruction, and stenosing peptic ulcer.

Monitor: Will induce drowsiness. ■ Monitor vital signs; observe closely. ■ See [Drug/Lab Interactions](#).

Patient Education: Do not drive or operate hazardous equipment until effects wear off. ■ May cause drowsiness and dizziness; request help to ambulate. ■ Avoid alcohol and other CNS depressants (e.g., diazepam [Valium], narcotics).

Maternal/Child: See [Contraindications](#), [Precautions](#), [Monitor](#), and [Side Effects](#). ■ Category B: use only when clearly needed. May increase risk of abnormalities during the first trimester. ■ Not recommended during breast-feeding. Small amounts may be distributed into breast milk, causing irritability or excitement in infants. ■ Use extreme caution in infants and children; may cause hallucinations, convulsions, or death. May also reduce mental alertness and cause paradoxical excitation.

Elderly: See [Dose Adjustments](#), [Precautions](#), [Monitor](#), and [Side Effects](#). ■ May cause confusion, dizziness, hyperexcitability, hypotension and/or sedation. ■ Sensitivity to anticholinergic effects is increased (e.g., blurred vision, constipation, dry mouth, urinary retention).

DRUG/LAB INTERACTIONS

Increases effectiveness of **epinephrine** and is often used in conjunction with it. ■ Potentiates **anticholinergics** (e.g., atropine); **alcohol**, **beta-blockers** (e.g., metoprolol [Lopressor], propranolol [Inderal]), **hypnotics**, **itraconazole** (Sporanox), **sedatives**, **tranquilizers**, and **other CNS depressants** (e.g., reserpine, antipyretics); **thioridazine** (Mellaril); **procarbazine** (Matulane); and **others**. Reduced dose of potentiated drug may be indicated. ■ Anticholinergic and CNS sedative effects prolonged by **MAO inhibitors** (e.g., selegiline [Eldepryl]). Concurrent use not recommended. ■ Effectiveness of many drugs is reduced in combination with diphenhydramine because of increased metabolism. ■ May inhibit the wheal and flare reaction to **antigen skin tests**.

SIDE EFFECTS

Rare when used as indicated: anaphylaxis; blurring of vision; confusion; constipation; diarrhea; difficulty in urination; diplopia; drowsiness; drug rash; dryness of mouth, nose, and throat; epigastric distress; headache; hemolytic anemia; hypotension; insomnia; nasal stuffiness; nausea; nervousness; palpitations; photosensitivity; rapid pulse; restlessness; thickening of bronchial secretions; tightness of the chest and wheezing; tingling, heaviness, weakness of hands; urticaria; vertigo; vomiting. Overdose may cause convulsions, hallucinations, and death in pediatric patients.

ANTIDOTE

For exaggerated drowsiness or other disturbing side effects, discontinue the drug and notify the physician. Side effects will usually subside within a few hours or may be treated symptomatically. Treat hypotension promptly; may lead to cardiovascular collapse. Use dopamine, norepinephrine, or phenylephrine. Epinephrine is contraindicated for hypotension; further hypotension will occur. Propranolol (Inderal) is the drug of choice for ventricular arrhythmias. Treat convulsions with diazepam (Valium) 0.1 mg/kg IV slowly. Some central anticholinergic effects may require physostigmine. Avoid anaesthetics (e.g., caffeine); may cause convulsions. Epinephrine must be available to treat anaphylaxis. Resuscitate as necessary.

DIPYRIDAMOLE

(dye-peer-ID-ah-mohl)

Coronary vasodilator

Diagnostic agent

Platelet aggregation inhibitor

Persantine

pH 2.2 to 3.2

USUAL DOSE

Myocardial perfusion imaging: 0.57 mg/kg of body weight equally distributed over 4 minutes (0.142 mg/kg/min). A 70-kg adult would receive a total dose of 39.9 mg (10 mg/min). Maximum dose is 60 mg. Thallium should be injected within 5 minutes following the 4-minute infusion of dipyridamole.

Platelet aggregation inhibitor (unlabeled): 250 mg/24 hr as an infusion.

DILUTION

Each 1 mL (5 mg) must be diluted with a minimum of 2 mL D5W, D5¹/₂NS, or D5NS. Total volume should range from a minimum of 20 mL to 50 mL (39.9 mg [8 mL] would be diluted in a minimum of 16 mL for a total infusion of 24 mL; additional diluent can be used to facilitate titration). May not be given undiluted; will cause local irritation.

Platelet aggregation inhibitor: Each 250-mg dose should be diluted with 250 mL D5W (1 mg/mL). Concentration may be increased if larger doses required.

Storage: Undiluted drug should be stored at CRT and protected from direct light; avoid freezing.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

A single dose must be equally distributed over 4 minutes (0.142 mg/kg/min).

Platelet aggregation inhibitor: 10 mg/hr as a continuous infusion. Use of a microdrip (60 gtt/mL) or infusion pump recommended.

ACTIONS

A coronary vasodilator that will cause an increase in coronary blood flow velocity of from 3.8 to 7 times greater than resting velocity. Action may result from the inhibition of adenosine uptake. Peak velocity is reached in 2.5 to 8.7 minutes. Will cause a 20% increase in HR and a mild but significant decrease in systolic and diastolic BP in the supine position. Vital signs may take up to 30 minutes to return to baseline measurements. Used in combination with thallium, visualization shows dilation with sustained enhanced flow of intact vessels, leaving reduced pressure and flow across areas of hemodynamically important coronary vascular constriction. Results achieved are comparable to exercise-induced thallium imaging. Metabolized in the liver. Excreted in bile. Secreted in breast milk.

INDICATIONS AND USES

An alternative to exercise in thallium myocardial perfusion imaging for the evaluation of coronary artery disease in patients who cannot exercise adequately.

Unlabeled uses: Prophylactic inhibition of platelet aggregation in thromboembolism and myocardial infarction.

CONTRAINDICATIONS

Hypersensitivity to dipyridamole.

PRECAUTIONS

Administered by or under the direction of the cardiologist. ■ Full facilities for treatment of any airway, cardiac emergency, or hypersensitivity, including laboratory analysis, must be available. ■ Theophylline (Aminophylline) and other emergency drugs must be immediately available. ■ Patients with a history of unstable angina or a history of asthma may be at greater risk; use extreme caution. ■ This drug has caused two fatal myocardial infarctions as well as other serious side effects in a small percentage of patients; clinical information to be gained must be weighed against risk to the patient.

Monitor: An IV line with a Y-tube or three-way stopcock must be in place. ■ Monitor vital signs continuously during infusion and for at least 15 minutes after or until return to baseline. ■ ECG monitoring using at least 1 chest lead should be continuous. ■ Patient is usually in a supine position, but tests have been conducted in a sitting position. Lower to supine with head tilted down (Trendelenburg) if hypotension occurs.

Maternal/Child: Category B; safety for use during pregnancy not established. Use only if clearly needed. ■ Temporarily discontinue breast-feeding. ■ Safety for use in pediatric patients not established.

DRUG/LAB INTERACTIONS

Theophylline bronchodilators (e.g., aminophylline, oxtriphylline [Choledyl], theophylline) reverse the effect of dipyridamole on myocardial blood flow. Interferes with dipyridamole-assisted **myocardial perfusion studies**. Withhold bronchodilators for 36 hours before testing.

SIDE EFFECTS

BP lability, chest pain/angina pectoris, dizziness, dyspnea, ECG abnormalities (e.g., extrasystoles, ST-T changes, tachycardia), fatigue, flushing, headache, hypertension, hypotension, nausea, pain (unspecified), paresthesia. Numerous other side effects occur in less than 1% of patients.

Major: Bronchospasm, cerebral ischemia (transient), fatal and nonfatal myocardial infarction, ventricular fibrillation, ventricular tachycardia (symptomatic) occurred in 0.3% of patients.

ANTIDOTE

Physician will be present throughout test administration. Theophylline (Aminophylline) is an adenosine receptor antagonist and will reverse the adenosine-mediated effects of dipyridamole (e.g., angina pectoris, bronchospasm, severe hypotension, ventricular arrhythmias). If bronchospasm or chest pain occur, administer 50 to 250 mg of theophylline at a rate not to exceed 50 mg over 30 seconds. If symptoms are not relieved by 250 mg of theophylline, sublingual nitroglycerin may be helpful. Persistent chest pain may indicate impending potentially fatal myocardial infarction. If patient condition permits, thallium may be injected and allowed to circulate for 1 minute before injection of theophylline; this will permit initial thallium perfusion imaging before reversal of vasodilatory effects of dipyridamole on coronary circulation. Use head-down supine position for hypotension before administering theophylline. After reversal of vasodilatory action, treat arrhythmias as indicated. Resuscitate as necessary.

DOBUTAMINE HYDROCHLORIDE

(doh-**BYOU**-tah-meen hy-droh-**KLOR**-eyed)

Inotropic agent
Cardiac stimulant

pH 2.5 to 5.5

USUAL DOSE

0.5 to 1 mcg/kg/min initially in patients likely to respond to minimum treatment. The usual effective initial dose ranges from 2.5 to 15 mcg/kg of body weight/min. AHA guidelines suggest 2 to 20 mcg/kg/min. Gradually adjust rate at 2- to 10-minute intervals to effect desired response. AHA guidelines recommend titrating so HR does not increase by more than 10% of baseline. Up to 40 mcg/kg/min has been used in some instances; increases potential for toxicity (e.g., myocardial ischemia). U.S. experience in controlled trials does not extend beyond 48 hours of therapy.

PEDIATRIC DOSE

2 to 20 mcg/kg/min. Initial dose usually 5 to 10 mcg/kg/min. Adjust rate to effect desired response; see [Maternal/Child](#).

DOSE ADJUSTMENTS

Lower-end initial doses may be appropriate in the elderly based on potential for decreased organ function, concomitant disease, or other drug therapy. See [Drug/Lab Interactions](#).

DILUTION

Available prediluted in D5W, or each 250-mg (20-mL) vial must be further diluted to at least 50 mL. Any amount of infusion solution desired above 50 mL may be used (250 mg in 1 L equals 250 mcg/mL; 250 mg in 500 mL equals 500 mcg/mL; 250 mg in 250 mL equals 1,000 mcg/mL). Adjust to fluid requirements of the patient. **Compatible** with D5W, D10W, D5 $\frac{1}{2}$ NS, D5NS, D5/Isolyte M, LR, D5LR, Normosol-M in D5W, 20% Osmitol in water, NS, or sodium lactate.

Filters: No data available from manufacturer. Another source suggests no significant drug loss through a 0.22-micron cellulose ester membrane filter.

Storage: When mixed in infusion solution, use within 24 hours. Pink coloring of solution does not affect potency; will crystallize if frozen.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not add to sodium bicarbonate or any other strongly alkaline solution" (e.g., aminophylline, barbiturates [e.g., phenobarbital (Luminal)]). Manufacturer recommends not using other drugs as additives, not using in conjunction with other agents, and not using with diluents containing both sodium bisulfate and ethanol.

One source suggests the following **compatibilities**:

Additive: Not recommended by manufacturer. Amiodarone (Nexterone), atracurium (Tracrium), atropine, calcium chloride, ciprofloxacin (Cipro IV), dopamine, enalaprilat (Vasotec IV), epinephrine (Adrenalin), flumazenil (Romazicon), heparin, hydralazine, isoproterenol (Isuprel), lidocaine, meperidine (Demerol), meropenem (Merrem IV), morphine, nitroglycerin IV, norepinephrine (Levophed), phentolamine (Regitine), phenylephrine (Neo-Synephrine), potassium chloride (KCl), procainamide (Pronestyl), propranolol (Inderal), ranitidine (Zantac), verapamil, zidovudine (AZT, Retrovir).

Y-site: Not recommended by manufacturer. Alprostadil, amifostine (Ethyol), amiodarone (Nexterone), anidulafungin (Eraxis), argatroban, atracurium (Tracrium), aztreonam (Azactam), bivalirudin (Angiomax), calcium chloride, calcium gluconate, caspofungin

(Cancidas), cefepime (Maxipime), ceftaroline (Teflaro), ceftazidime (Fortaz), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cladribine (Leustatin), dexmedetomidine (Precedex), diazepam (Valium), diltiazem (Cardizem), docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), epinephrine (Adrenalin), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), furosemide (Lasix), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), insulin (regular), labetalol, levofloxacin (Levaquin), lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, meperidine (Demerol), midazolam (Versed), milrinone (Primacor), morphine, nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), oxaliplatin (Eloxatin), pancuronium, potassium chloride (KCl), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), tacrolimus (Prograf), telavancin (Vibativ), theophylline, thiotepa, tigecycline (Tygacil), tirofiban (Aggrastat), vasopressin, vecuronium, verapamil, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Begin with recommended dose for body weight and seriousness of condition. Gradually increase to effect desired response. May take up to 10 minutes to achieve peak effect of a specific dose. Maintain at correct therapeutic level with microdrip (60 gtt/mL) or infusion pump. Half-life of dobutamine is only about 2 minutes. See Maternal/Child.

Infusion Rate (mL/hr) for Dobutamine 500 mcg/mL

ACTIONS

A synthetic catecholamine chemically related to dopamine, it is a direct-acting inotropic agent possessing beta-stimulator activity. Induces short-term increases in cardiac output by improving stroke volume with minimum increases in rate and BP, minimum rhythm disturbances, and decreased peripheral vascular resistance. Usually most effective for only a few hours. May improve atrioventricular conduction. Peak effect obtained in 2 to 10 minutes. Has a very short duration of action. Half-life is 2 minutes; may be up to 5 minutes in preterm infants. Metabolized in the liver and other tissues. Metabolites are primarily excreted in the urine.

INDICATIONS AND USES

Short-term inotropic support in cardiac decompensation resulting from depressed contractility (organic heart disease or cardiac surgical procedures).

Unlabeled uses: Increase cardiac output in pediatric patients with congenital heart disease undergoing cardiac catheterization.

CONTRAINDICATIONS

Hypersensitivity to any components (contains sulfites), idiopathic hypertrophic subaortic stenosis, shock without adequate fluid replacement.

PRECAUTIONS

Use extreme caution in myocardial infarction; increases in HR of more than 10% may increase myocardial ischemia and size of infarction. ■ Contains sulfites; use caution in patients with allergies. ■ Precipitous hypotension occurs rarely; usually reverses with a decrease in rate of administration; see **Antidote**. ■ Ineffective if marked mechanical obstruction (e.g., severe valvular aortic stenosis) is present. ■ Use for long-term treatment of CHF has been associated with increased risks of hospitalization and death.

Monitor: Correct hypovolemia and acidosis as indicated before initiating treatment. ■ Observe patient's response continuously; monitor HR, ectopic activity, BP, and urine flow. Measure pulmonary wedge pressure, central venous pressure, and cardiac output if possible. ■ May cause significant increase in BP or HR, especially systolic pressure. Patients with pre-existing hypertension may be at increased risk of developing an increased pressor response. ■ Monitor for changes in fluid balance, electrolytes, and acid-base balance. ■ Use digoxin preparation before starting dobutamine in patients with atrial fibrillation with rapid ventricular response. ■ See **Drug/Lab Interactions**.

Maternal/Child: Category B; use only if benefits outweigh risks. Safety for use in pregnancy, breast-feeding, and pediatric patients not established. ■ Increases cardiac output and systemic BP in pediatric patients of every age-group, usually at infusion rates that are lower than those that cause significant tachycardia. Less effective than dopamine in premature neonates.

Elderly: Lower-end initial doses may be indicated; see **Dose Adjustments**. ■ Differences in response compared to younger adults not identified, but greater sensitivity of some elderly cannot be ruled out.

DRUG/LAB INTERACTIONS

May be ineffective if **beta-blocking drugs** (e.g., propranolol [Inderal]) have been given. ■ Produces higher cardiac output and lower pulmonary wedge pressure when given concomitantly with **nitroprusside sodium**. ■ May cause serious arrhythmias in presence of **cyclopropane** or **halogen anesthetics**, severe hypertension with **oxytocic drugs**, or **guanethidine** (Ismelin). ■ Pressor response increased with **tricyclic antidepressants** (e.g., amitriptyline [Elavil], imipramine [Tofranil]) and **rauwolfia alkaloids** (e.g., reserpine); may cause hypertension. ■ Has been given concurrently without evidence of drug interaction with acetaminophen (Tylenol), atropine, digoxin preparations, folic acid, furosemide, glyceryl trinitrate (nitroglycerin), heparin, isosorbide dinitrate (Iso-Bid), lidocaine, morphine, potassium chloride, protamine, and spironolactone (Aldactone).

SIDE EFFECTS

Anginal pain, chest pain, headache, hypertension, hypokalemia, increased ventricular ectopic activity, myocardial ischemia, nausea, palpitations, shortness of breath, tachycardia. Hypersensitivity reactions (e.g., bronchospasm, eosinophilia, fever, skin rash) have been reported. Local inflammatory changes may occur with infiltration.

Overdose: In addition to all of the above, overdose may cause anorexia, anxiety, excessive hypertension or hypotension, myocardial ischemia, tremor, ventricular tachycardia, and/or fibrillation.

ANTIDOTE

Notify physician of all side effects. Decrease infusion rate and notify physician immediately if number of PVCs increases or there is a marked increase in pulse rate (30 or more beats) or BP (50 or more mm Hg systolic). For accidental overdose, reduce rate or temporarily discontinue until condition stabilizes. Maintain a patent airway with adequate oxygenation and ventilation. Treat ventricular tachyarrhythmias with propranolol (Inderal) or lidocaine. Hypertension usually responds to a reduced rate or temporarily discontinuing dobutamine. Reduce rate or discontinue dobutamine if hypotension occurs. May require treatment with vasopressors (e.g., dopamine, norepinephrine). See **Precautions**.

DOCETAXEL **BBW**

(doh-seh-TAX-ell)

Antineoplastic agent
(taxane)**Docetaxel, Taxotere****USUAL DOSE**

Premedication for all patients except those with hormone-refractory prostate cancer: Must be pretreated with oral corticosteroids to reduce the incidence and severity of fluid retention and hypersensitivity reactions. Usual regimen is dexamethasone (Decadron) 8 mg PO twice a day for 3 days. Begin 1 day before each docetaxel infusion.

Premedication for hormone-refractory prostate cancer: Administer oral dexamethasone 8 mg at 12 hours, 3 hours, and 1 hour before each docetaxel infusion (another steroid, prednisone, is part of the combination therapy).

One source suggests that pretreatment with diphenhydramine (Benadryl) and/or an H₂ antagonist (e.g., famotidine [Pepcid], ranitidine [Zantac]) given IV 30 minutes before docetaxel infusion may help reduce hypersensitivity reactions and cutaneous toxicity.

Breast cancer: 60 to 100 mg/M² as an infusion. Repeat every 3 weeks.

Combination therapy for adjuvant treatment of operable node-positive breast cancer: 75 mg/M² as an infusion. Administer 1 hour after doxorubicin 50 mg/M² and cyclophosphamide 500 mg/M². Repeat every 3 weeks for 6 cycles. Prophylactic G-CSF (e.g., filgrastim [Neupogen]) may be used to mitigate the risk of hematologic toxicity. See [doxorubicin](#) and cyclophosphamide monographs.

Prostate cancer (hormone refractory): 75 mg/M² as an infusion. Repeat every 3 weeks. Prednisone 5 mg PO twice daily is administered continuously throughout treatment. See [Premedication](#).

First-line treatment of non–small-cell lung cancer (NSCLC): 75 mg/M² as an infusion over 1 hour. Follow immediately with cisplatin 75 mg/M² as an infusion over 30 to 60 minutes. Repeat regimen every 3 weeks. **Premedicate** with antiemetics and hydration as required for cisplatin administration; see cisplatin monograph.

NSCLC after failure of prior chemotherapy: 75 mg/M² as an infusion. Repeat every 3 weeks. Larger doses increased toxicity, infection, and treatment-related mortality.

Gastric adenocarcinoma: 75 mg/M² as an infusion over 1 hour. Follow immediately with cisplatin 75 mg/M² as an infusion over 1 to 3 hours (both on Day 1 only). **Premedicate** with antiemetics and hydration as required for cisplatin administration; see cisplatin and fluorouracil monographs. Follow the cisplatin infusion with fluorouracil 750 mg/M² as an infusion equally distributed over 24 hours. Repeat fluorouracil dose for 4 more 24-hour infusions (total of 5 days). Repeat regimen every 3 weeks. In the study, G-CSF (filgrastim [Neupogen]) was recommended during the second and/or subsequent cycles to prevent or attenuate febrile neutropenia, documented infection with neutropenia, or neutropenia lasting more than 7 days.

Induction chemotherapy followed by radiotherapy for treatment of inoperable, locally advanced squamous cell cancer of the head and neck (SCCHN): 75 mg/M² as an infusion over 1 hour. Follow immediately with cisplatin 75 mg/M² as an infusion over 1 hour (both on Day 1 only). **Premedicate** with antiemetics and hydration as required for cisplatin administration; see cisplatin monograph. Follow the cisplatin infusion with fluorouracil 750 mg/M² as an infusion equally distributed over 24 hours. Repeat fluorouracil for four more 24-hour infusions (total of 5 days). See fluorouracil monograph. Repeat regimen every 3 weeks for a total of four cycles. Prophylactic antibiotics were used in clinical studies. Following chemotherapy, patients should receive radiotherapy.

Induction chemotherapy followed by chemoradiotherapy for treatment of locally advanced (unresectable, low surgical cure, or organ preservation) SCCHN: 75 mg/M² as an infusion over 1 hour. Follow with cisplatin 100 mg/M² as a 30-minute to 3-hour infusion (both on Day

Continued

1 only). **Premedicate** with antiemetics and hydration as required for cisplatin administration; see cisplatin monograph. Follow the cisplatin infusion with fluorouracil 1,000 mg/M² as an infusion equally distributed over 24 hours. Repeat fluorouracil for three more 24-hour infusions (total of 4 days). See fluorouracil monograph. Repeat regimen every 3 weeks for 3 cycles. Prophylactic antibiotics were used in clinical studies. Following chemotherapy, patients should receive chemoradiotherapy.

Treatment of ovarian cancer (unlabeled): 60 to 75 mg/M² as an infusion in combination with carboplatin. Repeat every 3 weeks.

Metastatic bladder cancer (unlabeled): 75 mg/M² as an infusion in combination with cisplatin.

Treatment of esophageal cancer (unlabeled): 75 mg/M² as a 1-hour infusion every 21 days used in combination with fluorouracil and cisplatin.

DOSE ADJUSTMENTS

All diagnoses: Withhold therapy if neutrophils below 1,500/mm³ or platelets below 100,000 cells/mm³. A 25% reduction in the dose of docetaxel is recommended during subsequent cycles following severe neutropenia (less than 500/mm³) lasting 7 days or more, febrile neutropenia, or a Grade 4 infection. ■ Withhold therapy if bilirubin is greater than the ULN or if AST and/or ALT is greater than 1.5 times the ULN concomitant with alkaline phosphatase greater than 2.5 times the ULN. ■ Discontinue therapy in patients who develop Grade 3 or higher peripheral neuropathy. ■ Dose selection should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy. ■ Consider additional dose adjustments when docetaxel is given in combination with other chemotherapeutic agents. ■ See [Precautions](#).

Breast cancer: Reduce dose to 75 mg/M² for patients initially dosed at 100 mg/M² who experience febrile neutropenia, severe neutropenia (neutrophils below 500/mm³ for more than 1 week), severe or cumulative cutaneous reaction, or severe peripheral neuropathy. Further reduce to 55 mg/M² or discontinue docetaxel if any of the previously listed reactions persist. ■ Patients receiving the lower dose of docetaxel (60 mg/M²) may have the dose increased gradually if lower dose was well tolerated. ■ Discontinue therapy in patients who develop Grade 3 or greater peripheral neuropathy.

Combination therapy for adjuvant treatment of operable node-positive breast cancer: Patients who experience febrile neutropenia should receive G-CSF (e.g., filgrastim [Neupogen]) in all subsequent cycles. Patients who continue to experience this reaction should remain on G-CSF and have their docetaxel dose decreased to 60 mg/M². ■ Reduce docetaxel dose to 60 mg/M² in patients who experience Grade 3 or 4 stomatitis. ■ Reduce docetaxel dose from 75 to 60 mg/M² in patients who experience severe or cumulative cutaneous reactions or moderate neurosensory signs and/or symptoms. If side effects persist at the lower dose, discontinue therapy.

Prostate cancer: Reduce taxotere dose from 75 to 60 mg/M² in patients who experience dose-limiting toxicities (e.g., febrile neutropenia, neutrophils less than 500 cells/mm³ for more than 1 week, severe or cumulative cutaneous reactions, or moderate neurosensory signs and/or symptoms). If side effects persist at the lower dose, discontinue therapy.

Non-small-cell lung cancer after failure of prior chemotherapy: In NSCLC patients who experience either febrile neutropenia, neutrophils less than 500 cells/mm³ for more than 1 week, severe or cumulative cutaneous reactions, or other Grade 3 or 4 nonhematologic toxicities, withhold docetaxel until resolution of toxicity, then resume at 55 mg/M². ■ Discontinue therapy in patients who develop Grade 3 or greater peripheral neuropathy.

First-line treatment of NSCLC: Reduce dose to 65 mg/M² in patients whose nadir of platelet count during the previous course of therapy was less than 25,000 cells/mm³, in patients who experienced febrile neutropenia, and in patients with serious nonhematologic toxicities. Dose may be further reduced to 50 mg/M² as indicated. See cisplatin monograph for cisplatin dose adjustments.

Gastric adenocarcinoma and head and neck cancer: Patients who experience febrile neutropenia, documented infection with neutropenia, or neutropenia lasting more than 7 days

should receive G-CSF (e.g., filgrastim [Neupogen]) in all subsequent cycles. Patients who continue to experience this reaction should remain on G-CSF and have their taxotere dose decreased to 60 mg/M². Reduce dose further to 45 mg/M² if subsequent episodes of complicated neutropenia occur. ■ Reduce taxotere dose from 75 to 60 mg/M² in patients who experience Grade 4 thrombocytopenia. ■ If the previously mentioned toxicities persist, discontinue therapy. Additional dose adjustments are outlined in the following chart.

Additional Recommended Dose Adjustments for Toxicities in Gastric Adenocarcinoma or Head and Neck Cancer Patients Treated with Docetaxel in Combination with Cisplatin and Fluorouracil	
Toxicity	Dose Adjustment
Diarrhea Grade 3	First episode: Reduce 5-FU dose by 20%. Second episode: Reduce docetaxel dose by 20%.
Diarrhea Grade 4	First episode: Reduce docetaxel and 5-FU doses by 20%. Second episode: Discontinue treatment.
Stomatitis Grade 3	First episode: Reduce 5-FU dose by 20%. Second episode: Stop 5-FU only at all subsequent cycles. Third episode: Reduce docetaxel dose by 20%.
Stomatitis Grade 4	First episode: Stop 5-FU only at all subsequent cycles. Second episode: Reduce docetaxel dose by 20%.
AST/ALT >2.5 to ≤5 × ULN and AP ≤2.5 × ULN, or AST/ALT >1.5 to ≤5 × ULN and AP >2.5 to ≤5 × ULN	Reduce docetaxel dose by 20%.
AST/ALT >5 × ULN and/or AP >5 × ULN	Discontinue docetaxel.
Peripheral neuropathy Grade 2	Reduce cisplatin dose by 20%.
Peripheral neuropathy Grade 3	Discontinue cisplatin treatment.
Ototoxicity Grade 3	Discontinue cisplatin treatment.
Rise in SCr ≥ Grade 2 (>1.5 × normal value) despite adequate rehydration	Determine CrCl before each subsequent cycle and consider the following dose reductions as outlined below.
CrCl ≥60 mL/min	Full dose of cisplatin given. Repeat CrCl before each treatment cycle.
CrCl >40 and <60 mL/min	Reduce dose of cisplatin by 50% at subsequent cycle. If CrCl was >60 mL/min at end of cycle, give full dose at the next cycle. If no recovery observed, omit cisplatin from the next treatment cycle.
CrCl <40 mL/min	Omit dose of cisplatin for that treatment cycle only . Discontinue cisplatin if CrCl remains at <40 mL/min. Reduce cisplatin dose by 50% if CrCl was >40 and <60 mL/min at end of cycle. Give full cisplatin dose if CrCl is >60 mL/min at end of cycle.
Plantar-palmar toxicity Grade 2 or greater	Discontinue fluorouracil until recovery, then reduce fluorouracil dose by 20%.
Other greater than Grade 3 toxicities except alopecia and anemia	Delay 5-FU chemotherapy (for a maximum of 2 weeks from the planned date of infusion) until resolution to ≤Grade 1. If medically appropriate, resume treatment.

DILUTION

Specific techniques required; see Precautions. Available in three formulations and in several concentrations; **read label carefully.** Formulations are **NOT** interchangeable in a dose. **Do not use the two-vial formulation (injection concentrate and diluent [contains 13% ethanol in water for injection]) with the one-vial formulation.**

Generic single-bottle formulations: Available as 10 mg/mL in 20 mg/2 mL, 80 mg/8 mL, and 160 mg/16 mL vials. Requires no initial dilution and is ready to add to an infusion solution; **read label carefully** to avoid overdose. Allow required number of vials to stand at room temperature for 5 minutes if refrigerated. Withdraw required amount of concentrate (10 mg/mL) and inject into a 250-mL infusion bag or bottle of NS or D5W; **see all formulations below**. Manually rotate to mix thoroughly.

Two-vial formulations (generic and Taxotere): Available in 20 mg/0.5 mL or in 80 mg/2 mL vials (**concentration is 4 times greater than the single-bottle formulation; read label carefully**). Allow required number of vials to stand at room temperature for 5 minutes if refrigerated. Reconstitute the appropriate vial (20 to 80 mg) with the entire contents of the diluent vial (1.8 mL for the 20-mg vial and 7.1 mL for the 80-mg vial). Resulting concentration is 10 mg/mL. Mix well by repeated inversions for at least 45 seconds. **Do not shake**. Allow to stand until most of the foam dissipates. After this initial reconstitution, withdraw the required amount of 10 mg/mL concentrate and inject into a 250-mL bag or bottle of NS or D5W; **see all formulations below**.

Docefrez (lyophilized powder): Available as 20 mg/vial and 80 mg/vial with diluent (35.4% ethanol in polysorbate 80) provided by manufacturer. Allow required number of vials to stand at room temperature for 5 minutes. Using a syringe with an 18- to 20-gauge, 1½-inch needle, withdraw the required amount of diluent. Reconstitute the 20-mg vial with 1 mL from its diluent vial (concentration is 25 mg/mL or 20 mg/0.8 mL), and reconstitute the 80-mg vial with 4 mL from its diluent vial (concentration is 24 mg/mL). **These concentrations differ from other formulations; read label carefully**. Shake reconstituted vial well to completely dissolve the powder. Solution should be clear but may have some air bubbles due to the polysorbate 80. After this initial reconstitution, withdraw the required dose and inject into a 250-mL bag or bottle of NS or D5W; **see all formulations below**.

All formulations: Final dilution should be in glass or polypropylene bottles or polypropylene or polyolefin plastic bags for infusion. Thoroughly mix the infusion by manual rotation. Should be administered through polyethylene-lined administration sets. Desired concentration should be between 0.3 and 0.74 mg/mL (100 mg in 250 mL = 0.4 mg/mL). If a dose greater than 200 mg is required, use a larger volume of NS or D5W so that a final concentration of 0.74 mg/mL is not exceeded. Solution should be clear.

Filters: Not required. Manufacturer indicates that studies show no loss of potency with in-line filtration through a 0.22-micron filter.

Storage: Taxotere (20 mg/0.5 mL): Unopened vials of docetaxel in cartons may be stored at 2° to 25° C (36° to 77° F). Protect from light. Freezing does not adversely affect unopened vials; **see all formulations**.

Generic 10 mg/mL solution and generic 20 mg/0.5 mL solution: Requirements are brand specific; check prescribing information; **see all formulations**.

Docefrez: Store unopened vials between 2° and 8° C (36° and 46° F) and protect from light. Reconstituted solution may be used immediately or is stable for a maximum of 4 hours stored between 2° and 25° C (36° and 77° F); **see all formulations**.

All formulations: Fully diluted infusion solutions in NS or D5W should be used within 4 hours (including the 1-hour infusion time).

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Leaches out plasticizers, including DEHP, from PVC infusion bags and administration sets. Use glass or polypropylene bottles or plastic (polypropylene or polyolefin) bags and polyethylene-lined administration sets to minimize patient exposure to leached DEHP. Do not allow concentrate to come into contact with plasticized PVC equipment or devices used to prepare solutions.

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), amifostine (Ethyol), amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), aztreonam (Azac-

tam), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefotetan, cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), clindamycin (Cleocin), dexamethasone (Decadron), diphenhydramine (Benadryl), dobutamine, dopamine, doripenem (Doribax), doxycycline (Diflucan), furosemide (Lasix), ganciclovir (Cytovene), gemcitabine (Gemzar), gentamicin, granisetron (Kytrel), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), imipenem-cilastatin (Primaxin), leucovorin calcium, lorazepam (Ativan), magnesium sulfate, mannitol, meperidine (Demerol), meropenem (Merrem IV), mesna (Mesnex), metoclopramide (Reglan), metronidazole (Flagyl IV), morphine, ondansetron (Zofran), oxaliplatin (Eloxatin), palonosetron (Aloxi), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, sulfamethoxazole/trimethoprim, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose, properly diluted, equally distributed over 1 hour. Room temperature should be cool and lighting should be low. Extended infusion times (e.g., 6 to 24 hours) or frequently repeated infusions (e.g., several days in a row) seem to increase the risk of dose-limiting mucositis.

ACTIONS

An antineoplastic. A novel, semisynthetic, antimicrotubule agent derived from the needles of the yew plant. It inhibits cancer cell division. Microtubules assemble and disassemble during the cell cycle. Docetaxel promotes assembly and blocks disassembly of microtubules, preventing the cancer cells from dividing. The end result is cancer cell death. Highly protein bound. Probably metabolized in the liver by CYP3A4, an isoenzyme of the P₄₅₀ family. Half-life is 11.1 hours. Eliminated primarily through feces and, to a lesser extent, urine and bile.

INDICATIONS AND USES

Treatment of locally advanced or metastatic breast cancer after failure of prior chemotherapy. ■ In combination with doxorubicin and cyclophosphamide for adjuvant treatment of operable node-positive breast cancer. ■ As a single agent in the treatment of locally advanced or metastatic NSCLC after failure of platinum-based chemotherapy (e.g., cisplatin). ■ In combination with cisplatin for treatment of patients with unresectable, locally advanced, or metastatic NSCLC who have not previously received chemotherapy for this condition. ■ In combination with prednisone for the treatment of androgen-independent (hormone refractory) metastatic prostate cancer. ■ In combination with cisplatin and fluorouracil for the treatment of advanced gastric adenocarcinoma, including adenocarcinoma of the gastroesophageal junction, in patients who have not received prior chemotherapy for advanced disease. ■ In combination with cisplatin and fluorouracil for induction therapy of locally advanced SCCHN. Following chemotherapy, patients should receive radiotherapy.

Unlabeled uses: Treatment of metastatic bladder cancer, esophageal cancer, ovarian cancer, soft tissue sarcomas, and adenocarcinomas of unknown primary site; consult literature.

CONTRAINDICATIONS

Baseline neutropenia less than 1,500 cells/mm³, history of hypersensitivity reactions to docetaxel or other drugs formulated with polysorbate 80, severe impaired liver function. In the United States, docetaxel is not recommended for patients with a bilirubin above the ULN or in patients with ALT and/or AST greater than 1.5 times the ULN range and increases in alkaline phosphatase greater than 2.5 times the ULN range; see [Precautions](#).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Usually administered by or under direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be readily available. ■ Myelosuppression may be more frequent and more severe in patients who have received prior cytotoxic drug therapy or radiation therapy. ■ Incidence of febrile neutropenia and/or neutropenic infection increased in patients receiving docetaxel (Taxotere) in combination with cisplatin and fluorouracil (5-FU). ■ Incidence of mortality increased in patients with abnormal liver function, in patients receiving higher doses, and in patients with NSCLC and a history of prior treatment with platinum-based chemotherapy who receive docetaxel as a single agent at a dose of 100 mg/M². Patients with elevations of bilirubin or abnormalities of transaminase concurrent with alkaline phosphatase are at increased risk for the development of grade 4 neutropenia, febrile neutropenia, infections, severe thrombocytopenia, severe stomatitis, severe skin toxicity, and toxic death. ■ Not recommended for patients with hepatic impairment; see [Contraindications](#). If docetaxel is considered essential for a patient with mild hepatic impairment, initial doses of 60 to 75 mg/M² should be used. Risk of toxicity and death is significant. Patients with isolated elevations of transaminases greater than 1.5 times the ULN have a higher rate of adverse events but not of death. ■ In addition to myelosuppression and hypersensitivity reactions, localized erythema of the extremities with edema followed by desquamation, severe fluid retention, severe neurosensory symptoms (e.g., dysesthesia, pain, paresthesia), and severe asthenia (usually in metastatic breast cancer patients) have been reported. Severe fluid retention may occur despite premedication with dexamethasone. ■ Use with caution in patients with pleural effusion; may be exacerbated by docetaxel-induced fluid retention. ■ Treatment-related acute myeloid leukemia (AML) or myelodysplasia has occurred in patients given docetaxel in combination with other chemotherapy agents and/or radiotherapy. ■ When administering combination therapy, consult all appropriate drug monographs for relevant information. ■ See [Drug/Lab Interactions](#).

Monitor: Obtain baseline CBC with differential and platelets; monitor frequently during therapy and before each dose. See [Dose Adjustments](#). ■ Obtain baseline bilirubin, AST, ALT, and alkaline phosphatase; monitor as indicated during therapy (recommended before each dose). ■ Determine absolute patency of vein. A stinging or burning sensation indicates extravasation; severe cellulitis and tissue necrosis may result. Discontinue injection; use another vein. ■ Obtain baseline vital signs, monitor during and for at least 1 hour following infusion. ■ Monitor for hypersensitivity reactions; may occur within minutes. Discontinue docetaxel if reaction is severe (e.g., bronchospasm, hypotension, generalized rash/erythema). Hypersensitivity reactions may occur even in patients premedicated with dexamethasone. Continue monitoring for a minimum of 1 hour following the infusion, especially during the first two treatment cycles. ■ Monitor for localized erythema of the palms of the hands and soles of the feet with or without desquamation. A reduced dose may be indicated if severe. ■ Monitor for fluid retention. Severe salt restriction and treatment with oral diuretics may be indicated. S/S of severe fluid retention include abdominal distention (severe), cardiac tamponade, dyspnea at rest, peripheral or generalized edema, pleural effusion. ■ Observe for signs of peripheral neurotoxicity (e.g., neurosensory symptoms such as dysesthesia, pain, paresthesia, and peripheral motor neuropathy manifested primarily as distal extremity weakness); docetaxel may need to be discontinued; see [Dose Adjustments](#). In patients with gastric adenocarcinoma or SCCHN, a baseline neurologic exam is recommended. Repeat every 2 cycles and at the end of treatment; see [Dose Adjustments](#). ■ Observe for signs of infection. Use of prophylactic antibiotics may be indicated pending C/S in a febrile, neutropenic patient. Monitor patients receiving docetaxel (Taxotere), cisplatin, fluorouracil (5-FU) combination therapy closely for febrile neutropenia and/or neutropenic infection. ■ Not highly emetogenic; routine prophylaxis with antiemetics may not be required. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³); see [Dose Adjustments](#). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Avoid pregnancy; nonhormonal birth control recommended. ■ Review of monitoring requirements (e.g., CBCs, liver function tests) and adverse events before therapy imperative. ■ Pretreatment with dexamethasone as prescribed is imperative. ■ Report pain or burning at injection site and any unusual or unexpected symptoms or side effects as soon as possible (e.g., constipation, fever, hypersensitivity reaction [e.g., difficulty breathing, itching, rash], nausea and vomiting, shortness of breath, swelling of feet and legs, weight gain). ■ May produce significant hypotension. Effects may be additive with current medications. Review all medications (prescription and nonprescription) with nurse and/or physician. ■ See Appendix D, p. 1255. ■ Obtain name and telephone number of a contact person for emergencies, questions, or problems. ■ Seek resources for counseling or supportive therapy. ■ Risk of delayed myelodysplasia or myeloid leukemia requires hematologic follow-up. Changes in blood counts due to leukemia and other blood disorders may occur years after treatment.

Maternal/Child: Category D; avoid pregnancy, may cause fetal harm. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients under 16 years of age not established. A colony-stimulating factor (e.g., filgrastim, sargramostim) has been used to reduce neutropenia and increase tolerance of the maximum dose.

Elderly: Dose selection should be cautious; see [Dose Adjustments](#). ■ May be at increased risk for developing side effects such as anemia, anorexia, diarrhea, dizziness, febrile neutropenia, infections, lethargy, peripheral edema, stomatitis, and weight loss. ■ Monitor hepatic function carefully.

DRUG/LAB INTERACTIONS

A substrate of CYP3A4. Metabolism may be modified by concomitant administration of other medications that induce, inhibit, or are metabolized by CYP3A4. Metabolism inhibited and serum levels increased with **strong CYP3A4 inhibitors** (e.g., imidazole antifungals [e.g., itraconazole (Sporanox), ketoconazole (Nizoral), voriconazole (VFEND)], protease inhibitors [e.g., atazanavir (Reyataz), indinavir (Crixivan), nelfinavir (Viracept), ritonavir (Norvir), saquinavir (Invirase)], clarithromycin [Biaxin], nefazodone, and telithromycin [Ketek]). Avoid use. A pharmacokinetic study suggests considering a 50% dose reduction of docetaxel if coadministration of a strong CYP3A4 inhibitor is required; monitor closely for toxicity. ■ Metabolism of docetaxel may be modified by **other agents that induce, inhibit, or are metabolized by CYP3A4** (e.g., cyclosporine [Sandimmune], phenytoin [Dilantin], phenobarbital [Luminal], tacrolimus [Prograf], and many others). ■ Additive bone marrow suppression may occur with **radiation therapy and/or other bone marrow-suppressing agents** (e.g., azathioprine [Imuran], chloramphenicol, melphalan [Alkeran]). Dose reduction may be required. ■ Leukopenic and/or thrombocytopenic effects may be increased with **drugs that cause blood dyscrasias** (e.g., anticonvulsants [e.g., carbamazepine (Tegretol), phenytoin (Dilantin)], NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]). Adjust dose based on differential and platelet count. ■ Risk of infection is increased with concurrent use of **other immunosuppressants** (e.g., azathioprine, chlorambucil [Leukeran], cyclophosphamide [Cytoxan], cyclosporine [Sandimmune], glucocorticoid corticosteroids [e.g., dexamethasone], muromonab CD-3 [Orthoclone], tacrolimus [Prograf]). ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents.

SIDE EFFECTS

Generally reversible but can be fatal. Most common side effects across all indications are alopecia, anemia, anorexia, asthenia, constipation, diarrhea, dysgeusia, dyspnea, febrile neutropenia, fluid retention (e.g., ascites, edema, pericardial effusion, pleural effusion), hypersensitivity reactions (e.g., back pain, chest tightness, chills, drug fever, dyspnea, flushing, hypotension, pruritus, rash), infection, mucositis, myalgia, nail disorders, nausea, neuropathy, neutropenia, pain, skin reactions, thrombocytopenia, and vomiting. Increased incidence of bone marrow suppression (anemia, leukopenia, neutropenia, thrombocytopenia) and/or severity of side effects is dose dependent and can be dose limiting. Abdominal pain; acute myeloid leukemia and myelodysplastic syndrome; acute pulmonary edema; acute respiratory distress syndrome; altered hearing; amenorrhea; arthralgia;

bleeding episodes; cardiac arrhythmias; CHF; colitis; confusion; conjunctivitis; cough; cutaneous reactions (e.g., localized rash on hands, feet, arms, face, thorax; erythema multiforme; severe hand and foot syndrome; Stevens-Johnson syndrome; toxic epidermal necrolysis); diarrhea; DIC (often in association with sepsis or multi-organ failure); dizziness; enteritis; esophagitis/dysphagia/odynophagia; fatigue; fever with or without infection; gastrointestinal pain and cramping; heartburn; hepatitis (sometimes fatal, primarily in patients with pre-existing liver disease); hypotension; increased ALT, AST, and bilirubin; infusion site reactions; interstitial pneumonia; lethargy; lymphedema; myocardial ischemia; neurosensory symptoms (e.g., dysesthesia, pain, paresthesia); neutropenic infection; paresthesias (e.g., pain, burning sensation); perforation of the large intestine; renal insufficiency; seizures or transient loss of consciousness; stomatitis; taste perversion; tearing; vasodilation.

Overdose: Bone marrow suppression, mucositis, peripheral neurotoxicity.

Post-Marketing: Deep vein thrombosis, dehydration, duodenal ulcer, dyspnea, esophagitis, GI hemorrhage, ileus, intestinal obstruction, ischemic colitis, MI, neutropenic enterocolitis, pulmonary embolism, pulmonary fibrosis, radiation pneumonitis, radiation recall phenomenon, renal failure (most commonly associated with concomitant nephrotoxic drugs), scleroderma-like changes (usually preceded by peripheral lymphedema), thrombophlebitis, transient visual disturbances.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. Most hypersensitivity reactions will subside with temporary discontinuation of docetaxel, and incidence seems to decrease with subsequent doses. Discontinue docetaxel if a severe hypersensitivity reaction occurs. Severe reactions may require epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., dexamethasone [Decadron]), or bronchodilators (e.g., albuterol [Ventolin], theophylline [Aminophylline]). Rechallenge may be considered if there is objective tumor response and no other options. Neutropenia can be profound, and the nadir usually occurs about Day 8. Recovery is generally rapid and spontaneous but may be treated with filgrastim (G-CSF, Neupogen) or pegfilgrastim (Neulasta). Severe thrombocytopenia may require platelet transfusions. Severe anemia (less than 8 Gm/dL) may require packed cell transfusions; moderate anemia (less than 11 Gm/dL) may be treated with darbepoetin alfa [Aranesp] or epoetin alfa (Epogen). Hypotension and bradycardia do not usually occur at the same time except in hypersensitivity. Treat only if symptomatic. Treat any serious or symptomatic arrhythmia (e.g., conduction abnormalities, ventricular tachycardia) promptly and monitor continuously during subsequent doses. Serious cutaneous reactions with desquamation (rare), serious fluid retention (more frequent with cumulative doses of 1,300 mg/M²), persistent febrile neutropenia, severe peripheral neuropathy, or severe liver impairment may require discontinuation of docetaxel. Cutaneous reactions (palmar-plantar erythrodysesthesia) that occur despite prophylaxis may respond to pyridoxine 50 mg three times daily. There is no specific antidote for overdose. Supportive therapy will help sustain the patient in toxicity. Resuscitate if indicated.

DOLASETRON MESYLATE(dohl-**AH**-seh-tron **MES**-ih-layt)Antiemetic
(5HT₃ receptor antagonist)

Anzemet

pH 3.2 to 3.8

USUAL DOSE

Prevention of postoperative nausea and/or vomiting: 12.5 mg as a single dose 15 minutes before cessation of anesthesia.

Treatment of postoperative nausea and/or vomiting: 12.5 mg as a single dose as soon as nausea or vomiting presents.

PEDIATRIC DOSE

Doses are those recommended for *pediatric patients 2 to 16 years of age*. Safety and effectiveness in pediatric patients under 2 years of age not established; see **Contraindications** and **Maternal/Child**. Dolasetron solution for injection may be mixed with apple or apple-grape juice for oral administration to pediatric patients. See prescribing information for oral doses.

Prevention of postoperative nausea and/or vomiting: 0.35 mg/kg up to a maximum dose of 12.5 mg as a single dose 15 minutes before cessation of anesthesia.

Treatment of postoperative nausea and/or vomiting: 0.35 mg/kg up to a maximum dose of 12.5 mg as a single dose as soon as nausea or vomiting presents.

DOSE ADJUSTMENTS

No dose adjustments required for the elderly, renal failure, or impaired hepatic function; however, caution and lower-end dosing is suggested in elderly patients. Consider decreased organ function and concomitant disease or drug therapy.

DILUTION

IV injection: A single dose may be given undiluted.

IV infusion: A single dose may be further diluted up to 50 mL in NS, D5W, D5¹/₂NS, D5LR, LR, or 10% mannitol.

Storage: Store vials at CRT; protect from light. Stable after dilution at CRT for 24 hours or 48 hours if refrigerated.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be mixed with other drugs. Flush the infusion line with a **compatible** IV solution before and after administration."

One source suggests the following **compatibilities**:

Y-site: Azithromycin (Zithromax), caspofungin (Cancidas), dexmedetomidine (Precedex), fenoldopam (Corlopam), hetastarch in electrolytes (Hextend), and oxaliplatin (Eloxatin).

RATE OF ADMINISTRATION

Flush infusion line before and after administration. May cause bradycardia, severe hypotension, and syncope during or shortly after administration.

IV injection: A single dose over 30 seconds.

IV infusion: Administer a single dose over 15 minutes.

ACTIONS

An antinauseant and antiemetic agent. A selective antagonist of specific serotonin (5-HT₃) receptors, similar to granisetron and ondansetron. 5-HT₃ receptors are located on the nerve terminals of the vagus in the periphery and centrally in the chemoreceptor trigger zone. By antagonizing these receptors, nausea and vomiting are prevented. Rapidly and completely metabolized to its active metabolite, hydrodolasetron. Maximum concentration occurs 0.6 hours after injection or infusion. Average half-life is 7.3 hours. Plasma clearance increased and half-life reduced in pediatric patients. Excreted in urine and feces. Not known if dolasetron is secreted in breast milk.

INDICATIONS AND USES

Prevention of postoperative nausea and vomiting in adults and pediatric patients 2 years of age and older when indicated. ■ Treatment of postoperative nausea and/or vomiting in adults and pediatric patients 2 years of age and older. Also available in tablet form.

Unlabeled uses: Prevention of radiotherapy-induced nausea and vomiting.

CONTRAINDICATIONS

Known hypersensitivity to dolasetron. ■ Contraindicated in adult and pediatric patients for the prevention of nausea and vomiting associated with initial and repeat courses of emetogenic cancer chemotherapy because of risk for dose-dependent QTc prolongation.

PRECAUTIONS

Prolongs the QT interval in a dose-dependent fashion. Torsades de pointes has been reported. Avoid use in patients with congenital long QT syndrome, hypokalemia, or hypomagnesemia. ■ Has been shown to cause dose-dependent prolongation of the PR and QRS interval. Second- or third-degree atrioventricular block, cardiac arrest, and serious ventricular arrhythmias, including fatalities in both adult and pediatric patients, have been reported. At particular risk are patients with underlying structural heart disease, pre-existing conduction system abnormalities, sick sinus syndrome, atrial fibrillation with slow ventricular response, or myocardial ischemia, elderly patients, or patients receiving drugs known to prolong the PR interval (such as verapamil) and QRS interval (e.g., flecainide [Tambocor] or quinidine); use with caution and monitor ECG. Avoid use in patients with or at risk for complete heart block unless they have an implanted pacemaker. ■ Use with caution in patients who have or may develop prolongation of cardiac conduction intervals, particularly QT intervals (e.g., patients with hypokalemia, hypomagnesemia, congenital QT syndrome, cumulative high-dose anthracycline therapy [e.g., doxorubicin (Adriamycin)], patients taking diuretics with potential for inducing electrolyte abnormalities [e.g., furosemide (Lasix), hydrochlorothiazide] or antiarrhythmic drugs or other drugs that lead to QT prolongation [amiodarone (Nexterone), procainamide (Pronestyl), quinidine]). ■ Cross-sensitivity has been reported in patients who received other selective 5HT₃-receptor agonists (e.g., granisetron [Kytril], ondansetron [Zofran]). These reactions have not been seen with dolasetron. ■ Available in tablet form. ■ See [Contraindications](#), [Maternal/Child](#), [Drug/Lab Interactions](#), and [Side Effects](#).

Monitor: Observe closely. Monitor VS. Any patient found to have a second-degree or higher AV conduction block should be monitored continuously. ■ Correct hypokalemia and hypomagnesemia before administration of dolasetron. Monitor after administration as clinically indicated. ■ Monitor ECG in patients with CHF, bradycardia, or renal impairment; in the elderly; and in all patients at risk for prolongation of the PR and QRS interval; see [Precautions](#). ■ Ambulate slowly to avoid orthostatic hypotension.

Patient Education: Request assistance for ambulation. ■ May cause serious cardiac arrhythmias; discuss medical history with physician and promptly report a perceived change in heart rate, fainting, or light-headedness. ■ Report promptly if nausea persists. ■ Maintain adequate hydration. ■ Review prescription medications with health care provider.

Maternal/Child: Category B: no evidence of impaired fertility or harm to fetus. Use during pregnancy only if clearly needed. ■ Use caution if required during breast-feeding. ■ See [Contraindications](#). ■ Safety and effectiveness for use in pediatric patients under 2 years of age not established. ■ Plasma clearance increased and half-life reduced in pediatric patients.

Elderly: Use with caution and continuous ECG monitoring in the elderly; they are at particular risk for prolongation of the PR, QRS, and QT interval. ■ See [Dose Adjustments](#) and [Contraindications](#).

DRUG/LAB INTERACTIONS

Does not induce or inhibit the cytochrome P₄₅₀ drug metabolizing system, but metabolism of its active metabolite, hydrodolasetron, is mediated by enzymes in the P₄₅₀ system. Plasma levels increased when given concurrently with **cimetidine** (Tagamet [inhibitor of cytochrome P₄₅₀]), and decreased when given concurrently with **rifampin** (Rifadin [in-

ducer of cytochrome P₄₅₀); clinical significance not known. ■ Clearance decreased when given concurrently with **atenolol**. ■ See **Precautions** and use extreme caution with **diuretics** with potential for inducing electrolyte abnormalities (e.g., furosemide [Lasix], hydrochlorothiazide [Hydrodiuril]) or **antiarrhythmic drugs or other drugs that lead to prolonged QT intervals** (e.g., amiodarone [Nexterone], procainamide [Pronestyl], quinidine). ■ Clearance not affected by **ACE inhibitors** (e.g., enalapril), **diltiazem** (Cardizem), **furosemide** (Lasix), **glyburide** (DiaBeta), **nifedipine** (Procardia), **propranolol** (Inderal), and **verapamil**. ■ Does not influence anesthesia recovery time.

SIDE EFFECTS

May cause bradycardia, severe hypotension, and syncope during or shortly after administration. Can cause ECG interval changes (PR, QT, JT prolongation, and QRS widening). These changes may lead to cardiovascular consequences (e.g., cardiac arrhythmias, heart block). Usually self-limiting with declining blood levels, but may last as long as 24 hours.

Dizziness, drowsiness, headache, pain, and urinary retention are most common. Sinus arrhythmia, hypotension, orthostatic hypotension, and numerous other side effects may occur in fewer than 2% of patients.

Overdose: Severe hypotension and dizziness.

Post-Marketing: Wide complex tachycardia, VT, VF, and cardiac arrest have been reported rarely.

ANTIDOTE

Most side effects will be treated symptomatically. Keep physician informed. Overdose in one patient was treated with plasma expanders (e.g., albumin, dextran), dopamine, atropine, and continuous BP and ECG monitoring. Epinephrine, atropine, and/or cardiac pacing may be required to treat ECG interval changes. Prolonged QT interval may lead to VT or other ventricular arrhythmias; telemetry monitoring may be indicated. There is no specific antidote. Treat anaphylaxis and resuscitate as necessary. Not known if dolasetron is removed by hemodialysis.

DOPAMINE HYDROCHLORIDE **BBW**

(DOH-pah-meen hy-droh-KLOR-eyed)

Inotropic agent
Cardiac stimulant
Vasopressor

pH 2.5 to 5

USUAL DOSE

Where appropriate, restoration of blood volume with a suitable plasma expander or whole blood should be instituted or completed before administration of dopamine; the goal is a central venous pressure of 10 to 15 cm H₂O or a pulmonary wedge pressure of 14 to 18 mm Hg.

Adults: 2 to 5 mcg/kg of body weight/min initially in patients likely to respond to minimum treatment. 5 to 10 mcg/kg/min may be required initially to correct hypotension in the seriously ill patient. Gradually increase by 5 to 10 mcg/kg/min at 10- to 30-minute intervals until optimum response occurs. Average dose is 20 mcg/kg/min; over 50 mcg/kg/min has been required in some instances but is not recommended. If more than 20 mcg/kg/min is required to maintain BP, consider use of norepinephrine (Levophed) in addition. Doses over 20 mcg/kg/min decrease renal perfusion.

Bradycardia: AHA guidelines recommend dopamine infusion 2 to 10 mcg/kg/min. Titrate to desired effect. Indicated if atropine is ineffective. Alternately, transcutaneous pacing or epinephrine infusion 2 to 10 mcg/min may be used.

PEDIATRIC DOSE

See *Maternal/Child*. Note comments in *Usual Dose*. Usual starting dose is 1 to 5 mcg/kg/min. Dose increments range from 2.5 to 5 mcg/kg/min. Usual maximum dose is 15 to 20 mcg/kg/min. Doses up to 50 mcg/kg/min have been administered. Titrate dose gradually to desired effect.

DOSE ADJUSTMENTS

Reduce dose to one tenth of the calculated amount for individuals who have been treated with MAO inhibitors (e.g., selegiline [Eldepryl]) within 2 to 3 weeks of administration of dopamine. ■ Lower-end initial doses may be appropriate in the elderly based on potential for decreased organ function and concomitant disease or drug therapy. ■ See *Drug/Lab Interactions*.

DILUTION

Each 200-mg, 400-mg, or 800-mg ampule must be diluted in 250 to 500 mL of the following IV solutions and given as an infusion: NS, D5W, D5NS, D5/½NS, D5LR, ¼ M sodium lactate, or LR injection. See the following chart.

Final Dopamine Concentration (mcg/mL) When Dopamine 40 mg/mL or 80 mg/mL Is Mixed with Various Volumes of Infusion Solution			
Concentration of Dopamine	40 mg/mL		80 mg/mL
Volume of Dopamine	5 mL (200 mg)	10 mL (400 mg)	10 mL (800 mg)
250 mL diluent	800 mcg/mL	1,600 mcg/mL	3,200 mcg/mL
500 mL diluent	400 mcg/mL	800 mcg/mL	1,600 mcg/mL
1,000 mL diluent	200 mcg/mL	400 mcg/mL	800 mcg/mL

Also available prediluted in 250 mL or 500 mL of D5W. Dopamine concentration varies. More concentrated solutions may be used if absolutely necessary to reduce fluid volume.

Storage: Store at CRT. Protect from freezing. Discard diluted solution after 24 hours. Do not use if solution is darker than slightly yellow.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be **INCOMPATIBLE** until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Do not add to sodium bicarbonate or any other strongly alkaline solution (e.g., aminophylline, barbiturates [e.g., phenobarbital (Luminal)]), oxidizing agents, or iron salts. Dopamine is inactivated in alkaline solution.” Do not mix with alteplase or amphotericin B.

One source suggests the following **compatibilities**:

Additive: Aminophylline, atracurium (Tracrium), calcium chloride, chloramphenicol (Chloromycetin), ciprofloxacin (Cipro IV), dobutamine, enalaprilat (Vasotec IV), flumazenil (Romazicon), gentamicin, heparin, hydrocortisone sodium succinate (Solu-Cortef), lidocaine, meropenem (Merrem IV), methylprednisolone (Solu-Medrol), nitroglycerin IV, oxacillin (Bactocill), potassium chloride (KCl), ranitidine (Zantac), verapamil.

Y-site: Aldesleukin (Proleukin), alprostadil, amifostine (Ethyol), amiodarone (Nexterone), anidulafungin (Eraxis), argatroban, atracurium (Tracrium), aztreonam (Azactam), bivalirudin (Angiomax), caspofungin (Cancidas), cefepime (Maxipime), ceftazidime (Fortaz), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), cladribine (Leustatin), daptomycin (Cubicin), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, docetaxel (Taxotere), doxorubicin liposomal (Doxil), enalaprilat (Vasotec IV), epinephrine (Adrenalin), esmolol (Brevibloc), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), fluconazole (Diflucan), foscarnet (Foscavir), furosemide (Lasix), gemcitabine (Gemzar), granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Voluven), labetalol, levofloxacin (Levaquin), lidocaine, linezolid (Zyvox), lorazepam (Ativan), meperidine (Demerol), methylprednisolone (Solu-Medrol), metronidazole (Flagyl IV), miconazole (Mycamine), midazolam (Versed), milrinone (Primacor), morphine, mycophenolate (CellCept IV), nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), ondansetron (Zofran), oxaliplatin (Eloxatin), pancuronium, pantoprazole (Protonix IV), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), theophylline, thiotepa, tigecycline (Tygacil), tirofiban (Aggrastat), vasopressin, vecuronium, verapamil, warfarin (Coumadin), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Begin with recommended dose for body weight and seriousness of condition. Gradually increase by 5 to 10 mcg/kg of body weight/min to produce desired response. Titrate to desired hemodynamic or renal response. When titrating to the desired increase in systolic BP, the optimum dosage rate for renal response may be exceeded and may necessitate a rate reduction after the hemodynamic condition is stabilized. Use of a volumetric infusion pump is recommended for accuracy. Optimum urine flow determines correct evaluation of dosage. Decrease dose gradually; may cause marked hypotension if discontinued suddenly. Expansion of blood volume with IV fluids may be indicated.

Dopamine Infusion Rate (mL/hr): 400 mcg/mL Concentration						
Desired Dose	Weight in Kilograms					
	50 kg	60 kg	70 kg	80 kg	90 kg	100 kg
	(mL/hr)	(mL/hr)	(mL/hr)	(mL/hr)	(mL/hr)	(mL/hr)
5 mcg/kg/min	37.5	45	52.5	60	67.5	75
10 mcg/kg/min	75	90	105	120	135	150
20 mcg/kg/min	150	180	210	240	270	300
30 mcg/kg/min	225	270	315	360	405	450
40 mcg/kg/min	300	360	420	480	540	600

Dopamine Infusion Rate (mL/hr): 800 mcg/mL Concentration						
Desired Dose	Weight in Kilograms					
	50 kg	60 kg	70 kg	80 kg	90 kg	100 kg
	(mL/hr)	(mL/hr)	(mL/hr)	(mL/hr)	(mL/hr)	(mL/hr)
5 mcg/kg/min	18.75	22.5	26.25	30	33.75	37.5
10 mcg/kg/min	37.5	45	52.5	60	67.5	75
20 mcg/kg/min	75	90	105	120	135	150
30 mcg/kg/min	112.5	135	157.5	180	202.5	225
40 mcg/kg/min	150	180	210	240	270	300

ACTIONS

Dopamine is a naturally occurring catecholamine that possesses alpha, beta, and dopaminergic receptor–stimulating actions. The effects of dopamine are dose-related. At low doses (0.5 to 2 mcg/kg/min), dopamine causes vasodilation in the renal, mesenteric, coronary, and intracerebral vascular beds, thereby increasing glomerular filtration rate, renal blood flow, sodium excretion, and urine flow. At medium doses (2 to 10 mcg/kg/min), beta-adrenoceptors are stimulated, resulting in improved myocardial contractility, increased sinoatrial rate, and enhanced impulse conduction in the heart. Systolic and pulse pressure may increase, but there is little, if any, effect on diastolic pressure at these doses. At higher doses (10 to 20 mcg/kg/min), alpha-adrenoceptors are stimulated, resulting in vasoconstriction and an increase in blood pressure. At doses above 20 mcg/kg/min, alpha effects predominate and vasoconstriction may compromise circulation in the limbs and override the dopaminergic effects of dopamine, reversing renal dilation and natriuresis. Dopamine is widely distributed. It has an onset of action of 5 minutes, a duration of action of 10 minutes, and a plasma half-life of 2 minutes. Metabolized in the liver, kidney, and plasma by monoamine oxidase (MAO) and catechol *O*-methyltransferase (COMT), with about 25% of the dose being converted to norepinephrine. Primarily excreted in urine.

INDICATIONS AND USES

To correct hemodynamic imbalances, including hypotension resulting from shock syndrome of myocardial infarction, trauma, endotoxic septicemia, open heart surgery, renal failure, and chronic cardiac decompensation. ■ Drug of choice for hypotension and shock. ■ AHA guidelines recommend dopamine as the second drug of choice after atropine to treat symptomatic bradycardia.

Unlabeled uses: Chronic obstructive pulmonary disease, congestive heart failure, infant respiratory distress syndrome, symptomatic bradycardia, calcium channel blocker overdose, beta-blocker overdose, and drug-induced hypovolemic shock; consult literature.

CONTRAINDICATIONS

Hypersensitivity to any components (contains sulfites), pheochromocytoma, uncorrected tachyarrhythmias, ventricular fibrillation.

PRECAUTIONS

Some preparations contain sulfites; use caution in patients with allergies. ■ Avoid hypovolemia. ■ Presence of hypoxia, hypercapnia, or acidosis may reduce the effectiveness of dopamine and/or increase the incidence of dopamine-induced adverse events. ■ Use caution in patients with a history of occlusive vascular disease (e.g., atherosclerosis, arterial embolism, Raynaud's disease).

Monitor: Recognition of signs and symptoms of hemodynamic imbalance and prompt treatment with dopamine will improve prognosis. ■ Close monitoring of BP, cardiac output, cardiac rhythm, and urine output required. Avoid hypertension. If possible, check central venous pressure or pulmonary wedge pressure before administration and as ordered thereafter. ■ Use larger veins (antecubital fossa) and avoid extravasation; may cause necrosis and sloughing of tissue. Central vein preferred for continuous infusions;

see **Antidote**. ■ If possible, correct hypovolemia with IV fluids, whole blood or plasma as indicated; correct acidosis if present. ■ Monitor for decreased urine output, increased tachycardia, or new arrhythmias. ■ With high-dose administration, palpate pulses and monitor extremities for signs of peripheral vasoconstriction (e.g., coldness, paresthesias). ■ Therapy may be continued until the patient can maintain hemodynamic and renal functions. ■ See **Maternal/Child** and **Drug/Lab Interactions**.

Maternal/Child: Category C: safety for use in pregnancy and breast-feeding not established. If used benefits must outweigh risks. ■ Safety for use in pediatric patients not established. Has been used, but experience is limited. ■ Do not administer into an umbilical arterial catheter. Vasospastic events have been reported when dopamine is infused through the umbilical artery.

Elderly: Lower-end initial doses may be appropriate; see **Dose Adjustments**. ■ Differences in response compared to younger adults not identified.

DRUG/LAB INTERACTIONS

Alkaline solutions, including sodium bicarbonate, inactivate dopamine. ■ May cause serious arrhythmias in presence of **cyclopropane or halogen anesthetics**. ■ May cause severe hypertension with **oxytocic drugs** (e.g., methylergonovine [Methergine] or oxytocin). ■ **MAO inhibitors** (e.g., selegiline [Eldepryl]) prolong and potentiate the effect of dopamine. Concurrent use may cause hypertensive crisis. ■ Concurrent administration of low-dose dopamine and diuretic agents may produce an additive or potentiating effect on urine flow. ■ Antagonizes effects of **guanethidine** (Ismelin). ■ Cardiac effects may be antagonized by **alpha- or beta-blocking agents** (e.g., metoprolol [Lopressor], propranolol [Inderal]). ■ **Tricyclic antidepressants** (e.g., amitriptyline [Elavil]) may potentiate the cardiovascular effects of dopamine. ■ May cause severe bradycardia and hypotension with **phenytoin** (Dilantin). ■ **Alpha-adrenergic blocking agents** (e.g., doxazosin [Cardura], tamsulosin [Flomax]) antagonize the peripheral vasoconstriction caused by high-dose dopamine. ■ **Butyrophenones** (e.g., haloperidol [Haldol]) and **phenothiazines** (e.g., chlorpromazine [Thorazine], prochlorperazine [Compazine]) can suppress the dopaminergic renal and mesenteric vasodilation induced with low-dose dopamine. ■ See **Dose Adjustments**.

SIDE EFFECTS

Aberrant conduction/arrhythmias, anginal pain, anxiety, azotemia, bradycardia, dyspnea, ectopic beats, headache, hypertension, hypotension, nausea, palpitation, piloerection, tachycardia, vasoconstriction, vomiting, widened QRS complex. Gangrene of the extremities has occurred with high doses administered for prolonged periods and in patients with occlusive vascular disease receiving a low dose of dopamine.

ANTIDOTE

Notify the physician of all side effects. Decrease infusion rate and notify the physician immediately for decrease in established urine flow rate, disproportionate rise in diastolic BP (i.e., a marked decrease in pulse pressure), increasing tachycardia, or new arrhythmias. For accidental overdose with hypertension, reduce rate or temporarily discontinue until condition stabilizes. Phentolamine, an alpha-adrenergic blocker, may be useful in an overdose situation that does not respond to discontinuation of dopamine.

To prevent sloughing and necrosis in areas where extravasation has occurred, use a fine hypodermic needle to inject 5 to 10 mg of phentolamine (Regitine) diluted in 10 to 15 mL normal saline liberally throughout the tissue in the extravasated area. Begin as soon as extravasation is recognized.

DORIPENEM

(DOR-i-PEN-em)

Doribax**Antibacterial
(carbapenem)****pH 4.5 to 5.5****USUAL DOSE**

18 years of age and older: 500 mg every 8 hours. Duration of therapy is based on diagnosis as listed in the following chart.

Doripenem Dosing Guidelines			
Infection	Dosage	Frequency	Duration
Complicated intra-abdominal infection	500 mg	q 8 hr	5-14 days*
Complicated UTI, including pyelonephritis	500 mg	q 8 hr	10 days†

*Duration includes a possible switch to an appropriate oral therapy after at least 3 days of parenteral therapy and once clinical improvement has been demonstrated.

†Duration can be extended up to 14 days for patients with concurrent bacteremia.

DOSE ADJUSTMENTS

Reduced doses are indicated based on degree of renal insufficiency as noted in the following chart.

Dosage of Doripenem in Patients with Renal Impairment	
Estimated CrCl (mL/min)	Recommended Dosage Regimen
>50 mL/min	No dosage adjustment necessary
≥30 to ≤50 mL/min	250 mg q 8 hr
>10 to <30 mL/min	250 mg q 12 hr

No dose adjustment indicated based on age, gender, race, or impaired hepatic function. ■ Dosing should be cautious in the elderly, and reduced doses may be indicated based on the potential for decreased renal function. ■ There is insufficient information to make dose adjustment recommendations for patients undergoing hemodialysis.

DILUTION

Available in vials containing 250 mg or 500 mg.

250-mg vial: Reconstitute the 250-mg vial with 10 mL of SWFI or NS. Shake gently to form a suspension. Resulting concentration is 25 mg/mL. **Caution: The constituted suspension is not for direct injection.** Withdraw the suspension using a syringe with a 21-gauge needle and add it to an infusion bag containing 50 or 100 mL of NS or D5W. Shake gently until clear. The final infusion solution concentration is approximately 4.2 mg/mL (50-mL infusion bag) or 2.3 mg/mL (100-mL infusion bag).

500-mg vial: Reconstitute a 500-mg vial with 10 mL of SWFI or NS. Shake gently to form a suspension with a resultant concentration of 50 mg/mL. **Caution: The reconstituted suspension is not for direct injection.** Withdraw the suspension using a syringe with a 21-gauge needle and add it to an infusion bag containing 100 mL of NS or D5W. Shake gently until clear. The final infusion solution concentration is 4.5 mg/mL.

To prepare a 250-mg dose from a 500-mg vial, follow the directions above for the 500-mg vial dilution. Remove 55 mL from the infusion bag that contains the 500-mg dose of doripenem diluted in NS or D5W and discard. The remaining solution will contain 250 mg of doripenem at a concentration of 4.5 mg/mL. Alternately to prevent waste, you could prepare 2 doses (one for immediate use and one for use in 8 hours) by dividing

the 10 mL of reconstituted solution in half and adding each 5 mL of reconstituted solution to 50 mL of NS or D5W. Refrigerate the unused dose; see [Storage](#).

Storage: Store unopened vial at CRT. Reconstituted vials are stable for 1 hour prior to transfer to an infusion bag. Infusion solutions diluted in NS are stable for 12 hours at RT and 72 hours refrigerated. Infusion solutions diluted in D5W are stable for 4 hours at RT and 24 hours refrigerated. (Times noted above reflect storage and infusion time.) Do not freeze infusion solutions.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Should not be mixed with or physically added to solutions containing other drugs.”

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), amikacin (Amikin), aminophylline, amiodarone (Nexterone), amphotericin B (conventional), amphotericin B cholesteryl (Amphotec), amphotericin B lipid complex (Abelcet), amphotericin B liposomal (AmBisone), anidulafungin (Eraxis), atropine, azithromycin (Zithromax), bumetanide, calcium gluconate, carboplatin (Paraplatin), caspofungin (Cancidas), ceftaroline (Teflaro), ciprofloxacin (Cipro IV), cisplatin (Platinol), cyclophosphamide (Cytosan), cyclosporine (Sandimmune), daptomycin (Cubicin), dexamethasone (Decadron), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doxorubicin (Adriamycin), enalaprilat (Vasotec IV), esmolol (Brevibloc), esomeprazole (Nexium IV), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fentanyl (Sublimaze), fluconazole (Diflucan), fluorouracil (5-FU), foscarnet (Foscavir), furosemide (Lasix), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), insulin, labetalol, levofloxacin (Levaquin), linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, mannitol (Osmitol), meperidine (Demerol), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), micafungin (Mycamine), midazolam (Versed), milrinone (Primacor), morphine, moxifloxacin (Avelox), norepinephrine (Levophed), ondansetron (Zofran), paclitaxel (Taxol), pantoprazole (Protonix IV), phenobarbital (Luminal), phenylephrine (Neo-Synephrine), potassium chloride, ranitidine (Zantac), sodium bicarbonate, sodium phosphate, tacrolimus (Prograf), telavancin (Vibativ), tigecycline (Tygacil), tobramycin, vancomycin, voriconazole (VFEND IV), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 1 hour.

ACTIONS

A synthetic, broad-spectrum, carbapenem antibiotic. Bactericidal to selected aerobic and anaerobic gram-positive and gram-negative bacteria. Bactericidal activity results from the inhibition of bacterial cell wall synthesis. Stable to hydrolysis by most beta-lactamases, including penicillinases and cephalosporinases produced by gram-positive and gram-negative bacteria, with the exception of carbapenem-hydrolyzing beta-lactamases. Less than 10% bound to plasma proteins. Penetrates into several body fluids and tissues, including those at the site of infection for the approved indications. Metabolized via dehydropeptidase-I. Elimination half-life is approximately 1 hour. Primarily eliminated unchanged by the kidneys.

INDICATIONS AND USES

As a single agent for treatment of complicated intra-abdominal infections and complicated urinary tract infections, including pyelonephritis caused by susceptible strains of microorganisms in patients 18 years of age or older.

CONTRAINDICATIONS

Known hypersensitivity to doripenem or to other carbapenems (e.g., ertapenem [Invanz], imipenem-cilastatin [Primaxin]). ■ Anaphylactic reactions to beta-lactams (e.g., penicillins and cephalosporins); see [Precautions](#).

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, doripenem should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Culture and sensitivity studies are indicated to determine susceptibility of the causative organism to doripenem. ■ Serious and occasionally fatal hypersensitivity reactions have been reported in patients receiving therapy with beta-lactams. More likely in patients with a history of sensitivity to multiple allergens; obtain a careful history. Cross-sensitivity among beta-lactam antibiotics is possible. ■ Seizures have been reported. Risk may be increased in patients with a history of CNS disorders (e.g., stroke or a history of seizures), in patients with compromised renal function, and in patients given doses greater than 500 mg every 8 hours. ■ Prolonged use may cause superinfection because of overgrowth of nonsusceptible organisms. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with doripenem. ■ Although cross-resistance may occur, some isolates resistant to other carbapenems may be susceptible to doripenem. ■ Pneumonitis has been reported when doripenem was used investigationally via inhalation. Do not administer doripenem by this route. ■ See [Drug/Lab Interactions](#).

Monitor: Baseline and periodic monitoring of renal function and CBC with differential may be beneficial. ■ Monitor for early symptoms or hypersensitivity reactions. Emergency equipment must be readily available. ■ Monitor for onset of CNS symptoms and/or seizures. ■ Monitor IV site carefully and rotate as indicated. ■ See [Drug/Lab Interactions](#).

Patient Education: Promptly report S/S of hypersensitivity reaction or pain at injection site. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Review history of any CNS disorder (e.g., stroke, history of seizures); may be at increased risk for seizures. ■ Patients with a history of seizures should review medication profile with physician before taking doripenem; see [Drug/Lab Interactions](#).

Maternal/Child: Category B: should be used during pregnancy and breast-feeding only if clearly needed. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Response similar to that seen in younger patients, but greater sensitivity of some older individuals cannot be ruled out (e.g., increased plasma concentrations). ■ Dosing should be cautious in the elderly; see [Dose Adjustments](#). ■ Monitoring of renal function may be indicated.

DRUG/LAB INTERACTIONS

Carbapenems may reduce serum **valproic acid** concentrations to subtherapeutic levels, resulting in loss of seizure control. Monitor valproic acid levels. Consider alternative antibacterial therapy. If administration of doripenem is necessary, supplemental anticonvulsant therapy should be considered. ■ Concurrent use with **probenecid** results in elevated doripenem plasma concentrations. Concurrent use is not recommended. ■ Does not appear to induce or inhibit the major cytochrome P₄₅₀ isoenzymes, so it should not affect the clearance of drugs that are metabolized by these pathways.

SIDE EFFECTS

The most common adverse reactions are diarrhea, headache, nausea, phlebitis, and rash (allergic rash, bullous dermatitis, erythema, erythema multiforme, macular/papular eruptions, urticaria). Other reactions may include anemia, CDAD, hepatic enzyme elevations, hypersensitivity reactions (including anaphylaxis), oral candidiasis, pruritus, and vulvomyotic infection.

Post-Marketing: Anaphylaxis, interstitial pneumonia, leukopenia, neutropenia, seizures, Stevens-Johnson syndrome, thrombocytopenia, and toxic epidermal necrolysis.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. Discontinue doripenem at the first sign of hypersensitivity. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]) and pressor amines (e.g., dopamine). Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Doripenem is partially removed by hemodialysis.

DOXERCALCIFEROL

(DOX-err-kal-sif-er-ol)

Vitamin D analog

Hectorol Injection**USUAL DOSE**

Optimal dose of doxercalciferol must be individualized. The dose is adjusted in an attempt to achieve intact parathyroid hormone (iPTH) levels within a targeted range of 150 to 300 pg/mL. See **Precautions** and **Monitor**. Recommended initial dose for a patient with an iPTH level greater than 400 pg/mL is 4 mcg administered as a bolus dose three times weekly at the end of dialysis (approximately every other day). Total weekly dose is 12 mcg/week. Maximum dose was limited to 18 mcg/week in clinical studies.

DOSE ADJUSTMENTS

Adjust dosing based on patient response in order to lower blood iPTH into the range of 150 to 300 pg/mL. The following chart is a suggested approach to dose titration. Doses higher than 18 mcg weekly have not been studied. During titration monitor iPTH, serum calcium, phosphorus, and calcium \times phosphorus product ($\text{Ca} \times \text{P}$) weekly. Maximize iPTH suppression while maintaining serum calcium and phosphorous levels in prescribed ranges; see **Monitor**. ■ Immediately suspend dosing if hypercalcemia, hyperphosphatemia, or a $\text{Ca} \times \text{P}$ product of greater than $55 \text{ mg}^2/\text{dL}^2$ is noted. Reinitiate therapy at a dose that is 1 mcg lower when parameters have normalized. ■ Patients with impaired hepatic function may not metabolize doxercalciferol appropriately, see **Precautions**.

Suggested Dose Adjustment Guidelines for Doxercalciferol

iPTH Level	Doxercalciferol Dose Guidelines
Decreased by <50% and above 300 pg/mL	Increase by 1 to 2 mcg at 8-week intervals as necessary
Decreased by >50% and above 300 pg/mL	Maintain
150-300 pg/mL	Maintain
<100 pg/mL	Suspend for 1 week, then resume at a dose that is at least 1 mcg lower

DILUTION

May be given undiluted. Available as 2 mcg/mL solution in 2-mL vials.

Storage: Store unopened vials at 25° C (77° F); range: 15° to 30° C (59° to 86° F). Protect from light. Discard unused portion.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Administer as a bolus dose at the end of dialysis.

ACTIONS

A synthetic vitamin D analog. Metabolizes to a naturally occurring, biologically active form of vitamin D₂ that regulates blood calcium at levels required for essential body functions (i.e., intestinal absorption of dietary calcium, tubular reabsorption of calcium by the kidney and, in conjunction with the parathyroid hormone [PTH], the mobilization of calcium from the skeleton). Acts directly on bone cells (osteoblasts) to stimulate skeletal growth, and on the parathyroid glands to suppress PTH synthesis and secretion. In uremic patients, deficient production of biologically active vitamin D metabolites leads to secondary hyperparathyroidism, which contributes to the development of metabolic bone disease. Doxercalciferol is activated in the liver. Peak blood levels are reached in 2.1 to 13.9 hours. Mean half-life range is 32 to 96 hours.

INDICATIONS AND USES

Reduction of elevated iPTH levels in the management of secondary hyperparathyroidism in patients undergoing chronic renal dialysis.

CONTRAINDICATIONS

Evidence of vitamin D toxicity, hypercalcemia, hyperphosphatemia, or known hypersensitivity to any ingredient in this product; see [Precautions](#).

PRECAUTIONS

Overdose of any form of vitamin D, including doxercalciferol, is dangerous. Progressive hypercalcemia due to overdose of vitamin D and its metabolites may require emergency attention. Acute hypercalcemia may exacerbate tendencies for cardiac arrhythmias and seizures and may potentiate the action of digoxin drugs. Chronic administration may place patient at risk of hypercalcemia, elevated Ca × P product, and generalized vascular and other soft-tissue calcification. If clinically significant hypercalcemia develops, dose should be reduced or held. Do not allow the Ca × P product to exceed 55 mg²/dL². See [Side Effects](#) and [Antidote](#). ■ To avoid possible additive effects and hypercalcemia, phosphate or vitamin D-related compounds should not be taken concomitantly with doxercalciferol. ■ Oversuppression of iPTH levels may lead to adynamic bone syndrome. ■ Hyperphosphatemia can exacerbate hyperparathyroidism. ■ Use caution in patients with impaired hepatic function. More frequent monitoring of iPTH, calcium, and phosphorus levels is recommended. ■ Patients with higher pretreatment serum levels of calcium (more than 10.5 mg/dL) or phosphorus (more than 6.9 mg/dL) may be more likely to experience hypercalcemia or hyperphosphatemia; see [Contraindications](#).

Monitor: During initiation of therapy, obtain baseline serum iPTH, calcium and phosphorus levels and determine levels weekly during the early phase of treatment (i.e., first 12 weeks). For dialysis patients, serum or plasma iPTH and serum calcium, phosphorus, and alkaline phosphatase should be determined periodically. See [Dose Adjustments](#). ■ Calculate Ca × P (should be less than 55 mg²/dL²). ■ Monitor serum calcium levels weekly after all dose changes and during subsequent dose titration. ■ Monitor for signs and symptoms of hypercalcemia. See [Side Effects](#). Radiographic evaluation of suspect anatomical regions may be useful in the early detection of generalized vascular or other soft-tissue calcification. ■ Oral calcium-based or other non-aluminum-containing phosphate binders and a low phosphate diet are indicated to control serum phosphorus levels in dialysis patients. Hyperphosphatemia can lessen the effectiveness of doxercalciferol in reducing blood PTH levels. After initiating doxercalciferol therapy, the dose of calcium-containing phosphate binders should be decreased to correct persistent mild hypercalcemia (10.6 to 11.2 mg/dL for 3 consecutive determinations), or increased to correct persistent mild hyperphosphatemia (7 to 8 mg/dL for 3 consecutive determinations). ■ Persistent or markedly elevated serum calcium levels may be corrected by dialysis against a reduced calcium or calcium-free dialysate. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Report symptoms of hypercalcemia promptly. Dose adjustment or treatment may be required. Strict adherence to dietary supplementation of calcium and re-

striction of phosphorus is required to ensure optimal effectiveness of therapy. Phosphate-binding compounds (e.g., calcium acetate [Phos-10]) may be needed to control serum phosphorus levels in patients with CRF, but excessive use of aluminum-containing products (e.g., aluminum hydroxide gel [Alternagel]) should be avoided. ■ Review all non-prescription drugs with physician.

Maternal/Child: Category B: safety for use in pregnancy not established, use only if clearly needed. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: No overall differences in effectiveness or safety observed.

DRUG/LAB INTERACTIONS

Specific interaction studies have not been performed. ■ **Digoxin** toxicity is potentiated by hypercalcemia. Use caution when doxercalciferol is prescribed concomitantly with digoxin compounds. ■ **Phosphate or vitamin D**-related compounds should not be taken concomitantly with doxercalciferol. ■ May reduce serum total **alkaline phosphatase levels**. ■ **Magnesium-containing antacids** may cause hypermagnesemia; concomitant use is not recommended. ■ Concomitant use with **cytochrome P₄₅₀ enzyme inducers** (e.g., glutethimide, phenobarbital [Luminal], phenytoin [Dilantin], rifampin [Rifadin]) may affect hydroxylation of doxercalciferol and require dose adjustments. ■ Concomitant use with **cytochrome P₄₅₀ enzyme inhibitors** (e.g., erythromycin, ketoconazole [Nizoral]) may inhibit metabolism of the active form of vitamin D, decreasing effectiveness.

SIDE EFFECTS

Dose-limiting side effects are hypercalcemia, hyperphosphatemia, and oversuppression of iPTH (less than 150 pg/mL). Overdose or chronic administration may lead to hypercalcemia. Signs and symptoms of vitamin D intoxication associated with hypercalcemia include: **Early:** anorexia, bone pain, constipation, dry mouth, headache, metallic taste, muscle pain, nausea, somnolence, vomiting, and weakness. **Late:** albuminuria, anorexia, apathy, arrested growth, cardiac arrhythmias, conjunctivitis (calcific), death, decreased libido, dehydration, ectopic calcification, elevated AST and ALT, elevated BUN, hypercholesterolemia, hypertension, hyperthermia, nocturia, overt psychosis (rare), pancreatitis, photophobia, polydipsia, polyuria, pruritus, rhinorrhea, sensory disturbances, somnolence, urinary tract infections, and weight loss.

Overdose: Hypercalcemia, hypercalciuria, hyperphosphatemia, and over-suppression of PTH secretion leading in certain cases to adynamic bone disease. High intake of calcium and phosphate concomitant with doxercalciferol may lead to similar abnormalities. High levels of calcium in the dialysate bath may contribute to hypercalcemia.

ANTIDOTE

Notify physician of any side effects. Treatment of patients with clinically significant hypercalcemia (more than 1 mg/dL above the upper limit of normal range) consists of immediate dose reduction or interruption of the therapy and includes a low-calcium diet, withdrawal of calcium supplements, patient mobilization, attention to fluid and electrolyte imbalances, assessment of electrocardiographic abnormalities (critical in patients receiving digoxin), forced diuresis, and hemodialysis or peritoneal dialysis against a calcium-free dialysate, as warranted. Monitor serum calcium levels frequently until calcium levels return to within normal limits. Not removed from blood during hemodialysis. When serum calcium levels return to within normal limits (usually 2 to 7 days), therapy may be restarted at a dose that is at least 1 mcg lower than prior therapy.

ADR, Adriamycin ■ **Doxil**

pH 3.8 to 6.5 ■ pH 6.5

USUAL DOSE

Assessment required before dosing; see [Precautions](#) and [Monitor](#).

CONVENTIONAL DOXORUBICIN

60 to 75 mg/M² once every 21 days as a **single agent**. An alternate dose schedule is 30 mg/M² once each day for 3 days. Repeat every 4 weeks. When used in **combination** with other agents, the most common dose of doxorubicin is 40 to 60 mg/M² every 21 to 28 days. Recent studies suggest that cardiotoxicity may be reduced and doses may be increased by administration of 20 mg/M² on a weekly basis or by giving larger doses (60 to 75 mg/M²) as a prolonged infusion (48 to 96 hours). A central venous catheter or infuse-a-port would be necessary. Dexrazoxane (Zinecard) is now available to reduce the incidence and severity of cardiomyopathy for women with metastatic breast cancer who have received 300 mg/M² of doxorubicin (see product insert).

Breast cancer with lymph node involvement after resection: Doxorubicin 60 mg/M² in combination with cyclophosphamide 600 mg/M² given IV sequentially on Day 1 of each 21-day treatment cycle. Four cycles have been administered.

Adjuvant treatment of operable node-positive breast cancer: Treatment protocol includes doxorubicin, cyclophosphamide, and docetaxel. Administer doxorubicin 50 mg/M² and cyclophosphamide 500 mg/M². One hour later, give docetaxel 75 mg/M². Repeat every 3 weeks for 6 cycles. See [docetaxel](#) and cyclophosphamide monographs.

DOXIL (LIPOSOMAL DOXORUBICIN)

AIDS-related Kaposi's sarcoma: 20 mg/M² once every 3 weeks. Continue as long as response is satisfactory and treatment is tolerated.

Ovarian cancer: 50 mg/M² as an infusion every 4 weeks for as long as the patient does not progress, shows no evidence of cardiotoxicity, and continues to tolerate treatment. A minimum of four courses is recommended.

Multiple myeloma: Given in combination with bortezomib (Velcade).

Bortezomib: Administer 1.3 mg/M² as an IV bolus on Days 1, 4, 8, and 11 every 3 weeks; see bortezomib monograph. **Doxil:** Administer 30 mg/M² on Day 4 following bortezomib. Continue regimen for up to 8 cycles until disease progression or the occurrence of unacceptable toxicity.

Breast cancer (unlabeled): 30 to 50 mg/M² over 1 hour every 2 to 4 weeks. Other combination protocols are in use.

PEDIATRIC DOSE

CONVENTIONAL DOXORUBICIN: 30 mg/M² once each day for 3 days. Repeat every 4 weeks. See [Maternal/Child](#).

DOXIL: Safety for use in pediatric patients not established.

DOSE ADJUSTMENTS

ALL DOXORUBICINS: **Elevated serum bilirubin:** Give 50% of above doses for serum bilirubin from 1.2 to 3 mg/mL and 25% for serum bilirubin above 3 mg/mL. ■ Reduce dose in patients with impaired hepatic function. ■ See [Precautions](#).

CONVENTIONAL DOXORUBICIN: Reduce dose in impaired kidney function. ■ Lower-end doses are appropriate for the elderly (inadequate marrow reserves) and those with prior therapy or neoplastic marrow infiltration.

Breast cancer with lymph node involvement after resection: Reduce dose to 75% of the starting dose for neutropenic fever/infection. If necessary, delay the next cycle of treatment

until the ANC is 1,000 cells/mm³ or more and the platelet count is 100,000 cells/mm³ or more and nonhematologic toxicities have resolved.

DOXIL: Dose adjustments are required in hematologic toxicity (see the following chart) and in patients with stomatitis or hand-foot syndrome (HFS) (see product literature for guidelines). Adjust or delay a dose as described in the product literature at the first sign of a Grade 2 or higher adverse event. Once the dose has been decreased, it should not be increased at a later time.

Doxil Dosing Based on Hematologic Toxicity			
Grade	ANC (cells/mm ³)	Platelets (cells/mm ³)	Modification
1	1,500-1,900 cells/mm ³	75,000-150,000 cells/mm ³	Resume treatment with no dose reduction
2	1,000-<1,500 cells/mm ³	50,000-<75,000 cells/mm ³	Wait until ANC ≥1,500 and platelets ≥75,000; redose with no dose reduction
3	500-999 cells/mm ³	25,000-<50,000 cells/mm ³	Wait until ANC ≥1,500 and/or platelets ≥75,000; redose with no dose reduction
4	<500 cells/mm ³	<25,000 cells/mm ³	Wait until ANC ≥1,500 and/or platelets ≥75,000; redose at 25% dose reduction or continue full dose with cytokine support

Dose adjustments for doxil and bortezomib combination therapy for treatment of multiple myeloma are listed in the following chart. See bortezomib monograph for additional dose adjustments.

Dose Adjustments for Doxil and Bortezomib Combination Therapy		
Patient Status	Doxil	Bortezomib
Fever ≥38° C ANC <1,000/mm ³	Do not dose this cycle if before Day 4; if after Day 4, reduce next dose by 25%.	Reduce next dose by 25%.
On any day of drug administration after Day 1 of each cycle: Platelet count <25,000/mm ³ Hemoglobin <8 Gm/dL ANC <500/mm ³	Do not dose this cycle if before Day 4; if after Day 4, reduce next dose by 25% in the following cycles if bortezomib is reduced for hematologic toxicity.	Do not dose; if 2 or more doses are not given in a cycle, reduce dose by 25% in the following cycles.
Grade 3 or 4 nonhematologic drug-related toxicity	Do not dose until recovered to Grade <2, and reduce dose by 25% for all subsequent doses.	Do not dose until recovered to Grade <2, and reduce dose by 25% for all subsequent doses.
Neuropathic pain or peripheral neuropathy	No dose adjustments.	See bortezomib manufacturer's prescribing information for dose adjustments in patients with neuropathic pain.

DILUTION

Specific techniques required; see Precautions.

CONVENTIONAL DOXORUBICIN: Each 10 mg must be diluted with 5 mL of NS. Do not use bacteriostatic diluent. An additional 5 mL of diluent for each 10 mg is recommended (2 mg/mL). Shake to dissolve completely. Also available in preservative-free solutions. May be further diluted in 50 mL or more D5W or NS and given as a continuous infusion through a central venous line.

Doxil: Doses up to 90 mg must be diluted in 250 mL D5W. Not a clear solution, but a translucent red liposomal dispersion. Do not use filters. Doses over 90 mg should be diluted in 500 mL D5W. See [Compatibility](#).

Filters: *Conventional doxorubicin:* Data not available from manufacturer; however, one source indicates no evidence of drug loss when administered through a 0.2-micron in-line nylon filter, and another source indicates no significant drug loss using various types of 0.2-micron filters.

Doxil: Do not use filters during preparation or administration.

Storage: *Conventional doxorubicin:* Refrigerate unopened vials; protect from light. Reconstituted solution stable for 7 days at CRT and 15 days refrigerated. Diluted solution stable 24 hours at room temperature, 48 hours if refrigerated; then discard. Protect from sunlight.

Doxil: Refrigerate unopened vials; avoid freezing for longer than 1 month. Refrigerate diluted solution and use within 24 hours.

COMPATIBILITY (Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

CONVENTIONAL DOXORUBICIN

Manufacturer lists fluorouracil and heparin as **incompatible** and states mixing with other drugs is not recommended unless specific **compatibility** data available.

One source suggests the following **compatibilities**:

Additive: Bleomycin (Blenoxane), cyclophosphamide (Cytoxan), dacarbazine (DTIC), ondansetron (Zofran), paclitaxel (Taxol), vinblastine, vincristine.

Y-site: Amifostine (Ethyol), anidulafungin (Eraxis), aztreonam (Azactam), bleomycin (Blenoxane), caspofungin (Cancidas), cisplatin (Platinol), cladribine (Leustatin), cyclophosphamide (Cytoxan), doripenem (Doribax), droperidol (Inapsine), etoposide phosphate (Etopophos), famotidine (Pepcid IV), filgrastim (Neupogen), fludarabine (Fludara), fluorouracil (5-FU), gemcitabine (Gemzar), granisetron (Kytrel), leucovorin calcium, linezolid (Zyvox), melphalan (Alkeran), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), mitomycin (Mutamycin), ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), sargramostim (Leukine), sodium bicarbonate, teniposide (Vumon), thiotepa, topotecan (Hycamtin), vinblastine, vincristine, vinorelbine (Navelbine).

DOXIL

Specific information not available. Manufacturer states, "Do not mix with other drugs unless specific **compatibility** data available. Do not use any other diluent (use D5W only). Do not use any bacteriostatic agents (e.g., benzyl alcohol)."

One source suggests the following **compatibilities**:

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), aminophylline, ampicillin, aztreonam (Azactam), bleomycin (Blenoxane), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), cefazolin (Ancef), cefepime (Maxipime), cefoxitin (Mefoxin), ceftriaxone (Rocephin), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytoxan), cytarabine (ARA-C), dacarbazine (DTIC), dexamethasone (Decadron), diphenhydramine (Benadryl), dobutamine, dopamine, droperidol (Inapsine), enalaprilat (Vasotec IV), etoposide (VePesid), famotidine (Pepcid IV), fluconazole (Diflucan), fluorouracil (5-FU), furosemide (Lasix), ganciclovir (Cytovene), gentamicin, granisetron (Kytrel), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), leucovorin calcium, lorazepam (Ativan), magnesium sulfate, mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metronidazole (Flagyl IV), ondansetron (Zofran), potassium chloride (KCl), prochlorperazine (Compazine), ranitidine (Zantac), sulfamethoxazole/trimethoprim, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vinblastine, vincristine, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

CONVENTIONAL DOXORUBICIN

IV injection: A single dose of properly diluted medication over a minimum of 3 to 5 minutes. Should be given through Y-tube or three-way stopcock of a free-flowing infusion of NS or D5W. Slow injection rate further for erythematous streaking along the vein or facial flushing.

Continuous infusion: Central venous line required. Equally distributed over 24 hours.

DOXIL

For IV infusion only; do not administer IM or SC. Rapid infusion may increase risk of acute infusion-related reactions (e.g., apnea, asthma, back pain, bronchospasm, chills, cyanosis, facial swelling, fever, flushing, headache, hypotension, pruritus, rash, shortness of breath, syncope, tachycardia, tightness in the chest or throat). Primarily occurs during the first infusion; may resolve with a reduced rate or may take up to a day after infusion completed to resolve. Avoid rapid flushing of the infusion line.

Begin with an initial rate of 1 mg/min to minimize the risk of infusion reactions. If no adverse infusion-related effects, the rate may be increased from the initial rate of 1 mg/min to evenly distribute and complete infusion over 1 hour.

ACTIONS

CONVENTIONAL DOXORUBICIN: A highly toxic antibiotic antineoplastic agent that is cell cycle specific for the S phase. Widely distributed and rapidly cleared from plasma, it interferes with cell division by binding with DNA to slow production of nucleic acid synthesis. Tissue levels remain constant for 7 to 10 days. Metabolized in the liver. Elimination half-life is 18 to 30 hours. Does not cross blood-brain barrier. Slowly excreted in bile and urine. Secreted in breast milk.

DOXIL: Doxorubicin encapsulated in long-circulating STEALTH liposomes (phospholipids). The small size of these liposomes and their persistence in the circulation enable them to evade immune system detection and penetrate the often altered and/or compromised vasculature of tumors. Once distributed to tumor tissue, the doxorubicin is released by an unknown mechanism. It differs from conventional doxorubicin because it mostly confines itself to vascular fluid volume. Metabolized and eliminated renally. Plasma clearance is slower. Half-life is extended to 55 hours. Concentration in Kaposi's sarcoma lesions is much higher than in normal skin (range is 3 to 53 times higher).

INDICATIONS AND USES

CONVENTIONAL DOXORUBICIN: To suppress or retard neoplastic growth. Regression has been produced in soft tissue and bone sarcomas; Hodgkin's disease; non-Hodgkin's lymphomas; acute leukemias; breast, GU, thyroid, lung, ovarian, and stomach carcinoma and transitional cell bladder carcinoma; neuroblastoma; Wilms' tumor; and many other carcinomas. ■ Adjuvant therapy in women with evidence of axillary lymph node involvement following resection of primary breast cancer. ■ Adjuvant treatment of operable node-positive breast cancer in combination with cyclophosphamide and docetaxel.

DOXIL: Treatment of AIDS-related Kaposi's sarcoma in patients whose disease has progressed on prior combination chemotherapy or who are intolerant to combination chemotherapy. ■ Treatment of metastatic carcinoma of the ovary in patients with disease that is refractory to platinum-based chemotherapy regimens (e.g., cisplatin [Platinol], carboplatin [Paraplatin]). ■ Treatment of multiple myeloma in combination with bortezomib (Velcade) in patients who have received one prior therapy but have not previously received bortezomib.

Unlabeled uses: *Doxil:* Treatment of refractory metastatic breast cancer.

CONTRAINDICATIONS

CONVENTIONAL DOXORUBICIN: Myelosuppression resulting from treatment with other antineoplastic agents, radiotherapy, impaired cardiac function, or previous treatment with complete cumulative doses of doxorubicin, daunorubicin, idarubicin, and/or other anthracyclines and anthracenes.

ALL DOXORUBICINS: History of hypersensitivity to conventional or liposomal formulations of doxorubicin or to their components.

PRECAUTIONS

ALL DOXORUBICINS: Follow guidelines for handling cytotoxic agents and patient excreta. Precautions recommended for up to 5 days after a dose. See Appendix A, p. 1251. ■ Usually administered by or under the direction of a physician specialist, with facilities for monitoring the patient and responding to any medical emergency. ■ For IV use only. Do not give IM or SC. ■ **Do Not Substitute** Doxil for conventional doxorubicin on a mg/mg basis. Severe side effects have resulted. Differences in liposomal products as well as conventional products can substantially affect the functional properties of these agents; do not substitute one agent for another. ■ Use extreme caution in pre-existing drug-induced bone marrow suppression, existing heart disease, hepatic impairment, previous treatment with other anthracyclines (e.g., daunorubicin), other cardiotoxic agents (e.g., bleomycin), concurrent cyclophosphamide therapy, or radiation therapy encompassing the heart; risk of cardiotoxicity increased and may occur at lower doses. ■ All forms of doxorubicin may cause cardiotoxicity. May be manifest by acute (e.g., sinus tachycardia, ECG abnormalities) or delayed (e.g., reduction in LVEF, CHF) events. Life-threatening or fatal congestive heart failure may occur during therapy or months after therapy is completed. Cardiotoxicity occurs with increasing frequency as cumulative doses increase above 300 mg/M². The risk of developing CHF increases rapidly with increasing total cumulative doses above 400 mg/M²; see [Antidote](#). Prior use of other anthracyclines or anthracenediones should be included in calculations of total cumulative dose. Patients with active or dormant cardiovascular disease or patients who have received radiotherapy to the mediastinal area or concomitant therapy with other anthracyclines (e.g., daunorubicin, idarubicin), anthracenediones, or other cardiotoxic agents (e.g., bleomycin, cyclophosphamide, mitoxantrone, mitomycin C) may be at greater risk. These recommendations may change in specific situations now that dexrazoxane is available to reduce the incidence and severity of cardiomyopathy; however, cardiac toxicity may occur at lower cumulative doses even if cardiac risk factors are not present. ■ May cause severe myelosuppression. ■ May have cross-sensitivity with lincomycin. ■ Not considered effective in the treatment of brain tumors, cancers of the kidney or large bowel, CNS metastasis, or malignant melanoma. ■ See [Maternal/Child](#) and [Side Effects](#).

CONVENTIONAL DOXORUBICIN: Used cautiously with other antineoplastic drugs to achieve tumor remission. ■ Secondary acute myelogenous leukemia (AML) and myelodysplastic syndrome (MDS) have been reported in adult and pediatric patients; the occurrence of refractory secondary AML or MDS is more common when doxorubicin is given in combination with DNA-damaging antineoplastic agents or radiotherapy, in patients heavily pretreated with cytotoxic drugs, or when doses of doxorubicin have been escalated.

DOXIL: Benefits must outweigh risks if Doxil is used in patients with a history of cardiovascular disease. ■ Acute infusion-related reactions and serious, sometimes life-threatening or fatal hypersensitivity/anaphylactoid-like reactions have been reported; see [Monitor](#). ■ Has caused hand-foot syndrome. Incidence may be increased with higher doses or increased frequency. Generally seen after 2 or 3 cycles, but may occur earlier. May be severe and require a dose adjustment or discontinuation of Doxil. ■ Severe, additive myelosuppression may occur in Kaposi's sarcoma patients and may be dose limiting.

Monitor: ALL DOXORUBICINS: Monitoring of CBC including differential and platelet count, uric acid levels, electrolytes, liver function (AST, ALT, alkaline phosphatase, and bilirubin), kidney function, ECG, chest x-ray, echocardiogram, and left ventricular ejection fraction (LVEF) is necessary before and during therapy. At a minimum, CBC with platelets should be monitored before each dose. Testing for renal and hepatic function may also be indicated; see [Dose Adjustments](#). ■ Observe for S/S of cardiotoxicity (e.g., fast or irregular HR, shortness of breath, swelling of the feet or lower legs). Endomyocardial biopsy or gated radionuclide scans have been used to monitor potential cardiac toxicity. ■ Maintain adequate hydration and urine alkalinization. ■ Allopurinol may prevent formation of uric acid crystals. ■ Be alert for signs of bone marrow suppression, bleeding, or infection. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and

secretions for occult blood). ■ Use of prophylactic antibiotics may be indicated pending C/S in a febrile, neutropenic patient. Sepsis in a neutropenic patient has resulted in discontinuation of treatment and in rare cases, death. ■ Prophylactic antiemetics are indicated. ■ See [Drug/Lab Interactions](#).

CONVENTIONAL DOXORUBICIN: Use only large veins. Avoid veins over joints or in extremities with compromised venous or lymphatic drainage. Determine absolute patency of vein. A stinging or burning sensation indicates extravasation; severe cellulitis and tissue necrosis will result. **Extravasation may occur with or without stinging or burning and even if blood returns well on aspiration of infusion needle.** Observe and touch site frequently to feel air and/or liquid under the skin. If extravasation occurs discontinue injection; use another vein.

DOXIL: Monitor for S/S of acute infusion reactions and/or hypersensitivity (e.g., apnea, asthma, back pain, bronchospasm, chills, cyanosis, facial swelling, fever, flushing, headache, hypotension, pruritus, rash, shortness of breath, syncope, tachycardia, tightness in the chest or throat). The majority of infusion-related reactions occur during the first infusion. ■ Extravasation may cause irritation at infusion site. Discontinue, use another vein.

Patient Education: ALL DOXORUBICINS: Urine and other body fluids will be reddish for several days (from dye, not hematuria). ■ Nonhormonal birth control recommended. May induce chromosomal damage in sperm. Effective contraceptive method for men required. ■ Effects may be additive with current medications. Review all medications (prescription and nonprescription) with nurse and/or physician. ■ Report promptly cough, fast heartbeat, shortness of breath and/or swelling of the feet or lower legs. ■ Report S/S of infection (e.g., chills, fever, painful urination), stomatitis, bothersome side effects, or any unusual bleeding (e.g., bruising, tarry stools). ■ Report IV site burning, stinging, puffiness, or the feeling of liquid under the skin and any other side effects promptly. ■ Report tingling, burning, redness, flaking, swelling, blisters or small sores on the palms of hands or soles of feet. ■ See [Precautions](#). ■ See Appendix D, p. 1255.

Maternal/Child: ALL DOXORUBICINS: Category D: avoid pregnancy; can cause fetal harm. ■ Has been used only when benefits outweigh risks. ■ Discontinue breast-feeding. ■ Treatment during childhood may result in abnormal cardiac function, especially in females. ■ Infants and children are at increased risk for developing delayed cardiotoxicity; follow-up cardiac evaluation is recommended; see [Precautions](#). ■ Infants and children may be at greater risk for developing acute myelogenous leukemia (AML) and other neoplasms. ■ Infants and children may develop S/S of acute “recall” pneumonitis with concomitant use of doxorubicin and dactinomycin (Cosmegen) after local radiation therapy. ■ In infants under 2 years of age, doxorubicin clearance is similar to adults, but clearance may be increased in pediatric patients over 2 years of age. ■ May contribute to prepubertal growth failure and/or gonadal impairment (which is usually temporary). ■ See [Precautions](#), extended recommendations for handling patient excreta.

DOXIL: Safety for use in pediatric patients not established.

Elderly: ALL DOXORUBICINS: Response similar to that seen in younger adults, but greater sensitivity of some older individuals cannot be ruled out. ■ Cardiotoxicity and myelotoxicity may be more severe in patients over 70 years of age. ■ Consider age-related organ impairment and concomitant disease and/or drug therapy; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Studies not yet completed for Doxil; interactions may be similar to conventional doxorubicins. ■ May exacerbate **cyclophosphamide**-induced hemorrhagic cystitis or increase hepatotoxicity of **6-mercaptopurine**. ■ May increase bone marrow toxicity of **other chemotherapeutic agents and radiation**. ■ **Barbiturates** increase clearance and decrease effects. ■ May decrease serum levels of **digoxin**. ■ May decrease serum levels of **anticonvulsants** (e.g., phenytoin [Dilantin], carbamazepine [Tegretol], valproate [Depacon]) when given concurrently with **cisplatin**. ■ Risk of cardiotoxicity increased in patients previously treated with maximum cumulative doses of **other anthracyclines** (e.g., idarubicin [Idamycin]) **and/or radiation encompassing the heart**. ■ Concurrent use with **hepatotoxic agents** (e.g., methotrexate) may increase risk of toxicity. ■ **Cyclosporine** (Sandimmune) **and streptozocin** (Zanosar) may decrease clearance and increase toxicity of

doxorubicin. ■ **Paclitaxel** (Taxol) appears to decrease the clearance of doxorubicin. Administration of doxorubicin before paclitaxel is recommended to prevent increased toxicity. ■ Coadministration with high-dose **progesterone** may increase doxorubicin toxicity. ■ Many drug interactions possible; observe patient closely. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Increased toxicity to mucosa, myocardium, skin (including redness and exfoliative changes), and liver possible when given concurrently **with or after radiation**. ■ Necrotizing colitis (e.g., bloody stools, cecal inflammation, severe and sometimes fatal infections) has been reported with the combination of doxorubicin by IV push daily for 3 days and **cytarabine** as a continuous infusion daily for 7 or more days. ■ **Dexrazoxane** is given with doxorubicin to reduce cardiotoxic effects. May also decrease anti-tumor effectiveness if given before a cumulative dose of doxorubicin 300 mg/M² is reached or other chemotherapeutic agents are included in the protocol (e.g., fluorouracil). ■ See **Precautions**.

SIDE EFFECTS

ALL DOXORUBICINS: Abdominal pain; alopecia (complete); anorexia; asthenia; bone marrow suppression (e.g., anemia, hypochromic anemia, leukopenia, neutropenia [ANC less than 1,000/mm³], thrombocytopenia may be dose-limiting); cardiac toxicity (e.g., CHF); constipation; decreased serum calcium; depressed QRS voltage; diarrhea; dry skin; esophagitis; fatigue; fever; gonadal suppression; headache; hyperpigmentation of nail beds and dermal creases; hypersensitivity reactions (including life-threatening or fatal anaphylaxis); hyperuricemia; increase in alkaline phosphatase, ALT, AST, bilirubin, BUN, glucose, SCr; mucositis; nausea; oral moniliasis; paresthesia; prolonged PT; rash; recall of skin reactions due to prior radiotherapy; stomatitis; weakness; vomiting.

DOXIL: In addition to all of the above, acute infusion reactions, hand-foot syndrome. **Kaposi's sarcoma** patients may be taking numerous other drugs that may confuse the overall side effect picture (e.g., didanosine [ddl], stavudine [D4T], sulfamethoxazole/trimethoprim, zalcitabine [ddC], zidovudine [AZT, Retrovir]).

Post-Marketing: Muscle spasms, myelogenous leukemia, pulmonary embolism, and skin and subcutaneous tissue disorders (e.g., erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis).

Overdose: **ALL DOXORUBICINS:** Increase in bone marrow suppression and mucositis.

ANTIDOTE

ALL DOXORUBICINS: Most side effects will either be tolerated or treated symptomatically. Keep the physician informed. Bone marrow toxicity may require cessation of therapy. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Acute cardiac failure occurs suddenly (most common when total cumulative dosage approaches 550 mg/M²) and frequently does not respond to currently available treatment (digoxin, diuretics [e.g., furosemide (Lasix)], ACE inhibitors [e.g., enalapril]). Close monitoring of accumulated dosage, bone marrow, ECG, chest x-ray, echocardiography, and systolic ejection fraction may prevent most serious and potentially fatal cardiac side effects. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Treat hypersensitivity reactions as required; discontinue therapy if severe.

CONVENTIONAL DOXORUBICIN: For extravasation flood the area with normal saline. Use a 27- or 25-gauge needle. Elevate the extremity, apply cold compresses, and ice for 30 minutes four times a day for 3 days. Site should be observed promptly by a reconstructive surgeon.

DOXIL: In addition to all of the above, treatment may have to be interrupted or discontinued for severe hand-foot syndrome or acute infusion reactions. Infusion reactions may resolve with slowing of infusion rate. May be able to control hand-foot syndrome by allowing it to resolve and by increasing intervals between subsequent cycles. For extravasation, discontinue infusion and apply ice over site for 30 minutes to alleviate local reaction.

DOXYCYCLINE HYCLATE(dox-ih-**SYE**-kleen **HI**-klayt)Antibacterial
(tetracycline)
Antiprotozoal
Antimalarial**Doxy 100, Doxy 200**

pH 1.8 to 3.3

USUAL DOSE**ADULTS AND PEDIATRIC PATIENTS OVER 45 KG**

200 mg the first day in one or two infusions followed by 100 to 200 mg/24 hr on subsequent days in one or two infusions. Depends on severity of the infection. Transfer to oral therapy as soon as practical.

Primary and secondary syphilis: 100 to 150 mg every 12 hours for 10 to 28 days.

Acute pelvic inflammatory disease: 100 mg every 12 hours. Used in combination with cefoxitin 2 Gm every 6 hours.

Prevention and/or treatment of anthrax post-exposure: 100 mg every 12 hours.

PEDIATRIC DOSE**PEDIATRIC PATIENTS 45 KG OR LESS (BUT OVER 8 YEARS)**

4.4 mg/kg of body weight/24 hr in one or two equally divided doses (2.2 mg/kg every 12 hours). Follow on subsequent days with 2.2 to 4.4 mg/kg/24 hr given once daily or in two equally divided doses (1.1 to 2.2 mg/kg every 12 hours). Do not exceed adult dose. See [Maternal/Child](#).

Prevention and/or treatment of anthrax post-exposure: 2.2 mg/kg every 12 hours.

DOSE ADJUSTMENTS

Reduction may be indicated in impaired liver function. ■ See [Drug/Lab Interactions](#).

DILUTION

Check expiration date. Outdated ampules may cause nephrotoxicity. Each 100 mg or fraction thereof is diluted with 10 mL of SWFI or NS. Further dilute each 10 mL with 100 to 1,000 mL of a **compatible** infusion solution such as NS, D5W, R, LR, D5LR, 10% invert sugar in water, Normosol-M or Normosol-R in 5% dextrose in water, or other **compatible** solutions (see literature). Recommended concentrations 0.1 to 1 mg/mL. 1,000 mL diluent equals 0.1 mg/mL, 100 mL equals 1 mg/mL. Protect from direct sunlight during infusion.

Storage: Store at CRT; protect from light. After reconstitution, must be refrigerated and used within 72 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Meropenem (Merrem IV), ranitidine (Zantac).

Y-site: Acyclovir (Zovirax), amifostine (Ethylol), amiodarone (Nexterone), aztreonam (Azactam), bivalirudin (Angiomax), cisatracurium (Nimbex), cyclophosphamide (Cytosan), dexmedetomidine (Precedex), diltiazem (Cardizem), docetaxel (Taxotere), etoposide phosphate (Etopophos), fenoldopam (Corlopam), filgrastim (Neupogen), fludaurine (Fludara), gemcitabine (Gemzar), granisetron (Kytril), hetastarch in electrolytes (Hextend), hetastarch in NS (Hespan), hydromorphone (Dilaudid), linezolid (Zyvox), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), morphine, ondansetron (Zofran), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepa, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

Each 100 mg or fraction thereof, properly diluted, over a minimum of 1 to 4 hours. 100 mg diluted in 100 mL equals 1 mg/mL and must be given over a minimum of 2

hours. 100 mg diluted in 200 mL equals 0.5 mg/mL and can be given in 1 hour if absolutely necessary. Infusion must be completed in 6 hours when diluted in LR injection with or without dextrose 5% and in 12 hours when diluted in other **compatible** solutions.

ACTIONS

A broad-spectrum tetracycline antibiotic, bacteriostatic against many gram-positive and gram-negative organisms and protozoa. Thought to interfere with the protein synthesis of microorganisms. Doxycycline is well distributed in most body tissues and is highly bound to plasma protein. Doxycycline may penetrate normal meninges, the eye, and the prostate more easily than most tetracyclines. Half-life is 12 to 22 hours. Partially metabolized in the liver and excreted in bile, urine, and feces. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Infections caused by susceptible strains or organisms, such as rickettsiae, spirochetal agents, and many other gram-negative and gram-positive bacteria. Types of infections treated may include GU infections, including those caused by *Chlamydia trachomatis* and *Neisseria gonorrhoeae*; respiratory tract infections, including mycoplasmal pneumonia, skin and soft tissue infections, and others. ■ To substitute for contraindicated penicillin or sulfonamide therapy. ■ Drug of choice when a tetracycline is indicated for treatment of an extrarenal infection in patients with renal impairment. ■ Adjunct to amebicides in acute intestinal amebiasis. ■ Prevention and/or treatment of anthrax in all its forms, including cutaneous and inhalation anthrax post-exposure.

CONTRAINDICATIONS

Known hypersensitivity to tetracyclines; pregnancy, breast-feeding. Not recommended in pediatric patients under 8 years.

PRECAUTIONS

Sensitivity studies indicated to determine susceptibility of the causative organism to doxycycline. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, doxycycline should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for at least 2 to 3 days after all symptoms of infection subside. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in impaired liver function. Doxycycline serum concentrations and liver function tests are indicated. ■ Pseudomembranous colitis has been reported. May range from mild to life threatening. Consider in patients that present with diarrhea during or after treatment with doxycycline. ■ Initiate oral therapy as soon as possible. ■ Organisms resistant to one tetracycline are usually resistant to others. ■ If syphilis is suspected, perform a darkfield examination before initiating tetracyclines.

Monitor: Determine absolute patency of vein and avoid extravasation; thrombophlebitis may occur. ■ Monitor blood glucose; may reduce insulin requirements. ■ See [Drug/Lab Interactions](#).

Patient Education: May cause dizziness or light-headedness; request assistance for ambulation. ■ Alert patient to photosensitive skin reaction. ■ Consider birth control options.

Maternal/Child: Category D: avoid pregnancy; see [Contraindications](#). ■ May cause skeletal retardation in the fetus and infants and permanent tooth discoloration in pediatric patients under 8 years, including in utero or through mother's milk. ■ Discontinue breast-feeding.

DRUG/LAB INTERACTIONS

Inhibits **oral contraceptives**; may result in pregnancy or breakthrough bleeding. ■ May alter **lithium** levels. ■ Interferes with bactericidal action of **all penicillins** (e.g., ampicillin, oxacillin). May be toxic with **sulfonamides**. ■ Serum levels decreased by **barbiturates**, **carbamazepine** (Tegretol), **hydantoin**s (e.g., phenytoin), and others. ■ May depress **plasma prothrombin activity**; a reduction in anticoagulant dose may be indicated.

SIDE EFFECTS

Relatively nontoxic in average doses. More toxic in large doses or if given too rapidly. Anogenital lesions, anorexia, blood dyscrasias, CNS toxicity (e.g., dizziness, light-headedness), diarrhea, dysphagia, enterocolitis, nausea, skin rashes, vomiting.

Major: Hypersensitivity reactions including anaphylaxis; blurred vision and headache (benign intracranial hypertension); bulging fontanels in infants; hepatotoxicity; pancreatitis; photosensitivity, pseudomembranous colitis, systemic candidiasis; thrombophlebitis.

ANTIDOTE

Notify the physician of all side effects. If minor side effects are progressive or any major side effect occurs, discontinue the drug, treat hypersensitivity reactions as indicated or resuscitate as necessary. Mild cases of colitis may respond to discontinuation of doxycycline. Treat antibiotic-related pseudomembranous colitis with fluid, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl). Not removed by hemodialysis.

DROPERIDOL **BBW**(droh-**PER**-ih-dohl)**Inapsine****Antiemetic
Anesthesia adjunct****pH 3 to 3.8****USUAL DOSE**

May cause serious proarrhythmic effects and death; reserve use to patients for whom other treatments are ineffective or inappropriate. Dose should be individualized and initiated at a low dose. Adjust upward, with caution, to achieve the desired effect. Consider age, body weight, physical status, underlying pathological conditions, use of other drugs, type of anesthesia to be used, and surgical procedure involved; see **Precautions**. Maximum recommended initial dose is 2.5 mg. Additional 1.25-mg doses may be given to achieve the desired effect but should be used only if the potential benefit outweighs the potential risk.

Prevention of perioperative nausea and vomiting: Dose should be individualized; maximum initial dose is 2.5 mg by slow IV injection. Additional 1.25-mg doses may be given with caution to achieve desired effect only if benefits outweigh potential risk. 0.625 to 1.25 mg has been shown to have an effect similar to ondansetron (Zofran) 4 mg.

PEDIATRIC DOSE

Prevention of perioperative nausea and vomiting, pediatric patients 2 to 12 years: The maximum recommended dose is 0.1 mg/kg (100 mcg/kg). Another source suggests 0.03 to 0.07 mg/kg/dose (30 to 70 mcg/kg/dose) over 2 minutes or up to 0.1 mg/kg/dose with caution to achieve desired effect only if benefits outweigh potential risk and total dose does not exceed 2.5 mg. May be given IM or IV. See **Maternal/Child**.

DOSE ADJUSTMENTS

Initiate at a low dose and adjust upward with caution to achieve the desired effect. ■ Reduce dose of narcotics and all CNS depressants to one fourth or one third of usual dose before, during, and for 24 hours after injection of droperidol. ■ If other CNS depressants (e.g., narcotics) have been given previously, reduce dose of droperidol. ■ Reduce dose for elderly, debilitated, and poor-risk patients and those with impaired kidney or liver function.

DILUTION

May be given undiluted. Give through Y-tube or three-way stopcock of the infusion set. May be added to a convenient volume of selected infusion solutions (D5W, NS, or LR).

Filters: No data available from manufacturer.

Storage: Store vials at CRT; protect from light. Diluted solutions stable at CRT for at least 48 hours (up to 7 days in selected solutions; see literature).

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Will precipitate if mixed with barbiturates" (e.g., phenobarbital [Luminal]).

One source suggests the following **compatibilities:**

Y-site: Acyclovir (Zovirax), amifostine (Ethyol), azithromycin (Zithromax), aztreonam (Azactam), bivalirudin (Angiomax), bleomycin (Blenoxane), cisatracurium (Nimbex), cisplatin (Platinol), cladribine (Leustatin), cyclophosphamide (Cytoxan), dexmedetomidine (Precedex), docetaxel (Taxotere), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), gemcitabine (Gemzar), granisetron (Kytrel), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), idarubicin (Idamycin), linezolid (Zyvox), melphalan (Alkeran), meperidine (Demerol), metoclopramide (Reglan), mitomycin (Mutamycin), ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), potassium chloride (KCl), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), teniposide (Vumon), thiotepa, vinblastine, vincristine, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

IV injection: Adults: 2.5 mg or fraction thereof over 1 to 2 minutes. **Pediatric patients:** A single dose or fraction thereof over a minimum of 2 minutes.

Infusion: Titrate by dose and desired patient response. Do not exceed rate for IV injection.

ACTIONS

An antianxiety agent that produces marked tranquilization and sedation. Has an antiemetic action also. It produces mild alpha-adrenergic blockade and produces peripheral vascular dilation. May decrease an abnormally high pulmonary arterial pressure. A dose-dependent and significant QT prolongation at all dose levels (0.1, 0.175, and 0.25 mg/kg) has been observed within 10 minutes of administration in patients without known cardiac disease. Effective in 3 to 10 minutes with maximum results in 30 minutes. Lasts 2 to 4 hours. Some effects persist for 12 hours. Metabolized in the liver. Excreted in urine and feces. Crosses placental barrier very slowly. Secreted in breast milk.

INDICATIONS AND USES

To reduce the incidence of nausea and vomiting associated with surgical and diagnostic procedures.

Unlabeled uses: Antiemetic in cancer chemotherapy including potent emetic agents (e.g., cisplatin). ■ Treatment of acute psychotic episodes manifested by severe agitation and combativeness. ■ Adjunct to local or general anesthesia.

CONTRAINDICATIONS

Known hypersensitivity to droperidol or other butyrophenones (e.g., haloperidol [Hal-dol]) and patients with known or suspected QT prolongation, including those with congenital long QT syndrome.

PRECAUTIONS

Use of agents other than droperidol is recommended. ■ QT prolongation and torsades de pointes have been reported with doses at or below those recommended. Some cases have occurred in patients with no known risk factors for QT prolongation, and some cases have been fatal. ■ Use with extreme caution in patients who may be at risk for development of prolonged QT syndrome (e.g., clinically significant bradycardia [less than 50 bpm]; CHF or any clinically significant cardiac disease; use of a diuretic; treatment with class IA antiarrhythmics and/or class III antiarrhythmics; treatment with MAO inhibitors [e.g., selegiline (Eldepryl)]; concomitant treatment with other drug products known to prolong the QT interval; electrolyte imbalance, in particular hypokalemia or hypomagnesemia; alcoholism; or concomitant treatment with drugs that may cause electrolyte imbalance or hypovolemia). See **Drug Interactions**. ■ Other risk factors may include patients over 65 years of age, alcohol abuse, pheochro-

mocytoma, and the use of agents such as benzodiazepines, volatile anesthetics, and IV opiates. ■ Correct hypokalemia and/or hypomagnesemia before administration. ■ When used without a general anesthetic, topical anesthesia is still required when appropriate (e.g., bronchoscopy). ■ May worsen symptoms of Parkinson's disease.

Monitor: A potent drug. Obtain a baseline ECG on all patients. Do not administer droperidol if a prolonged QT interval exists (QTc greater than 440 msec for males or 450 msec for females). ■ Monitor VS and ECG closely. Monitor for palpitations, syncope, and/or other symptoms of irregular cardiac rhythm and evaluate promptly. ■ Resuscitation equipment, a narcotic antagonist (if a narcotic has been used concurrently), IV infusion line, IV fluids, and equipment and drugs to manage emergency situations must be readily available. ■ In patients for whom the benefit is believed to outweigh the risks of potentially serious arrhythmias, monitor for arrhythmias during the treatment and for 2 to 3 hours after treatment. ■ Orthostatic hypotension is common; move and position patients with care. ■ EEG pattern may be slow in returning to normal postoperatively. See **Precautions**.

Patient Education: Avoid activities that require alertness for 24 hours after receiving droperidol. ■ Do not drink alcoholic beverages or take other CNS depressants (e.g., antihistamines, pain meds, sleeping pills) for 24 hours after receiving droperidol.

Maternal/Child: Category C: safety for use during pregnancy not established; is rarely used. Exceptions are selected use during cesarean section; it has also been used to treat hyperemesis gravidarum (no longer recommended). ■ Is secreted in breast milk; avoid breast-feeding. ■ Pediatric patients may be more susceptible to extrapyramidal side effects, especially acute dystonic reactions. ■ Safety for use in pediatric patients under 2 years not established.

Elderly: See **Dose Adjustments**. ■ More likely to experience hypotension, excessive sedation, and prolonged QT syndrome.

DRUG/LAB INTERACTIONS

Concurrent use with **fentanyl** (Sublimaze) may cause hypotension and decrease pulmonary arterial pressure. ■ May cause precipitous hypotension with **epinephrine**. ■ Use caution with **other CNS depressant drugs** (e.g., barbiturates, tranquilizers, opioids, and general anesthetics); may have additive or potentiating effects **with droperidol**; see **Dose Adjustments**. ■ Increased risk of QT prolongation and torsades de pointes with **other drugs known to increase the QT interval** (e.g., **class IA antiarrhythmics** [e.g., disopyramide (Norpace), procainamide (Pronestyl), quinidine] **and/or class III antiarrhythmics** [e.g., amiodarone (Nexterone), dofetilide (Tikosyn), ibutilide (Corvert), sotalol (Betapace)], **anticonvulsants** [e.g., fosphenytoin (Cerebyx)], **antidepressants** [e.g., amitriptyline (Elavil), imipramine (Tofranil)], **antihistamines** [e.g., diphenhydramine (Benadryl)], **antimalarials** [e.g., chloroquine], **antineoplastics** [e.g., doxorubicin (Adriamycin)], **azole antifungal agents** [e.g., itraconazole (Sporanox)], **calcium channel blockers** [e.g., nifedipine (Cardene)], **fluoroquinolones, other neuroleptics** [e.g., haloperidol, lithium], **and many others**); see **Precautions**. ■ Concurrent administration with **volatile anesthetics, benzodiazepines** (e.g., diazepam [Valium], midazolam [Versed]), or **IV opiates** (e.g., morphine) may produce prolonged QT syndrome. Initiate therapy at a low dose and adjust with caution. ■ Concomitant treatment with **diuretics** (e.g., furosemide [Lasix]), **laxatives, steroids with mineralocorticoid potential** (e.g., hydrocortisone) may cause electrolyte imbalance, hypovolemia, and/or induce hypokalemia or hypomagnesemia. ■ Concurrent use with **other agents that produce hypotension** may cause orthostatic hypotension; risk is increased with **agents that produce vasodilation** (e.g., amiodarone (Nexterone), milrinone [Primacor], nitroprusside sodium [Nitropress], nifedipine [Cardene]). ■ See **Dose Adjustments** and **Precautions**.

SIDE EFFECTS

Common: Abnormal EEG, chills, dizziness, hallucinations, hypotension, restlessness, shivering, tachycardia.

Major/overdose: Apnea; cardiac arrest; extrapyramidal symptoms; hypotension (severe); neuroleptic malignant syndrome (altered consciousness, muscle rigidity, and autonomic

instability); palpitations, syncope, or other symptoms of irregular cardiac rhythm; QT prolongation and torsades de pointes; respiratory depression; ventricular tachycardia; death.

ANTIDOTE

Notify the physician of any side effect. Minor side effects will probably be transient; for major side effects discontinue the drug, treat symptomatically, and notify the physician. Treat hypotension with fluid therapy (rule out hypovolemia) and vasopressors such as dopamine or levarterenol (Levophed). Phenylephrine may help to counteract the alpha-blocking effects of droperidol. Epinephrine is contraindicated for hypotension. Further hypotension will occur. Treat extrapyramidal symptoms with benztropine mesylate (Cogentin) or diphenhydramine (Benadryl). Treat cardiac arrhythmias as indicated (e.g., magnesium sulfate for torsades de pointes, lidocaine, for ventricular tachycardia). An increase in temperature, HR, or CO₂ production may be symptoms of neuroleptic malignant syndrome or malignant hyperpyrexia. Consider prompt treatment with dantrolene (Dantrium). Resuscitate as necessary.

ECULIZUMAB **BBW**

(eck-you-LIZ-you-mab)

Monoclonal antibody
Complement inhibitor

Soliris

pH 7

USUAL DOSE

A meningococcal vaccine must be administered at least 2 weeks before initial dosing with eculizumab to all patients who have not been previously vaccinated. A booster dose may be required for patients previously vaccinated. Revaccinate according to current medical guidelines. Quadrivalent, conjugated meningococcal vaccines are strongly recommended.

Paroxysmal nocturnal hemoglobinuria (PNH): Administer 600 mg as an infusion weekly for the first 4 weeks, followed by 900 mg for the fifth dose 1 week later, then 900 mg every 2 weeks thereafter.

Atypical hemolytic uremic syndrome (aHUS) in patients 18 years of age or older: Administer 900 mg as an infusion weekly for the first 4 weeks, followed by 1,200 mg for the fifth dose 1 week later, then 1,200 mg every 2 weeks thereafter.

PEDIATRIC DOSE

Atypical hemolytic uremic syndrome (aHUS) in patients less than 18 years of age: Administer eculizumab based on body weight as outlined in the following chart.

Atypical Hemolytic Uremic Syndrome (aHUS) Dose in Patients Less Than 18 Years of Age		
Patient Body Weight	Induction	Maintenance
40 kg and over	900 mg weekly × 4 doses	1,200 mg at week 5; then 1,200 mg every 2 weeks
30 kg to less than 40 kg	600 mg weekly × 2 doses	900 mg at week 3; then 900 mg every 2 weeks
20 kg to less than 30 kg	600 mg weekly × 2 doses	600 mg at week 3; then 600 mg every 2 weeks
10 kg to less than 20 kg	600 mg × 1 dose	300 mg at week 2; then 300 mg every 2 weeks
5 kg to less than 10 kg	300 mg × 1 dose	300 mg at week 2; then 300 mg every 2 weeks

DOSE ADJUSTMENTS

A variance of 1 to 2 days in the scheduled administration time points is allowed if indicated. ■ Age, gender, race, and renal function do not appear to influence the pharmacokinetics of eculizumab. ■ Supplemental dosing of eculizumab is required in the setting of concomitant support with PE/PI (plasmapheresis or plasma exchange, or fresh frozen plasma infusion). See the following chart for supplemental dosing based on the type of intervention.

Supplemental Dose of Eculizumab After PE/PI			
Type of Intervention	Most Recent Eculizumab Dose	Supplemental Eculizumab Dose with Each PE/PI Intervention	Timing of Supplemental Dose
Plasmapheresis or plasma exchange	300 mg	300 mg per each plasmapheresis or plasma exchange session	Within 60 minutes after each plasmapheresis or plasma exchange
Plasmapheresis or plasma exchange	600 mg or more	600 mg per each plasmapheresis or plasma exchange session	Within 60 minutes after each plasmapheresis or plasma exchange
Fresh frozen plasma (FFP) infusion	300 mg or more	300 mg per each unit of fresh frozen plasma	60 minutes before each 1 unit of fresh frozen plasma infusion

DILUTION

Available in 300 mg/30 mL single-use vials (10 mg/mL). Withdraw the required dose of eculizumab (2 vials are required for the 600-mg dose, 3 vials are required for the 900-mg dose, and 4 vials are required for the 1,200-mg dose) and transfer it to an infusion bag. Must be further diluted to a 5 mg/mL concentration by adding an amount of NS, ½NS, D5W, or Ringer's lactate to the infusion bag equal to the total volume of the eculizumab.

Preparation and Reconstitution of Eculizumab		
Eculizumab Dose	Diluent Volume	Final Volume
300 mg	30 mL	60 mL
600 mg	60 mL	120 mL
900 mg	90 mL	180 mL
1,200 mg	120 mL	240 mL

Invert gently to ensure thorough mixing. Allow the diluted solution to reach room temperature before infusion. Do not use an artificial heat source (e.g., microwave). Discard unused portions; contains no preservatives.

Filters: Specific information not available.

Storage: Refrigerate vials in original carton at 2° to 8° C (36° to 46° F) and protect from light. Do not use beyond the expiration date on the vial. Diluted solution is stable for 24 hours refrigerated or at CRT. Do not freeze or shake.

COMPATIBILITY

Specific information not available.

RATE OF ADMINISTRATION

Do not administer as an IV push or a bolus injection. For infusion via gravity feed, syringe-type pump, or infusion pump. A single dose as an infusion over 35 minutes. If infusion is slowed or stopped for any reason, the total infusion time should not exceed 2 hours.

ACTIONS

A recombinant, DNA-derived, humanized IgG monoclonal antibody. A genetic mutation in patients with paroxysmal nocturnal hemoglobinuria (PNH) leads to the generation of abnormal RBCs (known as PNH cells) that are deficient in terminal complement inhibitors; this deficiency makes these RBCs sensitive to persistent terminal complement-mediated destruction. Ongoing destruction of these RBCs is called hemolysis. Eculizumab, a complement inhibitor, specifically binds to the complement protein and prevents complement-mediated intravascular hemolysis. It improves the lives of patients suffering from this disease by directly targeting the underlying disease process and markedly decreasing the ongoing RBC destruction that causes the hemolysis responsible for the S/S of PNH. In aHUS, impairment in the regulation of complement activity leads to uncontrolled terminal complement activation, resulting in platelet activation, endothelial cell damage, and thrombotic microangiopathy. Eculizumab inhibits the complement-mediated TMA in patients with aHUS. Half-life is 190-354 hours.

INDICATIONS AND USES

A complement inhibitor for the treatment of patients with paroxysmal nocturnal hemoglobinuria (PNH) to reduce hemolysis. PNH is a rare, disabling, and life-threatening genetic mutation blood disorder defined by chronic RBC destruction (hemolysis). Symptoms may include anemia; disabling fatigue; dysphagia; dyspnea; erectile dysfunction; hemoglobinuria; jaundice; recurrent pain in the abdomen, back, or head; renal dysfunction; and thromboses. Average age of onset is the early 30s, with survival between 10 and 15 years from the time of diagnosis. ■ Treatment of patients with atypical hemolytic uremic syndrome (aHUS) to inhibit complement-mediated thrombotic microangiopathy. Effectiveness for this indication is based on the effects on thrombotic microangiopathy (TMA) and renal function. Prospective clinical trials are ongoing to confirm benefit.

Limitation of use: Eculizumab is NOT indicated for treatment of patients with Shiga toxin *E. coli*-related hemolytic uremic syndrome (STEC-HUS).

CONTRAINDICATIONS

Do not use in patients with unresolved serious *Neisseria meningitidis* infection or in patients not currently vaccinated against *N. meningitidis* unless the risk of delaying eculizumab therapy outweighs the risk of developing meningococcal infection.

PRECAUTIONS

For IV infusion only; do not administer by IV push or bolus injection.

■ Susceptibility to serious meningococcal infections (septicemia and/or meningitis) is increased. Meningococcal infections may become rapidly life threatening or fatal if not recognized and treated early. A meningococcal vaccine must be administered at least 2 weeks before initial dosing with eculizumab to all patients who have not been previously vaccinated unless the risks of delaying eculizumab therapy outweigh the risks of developing meningococcal infection. If urgent eculizumab therapy is indicated in an unvaccinated patient, administer the meningococcal vaccine as soon as possible. In clinical studies, such patients received antibiotics for prophylaxis of meningococcal infection until at least 2 weeks after vaccination. Benefits and risks of antibiotic prophylaxis not established. A booster dose may be required for patients previously vaccinated. Revaccinate according to current medical guidelines; see **Usual Dose**. Vaccination may not prevent meningococcal infections. ■ Use caution in patients with any systemic infection. ■ Eculizumab blocks terminal complement activation. Patients have increased susceptibility to infections, especially with encapsulated bacteria. Pediatric patients may be at increased risk of developing serious infections due to *Streptococcus pneumoniae* or *Haemophilus influenzae* type B (Hib). Administer vaccinations for prevention of these infections according to medical guidelines. ■ Serious hemolysis may occur in patients who discontinue eculizumab therapy; see **Monitor**. ■ A protein product; infusion reactions may occur. Hypersensitivity reactions, including anaphylaxis, are possible; however, infusion reactions severe enough to discontinue eculizumab did not occur during clinical trials. ■ Has a potential for immunogenicity. Low titers of an-

tibodies to eculizumab have been detected but did not appear to correlate to clinical response. ■ Continue established anticoagulant therapy during eculizumab treatment; the effect of withdrawal of anticoagulant therapy during eculizumab therapy has not been established. ■ Eculizumab is available through a restricted program under a Risk Evaluation and Mitigation Strategy (REMS). Prescribers must be enrolled in the program. Contact manufacturer for further information.

Monitor: Obtain baseline CBC with differential and platelets, lactic dehydrogenase (LDH), SCr, and bilirubin. ■ LDH levels increase during hemolysis and with TMA. Monitoring may assist in determining the effectiveness of eculizumab therapy. ■ **Monitor for early S/S of meningococcal infections** (moderate to severe headache with nausea or vomiting, fever, or a stiff neck or stiff back; fever of 103° F [39.4° C] or higher; fever and a rash; confusion; and/or severe muscle aches with flu-like symptoms and light sensitivity). Evaluate immediately and treat with antibiotics if indicated. Consider discontinuing eculizumab during treatment of serious meningococcal infections. ■ **Monitor for S/S of an infusion reaction** (e.g., chills, dyspnea, pruritus) during infusion and for at least 1 hour post-infusion. Slow or temporarily discontinue the infusion as indicated. ■ **Monitor patients with PNH who discontinue eculizumab for a minimum of 8 weeks to detect serious hemolysis and other reactions.** Serious hemolysis is identified by serum LDH levels greater than pretreatment levels along with a greater than 25% decrease in PNH clone size (in the absence of dilution by transfusion) in 1 week or less, a hemoglobin level of less than 5 Gm/dL or a decrease of more than 4 Gm/dL in 1 week or less, angina, a change in mental status, a 50% increase in SCr, or thromboses (e.g., blood clots). ■ **Monitor patients with aHUS who discontinue eculizumab for S/S of TMA complications for a minimum of 12 weeks.** Clinical S/S of TMA may include angina, dyspnea, mental status changes, seizures, or thrombosis. Changes in laboratory parameters that may indicate TMA include a decrease in platelet count or an increased SCr and LDH.

Patient Education: Read the patient medication guide before initiating eculizumab and before each dose. ■ Meningococcal vaccination is required before initiating therapy. Previously vaccinated individuals may require a booster dose. Vaccination may not prevent meningococcal infection. Important to receive and stay up-to-date on all recommended immunizations. Discuss immunization status with physician. ■ Eculizumab affects the immune system and can lower the ability to fight infections. Immediately report S/S of a meningococcal infection (moderate to severe headache with nausea or vomiting, fever, or a stiff neck or stiff back; fever of 103° F [39.4° C] or higher; fever and a rash; confusion; and/or severe muscle aches with flu-like symptoms and light sensitivity). Manufacturer supplies a patient safety card that lists these symptoms and is to be carried at all times and shown to all health care providers treating you. ■ Promptly report other S/S of an infection. ■ Promptly report chills, dyspnea, and/or itching during or soon after an infusion. ■ Report a suspected pregnancy and/or tell your doctor if you are breast-feeding. ■ Stopping the infusions may have serious side effects and requires prolonged monitoring for development of hemolysis or TMA. Increased risk of meningococcal infection continues for several weeks after eculizumab is discontinued.

Maternal/Child: Category C: use during pregnancy only if the benefits justify the potential risk to the fetus. Pregnant women with PNH and their fetuses have high rates of morbidity and mortality during pregnancy and postpartum. ■ Effects of eculizumab therapy during labor and delivery are unknown. ■ Use caution if breast-feeding; IgG is secreted in breast milk, but antibodies may not enter the neonatal and infant circulation in substantial amounts. Consider risks to infant versus benefits of breast-feeding. ■ Safety and effectiveness for treatment of PNH in pediatric patients less than 18 years of age not established. ■ Safety and effectiveness for treatment of aHUS appear similar in pediatric and adult patients. Follow medical guidelines for vaccinations for prevention of infections due to *Neisseria meningitidis*, *Streptococcus pneumoniae*, and Hib.

Elderly: Limited experience did not identify age-related differences in safety and effectiveness.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been completed. ■ Continue established anti-coagulant therapy during eculizumab treatment; the effect of withdrawal of anticoagulant therapy during eculizumab therapy has not been established.

SIDE EFFECTS

Meningococcal infections (meningitis and/or septicemia) and the progression of PNH are the most serious side effects reported; may be life threatening and may occur in patients who have been vaccinated. The most commonly reported side effects in patients with PNH are back pain, headache, nasopharyngitis, and nausea. The most commonly reported side effects in patients with aHUS are anemia, diarrhea, headache, hypertension, leukopenia, nausea, upper respiratory infection, UTI, and vomiting. Other reported side effects include abdominal pain, anemia, constipation, cough, extremity pain, fatigue, fever, herpes simplex infections, influenza-like illness, insomnia, myalgia, pain in extremities, peripheral edema, respiratory infections, sinusitis, and vertigo.

Post-Marketing: Cases of serious or fatal meningococcal infections have been reported.

ANTIDOTE

Keep physician informed of all side effects. Some will be treated symptomatically. Potential meningococcal infections must be evaluated immediately and treated with antibiotics promptly; may be life threatening. Treat hypersensitivity or infusion reactions as indicated; may respond to slowing or temporarily discontinuing the infusion or may require the use of epinephrine, corticosteroids, diphenhydramine bronchodilators (e.g., albuterol [Ventolin], aminophylline), IV saline, oxygen, and/or acetaminophen. Total infusion time should not exceed 2 hours. If serious hemolysis occurs after eculizumab is discontinued, the following treatments may be indicated: transfusion with packed RBCs (or an exchange transfusion if the PNH RBCs are more than 50% of the total RBCs by flow cytometry), anticoagulation, corticosteroids, or reinstatement of eculizumab. If TMA complications occur after eculizumab is discontinued, consider reinstatement of treatment, plasma therapy (plasma exchange or FFP infusion), or appropriate organ-specific supportive measures. Resuscitate as necessary.

EDETATE CALCIUM DISODIUM **BBW**

(ED-eh-tayt KAL-see-um DYE-so-dee-um)

Antidote
Chelating agent
Lead mobilization**Calcium Disodium Edetate, Calcium Disodium Versenate,
Calcium EDTA**

pH 6.5 to 8

USUAL DOSE

Specific fluid requirements indicated; see [Monitor](#) and [Maternal/Child](#). Do not exceed recommended daily dose.

Asymptomatic adults and pediatric patients with blood lead levels over 20 mcg/dL but under 70 mcg/dL: 1,000 mg/M²/24 hr (50 mg/kg/24 hr) for 3 to 5 days. After a rest period of 2 to 4 days (preferably up to 2 weeks) to allow for redistribution of lead, repeat the process, if indicated, based on severity of lead toxicity and patient tolerance.

Symptomatic adults and pediatric patients with blood levels over 70 mcg/dL: Dimercaprol (BAL) will be given IM in divided doses every 4 hours for a minimum of 3 or up to 5 days. 4 hours after the first dose of BAL begin edetate calcium disodium 1,000 mg/M²/24 hr (50 mg/kg/24 hr) for 5 days. If blood lead concentrations rebound to above 45 mcg/dL within 5 to 7 days after the initial course, repeat the edetate calcium disodium. Do not repeat the dimercaprol regimen.

DOSE ADJUSTMENTS

Reduce dose in pre-existing renal disease and/or adults with lead nephropathy. In adults with lead nephropathy dose is based on serum creatinine levels and repeated monthly until lead excretion is reduced toward normal according to the following chart.

Dose Adjustments in Impaired Renal Function and/or Adults with Lead Nephropathy	
Serum Creatinine Level	Dose
<2 mg/dL	1,000 mg/M ² /24 hr for 5 days
2-3 mg/dL	500 mg/M ² /24 hr for 5 days
3-4 mg/dL	500 mg/M ² /48 hr for 3 doses
>4 mg/dL	500 mg/M ² /week

DILUTION

Add total daily dose to 250 to 500 mL of D5W or NS for infusion.

Storage: Before use, store at CRT.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists amphotericin B (conventional), hydralazine, D10W, 10% invert sugar in NS, LR, Ringer's solution, 1/6 M lactate as **incompatible**. Must be diluted in specific IV solutions; see [Dilution](#).

RATE OF ADMINISTRATION

References vary greatly. Manufacturer recommends the total daily dose be evenly distributed over 8 to 12 hours. May cause an increase in intracranial pressure with too-rapid injection in patients with lead encephalopathy and cerebral edema.

ACTIONS

A chelating agent. Helps to remove metals, especially lead, from the body. Will form a stable chelate with metals that have the ability to displace calcium from the molecule (e.g., lead, zinc, cadmium). Distributed primarily in the extracellular fluid. Half-life is 20 to 60 minutes. Chelated compounds are excreted in urine; up to 50% in 1 hour and 95% in 24 hours. The primary source of lead chelated by edetate calcium disodium is from bone. Following administration, urinary lead output increases and blood lead concentra-

tion decreases, but brain lead is significantly increased due to internal redistribution of lead.

INDICATIONS AND USES

Reduction of blood levels and depot stores of lead in lead poisoning (acute and chronic) and lead encephalopathy in both pediatric and adult patients.

Unlabeled uses: Treatment of poisoning by radioactive and nuclear fission products such as plutonium, thorium, uranium, and yttrium. ■ Treatment of poisoning from other heavy metals such as chromium, manganese, nickel, zinc, and possibly vanadium.

CONTRAINDICATIONS

Anuria, active renal disease, or hepatitis.

PRECAUTIONS

Do not confuse with edetate disodium, which does not chelate lead but actually removes calcium from the body and can be very dangerous. ■ Patients with lead encephalopathy and cerebral edema may have a lethal increase in intracranial pressure with IV infusion; IM injection preferred; see **Maternal/Child**. ■ Equally effective with IM or IV administration. IM route is used for all patients with overt lead encephalopathy and has been suggested as the preferred route by some for young pediatric patients. ■ Usually given IM in pediatric patients, unless given concurrently with BAL (insufficient IM injection sites); see **Maternal/Child**. ■ May produce toxic and fatal effects. ■ Produces the same renal damage as lead poisoning (e.g., proteinuria and microscopic hematuria). ■ Nephrotoxicity is dose dependent and may be reduced by ensuring adequate diuresis before treatment begins. ■ Use with caution in mild renal disease; see **Dose Adjustments**. ■ Patients must be removed from the source of contamination promptly. ■ Use for diagnosis of lead poisoning as a lead mobilization test is controversial; see literature. Edetate calcium disodium mobilization test should not be used in symptomatic patients or in patients with blood levels above 55 mcg/dL for whom appropriate therapy is indicated. ■ Not effective in mercury, gold, or arsenic poisoning.

Monitor: Urine flow must be established before dimercaprol (BAL) or edetate calcium disodium is administered. IV fluids may be used. Avoid excessive fluid in patients with cerebral edema or lead encephalopathy. Once urine flow is established, further IV fluid is restricted in all patients to basal water and electrolyte requirements. ■ Monitor urinalysis, urine sediment, renal and hepatic function, and electrolyte levels before treatment; repeat daily in serious cases and on the second and fifth day in less serious cases. Daily urine specimens are recommended to determine status of renal function. ■ Monitor ECG and vital signs. ■ Elevated erythrocyte protoporphyrin levels (greater than 35 mcg/dL) indicate the need to perform a venous blood lead determination. ■ An elevation of urinary coproporphyrin (greater than 250 mcg/day in adults and greater than 75 mcg/day in pediatric patients under 80 lbs) and an elevation of urinary delta-aminolevulinic acid (greater than 4 mg/day in adults and greater than 3 mg/M²/day in pediatric patients) are associated with blood lead levels greater than 40 mcg/dL. ■ Excretion of calcium is not increased, but excretion of zinc and other essential metals is; monitor and replace as indicated. ■ Obtain specific fluid orders from the physician.

Patient Education: If no urine output for 12 hours, report immediately.

Maternal/Child: Category B: safety for use during pregnancy not established; benefits must outweigh risks. ■ Use caution in nursing mothers. ■ Lead poisoning is often more severe in pediatric patients compared with adult patients. Lead encephalopathy occurs more often in pediatric patients. May be incipient and thus overlooked. Mortality rate in pediatric patients has been high; see **Precautions**. ■ IV injection has been associated with fatality in some young children, and IM injection is considered to be the preferred route by some clinicians.

Elderly: Consider age-related organ damage.

DRUG/LAB INTERACTIONS

Steroids will increase renal toxicity. ■ Inhibits the action of **zinc insulin** preparations by chelating the zinc.

SIDE EFFECTS

Acute renal tubular necrosis, anemia, anorexia, arthralgia, cardiac rhythm irregularities, chills, excessive thirst, fatigue, fever, headache, hematuria, hypercalcemia, hypersensitivity (e.g., sneezing, nasal congestion), hypotension, increases in liver function tests (mild), leg and other muscle cramps, malaise, myalgia, nausea, numbness, proteinuria, tetany, tingling, transient bone marrow suppression, tremors, vomiting, weakness, zinc deficiency.

ANTIDOTE

Notify the physician of any side effects. Most will improve with a decrease in rate of the infusion or will be treated symptomatically. Discontinue if urine flow stops to avoid high tissue levels of the drug. Discontinue at the first sign of renal toxicity (e.g., presence of large renal epithelial cells or increasing numbers of RBCs). Treat cerebral edema with repeated doses of mannitol. Not known if edetate calcium disodium is dialyzable.

EDETATE DISODIUM **BBW**

(ED-eh-tayt DYE-so-dee-um)

Antihypercalcemic agent
Calcium chelating agent**EDTA Disodium, Endrate**

pH 6.5 to 7.5

USUAL DOSE

50 mg/kg of body weight/24 hr or in equally divided doses every 12 hours (25 mg/kg every 12 hours). Total dose should not exceed 3 Gm/24 hr. Usually given for 5 days, held for 2 days. Regimen may be repeated to a total of 15 doses.

PEDIATRIC DOSE

40 mg/kg of body weight/24 hr in equally divided doses every 6 to 12 hours (20 mg/kg every 12 hours, 10 mg/kg every 6 hours). Do not exceed 70 mg/kg/24 hr or adult dose, whichever is less. See instructions in [Usual Dose](#).

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly. Reduced doses may be indicated based on potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Recommended dose must be diluted in 500 mL D5W or NS and given as an infusion. A 0.5% solution will reduce the risk of thrombophlebitis. Do not exceed cardiac reserve in any patient. Use less diluent if necessary in pediatric patients. Must be diluted to at least a 3% solution.

Storage: Store at room temperature.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Must not exceed more than 15 mg of actual medication over 1 minute. Total dose usually given over 3 to 4 hours. Rapid IV infusion may cause a sudden drop in serum calcium, resulting in tetany, convulsions, arrhythmias, and death. Reduce rate and further dilute solution for pain at injection site.

ACTIONS

A calcium-chelating agent. Also forms chelates with other polyvalent metals (e.g., magnesium, zinc). Attracts calcium ions immediately on injection and becomes calcium disodium edetate. Capable of severely depleting the body of calcium stores. Exerts a negative inotropic effect on the heart. It is well distributed in extracellular fluids and rapidly excreted in the urine.

INDICATIONS AND USES

Treatment of cardiac arrhythmias (atrial and ventricular, especially when caused by digoxin toxicity). ■ Hypercalcemia.

CONTRAINDICATIONS

Anuria, known sensitivity to edetate disodium, renal disease.

PRECAUTIONS

Read label carefully. Deaths have been caused when edetate disodium was administered mistakenly for edetate calcium disodium. ■ Used only when the severity of disease indicates necessity. ■ May produce hypocalcemia quickly, especially if used for purposes other than chelating calcium. ■ Use repeatedly with caution because of potential for nephrotoxicity and mobilization of extracirculatory calcium stores. ■ Use caution in cardiac disease (may adversely affect myocardial contractility), diabetes (lower blood sugar may require less insulin), severe renal disease, liver disease, congestive heart failure (1 Gm of sodium in each 5 Gm), limited cardiac reserve and patients with a history of seizures or intracranial lesions.

Monitor: Monitor vital signs and ECG before and during therapy. ■ Confirm patency of vein, avoid extravasation; can cause tissue necrosis. ■ Routine electrolyte panel (potassium deficiency) and urine specimens for casts and cells necessary during therapy. Magnesium, zinc, and other trace element deficiencies can occur. ■ Keep patient in supine position during and after administration (15 to 30 minutes) to avoid postural hypotension. ■ Obtain blood for serum calcium levels just before beginning a new infusion; specific lab methods required. ■ Inhibits coagulation of blood (transient). Liver function tests may be indicated. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: safety for use in pregnancy or breast-feeding not established. Use with extreme caution and only if clearly needed.

Elderly: Reduced doses may be indicated; see [Dose Adjustments](#). Monitoring of renal function is suggested.

DRUG/LAB INTERACTIONS

Inhibits **mannitol**. ■ Potentiates **neuromuscular blocking antibiotics** (e.g., gentamicin). ■ Inhibits coagulation of **blood** (transient). ■ A sudden drop in calcium levels may decrease effects of **digoxin**. ■ Obtain blood for **serum calcium levels** just before beginning a new infusion. Specific laboratory methods must be used for accurate evaluation.

SIDE EFFECTS

Anorexia, arthralgia, circumoral paresthesias, diarrhea, fatigue, fever, glycosuria, headache, hyperuricemia, hypotension, malaise, nasal congestion, nausea, numbness, sneezing, tearing, thirst, thrombophlebitis, urinary urgency, vomiting.

Major: Anaphylaxis, anemia, cardiac arrhythmias, dermatitis, hemorrhage, hypocalcemic tetany, prolonged QT interval, renal tubular destruction (reversible), seizures, death.

ANTIDOTE

Notify the physician of any side effect. For progression of minor side effects or any major side effect, discontinue drug immediately and notify the physician. Calcium gluconate is the antidote of choice and should be available for infusion at all times (use extreme caution if patient is digitalized). Treat mild hypotension by maintaining in supine position until recovery. Additional hydration indicated with S/S of nephrotoxicity. Treat anaphylaxis and resuscitate as necessary.

EDROPHONIUM CHLORIDE

(ed-roh-**FOH**-nee-um **KLOR**-eyed)

Cholinergic
Cholinesterase inhibitor
Antidote
Diagnostic agent

Enlon, Tensilon, Tensilon PF

pH 5.4

USUAL DOSE

1 to 10 mg (0.1 to 1 mL) at specified intervals depending on usage. Maximum dose should never exceed 40 mg (4 doses of 10 mg each).

Myasthenia gravis diagnosis: 10 mg (1 mL) in tuberculin syringe. Give 2 mg (0.2 mL). If no reaction occurs in 45 seconds, give remaining 8 mg (0.8 mL). Test may be repeated after 30 minutes.

Myasthenia gravis treatment evaluation: 1 to 2 mg (0.1 to 0.2 mL) 1 hour after oral intake of drug being used for treatment. Package insert has a chart differentiating myasthenic and non-myasthenic responses.

Myasthenia crisis evaluation: 2 mg (0.2 mL) in tuberculin syringe. Give 1 mg (0.1 mL). If the patient's condition does not deteriorate, give 1 mg (0.1 mL) after 60 seconds. Improvement in cardiac status and respiration should occur.

Antagonist to curare and other nondepolarizing muscle relaxants: 10 mg (1 mL). May be repeated as necessary up to 4 doses. (Available in combination with atropine [Enlon-Plus] for use in reversal of nondepolarizing muscle relaxants.)

Terminate paroxysmal atrial tachycardia (unlabeled): 5 to 10 mg as a bolus injection. See [Dose Adjustments](#). Repeat once in 10 minutes if necessary.

Slow supraventricular tachycardias (unlabeled): 2 mg as a test dose. Repeat 2 mg every 1 minute until arrhythmia controlled or total dose of 10 mg is given. If HR decreases, may begin an infusion of 0.25 mg/min. May be increased to 2 mg/min if necessary.

PEDIATRIC DOSE

May be given IM if the IV route is not available; however, doses are different; check literature. See [Maternal/Child](#).

Myasthenia gravis diagnosis: Neonates: 0.1 mg (0.01 mL). **Infants:** 0.5 mg (0.05 mL).

Pediatric patients less than 34 kg: 1 mg (0.1 mL); if no response in 30 to 45 seconds, give 1 mg (0.1 mL) every 30 to 45 seconds up to 5 mg (0.5 mL). **34 kg or more,** give 2 mg (0.2 mL); if no response in 30 to 45 seconds, give 1 mg (0.1 mL) every 30 to 45 seconds up to 10 mg. Another source has the same dose for neonates but recommends 0.2 mg/kg/dose (0.02 mL/kg/dose) for **infants and other pediatric patients** with 20% of a dose given as a test dose slowly. If no response in 1 minute, give in 1-mg increments to a maximum calculated dose or 10 mg, whichever is less.

DOSE ADJUSTMENTS

Reduce antiarrhythmic dose to 5 to 7 mg in the elderly.

DILUTION

May be given undiluted. In the treatment of myasthenia crisis, this drug may be diluted in D5W or NS and given as a continuous IV. Use an infusion pump or microdrip (60 gtt/mL).

Filters: No data available from manufacturer.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Y-site: Heparin, hydrocortisone sodium succinate (Solu-Cortef), potassium chloride (KCl).

RATE OF ADMINISTRATION

2 mg (0.2 mL) or fraction thereof over 15 to 30 seconds.

Curare antagonist: A single dose over 30 to 45 seconds.

Antiarrhythmic: See [Usual Dose](#).

ACTIONS

An anticholinesterase and antagonist of nondepolarizing neuromuscular-blocking agents. Inhibits the enzyme acetylcholinesterase, allowing acetylcholine to accumulate at the myoneural junction. Restores normal transmission of nerve impulses. Acts within 30 to 60 seconds and has an extremely short duration of action, seldom exceeding 10 minutes. Produces vagal stimulation, shortens refractory period of atrial muscle, and slows conduction through the AV node.

INDICATIONS AND USES

Diagnosis of myasthenia gravis. ■ Evaluation of adequate treatment of myasthenia gravis. ■ Evaluation of emergency treatment of myasthenia crisis. ■ An antagonist to nondepolarizing muscle relaxants (e.g., atracurium [Tracrium]). ■ Adjunct in treatment of respiratory depression caused by curare overdosage.

Unlabeled uses: Termination of supraventricular tachycardia unresponsive to cardiac glycosides. Adenosine is the drug of choice. ■ Diagnosis of supraventricular tachycardia. ■ Evaluate function of a demand pacemaker.

CONTRAINDICATIONS

Apnea, known hypersensitivity to anticholinesterase agents, mechanical intestinal and urinary obstructions of mechanical type.

PRECAUTIONS

A physician should be present when this drug is used. ■ The term **crisis** is used when severe respiratory distress with ventilatory inadequacy occurs. The crisis may be secondary to a sudden increase in severity of myasthenia gravis (myasthenic crisis) or to overtreatment with anticholinesterase drugs (cholinergic crisis). If apnea is present, controlled ventilation must be secured before any testing with edrophonium. ■ Use caution when administering to patients being treated with anticholinesterase drugs (e.g., neostigmine). S/S of cholinergic crisis may mimic those of myasthenic weakness, and the patient's condition may worsen with administration of edrophonium. ■ Use caution in patients with bronchial asthma, cardiac arrhythmias, or myasthenia gravis treated with anticholinesterase drugs. ■ Isolated cases of respiratory or cardiac arrests have been reported. ■ Contains sulfites; use caution in patients with allergies.

Monitor: Atropine 1 mg must be available and ready for injection at all times. ■ Continuously observe patient reactions. ■ Anticholinesterase insensitivity may develop; withhold drugs and support respiration as necessary. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Safety for use during pregnancy and breast-feeding not established. Use during pregnancy only if benefit justifies potential risk to mother and fetus. ■ Discontinue breast-feeding. ■ Safety and effectiveness in reversing neuromuscular blockade in pediatric patients not established. However, doses of 0.1 to 1.43 mg/kg have been used; effects (antagonism) were more rapid than in adults.

DRUG/LAB INTERACTIONS

Muscarinic effects antagonized by **atropine**; see [Antidote](#). ■ May be inhibited by **corticosteroids and magnesium**. ■ May cause bradycardia with **digoxin glycosides**. ■ Briefly antagonizes the effects of **nondepolarizing neuromuscular blocking agents** (e.g., atracurium, pancuronium, vecuronium). ■ Prolongs muscle relaxant effect of **succinylcholine**.

SIDE EFFECTS

Abdominal cramps, anorexia, anxiety, bradycardia, bronchiolar spasm, cardiac arrhythmias and arrest, cold moist skin, contraction of the pupils, convulsions, diarrhea, dysphagia, fainting, increased lacrimation, increased pulmonary secretion, increased salivation, insomnia, irritability, laryngospasm, muscle weakness, nausea, perspiration, ptosis, respiratory arrest (either muscular or central), urinary frequency and incontinence, vomiting.

ANTIDOTE

If side effects occur, discontinue the drug and notify the physician. Atropine sulfate in doses of 0.4 to 0.5 mg IV will counteract most side effects and may be repeated every 3 to 10 minutes. Endotracheal intubation or tracheostomy is considered prophylactic in anesthesia or crises. Artificial ventilation, oxygen therapy, cardiac monitoring, adequate suctioning, and treatment of shock or convulsions must be instituted and maintained as necessary. Treat hypersensitivity reactions as indicated.

EDROPHONIUM CHLORIDE AND ATROPINE SULFATE

(ed-roh-**FOH**-nee-um and **AH**-troh-peen)

Enlon-Plus

Cholinergic
Cholinesterase inhibitor
Antidote

pH 4 to 5

USUAL DOSE

0.05 to 0.1 mL/kg (0.5 to 1 mg/kg of edrophonium with 0.007 to 0.014 mg/kg of atropine). Each 1 mL of prepared solution contains 10 mg edrophonium and 0.14 mg atropine. Must be administered at a point of at least 5% recovery of twitch response to neuromuscular stimulation. Use of peripheral nerve stimulator recommended. A total dose of 1 mg/kg of edrophonium is rarely exceeded. Length of action is usually sufficient to cover effects of commonly used short- and medium-acting nondepolarizing muscle relaxants (e.g., atracurium [Tracrium], vecuronium).

DOSE ADJUSTMENTS

None required; however, caution and lower-end dosing is suggested in elderly patients. Consider decreased organ function and concomitant disease or drug therapy. ■ Elderly patients and those with impaired renal or hepatic function may have a prolonged half-life and reduced clearance.

DILUTION

May be given undiluted through Y-tube or three-way stopcock of infusion set.

Storage: Available in vials containing 5 mL or 15 mL. Store at room temperature 15° to 26° C (59° to 78° F).

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

A single dose over 45 to 60 seconds.

ACTIONS

A combination of an acetylcholinesterase inhibitor and a parasympatholytic (anticholinergic) drug. Edrophonium antagonizes the effect of nondepolarizing neuromuscular blocking agents by inhibiting or inactivating acetylcholinesterase. Acetylcholine is not hydrolyzed as rapidly by acetylcholinesterase and accumulates, improving transmission of impulses across the myoneural junction. Unavoidable accumulation of acetylcholine at muscarinic cholinergic sites may cause bradycardia, bronchoconstriction, increased secretions, and other parasympathomimetic effects. Magnitude of effects varies depending on vagal nerve activity present. Atropine counteracts these side effects. Edrophonium is effective immediately with maximum antagonism within 1 to 2 minutes and lasts for 70 minutes. Atropine affects HR immediately, peaks in 2 to 16 minutes, and lasts for over 2 hours. With this combination agent, full reversal is usually accomplished before patient leaves recovery, muscarinic effects are minimized, and patient evaluation can be accomplished in OR. Some hepatic metabolism. Primarily excreted in urine, with some excretion in bile.

INDICATIONS AND USES

Reversal agent or antagonist of nondepolarizing neuromuscular blocking agents. Not effective against depolarizing neuromuscular blocking agents (e.g., succinylcholine). ■ Adjunctive treatment of respiratory depression of curare overdose.

CONTRAINDICATIONS

Acute glaucoma, adhesions between the iris and lens of the eye, known hypersensitivity to either component or sulfites, mechanical intestinal and urinary obstructions, and pyloric stenosis.

PRECAUTIONS

Administer only by or under the direct observation of the anesthesiologist. ■ May contain sulfites, and the stopper contains latex; use caution in patients with allergies. ■ Use caution in patients with bronchial asthma, cardiac arrhythmias, cardiovascular disease, myasthenia gravis (or symptoms of myasthenic weakness) treated with anticholinesterase drugs, prostatic hypertrophy, and debilitated patients with chronic lung disease. ■ Recurarization has not been reported after satisfactory reversal obtained. ■ See [Drug/Lab Interactions](#).

Monitor: An additional supply of atropine 1 mg must be available and ready for injection at all times. ■ Continuously observe patient reactions and monitor responses. Monitor ECG, vital signs, and reversal with a peripheral nerve stimulator. Ventilation (assisted or controlled) must be secured. ■ Anticholinesterase insensitivity may develop; reduce or withhold drugs and support respiration as necessary until sensitivity returns. ■ Confirm patency of vein; will cause tissue irritation. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: use during pregnancy only if benefits outweigh risks. ■ Safety for use during breast-feeding or in pediatric patients not established. ■ Pediatric patients may have increased vagal tone with greater variance in effects. ■ Atropine rate of clearance decreased in pediatric patients less than 2 years of age, but dose adjustment not indicated.

Elderly: Differences in response have not been identified; see [Dose Adjustments](#). ■ Half-life is prolonged and clearance is reduced in the elderly; elimination of nondepolarizing muscle relaxants is similarly decreased.

DRUG/LAB INTERACTIONS

Never administer before any **nondepolarizing muscle relaxant** (e.g., atracurium [Tracrium]). ■ May cause symptoms of anticholinesterase overdose (cholinergic crisis) with **anticholinesterase drugs**. ■ Frequency and duration of bradycardia increased with **narcotic analgesics** unless given with a potent inhalant anesthetic. ■ Excessive bradycardia may develop with **beta-adrenergic blocking agents** (e.g., atenolol [Tenormin], esmolol [Brevibloc], timolol [Timoptic]); atropine alone should be given before Enlon-Plus in these patients. ■ Bradycardia and first-degree heart block may be increased when **muscle relaxants** with no vagolytic effects (e.g., vecuronium) are reversed. ■ Cardiac arrest has occurred in digitalized patients and jaundiced patients receiving **anticholinesterase drugs**. ■ Prolongs muscle relaxant effect of **succinylcholine**. ■ Actions of **atropine** may interfere with absorption of other medications. ■ Concomitant use of atropine with other **cholinergic drugs** (e.g., antihistamines, antiparkinson agents, antipsychotics, tricyclic antidepressants) will increase mouth dryness and other side effects (e.g., decreased GI motility).

SIDE EFFECTS

Hypersensitivity reactions including anaphylaxis; arrhythmias in up to 10% of patients (e.g., bradycardia, first-, second-, and third-degree AV block, junctional rhythms, PACs, prolonged R-R interval, PVCs, P wave changes, tachycardia). All side effects of atropine and edrophonium can occur; refer to individual monographs.

Overdose: Cholinergic crisis due to overdose or concomitant use of other anticholinesterase drugs (bradycardia, diarrhea, increased bronchial and salivary secretions, nausea, sweating, vomiting), convulsions, delirium, fever, shock, tachycardia. In atropine poisoning (delirium, fever, tachycardia), death is usually due to medullary center paralysis.

ANTIDOTE

If side effects occur, discontinue drug and notify physician. Atropine sulfate in doses of 0.4 to 0.5 mg IV will counteract most side effects of edrophonium and may be repeated every 3 to 10 minutes. Endotracheal intubation or tracheostomy is considered prophylactic in anesthesia or crisis. In all situations treatment is symptomatic and includes artificial ventilation, oxygen therapy, cardiac monitoring, adequate suctioning, and treatment of fever, shock, or convulsions. Institute and maintain as necessary. Treat hypersensitivity reactions as indicated.

ENALAPRILAT **BBW**

(en-AL-ah-prill-at)

ACE inhibitor
Antihypertensive
Vasodilator

Vasotec IV

pH 6.5 to 7.5

USUAL DOSE

1.25 mg every 6 hours. Doses up to 5 mg every 6 hours have been tolerated for up to 36 hours, but clinical studies have not shown a need for dosage over 1.25 mg. Additional doses of 1.25 mg may be given every 6 hours except in dialysis patients. Dosage is the same when converting from oral to IV therapy. Resume oral therapy as soon as tolerated. See [Precautions](#).

PEDIATRIC DOSE

0.625 to 1.25 mg every 6 hours. See [Maternal/Child](#).

DOSE ADJUSTMENTS

Reduce initial dose to 0.625 mg in patients taking diuretics, patients with CHF, hyponatremia, severe volume or salt depletion, a CrCl less than 30 mL/min (SCr greater than 3 mg/dL), and dialysis patients; see [Rate of Administration](#). If the 0.625 dose is not clinically effective after 1 hour, it may be repeated. Reduce additional dose of 1.25 mg by one half for dialysis patients. ■ Blood levels markedly increased in the elderly; dose selection should be cautious. Consider decreased cardiac, hepatic, and renal function; concomitant disease; or other drug therapy. ■ See [Drug/Lab Interactions](#) and [Precautions](#).

DILUTION

May be given undiluted through the port of a free-flowing infusion of NS, D5W, D5NS, D5LR, or Isolyte E. May also be diluted in up to 50 mL of any of the same solutions and given as an infusion.

Storage: Store at CRT. Stable for up to 24 hours after dilution.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Dextran 40, dobutamine, dopamine, heparin, hetastarch in NS (Hespan), meropenem (Merrem IV), nitroglycerin IV, nitroprusside sodium, potassium chloride (KCl).
Y-site: Allopurinol (Aloprim), amifostine (Ethylol), amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), bivalirudin (Angio-max), butorphanol (Stadol), calcium gluconate, cefazolin (Ancef), ceftaroline (Teflaro), ceftazidime (Fortaz), chloramphenicol (Chloromycetin), cisatracurium (Nimbex), cladribine (Leustatin), clindamycin (Cleocin), dexmedetomidine (Precedex), dextran 40, dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), erythromycin (Erythrocin), esmolol (Brevibloc), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), filgrastim (Neupogen), ganciclovir (Cytovene), gemcitabine (Gemzar), gentamicin, granisetron

(Kytril), heparin, hetastarch in electrolytes (Hextend), hetastarch in NS (Hespan), hydrocortisone sodium succinate (Solu-Cortef), labetalol, lidocaine, linezolid (Zyvox), magnesium sulfate, melphalan (Alkeran), meropenem (Merrem IV), methylprednisolone (Solu-Medrol), metronidazole (Flagyl IV), morphine, nafcillin (Nallpen), nifedipine (Cardene IV), nitroprusside sodium, oxaliplatin (Eloxatin), pemetrexed (Alimta), penicillin G potassium, phenobarbital (Luminal), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), potassium phosphates, propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sodium acetate, sulfamethoxazole/trimethoprim, teniposide (Vumon), thiotepea, tobramycin, vancomycin, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

A single dose must be evenly distributed over 5 minutes. Extend rate of infusion up to 1 hour in patients at risk for severe hypotension (e.g., heart failure, hyponatremia, high-dose diuretic therapy, recent intensive diuresis or increase in diuretic dose, renal dialysis, or severe volume and/or salt depletion of any etiology).

ACTIONS

An antihypertensive agent. An angiotensin-converting enzyme inhibitor that prevents conversion of angiotensin I to angiotensin II. Peripheral arterial resistance is reduced in hypertensive patients. In patients with heart failure, significant reduction in pulmonary capillary wedge pressure (preload), peripheral vascular resistance (afterload), BP, and heart size occurs, as well as an increase in cardiac output (stroke index) and exercise tolerance time. Initial response may take 15 minutes to 1 hour. Peak BP reduction occurs in 1 to 4 hours, and effects last up to 6 hours. Peak effects of subsequent doses may be greater than the initial dose. Excreted in urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of hypertension when oral therapy is not practical. ■ Heart failure not adequately responsive to diuretics and digoxin. Enalaprilat is used in addition to digoxin and diuretics. ■ Hypertensive emergencies (effects are variable).

Unlabeled uses: Treatment of hypertension or renal crisis in scleroderma.

CONTRAINDICATIONS

Hypersensitivity to enalaprilat or its components, a history of angioedema related to previous treatment with an ACE inhibitor, or hereditary or idiopathic angioedema.

PRECAUTIONS

Has been used IV for up to 7 days. ■ Use caution in patients with a history of angioedema (see [Contraindications](#)), aortic stenosis, or hypertrophic cardiomyopathy. ■ Use caution in patients with collagen vascular disease and renal disease; neutropenia and/or agranulocytosis have been reported. Monitoring of WBC may be indicated. ■ Use caution in surgery, with anesthesia, or with agents that produce hypotension. ■ May rarely cause a syndrome that starts with cholestatic jaundice, progresses to hepatic necrosis, and may progress to death. Discontinue in patients who develop elevated liver enzymes or jaundice. ■ ACE inhibitors often cause a persistent, non-productive cough, which should resolve when drug is discontinued. ■ Average dose for conversion to oral therapy is 5 mg/day as a single dose. When a reduced dose of enalaprilat IV has been indicated (e.g., diuretics, impaired renal function, dialysis), reduce initial oral dose to 2.5 mg/day as a single dose. Adjust either by patient response. ■ Patients sensitive to one ACE inhibitor may be sensitive to another. ■ See [Monitor](#) and [Drug/Lab Interactions](#).

Monitor: Monitor vital signs very frequently. May cause precipitous drop in BP following the first dose. ■ Use extreme caution in fluid-depleted patients. Patients with congestive heart failure may become hypotensive at any time. Arrhythmias or conduction defects may occur. ■ Monitor BUN and SCr. An increase in either may require a decrease in dose of enalaprilat or discontinuation of a diuretic. ■ Diuretics given concomitantly may cause a precipitous drop in BP within the first hour of the initial dose; observe the patient closely. Severe dietary salt restriction or dialysis will aggravate this effect. ■ May cause oliguria or progressive azotemia in patients with severe congestive heart failure whose renal function is dependent on the activity of the renin-angiotensin-aldosterone system. Acute renal failure and death are possible. ■ May cause hyperkalemia. May cause a

significant increase in serum potassium with potassium-sparing diuretics or potassium supplements. Use with caution and only in documented hypokalemia. Use salt substitutes with caution. Monitor serum potassium levels. ■ Monitoring of WBC may be indicated in patients with collagen vascular disease or renal disease. ■ See [Drug/Lab Interactions](#).

Patient Education: Consider birth control options. ■ May cause dizziness; avoid sudden changes in posture and request assistance for ambulation if necessary.

Maternal/Child: Avoid pregnancy; Category C (first trimester) and Category D (second and third trimester). Can cause fetal and neonatal morbidity and death. Infants exposed to ACE inhibitors during the first trimester of pregnancy may have an increased risk of major congenital malformations. If pregnancy occurs, discontinue immediately; many alternate antihypertensive agents. ■ Observe any infant with in utero exposure for hypotension, oliguria, and hyperkalemia. ■ Has caused reversible acute renal failure in a premature infant whose mother received enalaprilat. ■ Safety for use in breast-feeding not established. ■ Safety for use in pediatric patients not established but has been used. ■ May contain benzyl alcohol, which has been associated with a fatal “gasping syndrome” in neonates.

Elderly: Dose selection should be cautious; see [Dose Adjustments and Precautions/Monitor](#). ■ May be less sensitive to effects due to a decrease in plasma renin activity or more sensitive to hypotensive effects due to increased blood levels (decreased renal excretion).

DRUG/LAB INTERACTIONS

Use caution in surgery, with **anesthesia**, or with any **agents that produce hypotension**. ■ May be used concomitantly with other **antihypertensive agents** (e.g., thiazide diuretics [chlorothiazide (Diuril)]). Effects are additive. ■ **Diuretics** given concomitantly may cause a precipitous drop in BP. ■ May cause hyperkalemia with **potassium-sparing diuretics** (e.g., spironolactone [Aldactone], triamterene [Dyrenium], amiloride [Midamor]), **potassium supplements, potassium-containing salt substitutes, or low-salt milk**. ■ Use caution and consider lower doses when administering **nitroglycerin, nitroprusside sodium, other nitrates, or other vasodilators** (e.g., hydralazine). ■ In patients with compromised renal function, concurrent use with **NSAIDs** (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]) may result in further deterioration of renal function. ■ Concurrent use with **NSAIDs** may also decrease the hypotensive effects of enalaprilat by inhibiting the renal prostaglandin synthesis and/or by causing sodium and fluid retention. ■ May increase **lithium** concentration, resulting in lithium toxicity. ■ Interaction with some **imaging agents** (e.g., iodohippurate, technetium) may render diagnostic renal function tests inconclusive. ■ May decrease **hemoglobin and hematocrit** slightly. ■ See [Precautions and Monitor](#).

SIDE EFFECTS

Abdominal pain, angioedema, anosmia (absence of sense of smell), atrial fibrillation, bradycardia, chest pain, conjunctivitis, cough (persistent dry), diarrhea, dizziness, dry eyes, dyspnea, eosinophilic pneumonitis, fatigue, flank pain, gynecomastia, headache, hepatotoxicity, herpes zoster, hoarseness, hyperkalemia, hypotension (severe), impotence, insomnia, muscle cramps, nausea, palpitations, paresthesias, photosensitivity, pneumonia, pruritus, pulmonary edema, pulmonary embolism and infarction, pulmonary infiltrates, rash, Raynaud’s phenomenon, renal failure (reversible), rhinorrhea, somnolence, sore throat, taste disturbances, tearing, toxic epidermal necrolysis, vomiting. Anaphylaxis has been reported.

ANTIDOTE

For minor side effects, notify the physician. Most will be tolerated or treated symptomatically. If symptoms progress or any major side effect occurs (angioedema, precipitous hypotension, hyperkalemia), discontinue drug and notify the physician immediately. Hypotension should respond to IV fluids if the patient’s condition allows their use. Other drugs in the regimen may need to be discontinued or the dosage reduced. Epinephrine, diphenhydramine (Benadryl), and hydrocortisone may be used to treat angioedema. Maintain the patient as indicated. If cardiac arrhythmias occur, treat appropriately. Hemodialysis may be useful in toxicity.

EPINEPHRINE HYDROCHLORIDE

(ep-ih-NEF-rin hy-droh-KLOR-eyed)

Cardiac stimulant
Bronchodilator
Antiallergic
Vasopressor

Adrenalin Chloride

pH 2.5 to 5

USUAL DOSE

Hypersensitivity reactions or bronchospasm: 0.1 to 0.25 mg (1 to 2.5 mL of a 1:10,000 concentration). Start with a small dose, giving only as much as required to alleviate undesirable symptoms, and repeat as necessary (usually every 20 to 30 minutes), gradually increasing dose depending on need. Another source suggests 0.2 to 0.5 mg of 1:10,000 concentration. May be repeated as necessary.

Bradycardia: AHA guidelines recommend epinephrine infusion 2 to 10 mcg/min; titrate to desired effect. Indicated if atropine is ineffective. Alternately, transcutaneous pacing or dopamine infusion 2 to 10 mcg/kg/min may be used.

Cardiac arrest: AHA guidelines recommend 1 mg (10 mL of a 1:10,000 concentration) IV; may repeat every 3 to 5 minutes. Follow each dose with a 20-mL IV flush to ensure delivery to systemic circulation. See Compatibility. Doses up to 0.2 mg/kg have been used for specific indications (beta-blocker or calcium channel blocker overdose). May also be given as a continuous infusion by adding 1 mg of epinephrine (1 mL of a 1:1,000 solution) to 500 mL NS or D5W. Begin with an infusion rate of 0.1 to 0.5 mcg/kg/min and titrate to response. The dose for a 70-kg patient would be 7 to 35 mcg/min. Higher doses of epinephrine are controversial.

Endotracheal: A diluted solution may be given through the endotracheal tube before an IV is established. AHA guidelines recommend 2 to 2.5 mg (of a 1:1,000 solution) diluted in 10 mL NS. Another source suggests administering the IV dose through the endotracheal tube if an IV line has not been established.

Vasopressor or maintenance dose: 1 to 10 mcg/min titrated to desired response. AHA guidelines recommend that epinephrine be used to treat symptomatic bradycardia after atropine as an alternative infusion to dopamine or to treat severe hypotension when atropine and transcutaneous pacing fail to correct the arrhythmia. For profound bradycardia or hypotension, 2 to 10 mcg/min may be given as an infusion (1 mg of 1:1,000 concentration in 500 mL NS or D5W) at a rate of 0.1 to 0.5 mcg/kg/min titrated to response.

PEDIATRIC DOSE

See Maternal/Child.

Hypersensitivity reactions or bronchospasm in infants and children: 0.01 mg/kg (0.1 mL/kg of a 1:10,000 concentration). May repeat at 20-minute to 4-hour intervals. One source suggests a maximum dose of 0.3 mg, another 0.5 mg. Usually given SC as a 1:1,000 concentration.

Severe anaphylactic shock in infants and children: One source suggests 0.1 mg IV of a 1:100,000 concentration (0.1 mL of 1:1,000 concentration diluted in 10 mL NS) given over 5 to 10 minutes. Another source suggests 0.01 mL/kg of a 1:1,000 concentration SC. Maximum 0.3 mL/dose. Repeat every 15 minutes as needed.

Bradycardia in infants and children: AHA guidelines recommend 0.01 mg/kg (0.1 mL/kg of 1:10,000 concentration) to treat symptomatic bradycardia. If IV access is not readily available, AHA guidelines recommend 0.1 mg/kg (0.1 mL/kg) of a 1:1,000 concentration via ET.

Asystolic or pulseless arrest in infants and children: AHA guidelines recommend 0.01 mg/kg (0.1 mL/kg of a 1:10,000 concentration). Another source recommends 0.01 mg/kg of a 1:10,000 concentration and suggests that the first dose should not exceed 1 mg (10 mL of a 1:10,000 concentration). Repeat every 3 to 5 minutes during arrest. Up to 0.1 to 0.2 mg/kg may be used if initial doses are ineffective. May be given via ET

(0.1 mg/kg [0.1 mL/kg of a 1:1,000 concentration]) every 3 to 5 minutes until IV established, then begin with first IV dose. A third source suggests 0.01 to 0.03 mg/kg (0.1 to 0.3 mL/kg) of 1:10,000 concentration initially. May repeat every 3 to 5 minutes in neonates. In infants and children subsequent doses of 0.1 mg/kg every 3 to 5 minutes may be given if needed. Prepare an infusion and titrate from 0.1 to 1 mcg/kg/min to desired effect. Use upper dosing range if asystole present. With higher dose, be aware of preservative content to avoid toxicity.

DOSE ADJUSTMENTS

See Drug/Lab Interactions. ■ Doses larger than 1 mg may not be indicated in patients over 65 years of age and patients in ventricular fibrillation.

DILUTION

Check label. Not all epinephrine solutions can be given IV. The 1:1,000 strength is for SC or IM use only. It must be further diluted with at least 10 mL of NS to prepare a 1:10,000 solution before IV use.

IV Injection: Available prediluted (0.1 mg/mL [1:10,000 solution]) in 10-mL syringes. Available in a 30-mL vial (30 mg [1:1,000 solution]) to facilitate larger doses or continuous infusion. Each 1 mg (1 mL) of 1:1,000 solution must be diluted in at least 10 mL of NS to prepare a 1:10,000 solution.

Infusion: For occasional use as a vasopressor or for maintenance, epinephrine may be further diluted in 250 to 500 mL D5W; see the following chart. Give through Y-tube or three-way stopcock of infusion set. See chart on inside back cover for additional **compatible** solutions.

Epinephrine HCl Infusion Rates						
Desired Dose	1 mg in 500 mL D5W (2 mcg/mL)			1 mg in 250 mL D5W 2 mg in 500 mL D5W (4 mcg/mL)		
	mcg/min	mcg/hr	mL/min	mL/hr	mcg/hr	mL/min
1	60	0.5	30	60	0.25	15
2	120	1	60	120	0.5	30
3	180	1.5	90	180	0.75	45
4	240	2	120	240	1	60
5	300	2.5	150	300	1.25	75
6	360	3	180	360	1.5	90
7	420	3.5	210	420	1.75	105
8	480	4	240	480	2	120

In **cardiac arrest**, 1 mg is sometimes added to 500 mL of NS or D5W.

Filters: No data available from manufacturer.

Storage: Store at CRT unless otherwise specified by manufacturer. Do not use if brown or if a sediment is present. Deteriorates rapidly. Protect from light and freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Readily destroyed and precipitate forms with alkalis, alkaline solutions (e.g., sodium bicarbonate and oxidizing agents).” **If coadministration with sodium bicarbonate is indicated, give at separate sites.** Unstable in any solution with a pH over 5.5 (e.g., aminophylline, ampicillin, lidocaine, warfarin [Coumadin]).

One source suggests the following **compatibilities:**

Additive: Amikacin (Amikin), dobutamine, furosemide (Lasix), ranitidine (Zantac), verapamil.

Y-site: Amiodarone (Nexterone), anidulafungin (Eraxis), atracurium (Tracrium), bivalirudin (Angiomax), calcium chloride, calcium gluconate, caspofungin (Cancidas), ceftazidime (Fortaz), cisatracurium (Nimbex), dexmedetomidine (Precedex), diltiazem (Cardizem), dobutamine, dopamine, famotidine (Pepcid IV), fenoldopam (Corlopan), fentanyl (Sublimaze), furosemide (Lasix), heparin, hetastarch in electrolytes (Hexend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), labetalol, levofloxacin (Levaquin), lorazepam (Ativan), midazolam (Versed), milrinone (Primacor), morphine, nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), pancuronium, pantoprazole (Protonix IV), phytonadione (vitamin K₁), potassium chloride (KCl), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), tigecycline (Tygacil), tirofiban (Aggrastat), vasopressin, vecuronium, warfarin (Coumadin).

RATE OF ADMINISTRATION

IV injection: Each 1 mg or fraction thereof over 1 minute or longer. May be given more rapidly in cardiac resuscitation; follow with 20-mL IV flush.

Infusion: Vasopressor or maintenance: 1 to 10 mcg/min titrated to desired patient response.

Cardiac arrest: Titrated to deliver a single dose over 3 to 5 minutes based on patient response. Must be delivered by central venous access. Use an infusion pump to control rate.

ACTIONS

A naturally occurring hormone secreted by the adrenal glands. A sympathomimetic drug, it imitates almost all actions of the sympathetic nervous system. Stimulates both alpha- and beta-adrenergic receptors. It is a vasoconstrictor and delays the absorption of many drugs; a potent cardiac stimulant, it strengthens the myocardial contraction (positive inotropic effect) and increases cardiac rate (positive chronotropic effect). Increases myocardial and cerebral blood flow during CPR. A potent dilator or relaxant of smooth muscle, especially bronchial muscle. Decreases blood supply to the abdomen and increases blood supply to skeletal muscles. Elevates systolic BP, lowers diastolic BP, and increases pulse pressure. Seldom used as a vasopressor because of its short duration of action. High-dose infusions (greater than 0.2 mcg/min) may produce profound vasoconstriction, compromising perfusion and possibly compromising renal and splanchnic blood flow. It is rapidly inactivated in the body by the liver and various enzymes and is excreted in changed form in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Cardiac resuscitation. First-line drug of choice when initial CPR, intubation, ventilation, and initial defibrillation have failed to achieve response in ventricular fibrillation, pulseless ventricular tachycardia, asystole, or pulseless electrical activity. ■ Drug of choice for anaphylactic shock. ■ Antidote of choice for histamine overdose and hypersensitivity reactions including bronchial asthma, urticaria, and angioneurotic edema. ■ Stokes-Adams syndrome. ■ Occasionally used as a vasopressor (e.g., symptomatic bradycardia).

CONTRAINDICATIONS

Anesthesia with halogenated hydrocarbons or cyclopropane; cerebral arteriosclerosis, hypertension, labor and delivery if maternal BP exceeds 130/80 mm Hg (may cause prolonged uterine atony with hemorrhage), hyperthyroidism, narrow-angle glaucoma, nervous instability, organic brain damage, patients receiving high doses of digoxin, shock. Do not use to treat overdosage of phenothiazines (e.g., chlorpromazine [Thorazine]); a further drop in BP will occur and irreversible shock may result. Do not use concurrently with esmolol (Brevibloc).

PRECAUTIONS

Usual route is SC except in cardiac resuscitation or as a vasopressor infusion. ■ Use caution in the elderly, in diabetics, in hypotension (except in anaphylactic shock), in patients receiving thyroid preparations, and in patients with cardiac disease, a history of seizures, or long-term emphysema or bronchial asthma with degenerative heart disease. ■ Often used with corticosteroids in treatment of anaphylactic shock. ■ Increasing BP and HR may cause myocardial ischemia, angina, and increased myocardial oxy-

gen demand. ■ Larger doses in cardiac arrest are based on optimal response range of epinephrine (0.045 to 0.2 mg/kg). May not improve survival or neurologic outcome and may cause postresuscitation myocardial dysfunction. ■ Higher doses may be required to treat poison-induced shock.

Monitor: Check BP and HR every 5 minutes. ■ Monitoring of ECG and serum potassium and glucose concentrations may be indicated. ■ Vasoconstriction-induced tissue sloughing can occur. Avoid administering in areas of limited blood supply (e.g., fingers, toes) or if peripheral vascular disease is present. ■ Infusion during cardiac arrest must be administered by central venous access to ensure delivery to systemic circulation and to avoid extravasation. ■ Intracardiac injection or IV injection in cardiac arrest must be accompanied by cardiac massage to perfuse drug into the myocardium and permit effective defibrillation. ■ Correct acidosis, hypoxemia. ■ See [Drug/Lab Interactions](#).

Maternal/Child: Category C: may cause anoxia in fetus. ■ Discontinue breast-feeding. May produce tachyarrhythmias in pediatric patients. ■ High doses in animals have caused increased hypertension with lower cardiac output. Risk of intracranial hemorrhage may be increased in infants and children (especially preterm infants) if hypotension is followed by hypertension. ■ See [Contraindications](#).

Elderly: May be more sensitive to the effects of beta-adrenergic receptor agonists (e.g., hypertension, hypokalemia, tachycardia, tremor). Patients with cardiac disease may be at increased risk for adverse effects. ■ See [Dose Adjustments](#) and [Precautions](#).

DRUG/LAB INTERACTIONS

May be used alternately with isoproterenol (Isuprel), but they may not be used together. Both are direct cardiac stimulants and death may result. Adequate interval between doses must be maintained. ■ Do not use concomitantly with **other sympathomimetic agents** (e.g., ephedrine, dopamine). Additive effects may cause toxicity. ■ Simultaneous use with **oxytocics** (e.g., methylergonovine), **MAO inhibitors** (e.g., isocarboxazid [Marplan]), **furozolidone** (Furoxone), or **guanethidine** (Ismelin) may result in hypertension or cause hypertensive crisis. ■ Pressor response increased by **tricyclic antidepressants** (e.g., amitriptyline [Elavil], imipramine [Tofranil]), **antihistamines** (e.g., diphenhydramine [Benadryl]), **rauwolfia alkaloids** (e.g., reserpine), **sodium levothyroxine**, and **urinary alkalinizers**; may cause hypertension. ■ May cause hypertension with **nonselective beta-adrenergic blockers** (e.g., propranolol). ■ Inhibited by **ergot alkaloids and phenothiazines** (e.g., prochlorperazine [Compazine]). ■ Inhibits **insulin and oral hypoglycemic agents**; increased dose may be required. ■ **Hydrocarbon anesthetics** (e.g., enflurane, halothane) and **digoxin** may sensitize the myocardium and increase the risk of arrhythmias. ■ Use with **theophylline** may increase cardiac, CNS, or GI side effects. ■ Concurrent use with **alpha-adrenergic blocking agents** (e.g., doxazosin [Cardura], labetalol, prazosin [Minipress], terazosin [Hytrin]) may antagonize the hypertensive effects of epinephrine. ■ Interacts with many other drugs. ■ See [Contraindications](#) for additional drug interactions.

SIDE EFFECTS

Often transitory; sometimes occur with average doses.

Anxiety, dizziness, dyspnea, glycosuria, pallor, palpitations.

Overdose (frequently caused by too-rapid injection): Bradycardia (transient followed by tachycardia), cerebrovascular hemorrhage, collapse (rapid), fibrillation, headache (severe), hypertension, hypotension (irreversible), pulmonary edema, pupillary dilation, renal failure, restlessness, tachycardia, weakness, death.

ANTIDOTE

Treatment is primarily supportive. If side effects from the average dose become progressively worse, discontinue the drug and notify the physician. IM or SC route may be preferable. For a severe reaction caused by toxicity, treat the patient for shock and administer an antihypertensive agent such as phentolamine (Regitine) or nitroprusside sodium. Treat cardiac arrhythmias with a beta-adrenergic blocker (propranolol). Resuscitate as necessary.

EPIRUBICIN HYDROCHLORIDE **BBW**

(ep-ee-ROO-bih-sin hy-droh-KLOR-eyed)

**Antineoplastic
(anthracycline antibiotic)****Ellence** ■ **Pharmorubicin PFS** **pH 3** ■ **pH 4 to 5.5****USUAL DOSE**

In combination therapies, epirubicin has been used instead of doxorubicin in the combination regimen. Usually given on the same days and at the same intervals as the doxorubicin it replaces.

ELLENC E

Recommended starting dose is 100 to 120 mg/M². Patients receiving the 120-mg/M² dose should also receive prophylactic antibiotic therapy with sulfamethoxazole/trimethoprim or a fluoroquinolone (e.g., ciprofloxacin [Cipro]). Ellence is usually given in repeated 3- to 4-week cycles. Total dose may be given on Day 1 of each cycle or equally divided and given on Days 1 and 8 of each cycle.

One regimen used is 60 mg/M² of epirubicin as an infusion on Days 1 and 8 given in a regimen with oral cyclophosphamide 75 mg/M² on Days 1 to 14 and fluorouracil 500 mg/M² on Days 1 and 8. Repeat every 28 days for six cycles. Another regimen used is 100 mg/M² of epirubicin as an infusion together with fluorouracil 500 mg/M² and cyclophosphamide 500 mg/M². All three agents are given on Day 1 and are repeated every 21 days for 6 cycles. In either regimen the total dose of epirubicin may be given on Day 1 of each cycle or equally divided and given on Days 1 and 8 of each cycle.

 PHARMORUBICIN PFS

Metastatic breast cancer: *Single agent:* 75 to 90 mg/M² once every 21 days. This dose may be divided and given on Day 1 and Day 2. An alternative weekly dose schedule of 12.5 to 25 mg/M² has been used and has been reported to produce less clinical toxicity than higher doses given every 3 weeks. ***Combination therapy:*** 50 mg/M². Used in combination with cyclophosphamide and fluorouracil.

Early-stage breast cancer (Stage II-III A): 50 to 60 mg/M² given on Days 1 and 8 every 4 weeks. Used in combination with cyclophosphamide and fluorouracil.

Small-cell lung cancer: *Single agent:* 90 to 120 mg/M² once every 3 weeks. ***Combination therapy:*** 50 to 90 mg/M². Several combinations have been used (e.g., with either cisplatin or ifosfamide; with cyclophosphamide and vincristine; with cyclophosphamide and etoposide, or with cisplatin and etoposide).

Non-small-cell lung cancer: *Single agent:* 120 to 150 mg/M² on Day 1 every 3 to 4 weeks. ***Combination therapy:*** 90 to 120 mg/M² on Day 1 every 3 to 4 weeks. Used in combination with cisplatin, etoposide, mitomycin, and vinblastine.

Non-Hodgkin's lymphoma: *Single agent:* 75 to 90 mg/M² once every 3 weeks. ***Combination therapy:*** 60 to 75 mg/M². Used in combination with cyclophosphamide, prednisone, and vincristine with or without bleomycin for the treatment of newly diagnosed non-Hodgkin's lymphoma.

Hodgkin's disease: *Combination therapy:* 35 mg/M² once every 2 weeks or 70 mg/M² once every 3 to 4 weeks. Used in combination with bleomycin, dacarbazine, and vinblastine.

Ovarian cancer: *Single agent:* 50 to 90 mg/M² once every 3 or 4 weeks in patients who have had prior therapy. ***Combination therapy:*** 50 to 90 mg/M² once every 3 or 4 weeks can be added to their regimen in patients who have had prior therapy; or the same dose in combination with cisplatin and cyclophosphamide is used for initial therapy of ovarian cancer.

Locally unresectable or metastatic gastric cancer: *Single agent:* 75 to 100 mg/M² once every 3 weeks. ***Combination therapy:*** 80 mg/M² once every 3 to 4 weeks. Used in combination with fluorouracil.

ALL FORMULATIONS

Soft tissue sarcoma (unlabeled): 60 mg/M²/day for 2 to 3 days every 3 weeks for 5 cycles. Used in combination with other agents or instead of doxorubicin.

Esophageal and esophagogastric junction cancers (unlabeled): 50 mg/M² on Day 1 of a 21-day treatment cycle. Used in conjunction with cisplatin and fluorouracil.

DOSE ADJUSTMENTS

ALL FORMULATIONS: Reduced dose required with elevated serum bilirubin. Give 50% of a dose for serum bilirubin from 1.2 to 3 mg/dL or AST 2 to 4 times upper limit of normal. Give 25% of a dose for serum bilirubin greater than 3 mg/mL or AST greater than 4 times upper limit of normal.

ELLECE: Consider reducing starting dose to 75 to 90 mg/M² in heavily pretreated patients, those with pre-existing bone marrow suppression, or in the presence of neoplastic bone marrow infiltration. ■ Consider reduced dose in patients with severe renal impairment (SCr greater than 5 mg/dL). ■ Base dose adjustments after the first treatment cycle on hematologic response during treatment cycle nadir and nonhematologic toxicities. In patients who received the full dose on Day 1, reduce dose to 75% of initial first dose in subsequent cycles for platelet count less than 50,000/mm³, absolute neutrophil count (ANC) less than 250/mm³, neutropenic fever, or Grade 3 or 4 nonhematologic toxicity. Delay dose in subsequent treatment cycles until platelet count recovers to at least 100,000/mm³, ANC recovers to at least 1,500/mm³, and nonhematologic toxicities have recovered to equal to or less than Grade 1. For patients receiving a divided dose, reduce the Day-8 dose to 75% of the Day-1 dose if platelet counts are 75,000 to 100,000/mm³ and ANC is 1,000 to 1,499/mm³. Omit the Day-8 dose if platelet counts are less than 75,000/mm³, ANC less than 1,000/mm³, or Grade 3 or 4 nonhematologic toxicity has occurred.

✦ **PHARMORUBICIN PFS:** Use lower dose in range for patients with inadequate marrow reserves due to old age, prior therapy, or neoplastic marrow infiltration. ■ Reduced dose, delay, or suspension of epirubicin may be required based on hematologic toxicity; manufacturer provides no specific recommendations. ■ No dose adjustment required in impaired renal function.

DILUTION

Specific techniques required; see Precautions.

ELLECE: Available as 2 mg/mL in 25-mL and 100-mL vials. A ready-to-use, preservative-free solution; further dilution not required. Must be given through Y-tube or three-way stopcock of a free-flowing infusion of NS or D5W.

✦ **PHARMORUBICIN PFS:** Available as 2 mg/mL in 5-mL, 25-mL, and 100-mL vials. Use of the 100-mL vial should be restricted to a pharmacy admixture program using a sterile transfer or dispensing device. Enter any vial only once and withdraw desired dose into a syringe. No further dilution is required.

Filters: Manufacturer indicates that studies show some initial potency loss in the first few minutes with the use of cellulose ester membrane or nylon filters; however, the total amount of drug loss is negligible. A second source has a similar statement.

Storage: Ellece: Refrigerate vials at 2° to 8° C (34° to 46° F); protect from light. Do not freeze. Refrigeration may result in a gel-formed product; will return to a slightly viscous to mobile solution within 2 to 4 hours. Must be used within 24 hours of removal from refrigeration. Discard unused solution.

✦ **Pharmorubicin:** Store unopened PFS vials in refrigerator; keep in original cartons to protect from light. Use any filled syringe within 24 hours if stored at room temperature and within 48 hours if refrigerated. Syringes prepared from the pharmacy bulk vial must be used within 24 or 48 hours of the initial puncture of that vial based on method of storage. Once the transfer set has been inserted in the bulk vial, any remaining undispensed drug must be discarded in 8 hours.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturers recommend not mixing with other drugs in the same syringe. Avoid prolonged contact with alkaline solutions; will result in hydrolysis of all forms of epirubicin. Do not mix with heparin or fluorouracil (5-FU); may precipitate. **Incompatible** with ifosfamide (Ifex) when combined in syringe or solution with mesna (Mesnex).

One source suggests the following **compatibilities**:

Additive: Ifosfamide (Ifex).

Y-site: Oxaliplatin (Eloxatin).

RATE OF ADMINISTRATION

IV injection: All formulations: An initial starting dose of 100 to 120 mg/M² should be infused over 15 to 20 minutes. Lower starting doses or modified doses may be administered over a minimum of 3 minutes and up to 20 minutes. Must be given through Y-tube or three-way stopcock of a free-flowing infusion of NS or D5W. Slow injection rate further for erythematous streaking along the vein or facial flushing.

ACTIONS

A semi-synthetic, anthracycline, antineoplastic antibiotic agent. Exact method of action is unknown. Rapidly and widely distributed into tissue. Inhibits DNA, RNA, and protein synthesis and interferes with replication and transcription. Free radicals cause further cytotoxic activity. Metabolized in the liver and by other organs and cells, including RBCs. WBC nadir is reached in 10 to 14 days and should return to normal by Day 21. Elimination half-life is 30 to 40 hours. Does not cross blood-brain barrier. Primarily excreted in bile; some excretion in urine.

INDICATIONS AND USES

ELLECE: Used in combination with other agents in the treatment of patients with evidence of axillary-node tumor involvement following resection in primary breast cancer.

PHARMORUBICIN: Treatment of metastatic as well as early stage breast cancer, small-cell lung cancer (both limited and extensive disease), advanced non-small-cell lung cancer, non-Hodgkin's lymphoma, Hodgkin's disease, Stage III and IV ovarian cancer, and metastatic and locally unresectable gastric cancers. May be used as a single agent or in combination with other chemotherapeutic agents.

Unlabeled uses: ALL FORMULATIONS: Treatment of soft-tissue sarcomas in combination with other agents. Treatment of esophageal and esophagogastric junction cancers in combination with other agents. Ellece has been used in place of Pharmorubicin for various indications.

CONTRAINDICATIONS

History of severe cardiac disease, myocardial insufficiency, recent MI, severe arrhythmias, or severe hepatic disease. ■ Baseline neutrophil count less than 1,500 cells/mm³ or myelosuppression resulting from treatment with other antineoplastic agents or radiation therapy. ■ Contraindicated in patients who have received previous treatment with maximum recommended cumulative doses of epirubicin, other anthracyclines, or anthracenediones (e.g., daunorubicin [Cerubidine], doxorubicin [Adriamycin], idarubicin [Idamycin], mitoxantrone [Novantrone] or mitomycin C). Hypersensitivity to epirubicin, other anthracyclines, or anthracenediones.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. In addition to standard precautions, treat spills or leakage with 1% sodium hypochlorite. For accidental contact with eyes or skin, flush with copious amounts of water, soap and water, or sodium bicarbonate. ■ Administered by or under the direction of the physician specialist, with facilities for monitoring the patient and responding to any medical emergency. ■ For IV use only. Do not give IM or SC. ■ May cause severe myelosuppression. ■ May cause serious, irreversible myocardial toxicity with congestive heart failure and/or cardiomyopathy as the cumulative dose approaches 900 mg/M². Cardiotoxicity may be acute or delayed, occurring months to years after treatment. Exceeding 900 mg/M² is not recommended; the maximum cumulative dose used in clinical trials was

720 mg/M². ■ Cardiotoxicity may occur at lower cumulative doses whether or not cardiac risk factors are present. ■ Use extreme caution in pre-existing drug-induced bone marrow suppression, existing heart disease, previous treatment with other anthracyclines (e.g., daunorubicin, doxorubicin, idarubicin), other cardiotoxic agents (e.g., bleomycin, trastuzumab [Herceptin]), or radiation therapy encompassing the heart; toxicity may occur at lower cumulative doses and may be additive; see [Drug/Lab Interactions](#). ■ Administration of epirubicin after previous radiation therapy may induce an inflammatory recall reaction at the irradiation site. ■ Incidence of secondary leukemia may be increased. Risk of developing acute myelogenous leukemia and/or myelodysplastic syndrome (AML/MDS) increases when epirubicin is given in combination with DNA-damaging antineoplastic agents, when patients have been heavily pretreated with cytotoxic drugs, or when doses of anthracyclines have been escalated. The cumulative probability of developing AML/MDS is particularly increased in patients who have received more than 720 mg/M² of epirubicin or more than 6,300 mg/M² of cyclophosphamide. ■ Thrombophlebitis and thromboembolic events, including pulmonary embolism, have been reported.

Monitor: Before beginning treatment with epirubicin, patients should recover from acute toxicities (e.g., stomatitis, neutropenia, thrombocytopenia, and infections) resulting from previous chemotherapy. ■ Obtain baseline CBC, including differential and platelet count; serum calcium, phosphate, and potassium; SCr; uric acid level; liver function tests (AST, ALT, alkaline phosphatase, and serum bilirubin). ■ Obtain baseline cardiac evaluations with an ECG and a MUGA scan or an echocardiogram to evaluate left ventricular ejection fraction (LVEF). Monitor lab values during therapy, especially before each dose. Monitor ECG, chest x-ray, echocardiogram, and/or radionuclide angiography in patients who have had mediastinal radiation, other anthracycline or anthracene therapy, those with pre-existing cardiac disease, or S/S of impending heart disease, or those who have received prior epirubicin cumulative doses exceeding 550 mg/M². ■ Monitor for signs of cardiac toxicity (e.g., rapid or irregular HR, shortness of breath, swelling of abdomen, feet, and lower legs); early signs usually include sinus tachycardia and non-specific ST-T wave changes in the ECG. ■ Use only large veins. Avoid veins over joints or in extremities with compromised venous or lymphatic drainage. Determine absolute patency of vein. Extravasation may occur with or without stinging or burning along the injection site even if blood returns well on aspiration of the infusion needle. Observe site frequently. Extravasation can result in severe cellulitis and tissue necrosis; if it occurs, discontinue injection; use another vein. ■ Prevention and treatment of hyperuricemia due to tumor lysis syndrome may be accomplished with adequate hydration, and if necessary, allopurinol and alkalization of urine. ■ Be alert for signs of bone marrow suppression, bleeding, or infection. ■ Use of prophylactic antibiotics may be indicated pending C/S in a febrile, neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antiemetics are indicated. ■ See [Drug/Lab Interactions](#).

Patient Education: Urine will be reddish for several days (from drug, not hematuria). ■ Effective contraception methods required for both men and women; avoid pregnancy. May induce chromosomal damage in sperm. ■ Report IV site burning, stinging, or puffiness promptly. ■ Report rapid or irregular HR, shortness of breath, and swelling of the abdomen, feet, or lower legs. ■ Report vomiting, dehydration, fever, or other evidence of infection. ■ Review side effects; may be severe (e.g., nausea and vomiting, cardiotoxicity). ■ See Appendix D, p. 1255.

Maternal/Child: Category D: can cause fetal harm. Avoid pregnancy. May cause testicular atrophy. ■ Discontinue breast-feeding. ■ Information on safety for use in pediatric patients not available. Some studies suggest that pediatric patients may be at greater risk for anthracycline-induced acute cardiotoxicity and/or chronic CHF.

Elderly: Cardiotoxicity and myelotoxicity may be more severe; monitor closely for dose-related toxicities. ■ See [Dose Adjustments](#). ■ There is a major decrease in plasma

clearance of epirubicin in women over 70 years of age; monitor closely for signs of toxicity. ■ See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

May increase bone marrow and GI toxicity of other **chemotherapeutic agents**. ■ Increased toxicity including skin redness and exfoliative changes possible when given concurrently with or after **radiation**. ■ Monitoring of cardiac function may be indicated in patients taking **medications that may cause heart failure** (e.g., calcium channel blockers such as verapamil), beta-blockers (e.g., propranolol). ■ Plasma clearance decreased and serum levels increased by **cimetidine** (Tagamet); discontinue cimetidine. ■ Epirubicin is extensively metabolized in the liver; **changes in hepatic function induced by concomitant therapies** may affect epirubicin metabolism, pharmacokinetics, effectiveness, and toxicity. ■ Risk of cardiotoxicity increased in patients previously treated with maximum cumulative doses of **other anthracyclines** (e.g., doxorubicin [Adriamycin], idarubicin [Idamycin]) **and/or radiation encompassing the heart**. ■ Risk of cardiotoxicity is also increased when epirubicin is administered with **other cardiotoxic agents**; if possible, epirubicin-based therapy should be delayed until other cardiotoxic agents have been cleared from the circulation. When possible, avoid for up to 24 weeks after stopping **trastuzumab**. Careful cardiac monitoring is required if delay is not feasible. ■ Leukopenic and/or thrombocytopenic effects may be increased with **drugs that cause blood dyscrasias** (e.g., anticonvulsants [e.g., carbamazepine (Tegretol), phenytoin (Dilantin)], NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]). Adjust dose based on differential and platelet count. ■ Administration of epirubicin immediately before or after **paclitaxel** increased the systemic exposure (AUC) of epirubicin. The mean AUC of epirubicin's metabolites increased when paclitaxel was administered immediately after epirubicin. Epirubicin had no effect on the exposure of paclitaxel. ■ Administration of epirubicin immediately before or after **docetaxel** had no effect on the systemic exposure of epirubicin. However, the mean AUC of epirubicin's metabolites increased when docetaxel was administered immediately after epirubicin. Epirubicin had no effect on the AUC of docetaxel. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents. Killed or inactivated vaccines may be administered; however, the response to these vaccines may be diminished. ■ See [Precautions](#).

SIDE EFFECTS

Dose-limiting toxicities are infection, myelosuppression (anemia, leukopenia, neutropenia, thrombocytopenia), and cardiotoxicity (usually delayed manifested by reduced LVEF and/or S/S of CHF [e.g., ascites, dependent edema, dyspnea, gallop rhythm, hepa-

tomegaly, pleural effusion, pulmonary edema, tachycardia]). Other serious cardiovascular adverse reactions that have occurred include AV block, bradycardia, bundle branch block, thromboembolism, and ventricular tachycardia. Severe cellulitis, vesication, local pain, and tissue necrosis can occur with extravasation. Venous sclerosis may result from injection into small veins or repeated injection into the same vein. Other side effects are alopecia, amenorrhea, anorexia, conjunctivitis, diarrhea, febrile neutropenia, fever, hot flashes, itching, keratosis, malaise, mucositis (esophagitis, stomatitis), nausea and vomiting, phlebitis, rash, recall of skin reaction associated with prior radiation. Hypersensitivity reactions have been reported.

Overdose: May cause an acute myocardial dysfunction within 24 hours. Pronounced mucositis, leukopenia, and thrombocytopenia may occur within 7 to 14 days.

Post-Marketing: Anaphylaxis; chills; dehydration; erythema; flushing; GI disorders (e.g., bleeding, burning, pain, ulceration); hyperpigmentation of the skin, nails, and oral mucosa; hyperuricemia; pneumonia; pulmonary embolism; sepsis; urticaria; and vascular disorders (arterial embolism, hemorrhage, phlebitis, shock, and thrombophlebitis).

ANTIDOTE

Most side effects will either be tolerated or treated symptomatically. Keep the physician informed. Hematopoietic toxicity (leukopenia, thrombocytopenia) may require dose reduction or cessation of therapy, antibiotics, platelet and granulocyte transfusions, darbepoetin alfa (Aranesp), epoetin alfa (Epogen), filgrastim (Neupogen), pegfilgrastim (Neulasta), or sargramostim (Leukine). Acute cardiac failure occurs suddenly (most common when total cumulative doses approach 900 mg/M^2) and frequently does not respond to currently available treatment. Close monitoring of accumulated dose, bone marrow, ECG, chest x-ray, echocardiography, and systolic ejection fraction may prevent most serious and potentially fatal cardiac side effects. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Dexrazoxane is currently available to prevent cardiotoxicity of doxorubicin in specific situations; in the future it may be considered with epirubicin. If extravasation occurs, attempt aspiration of the infiltrated epirubicin. Elevate the extremity and apply local intermittent ice compresses for up to 3 days. Observe the site frequently. Should be seen by a reconstructive surgeon if local pain persists or skin changes progress after 3 to 4 days. Ulceration may require early wide excision of the involved area. Treat hypersensitivity reactions as indicated.

EPOETIN ALFA **BBW**

(ee-POH-ee-tin AL-fah)

Recombinant human erythropoietin
Antianemic agent**EPO, Epogen, Eprex** , **Erythropoietin, Procrit**

pH 5.8 to 7.2

USUAL DOSE

In all situations, rate of hematocrit increase is dose dependent and varies among patients. Availability of iron stores, baseline hematocrit, and concurrent medical problems affect the rate and extent of response. In controlled clinical trials, patients experienced greater risks for death, serious adverse cardiovascular reactions, and stroke when administered erythropoiesis-stimulating agents (ESAs) to target a hemoglobin level of greater than 11 Gm/dL. Use the lowest dose for each patient that will gradually increase the hemoglobin concentration to avoid the need for RBC transfusion; see [Precautions](#) and [Monitor](#).

Anemia associated with chronic kidney disease (CKD) for patients on dialysis: Initiate epoetin when the hemoglobin level is less than 10 Gm/dL. **Starting dose:** 50 to 100 units/kg of body weight three times a week. May be given by IV or SC injection or into the venous line at the end of a dialysis session. The IV route is recommended in patients on hemodialysis; see [Precautions](#). A 55-kg (120-lb) individual would receive 2,750 units at 50 units/kg, 4,125 units at 75 units/kg, and 5,500 units at 100 units/kg. Entire contents of a vial (2,000, 3,000, or 4,000 units) has been used instead of an exact calculated dose.

Anemia associated with chronic kidney disease (CKD) for patients NOT on dialysis: Consider initiating epoetin only when the hemoglobin level is less than 10 Gm/dL and the following two considerations apply: (1) the rate of hemoglobin decline indicates the likelihood of requiring a RBC transfusion, and (2) reducing the risk of alloimmunization and/or other RBC transfusion-related risks is a goal. **Starting dose:** 50 to 100 units/kg of body weight three times a week.

Anemia in zidovudine-treated, HIV-infected patients: May be given IV or SC. 100 units/kg 3 times a week. Obtain endogenous serum erythropoietin level (before transfusion) before initiating therapy; see [Monitor](#). Serum erythropoietin levels in adults should be equal to or less than 500 mUnits/mL, and the zidovudine dose should be equal to or less than 4,200 mg/week.

Anemia associated with cancer patients on chemotherapy: SC injection recommended. ESAs shortened overall survival and/or increased the risk of tumor progression or recurrence in clinical studies of patients with certain types of cancer; see [Precautions](#). Initiate epoetin in patients on cancer chemotherapy only if the hemoglobin is less than 10 Gm/dL and there is a minimum of 2 additional months of planned chemotherapy. Use the lowest dose necessary to avoid RBC transfusions. **Starting dose:** 150 units/kg of body weight 3 times a week until completion of chemotherapy course. An alternative schedule is 40,000 units weekly until completion of chemotherapy course.

Reduction of allogeneic blood transfusions in surgery patients: SC injection recommended. Obtain hemoglobin before initiating therapy. Should be greater than 10 Gm/dL but less than or equal to 13 Gm/dL. 300 units/kg/day for 10 days before surgery, on the day of surgery, and for 4 days after surgery. An alternate regimen is 600 units/kg once each week on Days 21, 14, and 7 before surgery and again on the day of surgery. Deep venous thrombosis prophylaxis is recommended during epoetin therapy (e.g., enoxaparin [Lovenox]); see [Precautions](#).

PEDIATRIC DOSE

May be given by IV or SC injection. The IV route is recommended in patients on hemodialysis; see [Precautions](#). Use the lowest dose for each patient that will gradually increase the hemoglobin concentration to avoid the need for RBC transfusion; see [Precautions](#) and [Monitor](#).

Anemia of CKD requiring dialysis in pediatric patients 1 month to 16 years of age: Initial: 50 units/kg of body weight 3 times a week. The IV route is recommended for patients on

hemodialysis. May also be given into the venous line at the end of the dialysis session. Safety and effectiveness for use in infants under 1 month of age not established.

Anemia in zidovudine-treated, HIV-infected pediatric patients 8 months to 17 years (unlabeled): Doses of 50 to 400 units/kg 2 to 3 times a week have been reported. See all comments under the similar section in Usual Dose. Adjust dose to achieve and maintain the lowest hemoglobin level sufficient to avoid the need for RBC transfusion; see [Dose Adjustments](#).

Anemia associated with pediatric cancer patients on chemotherapy, ages 5 to 18 years: 600 units/kg IV weekly until completion of chemotherapy course. Do not exceed 40,000 units. Increase dose to 900 units/kg weekly if hemoglobin increases by less than 1 Gm/dL and remains below 10 Gm/dL after the initial 4 weeks of therapy. Do not exceed a dose of 60,000 units.

NEONATAL DOSE

Anemia of prematurity (unlabeled): 25 to 100 units/kg/dose SC 3 times a week or 200 to 400 units/kg/dose IV/SC 3 to 5 times a week for 2 to 6 weeks. Total dose per week is 600 to 1,400 units/kg. Use the lowest dose that will gradually increase the hemoglobin concentration to avoid the need for RBC transfusion; see [Precautions](#), [Monitor](#), and [Dose Adjustments](#).

DOSE ADJUSTMENTS

Dose adjustment is based on hemoglobin. Adjust dose to achieve and maintain the lowest hemoglobin level sufficient to avoid the need for RBC transfusion.

All adult and pediatric patients with CKD: When adjusting therapy, consider hemoglobin rate of rise, hemoglobin rate of decline, ESA responsiveness, and hemoglobin variability. A single hemoglobin excursion may not require a dose adjustment. Dose should be started slowly and adjusted for each patient to achieve and maintain the lowest hemoglobin level sufficient to avoid the need for RBC transfusion. Allow sufficient time before adjusting a dose; increased hemoglobin levels may not be observed for 2 to 6 weeks. ■ Do not increase the dose more frequently than once every 4 weeks. Decreases in dose can occur more frequently. ■ If the hemoglobin rises rapidly (e.g., more than 1 Gm/dL in any 2-week period), reduce the dose by 25% or more as needed to reduce rapid responses. ■ For patients who do not respond adequately after 4 weeks of therapy (e.g., the hemoglobin has not increased by more than 1 Gm/dL), increase the dose by 25%. ■ For patients who do not respond adequately over a 12-week escalation period, increasing the dose further is unlikely to improve response and may increase risks. Discontinue epoetin if responsiveness does not improve.

Patients with CKD on dialysis: If the hemoglobin level approaches or exceeds 11 Gm/dL, reduce or interrupt the dose of epoetin.

Patients with CKD NOT on dialysis: If the hemoglobin level exceeds 10 Gm/dL, reduce or interrupt the dose of epoetin.

Zidovudine-treated, HIV-infected patients and cancer patients on chemotherapy: If hemoglobin does not increase after 8 weeks of therapy, increase dose by 50 to 100 units/kg. May increase dose at 4- to 8-week intervals until hemoglobin reaches a level needed to avoid RBC transfusions or dose reaches 300 units/kg. ■ Withhold dose if the hemoglobin exceeds 12 Gm/dL. Restart dose at 25% below previous dose when hemoglobin falls to less than 11 Gm/dL. ■ Discontinue epoetin if increase in hemoglobin is not achieved at a dose of 300 units/kg for 8 weeks.

Cancer patients on chemotherapy: *Reduce dose* by 25% when the hemoglobin reaches a level needed to avoid transfusion or increases more than 1 Gm/dL in any 2-week period.

Withhold dose if the hemoglobin exceeds a level needed to avoid transfusion, and restart at 25% below the previous dose when the hemoglobin approaches a level at which transfusions may be required. ■ Increase adult dose to 300 units/kg three times a week or 60,000 units weekly if hemoglobin increases by less than 1 Gm/dL and remains below 10 Gm/dL after the initial 4 weeks of therapy. ■ Discontinue epoetin after 8 weeks if no response as measured by hemoglobin levels or by continued need for RBC transfusions.

DILUTION

Available in numerous concentrations; check dose on vial carefully. May be given undiluted as an IV injection. Do not shake during preparation; will render it biologically inac-

tive. Single-dose vial contains no preservatives. Use only 1 dose per vial, then discard. Never reenter vial. Now available in multidose vial with preservative; sterile technique imperative.

Storage: Refrigerate single and multidose vials before use, multidose vial after initial use. Discard in 21 days. Do not freeze or shake. Protect from light.

Filters: Not required; however, it was filtered during manufacturing with 0.2-micron millipore filters. No significant loss of potency expected with the use of non-protein binding filters of a similar size or larger.

COMPATIBILITY

Manufacturers state, "Do not dilute or administer in conjunction with other drug solutions." One source indicates there may be protein loss from adsorption to PVC containers and tubing. Manufacturer suggests it may be mixed 1-to-1 with bacteriostatic NS in a syringe when prepared from a single-dose vial for SC injection; see literature.

RATE OF ADMINISTRATION

A single dose over at least 1 minute.

ACTIONS

An amino acid glycoprotein manufactured by recombinant DNA technology. Has the same biologic effects as erythropoietin produced naturally by the kidneys. Stimulates bone marrow to produce RBCs, increasing the reticulocyte count within 10 days and the red cell count, hemoglobin, and hematocrit within 2 to 6 weeks. Normal iron stores are necessary because it steps up RBC production to a rate above what the body usually makes. New cells need iron, which is quickly depleted. Half-life is 4 to 13 hours. Continued therapy will maintain improved RBC levels and decrease need for transfusions.

INDICATIONS AND USES

Treatment of anemia associated with chronic kidney disease in adults and pediatric patients, including patients on dialysis and not on dialysis, to decrease the need for red blood cell (RBC) transfusion. ■ Treatment of anemias related to zidovudine (AZT, Retrovir) therapy in HIV-infected patients. ■ To reduce the need for allogeneic blood transfusions among patients with perioperative hemoglobin greater than 10 to less than or equal to 13 Gm/dL who are at high risk for perioperative blood loss from elective, non-cardiac, nonvascular surgery. ■ Treatment of chemotherapy-induced anemia in adult cancer patients who have non-myeloid malignancies in which anemia is due to the effect of concomitant myelosuppressive chemotherapy and who, upon initiation of therapy, have a minimum of 2 additional months of planned chemotherapy.

Limitations of use: Not indicated for use in patients receiving hormonal agents, therapeutic biologic products, or radiotherapy unless receiving concomitant myelosuppressive chemotherapy. ■ Not indicated for patients receiving myelosuppressive therapy when the anticipated outcome is cure; see **Precautions**. ■ Has not been shown to improve quality of life, fatigue, or patient well-being. ■ Not indicated in patients scheduled for surgery who are willing to donate autologous blood. ■ Not indicated in patients undergoing cardiac or vascular surgery. ■ Not indicated as a substitute for a RBC transfusion in patients who require immediate correction of anemia.

Unlabeled uses: Anemia of prematurity.

CONTRAINDICATIONS

Known hypersensitivity to epoetin alfa, uncontrolled hypertension, pure red cell aplasia (PRCA). Epoetin alfa from multidose vials containing benzyl alcohol is contraindicated in neonates, infants, pregnant women, and nursing mothers.

PRECAUTIONS

All patients: May be given IV or SC in patients not receiving dialysis. May be given to dialysis patients into the venous line at the end of the dialysis procedure to eliminate additional venous access. Erythropoiesis-stimulating agents (ESAs) increase the risk of death, MI, stroke, venous thromboembolism, and thrombosis of vascular access. Patients experienced greater risks of these adverse events when ESAs were administered to target a hemoglobin of greater than 11 Gm/dL. No trial has identified a hemoglobin target level, an epoetin alfa dose, or a dosing strategy

that does not increase these risks. Use the lowest epoetin alfa dose sufficient to reduce the need for RBC transfusions. ■ Use with caution in patients with coexistent cardiovascular disease and stroke. Patients with CKD who have an insufficient hemoglobin response to ESA therapy may be at even greater risk for cardiovascular reactions and mortality than other patients. ■ In clinical trials, ESAs increased the risk of death in patients undergoing CABG surgery and the risk of deep venous thrombosis in patients undergoing orthopedic procedures. ■ Increases in hemoglobin of greater than 1 Gm/dL during any 2-week period have been associated with an increased incidence of cardiac arrest, exacerbations of hypertension, congestive heart failure (CHF), vascular thrombosis/ischemia/infarction, acute MI, deep vein thrombosis (DVT), pulmonary embolus, and fluid overload/edema and may be associated with neurologic events (e.g., seizures, stroke). See [Dose Adjustments](#). ■ In addition to low baseline hematocrit and inadequate iron stores, delayed or diminished response may result from concurrent medical problems (infections, inflammatory or malignant processes, occult blood loss, underlying hematologic disease, folic acid or vitamin B₁₂ deficiency, hemolysis, aluminum intoxication, osteitis fibrosa cystica, pure red cell aplasia [PRCA], anti-erythropoietin antibody-associated anemia). Correct or exclude other causes of anemia before initiating therapy. ■ Not intended for use in anemias caused by iron or folate deficiencies, hemolysis, or GI bleeding or for use in treating symptoms of anemia, including dizziness, fatigue, low energy, poor quality of life, or shortness of breath. ■ Not a substitute for emergency transfusion in patients requiring immediate correction of severe anemia. ■ Administration of erythropoiesis-stimulating agents (ESAs) to cancer patients shortened the overall survival time and/or increased the risk of tumor progression or recurrence in clinical studies of some patients with breast, cervical, head and neck, lymphoid, and non-small-cell lung malignancies. The risks of shortened survival time and tumor progression have not been excluded when ESAs are dosed to achieve a hemoglobin of less than 12 Gm/dL. To minimize these risks, as well as the risks of serious cardiovascular and thrombovascular events, use the lowest dose needed to avoid a red blood cell transfusion. Use only to treat anemia due to concomitant myelosuppressive chemotherapy, and discontinue after completion of a chemotherapy course. Prescribers and hospitals are now required to enroll in and comply with the ESA APPRISE Oncology Program to prescribe and/or dispense ESAs to patients with cancer. See prescribing information Black Box Warning. ■ BP may increase during therapy with epoetin. Hypertensive encephalopathy and seizures have been observed. ■ Patients with uncontrolled hypertension should not be treated with epoetin until BP has been adequately controlled. ■ Pure red cell aplasia (PRCA) and severe anemia, with or without other cytopenias, in association with neutralizing antibodies to native erythropoietin has been observed. Most often reported in CKD patients receiving epoetin alfa by SC injection. Any patient who develops a sudden loss of response to epoetin alfa accompanied by severe anemia and low reticulocyte count should be evaluated. Physicians may contact manufacturer (Amgen) for help with the evaluation of these patients. ■ Epoetin increases the risk of seizures in patients with CKD. Use with caution in patients with a seizure disorder. ■ Safety and efficacy not established in patients with a known history of underlying hematologic disorders (e.g., sickle cell anemia, myelodysplastic syndrome, or hypercoagulable disorders). ■ Serious hypersensitivity reactions, including anaphylaxis, have been reported. ■ The formulation containing albumin carries a risk for transmission of viral diseases or Creutzfeldt-Jakob disease. However, donor screening and manufacturing processes make this risk extremely remote.

Monitor: Monitor hemoglobin weekly in patients who are initiating therapy. Continue until stable and the maintenance dose has been established, then monitor at regular intervals. ■ Monitor hemoglobin weekly for at least 4 weeks following adjustment of therapy. Once stabilized, continue to monitor at regular intervals. ■ A biologic product. Monitor for S/S of hypersensitivity reactions. ■ Monitor BP routinely; initiation or intensification of antihypertensive therapy and dietary restrictions may be necessary. If BP is difficult to control by pharmacologic or dietary measures, the dose of epoetin should be reduced or withheld. ■ Normal iron stores required to support epoetin-stimulated

erythropoiesis. Transferrin saturation should be at least 20% and ferritin at least 100 ng/mL. Monitor before and during therapy. Supplemental iron is usually required to increase and maintain transferrin saturation. Administration of IV parenteral iron may be necessary in some patients. ■ Monitor for the presence of premonitory neurologic symptoms during initiation of therapy or when dose is adjusted. Seizures have been reported; see [Precautions](#). ■ Monitor patients with pre-existing vascular disease carefully (especially those with CKD); increase in hematocrit may precipitate a cerebrovascular accident, transient ischemic attack, or myocardial infarction. ■ Dialysis patients may require additional anticoagulation with heparin to prevent clotting of artificial kidney or clotting of the vascular access (AV shunt) and to maintain efficiency of the dialysis procedure.

Patient Education: Risk of seizures, especially during first 90 days of therapy. Do not drive or operate heavy equipment. ■ Menses may resume; possibility of pregnancy. Contraception may be indicated. ■ Additional instruction (e.g., equipment, techniques) will be required in patients who will self-administer (manufacturer supplies brochure). ■ Stress importance of compliance with diet, iron, and vitamin (e.g., folic acid, B₁₂) supplementation and BP control. Close monitoring of BP and Hgb is imperative. ■ Promptly report S/S of hypersensitivity reaction, pain or swelling in legs, SOB, increase in BP, dizziness, or loss of consciousness. ■ Increased risk of mortality, serious cardiovascular events, thromboembolic events, and tumor progression or recurrence. ■ Read Medication Guide carefully. All patients should discuss the risks of using an ESA with a health care professional. ■ Cancer patients must sign a patient–health care provider acknowledgment form through the APPRISE Oncology Program before initiating therapy; see [Precautions](#).

Maternal/Child: Category C: may present risk to fetus; benefits must justify risk. ■ Some formulations contain benzyl alcohol; see [Contraindications](#). ■ Use caution in nursing mothers. ■ Indicated in pediatric patients ages 1 month to 16 years of age for the treatment of anemia associated with CKD requiring dialysis. ■ Indicated in pediatric cancer patients ages 5 to 18 years for the treatment of anemia due to myelosuppressive chemotherapy. ■ Has been used in zidovudine-treated and anemic pediatric patients ages 8 months to 17 years. Data limited. ■ Pharmacokinetics (absorption, distribution, metabolism, and excretion) in children and adolescents similar to adults. ■ Limited data available for use in neonates. Clearance may be increased compared to adults.

Elderly: Response similar to that found in younger patients; however, elderly patients may have a greater sensitivity to its effects. ■ Monitor blood chemistry and BP carefully due to increased risk of renal and/or cardiovascular complications.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Generally well tolerated. Occur most frequently in patients with chronic renal failure. Increased hypertension is common, and hypertensive encephalopathy and seizures can occur. Clotted vascular access (AV shunt) and clotting of the artificial kidney may occur during dialysis. Allergic reactions have been reported. Other reported side effects are those common to the underlying disease and not necessarily attributable to epoetin and include arthralgias, asthenia, bone marrow fibrosis, cerebrovascular accident or transient ischemic attack, chest pain, cough, CVA/TIA, diarrhea, dizziness, edema, fatigue, fever, headache, hyperkalemia, myocardial infarction, nausea, polycythemia, rash, respiratory congestion, shortness of breath, tachycardia, and vomiting. PRCA and severe anemia, with or without other cytopenias, in association with neutralizing antibodies has been reported; see [Precautions](#).

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Excessive hypertension may require discontinuation of epoetin until BP is controlled or may respond to reduction in dose of epoetin or to an increase in antihypertensive therapy. Reduce dose of epoetin in patients with an increase in hemoglobin over 1 Gm/dL in any 2-week period. Consider phlebotomy in toxicity. Additional heparin may be required

during dialysis to prevent clotting. If overdose or polycythemia does occur, monitor closely for cardiovascular events and hematologic abnormalities. When resuming therapy, monitor closely for evidence of rapid increases in hemoglobin concentration (greater than 1 Gm/dL within 14 days) and reduce dose as indicated. Permanently discontinue therapy in patients with antibody-mediated anemia. Patients should not be switched to other erythropoietic proteins because antibodies may cross-react. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary.

EPOPROSTENOL SODIUM

(eh-poh-**PROST**-en-ohl **SO**-dee-um)

Vasodilating agent
Antihypertensive
(pulmonary)

Flolan, Veletri

pH 10.2 to 10.8

USUAL DOSE

Acute dose initiation and chronic continuous infusion: May be given through a peripheral line on a temporary basis until a central venous line is established. A central venous catheter should be put in place as soon as possible and must be used for continuous long-term 24-hour administration with an ambulatory infusion pump. Begin infusion at 2 ng/kg/min. Increase in increments of 2 ng/kg/min every 15 minutes or longer until dose-limiting pharmacologic effects occur or until a tolerance limit to the drug is established and further increases in the infusion rate are not clinically warranted; see [Dose Adjustments](#). Most common S/S of dose-limiting effects include abdominal pain, flushing, headache, hypotension, nausea, respiratory disorders, sepsis, and vomiting. If dose-limiting pharmacologic effects occur, decrease infusion rate slowly until pharmacologic effects are tolerated; see [Dose Adjustments](#). If the initial dose of 2 ng/kg/min is not tolerated, use a lower dose. During the first 7 days of treatment in clinical trials, the dose was increased daily to a mean dose of 4.1 ng/kg/min on Day 7 of treatment. At the end of Week 12, the mean dose was 11.2 ng/kg/min. The mean incremental increase was 2 to 3 ng/kg/min every 3 weeks. May be given concomitantly with anticoagulant therapy in selected patients; see [Monitor](#).

DOSE ADJUSTMENTS

Changes in the chronic infusion rate are to be expected. If symptoms of primary pulmonary hypertension (PPH) persist, recur, or worsen, increase infusion rate promptly by 1 to 2 ng/kg/min. Wait at least 15 minutes to assess clinical response. Observe patient for several hours to confirm patient tolerance and take BP and HR in supine and standing positions. In trials most patients progressed to a dose a little less than their acute dose-initiation intolerable dose within 12 weeks. ■ Occurrence of dose-related side effects that do not resolve may require a decrease in the chronic infusion rate. Reduce dose gradually in 2-ng/kg/min increments and wait at least 15 minutes to assess clinical response. Use extreme caution if decreasing the dose; abrupt withdrawal or sudden large reductions may cause a rapid return of PPH symptoms and may precipitate death. ■ In patients receiving lung transplants, doses were tapered after the initiation of cardiopulmonary bypass. ■ Dose selection for the elderly should be cautious. ■ Asymptomatic increases in pulmonary artery pressure with increases in cardiac output may occur during acute dose initiation; consider dose adjustment. ■ See Precautions.

DILUTION

Infusion pump required. It must be small and lightweight; able to adjust infusion rates in 2-ng/kg/min increments; have occlusion, end of infusion, and low battery alarms; be accurate to $\pm 6\%$ of the programmed rate; be positive-pressure driven (continuous or pulsatile) with intervals between pulses not exceeding 3 minutes at rates required to deliver

drug; and have a disposable reservoir cassette made of polyvinyl chloride, polypropylene, or glass with a capacity of at least 100 mL. Pumps used during trials were manufactured by Pharmacia Deltec, Medfusion, Inc., and Baxter Health Care. The infusion pump used in the most recent clinical trials was the CADD-1 HFX 5100 (SIMS Deltec).

Flolan and Generic: Sterile diluent for epoprostenol is provided by the manufacturer. Do not use any other diluent. Concentration will be determined by desired dose/kg/min and parameters of ambulatory infusion pump to be used. See Rate of Administration. Two vials of provided sterile diluent will be required to prepare each 24-hour dose in each of the concentrations in the following chart.

Guidelines for Dilution of Epoprostenol (Flolan and Generic) to Various Concentrations	
To Make 100 mL of Solution with Final Concentration (ng/mL) of:	Directions
3,000 ng/mL	Dissolve contents of one 0.5-mg vial with 5 mL of STERILE DILUENT for epoprostenol. Withdraw 3 mL and add to sufficient STERILE DILUENT for epoprostenol to make a total of 100 mL.
5,000 ng/mL	Dissolve contents of one 0.5-mg vial with 5 mL of STERILE DILUENT for epoprostenol. Withdraw entire vial contents and add sufficient STERILE DILUENT for epoprostenol to make a total of 100 mL.
10,000 ng/mL	Dissolve contents of two 0.5-mg vials each with 5 mL of STERILE DILUENT for epoprostenol. Withdraw entire vial contents and add sufficient STERILE DILUENT for epoprostenol to make a total of 100 mL.
15,000 ng/mL	Dissolve contents of one 1.5-mg vial with 5 mL of STERILE DILUENT for epoprostenol. Withdraw entire vial contents and add sufficient STERILE DILUENT for epoprostenol to make a total of 100 mL.

Acute dose initiation may require more than one solution strength. 3,000 ng/mL and 10,000 ng/mL concentrations should be satisfactory to deliver between 2 and 16 ng/kg/min in adults. A maximum 2-day supply can be diluted at one time (200 mL). For use at room temperature, withdraw 33.3 mL and deposit in pump reservoir cassette or sterile infusion bag for each 8-hour period. If used with cold pouches and frozen gel packs, 100 mL can be placed in the pump reservoir cassette or a 100-mL sterile infusion bag for each 24-hour period. Frozen gel packs must be changed every 12 hours. Reservoir cassettes are disposable. Most patients prepare a 24-hour dose in a new reservoir cassette before a new dose is required and use cold pouches to maintain temperature. **Veletri:** Stable only when reconstituted as directed using SWFI or NS. Do not use any other diluent. A single reservoir or diluted solution prepared as directed can be administered at room temperature for up to 24 hours. If lower concentrations are chosen, pump reservoirs should be changed every 12 hours. See prescribing information for additional concentrations.

Guidelines for Dilution of Veletri to Various Concentrations	
To Make 100 mL of Solution with Final Concentration (ng/mL) of:	Directions
15,000 ng/mL*	Dissolve contents of one 1.5-mg vial with 5 mL of SWFI or NS. Withdraw entire vial contents and add sufficient volume of the IDENTICAL DILUENT to make a total of 100 mL.
30,000 ng/mL*	Dissolve contents of two 1.5-mg vials each with 5 mL of SWFI or NS. Withdraw entire vial contents and add sufficient volume of the IDENTICAL DILUENT to make a total of 100 mL.

*Higher concentrations may be prepared for patients who receive epoprostenol long-term.

Filters: An in-line 0.22-micron filter was used during clinical trials.

Storage: Flolan: Unopened vials of epoprostenol may be stored at 15° to 25° C (59° to 77° F [**generic** at CRT]) in the carton to protect from light. Diluent may be stored at 15° to 25° C (59° to 77° F [**generic** at CRT]). Protection from light not required. See expiration dates on both. Before use, reconstituted solutions (**Flolan and generic**) must be refrigerated and protected from light. Do not freeze. Reconstituted solution must be discarded after 48 hours or if accidentally frozen. While in use, must not be exposed to direct sunlight or temperatures above 25° C (77° F) or below 0° C (32° F). Stable in pump reservoir for only 8 hours at RT. Use of cold pouches with frozen gel packs can extend reservoir life to 24 hours. Time stored in refrigerator and in reservoir of pump must be included in maximum 48-hour time frame.

Veletri: Unopened vials may be stored at 20° to 25° C (68° to 77° F). Vials reconstituted with 5 mL of SWFI or NS must be protected from light and can be refrigerated at 2° to 8° C (36° to 46° F) for as long as 5 days or held at up to 20° to 25° C (68° to 77° F) for up to 48 hours. Do not freeze reconstituted solutions. Discard any reconstituted solution that has been frozen or refrigerated for more than 5 days or held at room temperature for more than 48 hours. See prescribing information for maximum duration of administration (hours) of fully diluted solutions in drug delivery reservoir.

COMPATIBILITY

Manufacturer states, “Stable only when reconstituted with the provided or recommended diluent. Must not be reconstituted or mixed with any other parenteral medications or solutions prior to or during administration.” One source suggests **compatibility** at the **Y-site** with bivalirudin (Angiomax).

RATE OF ADMINISTRATION

Administered by a continuous IV infusion through a central venous catheter. Peripheral access may be used temporarily until a central line can be placed. Titrate dose as outlined in Usual Dose and Dose Adjustments. Flow must not be interrupted for longer than 2 to 3 minutes. Time to completion of administration must never exceed more than 8 hours at room temperature, more than 24 hours with use of cold pouches and changing frozen gel packs every 12 hours, or more than 48 hours from time of initial reconstitution. If dose-limiting pharmacologic effects occur, decrease infusion rate slowly until pharmacologic effects are tolerated; see **Dose Adjustments**. The infusion rate may be calculated using the following formula:

$$\text{Infusion rate (mL/hr)} = \frac{\text{Dose (ng/kg/min)} \times \text{Weight in kg} \times 60 \text{ min/hr}}{\text{Final concentration (ng/mL)}}$$

The following charts may be used for infusion rates at a final concentration of 3,000 ng/mL or 15,000 ng/mL. See package insert for tables at additional concentrations.

Infusion Rates for Epoprostenol at a Concentration of 3,000 ng/mL								
Patient Weight	Dose or Drug Delivery Rate (ng/kg/min)							
	2	4	6	8	10	12	14	16
Infusion Delivery Rate (mL/hr)								
10 kg	—	—	1.2	1.6	2	2.4	2.8	3.2
20 kg	—	1.6	2.4	3.2	4	4.8	5.6	6.4
30 kg	1.2	2.4	3.6	4.8	6	7.2	8.4	9.6
40 kg	1.6	3.2	4.8	6.4	8	9.6	11.2	12.8
50 kg	2	4	6	8	10	12	14	16
60 kg	2.4	4.8	7.2	9.6	12	14.4	16.8	19.2
70 kg	2.8	5.6	8.4	11.2	14	16.8	19.6	22.4
80 kg	3.2	6.4	9.6	12.8	16	19.2	22.4	25.6
90 kg	3.6	7.2	10.8	14.4	18	21.6	25.2	28.8
100 kg	4	8	12	16	20	24	28	32

Infusion Rates for Epoprostenol at a Concentration of 15,000 ng/mL								
Patient Weight	Dose or Drug Delivery Rate (ng/kg/min)							
	4	6	8	10	12	14	16	16
Infusion Delivery Rate (mL/hr)								
20 kg	—	—	—	—	1	1.1	1.3	1.3
30 kg	—	—	1	1.2	1.4	1.7	1.9	1.9
40 kg	—	1	1.3	1.6	1.9	2.2	2.6	2.6
50 kg	—	1.2	1.6	2	2.4	2.8	3.2	3.2

70 kg	1.1	1.7	2.2	2.8	3.4	3.9	4.5	4.5
80 kg	1.3	1.9	2.6	3.2	3.8	4.5	5.1	5.1
90 kg	1.4	2.2	2.9	3.6	4.3	5	5.8	5.8
100 kg	1.6	2.4	3.2	4	4.8	5.6	6.4	6.4

ACTIONS

A naturally occurring prostaglandin. It directly vasodilates pulmonary and systemic arterial vascular beds and inhibits platelet aggregation. Right and left ventricle afterload is reduced, and cardiac output and stroke volume are increased. Effect on HR is dose related. Produces dose-related increases in cardiac index and stroke volume and dose-related decreases in pulmonary vascular resistance, total pulmonary resistance, and mean systemic arterial pressure. Has been shown to increase exercise capacity, improve hemodynamic status, and extend survival. Onset of action is immediate. Half-life is approximately 6 minutes at body pH of 7.4. Metabolized to two primary metabolites by rapid hydrolyzation and enzymatic degradation.

INDICATIONS AND USES

Treatment of pulmonary arterial hypertension (PAH [WHO Group 1]) to improve exercise capacity. Effectiveness established predominantly in patients with NYHA Func-

tional Class III-IV symptoms and etiologies of idiopathic or heritable PAH or PAH associated with connective tissue diseases.

CONTRAINDICATIONS

Congestive heart failure due to severe left ventricular systolic dysfunction, known hypersensitivity to epoprostenol or related compounds (e.g., alprostadil [prostaglandin E₁, Prostin VR Pediatric]), or patients who develop pulmonary edema during dose initiation.

PRECAUTIONS

Administered by or under the direction of the physician specialist. ■ During dose initiation, facilities for monitoring the patient and responding to any medical emergency must be available. ■ Causes of secondary pulmonary hypertension should be eliminated and diagnosis of PPH carefully established. ■ Abrupt withdrawal, interruptions in drug delivery, or sudden large reductions in dose may result in rebound pulmonary hypertension, including dyspnea, dizziness, and weakness. Death of one patient was attributed to these causes. Backup medication and equipment must always be available. ■ Use of a multilumen catheter should be considered if other IV therapy is used. ■ Not recommended for patients who develop pulmonary edema during acute dose initiation; may develop pulmonary venoocclusive disease; see [Contraindications](#). ■ Asymptomatic increases in pulmonary artery pressure with increases in cardiac output may occur during acute dose initiation; consider dose adjustment. ■ Cardiac catheterization is used during trials for acute dose initiation but is not necessary; consider benefit versus risk. In patients undergoing lung transplants, it is recommended that the dose of epoprostenol be tapered after initiation of cardiopulmonary bypass. ■ A potent inhibitor of platelet aggregation; an increased risk for hemorrhagic complications may occur, particularly in patients with other risk factors for bleeding. ■ See [Monitor](#), [Patient Education](#), [Drug/Lab Interactions](#).

Monitor: ECG monitoring and frequent monitoring of vital signs recommended during acute dose initiation. ■ Observe for dose-limiting side effects. ■ To reduce the risk of pulmonary thromboembolism or systemic embolism through a patent foramen ovale, anticoagulant therapy is recommended concomitantly unless contraindicated. ■ Therapy may be required for months or years; consideration must be given to the ability of the patient and family to manage this care. ■ Monitor standing and supine HR and BP for several hours after any adjustment. ■ Thorough patient teaching and continued support services are imperative to facilitate a good clinical outcome. ■ See [Precautions](#), [Patient Education](#), [Drug/Lab Interactions](#).

Patient Education: After initial dose titration and training, this is a self-administered drug. Must assume responsibility for drug reconstitution, drug administration, and care of the permanent central venous catheter. ■ Aseptic technique during reconstitution and with routine care of permanent indwelling central venous catheter is imperative to prevent infection. ■ Report fever or any sign of infection at catheter site (e.g., redness, warmth). ■ Delivery of medication cannot be interrupted. Interruption will cause a rapid return of PPH symptoms. ■ Should have access to a backup infusion pump and intravenous infusion sets to avoid potential interruption in drug delivery. ■ Dose adjustments should be made only under the direction of the physician except in an emergency situation (e.g., unconsciousness, collapse).

Maternal/Child: Category B: use only if clearly needed. No evidence of fetal harm in animal studies to date. ■ Safety for use during labor and delivery not established. ■ Use caution in nursing mothers; safety not established. ■ Safety for use in pediatric patients not established.

Elderly: See [Dose Adjustments](#). Decreased organ function (cardiac, hepatic, renal), concomitant disease, and other drug therapy may cause concern. Response of younger patients versus the elderly not documented.

DRUG/LAB INTERACTIONS

Has been used with digoxin, diuretics, anticoagulants, oral vasodilators, and oxygen. ■ Hypotension may be increased with **diuretics, antihypertensive agents, or other vasodilators**. ■ Risk of bleeding may be increased with **antiplatelet agents, anticoagulants, or**

NSAIDs (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]). ■ May decrease clearance of **furosemide** (Lasix), and **digoxin**; monitor digoxin levels.

SIDE EFFECTS

Acute dose initiation: Most common S/S of dose-limiting effects include flushing, headache, hypotension, nausea, and vomiting. Abdominal pain, agitation, anxiety/nervousness, back pain, bradycardia, chest pain, constipation, dizziness, dyspnea, dyspepsia, hyperesthesia, musculoskeletal pain, paresthesia, respiratory disorders, sepsis, sweating, tachycardia, and many other side effects may occur.

Chronic continuous infusion: Any of the above and arthralgia, bleeding at various sites, chills, diarrhea, fatigue, fever, flu-like symptoms, infection (may be local at site of catheter insertion), jaw pain, pallor, pulmonary edema, rash, sepsis, thrombocytopenia.

Overdose: Hypotension, hypoxemia, respiratory arrest, and death may occur.

Post-Marketing: Anemia, hypersplenism, hyperthyroidism, pancytopenia, splenomegaly.

ANTIDOTE

Continuous maintenance of drug flow imperative. Keep physician informed of all side effects. Most will be treated with dose reduction; some may require symptomatic treatment. Call 1-800-9-FLOLAN for drug or pump problems with Flolan.

EPTIFIBATIDE

(ep-tih-FY-beh-tide)

Platelet aggregation inhibitor

Integrilin

pH 5.35

USUAL DOSE

Used in combination with heparin and aspirin. A calculated CrCl greater than or equal to 50 mL/min is required in patients receiving the following doses. Use of the Cockcroft-Gault equation is recommended for calculating CrCl. Discontinue eptifibatide infusion before CABG surgery and in patients requiring thrombolytic therapy.

ACUTE CORONARY SYNDROME

Eptifibatide: 180 mcg/kg as an IV bolus as soon as possible following diagnosis. Follow with a continuous infusion of 2 mcg/kg/min until hospital discharge or initiation of coronary artery bypass graft (CABG) surgery for up to 72 hours. Alternately, if a patient is to undergo a percutaneous coronary intervention (PCI) while receiving eptifibatide, the infusion should be continued up to hospital discharge, or for 18 to 24 hours after the procedure, whichever comes first. Patient may receive up to 96 hours of therapy. See Dosing Chart by Weight on the following page and [Dose Adjustments](#). Dose in patients with a calculated CrCl greater than or equal to 50 mL/min weighing more than 121 kg should not exceed a bolus of 22.6 mg or an infusion rate of 15 mg/hr.

Aspirin: 160 to 325 mg PO initially and daily thereafter.

Heparin: Medical management: Suggested heparin dose to achieve the target aPTT of 50 to 70 seconds during medical management is **Weight 70 kg or more**, 5,000 units as an IV bolus followed by an infusion of 1,000 units/hr. **Weight less than 70 kg**, 60 units/kg as an IV bolus followed by an infusion of 12 units/kg/hr.

Patients undergoing PCI: Target ACT is 200 to 300 seconds during PCI. If heparin is initiated before PCI, give additional boluses during PCI as needed to keep ACT in range. Heparin infusion after PCI is discouraged.

PERCUTANEOUS CORONARY INTERVENTION (PCI)

Eptifibatide: 180 mcg/kg as an IV bolus immediately before initiation of PCI followed by a continuous infusion of 2 mcg/kg/min. Repeat bolus of 180 mcg/kg 10 minutes after the first bolus. Continue infusion until hospital discharge or for up to 18 to 24 hours, whichever comes first. A minimum of 12 hours of infusion is recommended. See the following

chart and **Dose Adjustments**. Dose in patients with a calculated CrCl greater than or equal to 50 mL/min weighing more than 121 kg should not exceed a bolus of 22.6 mg or an infusion rate of 15 mg/hr.

Aspirin: 160 to 325 mg PO 1 to 24 hours before PCI and daily thereafter.

Heparin: Target ACT is 200 to 300 seconds during PCI. In patients not treated with heparin within 6 hours of PCI, give 60 units/kg as a bolus. Give additional boluses as needed during PCI to keep ACT in range. Heparin infusion is discouraged after PCI.

FOR BOTH INDICATIONS

Refer to the following Eptifibatide Dosing Chart by Weight.

Eptifibatide Dosing Chart by Weight					
Patient Weight	180 mcg/kg Bolus Volume	2 mcg/kg/min Infusion Rate		1 mcg/kg/min Infusion Rate	
	From 2 mg/mL Vial	From 2 mg/mL 100-mL Vial	From 0.75 mg/mL 100-mL Vial	From 2 mg/mL 100-mL Vial	From 0.75 mg/mL 100-mL Vial
37-41 kg	3.4 mL	2 mL/hr	6 mL/hr	1 mL/hr	3 mL/hr
42-46 kg	4 mL	2.5 mL/hr	7 mL/hr	1.3 mL/hr	3.5 mL/hr
47-53 kg	4.5 mL	3 mL/hr	8 mL/hr	1.5 mL/hr	4 mL/hr
54-59 kg	5 mL	3.5 mL/hr	9 mL/hr	1.8 mL/hr	4.5 mL/hr
60-65 kg	5.6 mL	3.8 mL/hr	10 mL/hr	1.9 mL/hr	5 mL/hr
66-71 kg	6.2 mL	4 mL/hr	11 mL/hr	2 mL/hr	5.5 mL/hr
72-78 kg	6.8 mL	4.5 mL/hr	12 mL/hr	2.3 mL/hr	6 mL/hr
79-84 kg	7.3 mL	5 mL/hr	13 mL/hr	2.5 mL/hr	6.5 mL/hr
85-90 kg	7.9 mL	5.3 mL/hr	14 mL/hr	2.7 mL/hr	7 mL/hr
91-96 kg	8.5 mL	5.6 mL/hr	15 mL/hr	2.8 mL/hr	7.5 mL/hr
97-103 kg	9 mL	6 mL/hr	16 mL/hr	3 mL/hr	8 mL/hr
104-109 kg	9.5 mL	6.4 mL/hr	17 mL/hr	3.2 mL/hr	8.5 mL/hr
110-115 kg	10.2 mL	6.8 mL/hr	18 mL/hr	3.4 mL/hr	9 mL/hr
116-121 kg	10.7 mL	7 mL/hr	19 mL/hr	3.5 mL/hr	9.5 mL/hr
>121 kg	11.3 mL	7.5 mL/hr	20 mL/hr	3.7 mL/hr	10 mL/hr

DOSE ADJUSTMENTS

ACUTE CORONARY SYNDROME

In patients with a calculated CrCl less than 50 mL/min, give a bolus of 180 mcg/kg. Decrease rate of the continuous infusion to 1 mcg/kg/min. In patients with a calculated CrCl less than 50 mL/min or a SCr greater than 2 mg/dL and weighing more than 121 kg, a maximum bolus of 22.6 mg followed by a maximum infusion rate of 7.5 mg/hr should be administered.

PCI

In patients with a calculated CrCl less than 50 mL/min, give a bolus of 180 mcg/kg. Decrease rate of the continuous infusion to 1 mcg/kg/min. Repeat bolus of 180 mcg/kg 10 minutes after the first bolus. In patients with a calculated CrCl less than 50 mL/min or a SCr greater than 2 mg/dL and weighing more than 121 kg, a maximum bolus of 22.6 mg followed by a maximum infusion rate of 7.5 mg/hr should be administered.

ALL DIAGNOSES

Dose reduction may be indicated in patients over 75 years of age weighing less than 50 kg. ■ See Dosing Chart by Weight in **Usual Dose**. ■ See **Contraindications**.

DILUTION

The 10-mL vial contains 20 mg of eptifibatide; the 100-mL vials contain 75 mg or 200 mg of eptifibatide.

IV bolus: Given undiluted. Withdraw total bolus dose (usually from the 10-mL vial) into a syringe.

Infusion: Usually given undiluted directly from the 75 mg/100 mL (0.75 mg/mL) or the 200 mg/100 mL (2 mg/mL) vials using an IV infusion pump. The 100-mL vial should be spiked with a vented infusion set. Center the spike within the circle on the stopper top. May be diluted with NS or D5NS. Use of a metriset or infusion pump appropriate.

Storage: Refrigerate vials at 2° to 8° C (36° to 46° F) or they may be kept at CRT for up to 2 months. Protect from light until administration. Do not use beyond the expiration or discard date. Discard any unused portion left in the vial.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists furosemide (Lasix) as **incompatible** and states “is **incompatible** with any solution or drug not specifically listed as **compatible**.”

Manufacturer lists as **compatible** at **Y-site** with NS or D5NS with or without up to 60 mEq/L of potassium chloride as well as with alteplase (t-PA), atropine sulfate, dobutamine, heparin, lidocaine, meperidine (Demerol), metoprolol (Lopressor), midazolam (Versed), morphine, nitroglycerin IV, verapamil.

Another source adds the following **compatibilities**:

Y-site: Amiodarone (Nexterone), argatroban, bivalirudin (Angiomax), and micafungin (Mycamine).

RATE OF ADMINISTRATION

IV bolus: A single dose IV push over 1 to 2 minutes.

Infusion: See Dosing Charts by Weight under **Usual Dose**.

ACTIONS

A cyclic heptapeptide (amino acid) that reversibly binds to the platelet receptor glycoprotein GP IIb/IIIa of human platelets and inhibits platelet aggregation by preventing the binding of fibrinogen, von Willebrand factor, and other adhesive ligands to GP IIb/IIIa. Inhibits platelet aggregation in a dose- and concentration-dependent manner. Recovery of platelet function after termination of the eptifibatide infusion is rapid. Administered alone, eptifibatide has no measurable effect on PT or aPTT. Does not exert a pharmacologic effect on other integrins. Recommended regimens of a bolus followed by an infusion produce immediate inhibition of platelet aggregation and an early peak level, followed by a small decline, with steady state achieved within 4 to 6 hours. This decline can be prevented by administering a second bolus. Plasma elimination half-life is approximately 2.5 hours. 50% cleared from plasma by the kidneys. Balance of clearance is by nonrenal mechanisms. Has been shown to reduce clinical events (e.g., acute MI, need for urgent intervention) in patients undergoing PCI during drug administration and in those receiving medical management alone.

INDICATIONS AND USES

Used in combination with heparin, aspirin and, in selected situations, a thienopyridine (e.g., clopidogrel [Plavix], prasugrel [Effient]). ■ Treatment of patients with acute coronary syndrome (unstable angina or non-ST-segment elevation MI), including those who are to be managed medically and those undergoing PCI. In this setting, has been shown to decrease the rate of a combined endpoint of death or new MI. ■ Treatment of patients undergoing PCI, including those undergoing intracoronary stenting. In this setting has been shown to decrease the rate of a combined endpoint of death, new MI, or need for urgent intervention.

CONTRAINDICATIONS

Known hypersensitivity to any component of the product. ■ Current or planned administration of another parenteral glycoprotein GPIIb/IIIa inhibitor (e.g., abciximab [Reo-Pro], tirofiban [Aggrastat]). ■ Dependency on renal dialysis. ■ History of bleeding dia-

thesis or evidence of active abnormal bleeding within the previous 30 days. ■ History of stroke within 30 days or any history of hemorrhagic stroke. ■ Major surgery within the preceding 6 weeks. ■ Severe hypertension (systolic BP greater than 200 mm Hg or diastolic BP greater than 110 mm Hg) not adequately controlled on antihypertensive therapy.

PRECAUTIONS

Use caution when given with drugs that affect hemostasis (e.g., NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], clopidogrel [Plavix], dipyridamole [Persantine], ticlopidine [Ticlid], warfarin [Coumadin]). Limited data on the use of eptifibatide in patients receiving thrombolytic agents (e.g., alteplase [t-PA, Activase]), reteplase [Retavase], streptokinase [Streptase]) do not allow an estimate of the bleeding risk associated with concomitant use. Systemic thrombolytic therapy should be used with caution in patients who have received eptifibatide. See [Drug/Lab Interactions](#). ■ Use with caution in patients with renal insufficiency; clearance is reduced and plasma levels are elevated; see [Dose Adjustments](#). There is no experience in patients dependent on dialysis. ■ Bleeding is the most common complication encountered during therapy. ■ Risk of major bleeding increased inversely with patient weight, especially for patients weighing less than 70 kg. ■ Most major bleeding occurs at the arterial access site for cardiac catheterization or from the GI or GU tracts. ■ Acute profound thrombocytopenia has been reported; see [Monitor](#). ■ Because eptifibatide is readily reversible, procedures such as emergency CABG may be performed safely shortly after discontinuation of an infusion without the need for platelet transfusions. ■ Development of antibodies to eptifibatide and immune-mediated thrombocytopenia have been reported; may be associated with hypotension and/or other signs of hypersensitivity. ■ No clinical experience in patients with a baseline platelet count less than 100,000/mm³. Monitor closely if use is indicated.

Monitor: Before therapy obtain platelet count, hemoglobin or hematocrit, SCr, and PT/aPTT. Obtain ACT in patients undergoing PCI. ■ Maintain target aPTT between 50 and 70 seconds unless PCI is to be performed. During PCI, the ACT should be maintained between 200 and 300 seconds. ■ The aPTT or ACT should be checked before sheath removal. The sheath should not be removed unless the aPTT is less than 45 seconds or the ACT is less than 150 seconds. In patients treated with heparin, bleeding can be minimized by close monitoring of the aPTT. ■ If acute profound thrombocytopenia occurs or the platelet count drops to less than 100,000/mm³, heparin and eptifibatide should be discontinued. Monitor serial platelet counts, assess the presence of drug-dependent antibodies, and initiate appropriate therapy as indicated. ■ Monitor the patient for signs of bleeding; take vital signs (avoiding automatic BP cuffs); observe any invaded sites at least every 15 minutes (e.g., sheaths, IV sites, cutdowns, punctures, Foleys, NGs); watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, muscle weakness. Perform neuro checks frequently. If during therapy, bleeding cannot be controlled with pressure, heparin and eptifibatide should be discontinued. ■ Use care in handling patient; minimize use of urinary catheters, nasotracheal intubation, and nasogastric tubes. Avoid arterial puncture, venipuncture, and IM injection. Use extreme precautionary methods and only compressible sites if these procedures are absolutely necessary (i.e., avoid subclavian or jugular veins). Apply pressure for 30 minutes to any invaded site and then apply pressure dressings. Saline or heparin locks suggested to facilitate blood draws. ■ See [Precautions](#).

Additional monitoring for patients receiving PCI: After PCI, eptifibatide should be continued until hospital discharge or for up to 18 to 24 hours, whichever comes first. See suggested time frames under each dose. Heparin use is discouraged after the PCI procedure. The femoral artery sheath may be removed during eptifibatide infusion, but only after heparin has been discontinued and its effects largely reversed. Heparin should be discontinued 3 to 4 hours before pulling the sheath, and an aPTT less than 45 seconds or an ACT of less than 150 seconds should be documented. ■ Care should be taken to obtain proper hemostasis after removal of the sheath using standard compressive techniques followed by

close observation. Sheath hemostasis should be achieved at least 2 to 4 hours before hospital discharge.

Patient Education: Compliance with all measures to minimize bleeding (e.g., strict bed rest, positioning) is imperative. ■ Avoid use of razors, toothbrushes, and other sharp items. ■ Use caution while moving to avoid excessive bumping. ■ Report all episodes of bleeding and apply local pressure if indicated. ■ Expect oozing from IV sites.

Maternal/Child: Category B: safety for use in pregnancy not established; use only if clearly needed. ■ It is not known whether eptifibatide is excreted in breast milk; use caution if administered to a nursing mother. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Dose adjusted by weight; see [Dosing Charts by Weight in Usual Dose](#). ■ Clearance decreased and plasma levels increased in older patients; incidence of bleeding complications was higher and eptifibatide-associated bleeding was greater in the elderly during studies. ■ No apparent difference in effectiveness between older and younger patients.

DRUG/LAB INTERACTIONS

All studies with eptifibatide included the use of **aspirin and heparin**. In the ESPRIT study, **clopidogrel** (Plavix) or **ticlopidine** (Ticlid) were administered routinely, starting the day of PCI. Concomitant use, although indicated, increases the risk of bleeding. ■ Use caution when given with **drugs that affect hemostasis** such as **thrombolytics** (e.g., alteplase [t-PA, Activase], reteplase [Retavase], streptokinase [Streptase]), **oral anticoagulants** (e.g., warfarin [Coumadin]), **NSAIDs** (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]), **dipyridamole** (Persantine), **ticlopidine** (Ticlid), **clopidogrel** (Plavix), **selected antibiotics** (e.g., cefotetan). ■ Avoid concomitant treatment with **other inhibitors of platelet receptor glycoprotein GPIIb/IIIa** (e.g., abciximab [ReoPro], tirofiban [Aggrastat]); may have potentially serious additive effects. See [Contraindications](#). ■ **Enoxaparin** (Lovenox) 1 mg/kg SC every 12 hours for 4 doses has been administered without altering the effects of eptifibatide.

SIDE EFFECTS

Bleeding is the most frequent adverse event; may occur more frequently in patients undergoing CABG or PCI, or in the elderly or those weighing less than 70 kg. Bleeding is usually reported as mild oozing, but major bleeding (e.g., GI bleeding, pulmonary hemorrhage, intracranial hemorrhage, and stroke) may occur. Fatal bleeding events have been reported. Laboratory findings related to bleeding include decrease in hemoglobin, hematocrit, and platelet count and occult blood in urine and feces. Other side effects that have been reported include hypersensitivity reactions, hypotension, and thrombocytopenia (acute and profound). Incidence in studies similar to that seen with placebo.

Acute toxicity: Specific information not available for humans, but decreased muscle tone, dyspnea, loss of righting reflex, petechial hemorrhages in the femoral and abdominal areas, and ptosis occurred in animals.

Post-Marketing: Immune-mediated thrombocytopenia.

ANTIDOTE

Keep physician informed of laboratory values and side effects. Discontinue the infusion of eptifibatide and heparin if any serious bleeding not controllable with pressure occurs, if CABG surgery is initiated, and/or if patient requires thrombolytic therapy. If acute profound thrombocytopenia occurs or the platelet count drops to less than 100,000/mm³, heparin and eptifibatide should be discontinued. Monitor serial platelet counts, assess the presence of drug-dependent antibodies, and initiate appropriate therapy as indicated. Monitor closely; platelet transfusion may be required. If a hypersensitivity reaction should occur, discontinue the infusion and treat as indicated by severity (e.g., epinephrine, dopamine, theophylline, antihistamines such as diphenhydramine [Benadryl]) and/or corticosteroids as necessary. No specific antidote is available. Platelet inhibition reverses rapidly when infusion is discontinued. Hemodialysis may be useful in an overdose situation.

ERIBULIN MESYLATE

(ER-ih-BUE-lin MES-ih-late)

Antineoplastic

Halaven

USUAL DOSE

1.4 mg/M² IV over 2 to 5 minutes on Days 1 and 8 of a 21-day cycle.

DOSE ADJUSTMENTS

Dose adjustment not required based on age, gender, or race. ■ Reduce dose in patients with mild hepatic impairment (Child-Pugh Class A) to 1.1 mg/M² IV. ■ Patients with moderate hepatic impairment (Child-Pugh Class B) should receive 0.7 mg/M² IV. ■ Patients with moderate renal impairment (CrCl 30 to 50 mL/min) should receive 1.1 mg/M² IV. ■ Do not administer dose on Day 1 or Day 8 in patients with an ANC less than 1,000/mm³, platelets less than 75,000/mm³, or Grade 3 or 4 nonhematologic toxicities. ■ The Day 8 dose may be delayed for a maximum of 1 week. If toxicities do not resolve or improve to Grade 2 or less by Day 15, omit the dose. If toxicities resolve or improve to Grade 2 or less by Day 15, administer at a reduced dose as outlined in the following table and initiate the next cycle no sooner than 2 weeks later. ■ If a dose has been delayed for toxicity and the toxicities have recovered to Grade 2 severity or less, resume eribulin as outlined in the following table. ■ Do not re-escalate eribulin dose after it has been reduced.

Recommended Dose Reductions for Eribulin Mesylate	
Event Description	Recommended Eribulin Dose
Permanently reduce the 1.4 mg/M ² eribulin dose for any of the following: <ul style="list-style-type: none"> • ANC <500/mm³ for >7 days • ANC <1,000/mm³ with fever or infection • Platelets <25,000/mm³ • Platelets <50,000/mm³ requiring transfusion • Nonhematologic Grade 3 or 4 toxicities* • Omission or delay of Day 8 eribulin dose in previous cycle for toxicity 	1.1 mg/M ²
Occurrence of any event requiring permanent dose reduction while receiving 1.1 mg/M ²	0.7 mg/M ²
Occurrence of any event requiring permanent dose reduction while receiving 0.7 mg/M ²	Discontinue eribulin

*Toxicities graded in accordance with National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE) version 3.0.

DILUTION

Available in a single-use vial containing 1 mg/2 mL (0.5 mg/mL). Withdraw calculated dose and administer undiluted or may dilute in 100 mL NS.

Filter: Information not available.

Storage: Store unopened vials in carton at CRT. Store undiluted solution drawn up into a syringe for up to 4 hours at RT or 24 hours under refrigeration (4° C [40° F]). Store diluted solution for up to 4 hours at RT or 24 hours under refrigeration (4° C [40° F]). Discard unused portion of vial.

COMPATIBILITY

Manufacturer states, “Do not dilute in or administer through an IV line containing solutions with dextrose. Do not administer in the same intravenous line concurrent with other medicinal products.”

RATE OF ADMINISTRATION

An IV injection evenly distributed over 2 to 5 minutes.

ACTIONS

A synthetic analog of halichondrin B, a product isolated from a marine sponge. Eribulin is a non-taxane microtubule inhibitor. Inhibits the growth phase of microtubules without affecting the shortening phase and sequesters tubulin into nonproductive aggregates. Exerts its effects via a tubulin-based antimetabolic mechanism leading to G₂/M cell-cycle block, disruption of mitotic spindles and, ultimately, apoptotic cell death after prolonged mitotic blockage. Plasma protein binding is 49% to 65%. Mean elimination half-life is approximately 40 hours. There are no major human metabolites. Is eliminated primarily in feces unchanged. Small amount excreted as unchanged drug in urine.

INDICATIONS AND USES

Treatment of patients with metastatic breast cancer who have previously received at least two chemotherapeutic regimens for the treatment of metastatic disease. Prior therapy should have included an anthracycline and a taxane in either the adjuvant or metastatic setting.

CONTRAINDICATIONS

Manufacturer states, "None." ■ Do not administer in patients with an ANC less than 1,000/mm³, platelets less than 75,000/mm³, or Grade 3 or 4 nonhematologic toxicities. ■ Should be avoided in patients with congenital long QT syndrome.

PRECAUTIONS

May cause severe neutropenia (ANC less than 500/mm³) lasting more than 1 week. Higher incidence of Grade 4 neutropenia and febrile neutropenia seen in patients with ALT or AST greater than 3 times the ULN and in patients with a bilirubin greater than 1.5 times the ULN. ■ Grades 3 and 4 peripheral neuropathy have been reported. Peripheral neuropathy was the most common toxicity leading to discontinuation of therapy. Neuropathy may not be reversible. ■ QT prolongation, independent of eribulin concentration, was observed on Day 8 in an uncontrolled, open-label ECG study. ■ Has not been studied in patients with severe hepatic impairment (Child-Pugh Class C) or renal impairment (CrCl less than 30 mL/min). ■ See [Dose Adjustments](#).

Monitor: Obtain baseline CBC with platelets, bilirubin, liver function tests, SCr, and electrolytes. ■ Obtain CBC with platelets before each dose. Increase frequency of hematologic monitoring in patients who develop severe cytopenias (Grade 3 or 4); see [Dose Adjustments](#). ■ Assess for peripheral motor and sensory neuropathy before each dose; see [Dose Adjustments](#). ■ ECG monitoring is recommended in patients with CHF; bradyarrhythmias; drugs that prolong the QT interval, such as Class Ia and III antiarrhythmics (e.g., amiodarone [Nexterone], disopyramide [Norpace], dofetilide [Tikosyn], ibutilide [Corvert], *N*-acetylprocainamide, procainamide [Pronestyl], quinidine, sotalol [Betapace]); and electrolyte abnormalities. Correct hypokalemia or hypomagnesemia before initiating therapy and monitor electrolytes periodically during therapy. ■ Monitor for nausea and vomiting. Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ In patients with thrombocytopenia (platelet count less than 50,000/mm³), initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Avoid pregnancy. Nonhormonal birth control recommended. ■ Promptly report S/S of infection (e.g., fever, chills, cough, burning or pain on urination). ■ Report symptoms of peripheral neuropathy (e.g., numbness, tingling, or burning in hands or feet).

Maternal/Child: Category D: expected to cause fetal harm. ■ Discontinue breastfeeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: No overall differences in safety were observed between older and younger patients. ■ Consider age-related cardiac, hepatic, or renal dysfunction.

DRUG/LAB INTERACTIONS

No drug-drug interactions are expected with CYP3A4 inhibitors, CYP3A4 inducers, or P-glycoprotein (P-gp) inhibitors. No clinically relevant interaction observed with the strong CYP3A4 inhibitor and a P-gp inhibitor, ketoconazole (Nizoral). No clinically relevant interaction observed with the CYP3A4 inducer rifampin (Rifadin). ■ Does not inhibit CYP1A2, CYP2C9, CYP2C19, CYP2D6, CYP2E1, or CYP3A4 enzymes or induce CYP1A2, CYP2C9, CYP2C19, or CYP3A4 enzymes at relevant clinical concentrations and it is not expected to alter the plasma concentrations of drugs that are substrates of these enzymes. ■ A substrate and a weak inhibitor of the drug efflux transporter P-gp *in vitro*.

SIDE EFFECTS

The most common side effects were alopecia, anemia, asthenia, constipation, fatigue, nausea, neutropenia, and peripheral neuropathy. The most common serious side effects were febrile neutropenia and neutropenia. The most common side effect resulting in discontinuation of eribulin was peripheral neuropathy. Less frequently reported side effects included anorexia, arthralgia, cough, diarrhea, dyspnea, fever, headache, liver function test abnormalities, mucosal inflammation, myalgia, pain (back, bone, extremity), UTI, vomiting, and weight loss.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. Neutropenia can be profound. Severe peripheral neuropathies may necessitate discontinuation of eribulin. There is no specific antidote for overdose. Supportive therapy will help sustain the patient in toxicity. Resuscitate if indicated.

ERTAPENEM

(er-tah-PEN-em)

**Antibacterial
(carbapenem)****Invanz****pH 7.5****USUAL DOSE**

Duration of therapy is based on diagnosis as listed in the following chart. May be given IV for up to 14 days or IM for up to 7 days.

Ertapenem Dosing Guidelines			
Infection*	Daily Dose (IV or IM) in Adults and Pediatric Patients 13 Years of Age and Older	Daily Dose (IV or IM) in Pediatric Patients 3 Months to 12 Years of Age	Duration
Complicated intra-abdominal infections	1 Gm	15 mg/kg q 12 hr†	5-14 days
Complicated skin and skin structure infections, including diabetic foot infections‡	1 Gm	15 mg/kg q 12 hr†	7-14 days§
Community-acquired pneumonia	1 Gm	15 mg/kg q 12 hr†	10-14 days
Complicated urinary tract infections, including pyelonephritis	1 Gm	15 mg/kg q 12 hr†	10-14 days
Acute pelvic infections, including postpartum endomyometritis, septic abortion, and post-surgical gynecologic infections.	1 Gm	15 mg/kg q 12 hr†	3-10 days
Prophylaxis of surgical site infection in adults for elective colorectal surgery	1 Gm		Single intravenous dose given 1 hour before surgical incision

*Due to designated pathogens.

†Not to exceed 1 Gm/24 hr.

‡Has not been studied in diabetic foot infections with concomitant osteomyelitis.

§Adult patients with diabetic foot infections received up to 28 days of treatment (parenteral or parenteral plus oral switch therapy).

||Duration includes a possible switch to an appropriate oral therapy, after at least 3 days of parenteral therapy, once clinical improvement has been demonstrated.

DOSE ADJUSTMENTS

Reduce dose to 0.5 Gm (500 mg) daily in adults with a CrCl at or less than 30 mL/min/1.73 M², including adults with end-stage renal insufficiency (CrCl ≤10 mL/min/1.73 M²). No dose adjustment indicated in adults with a CrCl at or more than 31 mL/min/1.73 M². No data are available for pediatric patients with renal insufficiency or pediatric patients on hemodialysis. Give a supplementary dose of 150 mg to a patient who received the daily dose within 6 hours of a dialysis session. ■ No dose adjustment indicated based on age, gender, or impaired hepatic function. ■ Dosing should be cautious in the elderly, and reduced doses may be indicated based on potential for decreased organ function.

DILUTION

Reconstitute each 1 Gm of ertapenem with 10 mL SWFI, NS, BWFI. Shake well to dissolve.

Adults and pediatric patients 13 years of age and older: Further dilute in 50 mL of NS.

Pediatric patients 3 months to 12 years of age: Withdraw the volume equal to the 15 mg/kg dose and dilute in NS to a final concentration of 20 mg/mL or less.

Storage: Store unopened vials at or below 25° C (77° F). Use reconstituted and diluted solution within 6 hours when stored at RT. May refrigerate for up to 24 hours and use within 4 hours after removal. Do not freeze.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Do not mix or co-infuse ertapenem with other medications. Do not use diluents containing dextrose.”

One source suggests the following **compatibilities:**

Y-site: Heparin, hetastarch in NS (Hespan), potassium chloride (KCl), telavancin (Vibativ), tigecycline (Tygacil).

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 minutes.

ACTIONS

A unique, synthetic 1-beta-methyl-carbapenem structurally related to beta-lactam antibiotics. Effective against gram-positive and gram-negative aerobic and anaerobic bacteria. May effectively replace some combination therapies. Does not cover *Pseudomonas* and *Acinetobacter* species. Bactericidal activity results from inhibition of bacterial cell wall synthesis. Stable against hydrolysis by a variety of beta-lactamases, including penicillinases, cephalosporinases, and extended spectrum beta-lactamases. Hydrolyzed by metallo-beta-lactamases. Widely distributed throughout the body into many body tissues and fluids. Highly protein bound. Average half-life is 4 hours. Primarily excreted in urine (some as unchanged drug). Some excretion in feces. May cross the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of adult and pediatric patients with moderate to severe infections caused by susceptible strains of microorganisms in conditions that include complicated intra-abdominal infections; complicated skin and skin structure infections, including diabetic foot infections **without** osteomyelitis; community-acquired pneumonia; complicated urinary tract infections, including pyelonephritis; and acute pelvic infections, including postpartum endomyometritis, septic abortion, and post-surgical gynecologic infections. ■ Prophylaxis of surgical site infections in adults following elective colorectal surgery. ■ Not recommended for use in the treatment of meningitis in pediatric patients (lack of sufficient CSF penetration).

CONTRAINDICATIONS

Known hypersensitivity to any component of ertapenem or other drugs in the same class (e.g., imipenem-cilastatin), or in patients who have had anaphylactic reactions to beta-lactams (e.g., penicillins and cephalosporins); see **Precautions**. ■ The IM preparation is reconstituted with 1% lidocaine and is contraindicated for IV use and in patients with a known hypersensitivity to amide-type local anesthetics.

PRECAUTIONS

Confirm proper formulation for IV use; see **Contraindications**. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ertapenem should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Culture and sensitivity studies indicated to determine susceptibility of the causative organism to ertapenem. ■ Serious and occasionally fatal hypersensitivity reactions have been reported in patients receiving therapy with beta-lactams. More likely in patients with a history of sensitivity to multiple allergens; obtain a careful history and watch for early symptoms of hypersensitivity reactions. Emergency equipment must be readily available; cross-sensitivity is possible. ■ Prolonged use may cause superinfection because of overgrowth of nonsusceptible organisms. ■ CNS stimulation and seizures have been reported. Use with caution in patients with CNS disorders (e.g., brain lesions or history of seizures) and/or compromised renal function. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea

to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ertapenem. ■ See [Monitor](#) and [Drug/Lab Interactions](#).

Monitor: Monitor closely for S/S of hypersensitivity reactions (e.g., difficulty breathing, itching, rash, swelling of eyelids, lips, or face). ■ Obtain baseline CBC with differential and platelets, and baseline kidney and liver studies (e.g., CrCl, serum creatinine, ALT, AST, serum bilirubin). Monitor periodically during prolonged therapy. ■ Monitor patients who are at risk for CNS stimulation or are receiving anticonvulsant therapy. If focal tremors, myoclonus, or seizures occur, neurologic evaluation and dose reduction or discontinuation of ertapenem may be indicated. ■ Monitor IV site carefully and rotate as indicated. ■ See [Precautions](#).

Patient Education: Report promptly: fever, rash, sore throat, unusual bleeding or bruising, severe stomach cramps and/or seizures, and pain or discomfort at the injection site. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Patients with a history of seizures should review medication profile with physician before taking ertapenem; see [Drug/Lab Interactions](#).

Maternal/Child: Category B: use during pregnancy only if clearly needed. ■ Safety for use during breast-feeding not established; is found in breast milk. Benefits must outweigh risks to infant (e.g., diarrhea, candidiasis, or allergic response). Undetectable in breast milk 5 days after ertapenem is discontinued. ■ Following a 1-Gm daily IV dose, plasma concentrations and half-life of ertapenem in pediatric patients 13 to 17 years of age are comparable to those in adults. ■ Compared to plasma clearance in adults, plasma clearance (mL/min/kg) in pediatric patients 3 months to 12 years of age is approximately two-fold higher. 30 mg/kg/24 hr (15 mg/kg every 12 hours) is comparable to a 1-Gm dose daily in adults. Half-life in pediatric patients 3 months to 12 years of age is 2.5 hours compared to 4 hours for adults and pediatric patients 13 years of age or older. ■ Not recommended for use in infants under 3 months; no data available.

Elderly: Dosing should be cautious in the elderly; see [Dose Adjustments](#). ■ Response similar to that seen in younger patients, but may be more sensitive to side effects. ■ Monitoring of renal function may be indicated.

DRUG/LAB INTERACTIONS

Carbapenems may reduce serum **valproic acid** concentrations to subtherapeutic levels, resulting in a loss of seizure control. Monitor valproic acid levels. Consider alternative antibacterial therapy. If administration of ertapenem is necessary, supplemental anticonvulsant therapy should be considered. ■ **Probenicid** reduces the renal clearance of ertapenem. Coadministration is not recommended. ■ Probably does not inhibit the action of **digoxin** or **vinblastine**. ■ Probably does not inhibit metabolism mediated by most of the cytochrome P₄₅₀ isoenzyme system. ■ No other drug interaction studies have been conducted.

SIDE EFFECTS

Adults: CDAD, diarrhea, headache, infusion site reactions, nausea, vaginitis in females, and vomiting were most common and described as mild to moderate. The most commonly reported laboratory abnormalities were elevated ALT, AST, and alkaline phosphatase and increased platelets and eosinophils. Numerous other side effects occurred in fewer than 1% of patients.

Pediatric patients: Side effects similar to adults. CDAD, diarrhea, infusion site pain, erythema, and vomiting were most common.

Major: CDAD, CNS stimulation (e.g., anxiety, confusion, depression, insomnia, nightmares, paranoia, restlessness, seizures, tremor), hypersensitivity reactions (e.g., anaphylaxis, cardiovascular collapse, death, dyspnea, edema [facial, laryngeal, or pharyngeal], hypotension, itching, shock, urticaria), and pseudomembranous colitis.

Post-Marketing: Abnormal coordination, altered mental status (including aggression, delirium, and hallucinations), anaphylaxis, drug rash with eosinophilia and systemic symptoms (DRESS syndrome), dyskinesia, gait disturbance, muscular weakness, myoclonus, tremor.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. Discontinue ertapenem at the first sign of hypersensitivity (e.g., skin rash). Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine [Benadryl]), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Treat CNS symptoms as indicated; may require dose reduction and/or anti-convulsants (e.g., phenytoin [Dilantin], diazepam [Valium]) for seizures. Mild cases of CDAD may respond to discontinuation of the drug. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Ertapenem is partially removed by hemodialysis.

ERYTHROMYCIN LACTOBIONATE

(eh-rih-throw-MY-sin LAK-to-byeh-oh-nayt)

**Antibacterial
(macrolide)****Erythrocin****pH 6.5 to 7.7****USUAL DOSE**

IV formulation used when oral administration is not possible or when the severity of the infection requires immediate high serum levels of erythromycin. Begin oral therapy as soon as practical.

Antibacterial: 15 to 20 mg/kg of body weight/24 hr in equally divided doses every 6 hours (3.75 to 5 mg/kg every 6 hours). Range is 350 to 500 mg every 6 hours. Continuous infusion over 24 hours is preferred. Up to 4 Gm/24 hr has been given for severe infections. See [Elderly](#).

Legionnaires' disease: 1 to 4 Gm/day in divided doses (250 mg to 1 Gm every 6 hours). Optimum doses not established.

Pelvic inflammatory disease: 500 mg every 6 hours for 3 days. Follow with oral erythromycin 250 mg every 6 hours for 7 days.

Diabetic gastroparesis (unlabeled): 200 mg immediately before each meal. When practical, continue treatment with oral erythromycin 3 times daily, 30 minutes before meals, for 4 weeks.

PEDIATRIC DOSE

15 to 20 mg/kg of body weight/24 hr in equally divided doses every 6 hours is recommended (3.75 to 5 mg/kg every 6 hours). Another source recommends 20 to 50 mg/kg/24 hr in equally divided doses every 6 hours (5 to 12.5 mg/kg every 6 hours). See [Maternal/Child](#).

DOSE ADJUSTMENTS

Reduced dose may be required in impaired liver function.

DILUTION

Each 500 mg or fraction thereof must be reconstituted with 10 mL of SWFI without preservatives to avoid precipitation. Forms a 5% solution. Shake well to ensure dilution. May be further diluted with NS, Normosol, or LR. If a dextrose solution is used, add sodium bicarbonate (Neut) 1 mL for each 100 mL of solution.

Continuous infusion (preferred): Further dilute to a 1 mg/mL solution (e.g., each 1 Gm in 1,000 mL of NS, Normosol, or LR).

Intermittent infusion: Dilute to a final concentration of 1 to 5 mg/mL. No less than 100 mL of IV diluent should be used (1 Gm in 1,000 mL equals 1 mg/mL; 1 Gm in 200 mL equals 5 mg/mL). Available in ADD-Vantage vials for use with ADD-Vantage infusion containers.

Storage: Store unopened vials at CRT. Solutions diluted from *lyophilized powder vials* are stable for 8 hours at CRT. **ADD-Vantage vials:** Solutions diluted in NS must be completely administered within 8 hours; solutions diluted in D5W must be completely administered within 2 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities:**

Additive: Aminophylline, ampicillin, ascorbic acid, diphenhydramine (Benadryl), hydrocortisone sodium succinate (Solu-Cortef), lidocaine, penicillin G potassium and sodium, pentobarbital (Nembutal), potassium chloride (KCl), prochlorperazine (Compazine), ranitidine (Zantac), sodium bicarbonate, verapamil.

Y-site: Acyclovir (Zovirax), amiodarone (Nexterone), anidulafungin (Eraxis), bivalirudin (Angiomax), cyclophosphamide (Cytoxan), dexmedetomidine (Precedex), diltiazem (Cardizem), doxapram (Dopram), enalaprilat (Vasotec IV), esmolol (Brevibloc), famotidine (Pepcid IV), fenoldopam (Corlopam), foscarnet (Foscavir), heparin, hetastarch in electrolytes (Hextend), hydromorphone (Dilaudid), idarubicin (Idamycin), labetalol, lorazepam (Ativan), magnesium sulfate, meperidine (Demerol), midazolam (Versed), morphine, multivitamins (M.V.I.), nifedipine (Cardene IV), tacrolimus (Prograf), theophylline, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Administer with a volume control set. A slow infusion rate is recommended to reduce pain along the injection site.

Continuous infusion (preferred): A 0.1% to 0.2% solution equally distributed over 6 to 24 hours.

Intermittent infusion: 1 Gm or fraction thereof in at least 100 mL over 20 to 60 minutes.

Diabetic gastroparesis (unlabeled): 1 to 3 mg/kg/hr, usually approximately over 15 minutes.

ACTIONS

Macrolide antibiotic, bactericidal and bacteriostatic. Effective against a number of gram-positive and some gram-negative organisms as well as *Mycoplasma pneumoniae*. Inhibits protein synthesis by binding to ribosomal subunits of susceptible organisms. Diffuses readily into most bodily fluids. Metabolized by the liver and excreted in urine and bile. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of mild to moderate infections of the upper and lower respiratory tract, skin and skin structures, and gynecologic infections caused by susceptible organisms. ■ Alternative treatment in several sexually transmitted diseases in females with a history of penicillin sensitivity. ■ Legionnaires' disease. ■ Additional indications listed for oral formulation.

Unlabeled uses: Diabetic gastroparesis.

CONTRAINDICATIONS

Known erythromycin sensitivity. See [Drug/Lab Interactions](#). ■ Coadministration with ritonavir (Norvir) and cisapride is contraindicated. Contraindicated with astemizole and terfenadine (both have been removed from the market).

PRECAUTIONS

IV formulation used when oral administration is not possible or when the severity of the infection requires immediate high serum levels of erythromycin. Switch to oral therapy when appropriate. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to erythromycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, erythromycin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ Use caution in impaired liver function. ■ Hepatic dysfunction, with or without jaundice, has been reported in patients taking oral erythromycin. ■ Use caution in patients with a history of cardiac disease (may induce torsades de pointes). ■ Use caution in patients with myasthenia gravis;

weakness may be aggravated. ■ *Clostridium difficile*-associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with erythromycin.

Monitor: Monitor vital signs. ■ Monitor IV site for redness and inflammation. ■ See [Drug/Lab Interactions](#).

Patient Education: Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child: Category B: use only if clearly needed. ■ Considered safe for use in breast-feeding; use caution. ■ Some products contain benzyl alcohol; not recommended for use in neonates.

Elderly: When doses of 4 Gm/day or higher are used, the risk of developing erythromycin-induced hearing loss is increased in elderly patients, particularly those with impaired renal or hepatic function. ■ May be more susceptible to development of torsades de pointes. ■ May experience increased effects of oral anticoagulation; see [Drug/Lab Interactions](#).

DRUG/LAB INTERACTIONS

Contraindicated with **ritonavir**. ■ Antibacterial activity is antagonized by coadministration of **clindamycin**, **lincomycin**, and **chloramphenicol**. ■ May inhibit **penicillins**. ■ Will increase serum levels and potentiate the effects of **alfentanil**, **anticoagulants** (e.g., warfarin [Coumadin]), **astemizole** (see [Contraindications](#)), **bromocriptine** (Parlodel), **carbamazepine** (Tegretol), **cisapride** (Propulsid), **cyclosporine** (Sandimmune), **digoxin**, **disopyramide** (Norpace), **ergot alkaloids** (e.g., Hydergine), **lovastatin** (Mevacor), **methylprednisolone**, **midazolam** (Versed), **phenytoin** (Dilantin), **terfenadine** (see [Contraindications](#)), **theophyllines**, **triazolam** (Halcion), and **valproate**; serious toxicity may result. ■ Concomitant administration with **cisapride** is contraindicated. May cause serious cardiotoxicity. ■ Plasma concentrations of erythromycin may be increased by **antifungal agents** metabolized by CYP3A4 isoenzymes (e.g., fluconazole [Diflucan], ketoconazole [Nizoral], itraconazole [Sporanox]). May result in an increase in QT prolongation and ventricular arrhythmias. ■ Severe **vinblastine** toxicity has been reported in conjunction with erythromycin. ■ May increase serum levels of **sildenafil** (Viagra). ■ Coadministration with **HMG-CoA reductase inhibitors** (e.g., simvastatin [Zocor]) results in increased serum levels of the antihyperlipidemic agent and increases the risk of severe myopathy and rhabdomyolysis. ■ Concurrent use with **theophylline** (aminophylline) may decrease plasma levels of erythromycin. ■ Serotonin syndrome has been reported with coadministration of erythromycin and **serotonin-uptake inhibitors** (e.g., sertraline [Zoloft], fluoxetine [Prozac]). ■ May interfere with fluorometric determination of **urinary catecholamines**.

SIDE EFFECTS

Relatively free from side effects when given as directed. Nausea and vomiting, urticaria, and mild local venous discomfort. Increased incidence of usually reversible ototoxicity with larger doses. CDAD has been reported. Torsades de pointes has been reported; see [Elderly](#). Anaphylaxis may occur.

ANTIDOTE

Notify the physician of early or mild symptoms. For severe symptoms, discontinue the drug, treat hypersensitivity reactions, or resuscitate as necessary and notify physician. Treat CDAD with fluids, electrolytes, protein supplements, and oral vancomycin (Vancocin) or metronidazole (Flagyl) as indicated. In severe cases, surgical evaluation may be indicated. Not removed by peritoneal dialysis or hemodialysis.

ESMOLOL HYDROCHLORIDE

(EZ-moh-lohl hy-droh-KLOR-eyed)

Beta-adrenergic blocking agent

Antiarrhythmic

Brevibloc

pH 4.5 to 5.5

USUAL DOSE

Supraventricular tachycardia (SVT) or noncompensatory sinus tachycardia: Administer by continuous IV infusion with or without a loading dose. Additional loading doses and/or titration of the maintenance infusion (stepwise dosing) may be necessary based on desired ventricular response.

Esmolol Stepwise Dosing for Supraventricular Tachycardia or Noncompensatory Sinus Tachycardia

Step	Action
1	Optional loading dose (500 mcg/kg over 1 minute), then 50 mcg/kg/min for 4 min
2	Optional loading dose if necessary, then 100 mcg/kg/min for 4 min
3	Optional loading dose if necessary, then 150 mcg/kg/min for 4 min
4	If necessary, increase dose to 200 mcg/kg/min

In the absence of loading doses, continuous infusion of a single concentration of esmolol reaches a pharmacokinetic and pharmacodynamic steady-state in about 30 minutes. Effective maintenance dose for continuous and stepwise dosing is 50 to 200 mcg/kg/min, although doses as low as 25 mcg/kg/min have been adequate. Doses greater than 200 mcg/kg/min provide little additional lowering of heart rate, and the rate of adverse reactions increases. Maintenance infusions may be continued for up to 48 hours. See [Precautions/Monitor](#).

Intraoperative and postoperative tachycardia and/or hypertension: Immediate control: 1 mg/kg over 30 seconds. Follow with an infusion of 150 mcg/kg/min (0.15 mg/kg/min) if necessary. Adjust as required to maintain desired HR and/or BP.

Gradual control: Use procedure listed for SVT.

Immediate and gradual control: Higher doses (250 to 300 mcg/kg/min [0.25 to 0.3 mg/kg/min]) may be required to control hypertension. Maintenance infusion doses greater than 200 mcg/kg/min are not recommended for the treatment of tachycardia. They provide little additional lowering of heart rate, and the rate of adverse reactions increases.

Transition to alternative drugs: After control of HR and BP is achieved and clinical status is stable,

1. Administer the first dose of the alternative drug. In 30 minutes, reduce the esmolol infusion rate by one half (50%).
2. After administration of the second dose of the alternative drug, monitor patient response carefully. If control is satisfactory and is maintained for 1 hour, discontinue the esmolol infusion.

PEDIATRIC DOSE

See [Maternal/Child](#).

Antiarrhythmic (unlabeled): Pediatric patients 1 to 12 years of age: A loading dose of 100 to 500 mcg/kg (0.1 to 0.5 mg/kg) administered over 1 minute. Follow with a maintenance infusion of 25 to 100 mcg/kg/min (0.025 to 0.1 mg/kg/min). Titrate doses upward to response by 50 to 100 mcg/kg/min (0.05 to 0.10 mg/kg/min) at 5- to 10-minute intervals as needed. Dose requirements may be higher than in adults. Doses as high as 1,000 mcg/kg/min have been administered to pediatric patients 1 to 12 years of age.

Antihypertensive (postoperative [unlabeled]): Pediatric patients 1 to 12 years of age: A loading dose of 500 mcg/kg (0.5 mg/kg) administered over 1 minute. Follow with a maintenance infusion of 50 to 250 mcg/kg/min (0.05 to 0.25 mg/kg/min). Titrate doses upward 50 to 100 mcg/kg/min (0.05 to 0.1 mg/kg/min) as needed. Titrate to individual desired response. Dose requirements may be higher than in adults. Doses as high as 1,000 mcg/kg/min have been administered to pediatric patients 1 to 12 years of age.

DOSE ADJUSTMENTS

Reduced dose may be required in impaired renal function. No dose adjustment required if the maintenance infusion does not exceed 150 mcg/kg/min for more than 4 hours; no data available for higher doses or longer duration. ■ No dose adjustment indicated in impaired hepatic function. ■ Reduction required with transfer to alternate agent; see Monitor. ■ See Drug/Lab Interactions.

DILUTION

Available premixed as 10 mg/mL in 250 mL NS or as 20 mg/mL in 100 mL NS (double strength). Single-dose vials are available as 100 mg/10 mL and may be given by IV injection without further dilution or may be further diluted in D5W, D5R, D5LR, D5NS, D5½NS, NS, LR, ½NS, or D5W with KCl 40 mEq/L. Premixed solutions have a delivery port and a medication port (for withdrawing the initial bolus only). Ready-to-use vials may be used to administer initial and subsequent boluses.

Storage: Store vials and premix at CRT; protect from freezing and avoid excessive heat. Diluted solution stable at room temperature for 24 hours. If a bolus has been removed from the premixed bag, the bag should be used within 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with sodium bicarbonate and furosemide and states, "Do not add any additional medications to the bag" (premixed injection).

One source suggests the following **compatibilities**:

Additive: *Not recommended by manufacturer.* Aminophylline, atracurium (Tracrium), heparin.

Y-site: Amikacin (Amikin), aminophylline, amiodarone (Nexterone), ampicillin, atracurium (Tracrium), bivalirudin (Angiomax), butorphanol (Stadol), calcium chloride, ceftazolin (Ancef), ceftazidime (Fortaz), chloramphenicol (Chloromycetin), cisatracurium (Nimbex), clindamycin (Cleocin), dexmedetomidine (Precedex), diltiazem (Cardizem), dopamine, doripenem (Doribax), enalaprilat (Vasotec IV), erythromycin (Erythrocin), famotidine (Pepcid IV), fenoldopam (Corlopam), fentanyl (Sublimaze), gentamicin, heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), 6% hydroxyethyl starch (Voluven), insulin (regular), labetalol, linezolid (Zyvox), magnesium sulfate, methylglucoside, metronidazole (Flagyl IV), miconazole (Mycamine), midazolam (Versed), morphine, nafcillin (Nallpen), nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), pancuronium, penicillin G potassium, phenytoin (Dilantin), potassium chloride (KCl), potassium phosphates, propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sodium acetate, streptomycin, sulfamethoxazole/trimethoprim, tacrolimus (Prograf), tobramycin, vancomycin, vecuronium.

RATE OF ADMINISTRATION

IV injection: See Usual Dose.

Infusion: Titrate infusion according to procedure outlined in Usual Dose.

ACTIONS

A short-acting, B₁-selective adrenergic blocking agent with antiarrhythmic effects. Decreases HR and BP in a dose-related titratable manner. Hemodynamically similar to propranolol, but vascular resistance is not increased. Onset of action occurs within 1 to 2 minutes. Half-life is approximately 9 minutes, and the effects last about 20 to 30 minutes. Metabolized via esterases in RBCs and excreted in urine.

INDICATIONS AND USES

Management of supraventricular tachycardia (atrial fibrillation or atrial flutter) in situations requiring short-term control of ventricular rate with a short-acting agent (perioperative, postoperative, or other emergent circumstances). ■ Management of noncompensatory tachycardia when HR requires specific intervention. ■ Management of intraoperative and postoperative tachycardia and/or hypertension.

Limitation of use: Intended only for short-term use.

CONTRAINDICATIONS

Cardiogenic shock. ■ Decompensated heart failure. ■ Heart block greater than first degree. ■ Hypersensitivity reactions, including anaphylaxis, to esmolol or any of its inactive ingredients (cross-sensitivity between beta-blockers is possible). ■ IV administration of cardiodepressant calcium-channel antagonists (e.g., verapamil) and esmolol in close proximity (i.e., while the cardiac effects of the other drug are still present). ■ Pulmonary hypertension. ■ Severe sinus bradycardia. ■ Sick sinus syndrome.

PRECAUTIONS

For IV use only. ■ May cause hypotension at any dose but is dose related; risk is increased in patients with hemodynamic compromise, in patients receiving interacting medications, and with doses above 200 mcg/kg/min. Severe reactions may include loss of consciousness, cardiac arrest, and death. ■ Use caution in patients with first-degree AV block, sinus node dysfunction, or conduction disorders. May be at increased risk for bradycardia. Sinus pause, heart block, severe bradycardia, and cardiac arrest have occurred. ■ May further depress cardiac contractility and precipitate heart failure and cardiogenic shock. ■ Use caution in patients whose BP is primarily driven by vasoconstriction associated with hypothermia (e.g., intraoperative and postoperative tachycardia and hypertension). ■ Use with extreme caution in patients with reactive airway disease (e.g., asthma), diabetes mellitus and/or hypoglycemia, Prinzmetal's angina, pheochromocytoma, hypovolemia, peripheral circulatory disorders (Raynaud's disease, peripheral occlusive vascular disease), coronary artery disease, impaired renal function, metabolic acidosis, and hyperthyroidism. ■ In general, patients with reactive airway disease (e.g., asthma) should not receive beta-blockers. Titrate to the lowest possible effective dose. ■ In patients with hypoglycemia or diabetes who are receiving insulin or hypoglycemic agents, beta-blockers may mask tachycardia of hypoglycemia, but other manifestations of hypoglycemia such as dizziness and sweating may still be observed. ■ May exacerbate angina attacks in patients with Prinzmetal's angina; do not use nonselective beta-blockers (e.g., propranolol). ■ A paradoxical increase in BP may occur if beta-blockers are administered to patients with pheochromocytoma. If use is necessary, administer an alpha-blocker (e.g., phentolamine) before the beta-blocker. ■ Can worsen reflex tachycardia and increase the risk of hypotension in hypovolemic patients. ■ May increase serum potassium levels, causing hyperkalemia. Risk is increased in patients with renal impairment and is potentially life threatening in hemodialysis patients. ■ Use caution in patients with metabolic acidosis; hyperkalemic renal tubular acidosis has been reported. ■ Beta-adrenergic blockade may mask the clinical signs of hyperthyroidism (e.g., tachycardia). Abrupt withdrawal may precipitate thyroid storm. ■ Patients at risk for hypersensitivity reactions may be more reactive to allergen exposure when receiving beta-blockers and may be unresponsive to the usual doses of epinephrine used to treat anaphylactic or anaphylactoid reactions; see [Drug/Lab Interactions](#). ■ Infusion site reactions, including irritation, inflammation, and severe reactions (e.g., thrombophlebitis, necrosis, and blistering) have occurred; avoid infusion into small veins or through a butterfly catheter. ■ Although it has not been a problem with esmolol, it is recommended that the dose of beta-adrenergic blockers be reduced gradually to avoid rebound angina, MI, or ventricular arrhythmias. Use caution, especially in patients with coronary artery disease. ■ Intended for short-term use only. Transfer to an alternative antiarrhythmic agent (e.g., digoxin [Lanoxin], verapamil) is required after stable clinical status and HR control are obtained; see [Usual Dose](#). ■ See [Drug/Lab Interactions](#), [Monitor](#), and [Antidote](#).

Monitor: Continuous observation of the patient and ECG and BP monitoring are mandatory during administration. Hypotension should reverse within 30 minutes after decreasing the infusion rate or discontinuing the drug. ■ Well tolerated if administered through a central vein. Monitor for infusion site reaction and prevent extravasation. Restart at an alternate infusion site. ■ Titrate BP slowly in patients whose BP is primarily driven by vasoconstriction associated with hypothermia (e.g., intraoperative and postoperative tachycardia and hypertension). ■ May mask symptoms of hypoglycemia; monitor blood glucose in patients with diabetes. ■ Monitor electrolytes as indicated. Monitor patients with increased risk factors very closely; see [Precautions](#). ■ See [Drug/Lab Interactions](#) and [Contraindications](#).

Maternal/Child: Category C: safety for use in pregnancy not established. Use only when clearly indicated. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Numbers in clinical studies are insufficient to determine if the elderly respond differently from younger subjects. Consider age-related organ impairment (e.g., bone marrow reserve, renal, hepatic); monitor and reduce dose if indicated.

DRUG/LAB INTERACTIONS

The effects of esmolol on BP, contractility, and impulse propagation can be increased with concomitant use of other drugs that can lower BP, reduce myocardial contractility, or interfere with sinus node function or electrical impulse propagation in the myocardium. May result in severe hypotension, cardiac failure, severe bradycardia, sinus pause, sinoatrial block, atrioventricular block, and/or cardiac arrest. ■ **Sympathomimetic drugs having beta-adrenergic agonist activity** (e.g., epinephrine [Adrenalin], norepinephrine [Levophed]) will counteract the effects of esmolol. ■ Use with **calcium channel blockers** (e.g., verapamil) may potentiate both drugs and result in severe depression of myocardium and AV conduction, severe hypotension, and fatal cardiac arrest. ■ Increases **digoxin** blood levels, synergistic with digoxin; both drugs slow AV conduction. Concomitant use increases the risk of bradycardia. ■ Esmolol should not be used in patients receiving **vasoconstrictive or inotropic drugs** (e.g., norepinephrine [Levophed], digoxin) because of the potential for reduced cardiac contractility when the systemic vascular resistance is high. ■ Concomitant use with certain **antihypertensive agents** (e.g., clonidine [Catapres], guanfacine [Intuniv]) may precipitate increased withdrawal effects (withdrawal rebound hypertension). If antihypertensive therapy is to be interrupted or discontinued, discontinue the beta-blocker first and then gradually discontinue the antihypertensive agent. ■ Concomitant use with **catecholamine-depleting drugs** (e.g., reserpine) may produce additive effects. Monitor for hypotension and bradycardia. ■ May prolong neuromuscular blockade produced by **succinylcholine** and moderately prolong neuromuscular blockade produced by **mivacurium** (Mivacron). ■ May mask S/S of developing hypoglycemia in patients on **insulin or oral antidiabetic agents**. ■ Concurrent use with **xanthines** (e.g., aminophylline, theophyllines) may result in mutual inhibition of therapeutic effects. ■ Patients taking **beta-blockers** who are exposed to a potential allergen may be unresponsive to the usual dose of epinephrine used to treat a hypersensitivity reaction.

SIDE EFFECTS

Symptomatic hypotension (dizziness, excessive sweating) and asymptomatic hypotension are most common. Inflammation or induration of the infusion site, nausea, and somnolence are also fairly common. Abdominal discomfort, abnormal thinking, agitation, anxiety, confusional state, constipation, convulsions (with one death), depression, dry mouth, dyspepsia, flushing, headache, light-headedness, pallor, paresthesia, peripheral ischemia, speech disorders, and urinary retention have occurred.

Overdose: Cardiac effects (e.g., atrioventricular block [first-, second-, third-degree], bradycardia, cardiac failure [including cardiogenic shock], decreased cardiac contractility, hypotension, intraventricular conduction delays, junctional rhythms, cardiac arrest/asystole, and pulseless electrical activity); CNS effects (e.g., fatigue, lethargy, respiratory depression, seizures, sleep and mood disturbances, and coma). In addition, broncho-

spasm, hypoglycemia (especially in children), hyperkalemia, mesenteric ischemia, and peripheral cyanosis may occur.

Post-Marketing: Angioedema, cardiac arrest, coronary arteriospasm, psoriasis, urticaria.

ANTIDOTE

Notify the physician of all side effects. Decrease rate or discontinue drug if hypotension occurs. Hypotension should reverse within 30 minutes. Trendelenburg position may be appropriate. May require treatment with IV fluids or vasopressors (e.g., dopamine, nor-epinephrine [Levophed]), but protracted severe hypotension may result. Unresponsive hypotension and bradycardia may be reversed by glucagon 5 to 10 mg over 30 seconds followed by a continuous infusion of 5 mg/hr. Reduce rate as condition improves. Decrease rate of or discontinue esmolol if severe bradycardia develops. Treat with an anticholinergic drug (e.g., atropine) or cardiac pacing. Discontinue esmolol at the first S/S of cardiac failure and start supportive treatment (e.g., digoxin and diuretics). In shock resulting from inadequate cardiac contractility, consider IV dobutamine or dopamine. Glucagon may be useful. Discontinue the infusion if bronchospasm occurs. Administer a beta₂-stimulating agent (e.g., epinephrine, albuterol) and/or a theophylline derivative and monitor ventricular rate. Treat other side effects symptomatically and resuscitate as necessary.

ESOMEPRAZOLE SODIUM

(es-oh-MEP-rah-zohl SO-dee-um)

Proton pump inhibitor
(gastric acid inhibitor)

Nexium IV

pH 9 to 11

USUAL DOSE

Given as an alternative to oral therapy. Resume oral therapy as soon as practical. Safety and efficacy of IV use for more than 10 days not established. Dose and serum levels similar by IV or oral route.

Adults: 20 or 40 mg as an IV injection or infusion once daily for up to 10 days.

PEDIATRIC DOSE

Administered as an infusion over 10 to 30 minutes. See comments under **Usual Dose**.

1 to 17 years of age: Weight less than 55 kg: 10 mg. **Weight 55 kg or more:** 20 mg.

1 month to less than 1 year of age: 0.5 mg/kg.

DOSE ADJUSTMENTS

No dose adjustment is required based on age or gender, in the elderly, in patients with renal insufficiency, or in patients with mild to moderate liver impairment (Child-Pugh classes A and B). ■ Do not exceed a dose of 20 mg in patients with severe liver impairment (Child-Pugh class C [10 or over]).

DILUTION

Injection (adults): Each 20- or 40-mg dose must be reconstituted with 5 mL of NS. A single dose equals 5 mL. Mix gently until powder is dissolved.

Infusion (adults): Each 20- or 40-mg dose must be reconstituted with 5 mL of NS, LR, or D5W. A single dose equals 5 mL. Further dilute for infusion with NS, LR, or D5W to a final volume of 50 mL.

Infusion (pediatric patients 1 month to less than 1 year of age): Reconstitute a 20- or 40-mg vial with 5 mL of NS. Further dilute to a final volume of 50 mL with NS. Concentration of 20-mg vial equals 0.4 mg/mL; concentration of 40-mg vial equals 0.8 mg/mL. Withdraw desired dose (0.5 mg/kg) to administer as an infusion.

Infusion (pediatric patients 1 to 17 years of age): Reconstitute and further dilute as above. **40-mg vial:** Concentration is 0.8 mg/mL. For a 20-mg dose, withdraw 25 mL (for a 10-mg dose, withdraw 12.5 mL). **20-mg vial:** Concentration is 0.4 mg/mL. For a 20-mg dose,

administer 50 mL as an infusion. For a 10-mg dose, withdraw 25 mL and administer as an infusion.

Filters: Not required or recommended; no additional data available from manufacturer.

Storage: Before use, store in carton at CRT and protect from light. Reconstituted and diluted solutions may be stored at CRT. Administer reconstituted solutions within 12 hours of reconstitution. Administer diluted solutions within 6 hours if diluted in D5W and within 12 hours if diluted in NS or LR. Discard any unused solution.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, “Should not be administered concomitantly with any other medications through the same IV site and/or tubing.” Flush the IV line with a **compatible** IV solution (NS, LR, or D5W) before and after administration of esomeprazole.

One source suggests the following **compatibilities (not recommended by manufacturer):**
Y-site: Ceftaroline (Teflaro), doripenem (Doribax).

RATE OF ADMINISTRATION

Flush the IV line with a **compatible** IV solution (NS, LR, or D5W) before and after administration of esomeprazole.

Injection (adults): A single 20- or 40-mg dose evenly distributed over no less than 3 minutes.

Infusion (adults and pediatric patients): A single dose properly diluted as an infusion and evenly distributed over 10 to 30 minutes.

ACTIONS

A proton pump inhibitor. It suppresses gastric acid secretion by specific inhibition of the H^+/K^+ -ATPase in the gastric parietal cell. It blocks the final step in acid production, thus reducing gastric acidity. Effect is dose-related. Highly bound by serum protein. Extensively metabolized in the liver by the cytochrome P_{450} isoenzyme system (CYP2C19 and CYP3A4 isozymes). Half-life is 1.1 to 1.4 hours and is prolonged with increasing doses. Primarily excreted as metabolites in urine with some excretion in feces. Secreted in breast milk.

INDICATIONS AND USES

Short-term treatment of GERD with erosive esophagitis in adults and pediatric patients 1 month to 17 years of age. Used as an alternative to oral therapy when oral esomeprazole is not possible or appropriate.

CONTRAINDICATIONS

Known hypersensitivity to esomeprazole or its components (edetate disodium, sodium hydroxide) or to substituted benzimidazoles (e.g., lansoprazole [Prevacid], pantoprazole [Protonix]); angioedema and anaphylaxis have occurred.

PRECAUTIONS

For IV use only; do not give IM or SC. ■ Gastric malignancy may be present even though patient’s symptoms improve. ■ Discontinue as soon as the patient is able to resume oral therapy. ■ Atrophic gastritis has been reported with long-term treatment of omeprazole, an enantiomer (a compound with a mirror image molecular structure) of esomeprazole. ■ Decreased gastric acidity may increase bacterial count in GI tract. Risk of GI infections (e.g., *Salmonella* and *Campylobacter* and, in hospitalized patients, *Clostridium difficile*) may be slightly increased. ■ May be associated with an increased risk for osteoporosis-related fractures of the hip, wrist, or spine. Risk increased in patients receiving high-dose (multiple daily doses) and long-term therapy (a year or longer). Use lowest dose and shortest duration of therapy appropriate for the condition being treated. ■ Hypomagnesemia, both symptomatic and asymptomatic, has been reported rarely (usually with the use of PPIs for 3 months to more than a year). Arrhythmias, seizures, and tetany have occurred. Magnesium replacement and discontinuation of esomeprazole may be required. ■ May be associated with an increased risk of *Clostridium difficile*-associated diarrhea (CDAD). Consider in patients who develop diarrhea that does not improve. ■ See [Drug/Lab Interactions](#).

Monitor: Observe for S/S of allergic reaction; anaphylaxis has been reported in post-marketing reports. ■ Monitor vital signs, pain levels, and injection site. ■ Consider obtaining baseline and periodic magnesium levels if prolonged therapy is indicated or in patients taking digoxin or medications that may cause hypomagnesemia (e.g., diuretics).

Patient Education: Review prescription and non-prescription drugs with physician. ■ Oral route preferred. ■ Promptly report cardiovascular or neurologic symptoms, including dizziness, palpitations, seizures, or tetany; may be signs of hypomagnesemia.

Maternal/Child: Category B: use during pregnancy only if clearly needed. Congenital abnormalities in infants born to women who received omeprazole during pregnancy have been reported sporadically. ■ If the drug is indicated for the mother, breast-feeding should be discontinued. May have serious reactions in the infant and has a potential for tumorigenicity. ■ Safety and effectiveness for use of IV formulation in pediatric patients established for ages 1 month to 17 years.

Elderly: Safety and effectiveness similar to that seen in younger adults. ■ Consider potential for impaired liver function; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Extensively metabolized by CYP2C19 and CYP3A4. ■ Because of profound and long-lasting inhibition of gastric acid secretion, esomeprazole may interfere with the absorption of drugs in which gastric pH is an important determinant of their bioavailability. Absorption of **atazanavir** (Reyataz), **erlotinib** (Tarceva), **iron salts** (ferrous sulfate), and **ketoconazole** (Nizoral) can decrease; other drugs (e.g., digoxin [Lanoxin]) can increase. ■ Increases in INR and PT have been reported when administered concurrently with **warfarin**; monitoring of INR and PT indicated. ■ Concurrent use with **selected protease inhibitors** such as atazanavir (Reyataz) and nelfinavir (Viracept) is not recommended. Coadministration of proton pump inhibitors (e.g., esomeprazole [Nexium], pantoprazole [Protonix]) results in a significant reduction in plasma concentrations of atazanavir and nelfinavir, thus inhibiting their therapeutic effect. In contrast, elevated plasma concentrations have been reported with **other protease inhibitors** (e.g., saquinavir [Invirase]); monitoring of serum levels is recommended to avoid toxicity of the antiviral agent, and dose reduction should be considered. Unchanged serum levels have been reported with some other antiretroviral drugs. ■ The metabolism of **diazepam** (Valium) may be decreased and serum levels increased by esomeprazole; not considered clinically significant. ■ Administration with a **combined inhibitor of CYP2C19 and CYP3A4** (e.g., voriconazole [VFEND]) may more than double the exposure (concentration) of esomeprazole. With recommended doses of esomeprazole, a dose adjustment is not normally required; however, it may be indicated in patients who require higher doses. ■ Concurrent administration of **oral contraceptives, diazepam, phenytoin, or quinidine** did not change the pharmacokinetic profile of esomeprazole. ■ Drugs that **induce CYP2C19 or CYP3A4** (e.g., rifampin [Rifadin], St. John's wort) can substantially decrease esomeprazole concentrations. Avoid concomitant use. ■ Concomitant administration of esomeprazole and **tacrolimus** may increase serum levels of tacrolimus. ■ Concurrent administration with **naproxen** (Aleve) did not appear to alter pharmacokinetics in either drug. ■ Studies suggest no clinically significant interactions with other drugs metabolized by the cytochrome P₄₅₀ system (e.g., amoxicillin, clarithromycin [Biaxin], phenytoin [Dilantin], quinidine). ■ Avoid concurrent use with **clopidogrel** (Plavix); esomeprazole may interfere with the conversion of clopidogrel into its active form and decrease its effectiveness. ■ Coadministration with **cilostazol** (Pletal) may increase concentrations of cilostazol and its metabolite. Consider a dose reduction of cilostazol from 100 mg to 50 mg twice daily. ■ Concomitant use of proton pump inhibitors with high-dose **methotrexate** may elevate and prolong serum levels of methotrexate and/or its metabolite. May lead to methotrexate toxicity; consider withdrawal of esomeprazole. ■ Serum chromogranin A (CgA) levels increase secondary to drug-induced decreases in gastric acidity. Increased CgA levels may cause a false-positive result in diagnostic tests for neuroendocrine tumors. Temporarily discontinue esomeprazole before assessing CgA levels, and consider repeating the test if the initial CgA level is high.

SIDE EFFECTS

Generally well tolerated. Most commonly reported side effects include abdominal pain, constipation, diarrhea, dizziness, dry mouth, flatulence, headache, injection site pain or reaction, nausea, and pruritus. Numerous other side effects may occur in fewer than 1% of patients.

Post-Marketing: Agranulocytosis, alopecia, anaphylaxis (rare), blurred vision, bone fracture, CDAD, depression, hypomagnesemia, microscopic colitis, myalgia, pancreatitis, pancytopenia, hepatitis with or without jaundice (rare), serious dermatologic reactions (including erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis [some fatal]), and shock.

Overdose: Ataxia, changes in respiratory frequency, decreased motor activity, intermittent clonic convulsions. Consider possibility of multiple drug ingestion.

ANTIDOTE

Keep physician informed of all side effects. May be treated symptomatically. If hypomagnesemia develops, magnesium replacement and discontinuation of esomeprazole may be required. Discontinue and initiate appropriate treatment if S/S associated with post-marketing reports or overdose occur; see [Side Effects](#). Not removed by hemodialysis.

ETOMIDATE

(eh-TOM-ih-dayt)

Anesthetic, general
Anesthesia adjunct

Amidate**USUAL DOSE**

Rapid sequence intubation and/or induction of anesthesia: Dose must be individualized. 0.3 mg/kg IV (range: 0.2 to 0.6 mg/kg). Titrate to effect. Smaller, incremental doses may be administered to adult patients during short operative procedures to supplement subpotent anesthetic agents, such as nitrous oxide.

Anesthesia induction for short outpatient or ER procedures (unlabeled): 0.1 mg/kg has been used effectively. If analgesia is required, concurrent administration of fentanyl (Sublimaze) may be used.

PEDIATRIC DOSE

Rapid sequence intubation and/or induction of anesthesia: *Pediatric patients up to 10 years of age:* Safety and effectiveness have not been established.

Pediatric patients 10 years of age and older: See [Usual Dose](#).

Anesthesia induction for short outpatient or emergency department procedures (unlabeled): 0.1 mg/kg. 0.2 mg/kg has been used in pediatric patients for fractures or major joint reduction. If analgesia is required, concurrent administration of fentanyl (Sublimaze) may be used.

DOSE ADJUSTMENTS

Dose must be individualized for each patient. ■ Caution and lower-end dosing suggested in the elderly; consider decreased organ function and concomitant disease or drug therapy. ■ See [Drug/Lab Interactions](#).

DILUTION

May be given undiluted. Solution must be clear.

Filters: No data available from manufacturer.

Storage: Store at CRT. Discard unused portion.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Alfentanil (Alfenta), atracurium (Tracrium), atropine, dexmedetomidine (Precedex), ephedrine, fentanyl (Sublimaze), lidocaine, lorazepam (Ativan), midazolam (Versed), morphine, pancuronium, phenylephrine (Neo-Synephrine), succinylcholine, sufentanil (Sufenta).

RATE OF ADMINISTRATION

A single dose equally distributed over 30 to 60 seconds. More rapid injections may produce hypotension.

ACTIONS

A short-acting, non-barbiturate hypnotic without analgesic activity. Depending on the dose administered, it can produce all levels of CNS depression, from light sleep to coma. Anesthetic doses can induce loss of consciousness within 60 seconds. Does not cause significant cardiovascular or respiratory depression. Incidence of respiratory depression may be less than with propofol (Diprivan) or barbiturates (e.g., thiopental [Pentothal]). Has little or no effect on myocardial metabolism, cardiac output, peripheral circulation, or pulmonary circulation. Produces a slight increase in $Paco_2$. Does not elevate plasma histamine or cause signs of histamine release. Decreases cerebral blood flow and lowers intracranial pressure. Usually lowers intraocular pressure moderately. Onset of action is within 1 minute. Duration of action is dose dependent, usually 3 to 5 minutes at a dose of 0.3 mg/kg. Metabolized in the liver and excreted primarily in the urine. Half-life is approximately 75 minutes.

INDICATIONS AND USES

Induction of general anesthesia. Useful for short outpatient, dental, and short diagnostic procedures and in high-risk patients. Usefulness of its hemodynamic properties should be weighed against the high frequency of transient skeletal muscle movements. (May be beneficial in patients with cardiopulmonary impairment because of minimal depressant effects and lack of histamine release.) One source suggests it is the intubation agent of choice in trauma and CHF. ■ Supplementation of subpotent anesthetic agents (such as nitrous oxide in oxygen) during maintenance of anesthesia for short operative procedures such as dilation and curettage or cervical conization.

Unlabeled uses: Emergency department treatment of painful procedures such as abscess drainage, cardioversion, chest tube replacement, dislocation reduction, fracture reduction, foreign body removal.

CONTRAINDICATIONS

Hypersensitivity to etomidate. ■ Not recommended for use during labor and delivery.

PRECAUTIONS

For IV use only. ■ Should be administered by or under the direct supervision of persons trained in the administration of general anesthetics and in the management of complications encountered during general anesthesia (e.g., anesthesiologists, emergency department physicians) in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Induction doses of etomidate have been associated with the reduction of plasma cortisol and aldosterone concentrations that may last for 6 to 8 hours. Because of the hazards of prolonged suppression, etomidate is not intended for administration by prolonged infusion. Exogenous replacement (e.g., methylprednisolone [Solu-Medrol]) should be considered if concern exists for patients undergoing severe stress or for patients undergoing chronic oral corticosteroid therapy (e.g., prednisone).

Monitor: Monitor airway and vital signs. ■ Monitor injection site. Use of larger, more proximal arm veins is recommended to lessen incidence and severity of pain on injection. Avoid use of wrist or hand veins if possible. ■ See Precautions and Drug/Lab Interactions.

Patient Education: Avoid alcohol or other CNS depressants (e.g., antihistamines, benzodiazepines) for 24 hours following administration. ■ Do not perform tasks requiring men-

tal alertness (e.g., driving, operating hazardous machinery) for 24 hours following administration.

Maternal/Child: Category C: safety for use in pregnancy not established; benefit must justify potential risks to fetus; see **Contraindications**. ■ Safety for use during breast-feeding not established; effects unknown. Use caution. ■ Safety and effectiveness for use in pediatric patients under 10 years of age not established.

Elderly: See **Dose Adjustments**. ■ May be more sensitive to effects (e.g., decreases in heart rate, cardiac index, and mean arterial BP).

DRUG/LAB INTERACTIONS

Administration of **fentanyl** 0.1 mg before induction with etomidate may shorten immediate recovery period. ■ May have additive effects with concomitant **anesthetics, sedatives, hypnotics, and/or opiates** (e.g., fentanyl [Sublimaze]); reduced doses of etomidate may be indicated. ■ Does not significantly alter the usual dosage requirements of **neuromuscular blocking agents** (e.g., vecuronium, pancuronium). ■ Administration of **fentanyl or diazepam** before induction with etomidate may help decrease transient skeletal muscle movements. ■ Succinylcholine-induced arrhythmias may still occur if **succinylcholine** is used in combination with etomidate.

SIDE EFFECTS

The most common adverse reactions are transient venous pain on injection and transient skeletal muscle movements, including myoclonus, averting movements, and eye movements. Less frequently reported side effects include apnea of short duration (5 to 90 seconds with spontaneous recovery), arrhythmia, bradycardia, hypertension, hyperventilation, hypotension, hypoventilation, hiccups and/or snoring (may indicate partial airway obstruction), laryngospasm, postoperative nausea and vomiting, and tachycardia.

ANTIDOTE

Discontinue drug if significant side effects or overdose occur. Support patient. Establish and maintain an airway; administer oxygen with assisted ventilation if needed. Resuscitate as necessary.

ETOPOSIDE **BBW**

(eh-TOH-poh-syd)

**Antineoplastic
(mitotic inhibitor)****Etopophos PF, Etoposide Phosphate, VePesid, VP-16-213****pH 2.9 to 4****USUAL DOSE**

Testicular cancer: 50 to 100 mg/M² daily for 5 days or 100 mg/M²/day on Days 1, 3, and 5. Repeat at 3- to 4-week intervals. Used in combination with other chemotherapy agents.

Small-cell lung cancer: 35 mg/M²/day for 4 days to 50 mg/M²/day for 5 days. Repeat at 3- to 4-week intervals. Used in combination with other chemotherapy agents.

Kaposi's sarcoma (unlabeled): 150 mg/M²/day for 3 consecutive days every 4 weeks. Repeat cycles based on patient response.

Hematopoietic stem cell transplantation (unlabeled): 60 mg/kg as a single dose. Used in combination with other agents.

DOSE ADJUSTMENTS

Modify dose if indicated based on myelosuppressive effects of other drugs administered in combination and any previous radiation therapy or chemotherapy (compromised bone marrow reserve). Frequently given in combination with cisplatin, bleomycin, and doxorubicin. ■ Withhold dose if platelets less than 50,000/mm³ or absolute neutrophil count less than 500/mm³. Do not restart until adequate recovery. ■ Dose selection should be cautious in the elderly. Reduced doses may be indicated based on potential for decreased organ function and concomitant disease or drug therapy; see **Elderly**. ■ Reduce dose by 25% if CrCl is 15 to 50 mL/min. Further reduction may be indicated if the CrCl is less than 15 mL/min. One source recommends decreasing dose by 50% if CrCl is less than 10 mL/min. ■ Dose reduction may be required in impaired hepatic function. One source recommends a dose reduction of 50% with a bilirubin of 1.5 to 3 or an AST of 60 to 180 units and recommends omitting the dose in patients with a bilirubin of 3.1 or greater or an AST greater than 180 units.

DILUTION

Specific techniques required; see Precautions.

Nonphosphate Products (e.g., VePesid): Each 100 mg (5 mL) must be diluted in at least 250 mL of D5W or NS and given as an infusion (0.4 mg/mL). 500 mL of solution will yield 0.2 mg/mL. Maximum concentration to prevent precipitation is 0.4 mg/mL. Monitor closely for precipitation from dilution to completion of infusion. Undiluted etoposide has caused acrylic or ABS plastic devices to crack and leak; handle carefully during dilution process.

PHOSPHATE PRODUCT (E.G., ETOPOPHOS): Reconstitute each 100-mg vial with 5 or 10 mL of SWFI, D5W, or NS (with or without benzyl alcohol). 5 mL of diluent will yield 20 mg/mL, 10 mL will yield 10 mg/mL. Further dilute to concentrations as low as 0.1 mg/mL with D5W or NS for administration. A 1-mg/mL solution has a pH of 2.9. The water solubility of Etopophos decreases the potential for precipitation following dilution and during administration.

Storage: Nonphosphate Products (e.g., VePesid): May be stored at CRT before dilution. Stable after dilution at CRT for 96 hours (0.2 mg/mL solution) or 24 hours (0.4 mg/mL) in D5W or NS. **Phosphate Products (e.g., Etopophos):** Refrigerate in carton until use. Store reconstituted solutions in glass or plastic containers under refrigeration at 2° to 8° C (36° to 46° F) for 7 days. Solutions reconstituted with non-bacteriostatic diluents may be stored at CRT for up to 24 hours. Solutions reconstituted with bacteriostatic diluents may be stored at CRT for up to 48 hours. Store fully diluted solutions under refrigeration or at CRT for up to 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be **INCOMPATIBLE** until consulting a pharmacist; specific conditions may apply.

NONPHOSPHATE PRODUCTS (E.G., VEPESID)

Hydrolysis may occur in alkaline solutions.

One source suggests the following **compatibilities**:

Additive: Carboplatin (Paraplatin), cisplatin (Platinol), cytarabine (ARA-C), daunorubicin (Cerubidine), fluorouracil (5-FU), ifosfamide (Ifex), mitoxantrone (Novantrone), ondansetron (Zofran); another source adds mesna (Mesnex).

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), aztreonam (Azactam), cladribine (Leustatin), doxorubicin liposomal (Doxil), fludarabine (Fludara), gemcitabine (Gemzar), granisetron (Kytril), melphalan (Alkeran), methotrexate, micafungin (Mycamine), mitoxantrone (Novantrone), ondansetron (Zofran), paclitaxel (Taxol), piperacillin/tazobactam (Zosyn), sargramostim (Leukine), sodium bicarbonate, teniposide (Vumon), thiotepa, topotecan (Hycamtin), vinorelbine (Navelbine).

PHOSPHATE PRODUCTS (E.G., ETOPOPHOS)

One source suggests the following **compatibilities**:

Additive: Specific information not available; consult pharmacist.

Y-site: Acyclovir (Zovirax), amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), aztreonam (Azactam), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), caspofungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), cefotetan (Cefotan), cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), ciprofloxacin (Cipro IV), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytosan), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), daunorubicin (Cerubidine), dexamethasone (Decadron), diphenhydramine (Benadryl), dobutamine, dopamine, doripenem (Doribax), doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), famotidine (Pepcid IV), fluconazole (Diflucan), fludarabine (Fludara), fluorouracil (5-FU), furosemide (Lasix), ganciclovir (Cytovene), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), ifosfamide (Ifex), leucovorin calcium, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, mannitol, meperidine (Demerol), mesna (Mesnex), methotrexate, metoclopramide (Reglan), metronidazole (Flagyl IV), mitoxantrone (Novantrone), morphine, nalbuphine, ondansetron (Zofran), oxaliplatin (Eloxatin), paclitaxel (Taxol), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, streptozocin (Zanosar), sulfamethoxazole/trimethoprim, teniposide (Vumon), thiotepa, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vinblastine, vincristine, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

NONPHOSPHATE PRODUCTS (E.G., VEPESID): Total desired dose, properly diluted (0.2 to 0.4 mg/mL) and evenly distributed over at least 30 to 60 minutes. Rapid infusion may cause marked hypotension. May be extended if fluid volume is a concern.

PHOSPHATE PRODUCTS (E.G., ETOPOPHOS): Total desired dose, properly reconstituted and diluted, may be given evenly distributed over as little as 5 minutes or up to 210 minutes. Do not give as a bolus injection.

ACTIONS

A semi-synthetic derivative of podophyllotoxin. A topoisomerase II inhibitor that is cell cycle-specific for the G₂ phase. At high concentrations, it causes lysis of cells entering mitosis. At lower concentrations, cells are inhibited from entering prophase. Appears to cause DNA strand breaks. Etopophos (phosphate) is a water-soluble ester of etoposide that promptly converts to etoposide in plasma. The pharmacokinetics and pharmacodynamics of etoposide are similar after administration of either the phosphate or non-phosphate products. Half-life is from 4 to 11 hours (average is 7 hours). Highly protein-

bound to albumin. Metabolized in the liver. Primarily excreted as unchanged drug or metabolites through urine and bile (feces).

INDICATIONS AND USES

Treatment of refractory testicular tumors (used in combination with other agents after previous surgery, chemotherapy, and radiotherapy). ■ Treatment of small-cell lung cancer (used in combination with other chemotherapeutic agents as first-line treatment).

Unlabeled uses: Conditioning regimen for hematopoietic cell transplantation. Treatment of acute lymphocytic leukemias (ALL), Hodgkin's lymphoma, non-Hodgkin's lymphomas, carcinoma of the breast, Kaposi's sarcoma, neuroblastoma, Wilms' tumor, and many malignancies. Additional tumors have shown up to 20% response. Used alone or in combination with other agents.

CONTRAINDICATIONS

Hypersensitivity to etoposide, etoposide phosphate, or any other component of the formulations.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. Always wear impervious gloves when handling vials containing etoposide. If a solution of etoposide contacts the skin, wash the skin immediately and thoroughly with soap and water. If there is contact with mucous membranes, flush thoroughly with water. For IV infusion only; do not give as a bolus injection. ■ Usually administered by or under the direction of the physician specialist. ■ Severe myelosuppression with resulting infection or bleeding may occur. Deaths have been reported. ■ A low serum albumin may result in an increase of free (active) etoposide, resulting in an increased risk of toxicity. Occurs more frequently in pediatric patients. ■ Hypersensitivity reactions have been reported. ■ A potential carcinogen; acute leukemia with or without a preleukemic phase has been rarely reported. ■ Oral dose of nonphosphate product (e.g., etoposide) is usually twice the IV dose.

Monitor: Determine absolute patency and quality of vein and adequate circulation of extremity. Avoid extravasation; may result in cellulitis, pain, swelling, and necrosis. ■ Obtain baseline CBC with differential and platelets. Monitor before each dose and between courses. See [Dose Adjustments](#). ■ Examine patient's mouth for ulceration before each dose. ■ Monitor hepatic and renal function before and during therapy. ■ Bone marrow recovery from a course is usually complete within 21 days. No cumulative toxicity has been reported as yet. ■ Be alert for signs of bone marrow suppression or infection. ■ Monitor for S/S of hypersensitivity reactions (e.g., bronchospasm, chills, dyspnea, fever, hypotension, pruritus, rash, tachycardia, urticaria). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Maintain adequate hydration. ■ Prophylactic antiemetics may increase patient comfort.

Patient Education: Nonhormonal birth control recommended. ■ Report IV site burning or stinging promptly. ■ Report chills, difficult breathing, fever, and rapid heartbeat promptly. See Appendix D, p. 1255.

Maternal/Child: Category D: avoid pregnancy. Can cause fetal harm. ■ Discontinue breast-feeding. ■ Has been used in pediatric patients, but safety and effectiveness not established. Anaphylactic reactions have been reported. Higher rates of anaphylactic-like reactions have occurred in pediatric patients who have received infusions of etoposide at higher than recommended concentrations. See Precautions. ■ Depending on the preparation, VePesid may contain benzyl alcohol or polysorbate 80.

Elderly: Monitor renal, hepatic, and hematologic function closely. ■ See [Dose Adjustments](#). ■ Incidence of anorexia, asthenia, dehydration, elevated BUN levels, granulocytopenia, leukopenia (Grade III or IV), mucositis, and somnolence occur more frequently in the elderly. ■ May also be more sensitive to expected side effects (e.g., alopecia,

gastrointestinal effects, infectious complications, and myelosuppression). Potential for greater sensitivity increased if renal function impaired.

DRUG/LAB INTERACTIONS

All products: Concurrent or consecutive use with other **bone marrow suppressants** (e.g., bleomycin, cisplatin, doxorubicin) **and/or radiation therapy** may produce additive bone marrow suppression. See [Dose Adjustments](#). ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Clearance decreased and toxicity increased by **cyclosporine**.

NONPHOSPHATE PRODUCTS (E.G., VEPESID): May potentiate **warfarin**; monitor PT.

PHOSPHATE PRODUCT (E.G., ETOPOPHOS): Use caution with drugs that are **known to inhibit phosphatase activities** (e.g., levamisole [Ergamisol]).

SIDE EFFECTS

Bone marrow toxicity (e.g., leukopenia, neutropenia, thrombocytopenia) can be severe, is dose related, and may be dose limiting. Side effects are usually reversible: abdominal pain, alopecia, anaphylactic reactions (bronchospasm, chills, dyspnea, fever, hypotension), anemia, anorexia, constipation, diarrhea, dizziness, elevated liver function tests (e.g., AST, ALT), hepatic toxicity, hypertension, hypotension, interstitial pneumonitis/pulmonary fibrosis, local soft tissue toxicity following extravasation, malaise, mucositis, nausea, neuritic pain, paralytic ileus, peripheral neurotoxicity, pruritus, radiation recall dermatitis, rash, seizures, Stevens-Johnson syndrome, stomatitis, thrombophlebitis, toxic epidermal necrolysis, urticaria, vomiting. Hepatic toxicity and metabolic acidosis have occurred with higher-than-recommended doses.

ANTIDOTE

Notify the physician of all side effects; symptomatic treatment is often indicated, dose reduction or discontinuation may be necessary. For extravasation, discontinue the drug immediately and administer into another vein. No specific treatment for extravasation is recommended. Hypotension is usually due to a rapid infusion rate. Discontinue infusion. Trendelenburg position and IV fluids should reverse the hypotension; vasopressors (e.g., dopamine) may be required. After recovery, restart at slower rate. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Discontinue infusion at the first sign of a hypersensitivity reaction; antihistamines, corticosteroids, pressor agents, or volume expanders may be indicated. Resuscitate as necessary.

FACTOR IX (HUMAN) - FACTOR IX COMPLEX (HUMAN)

Antihemorrhagic

(FAK-tor 9)

AlphaNine SD, Mononine ■ Bebulin VH,
Profilnine SD

pH 7 to 7.4 ■ pH 7 to 7.4

USUAL DOSE

(International units [IU])

ALL FORMULATIONS

Completely individualized based on patient's circumstances, condition, degree of deficiency, and desired blood level percentage. Specific products may be indicated or preferred in some situations; see [Indications and Uses](#). Range is 10 to 75 International units (IU)/kg of body weight. May be repeated every 12 hours in some situations, required only every 2 or 3 days in others. Actual number of International units contained shown on each bottle or vial. Units required to raise blood level percentages can be calculated as follows:

$$\text{Body weight (kg)} \times \text{Desired increase (\% of normal)} \times 1 \text{ Unit/kg}$$

(70 kg \times 40% increase \times 1 IU/kg = 2,800 IU). To maintain levels above 25%, calculate each dose to raise level to 40% to 60% of normal.

Minor hemorrhage: A single injection calculated to increase plasma level to 20% to 30%. May be repeated in 24 hours if indicated.

Major trauma or surgery: Increase plasma level to 25% to 50% and maintain at that level for a minimum of 1 week or as indicated. May require daily injections (every 18 to 30 hours).

Dental extraction: Increase plasma level to 50% before procedure; repeat if indicated.

Prophylaxis: 10 to 20 IU/kg once or twice a week or increase plasma level to 20% to 30%.

FACTOR IX COMPLEX

Reversal of coumarin effect: 15 IU/kg.

DILUTION

Diluent usually provided. Some preparations also supply double-ended needles for dilution and filter needle for aspiration into a syringe. Sterile technique imperative. Confirm expiration date. Use plastic syringes to prevent binding to glass surfaces. Factor IX and diluent should be at room temperature. Direct diluent from above to side of vial to gently moisten all contents. Swirl gently to dissolve; avoid foaming. Do not shake. May take 1 to 5 minutes. Should be clear and colorless. Must be used within 3 hours to avoid bacterial contamination. The addition of 2 to 3 units of heparin/mL factor IX complex may reduce the incidence of thrombosis. May be given through an IV administration set (often provided) if multiple vials are required. Discard any unused contents. Discard all administration equipment after single use; do not attempt to resterilize.

AlphaNine SD: Follow general directions above. After diluent is drawn through double-ended needle, remove diluent bottle first; then remove double-ended needle. **Do not invert concentrate vial until ready to withdraw contents!** Air from syringe into vial required to withdraw contents. Withdraw through filter.

Mononine: Follow general directions listed previously. After diluent is drawn through double-ended needle, remove diluent bottle first; then remove double-ended needle. **Use only the provided self-venting filter spike to transfer Mononine to a syringe! Do not inject any air into Mononine vial; could cause product loss.** Discard filter and use only provided wing needle and micropore tubing to administer.

Filters: Usually supplied by manufacturer. If more than one vial is required for a dose, multiple vials may be drawn into the same syringe; however, a new filter needle must be

used to withdraw the contents of each vial of factor IX and/or factor IX complex (Human). Manufacturers of **AlphaNine SD** and **Mononine** provide a filter needle, which is to be used to withdraw reconstituted solution into a syringe. Discard filter needle after aspiration into the syringe. No further filtering is required for administration.

Storage: Store lyophilized powder at 2° to 8° C (36° to 46° F); do not freeze. Do not refrigerate after dilution. **Mononine** may be stored at room temperature before dilution for up to 30 days.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Average rate is 2 to 3 mL or 100 units/min. Completely individualized according to patient's condition. Decrease rate of administration for side effects such as burning or pain at injection site, chills, fever, flushing, headache, tingling, or changes in BP or pulse. Never exceed 10 mL/min.

ACTIONS

A lyophilized concentrate of human coagulation factors: IX (plasma thromboplastin and antihemophilic factor B), II (prothrombin), VII (proconvertin), and X (Stuart-Prower factor). In contrast to other products, AlphaNine SD and Mononine are highly purified factor IX and contain only minimal amounts of the other factors. All products are obtained from fresh human plasma and prepared, irradiated, and dried by specific processes. Additional processes are used to prepare AlphaNine SD and Mononine that markedly reduce the possibility of viral contamination. Concentration of 25 units/mL is 25 times greater than normal plasma. Preparations contain varying amounts of total protein in each vial. Half-life is approximately 24 hours (range 18 to 36 hours).

INDICATIONS AND USES

All factor IX products: Prevention/control of bleeding in patients with factor IX deficiency due to hemophilia B. Indicated to correct or prevent a dangerous bleeding episode or to perform surgery. ■ Prophylaxis to prevent spontaneous bleeding in patients with proven specific congenital deficiency (hemophilia B).

Factor IX (human): Preferred for surgical coverage; treatment of crush injuries and/or large IM hemorrhages requiring several days of replacement therapy; and treatment in neonates, individuals with severe hepatocellular dysfunction, or those with a history of thrombotic complications associated with factor IX complex.

Factor IX complex: Prevention/control of bleeding in patients with hemophilia A who have inhibitors to factor VIII. ■ Reversal of coumarin effect (fresh-frozen plasma preferred unless risk of hepatitis transfer would be life threatening). ■ Hemorrhage caused by hepatitis-induced lack of production of liver-dependent coagulation factors. ■ Proplex T is used for prevention or control of bleeding episodes in patients with factor VII deficiency.

CONTRAINDICATIONS

Factor IX complex: Known liver disease with suspicion of intravascular coagulation or fibrinolysis. ■ Factor VII deficiency except for Proplex T.

Mononine: Known hypersensitivity to mouse protein. ■ No other known contraindications for **AlphaNine SD** or **Bebulin VH**. ■ **AlphaNine SD**, **Bebulin VH**, and **Mononine** are not indicated for replacement of any other coagulation factors.

PRECAUTIONS

Used when plasma infusions would result in hypervolemia and/or proteinemia or when blood volume or RBC replacement is not indicated. ■ Use extreme caution in newborns, infants, postoperative patients, and patients with liver disease. Factor IX (human) (e.g., AlphaNine SD, Mononine) would be preferred because studies show no incidence of thrombin generation. ■ Fresh-frozen plasma may be required in addition to factor IX complex when prompt reversal is required. ■ Danger of thromboembolic episodes (DIC, myocardial infarction, pulmonary embolism, venous thrombosis) increases with plasma levels over 50%. ■ Large or frequently repeated doses of factor IX complex may cause intravascular hemolysis in patients with type A, B, or AB blood.

Monitor: Monitor the patient's levels of coagulation factors before, after, and between administrations. **Do not overdose;** see **Side Effects**. ■ AIDS or hepatitis is possible for the recipient. Health care professionals should exercise caution in handling. Possibility markedly reduced with additional preparation process of AlphaNine SD and Mononine. ■ Observe for signs and symptoms of postoperative thrombosis or disseminated intravascular coagulation (DIC). Risk multiplies with repeated administrations except for AlphaNine, AlphaNine SD, and Mononine.

Patient Education: Alert to possible risk of HIV virus and hepatitis. ■ Report early signs of hypersensitivity promptly (burning or pain along injection site, hives, rash, tightness of chest, wheezing). ■ Notify physician if medication seems less effective. May be developing antibodies to factor IX. ■ Carry identification card. ■ Proper preparation and administration imperative if given in home.

Maternal/Child: Category C: safety for use during pregnancy not established; use only if clearly indicated; see **Precautions**. ■ Use extreme caution in neonates with hepatitis; high rate of morbidity.

DRUG/LAB INTERACTIONS

Concurrent use of **aminocaproic acid** (Amicar) may increase risk of thrombosis.

SIDE EFFECTS

Burning or pain along injection site, changes in BP, chills, fever, flushing, headache, nausea, tingling, urticaria, vomiting.

Major: Anaphylaxis, DIC, hepatitis, myocardial infarction, postoperative thrombosis (rare with pure factor IX [Human] products), pulmonary embolism. Consider risk potential of contracting AIDS and hepatitis; markedly reduced with pure factor IX (Human) products (AlphaNine, AlphaNine SD, and Mononine).

ANTIDOTE

Temporarily discontinue or decrease rate of administration for minor side effects. For major symptoms, discontinue, and notify physician. Treat hypersensitivity reactions as indicated; a different lot may not cause reaction. For thrombosis or DIC, anticoagulation with heparin may be indicated.

FACTOR IX (RECOMBINANT)

(FAK-tor 9 [re-KOM-be-nant])

Antihemorrhagic

BeneFIX

USUAL DOSE

(International units [IU])

Adults and pediatric patients: Completely individualized based on the degree of deficiency, location and extent of bleeding, and the patient's clinical condition, age, and recovery of factor IX. All doses should be titrated to the patient's clinical response. Actual number of International units contained shown on each bottle or vial. Units required to raise blood level percentages are somewhat increased with this recombinant product compared to other factor IX products and can be calculated as follows:

Number of Factor IX IU Required =
 Body Weight (in kg) × Desired Factor IX Increase (% or IU/dL) × 1.3 IU/kg per IU/dL

In the presence of an inhibitor, higher doses may be required.

The following chart may be used to guide dosing in bleeding episodes and surgery.

Factor IX (Recombinant) Dosing Guidelines			
Type of Hemorrhage	Circulating Factor IX Activity Required (%)	Frequency of Doses (hours)	Duration of Therapy (days)
Minor Uncomplicated hemarthroses, superficial muscle, or soft tissue	20%-30%	12-24 hours	1-2 days
Moderate Intramuscle or soft tissue with dissection, mucous membranes, dental extractions, or hematuria	25%-50%	12-24 hours	Treat until bleeding stops and healing begins, about 2 to 7 days
Major Pharynx, retropharynx, retroperitoneum, CNS, surgery	50%-100%	12-24 hours	7-10 days

Source: Roberts and Eberst.

DILUTION

Sterile diluent, double-ended needle, filter spike, and infusion set provided. Sterile technique imperative. Confirm expiration date. Use plastic syringes to prevent binding to glass surfaces. Factor IX and diluent should be at room temperature. After removing the vial caps on factor IX and diluent, wipe with antiseptic and allow to dry. Insert short end of the double-ended needle in the diluent vial. Insert long end in the factor IX vial with the tip directed to the side of the wall to prevent excessive foaming. Fully invert the diluent vial to a vertical position and allow the diluent to run completely into the factor IX vial. If the diluent does not transfer completely, **do not use** (a very small amount remaining is permissible). Remove transfer needle. Gently rotate the vial to dissolve. Should be clear and colorless. Attach filter spike to the plastic syringe and insert in the reconstituted solution; invert and withdraw contents. **Do not** inject air into the vial; may cause partial loss of product. Multiple vials may be drawn in the same syringe, but a new sterile filter spike must be used for each vial. Must be used within 3 hours of reconstitution.

Filters: Supplied by manufacturer. If more than one vial is required for a dose, multiple vials may be drawn into the same syringe; however, a new filter needle must be used to withdraw the contents of each vial of factor IX (recombinant).

Storage: Refrigerate packaged product (2° to 8° C [36° to 46° F]). Packaged product may be stored at room temperature not exceeding 25° C (77° F) for up to 6 months (mark date

removed from refrigerator on carton). Avoid freezing. Do not use after the expiration date. Must be used within 3 hours of reconstitution.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

A single dose over several minutes. Average rate during studies was 50 units/kg infused over 10 minutes. Individualized according to patient's condition and comfort level. Decrease rate for side effects such as burning or pain at injection site, chills, fever, flushing, headache, tingling, or changes in BP or pulse.

ACTIONS

An antihemorrhagic. A purified protein produced by recombinant DNA technology for use in the treatment of factor IX deficiency. Its primary amino acid sequence is identical to a form of plasma-derived factor IX, and it has structural and functional characteristics similar to those of endogenous factor IX. Inherently free from the risk of transmission of human bloodborne pathogens such as HIV, hepatitis viruses, and parvovirus. Factor IX is the specific clotting factor deficient in patients with hemophilia B and in patients with acquired factor IX deficiencies. Factor IX (Recombinant) increases plasma levels of factor IX and can temporarily correct the coagulation defect in these patients. Half-life ranges from 11 to 26 hours.

INDICATIONS AND USES

Control and prevention of hemorrhagic episodes in patients with hemophilia B (congenital factor IX deficiency or Christmas disease), including control and prevention of bleeding in surgical settings.

CONTRAINDICATIONS

Known history of hypersensitivity to hamster protein. ■ Not indicated for the treatment of other factor deficiencies (e.g., factors II, VII, and X). ■ Not indicated for the treatment of hemophilia A patients with inhibitors to factor VIII. ■ Not indicated for the reversal of coumarin-induced anticoagulation. ■ Not indicated for the treatment of bleeding due to low levels of liver-dependent coagulation factors.

PRECAUTIONS

Usually administered under the supervision of a physician experienced in the treatment of hemophilia B. ■ Hypersensitivity reactions are possible. ■ BeneFIX contains only coagulation factor IX, but thromboembolic episodes (e.g., disseminated intravascular coagulation [DIC], myocardial infarction, pulmonary embolism, venous thrombosis) have been reported with other factor IX concentrates. These episodes increase with plasma levels over 50%. May be hazardous in patients with signs of fibrinolysis or DIC. ■ Because of potential thromboembolic problems, use caution in patients with liver disease, patients in the postoperative period, neonates, or in patients at risk of thromboembolic phenomena or DIC. Benefit must be weighed against risk.

Monitor: To ensure desired factor IX activity levels, precise monitoring using the factor IX activity assay is recommended, especially during surgical intervention. **Do not overdose;** see **Side Effects**. ■ Monitor for development of factor IX inhibitors. Patients dosed with high-purity factor IX products who develop inhibitors are at increased risk of anaphylaxis with repeat doses.

Patient Education: Hypersensitivity reactions can occur. Report difficulty breathing, hives, itching, tightness of the chest, and/or wheezing promptly. If self-administering, discontinue use and contact physician immediately.

Maternal/Child: Category C: use during pregnancy or during breast-feeding only if clearly indicated. ■ To this date, no adverse reactions related to treatment have been reported in pediatric patients.

Elderly: Response similar to other age-groups.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Allergic rhinitis, altered taste, burning or pain along injection site, burning sensation in jaw and skull, changes in BP, chills, dizziness, drowsiness, dry cough, fever, flushing, headache, lethargy, light-headedness, nausea, phlebitis at injection site, rash, tightness in the chest, tingling, urticaria, vomiting.

Major: Anaphylaxis, DIC, myocardial infarction, postoperative thrombosis (rare with pure factor IX products), pulmonary embolism.

ANTIDOTE

Temporarily discontinue or decrease rate of administration for minor side effects. If any major symptoms appear, discontinue drug and notify physician. Treat hypersensitivity reactions as indicated. For thrombosis or DIC, anticoagulation with heparin may be indicated.

FACTOR XIII CONCENTRATE (HUMAN)

Antihemorrhagic

(FAK-tor THIR-teen HUE-man)

Corifact

USUAL DOSE

(International units [IU])

Dose must be individualized based on body weight, laboratory values, and patient’s clinical condition.

Initial dose in adult and pediatric patients: 40 International units/kg.

Subsequent doses in adult and pediatric patients: Should be guided by the most recent trough factor XIII (coagulation factor XIII) activity level. Dose every 28 days (4 weeks) to maintain a trough factor XIII activity level of approximately 5% to 20%. Recommended dosing adjustments of ±5 units/kg should be based on trough factor XIII activity levels as shown in the chart in [Dose Adjustments](#) and on the patient’s clinical condition.

DOSE ADJUSTMENTS

Guide dose adjustments based on a specific assay used to determine factor XIII levels (e.g., Berichrom Activity Assay).

Dose Adjustment of Factor XIII Concentrate Using the Berichrom Activity Assay	
Factor XIII Activity Trough Level (%)	Dosage Change
One trough level of <5%	Increase by 5 units/kg
Trough level of 5% to 20%	No change
Two trough levels of >20%	Decrease by 5 units/kg
One trough level of >25%	Decrease by 5 units/kg

DILUTION

Available as a single-use vial containing 1,000 to 1,600 units of factor XIII as a lyophilized concentrate. Actual units of potency stated on vial label. Sterile diluent and Mix2Vial filter transfer set provided. Sterile technique imperative. Confirm expiration date. Record the batch number of the product in the patient’s medical record with each infusion. Bring factor XIII concentrate and diluent to RT. Place vial, diluent, and Mix2Vial transfer set on a flat surface. Remove flip caps on vial and diluent and wipe stoppers with provided alcohol swab; allow to dry. Peel away the lid on the Mix2Vial transfer set but leave it in the clear package. Hold the diluent vial tightly on a flat surface and pick up the Mix2Vial transfer set by its clear package. Push the plastic spike at the

blue end of the Mix2Vial transfer set through the center of the diluent vial stopper. Carefully remove only the clear packaging from the transfer set. Invert the diluent vial with the Mix2Vial transfer set attached, and push the plastic spike of the transparent adapter firmly through the center of the factor XIII concentrate. Diluent will automatically transfer into the vial. With all parts still attached, gently swirl to fully dissolve. **Do not shake.** Solution should be colorless to slightly yellowish and slightly opalescent. Grasp the factor XIII side with one hand and the diluent side with the other and unscrew the set into 2 pieces. Draw air into an empty 20 mL sterile syringe. With the factor XIII vial upright, screw the syringe to the Mix2Vial transfer set. Inject air into the factor XIII vial. Keep the syringe plunger pressed, and invert the system upside down to draw the concentrate into the syringe by pulling the plunger back slowly. Keep the plunger facing down and remove syringe from transfer set. Attach the syringe to a suitable IV administration set. If the same patient is to receive more than one vial, contents of multiple vials may be pooled. Use a separate, unused Mix2Vial transfer set for each vial. Must be used within 4 hours of reconstitution.

Filters: Mix2Vial filter transfer set provided.

Storage: Protect from light; refrigerate vials and diluent in carton at 2° to 8° C (36° to 46° F). Do not freeze. Stable for 24 months up to the expiration date on the carton under refrigeration. May be stored at RT not to exceed 25° C (77° F) for up to 6 months; however, it cannot be returned to refrigeration. Mark date removed from refrigeration. Do not use beyond expiration date on carton and vial labels or beyond end of RT storage, whichever comes first. Must be used within 4 hours of reconstitution. Do not refrigerate or freeze the reconstituted solution. Contains no preservatives; a single-use vial; discard partially used vials.

COMPATIBILITY

Manufacturer states, “Do not mix with other medicinal products, and administer through a separate infusion line.”

RATE OF ADMINISTRATION

Initial dose: Do not exceed 4 mL/min.

ACTIONS

A heat-treated, lyophilized factor XIII (coagulation factor XIII) concentrate made from pooled human plasma. Several manufacturing steps are used to inactivate or remove both enveloped and non-enveloped viruses. Factor XIII circulates in blood and is present in platelets, monocytes, and macrophages. Activated factor XIII (factor XIIIa) promotes cross-linking of fibrin during coagulation and is essential to the physiologic protection of the clot against fibrinolysis. Cross-linked fibrin is the end result of the coagulation cascade and provides tensile strength to a primary hemostatic platelet plug. Half-life is approximately 6.6 ± 2.29 days. The increase in plasma levels of factor XIII after administration lasts approximately 28 days.

INDICATIONS AND USES

Routine prophylactic treatment of congenital factor XIII deficiency in adult and pediatric patients. To be effective, a trough factor XIII activity level of approximately 5% to 20% should be maintained.

Limitation of use: There are no controlled trials demonstrating a direct benefit on treatment of bleeding episodes.

CONTRAINDICATIONS

Known anaphylactic or severe hypersensitivity reactions to human plasma-derived products or to any components of the product.

PRECAUTIONS

For IV use only. ■ Hypersensitivity reactions have occurred; emergency equipment, medications, and supplies must be available. ■ Neutralizing inhibitory antibodies against factor XIII have been detected in patients receiving factor XIII. ■ Thromboembolic complications have been reported. Assess benefit versus risk in pregnant women because of their hypercoagulable state and potential for increased risk of thromboembolic events. ■ Made from human plasma and may contain infectious agents (e.g., HIV,

Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C). Numerous steps in the manufacturing process are used to reduce the potential for infection. ■ Consider appropriate vaccination against hepatitis A and B.

Monitor: Monitor trough factor XIII activity levels as outlined in [Usual Dose](#) and [Dose Adjustments](#). ■ Monitor for S/S of hypersensitivity reactions (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Monitor for possible development of inhibitory antibodies (e.g., response to treatment is inadequate, expected plasma factor XIII activity levels are not attained, or breakthrough bleeding occurs). ■ Monitor for thromboembolic complications: (e.g., chest pain, dyspnea, edema, hemoptysis, leg pain, or positive Homans' sign). ■ Monitor for S/S of viral infection (e.g., chills, drowsiness, fever, runny nose followed by joint pain and rash or abdominal pain, dark urine, jaundice, nausea, vomiting).

Patient Education: Manufactured from pooled human plasma. Possibility of viral transmission exists. Promptly report S/S of viral infections (e.g., chills, drowsiness, fever, runny nose followed by joint pain and rash or abdominal pain, dark urine, jaundice, nausea, vomiting). ■ Promptly report difficulty breathing, pruritus, or rash. ■ Promptly report breakthrough bleeding.

Maternal/Child: Category C: use only if clearly needed; see [Precautions](#). ■ Use only if clearly needed in breast-feeding women. ■ No apparent differences in the safety profile in pediatric patients compared with adults. Pediatric patients less than 16 years of age had a shorter half-life and faster clearance compared with adults.

Elderly: Numbers in clinical studies insufficient to determine if elderly patients respond differently than younger subjects.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

The most commonly reported side effects included arthralgia, chills, elevated thrombin-antithrombin levels, fever, headache, hypersensitivity reactions (including allergy, erythema, pruritus, and rash), and increased hepatic enzymes. Other reported side effects included abdominal pain, diarrhea, epistaxis, flu-like syndrome, hematoma, URT infection, and vomiting.

Post-Marketing: Hypersensitivity reactions (including anaphylaxis), factor XIII inhibition (neutralizing antibodies), thrombotic events (e.g., embolism, thrombosis), viral infection (possible).

ANTIDOTE

Keep physician informed of side effects; most will be treated symptomatically. Discontinue administration and treat hypersensitivity reactions as indicated. A different lot may not cause a reaction. For thrombosis, anticoagulation may be indicated. Resuscitate as necessary.

FAMOTIDINE

(fah-MOH-tih-deen)

Antilucer agent
(H₂ antagonist)
Gastric acid inhibitor

Famotidine PF, Pepcid

pH 5.7 to 6.4

USUAL DOSE

20 mg (2 mL) every 12 hours. Increase frequency of dose, not amount, if necessary for pain relief. In hypersecretory states (e.g., Zollinger-Ellison syndrome), higher doses may be required. Adjust dose to individual patient needs.

PEDIATRIC DOSE

Age 1 to 16 years: Starting dose is 0.25 mg/kg every 12 hours. Treatment duration and dose must be individualized based on clinical response, pH determination, and/or endoscopy. Doses up to 0.5 mg/kg every 12 hours may be required for gastric acid suppression. Another source suggests 0.6 to 0.8 mg/kg/24 hr (0.3 to 0.4 mg/kg every 12 hours or 0.2 to 0.27 mg/kg every 8 hours). May need to reduce interval to every 8 hours because of increased elimination. Maximum dose is 40 to 80 mg/24 hr based on diagnosis.

Neonate (unlabeled): 0.5 mg/kg/dose/24 hr.

DOSE ADJUSTMENTS

Reduce dose by one-half or increase the dosing interval to 36 to 48 hours in patients with moderate or severe renal dysfunction (CrCl less than 50 mL/min). Adjust based on patient response. Half-life may exceed 20 hours if CrCl less than 10 mL/min.

DILUTION

IV injection: Available in vials containing 10 mg/mL and as premixed solution 20 mg/50 mL. Each 20-mg vial must be diluted with 5 to 10 mL of NS or other **compatible** infusion solutions for injection (e.g., D5W, D10W, LR, SWFI).

Intermittent infusion: Each 20 mg may be diluted in 100 mL of D5W or other **compatible** infusion solution and given piggyback.

Storage: Refrigerate vials before dilution. Manufacturer recommends use of diluted solutions within 48 hours. However, studies suggest diluted solutions are physically and chemically stable at RT for 7 days. Store premixed Galaxy containers at CRT; avoid excessive heat. If solution freezes, bring to RT; allow sufficient time to solubilize.

COMPATIBILITY(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

May form a precipitate with sodium bicarbonate in concentrations greater than 0.2 mg/mL.

One source suggests the following **compatibilities**:

Solutions: Selected TNA and TPN solutions and fat emulsion IV.

Additive: Cefazolin (Ancef), flumazenil (Romazicon), vancomycin.

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amifostine (Ethyol), aminophylline, amiodarone (Nexterone), ampicillin, ampicillin/sulbactam (Unasyn), amidulafungin (Eraxis), atropine, aztreonam (Azactam), bivalirudin (Angiomax), calcium gluconate, casprofungin (Cancidas), cefazolin (Ancef), cefotaxime (Claforan), cefotetan (Cefotan), cefoxitin (Mefoxin), ceftaroline (Teflaro), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), cisatracurium (Nimbex), cladribine (Leustatin), dexamethasone (Decadron), dexmedetomidine (Precedex), dextran 40, digoxin (Lanoxin), diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), droperidol (Inapsine), enalaprilat (Vasotec IV), epinephrine (Adrenalin), erythromycin (Erythrocin), esmolol (Brevibloc), etoposide phosphate (Etopophos), fenoldopam (Corlopam), filgrastim (Neupogen), fluconazole (Diflucan), fludarabine (Fludara), folic acid,

furosemide (Lasix), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), imipenem-cilastatin (Primaxin), insulin (regular), isoproterenol (Isuprel), labetalol, lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium sulfate, melphalan (Alkeran), meperidine (Demerol), methylprednisolone (Solu-Medrol), metoclopramide (Reglan), midazolam (Versed), morphine, nafcillin (Nallpen), nicardipine (Cardene IV), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), ondansetron (Zofran), oxacillin (Bactocill), oxaliplatin (Eloxatin), paclitaxel (Taxol), palonosetron (Aloxi), pemetrexed (Alimta), phenylephrine (Neo-Synephrine), phenytoin (Dilantin), phytonadione (vitamin K₁), potassium chloride (KCl), potassium phosphates, procainamide (Pronestyl), propofol (Diprivan), remifentanyl (Ultiva), sargramostim (Leukine), sodium bicarbonate, telavancin (Vibativ), teniposide (Vumon), theophylline, thiamine (vitamin B₁), thiotepa, ticarcillin/clavulanate (Timentin), tirofiban (Aggrastat), verapamil, vinorelbine (Navelbine).

RATE OF ADMINISTRATION

IV injection: Each 20 mg or fraction thereof over at least 2 minutes.

Intermittent infusion: Each 20-mg dose over 15 to 30 minutes.

ACTIONS

A histamine H₂ antagonist, it inhibits both daytime and nocturnal basal gastric acid secretion. It also inhibits gastric acid secretion stimulated by food and pentagastrin. Onset of action occurs within 30 minutes and lasts for 10 to 12 hours. No cumulative effect with repeated doses. 30 to 60 times more potent than cimetidine. Elimination half-life is 2.5 to 3.5 hours. Eliminated by renal and other metabolic routes. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Short-term treatment of active duodenal ulcers, benign gastric ulcers, and pathologic hypersecretory conditions in hospitalized patients or in patients unable to take oral medication. ■ Used orally for short-term treatment of gastroesophageal reflux disease (GERD) including erosive or ulcerative esophagitis.

Unlabeled uses: GI bleeding. ■ Stress ulcer prophylaxis.

CONTRAINDICATIONS

Known hypersensitivity to H₂ receptor antagonists (e.g., cimetidine [Tagamet], famotidine [Pepcid IV], ranitidine [Zantac]) or their components; cross-sensitivity has occurred.

PRECAUTIONS

Use with caution in patients with moderate or severe renal dysfunction; see [Dose Adjustments](#). ■ CNS adverse effects have been reported in patients with impaired renal function. ■ Gastric malignancy may be present even though patient is asymptomatic. ■ Effects maintained with oral dosage. Total treatment usually discontinued after 4 to 8 weeks.

Monitor: Use antacids concomitantly to relieve pain. ■ See [Precautions](#).

Patient Education: Stop smoking or at least avoid smoking after last dose of the day. ■ Gastric pain and ulceration may recur after medication is stopped.

Maternal/Child: Category B: use during pregnancy only when clearly needed. ■ Advisable to discontinue breast-feeding. ■ Plasma clearance is reduced and half-life is increased in pediatric patients under 3 months of age compared to older pediatric patients with pharmacokinetic parameters similar to adults.

Elderly: Response similar to that seen in younger patients; however, greater sensitivity in the elderly cannot be ruled out. ■ Consider risk of renal dysfunction; reduced doses and monitoring of renal function may be indicated; see [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

May inhibit gastric absorption of **ketoconazole** (Nizoral). ■ May decrease **cyclosporine** serum levels when famotidine is given concurrently with ketoconazole and cyclosporine.

SIDE EFFECTS

Constipation, diarrhea, dizziness, and headache are the most common side effects. Hypersensitivity reactions (bronchospasm, fever, pruritus, rash, eosinophilia) can occur. Abdominal discomfort, agitation, alopecia, anorexia, anxiety, arthralgias, confusion, decreased libido, depression, dry mouth, dry skin, elevated ALT, flushing, grand mal seizure, hallucinations, insomnia, interstitial pneumonia, malaise, muscular pain, nausea and vomiting, orbital edema, palpitations, paresthesias, somnolence, taste disorder, thrombocytopenia, tinnitus, and toxic epidermal necrolysis/Stevens-Johnson syndrome (very rare) have been reported. Convulsions in patients with impaired renal function have been reported rarely.

ANTIDOTE

Notify physician of all side effects. May be treated symptomatically or may respond to decrease in frequency of dosage. Resuscitate as necessary for overdosage.

FAT EMULSION, INTRAVENOUS **BBW***

Nutritional supplement
(fatty acid)

Intralipid 10%, 20%, & 30%, Liposyn II
10% & 20%, Liposyn III 10%, 20%, & 30%

pH 6 to 9

*This drug is on the Black Box Warning list; however, a BBW is not provided in the parenteral prescribing information.

USUAL DOSE

Some solutions may contain aluminum; see [Precautions](#).

Total parenteral nutrition component: 500 mL of 10% or 20% on the first day. Increase dose gradually each day. Do not exceed 60% of the patient's total caloric intake or 2.5 Gm/kg of body weight. Amino acids and carbohydrates should account for the remaining caloric input.

Prevention of fatty acid deficiency: 500 mL of 10% or 250 mL of 20% twice a week should supply the recommended 4% of caloric intake as linoleate.

PEDIATRIC DOSE

Some solutions may contain aluminum; see [Precautions](#).

Total parenteral nutrition component: 0.5 to 1 Gm/kg of body weight. Increase dose gradually each day. Do not exceed 60% of total caloric intake. Amino acids and carbohydrates should account for the remaining caloric input. Maximum dose recommended by the American Academy of Pediatrics is 3 Gm fat/kg/24 hr. Another source suggests maximum may be as high as 4 Gm fat/kg/24 hr.

Premature infants: Begin with 0.5 Gm fat/kg/24 hr (5 mL/kg/24 hr of 10% solution). See comments under [Pediatric Dose](#) and [Maternal/Child](#).

Prevention of fatty acid deficiency: 5 to 10 mL/kg/day of a 10% solution or 2.5 to 5 mL/kg/day of a 20% solution. 8% to 10% of caloric input should be supplied by IV fat emulsion. Essential fatty acid deficiency accompanied by stress may require an increased dose to correct the deficiency.

DOSE ADJUSTMENTS

Normal renal function required. Reduced dose may be indicated.

DILUTION

Follow manufacturer's specific instructions for preparation of each individual brand. Must be given as prepared by manufacturer; check labels for aluminum content; see [Precautions](#). Use only freshly opened solutions; discard remainder of partial dose. Do not use if there appears to be an oiling out of the emulsion. **Intralipid 30% is not to be given by direct IV infusion.** Packaged for bulk use in a pharmacy admixture program. Must be specifically combined with dextrose solutions and amino acids (TPN) so total fat content does not exceed 20%. Prepared for an individual patient in the pharmacy. Lipids may

extract phthalates from phthalate-plasticized PVC. Non-phthalate infusion sets recommended; available with most commercial products.

Filters: Do not use filters; will disturb emulsion. FDA suggests the use of a 1.2-micron filter for admixtures containing lipids (e.g., 3 in 1).

Storage: Must be stored at temperatures not exceeding 25° C (77° F). Specific storage conditions required (see literature). Do not freeze. Manufacturer recommends admixtures (3 in 1) be refrigerated for no more than 24 hours after mixing and completely infused within 24 hours after removal from refrigeration.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends not mixing with any electrolyte or other nutrient solution. Infuse separately; do not disturb emulsion; no additives or medications are to be placed in bottle or tubing with the exception of heparin 1 to 2 units/mL (may be added before administration [activates lipoprotein lipase]). In actual practice, carbohydrates, amino acids, and fat emulsion are mixed in specific percentages and in a specific order to meet individual total parenteral nutritional needs but should be prepared in the pharmacy. Any addition of supplemental vitamins, minerals, or electrolytes (e.g., calcium, magnesium, phosphates) may cause a precipitate unless a specific order is followed. Precipitates are difficult to detect in lipids.

One source suggests the following **compatibilities (not recommended by manufacturer):**

Y-site: Specific TNA solutions may be **compatible** at the **Y-site** with specific concentrations of amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), cefazolin (Ancef), cefotaxime (Claforan), cefotetan (Cefotan), cefoxitin (Mefoxin), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytosan), cyclosporine (Sandimmune), cytarabine (ARA-C), dexamethasone (Decadron), digoxin, diphenhydramine (Benadryl), dobutamine, dopamine, enalaprilat (Vasotec IV), erythromycin (Erythrocin), famotidine (Pepcid IV), fentanyl (Sublimaze), fluconazole (Diflucan), flourouracil (5-FU), furosemide (Lasix), gentamicin, granisetron (Kytril), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), insulin (regular), isoproterenol (Isuprel), leucovorin calcium, lidocaine, magnesium sulfate, mannitol, meperidine (Demerol), meropenem (Merrem IV), mesna (Mesnex), methotrexate, methylodopate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), metronidazole (Flagyl IV), mitoxantrone (Novantrone), morphine, nafcillin (Nallpen), nitroglycerin IV, nitroprusside sodium, norepinephrine (Levophed), octreotide (Sandostatin), oxacillin (Bactocill), paclitaxel (Taxol), penicillin G potassium, piperacillin/tazobactam (Zosyn), potassium chloride (KCl), prochlorperazine (Compazine), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, sulfamethoxazole/trimethoprim, tacrolimus (Prograf), ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

May be administered via a Y-tube or three-way stopcock near the infusion site. Rates of both solutions (fat emulsion and amino acid products) should be controlled by infusion pumps. Keep fat emulsion line higher than all other lines (has low specific gravity and could run up into other lines). Do not use filters; will disturb emulsion. FDA suggests use of at least a 1.2-micron filter for admixtures containing lipids (e.g., 3 in 1); precipitates difficult to detect in lipids.

Adult: 10%: 1 mL/min or 0.1 Gm fat/min for the first 15 to 30 minutes. If no untoward effects, the dose may be increased to 2 mL/min. The daily dose should not exceed 2.5 Gm fat/kg (25 mL of 10% solution per kg). On the first day of therapy, a maximum of 500 mL of 10% solution is recommended.

20%: 0.5 mL/min or 0.1 Gm fat/min for the first 15 to 30 minutes. If no untoward effects, the rate may be increased to 1 mL/min. The daily dose should not exceed 2.5 Gm fat/kg (12.5 mL of 20% solution per kg). On the first day of therapy, a maximum of 500 mL of 20% solution is recommended.

Premature infants: 0.5 Gm fat/kg/24 hr (5 mL of 10% or 2.5 mL of 20% per 24 hours). Adjust rate and/or increase amount based on the infant's ability to eliminate fat. See comments under [Usual Dose](#) and [Maternal/Child](#).

Pediatric: 10%: 0.1 mL/min for the first 10 to 15 minutes. Reduce initial rate to 0.05 mL/min for a 20% solution. If no untoward effects, rate may be increased to administer 1 mL/kg/hr of 10% solution or 0.5 mL/kg/hr of 20%. One source suggests a maximum rate of 0.17 Gm/kg/hr. An infusion pump is recommended. Do not exceed a rate of 50 mL/hr (20%) or 100 mL/hr (10%).

ACTIONS

An isotonic nutrient. Used as a source of calories and essential fatty acids. Contains emulsified fat particles about 0.4 to 0.5 micron in size. Total caloric value (fat, phospholipid, and glycerol) is 1.1 cal/mL for the 10% emulsion and 2 cal/mL for the 20% emulsion. Metabolized and used as a source of energy. Increases heat production and oxygen consumption. Decreases respiratory quotient. Cleared from the bloodstream by a process not fully understood.

INDICATIONS AND USES

To provide additional calories and essential fatty acids for patients requiring parenteral nutrition whose caloric requirements cannot be met by glucose or who will be receiving parenteral nutrition over extended periods (over 5 days usually). ■ Prevent essential fatty acid deficiency.

CONTRAINDICATIONS

Any condition that disturbs normal fat metabolism, such as pathologic hyperlipemia, lipid nephrosis, and acute pancreatitis with hyperlipemia. ■ Severe egg allergies.

PRECAUTIONS

Isotonic; may be administered by a peripheral vein or central venous infusion. ■ Fatty acids displace bilirubin bound to albumin. Use caution in jaundiced or premature infants. ■ Use caution in pulmonary disease, liver disease, anemia, or blood coagulation disorders, or when there is any danger of fat embolism. ■ Some solutions may contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. ■ See [Maternal/Child](#).

Monitor: Monitor lipids routinely; lipemia should clear daily. ■ Monitor hemogram, blood coagulation, liver function tests, triglycerides, and platelet count, especially in neonates. Discontinue use for significant abnormality. ■ See [Maternal/Child](#).

Maternal/Child: Category C: use in pregnancy only when clearly needed; safety not established. ■ Use caution if emulsion is administered to a woman who is breast-feeding. ■ Use extreme caution in neonates; death from intravascular fat accumulation in the lungs has occurred. Strict adherence to dose and rate of administration is imperative. Premature and small-for-gestational-age infants have poor clearance. Administration of less than the maximum recommended dose should be considered in these patients. Monitor serum triglycerides and/or plasma free fatty acid levels to assess infant's ability to eliminate infused fat from the circulation. Frequent, even daily, platelet counts are recommended in neonatal patients receiving TPN with IV fat emulsion.

DRUG/LAB INTERACTIONS

No specific information available; see [Dilution](#).

SIDE EFFECTS

Anaphylaxis, back pain, chest pain, cyanosis, a delayed overloading syndrome (focal seizures, fever, leukocytosis, splenomegaly, shock), dizziness, dyspnea, elevated tem-

perature, flushing, headache, hypercoagulability, hyperlipemia, nausea and vomiting, pressure over eyes, sepsis (from contamination of IV catheter), sleepiness, sweating, thrombophlebitis (from concurrent hyperalimentation fluids), thrombocytopenia in neonates (rare), and many others.

ANTIDOTE

Notify physician of all side effects. Many will be treated symptomatically. Treat hypersensitivity reactions promptly and resuscitate as necessary. For accidental overdose, stop the infusion. Obtain blood sample for inspection of plasma, triglyceride concentration, or measurement of plasma light-scattering activity by nephelometry. Repeat blood samples until the lipid has cleared. Stop infusion immediately for any signs of acute respiratory distress. May represent pulmonary embolus or interstitial pneumonitis, which may be caused by an unseen precipitate of electrolytes (e.g., calcium and phosphates) in the solution.

FENOLDOPAM MESYLATE

(feh-NOL-doh-pam MES-ih-layt)

Antihypertensive
Vasodilator

Corloпам

USUAL DOSE

Must be given as a continuous infusion. Avoid hypotension and rapid decreases in BP. Doses ranging from 0.01 to 1.6 mcg/kg/min were studied in clinical trials. Most references suggest an initial dose of 0.1 mcg/kg/min. Doses below 0.1 mcg/kg/min have modest effects and may have minimal use. Initial doses of 0.03 to 0.1 mcg/kg/min have been associated with less reflex tachycardia than initial doses of more than 0.3 mcg/kg/min. As the dose increases, there is a greater and more rapid reduction in BP. To achieve the desired reduction in BP, titrate initial dose upward or downward in increments of 0.05 to 0.1 mcg/kg/min, no more frequently than every 15 minutes. Extend duration of intervals as desired BP goal is approached. Maximum effect of each range usually attained within 15 minutes. When the desired response is achieved, fenoldopam may be discontinued gradually or abruptly; rebound elevation of BP has not been observed. See [Precautions](#) and [Drug/Lab Interactions](#).

See product insert for doses used in clinical trials for mild to moderate hypertension and hypertensive emergency. Manufacturer provides extensive charts documenting effects of a wide range of doses but does not suggest a standard initial dose. The manufacturer states that the initial dose may be chosen from the appropriate table and suggests selecting a dose that corresponds to the desired magnitude and rate of BP reduction.

PEDIATRIC DOSE

See comments under [Usual Dose](#). Usual starting dose in trials was 0.2 mcg/kg/min, with an effect on mean arterial pressure (MAP) seen in 5 minutes and a maximal effect seen after 20 to 25 minutes. Increased doses of up to 0.3 to 0.5 mcg/kg/min every 20 to 30 minutes were well tolerated. Tachycardia without further decrease in MAP occurred at doses greater than 0.8 mcg/kg/min. See [Maternal/Child](#).

DOSE ADJUSTMENTS

Dose adjustment is not required in end-stage renal disease; in patients on continuous ambulatory peritoneal dialysis (CAPD); in severe hepatic failure; or by age, gender, or race. Effects of hemodialysis have not been evaluated. ■ Caution and lower-end dosing suggested in elderly patients. Consider decreased organ function and concomitant disease or drug therapy.

DILUTION

Each 10 mg (1 mL) must be diluted with 250 mL of NS or D5W and given as a continuous infusion. (10 mg in 250 mL, 20 mg in 500 mL, or 40 mg in 1,000 mL all yield 40 mcg/mL.) Use of an infusion pump is recommended. For fluid-restricted patients, concentrations of 100 mcg/mL administered through a syringe pump have been used. 10 mg in 100 mL NS or D5W yields 100 mcg/mL.

Pediatric dilution: Mix to yield a final concentration of 60 mcg/mL (6 mg in 100 mL, 15 mg in 250 mL, or 30 mg in 500 mL of D5W or NS). Use of an infusion pump capable of delivering low infusion rates is required.

Storage: Store unopened ampules at CRT. Diluted solution is stable at CRT and normal light conditions for 24 hours. Discard any solution not used within 24 hours of preparation.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply. Consider specific use and need for continuous adjustment.

One source suggests the following **compatibilities**:

Y-site: Alfentanil (Alfenta), amikacin (Amikin), aminocaproic acid (Amicar), amiodarone (Nexterone), ampicillin/sulbactam (Unasyn), argatroban, atracurium (Tracrium), atropine, aztreonam (Azactam), butorphanol (Stadol), calcium gluconate, cefazolin (Ancef), cefepime (Maxipime), cefotaxime (Claforan), cefotetan (Cefotan), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), chlorpromazine (Thorazine), ciprofloxacin (Cipro IV), cisatracurium (Nimbex), clindamycin (Cleocin), dexmedetomidine (Precedex), digoxin (Lanoxin), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, dolasetron (Anzemet), dopamine, doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), ephedrine, epinephrine (Adrenalin), erythromycin (Erythrocin), esmolol (Brevibloc), famotidine (Pepcid IV), fentanyl (Sublimaze), fluconazole (Diflucan), gentamicin, granisetron (Kytril), heparin, hetastarch in electrolytes (Hexend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), isoproterenol (Isuprel), labetalol, levofloxacin (Levaquin), lidocaine, linezolid (Zyvox), lorazepam (Ativan), magnesium, mannitol (Osmitrol), meperidine (Demerol), metoclopramide (Reglan), metronidazole (Flagyl IV), micafungin (Mycamine), midazolam (Versed), milrinone (Primacor), morphine, nalbuphine, naloxone (Narcan), nicardipine (Cardene IV), nitroglycerin IV, norepinephrine (Levophed), ondansetron (Zofran), pancuronium, phenylephrine (Neo-Synephrine), piperacillin/tazobactam (Zosyn), potassium chloride, procainamide (Pronestyl), promethazine (Phenergan), propofol (Diprivan), propranolol, quinupristin/dalfopristin (Synercid), ranitidine (Zantac), remifentanyl (Ultiva), rocuronium (Zemuron), sufentanil (Sufenta), sulfamethoxazole/trimethoprim, theophylline, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vecuronium, verapamil.

RATE OF ADMINISTRATION

Do not give as a bolus injection; must be given as an infusion. Use of a calibrated, mechanical infusion pump is recommended for accurate, reliable delivery of desired infusion rate. Avoid hypotension and rapid decreases in BP. Infusion may be abruptly discontinued or gradually tapered as indicated by patient condition and/or use of other antihypertensive agents. See the following chart for desired infusion rates.

Fenoldopam Adult Infusion Rate Guidelines (40 mcg/mL dilution)					
Note: Concentration is different from Pediatric Patients (See Pediatric chart on next page)					
Body Weight (kg)	Desired Fenoldopam Dose				
	0.025 mcg/kg/min	0.05 mcg/kg/min	0.1 mcg/kg/min	0.2 mcg/kg/min	0.3 mcg/kg/min
	Infusion Rates (mL/hr) of 40 mcg/mL solution				
40 kg	1.5 mL/hr	3 mL/hr	6 mL/hr	12 mL/hr	18 mL/hr
50 kg	1.9 mL/hr	3.8 mL/hr	7.5 mL/hr	15 mL/hr	22.5 mL/hr
60 kg	2.3 mL/hr	4.5 mL/hr	9.0 mL/hr	18 mL/hr	27 mL/hr
70 kg	2.6 mL/hr	5.3 mL/hr	10.5 mL/hr	21 mL/hr	31.5 mL/hr
80 kg	3 mL/hr	6 mL/hr	12 mL/hr	24 mL/hr	36 mL/hr
90 kg	3.4 mL/hr	6.8 mL/hr	13.5 mL/hr	27 mL/hr	40.5 mL/hr
100 kg	3.8 mL/hr	7.5 mL/hr	15 mL/hr	30 mL/hr	45 mL/hr
110 kg	4.1 mL/hr	8.3 mL/hr	16.5 mL/hr	33 mL/hr	49.5 mL/hr
120 kg	4.5 mL/hr	9 mL/hr	18 mL/hr	36 mL/hr	54 mL/hr
130 kg	4.9 mL/hr	9.8 mL/hr	19.5 mL/hr	39 mL/hr	58.5 mL/hr
140 kg	5.3 mL/hr	10.5 mL/hr	21 mL/hr	42 mL/hr	63 mL/hr
150 kg	5.6 mL/hr	11.3 mL/hr	22.5 mL/hr	45 mL/hr	67.5 mL/hr

Fenoldopam Adult Infusion Rate Guidelines (40 mcg/mL dilution) (continued)						
Note: Concentration is different from Pediatric Patients (See Pediatric chart on next page)

ACTIONS

A peripherally acting rapid-acting vasodilator. Is an agonist at the D₁ receptor and binds with moderate affinity to the alpha₂ adrenoreceptor. Causes a dose-dependent fall in systolic and diastolic BP. May cause a reflex increase in HR. Onset of action begins within 5 minutes, and with continuous infusion, steady state concentrations (peak effects) are reached in 15 to 20 minutes. Increases renal blood flow by dilating both afferent and efferent arterioles. Maintains or increases glomerular filtration rate (GFR) in normotensive or hypertensive patients with or without renal insufficiency. Beneficial effects have not been seen in patients with heart failure, hepatic disease, or severe renal disease. Increases sodium excretion and decreases sodium reabsorption. Increases potassium, calcium, and phosphate excretion, with or without an increase in GFR. Elimination half-life is about 5 minutes. Metabolized in the liver primarily by conjugation (without cytochrome P₄₅₀ enzymes). Primarily eliminated in urine; some excretion in feces.

INDICATIONS AND USES

Adult patients: In-hospital, short-term (up to 48 hours) management of severe hypertension when rapid, but quickly reversible, emergency reduction of BP is indicated, including malignant hypertension with deteriorating end-organ function.

Pediatric patients: In-hospital, short-term (up to 4 hours) for reduction in BP.

Unlabeled uses: Renal protection before study with contrast dye.

CONTRAINDICATIONS

Manufacturer states, "None known."

PRECAUTIONS

Use limited to the hospital. Adequate personnel and appropriate equipment must be available for continuous monitoring. ■ Use extreme caution in patients with glaucoma or intraocular hypertension. Has caused a dose-dependent increase in intraocular pressure. ■ Causes a dose-related tachycardia with infusion rates above 0.1 mcg/kg. May diminish over time in adults but is consistent at higher doses. Has not been reported, but could lead to ischemic cardiac events or worsened heart failure. ■ Tachycardia occurred in pediatric patients at doses greater than or equal to 0.8 mcg/kg/min. ■ May produce symptomatic hypotension. ■ Although hypotension should be avoided in all patients, use extreme caution in patients with an acute cerebral infarction or hemorrhage. ■ The effect of fenoldopam in the presence of increased intracranial pressure has not been studied. ■ Rapidly decreases serum potassium leading to hypokalemia; see **Monitor**. ■ Use caution; contains sulfites. Sulfite sensitivity is seen more frequently in asthmatic individuals. ■ See **Drug/Lab Interactions**.

Monitor: Determine patency of vein; avoid extravasation. In adults, monitor BP and HR at least every 15 minutes. Avoid hypotension. More frequent monitoring may be required, but intra-arterial BP monitoring has not been required. ■ In pediatric patients, monitoring of BP and HR should be continuous. In studies, intra-arterial monitoring was utilized. ■ Monitor serum electrolytes frequently; monitoring of serum potassium is recommended every 6 hours. Has reduced serum potassium values to less than 3 mEq/L in less than 6 hours. Oral or intravenous supplements are required. ■ Transfer to oral antihypertensive agents when BP is stable. May be added during fenoldopam infusion or following its discontinuation; monitor effects carefully. ■ See [Precautions](#) and [Drug/Lab Interactions](#).

Patient Education: Report IV site burning or stinging promptly. ■ Request assistance to ambulate.

Maternal/Child: Category B: use only if clearly needed. ■ Use caution during breast-feeding; not known if fenoldopam is secreted in breast milk (is secreted in milk of rats). ■ Antihypertensive effects have been studied in pediatric patients under 1 month of age (at least 2 kg or full term) to 12 years of age. Pharmacokinetics are independent of age when corrected for body weight. Clinical studies did not include adolescents (12 to 16 years of age). Dose selection for this group should consider clinical condition and concomitant drug therapy.

Elderly: Dose selection should be cautious; see [Dose Adjustments](#). ■ Response similar to other age-groups.

DRUG/LAB INTERACTIONS

No specific drug interaction studies have been conducted. ■ Concurrent use not recommended with **beta-adrenergic blocking agents** (e.g., atenolol [Tenormin], esmolol [Brevibloc], metoprolol [Lopressor], propranolol). May cause unexpected hypotension from beta-blocker inhibition of the reflex response to fenoldopam (e.g., tachycardia). ■ Has been given safely with digoxin and sublingual nitroglycerin. ■ Limited experience with concomitant use of **other antihypertensive agents** (e.g., ACE inhibitors [e.g., enalapril (Vasotec)], alpha₁-adrenergic blockers [e.g., phentolamine (Regitine), prazosin (Mini-press)], calcium channel blockers [e.g., diltiazem (Cardizem), verapamil], **or thiazide or loop diuretics** [e.g., chlorothiazide (Diuril), furosemide (Lasix), torsemide (Demadex)]).

SIDE EFFECTS

Dose-dependent side effects may include hypotension with resulting tachycardia, flushing, headache, and nausea. Additional side effects unrelated to dose include abdominal pain or fullness, anxiety, back pain, constipation, diaphoresis, diarrhea, dizziness, increased SCr, injection site reaction, insomnia, nasal congestion, postural hypotension, urinary infection, and vomiting occurred in up to 5% of patients. Additional side effects have been reported in 0.5% to 5% of patients (see literature).

Major: Cardiac arrhythmias (e.g., bradycardia, extrasystoles, ST-T wave abnormalities, tachycardia), hypotension, hypokalemia, and myocardial infarction can occur with average doses.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically. Use oral and/or intravenous potassium to treat hypokalemia. Reduce dose gradually as desired BP is reached. Discontinue fenoldopam immediately for excessive hypotension. Half-life is short. Recovery should begin within 5 to 15 minutes; support patient as indicated (e.g., Trendelenburg position, IV fluids if appropriate). With short half-life the need for vasopressors is unlikely. Discontinue fenoldopam and treat life-threatening arrhythmias as indicated.

FENTANYL CITRATE

(FEN-tah-nil SIT-rayt)

Opioid analgesic
(agonist)
Anesthesia adjunct

Fentanyl, Fentanyl Citrate PF, Sublimaze

pH 4 to 7.5

USUAL DOSE

In all situations, use smallest effective dose at maximum intervals.

Adjunct to regional anesthesia: 50 to 100 mcg (0.05 to 0.1 mg).

Adjunct to general anesthesia: Low dose: 2 mcg/kg of body weight.

Moderate dose: 2 to 20 mcg/kg of body weight. Additional doses of 25 to 100 mcg may be administered as needed.

High dose: 20 to 50 mcg/kg of body weight. Additional doses of 25 mcg to one half the initial loading dose may be administered as needed.

General anesthetic: 50 to 100 mcg/kg of body weight administered with oxygen and a muscle relaxant.

Pain management (unlabeled): An initial dose of 25 to 100 mcg (0.025 to 0.1 mg). Follow with a continuous infusion of 1 to 2 mcg/kg/hr. Titrate to effect.

PEDIATRIC DOSE

Adjunct to general anesthesia in pediatric patients over 2 years of age: 1 to 3 mcg/kg/dose over 3 to 5 minutes. May repeat in 30 to 60 minutes. To give as an infusion, begin with 1 mcg/kg/hr and titrate to effect. Maximum dose is 3 mcg/kg/hr. See **Maternal/Child**.

Pain management (unlabeled): 0.5 to 2 mcg/kg/dose every 1 to 2 hours as needed or 0.5 to 2 mcg/kg/hr as a continuous infusion. Titrate to effect.

DOSE ADJUSTMENTS

Reduce dose in patients receiving other CNS depressants, such as general anesthetics, alcohol, anticholinergics, antihistamines, barbiturates, cimetidine (Tagamet), hypnotics, sedatives, psychotropic agents, and narcotic analgesics. When administered with narcotics, reduce initial narcotic dose to one fourth to one third of normal. ■ Reduce dose or increase intervals for elderly, debilitated, and poor-risk patients or those with impaired pulmonary, hepatic, or renal function. ■ See **Drug/Lab Interactions**.

DILUTION

Small volumes may be given undiluted (usually by the anesthesiologist). Further dilution with at least 5 mL of SWFI or NS for injection to facilitate titration is appropriate. Other IV solutions may be used. May be given through Y-tube or three-way stopcock of infusion set.

Storage: Store at room temperature and protect from light before dilution. Use promptly.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Y-site: Abciximab (ReoPro), alprostadil, amiodarone (Nexterone), amphotericin B cholesteryl (Amphotec), anidulafungin (Eraxis), argatroban, atracurium (Tracrium), atropine, bivalirudin (Angiomax), caffeine citrate, caspofungin (Cancidas), ceftaroline (Teflaro), cisatracurium (Nimbex), dexamethasone (Decadron), dexmedetomidine (Precedex), diazepam (Valium), diltiazem (Cardizem), diphenhydramine (Benadryl), dobutamine, dopamine, doripenem (Doribax), doxapram (Dopram), enalaprilat (Vasotec IV), epinephrine (Adrenalin), esmolol (Brevibloc), etomidate (Amidate), fenoldopam (Corlopan), furosemide (Lasix), heparin, hetastarch in electrolytes (Hextend), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), 6% hydroxyethyl starch (Volumen), ketorolac (Toradol), labetalol, levofloxacin (Levaquin), linezolid (Zyvox), lorazepam (Ativan), metoclopramide (Reglan), midazolam (Versed), milrinone (Prima-

cor), morphine, nafcillin (Nallpen), nesiritide (Natreacor), nicardipine (Cardene IV), nitroglycerin IV, norepinephrine (Levophed), oxaliplatin (Eloxatin), palonosetron (Aloxi), pancuronium, phenobarbital (Luminal), potassium chloride (KCl), propofol (Diprivan), ranitidine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), vecuronium.

RATE OF ADMINISTRATION

Administer over 1 to 5 minutes. Too-rapid administration may result in apnea or respiratory paralysis. Rate must be titrated by desired dose and patient response.

ACTIONS

An opium derivative, narcotic analgesic, which is a descending CNS depressant. Approximately 100 times more potent than morphine milligram for milligram. It has definite respiratory-depressant actions that outlast its analgesic effect. In healthy individuals, respiratory rate returns to normal more quickly than with other opiates. Effective within one circulation time and lasts about 30 minutes. Effects are cumulative with repeat doses. Has little hypnotic activity, and histamine release rarely occurs. Cardiovascular system remains stable. Depresses many other senses or reflexes. Half-life is approximately 3.6 hours. Metabolized in the liver and excreted in the urine. Crosses the placental barrier. May be secreted in breast milk.

INDICATIONS AND USES

Adjunct to general and regional anesthesia. ■ Short-term analgesia during perioperative period. ■ Useful in short-duration minor surgery in outpatients and in diagnostic procedures or treatments that require the patient to be awake or very lightly anesthetized (e.g., bronchoscopy, radiologic studies, burn dressings, cystoscopy). ■ For administration with a neuroleptic such as droperidol as an anesthetic premedication, for the induction of anesthesia, and as an adjunct in the maintenance of general and regional anesthesia. ■ For use as an anesthetic agent with oxygen in selected high-risk patients, such as those undergoing open heart surgery or certain complicated neurologic or orthopedic procedures.

CONTRAINDICATIONS

Patients with known intolerance to fentanyl. In general, narcotic analgesics are also contraindicated in acute or severe bronchial asthma and if an upper airway obstruction or significant respiratory depression is present. Fentanyl is not recommended for use in labor and delivery.

PRECAUTIONS

Schedule II opioid agonists, including hydromorphone, morphine, oxymorphone, oxycodone, fentanyl, and methadone, have the highest potential for abuse and risk of producing respiratory depression. Alcohol, CNS depressants, and other opioids potentiate the respiratory depressant effects of hydromorphone, increasing the risk of respiratory depression that might result in death; see [Drug/Lab Interactions](#). ■ Primarily used by or under the direct observation of the anesthesiologist. ■ Use caution in the elderly, in patients with impaired hepatic or renal function, and in patients with pulmonary disease; reduced dose may be indicated. ■ Use extreme caution in craniotomy, head injury, and increased intracranial pressure. ■ Respiratory depression may cause an increased P_{CO_2} , cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. ■ Symptoms of acute abdominal conditions may be masked. ■ Use caution in patients with bradyarrhythmias. ■ Cough reflex is suppressed. ■ Use caution in patients with benign prostatic hypertrophy, diarrhea resulting from poisoning until toxic material is eliminated, hypersensitivity to opiates, and in premature infants or labor and delivery of premature infants.

Monitor: Oxygen, controlled respiratory equipment, naloxone (Narcan), and neuromuscular blocking agents (e.g., succinylcholine) must always be available. May cause rigidity of respiratory muscles; may require a muscle relaxant to permit artificial ventilation. ■ Observe patient frequently, monitor vital signs and oxygenation. Patient will appear to be asleep and may forget to breathe unless commanded to do so. ■ Keep patient supine; orthostatic hypotension and fainting may occur. ■ See [Precautions](#).

Patient Education: Avoid alcohol or other CNS depressants (e.g., antihistamines, diazepam [Valium]). ■ Blurred vision, dizziness, drowsiness, or light-headedness may occur; request assistance with ambulation. ■ Review all medications for interactions.

Maternal/Child: Category C: safety for use in pregnancy not established; has impaired fertility and had embryocidal effects in rats. ■ Postpone breast-feeding for at least 4 to 6 hours after use of fentanyl. ■ Safety for use in pediatric patients under 2 years of age not established; has caused chest wall rigidity in neonates and may be associated with methemoglobinemia and hypotension in premature neonates; see **Precautions**.

Elderly: See **Dose Adjustments** and **Precautions**. ■ May markedly decrease pulmonary ventilation. ■ May be more sensitive to effects (e.g., respiratory depression, urinary retention, constipation). ■ Lower doses may provide effective analgesia. ■ Consider age-related organ impairment; may delay postoperative recovery.

DRUG/LAB INTERACTIONS

Concurrent use of **diazepam** (Valium) with higher doses of fentanyl may produce vasodilation, prolonged hypotension, and result in delayed recovery. ■ CNS toxicity increased by **antidepressants** (e.g., amitriptyline [Elavil], imipramine [Tofranil], nortriptyline [Aventyl]), **beta-adrenergic blocking agents** (e.g., propranolol), **MAO inhibitors** (e.g., selegiline [Eldepryl]), **neuromuscular blocking agents** (e.g., atracurium [Tracrium]), and **phenothiazines** (e.g., chlorpromazine [Thorazine]). Reduced dose of both drugs may be indicated. ■ Cardiovascular depression may result from concurrent use of **nitrous oxide and high-dose fentanyl**. ■ Monitor closely for S/S of respiratory depression and CNS depression with concurrent use of **protease inhibitors** (e.g., saquinavir [Invirase], ritonavir [Norvir]). ■ Concurrent use with **droperidol** (Inapsine) may cause hypotension and decrease pulmonary arterial pressure. ■ CNS and cardiovascular effects may be additive with concurrent use of tranquilizing agents (**anti-anxiety agents** [e.g., diazepam (Valium), midazolam (Versed)]). Consider differences in the duration of action of each drug and use caution.

SIDE EFFECTS

Bradycardia, constipation, diaphoresis, hypersensitivity reactions, hypertension, hypotension, hypothermia, increased intracranial pressure, nausea, orthostatic hypotension, respiratory depression (slight), respiratory muscle rigidity, urinary retention, vomiting.

Overdose: Anaphylaxis, apnea, cardiac arrest, circulatory collapse, coma, excitation, hypotension (severe), inverted T wave on ECG, myocardial depression (severe), pinpoint pupils, respiratory depression (severe), tachycardia, death.

ANTIDOTE

Buprenorphine is sometimes used before the end of surgery to reverse fentanyl-induced anesthesia. With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. Naloxone (Narcan) will reverse serious respiratory depression. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Treat hypotension with a Trendelenburg position and IV fluids or vasopressors (e.g., dopamine, norepinephrine [Levophed]) as needed. A fast-acting muscle relaxant (e.g., succinylcholine) may be required to facilitate ventilation. Use atropine to treat bradycardia. Muscle rigidity during anesthesia induction or surgery must be controlled with neuromuscular blocking agents (e.g., atracurium [Tracrium], vecuronium) and controlled ventilation with oxygen. Use a neuromuscular blocking agent prophylactically to prevent muscle rigidity or to induce muscle relaxation after rigidity occurs. Resuscitate as necessary.

FERUMOXYTOL

(FER-ue-MOX-i-tol)

Feraheme**Antianemic
Iron supplement****pH 6 to 8****USUAL DOSE**

An initial IV injection of 510 mg followed by a second IV injection of 510 mg 3 to 8 days later. After 1 month and an evaluation of the hematologic response, the recommended dose may be repeated in patients with persistent or recurrent iron deficiency anemia. Administer to hemodialysis patients at least 1 hour into dialysis session, after blood pressure has stabilized.

DOSE ADJUSTMENTS

No dose adjustment is required and no gender differences have been observed.

DILUTION

Available in a single-use vial containing 510 mg of elemental iron in 17 mL (30 mg/mL of elemental iron). Black to reddish brown in color. Administer as an undiluted IV injection.

Filters: Specific information not available.

Storage: Store unopened vials at CRT.

COMPATIBILITY

Specific information not available. Given as an IV injection. Consider flushing the IV line with NS before and after injection.

RATE OF ADMINISTRATION

May be administered at a rate up to 30 mg/sec (1 mL/sec). At this rate, a dose of 510 mg would be administered over a minimum of 17 seconds.

ACTIONS

An iron replacement product. A superparamagnetic iron oxide that is coated with a carbohydrate shell. The shell helps to isolate the bioactive iron from plasma components until the iron-carbohydrate complex enters the reticuloendothelial system macrophages of the liver, spleen, and bone marrow. The iron is released from the complex within the macrophages and then either enters the intracellular storage iron pool (e.g., ferritin) or is transferred to plasma transferrin for transport to erythroid precursor cells for incorporation into hemoglobin. Exhibits dose-dependent, capacity-limited elimination from plasma with a half-life of approximately 15 hours.

INDICATIONS AND USES

Treatment of iron deficiency anemia in adult patients with chronic kidney disease (CKD).

CONTRAINDICATIONS

Known hypersensitivity to ferumoxytol or any of its components. ■ Should not be used in patients with evidence of iron overload or in patients with anemia not caused by iron deficiency.

PRECAUTIONS

Use only when truly indicated. Excessive therapy with parenteral iron can lead to excess storage of iron with the possibility of iatrogenic hemosiderosis. One source recommends discontinuing oral iron before administering parental iron. ■ Life-threatening hypersensitivity reactions, including anaphylaxis, have been reported. Reactions have occurred after the first dose or subsequent doses of ferumoxytol. Facilities for monitoring the patient and responding to any medical emergency must be available. ■ Clinically significant hypotension may occur following injection. ■ May transiently affect the diagnostic ability of MRI studies. Anticipated MRI studies should be conducted before administration of ferumoxytol. Alteration of MRI studies may last for up to 3 months. See manufacturer's prescribing information if MRI studies must be obtained after ferumoxytol administration. Ferumoxytol does not interfere with x-ray, computed tomography (CT),

positron emission tomography (PET), single photon emission computed tomography (SPECT), ultrasound, or nuclear medicine imaging.

Monitor: Keep patient lying down after injection to prevent postural hypotension. BP should be stable in patients receiving hemodialysis before dose is administered. Continue to monitor BP following dose administration. ■ Observe for hypersensitivity reactions (e.g., anaphylaxis, cardiac or cardiopulmonary arrest, clinically significant hypotension, pruritus, rash, syncope, unresponsiveness, urticaria, or wheezing) for at least 30 minutes and until clinically stable after the injection. ■ Evaluate hematologic response (hemoglobin, hematocrit, ferritin, iron, and transferrin saturation) at least 1 month after the second injection. Regularly monitor response during parenteral iron therapy. Avoid evaluation of therapy immediately after therapy. In the 24 hours following administration, laboratory assays may overestimate serum iron and transferrin-bound iron by also measuring the iron in the ferumoxytol complex.

Patient Education: Review any possible reactions to past parenteral iron therapy. ■ Promptly report S/S of a hypersensitivity reaction (e.g., hives, itching, rash, shortness of breath, wheezing).

Maternal/Child: Category C: use during pregnancy only if potential benefit to the mother justifies the potential risk to the fetus. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: No overall difference in safety and efficacy were observed between older and younger patients. However, greater sensitivity of older patients cannot be ruled out.

DRUG/LAB INTERACTIONS

Drug-drug interaction studies have not been conducted. ■ May reduce the absorption of concomitantly administered **oral iron** preparations.

SIDE EFFECTS

The most common side effects are constipation, diarrhea, dizziness, hypotension, nausea, and peripheral edema. Serious side effects may include hypersensitivity reactions (e.g., anaphylaxis, pruritus, rash, urticaria, or wheezing) and hypotension. Other reported side effects are abdominal pain, back pain, chest pain, cough, dyspnea, ecchymosis, edema, fever, headache, infusion site swelling, muscle spasm, vomiting.

Post-Marketing: Anaphylactic/anaphylactoid reactions, angioedema, cardiac/cardiopulmonary arrest, CHF, cyanosis, hypotension (clinically significant), ischemic myocardial events, loss of consciousness, syncope, tachycardia/rhythm abnormalities, and unresponsiveness.

ANTIDOTE

Notify the physician of significant side effects. Treat hypersensitivity reactions, or resuscitate as necessary. Epinephrine (Adrenalin) and diphenhydramine (Benadryl) should always be available. In overdose, monitor CBC, iron studies, vital signs, blood gases, glucose, and electrolytes. Maintain fluid and electrolyte balance. Correct acidosis with sodium bicarbonate. Deferoxamine is an iron chelating agent and may be useful in iron toxicity or overdose. Dialysis will not remove iron alone but will remove the iron deferoxamine complex and is indicated if oliguria or anuria is present.

FIBRINOGEN CONCENTRATE (HUMAN)

Coagulation factor I

(fi-**BRIN**-oh-gen **KON**-sen-trayt)**RiaSTAP**

USUAL DOSE

Individualize dosing, duration of dosing, and frequency of administration based on the extent of bleeding, laboratory values, and clinical condition. A target fibrinogen level of 100 mg/dL should be maintained until hemostasis is obtained.

Dose when baseline fibrinogen level IS known: Calculate individually for each patient based on the target plasma fibrinogen level, which is based on the type of bleeding, actual measured plasma fibrinogen level, and body weight using the following formula:

$$\text{Dose (mg/kg)} = \frac{(\text{Target level [mg/dL]} - \text{Measured level [mg/dL]})}{1.7 \text{ (mg/dL per mg/kg body weight)}}$$

Dose when baseline fibrinogen level IS NOT known: 70 mg/kg.

DILUTION

Available as a single-use vial containing 900 to 1,300 mg lyophilized fibrinogen concentrate powder. Fibrinogen potency for each lot is printed on the vial label and carton. Bring fibrinogen concentrate to room temperature. Reconstitute with 50 mL SWFI. Gently swirl until the powder is completely dissolved. Solution should be colorless and may be clear or slightly opalescent. Do not shake. Administer within 24 hours of reconstitution.

Filters: Specific information not available.

Storage: Store in carton between 2° and 25° C (36° and 77° F). Protect from light. Do not freeze in powder or reconstituted form. Do not use beyond expiration date on vial. Reconstituted solution is stable for 24 hours at CRT. Discard partially used vials.

COMPATIBILITY

Manufacturer states, “Do not mix with other medicinal products or intravenous solutions, and should be administered through a separate injection site.”

RATE OF ADMINISTRATION

A single dose is to be given at a rate not to exceed 5 mL/min.

ACTIONS

Fibrinogen (factor I) is a soluble plasma glycoprotein made from cryoprecipitate derived from pooled human plasma. It is a physiologic substrate of three enzymes—thrombin, factor XIIIa, and plasmin—and is an essential part of the coagulation cascade required for forming blood clots and preventing bleeding. In patients with congenital fibrinogen deficiency, it replaces the missing or low coagulation factor (normal levels range from 200 to 400 mg/dL). Less than 100 mg/dL can be associated with spontaneous bleeding; without treatment, these patients are at risk for potentially life-threatening bleeding. Half-life is 78.7 ± 18.13 hours (range 55.73 to 117.26 hours).

INDICATIONS AND USES

Treatment of acute bleeding episodes in patients with congenital fibrinogen deficiency, including afibrinogenemia and hypofibrinogenemia. ■ Not indicated for use in dysfibrinogenemia (malfunction of fibrinogen in the blood).

CONTRAINDICATIONS

Known hypersensitivity to fibrinogen concentrate or its components.

PRECAUTIONS

For IV use only. ■ Administration under the supervision of a physician is recommended. ■ Severe hypersensitivity reactions, including anaphylaxis, may occur. Administer in a facility capable of monitoring the patient and responding to any medical emer-

gency. Epinephrine should be immediately available. ■ Thrombotic events (e.g., myocardial infarction, pulmonary embolism, arterial thrombosis, deep vein thrombosis) have occurred in patients with congenital fibrinogen deficiency with or without the use of fibrinogen concentrate therapy. Consider benefit versus risk. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C). Numerous steps in the manufacturing process are used to reduce the potential for infection.

Monitor: Monitor fibrinogen levels during treatment. A target fibrinogen level of 100 mg/dL should be maintained until hemostasis is obtained. ■ Observe for symptoms of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Monitor patients for S/S of thrombotic events.

Patient Education: Inform patient of risks for infectious agent transmission and of safety precautions taken during the manufacturing process. ■ Promptly report symptoms of a hypersensitivity reaction (e.g., difficulty breathing, feeling faint, hives, itching, tightness in the chest, wheezing). ■ Promptly report symptoms of a possible thrombosis (e.g., altered consciousness or speech; loss of sensation or motor power; new-onset swelling and pain in abdomen, chest, or limbs; shortness of breath).

Maternal/Child: Category C: safety and effectiveness for use during pregnancy, labor and delivery, and breast-feeding not studied; use only if clearly needed. ■ Clinical studies included 5 patients between 8 and 16 years of age; a shorter half-life and faster clearance was noted in these patients.

Elderly: Numbers in clinical studies are insufficient to determine if the elderly respond differently than younger subjects.

DRUG/LAB INTERACTIONS

No drug interaction studies have been conducted.

SIDE EFFECTS

The most common side effects reported include chills, fever, headache, hypersensitivity reactions, nausea, and vomiting. The most serious side effects include hypersensitivity reactions (e.g., anaphylaxis, dyspnea, hives, hypotension, rash, tightness of the chest, urticaria, and wheezing) and thrombotic events (e.g., myocardial infarction, pulmonary embolism, arterial thrombosis, deep vein thrombosis).

ANTIDOTE

Keep the physician informed of all side effects. Interrupt or discontinue injection, if indicated, until symptoms subside; then resume at a tolerated rate. ■ Discontinue fibrinogen concentrate if anaphylaxis or thrombotic events occur. Treat thrombotic events as indicated. Treat anaphylaxis with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol (Ventolin), IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

FILGRASTIM

(fill-GRASS-tim)

Colony-stimulating factor
Antineutropenic**G-CSF, Human Granulocyte
Colony-Stimulating Factor, Neupogen**

pH 4

USUAL DOSE

Do not use 24 hours before to 24 hours after the administration of cytotoxic chemotherapy because of the potential sensitivity of rapidly dividing myeloid cells to cytotoxic chemotherapy. Safety and effectiveness for use with concurrent radiation therapy has not been evaluated; simultaneous use should be avoided.

Cancer patients receiving myelosuppressive chemotherapy: 5 mcg/kg/24 hr as a single daily dose for 2 to 4 weeks based on specific chemotherapy protocol and post-nadir absolute neutrophil count (ANC). May be given IV by intermittent or continuous infusion, by SC injection, or as a 24-hour SC infusion. May be increased by 5 mcg/kg/24 hr increments for each chemotherapy cycle. Expect a transient increase in neutrophil counts in the first several days after initiation of therapy. Neutrophil response may not be adequate and dose increases as outlined may be required in heavily pretreated patients, those who have received prior radiation therapy to a significant portion of their medullary bone marrow (e.g., pelvis), bone marrow transplant patients, and/or those receiving dose-intensified chemotherapy. Maximum tolerated dose not identified. Up to 115 mcg/kg/24 hr has been used. In clinical trials, efficacy was observed at doses of 4 to 8 mcg/kg/day. For a sustained therapeutic response, therapy must be continued until the post-nadir ANC is 10,000/mm³ after the expected chemotherapy nadir (lowest point) has passed. Usually discontinued when this point is reached. (Average is 2 weeks or less.) In patients receiving dose-intensified chemotherapy, continue filgrastim until 2 consecutive ANCs equal to or greater than 10,000 cells/mm³ are documented. (Range is 6 to 28 days.) See [Monitor](#).

Patients with acute myeloid leukemia (AML) receiving induction or consolidation chemotherapy: Suggested dose is based on clinical studies: 5 mcg/kg/24 hr. Begin 24 hours after completion of induction or consolidation chemotherapy and continue daily until the ANC is equal to or greater than 1,000/mm³ for 3 consecutive days. May be given IV by intermittent or continuous infusion, by SC injection, or as a 24-hour SC infusion.

Bone marrow transplant (BMT): 10 mcg/kg/24 hr as an IV infusion over 4 or 24 hours or as a continuous 24-hour SC infusion. Give the first dose at least 24 hours after cytotoxic chemotherapy and 24 hours after bone marrow infusion.

DOSE ADJUSTMENTS

Reduce dose or discontinue filgrastim if ANC greater than 10,000/mm³ for 3 days. ■ During neutrophil recovery after BMT titrate the daily dose as shown in the following chart based on daily or three consecutive-day evaluations.

Guidelines for Filgrastim Dose Adjustments Following a Bone Marrow Transplant	
Absolute Neutrophil Count (ANC)	Filgrastim Dose
When ANC >1,000/mm ³ for 3 consecutive days	Reduce to 5 mcg/kg/day*
Then: If ANC remains >1,000/mm ³ for 3 more consecutive days	DC filgrastim*
Then: If ANC decreases to <1,000/mm ³	Resume at 5 mcg/kg/day

*If ANC decreases to less than 1,000/mm³ at any time during the 5 mcg/kg/day administration, increase filgrastim to 10 mcg/kg/day; the above steps should then be followed.

DILUTION

Available as a single-dose vial with either 300 mcg/mL or 480 mcg/1.6 mL and as a prefilled syringe with 300 mcg/0.5 mL or 480 mcg/0.8 mL. Remove from refrigerator to allow to warm to room temperature (never longer than 24 hours). Confirm expiration date to ensure valid product. Avoid shaking. Contains no preservatives; use sterile technique, entering vial only once to withdraw a single dose. Dilute with 10 to 50 mL D5W to concentrations of 15 mcg/mL or greater. With concentrations from 5 to 15 mcg/mL, filgrastim must be combined with albumin to a final concentration of 2 mg/mL to prevent adsorption to plastic (e.g., add 2 mL of 5% albumin to each 50 mL of D5W). Discard any unused portion. Should be clear and colorless. Do not dilute to less than 5 mcg/mL.

Storage: Store in refrigerator before use. Do not allow to freeze. Do not expose to direct sunlight. Refrigerate diluted solutions and use within 24 hours. Avoid shaking. Discard any vial or prefilled syringe left at RT for more than 24 hours.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not dilute with saline at any time; product may precipitate."

One source suggests the following **compatibilities**:

Solution: Diluted in D5W or D5W plus Albumin (human), filgrastim is **compatible** with glass bottles, PVC and polyolefin IV bags, and polypropylene syringes; see **Dilution**.

Y-site: Acyclovir (Zovirax), allopurinol (Aloprim), amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), bleomycin (Blenoxane), bumetanide, buprenorphine (Buprenex), butorphanol (Stadol), calcium gluconate, carboplatin (Paraplatin), carmustine (BiCNU), cefazolin (Ancef), cefotetan (Cefotan), ceftazidime (Fortaz), chlorpromazine (Thorazine), cisplatin (Platinol), cyclophosphamide (Cytoxan), cytarabine (ARA-C), dacarbazine (DTIC), daunorubicin (Cerubidine), dexamethasone (Decadron), diphenhydramine (Benadryl), doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), enalaprilat (Vasotec IV), famotidine (Pepcid IV), fluconazole (Diflucan), fludarabine (Fludara), gallium nitrate (Ganite), ganciclovir (Cytovene), gentamicin, granisetron (Kytril), hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), idarubicin (Idamycin), ifosfamide (Ifex), imipenem-cilastatin (Primaxin), leucovorin calcium, lorazepam (Ativan), mechlorethamine (nitrogen mustard), melphalan (Alkeran), meperidine (Demerol), mesna (Mesnex), methotrexate, metoclopramide (Reglan), mitoxantrone (Novantrone), morphine, nalbuphine, ondansetron (Zofran), potassium chloride (KCl), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, streptozocin (Zanosar), sulfamethoxazole/trimethoprim, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vinblastine, vincristine, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Recent studies suggest that an extended infusion time (intermittent or continuous) promotes increased recovery of neutrophils.

Intermittent infusion: A single dose over 15 to 30 minutes.

Continuous infusion: A single dose over 4 or 24 hours. In all situations flush IV line with D5W before and after administration.

ACTIONS

A human granulocyte colony-stimulating factor (G-CSF). Colony-stimulating factors are glycoproteins that bind to specific hematopoietic cell surface receptors and stimulate proliferation, differentiation commitment, and some end-cell functional activation. Endogenous granulocyte colony-stimulating factors are produced by monocytes, fibroblasts, and endothelial cells. They are lineage-specific with selectivity for the neutrophil lineage. With recombinant DNA technology, filgrastim is produced by specifically prepared *Escherichia coli* bacteria inserted with the human G-CSF gene. It regulates the production of neutrophils within the bone marrow. Although not species specific, it mimics the actions of endogenous glycoprotein. By accelerating the recovery of neutrophil counts following a variety of chemotherapy regimens, it decreases infections manifested

by febrile neutropenia, need for hospitalization, and IV antibiotic usage. May also cause some increase in lymphocyte and monocyte counts. Increase in circulating neutrophils is dose-dependent, and a return to baseline occurs shortly after discontinuation (50% of baseline in 1 to 2 days and to pretreatment levels in 1 to 7 days). Half-life is approximately 3.5 hours.

INDICATIONS AND USES

Decrease the incidence of infection (febrile neutropenia) in patients with non-myeloid malignancies receiving myelosuppressive anticancer drugs associated with a significant incidence of severe neutropenia with fever. ■ Reduce the time to neutrophil recovery and the duration of fever, following induction or consolidation chemotherapy treatment of adults with AML. ■ Decrease duration of neutropenia and related clinical problems (e.g., febrile neutropenia) in patients with non-myeloid malignancies receiving myeloablative chemotherapy followed by BMT. ■ Used SC to treat severe chronic neutropenia (e.g., congenital, cyclic, or idiopathic) after all diseases associated with neutropenia have been ruled out. ■ Used SC or as a 24-hour SC infusion to mobilize hematopoietic progenitor cells into the peripheral blood for collection by leukapheresis with transplantation after myeloablative chemotherapy.

Unlabeled uses: In combination with epoetin to treat anemia in myelodysplastic syndrome; consult literature.

CONTRAINDICATIONS

Hypersensitivity to *E. coli*-derived proteins, filgrastim, or any of its components (e.g., sorbitol, tween 80).

PRECAUTIONS

Should be administered under the direction of a physician knowledgeable about appropriate use for each indication (e.g., expert in bone marrow transplantation). ■ Frequently given by SC injection or SC continuous infusion. ■ Effective in patients receiving chemotherapy with protocols containing cisplatin, cyclophosphamide, doxorubicin, etoposide, ifosfamide, mesna, methotrexate, vinblastine, and similar antineoplastic agents. ■ Effectiveness has not been evaluated in patients receiving chemotherapy associated with delayed myelosuppression (e.g., nitrosoureas [carmustine]), with mitomycin C, or with myelosuppressive doses of antimetabolites (e.g., fluorouracil or cytosine arabinoside). ■ Use extreme caution in any malignancy with myeloid characteristics. The possibility that filgrastim can act as a growth factor for any tumor type, particularly myeloid malignancies, cannot be excluded. Safety in chronic myeloid leukemia (CML) and myelodysplasia has not been established. ■ Acute respiratory distress syndrome (ARDS) may occur in septic patients. Evaluate for ARDS if fever, lung infiltrates, or respiratory distress develop. ■ Hypersensitivity reactions have been reported. May occur with first or subsequent doses; see **Monitor**. ■ Splenic rupture has been reported; fatalities have occurred. ■ Only physicians qualified to treat sickle cell patients should prescribe filgrastim to them; severe sickle cell crises have been reported and fatalities have occurred. Consider risk versus benefit. ■ Use caution in patients with congenital severe chronic neutropenia (SCN); risk of developing cytogenetic abnormalities, myelodysplastic syndromes (MDS), and acute myelogenous leukemia (AML) may be increased. ■ Chronic use at varying doses over several years may cause subclinical splenomegaly in adults and pediatric patients. ■ Alveolar hemorrhage manifesting as pulmonary infiltrates and hemoptysis and requiring hospitalization has been reported in healthy donors undergoing peripheral blood progenitor cell (PBPC) mobilization. Hemoptysis resolved when filgrastim was discontinued.

Monitor: Obtain a CBC and platelet count before chemotherapy begins and twice weekly thereafter to monitor the neutrophil count and to avoid leukocytosis. Following cytotoxic chemotherapy, the neutrophil nadir occurs earlier during cycles when filgrastim is used, duration of severe neutropenia is reduced, and WBC differentials may have a left shift. ■ Increase monitoring of CBC and platelet count to 3 times a week after bone marrow infusion. ■ In patients with SCN, obtain CBC with differential and platelet count twice a week for the first 4 weeks of therapy and during the 2 weeks following any

dose adjustment. Once the patient is clinically stable, obtain labs monthly during the first year of therapy and quarterly or as indicated thereafter. ■ Perform annual bone marrow and cytogenetic evaluations in patients with congenital neutropenia throughout the duration of treatment. ■ Because higher doses of chemotherapy may be tolerated, side effects associated with the chemotherapeutic drug may be more pronounced; observe carefully. ■ Observe for S/S of hypersensitivity reactions. Symptoms usually occur within 30 minutes of administration, are more common with the IV route, and usually involve at least two body systems (e.g., skin [facial edema, rash, urticaria], respiratory [dyspnea, wheezing], and cardiovascular [hypotension, tachycardia]). ■ Evaluate patients complaining of left upper abdominal pain and/or shoulder tip pain for an enlarged spleen or splenic rupture. ■ Monitor respiratory status. ■ Use caution with any additional drugs known to lower the platelet count. ■ See **Precautions**.

Patient Education: Promptly report any symptoms of infection (e.g., fever), abdominal or shoulder tip pain, or hypersensitivity reaction (itching, redness, swelling at the injection site). ■ May be self-injected SC by the patient at home; requires instruction. Literature includes a patient handout.

Maternal/Child: Category C: safety for use during pregnancy not established. Very large doses have caused fetal damage and death in rabbits. Use only if benefit justifies the potential risk to the fetus. Women who become pregnant during filgrastim therapy are encouraged to enroll in Amgen's Pregnancy Surveillance Program. ■ Secretion through breast milk not established; use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Has been used in pediatric patients from 1 month to 18 years of age. Experience similar to adult population in patients with cancer. May cause bone pain, fever, or rash. ■ The relationship is unclear; however, pediatric patients with congenital neutropenia have developed cytogenetic abnormalities and have undergone transformation to MDS and AML while receiving filgrastim.

Elderly: Age-related differences in safety and efficacy have not been observed.

DRUG/LAB INTERACTIONS

Interaction with other drugs has not been evaluated. ■ Use with caution **any drug that may potentiate the release of neutrophils** (e.g., lithium). ■ Increased hematopoietic activity of the bone marrow in response to growth factor therapy has been associated with transient positive bone-imaging changes. Consider when interpreting **bone-imaging results**. ■ Increases in **LDH, serum alkaline phosphatase, and serum uric acid** have been seen.

SIDE EFFECTS

Diarrhea, fever, mucositis, nausea, and vomiting. No serious adverse reactions that would limit the use of the product have been reported. Hypersensitivity reactions (itching, redness, swelling at the injection site) have occurred; anaphylaxis has not occurred but is possible. Complaints of dose-related bone pain are common and may require analgesics. With doses above 5 mcg/kg/day, leukocytosis (WBC counts greater than 100,000/mm³) has occurred in 5% of patients with no adverse effects reported. Cutaneous vasculitis has occurred in a few patients. Reduced dose may be indicated with subsequent treatment.

Post-Marketing: Acute respiratory distress syndrome (ARDS), alveolar hemorrhage and hemoptysis, splenic rupture, and Sweet's syndrome (acute febrile neutrophilic dermatosis). Decreased bone density and osteoporosis have been reported in pediatric patients with severe chronic neutropenia (SCN) receiving chronic therapy.

ANTIDOTE

Notify physician promptly if any signs of infection (fever) or other potential side effects occur. Monitor potential leukocytosis with twice-weekly CBCs. Discontinue therapy after ANC surpasses 10,000/mm³ and the chemotherapy nadir has occurred. Discontinue filgrastim and notify physician immediately if a generalized hypersensitivity reaction should occur. Treat hypersensitivity reactions as indicated. Withhold or discontinue for other side effects (e.g., ARDS, hemoptysis).

FLUCONAZOLE

(flew-KON-ah-zohl)

Antifungal

Diflucan

pH 3.5 to 8

USUAL DOSE

IV dose has been used for a maximum of 14 days. Plasma levels are similar with IV or oral, so oral dose can replace IV dose at any time. See **Monitor**.

Oropharyngeal candidiasis: Initial dose of 200 mg followed by 100 mg/day for a minimum of 14 days. PO maintenance therapy usually required in AIDS patients to prevent relapse.

Esophageal candidiasis: Initial dose of 200 mg followed by 100 mg/day for a minimum of 21 days and for at least 2 weeks after symptoms subside. Up to 400 mg/24 hr may be used.

Urinary tract or peritoneal candidiasis: 50 to 200 mg/day has been used.

Systemic candidiasis: Optimum therapeutic dose and duration of therapy not established. Doses up to 400 mg/day have been used. Initial dose of 400 mg followed by 200 mg/day for a minimum of 28 days and for at least 2 weeks after symptoms subside.

Treatment of acute cryptococcal meningitis: Initial dose of 400 mg followed by 200 mg/day for a minimum of 10 to 12 weeks after CSF culture becomes negative. Another source suggests a loading dose of 400 mg twice a day for 2 days followed by 400 mg/day for the same duration.

Suppression of cryptococcal meningitis: 200 mg/day. Usually required in patients with AIDS to prevent relapse.

Prevention of candidiasis in bone marrow transplant: 400 mg/day. If severe neutropenia (less than 500/mm³) is expected, begin fluconazole prophylaxis several days ahead of expected neutropenia. Continue for 7 days after neutrophils reach 1,000/mm³.

PEDIATRIC DOSE

Experience with pediatric patients is limited; see **Maternal/Child**.

In pediatric patients, 3 mg/kg is equivalent to an adult dose of 100 mg, 6 mg/kg to 200 mg, and 12 mg/kg to 400 mg. Some older pediatric patients may have clearance similar to an adult. Do not exceed 600 mg/day.

Oropharyngeal candidiasis: Initial dose of 6 mg/kg of body weight followed by 3 mg/kg/day for a minimum of 14 days.

Esophageal candidiasis: Initial dose of 6 mg/kg of body weight followed by 3 mg/kg/day for a minimum of 21 days and for at least 2 weeks after symptoms subside. Up to 12 mg/kg has been used.

Systemic candidiasis: 6 to 12 mg/kg/day. See Comments in **Adult Dose**.

Treatment of acute cryptococcal meningitis: Initial dose of 12 mg/kg of body weight followed by 6 mg/kg/day for a minimum of 10 to 12 weeks after CSF culture becomes negative. Up to 12 mg/kg/day has been used.

Suppression of cryptococcal meningitis: 6 mg/kg/day.

NEONATAL DOSE

Experience is limited; see **Maternal/Child**.

2 weeks to 3 months of age with meningitis or septicemia: 5 to 6 mg/kg/day PO or by IV infusion over 1 hour, or 10 mg/kg as a **loading dose** followed by 5 mg/kg.

Birth to 2 weeks of age with meningitis or septicemia: Manufacturer suggests using pediatric doses and extending the intervals to once every 72 hours. Prolonged half-life is seen in premature newborns (gestational age 26 to 29 weeks). After 2 weeks, dose may be given every 24 hours.

DOSE ADJUSTMENTS

In all adult situations the infecting organism and response to therapy may justify increased doses up to 400 mg daily. ■ Reduce each dose by 50% in patients with a CrCl at or less than 50 mL/min. ■ Give 100% of the recommended dose after each dialysis in patients receiving regular dialysis. ■ See **Drug/Lab Interactions**.

DILUTION

Packaged prediluted and ready for use as an iso-osmotic solution containing 2 mg/mL in both glass bottles and Viaflex Plus plastic containers. Do not remove moisture barrier overwrap of plastic container until ready for use. Tear overwrap down side at slit to open, and remove sterile inner bag. Plastic may appear somewhat opaque due to sterilization process but will clear. Squeeze inner bag firmly to check for leaks. Discard if leakage noted; sterility is impaired. Do not use if cloudy or precipitated.

Storage: Store glass bottles between 5° C (41° F) and 30° C (86° F); store plastic containers between 5° C (41° F) and 25° C (77° F). Protect both from freezing.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Do not add supplementary medication."

One source suggests the following **compatibilities (not recommended by manufacturer):**

Additive: Acyclovir (Zovirax), amikacin (Amikin), amphotericin B (conventional), ceftazidime (Fortaz), ciprofloxacin (Cipro IV), clindamycin (Cleocin), gentamicin, heparin, meropenem (Merrem IV), metronidazole (Flagyl IV), morphine, potassium chloride (KCl), theophylline.

Y-site: Acyclovir (Zovirax), aldesleukin (Proleukin), allopurinol (Aloprim), amifostine (Ethylol), amikacin (Amikin), aminophylline, amiodarone (Nexterone), ampicillin/sulbactam (Unasyn), anidulafungin (Eraxis), aztreonam (Azactam), benztropine (Cogentin), bivalirudin (Angiomax), caspofungin (Cancidas), ceftazidime (Fortaz), cefepime (Maxipime), cefotetan (Cefotan), ceftazidime (Fortaz), cefazolin (Ancef), cefepime (Maxipime), cefotetan (Cefotan), ceftazidime (Fortaz), cefazolin (Ancef), ceftazidime (Fortaz), chlorpromazine (Thorazine), cisatracurium (Nimbex), daptomycin (Cubicin), dexamethasone (Decadron), dexmedetomidine (Precedex), diltiazem (Cardizem), dimenhydrinate, diphenhydramine (Benadryl), dobutamine, docetaxel (Taxotere), dopamine, doripenem (Doribax), doxorubicin liposomal (Doxil), droperidol (Inapsine), etoposide phosphate (Etopophos), famotidine (Pepcid IV), fenoldopam (Corlopam), filgrastim (Neupogen), fludarabine (Fludara), foscarnet (Foscavir), gallium nitrate (Ganite), ganciclovir (Cytovene), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, heparin in electrolytes (Hextend), immune globulin intravenous (Gamunex), leucovorin calcium, linezolid (Zyvox), lorazepam (Ativan), melphalan (Alkeran), meperidine (Demerol), meropenem (Merrem IV), metoclopramide (Reglan), metronidazole (Flagyl IV), midazolam (Versed), morphine, nafcillin (Nallpen), nitroglycerin IV, ondansetron (Zofran), oxacillin (Bactocill), paclitaxel (Taxol), pancuronium, pemetrexed (Alimta), penicillin G potassium, phenytoin (Dilantin), piperacillin/tazobactam (Zosyn), prochlorperazine (Compazine), promethazine (Phenergan), propofol (Diprivan), quinupristin/dalfopristin (Synercid 2 mg/mL), ranitidine (Zantac), remifentanyl (Ultiva), sargramostim (Leukine), tacrolimus (Prograf), telavancin (Vibativ), teniposide (Vumon), theophylline, thiotepa, ticarcillin/clavulanate (Timentin), tigecycline (Tygacil), tobramycin, vancomycin, vasopressin, vecuronium, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

A single dose as a continuous infusion at a rate not to exceed 200 mg/hr. Do not use plastic containers in series connections; air embolism could result.

ACTIONS

A synthetic, broad-spectrum, bis-Triazole antifungal agent. Inhibits fungal growth of *Candida* and *Cryptococcus neoformans* by acting on a key enzyme and depriving the fungus of ergosterol; the cell membrane becomes unstable and can no longer function normally. Human sterol synthesis is not affected. Peak plasma concentrations achieved in 1 to 2 hours; half-life extends for 30 hours (range 20 to 50 hours). Administration of a loading dose (on day 1) of twice the usual daily dose results in a plasma concentration close to steady state by day 2 when given IV or PO. Penetrates into all body fluids in similar and effective concentrations and remains constant with daily single-dose admin-

istration. 80% excreted as unchanged drug and about 11% excreted as metabolites in the urine. Secreted in breast milk.

INDICATIONS AND USES

Oropharyngeal and esophageal candidiasis. ■ Serious candidal infections, including GU tract infections, peritonitis, and systemic *Candida* infections including candidemia, disseminate candidiasis, and pneumonia. May be an appropriate and less toxic alternative to amphotericin B. ■ Cryptococcal meningitis, including suppressive therapy to prevent relapse. ■ Prevention of candidiasis in bone marrow transplant patients. ■ Used orally for additional indications (e.g., candidiasis prophylaxis).

Unlabeled uses: Has been used in many other fungal or parasitic infections.

CONTRAINDICATIONS

Hypersensitivity to fluconazole or any of its components. Use caution in patients hypersensitive to other azoles (e.g., ketoconazole). ■ Coadministration with drugs known to prolong the QT interval that are metabolized via the enzyme CYP3A4, such as astemizole (removed from market), cisapride (Propulsid), pimozone (Orap), and quinidine.

PRECAUTIONS

For IV use only; do not give IM. ■ Specimens for fungal culture and serologic and histopathologic testing should be obtained before therapy to isolate and identify causative organisms. Therapy may begin as soon as all specimens are obtained and before results are known. ■ Inadequate treatment may lead to a recurrence of active infection; continue treatment until clinical parameters or laboratory tests indicate that active fungal infection has subsided. See specific recommendations in **Usual Dose**. ■ Use caution in patients with pre-existing liver disease. ■ Serious hepatotoxicity may occur. Causal relationship uncertain, but many patients are taking hepatotoxic drugs for treatment of malignancies and AIDS. Note any abnormal liver function tests (e.g., AST). If any clinical signs and symptoms consistent with liver disease develop, discontinue drug. Has caused deaths. ■ Associated with prolongation of the QT interval. Rare cases of torsades de pointes have been reported. More common in seriously ill patients with multiple confounding factors, such as heart disease, electrolyte abnormalities, and concomitant medications that may have been contributory (e.g., class IA antiarrhythmic agents [e.g., quinidine, procainamide (Pronestyl)] and class III antiarrhythmic agents [e.g., amiodarone (Nexterone), sotalol]). ■ Exfoliative skin disorders have been reported. ■ Anaphylaxis has been reported rarely. ■ See **Drug/Lab Interactions**.

Monitor: Obtain baseline liver function tests and monitor periodically during treatment. ■ Observe for S/S of hypersensitivity or skin reactions. ■ Consider ECG monitoring in patients at risk for QT prolongation. ■ See **Drug/Lab Interactions**.

Patient Education: May cause serious problems with selected medications; review prescription and nonprescription drugs with physician or pharmacist. ■ May cause dizziness or seizures. Do not drive or operate hazardous machinery until effects of fluconazole are known.

Maternal/Child: Category D: safety for use in pregnancy and breast-feeding not established. There have been rare cases of distinct congenital anomalies in infants exposed in utero to high-dose maternal fluconazole during most or all of the first trimester. ■ Use caution if administered to nursing mothers. ■ Safety profile has been studied in pediatric patients ages 1 day to 17 years. Efficacy in pediatric patients under 6 months of age has not been established. However, a small number of patients ranging from age 1 day to 6 months have been treated safely (unlabeled).

Elderly: Differences in response compared to younger adults not identified; however, may be at increased risk for side effects (e.g., acute renal failure, anemia, diarrhea, rash, and vomiting). ■ Use caution, consider decreased cardiac, hepatic, or renal function and effects of concomitant disease or other drug therapy. ■ See **Dose Adjustments** and **Drug/Lab Interactions**.

DRUG/LAB INTERACTIONS

A potent CYP2C9 inhibitor and a moderate CYP3A4 inhibitor. Closely monitor patients who are treated concomitantly with **drugs with a narrow therapeutic index metabolized by**

CYP2C9 or CYP3A4. The enzyme-inhibiting effect of fluconazole can last for 4 to 5 days after it is discontinued. ■ Avoid concurrent use with **erythromycin**; may increase the risk of cardiotoxicity (prolonged QT interval, torsades de pointes) and, consequently, sudden death. Potentiated by **hydrochlorothiazide** (HydroDIURIL); decreases renal clearance of fluconazole. ■ Inhibits metabolism and increases serum levels of **cyclosporine**, **phenytoin**, **sirolimus** (Rapamune), **tacrolimus** (Prograf), and **theophyllines**; careful monitoring of their plasma levels is required; nephrotoxicity has been reported with tacrolimus. ■ Potentiates **coumarin-type anticoagulants** (e.g., warfarin); monitor PT and INR frequently. ■ Potentiates **sulfonylureas** (oral hypoglycemic agents [e.g., glimepiride (Amaryl), glipizide (Glucotrol XL), glyburide (DiaBeta), tolbutamide]); monitor blood glucose levels. Adjust the dose of the oral hypoglycemic agent as indicated. ■ **Rifampin** increases metabolism; fluconazole dose may need to be increased. One source recommends avoiding concurrent use. ■ Increases serum levels of **zidovudine** (AZT, Retrovir). ■ Increases serum levels of **rifabutin** (Mycobutin). Uveitis has been reported in patients receiving rifabutin and fluconazole concomitantly. Monitoring is recommended. ■ Risk of cardiac arrhythmias increased with **cisapride** (Propulsid); concurrent use not recommended; see **Contraindications**. ■ Fluconazole may inhibit metabolism and increase plasma concentrations of **carbamazepine** (Tegretol); monitor carbamazepine concentrations. ■ Avoid concomitant use with **voriconazole** (VFEND). Potential for voriconazole toxicity remains if voriconazole is initiated within 24 hours of the last dose of fluconazole. ■ May decrease metabolism and increase serum concentrations of **celecoxib** (Celebrex) and other **NSAIDs** (e.g., diclofenac [Arthrotec], naproxen [Aleve, Naprosyn]). Monitor for toxicity related to NSAIDs and adjust dose as needed. ■ May decrease metabolism and increase serum concentrations of **selected benzodiazepines** that are metabolized by the cytochrome P₄₅₀ system (e.g., diazepam [Valium], midazolam [Versed], triazolam [Halcion]); a decrease in benzodiazepine dose should be considered. ■ May increase serum concentrations and adverse effects of **alfentanil** (Alfenta), **buspirone** (BuSpar), **calcium channel blockers** (e.g., amlodipine [Norvasc], felodipine [Plendil], isradipine [Dynacirc CR], nifedipine [Procardia XL], **corticosteroids**, **fentanyl** (Sublimaze), **haloperidol** (Haldol), **losartan** (Cozaar), **methadone** (Dolophine), **nisoldipine** (Sular), **sirolimus** (Rapamune), **tolterodine** (Detrol), **tricyclic antidepressants** (e.g., amitriptyline [Elavil], imipramine [Tofranil]), and **vinca alkaloids** (e.g., vincristine). Reduce doses of the above drugs as indicated to avoid toxicity. Dose may need to be increased when fluconazole is discontinued. **Tolterodine** dose should be limited to no more than 1 mg twice daily when coadministered with fluconazole. ■ Coadministration may increase plasma levels of **protease inhibitors** (e.g., nelfinavir [Viracept], ritonavir [Norvir]), saquinavir [Invirase]), increasing the risk of toxicity. ■ Increases serum levels of **HMG-CoA reductase inhibitors** (e.g., atorvastatin [Lipitor], lovastatin [Mevacor], simvastatin [Zocor]); rhabdomyolysis has been reported. If coadministration is necessary, reduced doses of the HMG-CoA reductase inhibitor are indicated. **Pravastatin** (Pravachol) levels may be the least affected. ■ May increase the plasma concentrations and therapeutic effects of **zolpidem** (Ambien). ■ An increase in serum bilirubin and creatinine have been observed with concurrent use of **cyclophosphamide** (Cytoxan) and fluconazole (Diflucan). Use caution and monitor if combined use is required. ■ May **elevate liver function tests** (e.g., ALT, AST, alkaline phosphatase, and bilirubin).

SIDE EFFECTS

Abdominal pain, diarrhea, dizziness, dry mouth, dyspepsia, exfoliative skin disorders, headache, hepatic reactions, hypercholesterolemia, hypersensitivity reactions (including anaphylaxis with angioedema, face edema, and pruritus), hypertriglyceridemia, hypokalemia, increased appetite, increased sweating, leukopenia (including neutropenia and agranulocytosis), nausea, pallor, QT prolongation, rash, seizures, taste perversion, thrombocytopenia, torsades de pointes, tremor, vomiting.

Overdose: Cyanosis, decreased motility, decreased respirations, hallucinations, lacrimation, loss of balance, salivation, urinary incontinence. Clonic convulsions preceded death in experimental animals. Changes in renal and hematologic function test results and he-

patric abnormalities have been seen in some patients, particularly those with serious underlying diseases such as AIDS and cancer. Clinical significance and relationship to treatment are unclear.

Post-Marketing: Asthenia, cholestasis, fatigue, fever, hepatocellular damage, insomnia, malaise, myalgia, paresthesia, somnolence.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Discontinue drug and notify physician of abnormal liver function tests progressing to clinical signs and symptoms of liver disease. Rash may be the first sign of an exfoliative skin disorder in immunocompromised patients; discontinue drug and notify physician. In overdose a 3-hour dialysis session will decrease plasma levels by 50%. Treat anaphylaxis or resuscitate if indicated.

<p>FLUDARABINE PHOSPHATE BBW (floo-DAIR-ah-bean FOS-fayt)</p>	<p>Antineoplastic (antimetabolite)</p>
<p>Fludara</p>	<p>pH 7.2 to 8.2 (lyophilized) pH 7.3 to 7.7 (liquid)</p>

USUAL DOSE

25 mg/M²/day for 5 consecutive days. Repeat every 4 weeks. Optimum duration of treatment not established. If there is no major toxicity, treat until maximum response achieved, then administer three additional complete cycles.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established; see [Maternal/Child](#). **Pediatric acute lymphocytic leukemia (ALL) patients (unlabeled):** Give an initial loading bolus of 10.5 mg/M² on Day 1 followed by a continuous infusion of 30.5 mg/M²/day on Days 1 through 5.

Pediatric patients with solid tumors (unlabeled): Dose-limiting myelosuppression was observed with a loading dose of 8 mg/M² on Day 1 followed by a continuous infusion of 23.5 mg/M²/day on Days 1 through 5. Maximum tolerated dose in solid tumor pediatric patients was a loading dose of 7 mg/M²/day followed by a continuous infusion of 20 mg/M²/day for 5 days.

DOSE ADJUSTMENTS

Decrease or delay dose based on evidence of hematologic or nonhematologic toxicity. Increased toxicity may occur in the elderly and in patients with renal insufficiency or bone marrow impairment. Monitor closely and adjust dose as indicated. ■ Adjust initial starting doses for patients with renal impairment as indicated in the following table.

Fludarabine Starting Dose Adjustment for Renal Impairment	
Creatinine Clearance	Starting Dose
≥80 mL/min	25 mg/M ² (full dose)
50-79 mL/min	20 mg/M ²
30-49 mL/min	15 mg/M ²
<30 mL/min	Do not administer

DILUTION

Specific techniques required; see [Precautions](#). Available as a sterile solution 50 mg/2 mL (25 mg/mL) or as a lyophilized solid cake (50 mg) requiring reconstitution with 2 mL of SWFI (25 mg/mL). Should dissolve within 15 seconds. In clinical studies, each single

dose was further diluted in 100 to 125 mL of NS or D5W and given as an infusion over 30 minutes.

Filters: Specific information from studies not available; contact manufacturer for further information.

Storage: Refrigerate between 2° and 8° C (36° to 46° F) before dilution. No preservative; use within 8 hours of dilution.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer states, "Should not be mixed with other drugs."

One source suggests the following **compatibilities (not recommended by manufacturer):**

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), amikacin (Amikin), aminophylline, ampicillin, ampicillin/sulbactam (Unasyn), aztreonam (Azactam), bleomycin (Blenoxane), butorphanol (Stadol), carboplatin (Paraplatin), carmustine (BiCNU), cefazolin (Ancef), cefotaxime (Claforan), cefotetan (Cefotan), ceftazidime (Fortaz), ceftriaxone (Rocephin), cefuroxime (Zinacef), cisplatin (Platinol), clindamycin (Cleocin), cyclophosphamide (Cytosan), cytarabine (ARA-C), dacarbazine (DTIC), dactinomycin (Cosmegen), dexamethasone (Decadron), diphenhydramine (Benadryl), doxorubicin (Adriamycin), doxycycline, droperidol (Inapsine), etoposide (VePesid), etoposide phosphate (Etopophos), famotidine (Pepcid IV), filgrastim (Neupogen), fluconazole (Diflucan), fluorouracil (5-FU), furosemide (Lasix), gemcitabine (Gemzar), gentamicin, granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), hydromorphone (Dilaudid), ifosfamide (Ifex), imipenemcilastatin (Primaxin), lorazepam (Ativan), magnesium sulfate, mannitol, mechlorethamine (nitrogen mustard), melphalan (Alkeran), meperidine (Demerol), mesna (Mesnex), methotrexate, methylprednisolone (Solu-Medrol), metoclopramide (Reglan), mitoxantrone (Novantrone), morphine, multivitamins (M.V.I.), nalbuphine, ondansetron (Zofran), pentostatin (Nipent), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), promethazine (Phenergan), ranitidine (Zantac), sodium bicarbonate, sulfamethoxazole/trimethoprim, teniposide (Vumon), thiotepe, ticarcillin/clavulanate (Timentin), tobramycin, vancomycin, vinblastine, vincristine, vinorelbine (Navelbine), zidovudine (AZT, Retrovir).

RATE OF ADMINISTRATION

Single daily dose properly diluted for infusion over 30 minutes.

ACTIONS

A potent antineoplastic agent. A fluorinated nucleotide analog of the antiviral agent vidarabine. Rapidly converts to the active metabolite 2-fluoro-ara-ATP and interferes with the synthesis of DNA. Actual mechanism of action unknown and may be multifaceted. Median time to response in studies of patients with refractory chronic lymphocytic leukemia (CLL) was 7 to 21 weeks (range 1 to 68 weeks). Elimination half-life is approximately 20 hours. Total body clearance of the active metabolite is correlated with the CrCl, indicating the importance of renal excretion for drug elimination.

INDICATIONS AND USES

Treatment of patients with B-cell CLL who have not responded to or progressed during treatment with at least one standard alkylating agent-containing regimen. ■ Safety and effectiveness in previously untreated or nonrefractory patients with CLL not established. **Unlabeled uses:** Treatment of non-Hodgkin's lymphoma, acute lymphocytic leukemia, acute myeloid leukemia, prolymphocytic leukemia or prolymphocytoid variant of CLL, mycosis fungoides, hairy-cell leukemia, and Waldenström's macroglobulinemia. Dose and/or efficacy not established.

CONTRAINDICATIONS

Hypersensitivity to fludarabine or its components (e.g., mannitol and sodium hydroxide). ■ Not recommended for use in patients with severely impaired renal function (CrCl less than 30 mL/min). ■ Not recommended for use in combination with pentostatin (Nipent); see [Drug/Lab Interactions](#).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist. ■ Use with caution in advanced age, renal insufficiency, or bone marrow impairment, or in patients with immunodeficiency or a history of opportunistic infection. ■ Severe myelosuppression (anemia, neutropenia, and thrombocytopenia) is common. Median time to nadir counts was 13 days for granulocytes and 16 days for platelets. ■ Most patients have hematologic impairment at baseline because of disease or prior myelosuppressive therapy. Myelosuppression may be severe and cumulative. ■ Several instances of trilineage bone marrow hypoplasia or aplasia resulting in pancytopenia, sometimes resulting in death, have been reported. Clinically significant cytopenias lasted from 2 months to 1 year and occurred in untreated and previously treated patients. ■ Use of irradiated blood product is recommended for patients requiring transfusions during fludarabine therapy because transfusion-associated graft-versus-host disease has been reported. ■ Use caution in patients with large tumor burdens; may cause tumor lysis syndrome. Response can occur within 1 week. ■ Life-threatening and sometimes fatal cases of autoimmune phenomena, such as hemolytic anemia, autoimmune thrombocytopenia/thrombocytopenic purpura (ITP), Evan's syndrome, and acquired hemophilia, have been reported; see [Antidote](#). ■ Serious, sometimes fatal infections, including opportunistic infections and reactivations of latent viral infections (e.g., varicella zoster virus [VZV], Epstein-Barr virus, and JC virus [progressive multifocal leukoencephalopathy]), as well as disease progression and transformation (e.g., Richter's syndrome) have been reported. ■ Severe neurotoxicity characterized by delayed blindness, coma, and death has been reported in patients who received doses that were approximately 4 times greater than the recommended dose. Significant neurotoxicity has also been reported in patients receiving doses in the recommended range. Symptoms may appear 7 to 225 days after the last dose. ■ See [Side Effects](#).

Monitor: Observe closely for signs of toxicity, both hematologic and nonhematologic. ■ Obtain baseline CBC, including differential and platelet count. Repeat regularly to monitor hematopoietic suppression (especially neutrophils and platelets) and hemolysis. ■ Obtain baseline CrCl. ■ Observe closely for all signs of infection and any fever of unknown origin. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Consider prophylactic therapy in patients at risk for developing opportunistic infections. ■ Nausea and vomiting usually less severe than many antineoplastics; prophylactic administration of antiemetics may be indicated. ■ Monitor for early signs of tumor lysis syndrome (e.g., flank pain, hematuria). Prevention and treatment of hyperuricemia due to tumor lysis syndrome may be accomplished with adequate hydration and, if necessary, allopurinol (Aloprim) and alkalization of urine. ■ Monitor for evidence of hemolysis. ■ Monitor for S/S of neurotoxicity (e.g., agitation, coma, confusion, seizures). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education: Avoid pregnancy; birth control recommended for both males and females during therapy and for at least 6 months after fludarabine regimen has been completed. ■ Use caution while driving or operating machinery. Agitation, confusion, fatigue, seizures, visual disturbances, and weakness have been reported. ■ Adherence to periodic blood count monitoring is imperative. ■ See Appendix D, p. 1255.

Maternal/Child: Category D: both males and females should use contraception and avoid pregnancy; may cause fetal harm; see [Patient Education](#). ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established; however, data have been submitted to the FDA using the doses described under Pediatric Dose. In pediatric patients, platelet counts appeared to be more sensitive than hemoglobin and WBCs to the effects of fludarabine.

Elderly: See [Precautions](#) and [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Do not use with **pentostatin** (Nipent); may increase risk of fatal pulmonary toxicity. ■ Do not administer **live virus vaccines** during or after treatment with fludarabine.

SIDE EFFECTS

Are frequent, may be dose limiting, and may cause death. Most common side effects include myelosuppression (anemia, neutropenia, thrombocytopenia), chills, cough, diarrhea, fatigue, fever, infection (including opportunistic and pneumonia), mucositis, nausea and vomiting, and weakness. The most serious side effects include CNS toxicity, hemolytic anemia, pulmonary toxicity, and severe bone marrow suppression. Other reported side effects include agitation, anorexia, arrhythmia, bone marrow aplasia or hypoplasia (may result in pancytopenia), cerebral hemorrhage, coma, confusion, dyspnea, dysuria, edema, elevated hepatic enzymes, esophagitis, GI bleeding/hemorrhage, headache, heart failure, hemorrhagic cystitis, infection, malaise, myalgia, pain, paresthesia, peripheral neuropathy, pulmonary toxicity (ARDS, dyspnea, interstitial pulmonary infiltrate, pulmonary fibrosis, pulmonary hemorrhage, respiratory distress and failure), rashes, seizures, sinusitis, stomatitis, visual disturbances. Onset of flank pain and hematuria may indicate tumor lysis syndrome (hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure); one reported.

Overdose: Severe bone marrow suppression (neutropenia and thrombocytopenia). Severe neurologic toxicity including delayed blindness, coma, and death occurred from 21 to 60 days after the last dose in 36% of patients treated with doses only 4 times greater than the recommended dose. Has occurred (in no more than 0.2% of patients) with average doses.

Post-Marketing: Erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis, and pemphigus (some with fatal outcomes); rare cases of myelodysplastic syndrome and acute myeloid leukemia associated with prior, concomitant, or subsequent treatment with alkylating agents, topoisomerase inhibitors (e.g., irinotecan [Camptosar]), or irradiation; progressive multifocal leukoencephalopathy (PML) within a few weeks to a year (most with a fatal outcome; some patients had prior and/or concurrent chemotherapy); trilineage bone marrow hypoplasia or aplasia resulting in pancytopenia and death; and worsening or flare-up of pre-existing skin cancer lesions and/or new onset of skin cancer during or after treatment with fludarabine.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Some toxicity is necessary to produce remission. Delay or discontinue the drug for serious hematologic depression. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Restart as soon as signs of bone marrow recovery occur. Delay or discontinue if neurotoxicity occurs. There is no specific antidote; supportive therapy as indicated will help sustain the patient in toxicity. Symptoms of pulmonary toxicity may improve with the use of corticosteroids; rule out an infectious origin before use. Steroids may or may not be useful in controlling hemolytic episodes.

FLUMAZENIL **BBW**

(floo-MAZ-eh-nill)

Benzodiazepine antagonist

Antidote

Romazicon

pH 4

USUAL DOSE

Reversal of conscious sedation or in general anesthesia: 0.2 mg (2 mL) as an initial dose. Assess level of consciousness. May be repeated at 1-minute intervals, assessing level of consciousness between each dose, until desired level of consciousness achieved or a total cumulative dose of 1 mg (10 mL) has been given (average dose to awakening is 0.6 mg to 1 mg). If re sedation occurs (may occur if flumazenil wears off before the benzodiazepine) the above process may be repeated at 20-minute intervals as indicated. Do not give more than a cumulative dose of 1 mg in a 20-minute period or 3 mg in any 1 hour.

Management of suspected benzodiazepine overdose: 0.2 mg (2 mL) as an initial dose. Assess level of consciousness. If results inadequate, give an additional dose of 0.3 mg (3 mL) in 1 minute. If results are still inadequate, 0.5 mg (5 mL) may be repeated at 1-minute intervals. Assess level of consciousness between each dose until desired level of consciousness achieved or a total cumulative dose of 3 mg (30 mL) has been given (average dose to awakening is 1 mg to 3 mg). If a partial response is achieved with 3 mg, continue dosing in 0.5-mg increments until awakening or a cumulative dose of 5 mg is reached (rarely required). If patient has not responded to a cumulative dose of 5 mg within 5 minutes, benzodiazepines are not the major cause of sedation; discontinue use. If desired results are achieved and re sedation occurs (expected), no more than 1 mg given in 0.5-mg increments may be given in any 20-minute period and no more than a cumulative total dose of 3 mg in any 1 hour.

PEDIATRIC DOSE

Reversal of conscious sedation: 0.01 mg/kg (up to 0.2 mg). Assess level of consciousness. May repeat at 1 minute intervals, assessing level of consciousness between each dose until desired level of consciousness achieved or a maximum total dose of 0.05 mg/kg (or 1 mg) has been given. Mean total dose administered in trials was 0.65 mg. See *Maternal/Child*.

DOSE ADJUSTMENTS

Not required for the elderly. ■ Reduce dose and extend intervals after the initial dose in impaired liver function. ■ Individualize dose in high-risk patients. Administer the smallest amount that is effective and wait for peak effect (6 to 10 minutes). Slower titration rates and lower total doses may be especially important in these patients (see *Precautions*) to reduce emergent confusion and agitation, to prevent seizures, and to evaluate effect.

DILUTION

May be given undiluted through a free-flowing IV into a large vein (to minimize pain at injection site). **Compatible** with D5W, D2½W, LR, ½NS, and NS if further dilution required by a specific situation.

Storage: Store unopened vials at CRT. Discard in 24 hours if drawn undiluted into a syringe or diluted in any solution.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following **compatibilities**:

Additive: Aminophylline, dobutamine, dopamine, famotidine (Pepcid IV), heparin, lidocaine, procainamide (Pronestyl), ranitidine (Zantac).

RATE OF ADMINISTRATION

Series of small injections allows control of the reversal of sedation to desired endpoint, avoids abrupt awakening, and minimizes the possibility of adverse effects. Rapid

injection may cause withdrawal symptoms in patients with long-term exposure to benzodiazepines.

Reversal of conscious sedation or in general anesthesia: Each single dose over 15 seconds.

Management of suspected benzodiazepine overdose: Each single dose (0.2 mg [2 mL], 0.3 mg [3 mL], 0.5 mg [5 mL], respectively) is given over 30 seconds.

ACTIONS

A benzodiazepine antagonist. Competes with benzodiazepines, inhibiting their effect at benzodiazepine receptor sites. Action is very specific and reverses the effects of benzodiazepines only. Antagonizes (reverses) the sedation, impairment of recall, psychomotor impairment, and ventilatory depression produced by benzodiazepines. Duration and degree of reversal are related to dose and plasma concentration (both for amount of benzodiazepine and amount of flumazenil). Onset of action usually occurs within 1 to 2 minutes of reaching the appropriate dose, with peak effect at 6 to 10 minutes. Enables the physician to control the duration of action of benzodiazepines and to evaluate the patient's postoperative condition earlier and may facilitate the postprocedural course. In overdose, it allows the physician to communicate sooner with patients who have taken an excessive dose. Extensively metabolized in the liver. Half-life is 40 to 80 minutes. Excreted in changed form in urine and to a small extent in feces.

INDICATIONS AND USES

Adults: Complete or partial reversal of the effects of general anesthesia induced and/or maintained with benzodiazepines (e.g., diazepam [Valium], midazolam [Versed]). ■ Complete or partial reversal of the sedative effects of benzodiazepines used to produce and/or maintain conscious sedation (e.g., diagnostic and therapeutic procedures). ■ Adjunct to conventional treatment in managing benzodiazepine overdose (e.g., chlordiazepoxide [Librium], diazepam [Valium], lorazepam [Ativan], midazolam [Versed]).

Pediatric patients 1 to 17 years of age: Reversal of conscious sedation induced with benzodiazepines; see *Maternal/Child*. ■ Not approved for other indications but has been used at doses similar to those used for reversal of conscious sedation; see *Maternal/Child*.

CONTRAINDICATIONS

Known hypersensitivity to flumazenil or any benzodiazepine, patients who are on benzodiazepine therapy for control of potentially life-threatening conditions (e.g., control of intracranial pressure, status epilepticus), and patients showing signs of serious cyclic antidepressant overdose. ■ Use in treatment of benzodiazepine dependence is not recommended.

PRECAUTIONS

Excess administration increases risk of side effects and decreases desired therapeutics of benzodiazepines. ■ Will not reverse the central nervous system (CNS) effects of drugs such as alcohol, analgesics, antidepressants, barbiturates, and narcotics. In overdose, will bring the patient to a conscious state only if a benzodiazepine is responsible for the sedation. Has reversed benzodiazepine-induced hypotension and bradycardia unresponsive to other measures (e.g., IV fluids, atropine, dopamine). ■ Convulsions may occur, especially in patients who rely on benzodiazepines to control seizures or are physically dependent on benzodiazepines for long-term sedation, in overdose cases in which patients are showing signs of serious cyclic antidepressant overdose (some clinicians recommend a diagnostic ECG or quantitative analytical testing before use—see *Contraindications*), or in ICU patients who may have an unrecognized dependence on benzodiazepines because of frequent use as a sedative (can occur with only 3 to 5 days of benzodiazepine administration). Intubation with ventilatory and circulatory support may be the treatment of choice for these high-risk patients; see *Dose Adjustments*. ■ Risk of adverse reactions increased in patients with a history of alcohol, benzodiazepine, or sedative use (increased frequency of benzodiazepine tolerance and dependence). Can precipitate benzodiazepine withdrawal (also high-risk; see *Dose Adjustments*). ■ Use extreme caution in head injury (may alter cerebral blood flow or cause convulsions). ■ Do not use until effects of neuromuscular blockade have been

fully reversed. ■ May cause panic attacks in patients with a history of panic disorder. ■ Flumazenil may not completely reverse respiratory depression due to benzodiazepines in patients with serious lung disease. Additional ventilatory support may be required. ■ Half-life prolonged based on amount of hepatic impairment. ■ Ingestion of food increases clearance of flumazenil.

Monitor: Confirm secure airway, ventilation, and IV access before administration as indicated. ■ Monitor BP, HR, and respirations closely. ECG monitoring and oxygenation determination by pulse oximetry is recommended. ■ Emergency equipment and supplies, including drugs for seizure control (see [Antidote](#)), must always be available. ■ Observe continuously for re sedation, respiratory depression, pre seizure activity, or other residual benzodiazepine effects for an appropriate period (2 or more hours). ■ Extend observation time for larger doses, in presence of long-acting benzodiazepines (e.g., diazepam [Valium]), or large doses of short-acting benzodiazepines (e.g., more than 10 mg of midazolam [Versed]). ■ Observe ambulatory patients for a minimum of 2 hours after a 1-mg dose; re sedation after 2 hours is unlikely. Extend observation time as above. ■ Awake patients may require pain medication sooner than those without benzodiazepine reversal. ■ All postprocedural instructions must be given to the patient verbally and in writing; does not reverse benzodiazepine amnesia. ■ See [Drug/Lab Interactions](#).

Patient Education: Review medication use, especially benzodiazepine, alcohol, and sedative use prior to surgery or procedure. ■ Effects of benzodiazepines may recur; for 24 to 48 hours memory and judgment may be impaired. ■ All instructions should be in writing. ■ Do not drive, operate hazardous machinery, or engage in activities that require alertness. ■ Do not take alcohol, other CNS depressants (e.g., antihistamines, barbiturates), or nonprescription drugs for 24 hours.

Maternal/Child: Category C: use only if benefit justifies risk. ■ Not recommended during labor and delivery because effect on newborn unknown. ■ Safety for use in breastfeeding not established. ■ Safety and effectiveness for reversal of conscious sedation induced with benzodiazepines have been established in pediatric patients 1 to 17 years of age. Re sedation may occur, especially in pediatric patients 1 to 5 years of age. Safety and effectiveness of repeated flumazenil doses in pediatric patients experiencing re sedation have not been established. ■ Safety and effectiveness for other uses listed under adult indications have not been established. However, published anecdotal reports have cited safety profiles and dosing guidelines similar to those used in reversal of conscious sedation. ■ Half-life appears to be shorter and more variable in pediatric patients.

Elderly: See [Dose Adjustments](#). Age-related differences in safety and effectiveness have not been observed; however, a greater sensitivity of some older patients cannot be ruled out. ■ Monitor carefully; benzodiazepine-induced sedation may be deeper and more prolonged.

DRUG/LAB INTERACTIONS

May cause cardiac arrhythmias or convulsions in cases of mixed drug overdose. These toxic effects may emerge (especially with **cyclic antidepressants** [e.g., amitriptyline (Elavil), imipramine (Tofranil)]) with reversal of benzodiazepine effect; see [Precautions](#). May reverse sedative and anticonvulsant effects. ■ May precipitate withdrawal symptoms if given to chronic **benzodiazepine** users. ■ No specific deleterious interactions noted when flumazenil administered after **narcotics, inhalational anesthetics, muscle relaxants, and muscle relaxant antagonists** administered in conjunction with sedation or anesthesia. ■ Not recommended for use in **epileptic patients** who have been receiving benzodiazepines for a prolonged period. ■ Lab test interactions have not been evaluated.

SIDE EFFECTS

Most common at doses above 1 mg and/or with abrupt reversal.

Abnormal vision, agitation, anxiety, dizziness, dry mouth, dyspnea, emotional lability, fatigue, flushing, headache, hot flashes, hypertension, hyperventilation, insomnia, invol-

untary movements, irritability, muscle tension, nausea, pain or reaction (rash, thrombophlebitis) at the injection site, palpitations, panic, paresthesia, sweating, tachycardia, tinnitus, tremors, and vomiting. Convulsions, fear, and panic attacks may occur; see **Precautions**. Deaths have been reported. Risk increased in patients with serious underlying disease or in patients who overdose on non-benzodiazepine drugs (usually cyclic antidepressants).

Overdose: Agitation, anxiety, arrhythmias, convulsions, hyperesthesia, increased muscle tone.

ANTIDOTE

Notify the physician of any side effect. Treat symptoms of benzodiazepine withdrawal (agitation, confusion, dizziness, emotional lability, or sensory distortions) with a barbiturate, benzodiazepine, or other sedative. Larger doses may be required because of presence of flumazenil. Treat convulsions from overdose with barbiturates, benzodiazepines, and phenytoin (Dilantin). Maintain an adequate airway, adequate ventilation, and IV access at all times. Hemodialysis not effective in overdose if 1 hour has passed since administration.

FLUOROURACIL **BBW**

(flew-roh-**YOUR**-ah-sill)

**Antineoplastic
(antimetabolite)**

Adrucil, 5-Fluorouracil, 5-FU

pH 9.2

USUAL DOSE

Many dosing regimens are in use. May be given as an injection or as a continuous infusion. Manufacturer recommends 12 mg/kg of body weight/24 hr for 4 days. Total dose should not exceed 800 mg/24 hr. If no toxicity is observed, one half dose (6 mg/kg) is given on Days 6, 8, 10, and 12 unless toxicity occurs. No medication is given on Days 5, 7, 9, or 11. Discontinue therapy on Day 12, even if no toxicity is apparent. See **Precautions/Monitor**. The most common form of maintenance therapy is to repeat the entire course of therapy beginning 30 days after the previous course is completed and any toxicity has subsided or to give a single dose of 10 to 15 mg/kg/week, not to exceed 1 Gm/week. Dose adjustments of subsequent doses are made depending on side effects and tolerance.

Advanced colorectal cancer (unlabeled dose): Various protocols have been used. Examples are leucovorin calcium 20 mg/M² followed by fluorouracil 425 mg/M², or leucovorin calcium 200 mg/M² followed by fluorouracil 370 mg/M² daily for 5 days. Repeat at 4-week intervals twice, then repeat every 28 to 35 days based on complete recovery from toxic effects. Do not initiate or continue in any patient with GI toxicity until completely subsided. Reduce fluorouracil dose based on tolerance to previous course; reduce 20% for moderate hematologic or GI toxicity, 30% for severe toxicity. Increase fluorouracil dose 10% if no toxicity. Leucovorin calcium dose is not adjusted. Alternatively, fluorouracil may also be used in combination with levoleucovorin; dose is different; see levoleucovorin monograph. Fluorouracil and leucovorin calcium are also used in combination with irinotecan (Camptosar); see irinotecan monograph.

Breast cancer (unlabeled dose): Various protocols have been used. An example is fluorouracil 600 mg/M² on Days 1 and 8 of each cycle combined with cyclophosphamide (Cytosan) 100 mg/M² on Days 1 through 14 of each cycle and methotrexate 40 mg/M² on Days 1 and 8 of each cycle. Repeat cycles monthly (allowing a 2-week rest between

cycles). Repeat for 6 to 12 cycles (6 to 12 months). Doxorubicin (Adriamycin) has also been included in this regimen. In patients older than 60 years, reduce the fluorouracil dose to 400 mg/M² and the initial methotrexate dose to 30 mg/M².

DOSE ADJUSTMENTS

For poor-risk patients or those in a poor nutritional state, either reduce dose by one half or more throughout a course of therapy or give 6 mg/kg/day for 3 days. If no toxicity observed, give 3 mg/kg on Days 5, 7, and 9. Give nothing on Days 4, 6, or 8. Do not exceed 400 mg/day. ■ Dose based on ideal body weight in presence of edema, ascites, or obesity. ■ Reduce dose in patients who have received high-dose pelvic irradiation or other cytotoxic drug therapy with alkylating agents (e.g., cisplatin, ifosfamide [Ifex]). ■ One source recommends a dose adjustment in patients with impaired hepatic function. Give the full dose if the bilirubin is 5 or less on the day of administration; omit the dose if the bilirubin is greater than 5. ■ Used with other antineoplastic drugs in reduced doses to achieve tumor remission. ■ See [Usual Dose](#).

DILUTION

Specific techniques required; see Precautions. May be slightly discolored without affecting safety and potency. Dissolve any precipitate by heating to 60° C (140° F) and shaking vigorously. Cool to body temperature before using.

IV injection: May be given undiluted. May inject through Y-tube or three-way stopcock of a free-flowing infusion.

Infusion: May be further diluted with D5W or NS and given as an infusion. Doses up to 2 Gm are being given with extreme caution under the specific supervision of experienced specialists. Leucovorin calcium has been mixed into the solution with fluorouracil.

Storage: Store at room temperature; protect from light.

COMPATIBILITY

(Underline Indicates Conflicting Compatibility Information)

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

One source suggests the following compatibilities:

Additive: Bleomycin (Blenoxane), cyclophosphamide (Cytoxan), etoposide (VePesid), hydromorphone (Dilaudid), ifosfamide (Ifex), methotrexate, mitoxantrone (Novantrone), vincristine.

Y-site: Allopurinol (Aloprim), amifostine (Ethyol), anidulafungin (Eraxis), aztreonam (Azactam), bleomycin (Blenoxane), cisplatin (Platinol), cyclophosphamide (Cytoxan), doripenem (Doribax), doxorubicin (Adriamycin), doxorubicin liposomal (Doxil), etoposide phosphate (Etopophos), fludarabine (Fludara), furosemide (Lasix), gemcitabine (Gemzar), granisetron (Kytril), heparin, hydrocortisone sodium succinate (Solu-Cortef), leucovorin calcium, linezolid (Zyvox), mannitol, melphalan (Alkeran), methotrexate, metoclopramide (Reglan), mitomycin (Mutamycin), ondansetron (Zofran), paclitaxel (Taxol), palonosetron (Aloxi), pemetrexed (Alimta), piperacillin/tazobactam (Zosyn), potassium chloride (KCl), propofol (Diprivan), sargramostim (Leukine), teniposide (Vumon), thiotepa, vinblastine, vincristine.

RATE OF ADMINISTRATION

IV injection: A single dose over 1 to 15 minutes.

Infusion: A single dose is usually administered over 24 hours. Toxicity may be lessened by extended administration.

ACTIONS

An antimetabolite. A fluorinated pyrimidine antagonist, cell cycle specific, that interferes with the synthesis of DNA and RNA. Through various chemical processes this deprivation acts more quickly on rapidly growing cells and causes their death. Distributes into tumors, intestinal mucosa, bone marrow, liver, and readily crosses the blood-brain barrier into cerebrospinal fluid and brain tissue. Metabolized by the liver within 3 hours. Half-life is approximately 16 minutes. Excretion is through the urine and as respiratory CO₂.

INDICATIONS AND USES

To suppress or slow neoplastic growth. Palliative treatment of cancers of the breast, colon, pancreas, rectum, and stomach. May be used alone or in combination with other agents.

Unlabeled uses: Has been used for the treatment of bladder, cervical, endometrial, esophageal, head and neck, ovarian, prostatic, skin (topical), and other cancers. Consult oncology literature for protocols in use.

CONTRAINDICATIONS

Potentially serious infections, depressed bone marrow function, poor nutritional state, hypersensitivity, major surgery within the previous month.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1251. ■ Administered by or under the direction of the physician specialist with facilities for monitoring the patient and responding to any medical emergency. Hospitalization, at least during the initial course of therapy, is recommended. ■ Use caution in patients who have had high-dose pelvic irradiation, previous alkylating agents (e.g., cisplatin), other antimetabolic drugs (e.g., methotrexate), metastatic tumor involvement of the bone marrow, impaired hepatic or renal function, or dihydropyrimidine dehydrogenase deficiency. ■ Pseudomembranous colitis has been reported. May range from mild to life threatening. Consider in patients that present with diarrhea during or after treatment with fluorouracil.

Monitor: Confirm patency of vein. Avoid extravasation. Change peripheral injection site every 48 hours. ■ Obtain a CBC with differential and platelet count before each dose. When given with leucovorin calcium, repeat weekly the first two courses and then at the time of anticipated WBC nadir in following courses. Electrolytes and liver function tests should be done before the first three courses, then every other course. ■ Be alert for signs of bone marrow suppression or infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Examine mouth and lips daily for sores or other signs of stomatitis. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Toxicity increased by any form of therapy that adds to stress, poor nutrition, and bone marrow suppression. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See [Drug/Lab Interactions](#).

Patient Education: Nonhormonal birth control recommended. ■ See Appendix D, p. 1255. ■ Report IV site burning and stinging promptly. ■ Drink at least 2 liters of fluid each day.

Maternal/Child: Category D: avoid pregnancy; can cause fetal harm. ■ Discontinue breastfeeding. ■ Safety for use in pediatric patients not established.

Elderly: May be more sensitive to toxic effects of the drug. Consider age-related organ impairment. ■ See [Dose Adjustments](#).

DRUG/LAB INTERACTIONS

Potentiates **anticoagulants**. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ **Cimetidine** (Tagamet), **interferon alfa**, and **leucovorin calcium** may increase toxicity. ■ Additive bone marrow suppression may occur with **radiation therapy**, **other bone marrow-suppressing agents** (e.g., azathioprine [Imuran], chloramphenicol, irinotecan [Camptosar], melphalan [Alkeran], vinorelbine [Navelbine]), **and/or agents that cause blood dyscrasias** (e.g., metronidazole [Flagyl IV]). ■ **Thiazide diuretics** (e.g., chlorothiazide [Diuril]) may prolong antineoplastic-induced leukopenia. ■ May decrease metabolism and increase serum levels of **phenytoin** (Dilantin).

SIDE EFFECTS

Abnormal bromsulphalein (BSP), prothrombin, total protein, sedimentation rate; alopecia (reversible), anaphylaxis, bleeding, bone marrow suppression (agranulocytosis, anemia, leukopenia, pancytopenia, thrombocytopenia), cerebellar syndrome, cramps, dermatitis, diarrhea, disorientation, dry lips, erythema, esophagopharyngitis and stomatitis

(may lead to sloughing and ulceration), euphoria, frequent stools, GI ulceration and bleeding, headache, hemorrhage from any site, increased skin pigmentation, infection, lacrimal duct stenosis, mouth soreness and ulceration, myocardial ischemia, nail changes, nausea, palmar-plantar erythrodysesthesia syndrome (tingling of hands and feet followed by pain, redness, and swelling), photophobia, photosensitivity, pneumopathy (cough, shortness of breath), thrombophlebitis, visual changes, vomiting (intractable). Diarrhea and stomatitis are most common and may be more severe with a prolonged duration in patients on combination therapy. Pseudomembranous colitis has been reported.

ANTIDOTE

Keep physician informed of any side effects. Discontinue the drug and notify physician promptly at the first sign of toxicity (e.g., bleeding, diarrhea, esophagopharyngitis, gastritis, intractable vomiting, rapidly falling white count, sores in or around the lips or mouth, stomatitis). Nadir of leukocyte count occurs around days 9 to 14. Recovery should be by day 30. Discontinue the drug if the WBC count is less than $3,500/\text{mm}^3$ or platelets are less than $100,000/\text{mm}^3$; should reach $4,000/\text{mm}^3$ and $130,000/\text{mm}^3$ respectively in 2 weeks; if they do not, discontinue treatment. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes, and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Continue to monitor for 4 weeks. Palmar-plantar erythrodysesthesia syndrome has been treated with oral pyridoxine (vitamin B₆), 100 to 150 mg daily. Death may occur from the progression of many side effects. There is no specific antidote; supportive therapy as indicated will help sustain the patient in toxicity.

FOLIC ACID

(FOH-lik AS-id)

Nutritional supplement
(vitamin)
Antianemic

pH 8 to 11

USUAL DOSE

Therapeutic dose: 0.1 to 1 mg daily (never give less than 0.1 mg). Larger doses may be required.

Maintenance dose: 0.4 mg daily. **Pregnant or lactating females:** 0.8 mg daily.

PEDIATRIC DOSE

See [Maternal/Child](#).

Therapeutic dose: 0.1 to 1 mg daily (never give less than 0.1 mg).

Maintenance dose: **Infants:** 0.1 mg daily. **Under 4 years:** Up to 0.3 mg daily. **Over 4 years:** Same as adult.

DOSE ADJUSTMENTS

Increased initial and maintenance doses may be required in alcoholism, hemolytic, anemia, anticonvulsant therapy, or chronic infection.

DILUTION

Each dose (up to 5 mg) should be diluted in at least 50 mL of SWFI, D5W, or NS. May be added to most IV solutions and given as an infusion.

Storage: Protect from light and freezing.

COMPATIBILITY

Consider any drug **NOT** listed as compatible to be **INCOMPATIBLE** until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with calcium gluconate (even though a precipitate cannot be seen), doxapram (Dopram), heavy metal ions, iron sulfate, oxidizing agents, reducing agents, solutions with a pH less than 5.

One source suggests the following **compatibilities**:

Y-site: Famotidine (Pepcid IV).

RATE OF ADMINISTRATION

5 mg or fraction thereof over a minimum of 1 minute; usually given over 30 minutes or more in an infusion.

ACTIONS

Folic acid (pteroylglutamic acid) is part of the vitamin B complex. In humans, exogenous folate is required for nucleoprotein synthesis and the maintenance of normal erythropoiesis. It is the precursor of tetrahydrofolic acid, an important cofactor involved in the synthesis of amino acids and DNA. Stimulates the production of RBCs, WBCs, and platelets. Metabolized in the liver and excreted in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

For prevention and treatment of folic acid deficiency. Megaloblastic anemias resulting from folic acid deficiency may be seen in sprue, anemias of malnutrition, pregnancy, infancy, and childhood, developmental or surgical anomalies of the GI tract, as well as other conditions.

CONTRAINDICATIONS

Pernicious anemia unless used in combination with diagnostic testing.

PRECAUTIONS

Folic acid is not commonly administered by the IV route. Oral or IM administration provides adequate absorption in most cases. ■ Obscures the peripheral blood picture and prevents the diagnosis of pernicious anemia. May actually aggravate the neurologic symptoms.

Monitor: Obtain CBC before and during therapy.

Maternal/Child: Category A: an important vitamin before and during pregnancy. Folate-deficient mothers have a higher incidence of fetal anomalies and complications of pregnancy. ■ Safe for use during breast-feeding; infant may require supplementation if mother is folate deficient. ■ Some products contain benzyl alcohol as a preservative. Avoid use in neonates.

Elderly: More likely to have folate deficiency.

DRUG/LAB INTERACTIONS

Toxic effects of antineoplastic folic acid antagonists are blocked by **folinic acid** (leucovorin calcium) but not by folic acid IV. ■ Increases **hydantoin** metabolism (e.g., phenytoin [Dilantin]); seizures may result. ■ Inhibited by **dihydrofolate reductase inhibitors** (e.g., methotrexate, trimethoprim), **pyrimethamine, and triamterene** and by depressed **hematopoiesis, alcoholism**, and deficiencies of **vitamins B₆, B₁₂, C, and E**. ■ **Aminosalicyclic acid** (Pamisol) or **sulfasalazine** (Azulfidine) may decrease serum folate levels. ■ **Oral contraceptives** may inhibit folate metabolism.

SIDE EFFECTS

Almost nonexistent. Confusion, some slight flushing or feeling of warmth, nausea; anaphylaxis can occur.

ANTIDOTE

If anaphylaxis occurs, discontinue drug, treat anaphylaxis, and notify physician. Resuscitate as necessary.

FOMEPIZOLE INJECTION

(foh-**MEP**-ih-zoll in-**JEK**-shun)

Antidote

Antizol

USUAL DOSE

Ethylene glycol is the main component of antifreeze and coolants. Methanol is the main component of windshield washer fluid and a component of products such as Sterno (for fondue pots), Heet (gasoline antifreeze), and various paint products. Begin fomepizole treatment immediately upon suspicion of ethylene glycol or methanol ingestion based on patient history and/or anion gap metabolic acidosis, increased osmolar gap, visual disturbances, or oxalate crystals in the urine, or a documented serum ethylene glycol or methanol concentration greater than 20 mg/dL.

Adults with blood concentrations over 20 mg/dL but less than 50 mg/dL: Administer a loading dose of 15 mg/kg as a slow intravenous infusion. Follow with 10 mg/kg every 12 hours times 4 doses, then 15 mg/kg every 12 hours until ethylene glycol or methanol concentrations are undetectable or have been reduced below 20 mg/dL, and the patient is asymptomatic with normal pH.

Adults with blood concentrations of 50 mg/dL or higher, renal failure, or significant or worsening metabolic acidosis: In addition to dosing as above, dialysis should be considered to correct metabolic abnormalities and to lower the ethylene glycol or methanol concentrations below 50 mg/dL.

Dosage with renal dialysis: Amount of loading dose and following doses (mg/kg) remains the same, but fomepizole is dialyzable and the frequency of dosing should be increased to every 4 hours during hemodialysis. Base frequency on the following chart.

Fomepizole Dosing in Patients Requiring Dialysis	
DOSE AT THE BEGINNING OF HEMODIALYSIS	
If <6 hours since last fomepizole dose Do not administer dose	If ≥6 hours since last fomepizole dose Administer next scheduled dose
DOSING DURING HEMODIALYSIS	
Dose every 4 hours	
DOSING AT THE TIME HEMODIALYSIS IS COMPLETED	
Time between last dose and the end of the hemodialysis	
<1 hour	Do not administer dose at the end of hemodialysis
1-3 hours	Administer 1/2 of next scheduled dose
>3 hours	Administer next scheduled dose
MAINTENANCE DOSING OFF HEMODIALYSIS	
Give next scheduled dose 12 hours from last dose administered	

DOSE ADJUSTMENTS

Fomepizole has not been studied sufficiently to determine whether the pharmacokinetics differ for the elderly (see [Elderly](#)), pediatric patients, between genders, in renal insufficiency (excreted renally), or in hepatic insufficiency (metabolized by the liver).

DILUTION

Fomepizole solidifies at temperatures less than 25° C (77° F). If it is solidified, liquefy by running the vial under warm water or by holding in the hand. Solidification does not

affect the efficacy, safety, or stability. Withdraw the appropriate dose. Each single dose **must be diluted** in at least 100 mL of NS or D5W and given as an infusion. Mix well.

Storage: Store vials at CRT 20° to 25° C (68° to 77° F). Diluted solutions are stable refrigerated or at CRT for 48 hours; however, manufacturer states should be used within 24 hours of dilution.

COMPATIBILITY

Specific information not available. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Each single dose must be given as a slow intravenous infusion equally distributed over 30 minutes. **Do not give undiluted or by bolus injection;** has caused serious venous irritation and phlebosclerosis.

ACTIONS

A synthetic competitive alcohol dehydrogenase inhibitor. Effectively blocks formation of toxic metabolites (glycolic and oxalic acids [ethylene glycol]) and (formic acid [methanol]). These toxins can induce metabolic acidosis, nausea and vomiting, seizures, stupor, coma, calcium oxaluria, acute tubular necrosis, blindness, and death. Has shown minimal CNS depressant effects. Plasma half-life varies with dose and has not been calculated. Rapidly distributes into total body water. Metabolized in the liver by the P₄₅₀ mixed-function oxidase system. Significant increases in the elimination rate occur after 30 to 40 hours. Excreted in urine.

INDICATIONS AND USES

An antidote for ethylene glycol (antifreeze) or methanol (windshield wiper fluid) poisoning, or for use in suspected ethylene glycol or methanol ingestion either alone or in combination with hemodialysis.

CONTRAINDICATIONS

Known serious hypersensitivity to fomepizole or other pyrazoles (e.g., sulfinpyrazone [Anturane]).

PRECAUTIONS

Acute ethylene glycol or methanol poisoning is a medical emergency that is characterized by a syndrome that can include CNS depression, severe metabolic acidosis, renal failure, and coma. Can be lethal if left untreated or when treatment is delayed due to delayed diagnosis. The lethal dose of ethylene glycol is approximately 1.4 mL/kg. The lethal dose of methanol is approximately 1.2 mL/kg. ■ If ethylene glycol or methanol poisoning is left untreated, the natural progression of the poisoning leads to accumulation of toxic metabolites, including glycolic and oxalic acids (ethylene glycol) and formic acid (methanol). These metabolites can induce metabolic acidosis, nausea and vomiting, seizures, stupor, coma, calcium oxaluria, acute tubular necrosis, and death. ■ The diagnosis of these poisonings may be difficult because ethylene glycol and methanol levels diminish in the blood as they are metabolized. ■ The ethylene glycol or methanol concentrations and the acid-base balance, as determined by serum electrolyte (anion gap) and/or arterial blood gas analysis, should be frequently monitored and used to guide treatment. ■ Fomepizole has caused minor hypersensitivity reactions (mild rash, eosinophilia).

Monitor: Maintain a patent airway and support ventilation as indicated; CNS and respiratory distress may occur suddenly. ■ Gastric lavage may be indicated if performed soon after ingestion or in patients who are comatose or at risk for seizures. ■ Patients must be managed for metabolic acidosis, acute renal failure (ethylene glycol), adult respiratory distress syndrome, visual disturbances (methanol), and hypocalcemia which may result in tetany. Sodium bicarbonate may be required to treat metabolic acidosis. Correct electrolyte imbalance and maintain adequate urine output with IV fluids. A decrease in the amount of fluids will be required in impending renal failure to prevent fluid overload; monitor closely. ■ Potassium supplementation and oxygen administration are usually necessary. ■ Administer IV calcium to patients with seizures or tetany that may be caused by decreased calcium, but do not attempt to correct hypocalcemia itself (may

increase precipitation of calcium oxalate crystals in the tissues). ■ Hemodialysis is necessary in the anuric patient and should be considered in patients with severe metabolic acidosis or azotemia and in any patient with high ethylene glycol or methanol concentrations (equal to or greater than 50 mg/dL). ■ ECG should be continuous to monitor for cardiac irregularities. ■ EEG may be required in the comatose patient. ■ The effective inhibition of alcohol dehydrogenase requires fomepizole plasma concentrations in the range of 100 to 300 micromol/L (8.6 to 24.6 mg/L). ■ To assess treatment success, obtain baseline and frequently monitor measurements of blood gases, pH, electrolytes, BUN, creatinine, and urinalysis in addition to other laboratory tests as indicated by each patient's condition. ■ To assess the status of ethylene glycol or methanol and their respective metabolite clearance, obtain baseline ethylene glycol or methanol plasma and urine concentrations and presence of urinary oxalate crystals (ethylene glycol) and monitor frequently. ■ Obtain baseline and monitor hepatic enzymes and WBC counts during treatment; transient increases in serum transaminase levels and eosinophilia have been noted with repeated fomepizole dosing. ■ Monitor for signs of hypersensitivity reactions; see **Precautions**.

Patient Education: Monitoring of urine output imperative. ■ Cooperation with adequate hydration and frequent laboratory analysis required. ■ Request assistance with ambulation.

Maternal/Child: Category C: use during pregnancy only if clearly needed. ■ Decreased testicular mass in rats. ■ Use caution during breast-feeding; not known if fomepizole is secreted in breast milk. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly: Risk of toxic reactions may be greater in patients with impaired renal function; consider age-related renal impairment.

DRUG/LAB INTERACTIONS

Has not been studied, but reciprocal interactions (increasing or decreasing clearance, effects, or toxicity) may occur with concomitant use of **drugs that induce or inhibit the cytochrome P₄₅₀ system** (e.g., carbamazepine [Tegretol], cimetidine [Tagamet], ketoconazole [Nizoral], phenytoin [Dilantin]). Oral fomepizole significantly reduced the rate of elimination of **ethanol** (by 40%) in healthy subjects. Ethanol decreased the rate of elimination of fomepizole (by 50%).

SIDE EFFECTS

Most common side effects are dizziness, headache, and nausea. Abdominal pain, abnormal smell, anemia, anorexia, arrhythmias (bradycardia, tachycardia), back pain (lower), blurred vision, decreased awareness of surroundings, diarrhea, DIC, feeling of drunkenness, fever, hangover, heartburn, hiccups, hypersensitivity reactions (e.g., mild rash, eosinophilia), hypotension, injection site reaction, light-headedness, lymphangitis, multi-system organ failure, nystagmus, pharyngitis, phlebitis, phlebosclerosis, seizure, shock, slurred speech, somnolence, taste changes (bad or metallic), vertigo, visual problems, vomiting occurred in up to 6% of patients.

Overdose: Dizziness, nausea, and vertigo occurred in healthy volunteers given 3 to 6 times the recommended dose.

ANTIDOTE

Keep physician informed of all side effects, laboratory results, and concurrent medical problems. Dialysis may be indicated for changes in patient condition (e.g., renal failure, significant or worsening metabolic acidosis, or a measured ethylene glycol or methanol concentration of greater than 50 mg/dL) or in the treatment of overdose. Treat side effects symptomatically as indicated. Resuscitate as necessary.

FOSAPREPITANT DIMEGLUMINE

(fos-ap-RE-pi-tant dye-MEG-loo-meen)

Emend

Antiemetic
Receptor antagonist
(Substance P/NK₁)

USUAL DOSE

Administered as a single-dose regimen or as part of a 3-day antiemetic dosing regimen for chemotherapy-induced nausea and vomiting (CINV). In the 3-day dosing regimens, **fosaprepitant 115 mg IV may be substituted for aprepitant 125 mg PO 30 minutes prior to chemotherapy on Day 1 only.** The regimens are listed in the following tables.

Single-Dose Regimen for the Prevention of Nausea and Vomiting Associated with Highly Emetogenic Cancer Chemotherapy				
	Day 1	Day 2	Day 3	Day 4
Fosaprepitant IV*	150 mg IV	None	None	None
Dexamethasone†	12 mg PO	8 mg PO	8 mg PO twice daily	8 mg PO twice daily
5-HT ₃ antagonist (e.g., dolasetron, ondansetron)	Consult prescribing information for the selected 5-HT ₃ antagonist for dosing information	None	None	None

*Administer fosaprepitant 30 minutes before chemotherapy.

†Administer dexamethasone (Decadron) 30 minutes before chemotherapy on Day 1 and in the morning on subsequent days. The dose was chosen to account for the drug interaction.

3-Day Dose Regimen for the Prevention of Nausea and Vomiting Associated with Highly Emetogenic Cancer Chemotherapy				
	Day 1	Day 2	Day 3	Day 4
Fosaprepitant IV* or Aprepitant PO*	115 mg IV or 125 mg PO	80 mg PO	80 mg PO	None
Dexamethasone†	12 mg PO	8 mg PO	8 mg PO	8 mg PO
5-HT ₃ antagonist (e.g., dolasetron, ondansetron)	Consult prescribing information for the selected 5-HT ₃ antagonist for dosing information	None	None	None

*Administer fosaprepitant 30 minutes before chemotherapy on Day 1 and in the morning on subsequent days.

†Administer dexamethasone (Decadron) 30 minutes before chemotherapy on Day 1 and in the morning on subsequent days. The dose was chosen to account for the drug interaction.

3-Day Dose Regimen for the Prevention of Nausea and Vomiting Associated with Moderately Emetogenic Cancer Chemotherapy			
	Day 1	Day 2	Day 3
Fosaprepitant IV* or Aprepitant PO*	115 mg IV or 125 mg PO	80 mg PO	80 mg PO
Dexamethasone†	12 mg PO	None	None
5-HT ₃ antagonist (e.g., dolasetron, ondansetron)	Consult prescribing in- formation for the se- lected 5-HT ₃ antago- nist for dosing information	None	None

*Administer fosaprepitant 30 minutes before chemotherapy on Day 1 and in the morning on subsequent days.

†Administer dexamethasone (Decadron) 30 minutes before chemotherapy on Day 1. The dose was chosen to account for the drug interaction.

DOSE ADJUSTMENTS

No dose adjustment indicated based on age, race, gender, body mass index (BMI), renal status (including patients with ESRD on dialysis), or mild to moderate hepatic insufficiency. Data in patients with severe hepatic insufficiency (Child-Pugh score >9) not available.

DILUTION

Reconstitute each 115-mg or 150-mg vial with 5 mL of NS. Direct stream of NS to side of vial to avoid foaming. Swirl gently; do not shake. Prepare an infusion bag with 110 mL of NS for the 115-mg dose and prepare an infusion bag with 145 mL of NS for the 150-mg dose. Withdraw entire volume of reconstituted vial and transfer it into the infusion bag. Gently invert the bag 2 to 3 times. Final concentration is 1 mg/mL.

Storage: Store unopened vials at 2° to 8° C (36° to 46° F). Diluted solution is stable for 24 hours at RT.

COMPATIBILITY

Manufacturer states, "Should not be mixed or reconstituted with solutions for which physical and chemical **compatibility** have not been established. Fosaprepitant (Emend) for injection is **incompatible** with any solutions containing divalent cations (e.g., calcium or magnesium), including lactated Ringer's solution and Hartmann's solution."

RATE OF ADMINISTRATION

115-mg dose: A single dose as an infusion equally distributed over 15 minutes.

150-mg dose: A single dose as an infusion equally distributed over 20 to 30 minutes.

ACTIONS
